The second principal form of the *mukataʿa* was the *emânet* (trusteeship), held by the *emin* (trustee, agent). In contrast to the situation of the *timar* holder, the *emin* turned all his proceeds over to the treasury and was compensated entirely by salary, thus being the closest Ottoman equivalent to the modern government official. The legal basis for this arrangement was that the *emin* did no more than administer the *mukataʿa;* he undertook no additional service, and so had no right to share in the profits of the *mukataʿa* that he held. This was the least common type of administrative position in Ottoman times, for the most part used for urban custom houses and market police, which were very close to, and under the supervision and control of, the central government and its agents, and which did not need the profit motive in order to assure efficiency on the part of the holders.

The most common kind of *mukataʿa,* and therefore the most prevalent type of administrative unit in the Ottoman system, was the tax farm (*iltizam*), which combined elements of both the *timar* and *emânet.* As in the former, the tax farmer (*mültezim*) could keep a part—but only a part—of the tax he collected, and, like the *emin,* had to deliver the balance to the treasury. This was because his service consisted only of his work in administering the *mukataʿa,* for which he was given a share of his collection instead of the *emin*'s salary. The tax farmer thus was given the inducement of profit to be as efficient as possible. Most of Anatolia and the Arab provinces were administered in this way because they were conquered at a time when the government's need for cash to pay the salaried Janissary infantry and to supply an increasingly lavish court required the treasury to seek out all the revenues it could find. As the *timar*-based *sipahi* cavalry became less important, and as the Turkish notables who held most of the *timar*s lost most of their political power during the time of Süleyman, the estates gradually fell into the hands of the *devşirme* class.

The dual system of law

The legal and customary bases of organization and action in Ottoman society depended on a dual system of law —the Sharīʿah or religious law, and the *kanun,* or civil law. The former, the basic law of Ottoman society, as it was of all Muslim communities, was considered to be a divinely inspired corpus of political, social, and moral regulations and principles, which were supposed to cover all aspects of life for Muslims. But it was highly developed only in the fields of personal behaviour covered in detail in the early Muslim community and reflected in the Qurʾān and early Muslim tradition. It never was developed in detail in matters of public law, state organization, and administration. Its general principles left room for interpretation and legislation on specific matters by secular authorities; and the Muslim judges of the Ottoman Empire recognized the right of the sultan to legislate in civil laws, so long as he did not conflict with the Sharīʿah in detail or principle. The Sharīʿah, therefore, provided the principles of public law, and covered matters of personal behaviour and status in the Muslim *millet* in the same way that the members of the Christian and Jewish *millet*s were subject to their own religious codes. The Sharīʿah was interpreted and enforced by members of the Cultural Institution—the *ʿulamāʾ*—just as the laws of each non-Muslim *millet* were enforced by its leaders. Strictly speaking, the *ʿulamāʾ* members had the right to invalidate any law they felt contradicted the Sharīʿah, but they rarely did this because, as part of the ruling class, they were under the authority of the sultan and could be removed from their positions. The sultan therefore was relatively free to legislate changes in Ottoman institutions and practices to meet the needs of the time; this was a major factor in the long survival of the empire, even during centuries of decline. It must be noted, however, that with the restricted scope of the Ottoman ruling class and state and the large areas of power and function left to the religious communities and guilds as well as to the Ottoman officials who held the different kinds of *mukataʿa*s, the sultans were never as autocratic as has been commonly assumed. It was only in the 19th century that Ottoman reformers centralized government and society on Western lines and restricted or ended the traditional autonomies, which had done so much to decentralize power in the previous centuries.

DECLINE OF THE OTTOMAN EMPIRE, 1566–1807

Internal problems. The reign of Süleyman the Magnificent marked the peak of Ottoman grandeur, but elements of weakness crept in and began the slow but steady decline that followed. An important factor of decline was the increasing lack of ability and power of the sultans themselves. Süleyman tired of the long military campaigns and arduous duties of administration concentrated in his person, and withdrew more and more from public affairs to devote himself to the pleasure of his harem. To take his place, the office of grand vizier was built up to become second only to the sultan in authority and revenue, including the right to demand and obtain absolute obedience. But while the grand vizier was, indeed, able to replace the sultan in official functions, he could not take his place as the focus of loyalty for all the different classes and groups in the empire. The resulting separation of political loyalty and central authority led to a decline in the government's ability to impose its will.

Decline of the sultans

Triumph of the devşirme. The mid-16th century also saw the triumph of the *devşirme* over the Turkish nobility, which lost almost all of its power and positions in the capital and returned to its old centres of power in southeastern Europe and Anatolia. In consequence, many of the *timar*s formerly assigned to the notables to support the *sipahi* cavalry were seized by the *devşirme* and transformed into great estates, for all practical purposes as private property, thus depriving the state of their services as well as of the revenue they could have produced if they had been transformed into tax farms. Whereas the *sipahi*s did not entirely disappear as a military force, the Janissaries and the associated artillery corps became the most important segments of the Ottoman army.

Corruption and nepotism. Because the sultans no longer could control the *devşirme* by playing the Turkish notables off against them, the *devşirme* gained control of the sultans and used the government for its own benefit rather than for that of the sultan or his empire. In consequence, the evils of corruption and nepotism took hold at all levels of administration. In addition, with the challenge of the notables gone, the *devşirme* class itself broke into countless factions and parties, each working for its own advantage by supporting the candidacy of one or another of the imperial princes and each in close alliance with corresponding palace factions led by the mothers, sisters, and wives of each prince. Following Süleyman, therefore, accession and appointments to positions came less as the result of ability than as a consequence of the political manoeuvrings of the *devşirme*-harem political parties. Those in power found it more convenient to control the princes by keeping them uneducated and inexperienced, and the old tradition by which young princes were educated in the field, was replaced by a system in which all the princes were isolated in the private apartments of the harem and limited to the education its permanent inhabitants could provide. In consequence, few of the sultans after Süleyman had the ability to exercise real power even when circumstances might have enabled them to do so.

But the lack of ability did not end the sultans' desire for power; because they lacked the devices developed by their predecessors to achieve this end, they developed new ones. Selim II (ruled 1566–74), known as the Sot, and Murad III (ruled 1574–95) both gained power by playing off the different factions and by weakening the office of grand vizier, the main administrative vehicle for factional and party influence in the declining Ottoman state. As the grand viziers lost their dominant position following the downfall of Mehmed Sokollu (served 1560–79), power fell first into the hands of the women of the harem, during the "Sultanate of the Women" (1570–78), and then into the grasp of the chief Janissary officers, the *ağa*s who dominated from 1578 to 1625. But no matter who controlled the apparatus of government during this time, the results were the same—a growing paralysis of administration throughout the empire and a pulling apart of the different groups into separate and hostile communities.

Economic difficulties. Under such conditions, it was inevitable that the Ottoman government could not meet the increasingly difficult problems that rose to plague the empire in the 16th and 17th centuries. Economic difficulties began in the late 16th century when the Dutch and British were able to completely close the old international trade routes through the Middle East. As a result, the prosperity of the Arab provinces declined and, in addition, the Ottoman economy was upset by inflation, started by the influx of precious metals into Europe from the Americas and by an increasing imbalance of trade between East and West. As the treasury lost more of its revenues to the depredations of the *devşirme*, it began to meet its obligations by debasing the coinage, heavily increasing taxes, and resorting to confiscations—all of which further worsened the situation. All those persons depending on salaries found themselves underpaid, and the result was further theft and corruption. Holders of the *timar*s and tax farms started using them as sources of revenue to be milked as rapidly as possible, rather than as long-term holdings whose prosperity had to be maintained to provide for the future; political influence and corruption also enabled them to transform these holdings into private property, either as life holdings (*malikâne*) or as religious endowments (*vakf*), without any further obligations to the state. Inflation also hit the traditional industries and trades. Functioning under strict price regulations, the guilds were unable to provide quality goods at prices low enough to compete with the cheap European manufactured goods that entered the empire without restriction due to the capitulations agreements. In consequence, traditional Ottoman industry fell into rapid decline.

The decline of Ottoman industry

Social erosion. These conditions were exacerbated by a large increase of population during the 16th and 17th centuries—part of the general population rise that occurred in much of Europe at this time. The amount of subsistance available was not only unable to expand to meet the needs of the rising population, but in fact fell as the result of the political and economic conditions then prevalent in the Ottoman Empire; social distress increased, and upset resulted. Landless and jobless peasants fled from the lands as did cultivators subjected to confiscatory taxation at the hands of timariots and tax collectors, thus reducing food supplies even more. Many of them fled to the cities, where they added to the problem of food supply and reacted against their troubles by rising against the established order; many more remained in the countryside and joined rebel bands, known as *levend*s and Jelālīs (Celâlis), which took what they could from those who remained to cultivate and trade.

The central government became weaker; and as more peasants joined rebel bands, they were able to take over large parts of the empire, keeping all the remaining tax revenues for themselves and often cutting off the regular food supplies of the cities as well as of the Ottoman armies still guarding the frontiers. Under such conditions, the armies themselves broke up, with most of the salaried positions in the Janissary corps and other corps falling into the hands of urban investors, who used them simply as new sources of revenue, without performing any military services in return. Thus it was that the Ottoman armies came to be composed primarily of fighting contingents supplied by the vassals of the sultan (particularly the Crimean Tartar khans), together with whatever rabble could be dragged from the streets of the cities whenever required by campaigns. The Ottoman army still remained strong enough to curb the most pressing provincial revolts; but the latter proliferated through the centuries of decline, making effective administration outside the major cities still under the government's control almost impossible. In many ways the substratum of Ottoman society—formed by the *millet*s and various economic, social and religious guilds and buttressed by the organization of the Ottoman *'ulamā'*—cushioned the mass of the people and the ruling class itself from the worst effects of this multisided disintegration.

External relations. Despite these difficulties, the internal Ottoman weakness was evident to only the most discerning Ottoman and foreign observers during much of the 17th century. Most Europeans continued to fear the Ottoman army much as it had been feared two centuries before; and whereas its ability was reduced, it remained strong enough not only to prevent the provincial rebels from assuming complete control but also to make a few more significant conquests in both East and West. Whereas the empire now suffered defeats for the first time, it still retained reserve strength sufficient for it to recoup when needed and to prevent the loss of any integral parts of the empire. Although the Ottoman navy was destroyed by the fleet of the Holy League at the Battle of Lepanto (1571), it was yet able to rebuild and regain naval mastery in the eastern Mediterranean through most of the 17th century, taking Tunis from the Spanish Habsburgs (1574), Fez from the Portuguese (1578), and Crete from Venice (1669). In consequence, so long as Europe continued to fear the Ottomans, no one tried to upset the precarious peace treaties concluded in Süleyman's later years; and the Ottomans were shielded from the results of their own weakness.

Superiority of Ottoman navy

Military campaigns. Despite the upsets then disturbing the Ottoman body politic, the Porte undertook new campaigns. When the rising Principality of Moscow conquered the last Mongol states in Central Asia and reached the Caspian, thus posing a threat to the Ottoman position north of the Black Sea and in the Caucasus, Murad II conquered the Caucasus and, taking advantage of anarchy in Iran following the death of Shāh Ṭahmāsp I in 1576, seized the long-coveted Azerbaijan. He thus brought the empire to the peak of its territorial extent and added wealthy new provinces whose revenues, for a half century at least, rescued the Ottoman treasury from the worst of its financial troubles and gave the empire a respite in which it could at least try to remedy its worst problems.

Reform efforts in the 17th century were undertaken by sultans Osman II (ruled 1618–22) and Murad IV (ruled 1623–40) and by a famous dynasty of Köprülü grand viziers who served under Sultan Mehmed IV (ruled 1648–1687)—Mehmed Köprülü (served 1656–61) and Ahmed Köprülü (served 1661–76). Each of these early reformers rose as the result of crises and military defeats that threatened the very existence of the empire. Each was given the power needed to introduce reforms because of the fears of the ruling class that the empire, on which its privileges depended, was in mortal danger.

Exposure of Ottoman weakness. In a war between the Ottomans and the Habsburgs (began 1593) the Austrians were able to take much of central Hungary and Romania, and only an accidental Ottoman triumph in 1596 enabled the Sultan to sufficiently recoup so that the Habsburgs agreed to the Treaty of Zsitvatorok (1606), by which agreement Ottoman rule of Hungary and Romania was restored. The treaty itself, however, like the events that led up to it, for the first time showed Europe the extent of Ottoman weakness and so exposed the Ottomans to considerable new dangers in subsequent years. In the East, anarchy in Iran was brought to an end by Shāh 'Abbās I (ruled 1587–1629), who not only restored Iranian power but drove the Ottomans out of Azerbaijan and the Cauca-

sus (1603), conquered Iraq (1624), and threatened to take the entire Ottoman Empire. Though Murad IV was able to retake Iraq (1638), Iran remained a major threat. Finally, a long war with Venice (1645–69), occasioned by Ottoman efforts to capture Crete, exposed Istanbul to a major Venetian naval attack. Although finally pushed back in a naval campaign culminating in the Ottoman conquest of Crete (1669), the Venetians still posed a major threat, which, like those that had occurred earlier in the century, stimulated the ruling class to accept needed reforms.

Reforms. The Ottoman reforms introduced during the 17th century were too limited in nature and scope to permanently arrest the Ottoman decline. Basically, they were no more than efforts to restore to the state the inherited system of government and society that had operated successfully in the past. Corrupt officials were executed. Efforts were made to restore the *timar* and tax-farm systems as the basis of the administration and army. Provincial revolts were suppressed, peasants were forced back to the lands, and cultivation was increased. Debased coins were replaced by coins of full face value. Industry and trade were encouraged, and corruption and insubordination were driven out.

Such reforms were sufficient to end the immediate difficulties. But they were successful only for the moment because the reformers were allowed only to act against the results of the decay and not its cause—the selfish rule of the ruling class—which continued. As soon as the worst consequences of decay had been alleviated, the old groups returned to power and resumed their old ways.

Failure to assess new Europe

Moreover, the reformers really did not understand that the Europe now faced by the Ottomans was far more powerful than that which the great sultans of the past had defeated; thus even if the reforms had been more permanently successful, they could not have corrected the increasing Ottoman weakness relative to the powerful nation-states then rising in Europe. Such an understanding was to come to the Ottoman reformers only in the 19th century.

Military defeats, 1683–1792. The traditional 17th-century reforms did, however, produce at least a semblance of revival. By 1681 the Ottoman army seemed so strong that Grand Vizier Kara Mustafa Paşa (served 1676–83), brother-in-law of Ahmed Köprülü, was emboldened to move again into central Europe and besiege Vienna (July–September 1683). His effort quickly overextended the fragile bases of the Ottoman revival.

Anti-Ottoman coalition. The aroused defenders, stimulated by the Polish king Jan Sobieski (ruled 1674–96), not only held out but also built a major European coalition that moved to bring destruction to the Ottoman Empire during the subsequent century: the Habsburgs set out to reconquer Hungary, Serbia, and the Balkans; Venice hoped to regain its naval bases on the Adriatic and in the Morea and to resume its naval and commercial power in the Levant; Russia worked to extend its lands to the open seas. Only the enemies of the coalition in Europe, led by France and Sweden, tried to support the Ottomans; neutral Britain and Holland, to guard the commercial privileges they had secured from the sultan through the Capitulations, worked to prevent any nation from gaining control of the entire Ottoman Empire and from becoming, thereby, preponderant in Europe.

Russia and Austria fought the Ottomans not only by direct military attack but also by fomenting dissatisfaction and revolt on the part of the non-Muslim subjects of the Sultan. Against such an attack, the Ottomans could only conciliate their subjects where possible and repress them when conciliation was rejected, taking advantage, at every opportunity, of every rivalry that arose between the Habsburgs and Russians for predominance in the Balkan provinces of the empire.

European wars. In consequence of this situation, the Ottoman Empire was at war with European enemies for 41 years between the second siege of Vienna (1683) and the Treaty of Jassy (1792). From 1683 to 1699 it fought the armies of the Holy League in a disastrous war culminating in the Treaty of Carlowitz (1699). In 1710 and 1711 it fought Russia again and at the Treaty of the Pruth (1711) regained some territories previously lost. The war of 1714–18 with Venice and Austria was concluded by the Treaty of Passarowitz (1718); and three wars with Russia and Austria—in 1736–39, 1768–74, and 1787–92—culminated in the treaties of Belgrade (1739), Küçük Kaynarca (1774), and Jassy (1792). As a result of these wars, the Ottomans lost Hungary, the Banat of Temisvar, Transylvania, and Bukovina in Europe, establishing their boundary on the Danube, where it had last been early in the 16th century. To Russia they lost all their possessions on the northern coasts of the Black Sea from the principalities to the Caucasus, including Bessarabia, Podolya, and the Crimea, the soldiers of which had provided the strongest element in the Ottoman army during the previous century. In addition, the Ottomans were compelled to allow the Russians and Austrians to intervene legally on behalf of the sultan's Christian subjects in a manner that opened the way to an increased European influence in internal Ottoman affairs.

Loss of territory

Imperial decline in the 18th and early 19th centuries. The manifestations of decline were only continuations and elaborations of earlier conditions. But a new factor of decline was added—the weakness of the central government resulted in the loss of control of most of the provinces to local rulers, called notables (*a'yan*), who took more or less permanent control of large areas, creating a situation that in many ways resembled European feudalism much more than the traditional Ottoman *timar* system ever did.

Rise of local rulers. These notables were able to build up their power and maintain control not only because the Sultan's government lacked the military resources to suppress them but also because the local populations themselves preferred the notables' rule to that of the corrupt and incompetent Ottoman officials of the time. In the Balkans and Anatolia, local rulers solidified their positions by taking advantage of currents of local nationalism that were arising among the Balkan Christians and the Muslim Turks. The notables formed private armies of mercenaries and slaves, with which they sometimes provided important contributions to the Ottoman armies in return for recognition of their autonomy by the sultans. These rulers were able to exercise almost complete authority, collecting taxes for themselves and sending only nominal payments to the treasury, thus further increasing its problems. The central government maintained its position by playing off the local rebels against each other, using the leverage of Ottoman support to its own advantage, and securing considerable payments of cash and military contributions when needed. The treasury, therefore, did not suffer as much from these provincial revolts as might be imagined; but the revolts did disrupt the established food supplies of the empire sufficiently for large-scale famines to arise in the major cities on a regular basis. In response, the urban populace became a restless, misruled, and anarchic mass that broke loose at the slightest provocation, responding to unemployment, famine, the plague, and the like with riots and summary executions of the officials considered responsible. Such violence, while manifesting Ottoman difficulties, did not remedy them and, in fact, made things worse. Remedy lay only in the hands of the ruling class; but its reaction was quite different.

Urban anarchy

Resistance to change. Most Ottomans saw little need for the empire to change because they actually benefitted financially from the existing anarchy and lack of control by the sultan. In addition, the ruling class was completely isolated from developments outside its own sphere; it assumed that the remedies to Ottoman decline lay entirely within Ottoman practice and experience. This resulted from the basic belief of Ottoman society in its own superiority over anything the infidel could possibly produce —a belief that had far more basis in the 16th century, when it was developed, than in the 18th century. All of the developments in industrial and commercial life, in science and technology, and particularly in political and military organization and techniques that had occurred in Europe since the Reformation were simply unknown to

the Ottomans. The only direct Ottoman contacts with Europe were on the battlefield, where most Ottomans still assumed that their military reverses were caused not by the superiority of Western armies as such but rather by Ottoman failure to apply fully the techniques that had worked so well in the past. So the 18th-century reforms largely paralleled those of the traditional Ottoman reformers of the 17th century, with only occasional efforts to add new military organizations and to make use of specific European weapons and techniques of undeniable superiority.

Contacts with the West. For a few Ottomans this isolation was at least partially broken down when some channels of contact opened with the West during the 18th century—a few Ottoman ambassadors went to Europe to participate in negotiations and sign treaties; more and more European merchants, travellers, and consuls came into the Ottoman Empire; a very few Ottoman men of science and philosophy began to correspond with their Western counterparts; members of the Ottoman minorities entered into correspondence with their relatives in the West. But such contacts had very limited effects; only a small number of Ottomans experienced them, and even when they did learn something, the effect was quite superficial because the resulting information did not fit into the patterns of thought of even the most educated Ottomans. Those few who did understand something of what they heard usually were only voices in the wilderness, and their efforts to apply and spread what they knew had little overall effect.

Such contacts did lead to changes in the modes of living of a few upper class Ottomans and to some military innovations, but to nothing more. Starting in the so-called Tulip Period (1717–30; see below) some Ottomans under the influence of Grand Vizier İbrahim Paşa began to dress like Europeans, and the palace began to imitate European court life and pleasures. Sultan Ahmed III (ruled 1703–30) built several lavish summer residences on the Bosporus and the Golden Horn (an inlet that forms the harbour of Istanbul), and these were imitated by members of his immediate entourage, who held frequent garden parties in imitation of the pleasures of Versailles. The sultan and his ministers were no longer confined behind the walls of the palace; and the new era was celebrated by Nedim, the court poet, who reflected a considerable awareness of his environment and an appreciation of nature. Growing tulips, as a mark of westernization, became an obsession with rich and poor alike, and the flower gave its name to the period. In 1727 Turkish language books were printed for the first time in the empire by a Hungarian convert named İbrahim Müteferrika; and while the press was closed by the government at times, during the remainder of the century it provided a number of books on history and geography that further opened the minds of those who saw and read them.

The Tulip Period

Military reforms. As a result of contact with European armies and the influence of European renegades in Ottoman service, a few attempts were made during the century to adopt Western-type uniforms, weapons, and tactics. Because the members of the established military corps could not and would not surrender their old ways, entirely new corps were formed to handle the new weapons under the direction of European instructors. But the new corps had no effect at all on the Janissaries and the other older corps that continued to form the bulk of the army; the latter accurately saw that the new ways were threats to their privileges and security. The new corps were, therefore, no more than special mercenary bodies built up under the stimulus of individual Ottomans, lasting only so long as the latter remained in power. The most successful and lasting Ottoman military reform during this time came in the navy, which was modernized by Grand Admiral Gazi Hasan Paşa (served 1770–89), with the support and encouragement of Sultan Abdülhamid I (ruled 1774–89); this success came largely because the Ottoman naval establishment was wiped out at the Battle of Çeşme (1770) by a Russian fleet, and there was no such inbred resistance as that which stifled significant reforms elsewhere. Important reforms introduced into the army under Grand Vizier Halil Hamid Paşa (served 1782–85), with the help of Western technicians, were limited to new corps especially created for the purpose, while the bulk of the Ottoman army continued to remain without change.

Selim III (ruled 1789–1807). These 18th-century reform efforts culminated during the reign of Sultan Selim III, who is thought by some to have been the originator of modern reform in the Ottoman Empire. While still a prince, Selim developed plans for modernizing the Ottoman army. He came to the throne during the 1787–92 war with Austria and Russia and had to postpone serious reform efforts until its completion. Early efforts to modernize the Janissary corps created such opposition that Selim thereafter concentrated on creating a new European-style army, called the *nizam-ı cedid* ("new order"), using the modern weapons and tactics developed in Europe. This new force, never numbering more than 10,000 active soldiers, was trained in Istanbul and in certain Anatolian provincial centres by officers and military experts sent by the different European powers that were competing for the sultan's support at the time. So as not to disturb the established Ottoman institutions, it was financed by an entirely new treasury, called the *irad-i cedid* ("new revenue"), whose revenues came from taxes imposed on previously untaxed revenue sources and from the confiscation of some *timar*s whose holders were not fulfilling their military and administrative duties to the state. Under the guidance of European technicians, factories were constructed to manufacture modern weapons and ammunitions, and technical schools were opened to train Ottoman officers. Limited efforts also were made to rationalize the Ottoman administrative machinery, but largely along traditional lines.

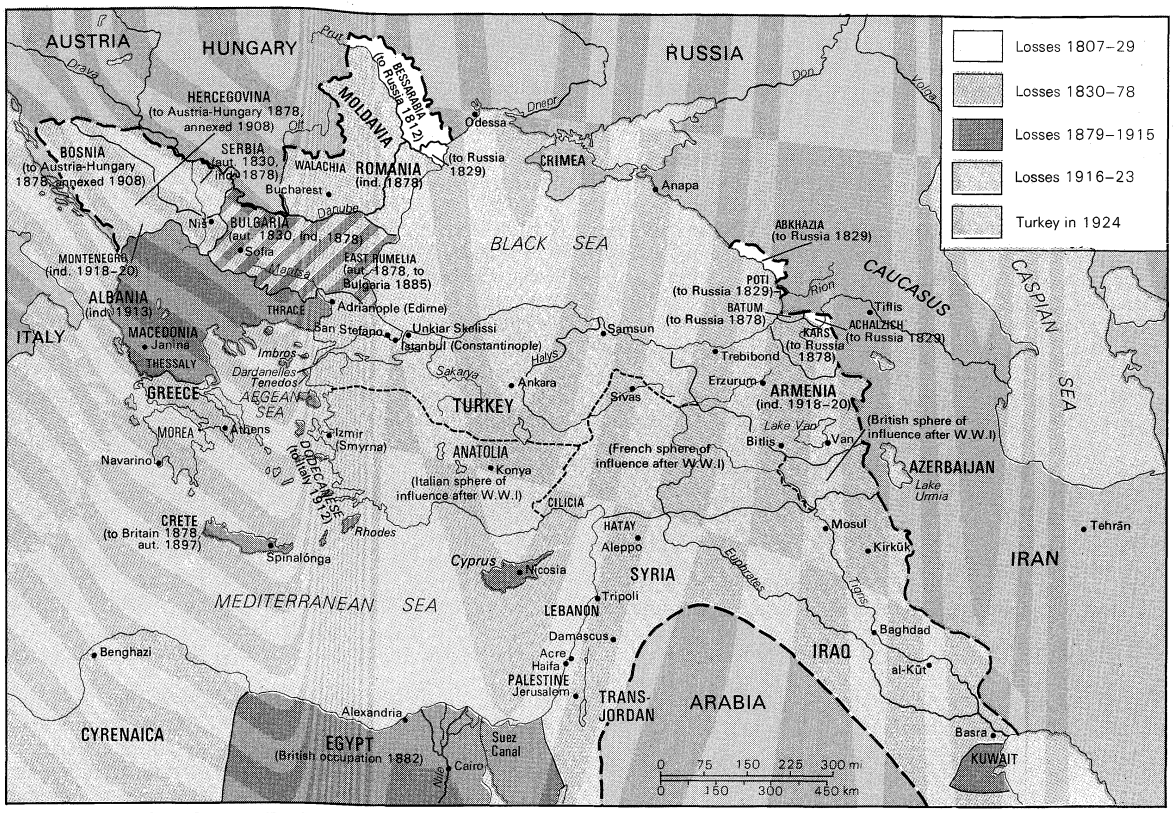
Modern reform

The older military corps, however, remained intact and hostile to the new force, and Selim was therefore compelled to limit its size and use. At the same time, much of his energy was diverted by the rise of powerful autonomous notables in southeastern Europe, Anatolia, and the Arab provinces, as well as by a French Expedition to Egypt (1798–1801), which eventually drew him into alliances with Great Britain and Russia. The rise of nationalism among Ottoman subject peoples stimulated by agents of Russia, Austria, and Revolutionary France, and culminating in the beginning of a Serbian revolution (1804) and a new war with Russia (1806–12) also made it impossible for Selim to resist the wishes of the Janissaries, who still formed the bulk of his army. Finally, the sultan's personal weakness, which led him to desert the reformers and the new army whenever opposition became strong, left him with little significant support in 1807, when he was attacked and overthrown by a conservative coalition. While Selim was imprisoned in the palace, a conservative reaction under Sultan Mustafa IV (1807–08) ended the reforms and massacred most of the reformers. An effort to restore Selim led by the Bulgarian notable Bayrakdar Mustafa Paşa led to Selim's death and, after the short rule of Mustafa IV, the accession of his reforming cousin, Mahmud II (ruled 1808–39). Selim's reforms were largely abandoned for some time. But the greatly increased knowledge of the West in the Ottoman Empire, made possible by the schools established for the *nizam-ı cedid* as well as by the increased numbers of Westerners present in Istanbul during the era of the French Revolution, began the process by which the old Ottoman isolation was finally and definitively broken. This set the stage for more significant reforms, which transformed the empire during the remainder of the 19th century. (S.J.S.)

II. European domination and the establishment of a Turkish national state

THE EMPIRE, FROM 1807 TO 1920

The triumph of the antireform coalition, which had overthrown Selim III, was interrupted in 1808 when the surviving reformers within the higher bureaucracy found support among the *a'yan* (local notables) of Rumelia (Ottoman possessions in the Balkans), who were worried



The dissolution of the Ottoman Empire, 1807–1924.

Interruption of conservative rule

by possible threats to their own position. These were led by Bayrakdar (Standard Bearer) Mustafa Paşa. The forces of Mustafa and the grand vizier Çelebi Mustafa Paşa together recovered Istanbul; deposed Mustafa IV; set up Mahmud II, the son of Abdülhamid I; and recommenced some of the reforming policies that had been initiated by Selim.

The *aʿyan* took care to protect their own interests by securing in the Covenant of Union (Sened-i Ittifak) a definition and guarantee of their own rights against the central government. Their victory, however, was short-lived. A further Janissary uprising in November 1808 led to the death of the Bayrakdar and to the re-establishment of conservative rule.

Mahmud II (ruled 1808–39). The Ottoman situation at the end of 1808 appeared desperate. Within the empire the authority of the central government was minimal. Control of North Africa had long since faded. In Egypt, the Ottoman Viceroy Muḥammad ʿAlī (*q.v.*) was laying the foundations for independent power. In Iraq the Georgian Mamlūk pashas paid only lip service to the authority of the Porte, as did various independent local governors in Syria. In Arabia the Wahhābīs mocked Ottoman pretensions. In all Anatolia only two provinces were really under central control, while in the European provinces power had fallen into the hands of such formidable local notables as Ali Paşa, who controlled southern Albania, and Osman Pasvanoğlu, who had dominated northern Bulgaria until his death in 1807. Serbia under the leadership of George Petrović (Karageorge) had been in revolt since 1804; at first the Serbs had risen in desperation against the terrorist policies of the Janissaries, who had usurped the power of the local governor, but they had subsequently demanded autonomy and, in 1807, allied with Russia.

The external threat to the empire was no less ominous. Selim III had hoped to enlist French aid in order to recover territory lost to Russia; as a result, the Ottomans found themselves at war with both Russia, which invaded the Principalities in November 1806, and Britain, which attempted to seize the Dardanelles with a naval force (February 1807) and invaded Egypt (March 1807). Meanwhile Napoleon, through the agreements of Tilsit (July 7, 1807) and Erfurt (October 12, 1808), had not only abandoned active opposition to Russia but had accepted its occupation of the Principalities.

The preoccupation of the European powers with other interests helped the Ottomans mend the international problems. Britain made peace on January 5, 1809 (Peace of the Dardanelles); and Russia, on May 28, 1812 (Treaty of Bucharest), by which the Principalities were returned to Ottoman rule although Russia retained most of Bessarabia.

Internal reform. Mahmud II was then able to concentrate on internal reform. The basic element in Mahmud's reforms was the reconstruction of the army to make it a fit instrument for preserving the Ottoman Empire against both the encroachments of European powers and the centrifugal ambitions of local potentates. This policy brought him into head-on collision with the Janissaries. In 1826 Mahmud set out his proposals for a new European style army; on June 15 the Istanbul Janissaries mutinied in protest and were promptly and efficiently massacred by the sultan—an episode known to later Ottoman historians as "The Auspicious Incident."

Reconstruction of the army

As a tactician, Mahmud proved to be superior to Selim. He had the support of most of the higher *ʿulamāʾ*. Whereas in 1807 the Janissaries had enjoyed the approval of the population of Istanbul, in 1826 only two guilds gave them active help. Mahmud had built up a cooperative group among the Janissary officers and had carefully arranged to have loyal troops at hand. Perhaps most important of all, Mahmud presented his proposals not as dangerous and infidel innovations but as a restoration of the military system of the Ottoman golden age.

The destruction of the old army was completed in 1831 by the final abolition of the feudal (*timar*) system. The remaining fiefs were resumed by the government. Although the new army was dressed, equipped, and trained in the style of European armies and helped by a succession of European advisers (including the future chief of the German General Staff, Helmuth von Moltke), it differed from the former army in its greater loyalty to the

sultan. It thus became an instrument of political centralization, and it provided the major motive for modernization. The continuing need to pay and equip the army and to train its officers and other specialized personnel in a sustained, but ultimately vain, attempt to keep pace with the European powers, stimulated reform of the political and economic institutions of the Ottoman Empire. The modernization of higher education began with the need to train officers, army doctors, and veterinary surgeons; that of the taxation system began with the need to pay the army; that of the administration, with the need to collect the taxes, and so on. Ultimately the entire system of minimal government—by which political, economic, and social decisions were left to local organizations—was replaced by one in which the state came to centralize decisions in its own hands.

Move toward centralization. Mahmud began by curbing the power of rival claimants. He undermined the influence of the *'ulamā'* and of popular religious organizations. He created a new directorate of *evkâf* (charitable endowments) in 1826, hoping to gain control of the hitherto independent financial base of *'ulamā'* power. To make his power more effective, he built new roads and, in 1834, inaugurated a postal service.

Administrative reorganization

The central administration was reorganized. New European-style ministries were created to replace the ancient bottleneck of power caused by the universal administrative responsibility of the grand vizier. New councils were established to assist in long term planning; one—the Supreme Council of Judicial Ordinances (1838)—subsequently became the principal legislative body. Bureaucrats were given greater security by abolishing the practice of confiscating their property at death, while the opening of a translation bureau (1833) and the reopening of embassies abroad gave some the opportunity to learn European languages and encounter European ideas.

The reformed army and administration became the agents by which the sultan extended his authority over the semi-independent governors, local notables, valley lords (*derebeys*), and other groups, that had wielded political power in various parts of the empire. This process had begun immediately after 1812. The Serbian revolt had been temporarily suppressed in 1813, although it broke out again in 1815. Firm Ottoman governmental control was established over Anatolia, Iraq, and much of Rumelia.

The only local ruler who succeeded in asserting his own authority, unaided against the Porte, was Muḥammad 'Alī of Egypt, who was carrying through a still more radical program of modernization. In 1831 Egyptian forces invaded Syria, routed the Ottomans at Konya (December 27, 1832) and threatened Istanbul. Mahmud was forced to seek Russian aid, and on July 8, 1833, he signed the Treaty of Hünkâr İskelesi (Unkiar Skelessi); Muḥammad 'Alī was, for a time, left in possession of Syria, but Mahmud had not abandoned his claims. In 1839 he attacked the Egyptians; once more the Ottomans were defeated (June 24, 1839). With the help of the European powers (except France) through the Treaty of London (July 15, 1840), the Ottomans recovered Syria and eventually consolidated their authority there; but Muḥammad 'Alī obtained recognition as hereditary ruler of Egypt (1841).

Attempts to extend Ottoman control in the European provinces, notably in Greece, Serbia, and the Principalities, were frustrated. The Greek revolt was the product of the economic prosperity of the Napoleonic Wars, exposure to western European ideas, and a reaction against Ottoman centralization. It had two sources. The first lay in the opposition of peasants and bandits; the second, in the plots of certain intellectuals organized through the Philikí Etairía (a political society) and led by Alexander Ypsilantis, who invaded Moldavia in March 1821. Ypsilantis was defeated, but a rising began in the Peloponnesus. A stalemate developed; but the Ottomans were reinforced, in 1825, by Egyptian troops and threatened to put down the revolt. The destruction of the combined Ottoman and Egyptian fleets by Russian, French, and British naval forces at Navarino, in the southwestern Peloponnese (October 20, 1827) prevented the Muslims from supplying their armies and made Greek independence inevitable. The Ottomans were forced to recognize first Greek autonomy (1829), and then independence (1832).

Similarly, Ottoman efforts to regain control of Serbia and the Principalities were obstructed by Russian opposition, leading to the Russo-Ottoman War (1828–29). By the Treaty of Edirne (Adrianople) on September 14, 1829, the Ottomans ceded to Russia the mouth of the Danube and important territories in eastern Asia Minor and conceded new privileges to the Principalities and Serbia. Serbian autonomy was recognized in 1830 and was extended over the full area of the state in 1833.

Changes in the empire

By the death of Mahmud II (July 1, 1839) the Ottoman Empire was diminished in extent; it was more consolidated and powerful but increasingly subject to European pressures, with Russia supporting and Britain opposing separatist movements and the other powers oscillating between. The cure, however, had begun. Mahmud had established the "respectability of change," and its symbol was the replacement of the turban with the fez (1828).

The Tanzimat (1839–76). The "Tanzimat" is the name given to the series of Ottoman reforms promulgated during the reigns of Mahmud's sons Abdülmecid I (ruled 1839–61) and Abdülaziz (ruled 1861–76). The best known of these reforms are the Hatt-ı Şerif of Gülhane (Noble Edict of the Rose Chamber; November 3, 1839) and the Hatt-ı Hümayun (Imperial Edict, February 18, 1856).

Purpose of the Tanzimat. The Tanzimat has been the subject of much controversy. Many Western writers have dismissed the promises of reform as an Ottoman desire to win European diplomatic support at critical moments, and some features of the Tanzimat appear to support such a view. The promises of equality for Christian subjects were not always implemented—for example, it was proposed in 1855 to end the poll tax paid by non-Muslims and to allow them to enter the army; but the old poll tax was merely replaced by a new exemption tax levied at a higher rate, and Christians were still excluded from the army. It is also true that the timing of reform announcements coincided with crises—the 1839 edict came when the Ottomans needed European help against Muḥammad 'Alī; the 1856 edict when the Ottomans needed European acceptance in the wake of the Crimean War; and the 1876 constitution when European pressure for reforms was mounting.

This view of the Tanzimat is based, however, upon a misconception of its purpose. Europeans, who were principally concerned with winning better conditions for Ottoman Christians, looked first at those elements of the Tanzimat that appeared to be directed toward this goal (*e.g.*, a proclamation in the 1839 edict of the principles of individual liberty, freedom from oppression, and equality before the law and a substantial section of the 1856 edict that was concerned with the rights of Christians). But to the Ottomans the purpose of reform was to preserve the Ottoman state. While it was necessary to make some concessions to European powers and to their own non-Muslim subjects, and, although some Tanzimat statesmen saw equality as an ultimate goal, it was preservation that required the mobilization of resources for modernization. The central reforms, therefore, were in the army (notably major reorganizations of 1842 and 1869, the latter following the pattern of the successful Prussian conscript system); in the administration, both at the centre and in the provinces; and in society, through changes in education and law.

Reform in education. Before the reforms, education in the Ottoman Empire had not been a state responsibility but had been provided by the various *millets*; education for Muslims was controlled by the *'ulamā'* and was directed toward religion. The first inroads into the system had been made with the creation of naval (1773), military (1793), engineering, medical (1827), and military science (1834) colleges. In this way specialized Western-type training was grafted onto the traditional system to produce specialists for the army. Similar institutions for diplomats and administrators were founded, including

the translation bureau (1833) and the civil service school (1859); the latter was reorganized in 1877 and eventually became the faculty of political science in the University of Ankara (1950) and the major training centre for higher civil servants.

Comprehensive education plan

In 1846 the first comprehensive plan for state education was made. It provided for a complete system of primary and secondary schools leading to university, all under the Ministry of Education. A still more ambitious educational plan, inaugurated in 1869, provided for free and compulsory primary education. Both schemes progressed slowly because of a lack of money, but they provided a framework within which development toward a systematic, secular pattern could take place.

By 1914 there were more than 36,000 Ottoman schools, although the great majority were small, traditional primary schools. The development of the state system was aided by the example of progress among the non-Muslim *millet* schools, in which the education provided was more modern than in the Ottoman schools; by 1914 these included more than 1,800 Greek schools with about 185,000 pupils and some 800 Armenian schools with more than 81,000 pupils. Non-Muslims also used schools provided by foreign missionary groups in the empire; by 1914 there were 675 U.S., 500 French Catholic, and 178 British missionary schools, with more than 100,000 pupils among them. These foreign schools included such famous institutions as Robert College (founded 1863), the Syrian Protestant College (1866; later the American University of Beirut), and the Université Saint-Joseph (1874).

Reforms in law. Law too, to a large extent, had been the responsibility of the various *millets*. The Capitulations exempted foreigners and those Ottoman citizens on whom foreign consuls conferred protection from the application of criminal law. The Tanzimat reformers had two objects in the reform of law and legal procedure—to make Ottoman law acceptable to Europeans so that the capitulations could be abolished and sovereignty recovered, and to modernize the traditional Islāmic law. Their efforts resulted in the promulgation of a number of codes —a commercial code (effective in 1850), a commercial procedure (1861), a maritime code (1863), and a penal code (1858). French influence predominated in these, as it did in the civil code of 1870–76. Increasingly, the laws were administered in new state courts, outside the control of the *'ulamā'*. Although they failed to achieve the purposes intended, they provided the basis for future success.

Obstructions to reforms. The Tanzimat reforms moved steadily in the direction of modernization and centralization. The reformers were handicapped by lack of money and skilled men; and they were opposed by traditionalists, who argued that the reformers were destroying the empire's fundamental Islāmic character and who often halted the progress of reform. Centralization, meanwhile, was slowed by European interference, which obstructed the Ottoman attempt to recover power in Bosnia and Montenegro in 1853; forced the granting of autonomy to Mount Lebanon in 1861; and considered, but eventually rejected, intervention to prevent the Ottomans from suppressing a Cretan revolt of 1868. Although Britain and France helped the Ottomans resist Russian pressure during the Crimean War (1853–56), the Ottomans derived no real benefits from the peace settlement; and new arrangements helped to bring about the unification of the Principalities (1859) and paved the way for the emergence of independent Romania.

European interference

The very success of the Tanzimat reformers revealed a novel weakness. The effect of centralization removed the checks on the power of the sultan. After the death of Ali Paşa, Abdülaziz so abused his unrestrained authority as to produce a major crisis in 1875–78.

The 1875–78 crisis. Drought in 1873 and floods in 1874 produced widespread discontent and even famine among an Ottoman peasantry already disturbed by its increased burdens under a landholding system that had spread in the Balkans in the 19th century and by increased taxation and greater liability to conscription as a result of the 1869 military reorganization. The burden of taxation had been aggravated by the Ottoman problems of debt repayment. The first Ottoman foreign loan was in 1854; by 1875 the nominal public debt was £200,000,000 with annual repayments and amortization taking £12,000,000, or more than half the national revenue, but the Ottomans could pay only half the interest due because a world financial crisis in 1873 had made new credit difficult to obtain.

Balkan discontent was fanned by nationalist agitation supported by Serbia and by émigré Slav organizations. It culminated in risings largely of Christian peasants against Muslim lords in Bosnia and Hercegovina (July 1875) and in Bulgaria (August 1876). Ottoman efforts to suppress the risings led to war with Serbia and Montenegro (July 1876) and to attempts by European powers to force Ottoman reforms.

Agreement among the European powers proved impossible; and when the Ottomans rejected its demands, Russia decided to act alone and declared war (April 24, 1877). The war ended in defeat for the Ottomans, but their unexpected resistance at Plevna (modern Pleven, Bulgaria; July–December 1877) allowed other European powers, led by Britain, to intervene. According to the Treaty of San Stefano (March 3, 1878), the Ottomans were to recognize the independence of Romania, Serbia, and Montenegro and cede territory to them; to concede autonomy to an extensive new state of Bulgaria; to cede territory to Russia in the Dobruja (west of the Black Sea) and eastern Asia Minor; and to introduce various administrative reforms and pay an indemnity.

Russo-Turkish War, 1877–78

Diplomatic pressure from other European powers led to the modification of these terms at the Congress of Berlin (June–July 1878). The major changes concerned autonomous Bulgaria, which was substantially reduced in size and divided into two parts—the northern part to have political and the southern (eastern Rumelia) to have administrative autonomy. The independence of Serbia, Montenegro, and Romania was recognized, but their territorial gains were much reduced. Russia retained its acquisitions of Kars and Batum in Asia Minor. Austria-Hungary was given control of Bosnia and Hercegovina and the strategic district of Novi Pazar, in Yugoslavia. By a separate convention Cyprus was put under British rule.

The settlement was a major defeat for the Ottomans. Eastern Rumelia was soon lost, when it united with Bulgaria in 1885. The Ottoman territories in Europe were reduced to Macedonia, Albania, and Thrace, and European influence had attained new dimensions. Britain now proposed to supervise governmental reforms in the Asian provinces, although this was skillfully frustrated by Abdülhamid II (ruled 1876–1909). In addition, the Ottomans were soon forced to accept new financial controls. By the Decree of Muharrem (December 1881) the Ottoman public debt was reduced from £191,000,000 to £106,000,000, certain revenues were assigned to its service, and a European-controlled organization (the Ottoman Public Debt Administration—OPDA) was set up to collect them.

The OPDA subsequently played an important part in Ottoman affairs, acting as agent for the collection of other revenues and as an intermediary with European companies seeking investment opportunities. Its influence should not, however, be exaggerated. It remained under Ottoman political control, and its existence even enabled the Ottomans to add to the debt at the annual rate of £3,000,000 throughout the reign of Abdülhamid; nor was the burden of repayments a major drain on the country's resources. But taken in conjunction with the activities of European-controlled banks and with the tariff limitations imposed on the Ottomans by the capitulations, the result was a distinct restriction on Ottoman ability to guide the allocation of resources.

The constitution, 1876. Perhaps more significant than external changes were the internal political developments that brought about the first Ottoman constitution, December 23, 1876. The Tanzimat had produced three types of criticism within the Muslim community. The first was a simple traditionalist opposition. The second was a more

sophisticated critique elaborated by certain intellectuals, many of whom had bureaucratic training and some knowledge of Western ideas. The third was a determination to depose the sultan (see below).

The Young Ottomans

The intellectuals were known as the Young Ottomans. Although some had taken part in a secret society (the "Patriotic Alliance") in 1865 and had some similarity of background, the Young Ottomans were not an organized political party; they are considered as a group largely through the accident of their assembly in Paris and London in 1867–71. Their political views ranged from secular, cosmopolitan revolutionism to profoundly Islāmic traditionalism. Because his views occupied a middle ground among these intellectuals and because of his lucidity of expression, Namık Kemal (1840–88) has often been regarded as the representative figure, although he is no more representative than the others. His views, however, had the greatest effect on later reformers.

Kemal criticized the Tanzimat reformers for their indiscriminate adoption of Western innovations. While admiring much of Western civilization, he believed that the principles underlying its best institutions were to be found in Islām. In particular he derived from early Islāmic precept and practice the idea of a representative assembly that could check the unbridled power of the sultan and his ministers. He helped to form and popularize the idea of a constitution and of loyalty to the Ottoman fatherland. Like others, he was assisted by the development of an Ottoman press, which had its origins in the 1830s but began to express opinions, occasionally critical of the government, in the 1860s, which saw the establishment of the *Tercüman-ı Ahval* (1860) and the *Tasvir-i Efkâr* (1862), both of which, along with later newspapers, became the vehicles for Young Ottoman ideas.

But it was the third line of criticism that was most important. Arising within the higher Ottoman bureaucracy itself, it was led by Midhat Paşa. Midhat and others became convinced by their own exclusion from power and by the disastrous results of Abdülaziz's policies that some check was needed upon the sultan's power. The traditional check was deposition, and this was accomplished (May 30, 1876) following a riot by theological students and the removal of the hated grand vizier Mahmud Nedim Paşa. A new Cabinet was formed, which included Midhat and other partisans of reform. A new sultan, Murad V (ruled 1876), with a reputation for liberalism was installed; but Murad became insane and was deposed in August and replaced by Abdülhamid II. The experience convinced Midhat of the necessity of a permanent check upon the power of the sultan, such as could be provided by a representative assembly that would give ministers a basis of support independent of the sultan. Accordingly, Abdülhamid was persuaded to agree to a constitution.

First Ottoman constitution

Although earlier documents had had constitutional implications and although the development of councils—particularly provincial councils with their elected elements—had had parliamentary aspects, the December 23 document was the first comprehensive Ottoman constitution and, except for a Tunisian organic law of 1861, the first in any Islāmic country. The constitution was derived entirely from the will of the ruler, who retained full executive power and to whom ministers were individually responsible. In legislation the sultan was assisted by a two-chamber Parliament—the lower indirectly elected and the upper nominated by the ruler. Rights of ruler and ruled were set out, but the system it established might best be described as attenuated autocracy. Midhat has been criticized for accepting certain amendments demanded by Abdülhamid, including the then notorious article 113, which gave the sultan the right to deport persons harmful to the state; but it is clear that the majority of Midhat's colleagues were content with these amendments, and that the amendments made little difference, so great were the sultan's powers within and outside the constitution. The Parliament summoned under the constitution in March 1877 was dissolved in less than a year and was not recalled until 1908. The liberals were exiled; some, incuding Midhat, were put to death.

Abdülhamid II (ruled 1876–1909). The reign of Abdülhamid II is often regarded as having been a reaction against the Tanzimat; but, insofar as the essence of the Tanzimat reforms was centralization rather than liberalization, Abdülhamid may be seen as its fulfiller rather than its destroyer. The continued development of the army and administration, the formation of a gendarmerie, the growth of communications—especially the telegraph and railways—and the formation of an elaborate spy system enabled the sultan to monopolize power and crush opposition. His brutal repression of the Armenians in 1894–96 earned him the European title red sultan. But Abdülhamid's reign also made positive advances in education (including the foundation of the University of Istanbul in 1900); in legal reform, led by his grand vizier Mehmed Said Paşa; and in economic development, through the construction of railways in Asia Minor and Syria with foreign capital and of the Hejaz Railway from Damascus to Medina with the help of international Muslim subscriptions.

Pan-Islāmism. The Hejaz Railway constituted one element in Abdülhamid's Pan-Islāmic policies. Political Pan-Islāmism had made its first appearance in Ottoman policy at the Treaty of Küçük Kaynarca (1774) with Russia, when the Ottoman sultan had put forward claims to religious jurisdiction over Muslims outside his territories (particularly those in the Crimea). Some years later the theory was elaborated by the addition of the baseless legend that in 1517 the ʿAbbāsid caliphate had been transferred to the Ottoman sultan. With the extinction of many independent Muslim states and their absorption into the empires of European powers, this myth of the caliphate became a useful weapon in the Ottoman diplomatic armoury and was exploited by Abdülhamid as a means of deterring European powers from pressing him too hard, lest he create dissension within their own territories. In addition, stress on popular Islām through the press and other publications and through the Sultan's patronage of dervish orders served to rally Muslim opinion within the empire behind him.

Power of the myth of the caliphate

Preservation of the empire. Abdülhamid had reasonable success in preserving the empire after 1878. Apart from eastern Rumelia, no further territories were lost until 1908 (Ottoman authority in Tunisia, occupied by France in 1881, and that in Egypt, occupied by Britain in 1882, was already insignificant). In Crete the Ottomans suppressed revolts and defeated Greece when it intervened in 1897 in support of the Cretans. The European powers, however, forced Abdülhamid to concede autonomy to Crete. He was more successful in obstructing the efforts of the powers to force the introduction of substantial reforms in Macedonia. In Arabia the Ottomans continued the expansion of their power that had begun in the early 1870s.

The Young Turk Revolution, 1908. Several conspiracies took place against Abdülhamid. In 1889 a conspiracy in the military medical college spread to other Istanbul colleges. These conspirators came to call themselves Union and Progress (İttihad ve Terakki). When the plot was discovered, some of its leaders went to reinforce Ottoman exiles in Paris, Geneva, and Cairo, where they helped to prepare the ground for a revolution by developing a comprehensive critique of the Hamidian system. The most noteworthy among these were Murad Bey, Ahmed Rıza, and Prince Sabaheddin. As editor of *Mizan* ("Balance"), published first in Istanbul (1886) and later in Cairo and Geneva, Murad Bey preached liberal ideas combined with a strong Islāmic feeling; this last may have contributed to his defection and return to Istanbul in 1897. Ahmed Riza in Paris edited *Meşveret* ("Consultation"), in which he set out ideas of reform, strongly flavoured by positivism. His advocacy of a strong central government within the Ottoman Empire and the exclusion of foreign influence led to a major split within the Young Turk exiles at the 1902 Paris Congress; Ahmed Rıza clashed with Sabaheddin, who, with Armenian support, favoured administrative decentralization and European assistance to promote reform. Sabaheddin set up the League of Private Initiative and Decentralization.

The émigrés could supply literary sustenance to dissidents, but Abdülhamid could not be overthrown so long as the army remained loyal. The real origin of the Young Turk Revolution of 1908 lay in the discontent within the 3rd Army Corps in Macedonia, where officers acted quite independently of the Committee of Union and Progress (CUP) in Paris. It is still unclear if a coordinated conspiracy existed in Macedonia or if a number of separate centres of disaffection, linked haphazardly through individuals, dervish orders, Freemason lodges, etc., coalesced in July 1908 under the banner of the CUP through the pressure of events. On July 3, 1908, Maj. Ahmed Niyazi (1873–1912), apparently fearing discovery by an investigatory committee, decamped from Resne with 200 followers, including civilians, leaving behind a demand for the restoration of the constitution. The Sultan's attempt to suppress this rising failed, and rebellion spread rapidly. Unable to rely on other troops, on July 24 Abdülhamid announced the restoration of the constitution.

Goals of rebel leaders

The young officers who had made the revolution, like their civilian supporters, were primarily concerned with preserving the Ottoman Empire; they feared that Hamidian policies and European interventions were endangering its existence. Personal grievances concerned with pay, promotion, etc., also played a part. Though some writers have argued that a new type of officer of lower than usual social origins influenced this discontent, there is little evidence to support such a theory. It is clear, however, that the officers had not thought much beyond their demand for the restoration of a constitution that had proved ineffectual in 1877–78. They had no program of action and were content to leave government to the established bureaucrats.

In April 1909, however, an army mutiny in Istanbul (known because of the Julian calendar as the "31st March Incident") exposed the weakness of the CUP and at the same time gave it a new opportunity. The mutiny resulted from the discontent of ordinary soldiers arising from their conditions and their neglect by college-trained and politically ambitious officers, and from what they regarded as infidel innovations. They were encouraged by a religious organization—the Mohammedan Union. Government weakness allowed the mutiny to spread; and although order was eventually restored in Istanbul and more quickly elsewhere, a force from Macedonia (the Action Army) led by Mahmud Şevket Paşa marched on Istanbul and occupied the city (April 24).

Dissolution of the empire. Abdülhamid was deposed and replaced by Sultan Mehmed V (ruled 1909–18), son of Abdülmecid. The constitution was amended to transfer real power to the Parliament. The army, and particularly Şevket Paşa became the real arbiters of Ottoman politics.

Rise of the CUP. Although the removal of many of its political opponents had allowed the CUP to move into a more prominent position in government, it was still weak. It had a core of able, determined men but a much larger collection of individuals and factions that wore the Unionist label so lightly that they easily merged into other parties. Although the CUP won an overwhelming majority in the election of April 1912, its support rapidly melted away following military losses to Italy. Evidence of army hostility finally forced the CUP out of office in July 1912, to be succeeded by a political coalition called the Liberal Union.

The Liberal Union, too, lost support following defeats in the Balkans. This provided the opportunity for a small group of CUP officers and soldiers to stage a coup (January 23, 1913), known as the Sublime Porte Incident, to force the resignation of the grand vizier Mehmed Kâmil Paşa and establish a new cabinet under Şevket. Şevket, however, was not a Unionist and it was only after his assassination (June 11, 1913) that the CUP at last succeeded in establishing a Unionist-dominated government under Said Halim Paşa.

The Sublime Porte Incident

Internal developments. The disastrous results of the Young Turks' external policies have overshadowed the important internal developments of the years 1908–18. Further administrative reforms, particularly of provincial administration in 1913, led to more centralization, although by European standards the central Ottoman government remained relatively weak, particularly in the provinces distant from Istanbul. The burden of taxation was well below that of European powers.

The Young Turks were the first Ottoman reformers to promote industrialization, with a Law for the Encouragement of Industry (1909, revised 1915). Although they had little success, they did build a framework for later state-directed economic planning. Considerable attention was given to education, especially to the neglected area of primary education. The process of secularization of the law was carried much further. A major development in national journalism took place, and the position of women improved. The whole period was one of intense social and political discussion and change.

Turkish nationalism. The basic ideologies of the state remained Ottomanism and Islām, but a new sense of Turkish identity began to develop. This new concept was fostered by educational work of the Turkish Society (1908) and the Turkish Hearth (1912). A political twist was given by the adherents of Pan-Turkism and Pan-Turanianism. Pan-Turkism, which aimed at the political union of all Turkish-speaking peoples, began among Turks in the Crimea and on the Volga. Its leading exponent was Ismail Bey Gasprinski (Gaspirali; 1851–1914), who attempted to create a common Turkish language. Many Pan-Turkists migrated to Ottoman lands, especially after 1905. One of them, Yusuf Akçuraoğlu, argued in *Üç tarz-ı siyaset* (1903; "Three Kinds of Policy") that Turkism provided a better basis for the Ottoman Empire than either Islām or Ottomanism. Pan-Turanianism developed from a now much-disputed 19th-century theory of the common origin of Turkish, Mongol, Tungus, Finnish, Hungarian, and other languages; in certain very limited circles it looked forward to a great political federation of speakers of these languages, extending from Hungary to the Pacific.

Pan-Turkism and Pan-Turanianism

These ideas, however, found little support within the Ottoman government. The accusation that the Young Turks pursued a deliberate policy of Turkification within the empire so as to alienate non-Turks and promote the rise of Arab and Albanian nationalism is an oversimplification. The extension of government activity inevitably brought with it the language of government—Turkish. This produced some reaction from speakers of other languages, but the evidence suggests that it did not override basic feelings of Muslim solidarity, except among some small minorities. It was among the Christian groups that distinct separatist ideas were developed.

Foreign relations. The foreign relations of the Ottoman Empire under the Young Turks led to disaster. The 1908 revolution provided an opportunity for several powers to press home their designs upon the empire. On October 5, 1908, Austria annexed Bosnia and Hercegovina and Bulgaria proclaimed its independence. Italy seized Tripoli and occupied the Dodecanese, a group of Aegean islands; by the Treaty of Lausanne (October 18, 1912) Italy retained the former but agreed to evacuate the Dodecanese. In fact, however, it continued to occupy them.

The two Balkan Wars (1912–13) almost completed the destruction of the Ottoman Empire in Europe. In the first (October 1912–May 1913), the Ottomans lost almost all of their European possessions, including Crete, to Bulgaria, Serbia, Greece, Montenegro, and the newly created state of Albania (Treaty of London, May 30, 1913). In the second (June–July 1913), fought between Bulgaria and the remaining Balkan states, including Romania, over the division of Macedonia, the Ottomans intervened against Bulgaria and recovered part of eastern Thrace including Edirne (Adrianople). The Ottomans had lost 83% of the territory and 69% of the population of their European provinces.

The people. In 1914 the total population of the Ottoman Empire was approximately 25,000,000, of which about 10,000,000 were Turks; 6,000,000, Arabs; 1,500,000 each, Kurds and Greeks; and between 1,000,000 and 1,500,000 Armenians. The population of the empire (excluding such virtually independent areas as Egypt, Romania, and Serbia) in the period immediately prior to the

Population of the empire

losses of 1878 is estimated to have been about 26,000,000. Natural increases and Muslim immigration from Russia and the Balkans virtually made up the losses, and in 1914 the population was more homogeneous in religion and, though less so, in language.

World War I, 1914–18. The Ottoman entry into World War I resulted from an overly hasty calculation of likely advantage. German influence was strong, but not decisive; Germany's trade with the Ottomans still lagged behind that of Britain, France, and Austria and its investments, which included the Baghdad railway, were smaller than those of France. A mission to Turkey led by the German military officer Otto Liman von Sanders in 1913 was only one of a series, and Liman's authority was much more limited than contemporaries supposed. Except for the interest of Russia in Istanbul and the Straits, no European power had really vital interests in the Ottoman Empire. The Ottomans might have remained neutral, as a majority of the cabinet wished to do, at least until the situation became clearer. But the opportunism of the minister of War Enver Paşa, early German victories, friction with the Triple Entente (France, Russia, and Great Britain) arising out of the shelter given by the Ottomans to German warships, and basic hostility to Russia combined to produce an Ottoman bombardment of the Russian Black Sea ports (October 28, 1914) and a declaration of war by the Entente against the Ottoman Empire.

The Ottomans made a substantial contribution to the Central Powers' war effort. Their forces fought in eastern Asia Minor, Azerbaijan, Mesopotamia, Syria and Palestine, and at the Dardanelles, as well as on European fronts, and they held down large numbers of Entente troops. In September 1918 they dominated Transcaucasia. During the war the Young Turks also took the opportunity to attack certain internal problems—the Capitulations were abolished unilaterally (September 1914), the autonomous status of Lebanon was ended, a number of Arab nationalists were executed in Damascus (August 1915 and May 1916), and the Armenian community in eastern Asia Minor and Cilicia was massacred or deported as part of a deliberate policy of eliminating one cause of European interference. Possibly a million Armenians either fled or were killed (principally by Kurdish irregulars) or deported.

From the end of 1916 army desertions took place on a massive scale, and economic pressures became acute. The surrender of Bulgaria (September 28, 1918), which severed direct links with Germany, was the final blow. The CUP Cabinet resigned on October 7, and a new government was formed under Ahmed Izzet Paşa (1864–1937) on October 9. On October 30 the Ottomans signed the Armistice of Mudros.

Allied war aims and the proposed peace settlement. Partition of Ottoman territories

Entente proposals for the partition of Ottoman territories were formulated in a number of wartime agreements. By the Istanbul Agreements (March–April 1915) Russia was promised Istanbul and the Straits; and France, a sphere of influence in Syria and Cilicia. Britain had already annexed Cyprus and declared a protectorate over Egypt. By the Anglo-French Sykes-Picot Agreement (January 3, 1916) the French sphere was confirmed and extended eastward to Mosul in Iraq. A British sphere in Mesopotamia as far north as Baghdad, control of Haifa and Acre, and a linking sphere of influence were recognized. Palestine was to be placed under an international régime. In compensation, the Russian gains were extended (April–May 1916) to include the Ottoman provinces of Trabzon, Erzurum, Van, and Bitlis in eastern Asia Minor. By the London Agreement (April 26, 1915) Italy was promised the Dodecanese and a possible share of Asia Minor. By the Agreement of St.-Jean-de-Maurienne (April 1917) Italy was promised a large area of southwestern Anatolia, including Izmir (Smyrna) and a further sphere to the north. Britain made various promises of independence to Arab leaders, notably in the Ḥusayn-MacMahon correspondence, 1915–16, and, in the Balfour Declaration (November 2, 1917), promised to support the establishment of a national home for the Jewish people in Palestine.

The Russian withdrawal in 1917 and postwar bargaining led to some modifications of these agreements, and the Allied terms were not finally presented until 1920. By the Treaty of Sèvres (August 10, 1920) the Ottomans retained Istanbul and part of Thrace, but lost the Arab provinces and a large area of Asia Minor to a newly created Armenian state with access to the sea, surrendered the islands of İmroz and Bozcaada to Greece, and accepted arrangements that implied the eventual loss of Izmir to Greece. The Straits were internationalized, and strict European control of Ottoman finances was established. An accompanying tripartite agreement between Britain, France, and Italy defined the extensive spheres of influence of the latter two powers. The treaty was ratified only by Greece and was abrogated by the Treaty of Lausanne (July 24, 1923) as the result of a determined struggle for independence waged under the leadership of the outstanding Ottoman wartime general Mustafa Kemal, later known as "Atatürk."

The War of Independence, 1919–23. Although the legal Ottoman government in Istanbul, under the 36th, and last, Ottoman sultan Mehmed VI Vahideddin (ruled 1918–22) had decided that resistance to Allied demands was impossible, pockets of resistance remained in Asia Minor after the armistice. These included bands of irregulars and deserters, certain intact Ottoman forces, and various societies for the defense of rights. Resistance was stimulated by the Greek occupation of Izmir (May 15, 1919). At this time Mustafa Kemal was sent on an official mission to eastern Asia Minor, landing at Samsun on May 19. He immediately began to organize resistance, despite official Ottoman opposition. Through the Association for the Defence of the Rights of Eastern Anatolia (founded March 3, 1919), he summoned a congress at Erzurum (July–August), followed by a second congress at Sivas (September) with delegates representing the whole country. A new Association for the Defence of the Rights of Anatolia and Rumelia was established, and an executive committee with Mustafa Kemal as chairman was created to conduct resistance. Congress at Erzurum

The official government yielded to Kemalist pressure. The unpopular grand vizier, Damad Ferid Paşa, resigned and was replaced by the more sympathetic Ali Rıza Paşa. Negotiations with the Kemalists were followed by the election of a new parliament, which met in Istanbul in January 1920. A large majority in parliament was opposed to the official government policy and passed the "National Pact," which embodied the political aims of independence roughly within the October 1918 armistice lines and which had been formulated at Erzurum and Sivas. The Allies countered by extending the occupied area of Istanbul (March 16, 1920) and by arresting and deporting many deputies. Damad Ferid became grand vizier again on April 5 and, with religious support, set out to crush the Kemalists.

The Kemalists were now faced with local risings, official Ottoman forces, and the Greeks. The first necessity was to establish a legitimate basis of action. A parliament (the Grand National Assembly) met at Ankara on April 23 and asserted that the sultan's government was under infidel control and that it was the duty of Muslims to resist foreign encroachment. In the Fundamental Law of January 20, 1921, the assembly declared that sovereignty belonged to the nation and that the assembly was the "true and only representative of the nation." The name of the state was declared to be "Turkey" ("Türkiye"); and executive power was entrusted to an executive council, headed by Mustafa Kemal, who could now concentrate on the war.

TURKEY SINCE 1920

The uprisings and Ottoman forces were both defeated, principally by irregular forces, who at the end of 1920 were brought under Kemal's control. In 1920–21 the Greeks made major advances, almost to Ankara, but were defeated at the Battle of the Sakarya River (August 24, 1921) and began a long retreat that ended in the Turkish occupation of Izmir (September 9, 1922).

The Kemalists had already begun to gain European rec-

ognition. On March 16, 1921, the Soviet-Turkish Treaty gave Turkey a favourable settlement of its eastern frontier by restoring Kars and Ardahan. Domestic problems induced Italy to begin withdrawal from the territory it occupied; and, by the Treaty of Ankara (Franklin-Bouillon Agreement, October 20, 1921), France agreed to evacuate Cilicia. Finally, by the Armistice of Mudanya the Allies agreed to Turkish reoccupation of Istanbul and eastern Thrace.

New Turkish frontier

A comprehensive settlement was eventually achieved at the Lausanne Conference (November 1922–July 1923). The Turkish frontier in Thrace was established on the Maritsa River, and Greece returned the islands of İmroz and Bozcaada. A compulsory exchange of populations was arranged, as a result of which an estimated 1,300,000 Greeks left Turkey in return for 400,000 Turks. The question of Mosul was left to the League of Nations, which in 1925 recommended its retention by Iraq. The Lausanne Treaty also provided for the apportionment of the Ottoman Public Debt, for the gradual abolition of the Capitulations (Turkey regained tariff autonomy in 1929), and for an international régime for the Straits. Turkey did not recover complete control of the Straits until the 1936 Montreux Convention.

The result of the war and the peace settlement created a state in which the great majority spoke Turkish. Though there has been a tendency to see this as the almost inevitable consequence of the rise of Turkish and Arab nationalisms, it seems in fact to have been the accident of war that broke off the Arab provinces. Whatever the views of Mustafa Kemal himself, it is clear that the majority of his followers thought of themselves primarily as Muslims; in the elaborate religious ceremony that preceded the opening of the Grand National Assembly there was no word of Turks or Turkey but only of the need to save "religion's last country." The creation of a sense of Turkish nationhood was the product of a long effort in which Mustafa Kemal played the dominant role.

Kemalism, 1922–38. Construction of a new political system began with the abolition of the sultanate and the declaration of a republic. Loyalty to the Ottoman dynasty was strong even among Kemalists; but Vahideddin's identification with the Allies weakened his support.

Abolition of the sultanate and caliphate. An Allied invitation to the sultan to nominate representatives to Lausanne aided Kemal—a split Turkish delegation would be self-defeating. With a brilliant mixture of threats and persuasion, Kemal was able, therefore, to induce the Assembly to abolish the sultanate (November 1, 1922). Vahideddin left Turkey, and his cousin Abdülmecid (died 1944) was installed as the first and last Ottoman caliph who was not also sultan. The caliphate was finally abolished on March 3, 1924, and all members of the Ottoman dynasty were expelled from Turkey. Before that

Republic of Turkey

the assembly had declared Turkey to be a republic and had elected Mustafa Kemal as first president (October 29, 1923). A full republican constitution was adopted on April 20, 1924; it retained Islām as the state religion, but in April 1928 this clause was removed and Turkey became a purely secular republic.

Kemal's government. The assembly was the instrument of Kemal's will. The first assembly had contained large factions hostile to his policies, including religious conservatives, merchants, and former members of the CUP. In opposition to his 197 acknowledged supporters, who were known as the "First Group," there were 118 opponents, members of a "Second Group." The first Assembly was dissolved on April 16, 1923, and Mustafa Kemal took care to keep his opponents out of the second assembly; only three of the Second Group were returned. Kemal's own party, which became the Republican People's Party (RPP), dominated all assemblies until 1950; this period saw a heavy preponderance in the Assembly of urban professional men and of officials with university education. With an outlook different from that of the illiterate Turkish peasant they carried out a revolution from the top.

Opposition. There was little opposition to Mustafa Kemal—the small Progressive Party (founded, November 17, 1924; dissolved, June 5, 1925) had only 29 members and was suppressed because Kemal feared that its leading members, who included some of his most notable associates in the war of independence, might have too much influence in the army; the short-lived Liberal Republican Party (August 12–December 18, 1930) was an abortive attempt by Kemal to organize a moderate opposition to his own party. Otherwise Kemal ruled quite autocratically. A plot against his life in 1926 gave him the chance to deal with his rivals, who were tried by a special court and many of them sentenced to death, imprisonment, or exile. Opposition outside the assembly, of which the most dangerous were the Kurdish revolts of 1925, 1930, and 1937, was suppressed vigorously.

Kemalist policies. The bases of Mustafa Kemal's policies were enshrined in the Republican People's Party program of 1931 and subsequently (February 1937) written into the Turkish constitution. These were the six principles of republicanism (the creation of the republic), nationalism, populism, statism (*devletçilik*), secularism, and revolution. Revolution was implicit in the whole radical reorganization of the political, social, and economic systems. Populism was the effort to mobilize popular support from the top through such characteristic devices as the People's Houses (1931–51), which spread the new concept of a national culture in provincial towns, and the village institutes, which performed the same educational and proseletyzing role in the countryside. The creation of a sense of nationalism was encouraged by changes in school curricula, by the rewriting of history to glorify the Turkish past, by the "purification" of the language by a reduction of the number of words of foreign origin (sometime later, this effort appeared to be redundant in the light of a promulgation that all languages were descended from Turkish), and by the renunciation of Pan-Islāmic, Pan-Turkish, and Pan-Ottoman goals in foreign policy.

Mustafa Kemal's six principles

Statism was the movement toward state-controlled economic development; the shortage of skilled labour and entrepreneurs (particularly owing to the reduction of the Greek and Armenian communities, which in 1914 had controlled 80% of Ottoman finance, industry, and commerce), the lack of capital, and the intense nationalist desire for industrial self-sufficiency that would banish foreign influence, all stimulated a movement in the 1930s towards state ownership or control. This was achieved through investment banks, monopolies, state industrial enterprises, and planning. A five-year plan was instituted in 1934. Although the immediate results were disappointing, the policy of state-inspired economic growth was important for future economic advance.

Under secularism is included the reform of law, involving the abolition of religious courts and schools (1924) and the adoption of a purely secular system of family law. The substitution of Latin for the Arabic alphabet in writing Turkish was a significant step toward secularism and made learning easier; other measures included the adoption (1925) of the Gregorian calendar that had been jointly used with the Hijrī calendar since 1917; the replacement of Friday by Sunday as the weekly holiday (1935); the adoption of surnames (1935); and, most striking of all, the abolition of the fez (1925). The wearing of clerical garb outside places of worship was forbidden in 1934.

These changes, coupled with the abolition of the caliphate, and the elimination of the dervish orders after a Kurdish revolt in 1925, dealt a tremendous blow to Islām's position in social life, completing the process begun in the Tanzimat. With secularism there came a steady improvement in the status of women, who were given the right to vote and to sit in the parliament.

Vital as the changes made were, in many cases they were primarily matters of appearance and style. Structural changes in society took longer. At the first census, in 1927, the population was put at 13,600,000, of which 24% was urban. In 1940 the population was 17,800,000, but the urban percentage was almost unchanged. In 1938 the per capita income and literacy were both below comparable figures for developed countries.

Foreign policy was subordinated to internal change. The loss of Mosul was accepted (June 5, 1926). Hatay, however, was recovered. It was given internal autonomy by France in 1937, occupied by Turkish troops in 1938, and incorporated into Turkey in 1939. Turkey followed a neutralist policy, supported the League of Nations, which it joined in 1932, and sought alliances with other minor powers, leading to the Balkan Entente (1934) and the Sa'dābād Pact with Iran, Iraq, and Afghanistan (1937).

Neutralist policy

World War II and the postwar era, 1938–50. Atatürk's autocratic, dominating, and inspiring personality had directed and shaped the Turkish republic. At this death in 1938, his closest associate İsmet İnönü (born 1884) was elected president. With the approach of war, foreign affairs assumed greater importance. An alliance with Britain and France (October 19, 1939) was not implemented because of Germany's early victories. After Germany's invasion of Russia (June 22, 1941), there was popular support for an alliance with Germany, which seemed to offer prospects of realizing old Pan-Turkish aims. Although a nonaggression pact was signed with Germany (June 18, 1941), Turkey clung to neutrality until an Axis defeat was seen to be inevitable, when it entered the war on the Allied side (February 23, 1945). The great expansion of Soviet power exposed Turkey, in June 1945, to demands that control of the Straits be given to Black Sea powers and for the cession of territory in eastern Asia Minor. It was also suggested that a large area of northeastern Anatolia be ceded to Soviet Georgia and a more democratic government established in Turkey. This caused Turkey to seek U.S. assistance; it received U.S. military aid beginning in 1947 (providing the basis for a large and continuing flow of military aid) and economic assistance beginning in 1948.

Economic problems. The war also brought changes in domestic policy. The army had been kept small throughout the Atatürk period, and defense expenditure had been reduced to 28% of the budget. The army was rapidly expanded in 1939, and defense expenditures rose to between 50% and 60% of the budget for the duration of the war. Substantial deficits were incurred, imposing a severe economic strain, which was aggravated by shortages of raw materials. By 1945 agricultural output had fallen to 70% of the 1939 figure; per capita income, to 75%. Inflation was strong; official statistics show a rise of 354% between 1938 and 1945, but this probably understates the fall in the value of money, which in 1943 was less than one-fifth its 1938 purchasing power. One means chosen by the government to raise money was a capital levy introduced in 1942, arranged to fall with punitive force upon the non-Muslim communities and upon the Dönmes (Jewish converts to Islām). The war did provide some stimulus to industry, however, and enabled Turkey to build up substantial foreign credits, which could be used to finance postwar economic development.

Political changes. The most notable change in the postwar years was the liberalization of political life. The investment in education was beginning to show some return, and literacy had risen to 29% by 1945. A growing class of professional and commercial men demanded more freedom. The Allied victory had made democracy more fashionable; accordingly, the government made concessions allowing new political parties, universal suffrage, and direct election.

Political liberalization

From a split within the Republican People's Party (RPP), the Democrat Party (DP) was founded in 1946 and immediately gathered support. Despite government interference, the DP won 61 seats in the 1946 general election. Some elements in the RPP, led by the prime minister Recep Peker (served 1946–47), wished to suppress the DP, but they were prevented by İnönü. In his declaration of July 12, 1947, İnönü stated that the logic of a multiparty system implied the possibility of a change of government. Prophetically, he renounced the title of "National Unchangeable Leader," which had been conferred upon him in 1938. Peker resigned and was succeeded by more liberal prime ministers in Hasan Saka (served 1947–49), and Şemseddin Günaltay (served 1949–50).

Other restrictions on political freedom, including press censorship, were relaxed. The period saw the establishment of the first mass circulation, independent newspapers. Trade Unions were permitted in 1947, although they were not given the right to strike until 1963. A far-reaching measure of land redistribution was passed in 1945, although little was done to implement it before 1950. Other political parties were established including the conservative National Party (1948); Socialist and Communist activities, however, were severely repressed.

In the more open atmosphere the DP was able to organize in the villages. The RPP, despite its Village Institutes, had always been the government party and had had little real grass-roots organization. The Democrats were much more responsive to local interests. The DP won a massive victory in the 1950 elections, claiming 54% of the vote and 396 out of 487 seats. The RPP won 68 seats; the National Party, one. The DP victory has been attributed variously to U.S. influence, to social change, to a desire for economic liberalization, to better organization, to religious hostility to the RPP, and to a bad harvest in 1949. Perhaps the basic reason was that in 27 years the RPP had made many enemies.

Turkey under the Democrats, 1950–60. In the DP government Celâl Bayar became president; Adnan Menderes, prime minister (a post which for the first time came to surpass that of the president in importance).

The economy. The Democrats were pledged to a program of economic growth, to be achieved through a reduction of state interference. At first they had much success; in 1950–53 Turkey's average annual rate of economic growth was 6%, and annual per capita income rose at a rate of 3%. Good harvests in 1950 and 1953 and the Korean War boom assisted. But problems appeared after 1953. In 1954 a poor harvest obliged Turkey to import wheat again. A shortage of foreign exchange limited the purchase of essential materials and parts, which handicapped industry. After a sudden favourable surge in the early 1950s, the terms of trade moved steadily against Turkey. Inflation, which averaged 15% or more annually, became a serious problem. The government attempted unsuccessfully to check the price rise by legislation, but its policies contributed to inflation as the result of a continued rise in public expenditure. Despite the problems, the DP achieved considerable success over the decade 1950–60. The proportion of the gross national product going to investment was raised (with overseas aid) from about 10% to between 12% and 15%, and annual growth averaged 5%.

Political repressions. The political fortunes of the Democrat government closely reflected the economic changes. In the 1954 elections—the Democratic peak—the DP took 57% of the vote and gained 503 out of 541 seats; the RPP took 35% and 31 seats. Subsequent economic difficulties led to mounting criticism within and outside the DP, to which the government replied with increasing repression. In 1953 much of the property of the RPP was confiscated, forcing the closure of the People's Houses. The RPP newspaper presses in Ankara were seized. In 1954 the National Party was dissolved because of its opposition to Kemalist principles (it was immediately reformed as the Republican Nation's Party and united in 1958 with the Peasants' Party to form the Republican Peasants' Nation Party). Laws passed in 1954 provided for heavy fines on journalists who damaged the prestige of the state or the law; several prominent journalists were prosecuted under this law, which was made more severe in 1956, in which year other laws substantially abridged the independence of civil servants (including university teachers) and judges. In October 1955 critics within the DP were expelled; these critics subsequently formed the Freedom Party (December 1955), which later (1958) merged with the RPP. In 1956 limitations were placed upon public meetings.

Seizure of RPP newspaper presses

The DP's loss of popularity was reflected in the elections of October 1957, when they won only 48% of the vote and 424 out of 610 seats. The RPP took 41% and 178 seats. The three opposition parties had attempted to form an electoral coalition, but a law passed that September

had declared such coalitions illegal. The combined opposition vote was 52% of the total, and many persons believed that this government action had deprived them of victory. Opposition attacks upon the DP became stronger, and it was accused of unconstitutional action. At the same time, the Democrats, fearing a revolution, redoubled control. In December 1959 an alleged plot (the so-called Nine Officers' Plot) was unearthed; some of the accused were so clearly innocent that punishment fell upon the accuser, but it appears that there had been a conspiracy of some sort.

A charge on which the RPP laid great stress was that the DP was reversing the principles of secularism and favouring conservative religious organizations. The DP had relaxed some of the secularist policies of pure Kemalism, following in the steps of the RPP in the years 1945–49. Religious instruction in schools had been extended and the organization of religious schools permitted. Arabic had been reinstated for the call to prayer, and radio readings of the Qur'ān had been allowed. These, however, were modest concessions in themselves, and the Democrats had clearly demonstrated their unwillingness to tolerate religious influence in politics by suppressing the activities of dervish orders in 1950–52.

Growth of economic problems

The years 1958–60 saw a further worsening of the economic situation as the government reluctantly introduced restrictive measures. Returns on new investment fell and inflation continued. Serious problems of housing, unemployment, etc., were emerging in the large towns, whose population had been growing annually at the rate of about 10%, so that by 1960 the proportion of urban population to the whole had risen, to 32%. RPP attacks became more bitter, and the government's response stronger. In April 1960 the government ordered the army to prevent İnönü from campaigning in Kayseri and followed this by forming a committee to investigate the affairs of the RPP. It was widely believed that the next action would be to close the RPP. Student demonstrations followed, and martial law was declared on April 28. The army had been brought directly into the political arena.

Military takeover. Relatively neglected from 1923 to 1939, the army during the war had undergone a rapid expansion and a considerable modernization subsequently with the aid of U.S. advisers. Many officers feared that the DP threatened the principles of the secular, progressive Kemalist state. Some younger officers saw the army as the direct instrument of unity and reform. On May 3, 1960, the commander of the land forces, Gen. Cemal Gürsel, demanded political reforms, and resigned when they were refused. On May 27 the army acted; an almost bloodless coup was carried out by officers and cadets from the Istanbul and Ankara War colleges. The leaders established a 38-man "National Unity Committee" with Gürsel as chairman. The Democrat leaders were imprisoned.

The National Unity Committee, 1960–61. From the outset, a clear division existed among the officers who had carried out the coup. One group, predominantly of younger officers, believed that to restore national unity and carry out major social and economic reforms it was necessary to retain power for some years; this group included both those who supported a nationalistic and Islāmist policy and those who favoured accelerated secularization. Another group, which included most of the senior officers, wanted to withdraw the army from politics as soon as possible. In November 1960 the dispute was decided against the first group, and 14 were expelled from the committee and and sent into diplomatic exile.

Work of the National Unity Committee

The main work of the National Unity Committee was to destroy the DP and to prepare a new constitution. Substantial purges took place—5,000 officers including 235 out of 260 generals were dismissed or retired; 147 university teachers left their jobs; 55 wealthy landowners were banished from eastern Anatolia, their lands confiscated. The DP was abolished (September 29, 1960), and many Democrats were brought to trial at Yassi Ada (October) on charges of corruption, unconstitutional rule, and high treason. Of 601 tried, 464 were found guilty. Three former ministers, including Menderes, were executed; 12 others, including Bayer, had their death sentences commuted to life imprisonment.

Work on the new constitution began immediately after the coup, when a committee of five law professors was appointed to prepare a draft. This was submitted to the National Unity Committee on October 18. The Committee appointed a second committee to redraft the constitution; the new draft was presented to a Constituent Assembly, which met in January 1961. The constitution was completed in May and approved by 61% of the voters at a referendum in July.

The new constitution established a two chamber parliament—consisting of the Senate and the National Assembly. A separate electoral law provided for proportional representation. The president was elected by the Senate and National Assembly together. The constitution also provided for a Constitutional Court and a State Planning Organization. The first elections were held in October 1961. The army then withdrew from direct political involvement, although the members of the National Unity Committee retained some influence as life members of the Senate.

Period of transition, 1961–65. No party won a majority in October 1961. The RPP won 38% of the votes and 173 of the 450 Assembly seats. The newly formed Justice Party (JP), led by retired general Rağip Gümüspala, received 35% and 158 seats. The remaining seats were divided between two smaller parties—the Republican Peasants' Nation Party, which took 54 seats, and the liberal New Turkey Party, which gained 65. The results demonstrated the enduring popularity of the old Democrat Party. Its votes had been divided among the three smaller parties, the majority of them going to the Justice Party, which had also emerged as the largest party in the Senate. The RPP had failed to hold all its 1957 vote and had suffered by identification with the army coup.

The new Grand National Assembly elected General Gürsel as president. The RPP leader İnönü formed a coalition government with the JP, but the coalition survived only until June 1962, when it broke up over the question of an amnesty for the imprisoned Democrats. After some delay and splits within the parties (which led to the formation of the Nation Party by dissidents who withdrew from the Republican Peasants' Nation Party), the RPP formed a coalition with the two smaller parties. This accelerated the tendency for former Democrat voters to turn to the JP.

In the local elections of 1963 the JP made extensive gains at the expense of the two smaller parties. This led to the breakup of the coalition, and because the JP was unable to form a government, İnönü formed a minority government from his own party alone, but with voting support from the New Turkey Party. The RPP government resigned after a defeat on the budget in February 1965 and was replaced by a coalition of all the other parties under the leadership of an independent, Suat Hayri Ürgüplü; this coalition acted as caretaker until the elections of October 10, 1965.

The national remainder principle

In December 1964 a new electoral law had introduced the principle of "the national remainder," by which a certain number of seats were distributed to parties according to their proportion of the vote. The law had been intended to operate in favour of the smaller parties and against the JP, but in the election the JP won a surprising majority with 53% of the votes and 240 seats. The RPP received 29% and 134 seats; and the smaller parties, 76 seats. The new JP leader Süleyman Demirel, a former engineer, was able to form a government.

Political moderation had triumphed in the years 1961–65. The army had stood aloof while power came gradually to a party that drew its main support from the same groups and areas as the Democrats and that espoused a similar philosophy. Attempts to restore army rule had failed. Intervention proposed by senior officers in October 1961 had been rejected by others. Two projected coups had been foiled in February 1962 and May 1963. In December 1962, 11 air force officers were removed for their radical views. Members of another secret society within the army—the Young Kemalists—were arrested in April 1963. Criticism of the 1960 revolution was

made illegal in 1962; army leaders contented themselves with occasional warnings.

The trend was toward liberalization—283 Democrat prisoners were released in October 1962, and the remainder in October and November 1964. The landowners and university teachers were allowed to return to their lands and classes. Some army radicals were absorbed into the political system; the secularists went into the RPP, and the Islāmists in July 1965 took over the Republican Peasants' Party (one of the two halves into which the old Republican Peasants' Nation Party had split in 1962; the other section was the Nation Party). For the first time the Marxist-influenced left wing attained a degree of political respectability—the Turkish Worker's Party (TWP), founded in 1961, was taken over by Marxists, in 1962; with a policy of socialism and neutralism, it won 3% of the vote and 15 seats in 1965.

Much of the credit for this peaceful evolution must go to İnönü, who used his prestige with the army to ward off further intervention by the army and to prevent his own party from advocating policies that would have made parliamentary government impossible, all the while permitting power to seep to the JP.

Moderation and compromise had, however, produced uncertainty in handling such major issues as taxation and land reform. Under Atatürk the process of shifting the burden of taxation from peasant to town dweller had begun with the abolition of the agricultural land tax in 1925. Agricultural subsidies had been greatly increased under the DP. In consequence the agricultural sector was large and inefficient, and it made a small contribution to the national revenue. In 1962 the land tax was equal to only 0.2% of the value of the produce. Although a substantial amount of state land had been distributed under the 1945 land reform, most of the large private estates, particularly those in eastern Anatolia, were still intact. The State Planning Organization proposed a graduated land tax; but only a modest agricultural income tax was introduced (1964), and land reform was discussed but not enacted.

JP policy

Political development, 1965–70. The JP's policy emphasized industrialization and welfare legislation. The latter was partly inspired by the need to counter the appeal of left-wing groups, represented in politics by the TWP and elsewhere by more active trade unions and militant students. Beginning in 1960 demonstrations by left-wing students and counter demonstrations by traditionalist and nationalistic student groups became a feature of Turkish life and led to violent clashes. These and other manifestations of violent unrest had produced increasing problems of internal security.

Relations with the RPP were also bitter. The opposition accused the JP of favouring illegal religious organizations, and in fact the JP did depend upon support from religious conservatives and peasants as well as from professional and business elements. Nevertheless, Demirel exercised considerable skill in keeping the JP on the path of moderation and, by his balancing, managed to ward off a second military intervention, although the new president, Gen. Cevdet Sunay, whose term began in March 1966, maintained careful vigilance on behalf of the army. Military threats forced the withdrawal in 1969 of a bill passed by the assembly to restore political rights to the former Democrat leaders. This bill eventually became law in 1969.

While Demirel held the JP factions together in a moderate policy, the RPP moved steadily to a position described as "left of centre." From the Atatürk period it had been an alliance of urban intellectuals, often with official backgrounds, and wealthy landowners from eastern Anatolia. This had made it difficult for the RPP to support radical land reform. In 1966 the party adopted a policy of democratic Socialism, which caused a number of conservatives to leave the RPP and form the Reliance Party (May 1967). Their loss was partly balanced by an agreement between İnönü and Celâl Bayar (May 1969) that attracted some former Democrat support to the RPP.

A new election was held in October 1969. The national remainder system, which had favoured the smaller parties, was dropped and the election was decided by simple proportional representation. The representation of the small parties was thus cut substantially, and the two main parties won more seats with fewer votes. The JP won 47% of the vote and 254 seats, and the RPP 27% and 143 seats; the third largest was the Reliance Party, with 7% and 15 seats. In general the extremist parties of left and right did badly, but neither of the two major parties could be too gratified. The drop in the JP vote was the first swing against the party since 1961. The factional struggle within it increased; some rightists were excluded from the new Cabinet (November 1969). The right retaliated by bringing down the government in February 1970, and the new government formed by Demirel lacked a dependable majority and was in a weak position to deal with the growth in violence. The RPP was also unhappy with the lowest share of the vote in its history.

Exclusion of rightists

Economic and social development, 1960–70. Financial problems and the continued deterioration in the terms of trade made it seem unlikely that the 5% rate of growth achieved under the Democrats could be maintained in 1960. But, in fact, Turkey averaged over 6% throughout the decade. Although some members of the State Planning Organization resigned in 1962–63 because they doubted that resources were available to meet the 1962–67 five-year plan target of 7% a year, the final result of 6.6% was very satisfactory. The next plan (1968–72) had a similar target. Even with the annual rate of population growth (nearly 3% per annum in the 1950s, about 2½% in the 1960s) a substantial growth of per capita income was achieved. Agriculture failed to achieve its target, but important structural changes took place in this sector. The percentage of population dependent upon agriculture fell to 71% (compared with 82% in 1927), and the expansion of cultivation since the early 1950s produced a substantial fall in the ratio of population to cultivated land. Industrial output increased at the annual rate of 9%, to which the private sector contributed more than its target.

Statism in Turkey was strengthened by the establishment of the State Planning Organization and by the favourable attitudes of both the RPP and the JP toward the leading role of the state. The financing of economic development, however, raised problems because of the large amount of outside investment—an Aid Turkey Consortium was established by western European countries (July 31, 1962) and later joined by the U.S. and the World Bank, falling U.S. aid was, to some extent, balanced by new assistance from the U.S.S.R.; another valuable source of foreign exchange was the remittances of Turkish workers in Europe, which became an important feature after 1958 and helped to alleviate the problems of underemployment in Turkey. But as a result Turkey suffered sustained inflation and was forced to devalue in August 1960 and again in August 1970. One important motive for rapid growth was provided by the desire for association with the European Economic Community (EEC). An agreement was negotiated (September 12, 1963) on associate membership, which envisaged full membership in about 25 years.

Rise in literacy

Significant social changes also took place. By 1968 the percentage of literacy had risen to 49%; but because of a relatively low rate of expenditure on education in the 1950s and early 1960s (2–3% of GNP), secondary education was not expanded sufficiently and there was some reversion to illiteracy. With increased urbanization and industrialization, trade unionism developed in the 1950s and grew more rapidly after 1960. Strikes took place for the first time in 1962, and the right to strike was conceded in 1963. A great expansion in the number of government employees took place, rising from 66,000 in 1939 to 246,000 in 1955 and 400,000 in 1960. Whereas older bureaucrats had tended to come from bureaucratic families in western Turkey, many new entrants came from eastern and central Anatolia.

Foreign policy, 1950–70. There were no substantial divisions between the major parties regarding Turkish foreign policy. The 1946 Soviet challenge confirmed the

Turkish inclination toward the West. Early RPP efforts to join the North Atlantic Treaty Organization (NATO) were rewarded under the Democrats in September 1951, although Turkey did not achieve full membership until February 1952. Menderes had already demonstrated firm support for the West by sending a Turkish contingent to assist the UN forces in Korea in 1950. Turkey continued to rest primarily upon NATO throughout the 1950s and gave further demonstrations of its European proclivities by joining the Organization for European Economic Co-operation (OEEC) and the Council of Europe.

Turkey also revived its policy of the 1930s of seeking regional alliances. A friendship agreement with Greece and Yugoslavia (February 1953) blossomed into the subsequent defense (Balkan) pact of August 1954. A mutual aid pact with Pakistan (April 1954) became the forerunner of the Baghdad Pact, inaugurated by the Turko-Iraqi agreement of February 1955, which later included Britain, Iran, and Pakistan. A separate bilateral defense agreement with the United States was signed in March 1959. Relations with the Arab countries before 1958, except for those with Iraq, were not warm. Several differences occurred with Egypt, often arising from Turkey's Western alignment. Hatay remained a source of dispute with Syria, and in 1956 and 1957 Turkish forces took up threatening postures on the borders. At the time of a revolution in Iraq (July 1958) Turkey was apparently dissuaded from armed interference against the government only by U.S. pressures. In 1962 there was considerable friction arising from Iraqi claims that Turkey was giving assistance to the Kurdish rebels in Iraq.

The problem of Cyprus

The most vexing problem was that of Cyprus, arising in the 1950s as a result of agitation by the majority Greek Cypriot community for the end of British rule and for union with Greece. Strife ensued involving the Turkish Cypriot community, which appealed to Ankara for support. This led to friction between Greece and Turkey (September 1955); and anti-Greek riots, resulting in considerable destruction of property, took place in Istanbul, Izmir, and Ankara. An agreement was reached, however, in Zürich and London in February 1959 between Britain, Greece, Turkey, and representatives of the two Cypriot communities and was guaranteed by the three states concerned. This provided for an independent republic of Cyprus, safeguards for the Turkish minority, and small Greek and Turkish garrisons.

Cyprus became independent in 1960 but tensions again developed between the two communities, leading to civil war in December 1963. Public opinion in Turkey supported military intervention on behalf of the Turkish Cypriots, and in August 1964 Turkish aircraft attacked coastal areas of Cyprus. Greek citizens were expelled from Turkey in 1964–65. The U.S. warned Turkey and Greece against intervention, and UN action restored peace. There was still no agreement, however, and in December 1965 the UN again called upon Greece and Turkey to exercise restraint. An attempt by Demirel and the Greek prime minister to reach agreement at a meeting in September 1967 failed. That November Turkey again threatened military intervention, but war was averted by UN and United States pressure, which procured the withdrawal of Greek regular troops that had been introduced into Cyprus.

The Cyprus problem had several ramifications in Turkish politics. Resentment of United States intervention was expressed in riots and attacks on United States property at Adana in March 1966. Left-wing hostility to United States economic and alleged political influence also became more vocal. In this climate and in the context of the general East-West détente Turkey made an attempt to improve its relations with the Soviet Union. Menderes had planned to visit Moscow in July 1960 and, although the 1960 revolution caused a temporary setback, in August 1964 the Turkish foreign minister visited the Soviet Union. This was the first of a series of high-level visits, which led to economic and cultural agreements. The improvement of relations with the Soviet Union was assisted by the softening of Soviet support for Greece over Cyprus and by the desire for closer economic relations following the United States decision to phase out economic aid to Turkey by 1972. Nonetheless, the thaw in Turkey's relations with the Soviet Union represented only a slight shift in Turkey's continued broad identification with the West. (M.E.Y.)

BIBLIOGRAPHY

General studies: J.F. VON HAMMER-PURGSTALL, *Geschichte des osmanischen Reiches*, 10 vol. (1827–35, reprinted 1963); French trans. by J.J. (1815, reprinted 1963), a detailed study of Ottoman administrative organization in the 16th century; H.A.R. GIBB and HAROLD BOWEN, *Islamic Society and the West*, 1 vol. in 2 pt.

(1950–57, reprinted 1965), emphasizes Ottoman organization in 18th century, but adds considerable information on earlier periods based on examination of Turkish and Western sources; S.J. SHAW, "The Ottoman View of the Balkans," in C. and B. JELAVICH (eds.), *The Balkans in Transition*, pp. 56–80 (1963), a new interpretation of Ottoman administrative organization, based on an examination of Ottoman archives; S.J. SHAW, *The Financial and Administrative Organization and Development of Ottoman Egypt, 1517–1798* (1962), a detailed study of the Ottoman provincial system, as applied in Egypt, based on exhaustive research in Ottoman archives; summarized in Shaw's "Landholding and Land-tax Revenues in Ottoman Egypt," in P.M. HOLT (ed.), *Political and Social Change in Modern Egypt*, pp. 91–103 (1968); A.D. ALDERSON, *The Structure of the Ottoman Dynasty* (1956), a detailed study of the Ottoman Imperial Institution and the development of the Ottoman dynasty; ROBERT MANTRAN, *Istanbul dans la second moitié du XVII^e siècle* (1962), an exhaustive study of Ottoman political, economic, and social life in the 17th century, based on research in archives and contemporary travellers' accounts; BERNARD LEWIS, *Istanbul and the Civilization of the Ottoman Empire* (1963); RAPHAELA LEWIS, *Everyday Life in Ottoman Turkey* (1971).

Decline of the Ottoman Empire, 1566–1807: PAUL RYCAUT, *The History of the Turkish Empire from the Year 1623 to the Year 1677*, 2 vol. (1680) and *The Present State of the Ottoman Empire* (1668), a contemporary Western description of Ottoman institutions and society in the age of decline; W.L. WRIGHT, JR., *Ottoman Statecraft: The Book of Counsel for Vezirs and Governors . . . of Sari Mehmed Pasha* (1935), a 17th-century Ottoman analysis and description of decline; T.M. BARKER, *Double Eagle and Crescent: Vienna's Second Turkish Siege and its Historical Setting* (1967), a detailed study of the Eastern Question relative to the Ottoman Empire in the late 17th century; LADY MARY WORTLEY MONTAGU, *The Complete Letters of Lady Mary Wortley Montagu*, ed. by ROBERT HALSBAND, 3 vol. (1965–66), an early 18th-century Western account of Ottoman society and institutions in the age of decline; M.L. SHAY, *The Ottoman Empire from 1720 to 1734* (1944, reprinted 1968), a description of Ottoman life during the Tulip Period, based on reports of Venetian consuls in Istanbul; BARON F. DE TOTT, *Memoires du Baron de Tott, sur les Turcs et les Tartares*, 4 pt. (1784; Eng. trans., 2 vol., 1785), an account of Ottoman military organization, problems, and reforms in the late 18th century, written by the most famous of the European military officers in Ottoman service at that time; M.S. ANDERSON, *The Eastern Question, 1774–1923* (1966), an authoritative study of the Eastern Question, relating to the Ottoman Empire, based entirely on Western sources and studies; S.J. SHAW, *Between Old and New: The Ottoman Empire under Sultan Selim III, 1789–1807* (1971), a detailed study of Ottoman reform effort in the late 18th and early 19th century, with an account of diplomatic and military relations with Europe, and problems in the Balkan, Anatolian, and Arab provinces.

The Ottoman Empire and Turkey (from 1807 to the present): The best general history covering this period is B. LEWIS, *The Emergence of Modern Turkey*, 2nd ed. (1968). N. BERKES, *The Development of Secularism in Turkey* (1964), covers similar ground but concentrates on the development of ideas. R.E. WARD and D.A. RUSTOW (eds.), *Political Modernization in Japan and Turkey* (1964), has valuable essays on general themes. For diplomacy the best outline is M.S. ANDERSON, *The Eastern Question, 1774–1923* (1966). Useful for the European provinces is L.S. STAVRIANOS, *The Balkans Since 1453* (1958), which has an excellent bibliography. For the Tanzimat, see R.H. DAVISON, *Reform in the Ottoman Empire, 1856–1876* (1963). Although old, E.P. ENGELHARDT, *La Turquie et Le Tanzimat*, 2 vol. (1882–84), is still a valuable source of information. R. DEVEREUX, *The First Ottoman Constitutional Period: A Study of the Midhat Constitution and Parliament* (1963), is a careful study of the 1876 crisis and the establishment of the first Ottoman Parliament. For the Young Ottomans, see S. MARDIN, *The Genesis of Young Ottoman Thought* (1962); and for the Young Turks, E. RAMSAUR, *The Young Turks: Prelude to the Revolution of 1908* (1957); and F. AHMAD, *The Young Turks: The Committee of Union and Progress in Turkish Politics, 1908–14* (1969). The Ottoman public debt is considered in D.C. BLAISDELL, *European Financial Control in the Ottoman Empire* (1929). AHMED EMIN, *Turkey in the World War* (1930), is still the only account, although relations with Germany can be followed in U. TRUMPENER, *Germany and the Ottoman Empire, 1914–1918* (1968).

Several books consider aspects of Allied war aims in the Near East. Although outdated in parts, H.N. HOWARD, *The Partition of Turkey: A Diplomatic History, 1913–1923* (1931, reprinted 1966), is comprehensive. On the Kemalist movement, see E.D. SMITH, *Origins of the Kemalist Movement and the Government of the Grand National Assembly, 1919–1923* (1959). LORD KINROSS, *Atatürk: The Rebirth of a Nation* (1964), is a good, recent biography. On political developments in Turkey and particularly the rise of the Democrat Party, see K.H. KARPAT, *Turkey's Politics* (1959). R.D. ROBINSON, *The First Turkish Republic* (1963), is a good general account, strongest on economic aspects. F.W. FREY, *The Turkish Political Elite* (1965), is an illuminating and detailed analysis of the membership of the Grand National Assembly. For the 1960 military coup, see W.F. WEIKER, *The Turkish Revolution, 1960–1961* (1963); and for the period from 1961–65, C.H. DODD, *Politics and Government in Turkey* (1969). The chronologies by G. JASCHKE are very useful for Turkish history since 1918. The earlier ones appeared mostly in *Die Welt des Islams* and subsequent ones are *Die Türkei in den jahren 1935–1941* (1943), *Die Türkei in den jahren 1942–1951* (1955), and *Die Türkei in den jahren 1952–1961* (1965). An outline of foreign policy is in ALTEMUR KILIC, *Turkey and the World* (1959). For economic developments, see M.W. THORNBURG, G. SPRY, and G. SOULE, *Turkey: An Economic Appraisal* (1949); and Z.Y. HERSHLAG, *Turkey: The Challenge of Growth* (1968). For education, see A.M. KAZAMIAS, *Education and the Quest for Modernity in Turkey* (1966). There are good bibliographies of works in Turkish in the books by Lewis, Karpat, Dodd, and Hershlag.

Ou-yang Hsiu

The Chinese poet, historian, and statesman Ou-yang Hsiu (in Pin-yin romanization, Ou-yang Xiu) reintroduced the unadorned "ancient style" in literature and as a statesman sought to reform political life through adherence to Classical Confucian principles. He was born in 1007 in what is today Mien-yang, Szechwan Province, where his father was a judge. Orphaned at three, he and his mother went to live with his uncle in Hupeh. Although the story that the family was so poor that he had to learn writing in the sand with a reed is apocryphal, they probably lived in straitened circumstances. In 1030 he placed first in the doctoral examinations and was appointed a judge at the western capital, Lo-yang. He was already known as a brilliant young writer, and at Lo-yang he befriended the renowned essayist Yen Shu and the famous poet Mei Yao-ch'en. These friendships not only enhanced Ou-yang's status but, more important, reinforced his strong preference for the simplicity and clarity of the "ancient style." Some years before, he had read the works of Han Yü, the great master of T'ang dynasty literature, whose pure and easy "ancient style," free of outworn metaphors and allusions, had greatly impressed him. Eventually, his leadership and advocacy of that style paved the way for a new literary movement.

In 1034 he was appointed a collator of texts in the Imperial library at the capital, K'ai-feng. Two years later, when Fan Chung-yen, a government official, was banished, at the insistence of an Imperial counsellor, for speaking out against certain official practices and institutions, Ou-yang did not hesitate to attack the counsellor in writing. As a result, he, too, was banished and demoted to low judicial office in Hupeh and Hunan provinces, where he wrote the *Hsin Wu Tai shih* ("New History of the Five Dynasties"), a period of political chaos lasting through almost the entire 10th century. Ou-yang's strong sense of fairness led him to devote separate sections to political outcasts such as martyrs, rebels, and traitors, a radical departure from previous dynastic histories.

Writing of the "New History of the Five Dynasties"

Highly recommended by Fan Chung-yen, who was back at the capital, and other high officials, Ou-yang was recalled to the capital in 1043 to become Imperial counsellor. When Fan and others were dismissed for forming a private group of political reformers, Ou-yang, in a notable essay on partisanship, defended associations of gentlemen as politically constructive. His courage and forthright opinions earned the respect of the emperor, Sung Jen Tsung, and he was commissioned to record Jen Tsung's daily life and to draft edicts. His frank opinions and severe criticisms of others created many enemies, and in 1045 he was accused of and tried for having had illicit relations with his niece many years before—a charge to which his romantic life with women and wine,

Career in government

during his days in Lo-yang, lent support. Although he was finally acquitted, his reputation was seriously impaired. He was demoted and sent to Anhwei Province, where he served as magistrate of one country after another. The beautiful countryside intensified his partiality for wine. He called himself the "Old Drunkard," built a pavilion of that name, and wrote an essay about it, which has become one of the most celebrated works in Chinese literature. After a term (1050) as defense commander of the southern capital of Kuei-te, in Honan province, he was recalled to the capital in 1054 to become an academician of the Hanlin Academy. It has been more than nine years since he was exiled from the capital, and the new appointment signified a promotion. As always, his moral courage and outspoken manner did not endear him to his colleagues. He was first ordered to write the *Hsin T'ang shu* ("New History of the T'ang Dynasty"). A year later, with his work only begun, he was sent as ambassador to the Manchurian Khitans, who ruled most of Northern China. In 1057 he was placed in charge of civil service examinations. He favoured those who wrote in the "ancient style" but failed those who employed literary embellishments. For thus imposing his own ideas of literature on the traditional examination system, he was physically attacked by disgruntled candidates. He survived, however, and the literary style championed by him set a new course for Chinese literature. He praised and promoted brilliant young writers such as Wang An-shih and Su Tung-p'o.

Champion of the "ancient style"

When the "New History" was finished in 1060, he was rapidly promoted to the highest councils of state, leaving a remarkable record in social, financial, and military affairs. Although never original in political ideas, he had been an advocate of progressive ideas. Now in his 50s, however, he became more cautious; and this approach probably contributed not a little to these solid accomplishments. But age did not temper his independence, directness, and critical attitude. Eventually his position at court became untenable, and at 60 he was approaching the end of his political career. Someone holding a grudge against him accused him of having an affair with his daughter-in-law, and although the woman's own father came to his defense and the accusation was found to be sheer rumour, Ou-yang's prestige was injured and he became increasingly isolated in the capital. He repeatedly asked to be relieved, but instead the new emperor sent him to be magistrate successively in Anhwei, Shantung, and Honan. In Shantung he opposed the reforms of his former protégé Wang An-shih, particularly a system of loans to farmers at a low interest rate, and refused to carry them out in his districts. Perhaps Ou-yang was opposed not so much to the measures themselves as to the excessive bureaucracy that had become a burden to the people. Nevertheless, it is clear that he had become a disappointed conservative. In 1071 he was retired with the title of grand preceptor of the crown prince. He intended to make his permanent home in beautiful Anhwei, the place of his Old Drunkard Pavilion (Ts'ui Weng T'ing), but within months he died in his 66th year.

His library consisted of 10,000 books and a large collection of literary remains and archaeological records from ancient times. He was honoured posthumously with the title Wen-chung (literary and loyal).

BIBLIOGRAPHY. JAMES T.C. LIU, *Ou-yang Hsiu: An Eleventh-Century Neo-Confucianist* (1967; orig. pub. in Chinese, 1963), an excellent biography; CHANG CARSUN, *The Development of Neo-Confucian Thought*, vol. 1, pp. 91–92, 137–138 (1957), for a brief account of Ou-yang's thought; SHOU-YI CH'EN, *Chinese Literature*, pp. 355–359 (1961), for an appraisal of his literary merits and influence; HERBERT A. GILES, *A History of Chinese Literature*, pp. 212–216 (1923), for excerpts of essays.

(W.-t.C.)

Ovid

One of the greatest poets of classical Rome and second to none in the influence of his poetry on European literature, Ovid is the arch-poet of love, a theme that in his work achieved a new range and significance, being raised in his masterpiece, the *Metamorphoses,* to epic stature. In technical accomplishment he is unexcelled, and the poetical resources of the Latin language were permanently enriched by his craftsmanship.

By courtesy of the Galleria degli Uffizi, Florence

Ovid, marble bust. In the Uffizi, Florence.

Early years. Publius Ovidius Naso was, like most Roman men of letters, a provincial. He was born on March 20 in 43 BC at Sulmo (modern Sulmona), a small town about 90 miles (140 kilometres) east of Rome. More than once in his poetry he refers affectionately to the green and pleasant fields of his native land. His family was old and respectable, sufficiently well-to-do for his father to be able to send him and his elder brother to Rome to be educated. At that time Ovid must have been about 12 years old, having passed rapidly through the primary and secondary stages of his education. At Rome he embarked, under the best teachers of the day, on the third stage, that of the schools of rhetoric.

In these establishments Roman boys studied to achieve absolute mastery of the art of fluent extempore speaking on any subject. For the majority, since philosophy tended to be despised by practical men, this was the final and most important part of their education. The method used was that of formal declamation on prescribed themes, usually of a legal or pseudo-legal character. These themes were based on imaginary situations that were often improbable and sometimes bizarre. In contrast to his brother, whose early death robbed the Roman bar of a promising recruit, Ovid had no liking for the legalistic exercises most in vogue. The elder Seneca (*c.* 55 BC–*c.* AD 37), who has left us a valuable account of Ovid at this period of his life, remarks that he was irked by formal argument and preferred the themes called "ethical," in which the point at issue turned on moral and psychological considerations. There is no doubt that Ovid's time in the schools profoundly affected his poetry. Oratory as there practiced was "rhetorical" in the most extreme sense, dominated by constant striving for effect, by the search for point, paradox, and antithesis and by the ambition to outdo the previous speaker by some fresh and ingenious perversion of probability. The intensely competitive atmosphere was calculated to foster Ovid's natural gift for effective expression and to encourage his interest in the communication of emotion.

As a member of the Roman knightly class (whose rank lay between the commons and the Senate) Ovid was marked by his position, and intended by his father, for an official career. First, however, he spent some time at Athens (then a favourite finishing-school for young men of the upper classes) and travelled in Greek lands with his friend Pompeius Macer, like himself a poet. This experience bore fruit in his poetry, in the form of mytho-

logical associations that are firmly rooted in the classical landscapes. Afterward, Ovid dutifully held some minor judicial posts, the first steps on the official ladder; but he soon decided that public life did not suit him. One legacy of this period would seem to be the predilection for legal phrases and metaphors that he shows in his earlier poems. From now on Ovid abandoned business to cultivate poetry and the society of poets, including his contemporary Sextus Propertius and the somewhat older Horace. Virgil he had not met and Tibullus died before he could get to know him well. It is interesting and may be significant that the warmest tribute Ovid pays to a contemporary poet is to Tibullus, in a funeral elegy on his death. Tibullus, like himself, was a member of the literary circle of the patron Marcus Valerius Messala, whereas Virgil, Horace, and Propertius all belonged to the group around Gaius Maecenas, which was more representative of what might be called the Augustan establishment. Certainly the type of poetry he wrote during the first period of his career reflects a view of life, love, and poetry somewhat at odds with the sober "official" moral attitudes encouraged by Augustus. As a witty and irreverent skeptic whose only declared commitment was to poetry, he could not be expected to regard the official myths of Augustan politics as highly as did, for instance, his older contemporaries Virgil and Horace. They had lived through the chaos of civil war until 31 BC, when Octavian (later named Augustus) won the decisive battle at Actium. Ovid was only 12 when this battle was fought, so he had no emotional reason to share the special gratitude of an older generation toward Augustus for introducing peace.

Publication of his first love elegies

His first poems, the *Amores* (*Loves*), were published at intervals, beginning about 20 BC, in five books (reduced in number to 50 poems, they were afterward republished in a three-book edition). They form a series of short poems in the elegiac metre depicting the various phases of a love affair with a woman called Corinna (almost certainly a figment of the poet's imagination). Inspiration and treatment, however, are more intellectual than emotional, and the collection verges on a tongue-in-cheek mockery of the genre. A poem that was later to play a part in his downfall, the *Ars amatoria* (*Art of Love*), was published *c.* 1 BC. The message of this brilliant treatise on the art of seduction and intrigue was essentially subversive of the official program of moral reforms then being fostered by Augustus, and it cannot have been well received by those who were seriously committed to the goals and aspirations of Augustanism. It also included a number of references, in their contexts both flippant and tactless, to symbols of Augustus' personal prestige. A mock recantation that soon followed, the *Remedia amoris* (*Cure for Love*), cannot have helped matters. During this period Ovid also published his *Epistulae Heroidum* (*Letters from Heroines*), a series of clever, though in sum perhaps monotonous, dramatic soliloquies. While the theme of these character sketches is love, the material is mythological; and here can be seen, in embryo, the *Metamorphoses*.

Maturity: the major poems. As a writer of love elegy, Ovid had spoken in character, claiming the respect and attention due to experience and even revelation. Perhaps the fruits of some wild oats may be detected in the *Amores, Ars amatoria,* and *Remedia amoris,* but the biographer must discount most of Ovid's protestations as properly belonging to a conventional literary pose. In fact Ovid seems to have been, by contemporary standards, a respectable family man. He was first married for a short time, when very young, to a wife of whom he says no more than that she was unsuitable. To his second wife he imputes no blame, but this marriage also was brief. His third union, to a member of an important noble family, was stable and apparently based on mutual affection. We hear also of one daughter, perhaps of the second marriage. Having published a substantial body of highly original work, Ovid was by now established as the leading living poet of Rome (Horace, the last of the great Augustans, had died in 8 BC, and there were no other possible rivals). In the last poem of the *Amores,* Ovid had promised that he would soon turn to more ambitious themes.

Leading poet of Rome

This promise he now redeemed by the publication of work in three major genres.

His tragedy *Medea* has been lost. It was praised by the critic Quintilian and the historian Tacitus and can hardly have failed to influence Seneca's play on the same theme.

The Fasti. Ovid's *Fasti* (*Calendar*) is an account of the Roman year and its religious festivals, consisting of 12 books, one to each month, of which only the first six survive. The various festivals are described as they occur and are traced to their legendary origins. Such "aetiological" poetry was characteristic of poets of the Hellenistic Age (after 323 BC), especially of Callimachus; and in choosing this genre Ovid was deliberately challenging Propertius' claim to be "the Roman Callimachus." Thus the *Fasti* was a national poem, intended to take its place in the Augustan literary program and perhaps designed to rehabilitate its author in the eyes of the ruling dynasty. It contains a good deal of flattery of the imperial family and much perfunctory patriotism, for which the undoubted brilliance of the narrative passages does not atone.

The Metamorphoses. The *Metamorphoses* ("Transformations") must also be interpreted against its contemporary literary and political background. Even Virgil and Horace, the most "Augustan" of the Augustans (both were personal friends of Augustus), had shown reluctance to produce on demand the sort of official poetry that is apt to be expected of a poet laureate—martial epics celebrating important victories and the like. When Virgil did finally write his epic, the *Aeneid,* it was a very different poem from what contemporaries had been led to expect. The *Aeneid* is an astonishing tour de force: a recognizably Augustan poem that is yet something much greater and more universal. This unique character of Virgil's poem, which immediately became canonized as the national epic, posed an acute problem for his successors. The *Aeneid* was both spur and stumbling block; and most subsequent aspirants to epic honours stumbled. After Virgil, a straightforward historical or mythological epic would represent an anticlimax. Ovid was warned against this pitfall alike by his instincts and his intelligence; he chose, as Virgil had done, to write an epic on a new plan, unique and individual to himself.

Themes and rhetoric of the *Metamorphoses*

The *Metamorphoses* is a long poem in 15 books, written (unlike all Ovid's other surviving works) in hexameter verse. It is a collection of mythological and legendary stories in which metamorphosis (transformation) plays some part, however minor. The stories are told in chronological order from the Creation (the first metamorphosis, of chaos into order) to the death and deification of Julius Caesar (the culminating metamorphosis, again of chaos —that is, the Civil Wars—into order—that is, the Augustan Peace). The importance of metamorphosis is more apparent than real; the essential theme of the poem is passion, and this gives it more unity than all the ingenious linking and framing devices the poet uses. The erotic emphasis that had dominated Ovid's earlier poetry has now been broadened and deepened into an exploration of nearly every variety of human emotion—for his gods are nothing if not human. This undertaking brought out, as his earlier work had not, Ovid's full powers: his wit and rhetorical brilliance, his mythological learning, his gifts of narrative and description, and the peculiar qualities of his fertile imagination. Like most classical Latin poetry, the *Metamorphoses* is a highly literary work. The vast quantities of verse in both Greek and Latin that Ovid had read and assimilated are transformed, through a process of creative adaptation, into original and unforeseen guises. The style also represents an individual modification of inherited usage. It is designed to respond unobtrusively to the many variations of genre and tone within the poem and also to carry the reader at an equable and agreeable pace through its considerable length. In both material and treatment the *Metamorphoses* is not merely un-Augustan: it is, language apart, as much Greek as Roman. By AD 8, if not yet formally published, it was complete; and it was at that precise moment, when Ovid seemed securely placed on a pinnacle of successful achievement, that there fell, with stunning suddenness, a blow that shattered his life.

Banishment and death. Ovid was at the time on the island of Elba. He was recalled to Rome for a personal interview with Augustus, in which, after a severe dressing down, he was ordered into immediate banishment at Tomis on the Black Sea. The reasons for his punishment are mentioned several times by Ovid himself: a poem—the *Ars amatoria*—and another unnamed offense. What the latter was he does not specify, beyond insisting that it was an indiscretion (Latin *error*), not a crime. The precise relationship between the two charges is obscure: the *Ars amatoria* had been published several years previously; that it was brought up against its author now seems to imply that it was connected in some way with the more recent *error*. Whatever this was, it was taken as a personal affront to Augustus and his family and bitterly resented as such. This is shown not only by Augustus' own attitude but also by that of his adopted son and successor Tiberius, who paid no attention to Ovid's appeals. Here it is relevant to recall the generally irritant, if not actually subversive, quality of Ovid's poetry. His view of the world was that of an artist, a skeptic, and an individualist. No successful man lacks enemies, as he himself had remarked in the *Remedia amoris*. Not only in the *Ars amatoria* but also in some parts of the *Metamorphoses* is there apparent disrespect for certain officially approved values that might have been enough, skillfully exploited, to create an image of their author as a social and political dissident. If Augustus' mind had already been poisoned against Ovid, or if he had been abruptly reminded of these earlier pinpricks by Ovid's *error*, whether or not it was serious, he may have grasped at the opportunity to rid Rome of a man who, if not dangerous, was personally offensive to him. Augustus was usually ruthless in such cases, but public opinion might have been aroused by the assassination or judicial murder of the leading poet of Rome. A living death in Tomis was perhaps in the event a more severe punishment.

Causes of his banishment

Ovid's situation was curious. The charge on which he was arraigned was one of high treason (Latin *majestas*), which could cover a multitude of sins. He was tried in the Emperor's private court, and the sentence was personally decided and pronounced by the Emperor. In effect he was to be detained at Augustus' pleasure. He was deprived of neither his citizenship nor his property, nor was he forbidden to write poetry or to communicate with his family and friends. Yet his books were removed from the public libraries, and none of the poems sent from Tomis in the first years of his exile, except those to his wife and to Augustus, is addressed to its recipient by name. Clearly, Ovid was unsafe to know; and until the death of Augustus, at least, his poetry must have circulated privately. The mystery that still surrounds the episode itself shows that Augustus was successful in stifling overt comment.

Toward the end of AD 8 Ovid set out for Tomis, where he arrived in the spring of the following year. The place (modern Constanţa, Romania) was a semi-Hellenized port on the extreme edge of the Roman Empire, exposed to periodic attacks by the surrounding barbarian tribes. Books and civilized society were lacking; little Latin was spoken; the climate was severe. From time to time there was actual danger and, with other able-bodied citizens, Ovid took his turn in the home guard. He was alone, for his wife had stayed in Rome to protect his property and to make what intercession she could through influential friends. She was never to see him again. In his solitude and depression, he turned again to poetry, now of a more personal and introspective sort. The *Tristia* (*Sorrows*) and *Epistulae ex Ponto* (*Letters from the Black Sea*) are all, in various guises, appeals for clemency. All, even those to his wife, are "public" poems, intended to present his case to the Emperor and, eventually, to the world. Though not written as spiritual autobiography, they nevertheless offer a unique document of the life of a poet in exile. Properly understood, they are as revealing of their author as anything he ever wrote. Particularly interesting is the apologia that forms the second book of the *Tristia*: a puzzling poem that may have damaged his case more than it helped because, to whatever flattery and self-abasement he descends in this and the other poems of exile, he never withdraws from the one position with which his personal self-respect was identified—his status as a poet. Again and again it is implied or even stated outright that over poetry the Emperor has no power. Critics who find Ovid's conduct in adversity unmanly have failed to see that, in what mattered most to him, he never yielded.

Poems of exile

That his poetical powers were not as yet seriously impaired is shown by his poem *Ibis*. This, written not long after his arrival at Tomis, is a long and elaborate curse directed at an anonymous enemy. It is a tour de force of abstruse mythological learning, composed largely without the aid of books. But in the absence of any sign of encouragement from home, Ovid lacked the heart to continue to write the sort of poetry that had made him famous, and the later *Epistulae ex Ponto* make melancholy reading. Yet life was not uniformly gloomy. As Ovid settled down and became reconciled to the fact that Tomis was his home, he began to see some virtues in the place and its inhabitants. He took an interest in local history and politics and even wrote poetry in the local language, Getic. He seems to have been genuinely touched by the honours which the Tomitans paid him. Nevertheless, death, when it came in AD 17, cannot have been wholly unwelcome.

Character and significance. Often Ovid has been patronized and pitied. The key to an understanding of his character and of his poetry is that he was a rationalist and an extremely intelligent one; he had, for instance, an instinctive sympathy with the materialist poet Lucretius. He was too skeptical and too intellectually independent to devote himself to any cause except that of poetry. That was the faith in which he lived and died and which pervades his work, from the *Amores* to the poems of exile. To poetry his devotion was absolute; his sensuous appreciation of words and his delight in manipulating language is that of a lover. With these qualities went a rich vein of fantasy and an exuberant creativity. His understanding of human nature, if less profound than Virgil's, was wider and perhaps to ordinary people more appealing and comprehensible. He was a kind friend, a humorous and understanding lover, but above all a man of letters, a creator and craftsman—in the fullest and most exact sense of the word, a poet.

Influence on later poetry

In classical antiquity, Ovid's influence on later poetry was primarily technical. He had perfected both the elegiac couplet and the hexameter as all-purpose metres and as instruments of fluent communication. Even the poets most obviously indebted to Virgil betray Ovid's influence in nearly every line. In the Middle Ages, like most ancient writers, he was regarded as an authority, a source of doctrine and erudition. The *Metamorphoses*, in particular, offered one of the most accessible and attractive avenues to the riches of Greek mythology. But his chief appeal, then and subsequently, stems from the humanity of his writing: its gaiety, its sympathy, its exuberance, its pictorial and sensuous quality. It is these things, together with his apparently genuine liking for women as a sex, that have recommended him, down the ages, to the troubadours and the poets of courtly love, to Chaucer, Shakespeare, Goethe, and to Ezra Pound.

MAJOR WORKS

Amores (published at intervals beginning *c.* 20 BC); *Ars amatoria* (*c.* 1 BC); *Medea* (now lost); *Fasti* (unfinished; AD 1–8); *Metamorphoses* (AD 1–8); *Tristia, Epistulae ex Ponto* (both AD 9–17).

BIBLIOGRAPHY. For current work, see *L'Année Philologique*, ed. by J. MAROUZEAU and J. ERNST (annual); and the periodical surveys: R.J. GARIEPY, "Recent Scholarship on Ovid (1958–1968)," *The Classical World*, 64:37–56 (1970); and WALTHER KRAUS, "Der Forschungskericht: Ovid," *Anzeiger für die Altertumswissenschaft*, 11:129–146 (1958), 16:1–13 (1963), and 18:193–207 (1965), which also provide access to the older literature. For Ovid's posthumous survival, see WILFRIED STROH (comp.), *Ovid im Urteil der Nachwelt* (1969). The standard texts of Ovid's works are those in the "Teubner Series" by RUDOLF EHWALD and F.W. LENZ (1888–1932); in J.P. POSTGATE, *Corpus poetarum Latinorum*, vol. 1 by ARTHUR PALMER *et al.* (1894); in the "Oxford Classical

Texts," by S.G. OWEN *et al.* (1915–); and (with English translation) in the "Loeb Series" by GRANT SHOWERMAN *et al.*, 5 vol. (1914–31). The earliest English translation of Ovid is that of the *Metamorphoses* by W. CAXTON (facsimile ed. 1968). Other older versions include the *Metamorphoses* by A. GOLDING, "Shakespeare's Ovid" (1567; new ed. by J.F. NIMS, 1965); of the *Elegies* (*Amores*) by CHRISTOPHER MARLOWE (1596); and of the *Epistles* (*Heroides*), *Ars amatoria*, and *Metamorphoses* by JOHN DRYDEN, ALEXANDER POPE, WILLIAM CONGREVE *et al.* (1680–1717). The numerous modern versions vary greatly in style: see, for instance, A.E. WATTS, *Metamorphoses* (1954), with etchings by Picasso; PAUL TURNER, *Ars amatoria* (1968), prose; GUY LEE, *Amores* (1968). There are many translations into other European languages. The chief source of biographical data is Ovid's poetry, especially his autobiographical elegy (*Tristia* IV. 10). The best general studies are L.P.WILKINSON, *Ovid Recalled* (1955); and HERMANN FRANKEL, *Ovid: A Poet Between Two Worlds* (1945). On Ovid's banishment, see J.C. THIBAULT, *The Mystery of Ovid's Exile* (1964). On the *Metamorphoses*, see BROOKS OTIS, *Ovid As an Epic Poet*, 2nd ed. (1970).

(E.J.Ke.)

Owen, Sir Richard

A British anatomist and paleontologist, Sir Richard Owen is remembered now for his many significant publications, his reconstructions of giant flightless birds, his early recognition of the difference between "homology" (fundamental agreement in structure between parts of different animals regardless of their function) and "analogy" (parts resembling one another only in function), his skill as a lecturer, and his extreme hostility to Charles Darwin and the concept of evolution by natural selection. He was the last British speculative transcendental anatomist who held that the Platonic "idea" of an object was more real than the object itself.

Owen, oil painting by H.W. Pickersgill, 1845. In the National Portrait Gallery, London.

Richard Owen was born at Lancaster, Lancashire, on July 20, 1804, the son of Richard Owen, merchant in the West Indies trade, and Catherine (*née* Parrin), of a French Huguenot family. Educated at Lancaster Grammar School, he was apprenticed in 1820 to a group of Lancaster surgeons but in 1824 went to Edinburgh to continue medical training. In 1825 he transferred to St. Bartholomew's Hospital in London to work under John Abernethy, the great surgeon, and in the following year was admitted to the Royal College of Surgeons of England, where he was engaged as curator of the Hunterian Collections (made by John Hunter, the great anatomist) and set up in medical practice. In 1830 he met Georges Cuvier, a celebrated French paleontologist, and the following year visited him in Paris, where he studied specimens in the Muséum d'Histoire Naturelle. Elected a Fellow of the Royal Society in 1834, in 1835 he married Caroline Clift (who died in 1873) and had one son, William (1837–86). In 1836 Owen became Hunterian Professor at the Royal College of Surgeons and in 1837 its Professor of Anatomy and Physiology, as well as Fullerian Professor of Comparative Anatomy and Physiology at the Royal Institution. Leaving medical practice and devoting himself to research, he was appointed superintendent of the natural history departments of the British Museum in 1856. From then until his retirement in 1884 he was largely occupied with the development of the British Museum (Natural History) in South Kensington, London.

Attitude to Darwin

Owen's character was not free from ambition for priority, intolerance of competition, and jealousy. This showed itself particularly in the case of the publication by Darwin in 1859 of *Origin of Species*. Darwin had been a good friend for 20 years, but Owen, recognizing that his own pre-eminent position in biology would be eclipsed by Darwin, set about to discredit him. He wrote a very long anonymous review of the book (*The Edinburgh Review*, 1860), on which Darwin commented:

> It is extremely malignant, clever, and I fear will be very damaging. . . . It requires much study to appreciate all the bitter spite of many of the remarks against me. . . . He misquotes some passages, altering words within inverted commas. . . .

As Darwin's thesis began to become more widely known and accepted, it seems that Owen shifted his position somewhat. The *London Review* (no. 12, 1866) apparently received a "communication" from him in which, although he denied the Darwinian doctrine, he admitted the accuracy of its basis, claiming to have been the first to have pointed out the truth of the principle on which it was founded.

On retirement he was created a knight of the Order of the Bath. He died on December 18, 1892, at Sheen Lodge, Richmond Park, London.

Major areas of study

Among his earliest publications were the Descriptive and Illustrated Catalogue of the physiological series of Comparative Anatomy contained in the Museum of the Royal College of Surgeons in London (1833), which enabled him to acquire the great knowledge of comparative anatomy that he used in his numerous researches on living and fossil forms. His *Memoir on the Pearly Nautilus* (1832) was a classic. Other works included *Odontography* (1840–45), *Lectures on Comparative Anatomy and Physiology of the Vertebrate Animals* (1846), *A History of British Fossil Mammals and Birds* (1846), *A History of British Fossil Reptiles* (1849–84), and *On the Anatomy of Vertebrates* (1866–68).

In 1863 he published a description of *Archaeopteryx*, the first known fossil bird (*Philos. Trans. Roy. Soc. London*, pp. 33–47) that he had obtained for the museum; but when this was re-examined in 1954, it was found that Owen had got it upside down, dorsal for ventral, and had missed the two most important features: the breastbone, which was flat, proof that the bird could not fly but glided; and the natural cast of the brain case, which was like that of a reptile. The high reputation that Owen enjoyed needs to be considered critically and objectively. Actually, as early as 1858 his transcendental views on anatomy, particularly the view that the vertebrate skull was only modified vertebrae, was completely demolished by the English biologist Thomas Huxley.

BIBLIOGRAPHY. The only biography of the subject is *The Life of Richard Owen*, 2 vol. (1894), written by his grandson, RICHARD OWEN. It contains Owen's full bibliography.

(G.de B.)

Owen, Robert

Robert Owen, a Welsh manufacturer turned reformer, became one of the most influential of the utopian Socialists of the early 19th century. Friedrich Engels called him "a man of almost sublime and childlike simplicity of character, and at the same time one of the few born leaders of men."

Early life. Owen was born on May 14, 1771, at Newtown, Montgomeryshire. He attended local schools until

the age of ten, when he became an apprentice to a clothier. His employer had a good library, and young Owen spent much of his time reading. He did so well in business that by the time he was 19 he had become superintendent of a large cotton mill in Manchester, which he soon had made one of the foremost establishments of its kind in Great Britain. Owen made use of the first American sea island cotton (a fine, long-staple fibre) ever imported into the country and made improvements in the quality of the cotton spun. On becoming manager and a partner in the Manchester firm, Owen induced his partners to purchase the New Lanark mills in Lanarkshire.

The success at New Lanark

In the town of New Lanark lived 2,000 people, 500 of whom were young children from the poorhouses and charities of Edinburgh and Glasgow. The children, especially, had been well treated by the former proprietor, but the condition of the people was unsatisfactory. Crime and vice bred by demoralizing conditions were common, education and sanitation alike were neglected, and housing conditions were intolerable. Owen improved the houses and, mainly by his own personal influence, encouraged the people in habits of order, cleanliness, and thrift. He opened a store at which goods of sound quality could be bought at little more than cost price and at which the sale of alcoholic beverages was placed under strict supervision. His greatest success, however, was in the education of the young, to which he devoted special attention. In 1816 he opened the first infant school in Great Britain at the New Lanark mills and thereafter gave it his close personal supervision.

Though Owen at first was regarded with suspicion as an outsider, he soon won the confidence of the people. The mills continued to thrive commercially, but some of Owen's schemes entailed considerable expense, which displeased his partners. Finally, frustrated by the restrictions imposed on him by his partners, who wished to conduct the business along more ordinary lines, he organized a new firm in 1813. Its members, content with a 5 percent return on their capital and ready to give freer scope to his philanthropy, bought out the old firm. Stockholders in the new firm included the legal reformer Jeremy Bentham and the Quaker William Allen.

The reformer. In the same year (1813) Owen published two of the four essays in *A New View of Society, or Essays on the Principle of the Formation of the Human Character*, in which he expounded the principles on which his system of educational philanthropy was based. Having at an early age lost all belief in the prevailing forms of religion, he had thought out for himself a creed that he took to be an entirely new and original discovery.

The chief points in Owen's philosophy were that man's character is formed by circumstances over which he has no control and that he is not a proper subject either of praise or of blame. These convictions led him to the conclusion that the great secret in the right formation of man's character is to place him under the proper influences from his earliest years. The irresponsibility of man and the effect of early influences are the keynote of Owen's whole system of education and social amelioration.

New Lanark as a Mecca for social reformers

For the next few years, Owen's work in New Lanark was to have a national, even European, significance. New Lanark became a place of pilgrimage for social reformers, statesmen, and royal personages. According to the unanimous testimony of all who visited it, the results achieved by Owen were singularly good. Children brought up on his system were generally felt to be graceful, genial, and unconstrained; health, plenty, and relative contentment prevailed. The business was a commercial success.

In 1815 Owen, apparently single-handedly, started agitation for factory reform, with only little effect, and by 1817 his work as a practical reformer had given way to ideas—still vital—that were to make him the forerunner of Socialism and the cooperative movement. Owen argued that the competition of human labour with machinery was a permanent cause of distress and held that the only effective remedy lay in the united action of men and the subordination of machinery to man. His proposals for the treatment of pauperism were based on those principles.

Owen recommended that villages of "unity and cooperation" be established for the unemployed. Each village would consist of about 1,200 persons living on 1,000 to 1,500 acres (400 to 600 hectares); all would live in one large structure built in the form of a square, with public kitchen and messrooms. Each family would have its own private apartment and the entire care of the children till the age of three, after which they would be raised by the community. Parents would have access to them at meals and all other proper times. Such communities, Owen believed, might be established by individuals, by parishes, by counties, or by the state; in each case there would be supervision by duly qualified persons. Work and the enjoyment of its results would be shared in common.

The size of the projected community had been suggested by that of the village of New Lanark, and Owen soon advocated an extension of the scheme to the reorganization of society in general. Under his plan, largely self-contained communities of from 500 to 3,000 would first be set up, mainly agricultural and possessing the most modern machinery. As they increased in number, he wrote, "unions of them, federatively united, should be formed in circles of tens, hundreds, and thousands," until they embraced the whole world in a common interest.

Owen's plans for the cure of pauperism were received with considerable favour until, at a large meeting in London, Owen declared his hostility to the received forms of religion. Many of his supporters believed that this action made him suspect to the upper classes, though he did not lose all support from them. To carry out his plan for the creation of self-contained communities, in 1825 he bought 30,000 acres of land in Indiana from a religious community and renamed it New Harmony. For a time, life in the community was well ordered and contented under Owen's practical guidance, but differences about the form of government and the role of religion soon appeared, and numerous attempts at reconstruction failed to compose them, though it is agreed that an admirable spirit prevailed amid all the dissensions. Owen withdrew from the community in 1828, having lost £40,000—80 percent of his fortune. The other chief Owenite community experiments were in Great Britain—at Queenwood, Hampshire (1839–45), in which Owen took part for three years; at Orbiston, near Glasgow, Lanarkshire (1826–27); and at Ralahine, County Cork (1831–33); he was not directly concerned with either of the later ones.

Community in New Harmony, Indiana

Work with unions. In his "Report to the County of Lanark" (a body of landowners) in 1820, Owen declared that reform was not enough, that a transformation of the social order was required. His proposals for communities attracted the younger workers, brought up under the factory system, and between 1820 and 1830 numerous societies were formed and journals organized to advocate his views. The growth of labour unionism and the emergence

of a working class point of view caused Owen's doctrines to be accepted as an expression of the workers' aspirations, and when he returned to England from New Harmony in 1829 he found himself regarded as their leader. In the unions, Owenism stimulated the formation of self-governing workshops. The need for a market for the products of such shops led to the formation of the National Equitable Labour Exchange in 1832, applying the principle that labour is the source of all wealth.

The unprecedented growth of labour unions made it seem possible that the separate industries and eventually all industry might be organized by these bodies. Owen and his followers carried on ardent propaganda all over the country, with the result that the new National Operative Builders Union turned itself into a guild to carry on the building industry, and the Grand National Consolidated Trades Union was formed (1834). Though the enthusiasm of the unions and the numbers of labourers joining them were remarkable, determined opposition by employers and severe repression by the government and law courts ended the movement within a few months. It was two generations before Socialism, first popularly discussed at this time, again influenced unionism. Throughout these years Owen's community ideas maintained a hold, and ultimately they provided the basis for the worldwide consumers' cooperative movement. After 1834 Owen devoted himself to preaching his educational, moral, rationalist, and marriage-reform ideas. At the age of 82 he became a spiritualist. He died six years later, on November 17, 1858, at Newtown.

Opposition to Owenism

Owen's influence. The great-hearted cotton manufacturer who made such a strong impression on those who knew him failed, despite his arduous labours, to achieve a lasting effect on the industrial world of the 19th century. He was most successful in his early years with the experiment at New Lanark. When he left the life of the factory and set up as a reformer, he exaggerated the degree to which society and individuals can be changed by persuasion. It is said that, when Ralph Waldo Emerson asked Owen in his old age, "Who is your disciple? How many men possessed of your views, who will remain after you, are going to put them in practice?" Owen candidly replied, "Not one."

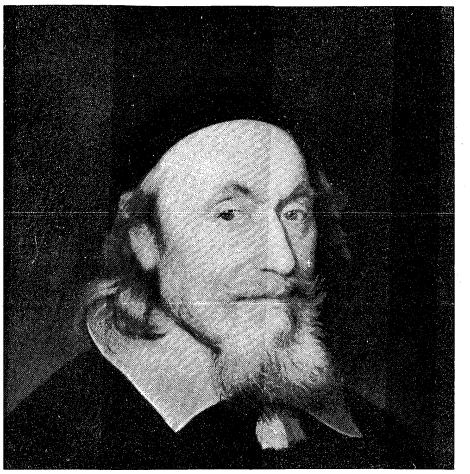
BIBLIOGRAPHY. Owen wrote his own biography, *Life of Robert Owen Written by Himself*, 2 vol. (1857–58). Of his numerous works expounding his ideas, the most important include *A New View of Society, and Other Writings* (1813–21, reprinted 1927); *Two Memorials on Behalf of the Working Classes* (1818); and *Lectures on an Entire New State of Society* (1830). Two lives of Owen are F. PODMORE, *Robert Owen: A Biography* (1906); and G.D.H. COLE, *The Life of Robert Owen*, 3rd ed. (1965). Other works dealing with Owen and his ideas are LEONARD WOOLF, *Co-operation and the Future of Industry* (1919); R.W. LEOPOLD, *Robert Dale Owen* (1940); MARGARET COLE, *Robert Owen of New Lanark* (1953); and J.F.C. HARRISON, *Robert Owen and the Owenites in Britain and America* (1969).

(D.F.Do.)

Oxenstierna, Axel, Count

Chancellor of Sweden for 42 years, Count Oxenstierna was one of his country's greatest public servants. Although a champion of the privileges of the nobility against monarchy, he became the close friend and adviser of King Gustavus II Adolphus (*q.v.*). After the King's death he guided Sweden through the Thirty Years' War and was virtual ruler of the country during the minority of Queen Christina.

Oxenstierna was born near Uppsala on June 16, 1583, of a noble family that had played a considerable part in Sweden's history. After receiving his education at Rostock and other German universities, he was in 1605 appointed to a post in the exchequer; in June 1609, at the early age of 24, he was made a member of the council of state. He soon established an ascendancy in that body, and on the death of Charles IX in 1611, it was he who extorted from the new king, Gustavus II Adolphus, a charter guaranteeing the nation against the royal abuses that had latterly prevailed. One of Gustavus' first acts was to appoint Oxenstierna chancellor (January 1612).



Oxenstierna, detail of an oil painting by David Beck (1621–56). In the Nationalmuseum, Stockholm.
By courtesy of the Nationalmuseum, Stockholm

Oxenstierna had emerged as the champion of the aristocracy against the violence of the monarchy; and the charter might well have initiated a constitutional struggle if strong ties of respect and affection had not soon developed between the King and Chancellor. They became, indeed, ideal collaborators and share the credit for the achievements of the reign. Oxenstierna's contributions were in the spheres of administrative reform and diplomacy. He drafted the *riksdagsordning* ("parliamentary law") of 1617, which stabilized the constitution of the Riksdag; he drew up the ordinance of 1619 on the development of the towns; he carried through a reform in local government in 1623; and he issued a chancery ordinance in 1626 that organized the business of that office. He was mainly responsible for the building of the house of the nobility in Stockholm and for the *riddarhusordning* ("upper house law"; 1626), which divided the nobility into three classes and specified the members of each. As a diplomat he was entrusted with a long succession of major negotiations: the Peace of Knäred (with Denmark, 1613), the Truce of Ogra (with Poland, 1622), the negotiations with Denmark at Sjöaryd (1624). When Gustavus transferred his war against Poland to Prussia in 1626, Oxenstierna was brought over and installed as governor general, and it was he who negotiated the advantageous Truce of Altmark with Poland in 1629. In November 1631 the King called him to Germany (see THIRTY YEARS' WAR).

Disagreements with Gustavus

Oxenstierna had been more reluctant than Gustavus to intervene in Germany and would probably have preferred, in the first instance, a final settlement with Denmark—always, in his view, Sweden's main enemy. Moreover, he disliked the French alliance; considered that Gustavus made a capital error in not marching on Vienna after the Battle of Breitenfeld; disapproved the King's candidature for the Polish throne in 1632; and tacitly opposed the project for marrying Christina to the electoral prince of Brandenburg, Frederick William. His removal to Germany placed the main burden of Swedish diplomacy again on his shoulders; but the King also now entrusted him with military commands, such as the formation and leadership of the army that relieved Gustavus at Nürnberg in August 1632.

The death of Gustavus, in November 1632, put the supreme direction of the Swedish cause in Germany into Oxenstierna's hands. Preserving to himself much of the king's authority and prestige, he negotiated with electors as an equal; and the project of making him elector of Mainz was canvassed. In the League of Heilbronn (1633), he created a *corpus evangelicorum* of the kind that Gustavus had planned, with himself as its director; but he never managed to persuade the North German princes to join it. The disaster at Nördlingen (1634) destroyed his hopes of keeping Sweden's allies loyal, and many of them made peace at Prague in 1635. In the same year the regency at home, in an access of defeatism that

provoked Oxenstierna's indignation, purchased renewal of the truce with Poland by sacrificing the tolls that the Swedes had been levying in the Prussian harbours from 1627. Faced with overwhelming financial and military difficulties, he was for a time the virtual prisoner of his mutinous unpaid soldiery. He hesitated long between buying a peace on the best terms that he could get and accepting a French alliance and indefinite continuation of the war: it was not until 1638 that the intransigence of the Holy Roman emperor, Ferdinand III, forced him to the second alternative. Thenceforward he was the strongest advocate of fighting on until peace could be had on really favourable terms. Political enemies at home accused him of prolonging the war for his own ends; but the terms obtained by Sweden under the Peace of Westphalia, in 1648, justified his obstinacy. Meanwhile, he had launched the sudden attack on Denmark in 1643: the morality of it was dubious, but at Brömsebro in 1645 he was able to dictate a peace that wiped out the humiliations suffered at Knäred in 1613.

Peace of Westphalia

As chancellor, Oxenstierna was one of the five regents who were to govern Sweden during Christina's minority; he also drew up (probably with Gustavus' approval) the *regeringsform* ("form of government") accepted by the Riksdag in 1634. It was not until his return to Sweden in 1636 that he participated in the regency's government; but for the next eight years or so he was the real ruler of the country. His relations with the Queen, after she attained her majority (1644), were never as cordial as with her father: she saw in him the leader of an aristocracy anxious to limit the crown's powers and perhaps even to set up a republic. Others disliked him as the defender of noble privileges and noble encroachments on the liberties of the peasantry, though he repeatedly urged moderation on his colleagues in this regard. He had to face the intrigues of a hostile party at court; and he clashed with Christina on foreign and ecclesiastical policy, on the question of the succession, and on her proposal to abdicate. After 1650, however, relations improved; and he was as firmly established in office as at any time in his career when he died, in Stockholm, on August 28, 1654.

Sagacious, imperturbable, courageous, and industrious, unhurried in negotiation, and not without a pungent humour, Oxenstierna felt the service of the state to be equally congenial and obligatory. Though he never forgot the interests of his class, it may fairly be said that as a rule his single-minded patriotism transcended them.

BIBLIOGRAPHY. No full biography of Oxenstierna exists. NILS AHNLUND's magisterial monograph, *Axel Oxenstierna intill Gustav Adolfs död* (1940), stops short at 1632. WILHELM THAM, *Axel Oxenstierna: Hans ungdom och verksamhet intill år 1612* (1935), is indispensable for the early years. Oxenstierna's enormous correspondence has been in course of publication since 1888. The first series has reached volume 15 and the year 1636; of the second, 12 volumes have so far appeared—*Rikskansleren Axel Oxenstiernas skrifter och brevväxling* (1888–).

(M.Ro.)

Oxidation–Reduction Reactions

In the classification of chemical reactions, the terms oxidation and reduction cover a large and diverse body of processes. Many oxidation–reduction reactions are as common and familiar as fire, the rusting and dissolution of metals, the browning of fruit, and respiration and photosynthesis—basic life functions. To understand the details of oxidation–reduction, a wider knowledge of chemical reactions in general is required than can be provided in this article. For this background, see CHEMICAL REACTIONS; CHEMICAL BONDING; PERIODIC LAW.

GENERAL CONSIDERATIONS OF REDOX REACTIONS

Characteristics of redox processes

Major classifications. Most oxidation–reduction (redox) processes involve the transfer of oxygen atoms, hydrogen atoms, or electrons, with all three processes sharing two important characteristics: (1) they are coupled —*i.e.*, in any oxidation reaction a reciprocal reduction occurs; (2) they involve a characteristic net chemical change—*i.e.*, an atom or electron goes from one unit of matter to another. Both reciprocity and net change are illustrated below in examples of the three most common types of oxidation–reduction reactions.

Oxygen-atom transfer. Carbon reacts with mercury(II) oxide (a compound in which mercury has a bonding capacity expressed as +2; see below *Oxidation-state change*) to produce carbon dioxide and mercury metal. This reaction can be written in equation form:

$$\underset{\text{carbon}}{C} + \underset{\substack{\text{mercury(II)}\\\text{oxide}}}{2HgO} \longrightarrow \underset{\substack{\text{carbon}\\\text{dioxide}}}{CO_2} + \underset{\text{metal}}{Hg}\ .$$

Carbon, receiving oxygen, is oxidized; mercury(II) oxide, losing oxygen, undergoes the complementary reduction; and the net change is the transfer of two oxygen atoms from mercury(II) oxide units to a carbon atom.

Hydrogen-atom transfer. Hydrogen atoms are transferred from hydrazine, a compound of nitrogen and hydrogen, to oxygen in the following reaction:

$$\underset{\text{hydrazine}}{N_2H_4} + \underset{\text{oxygen}}{O_2} \longrightarrow \underset{\text{nitrogen}}{N_2} + \underset{\text{water}}{2H_2O}\ .$$

Hydrazine, losing hydrogen, is oxidized to molecular nitrogen, while oxygen, gaining hydrogen, is reduced to water.

Electron transfer. Zinc metal and copper(II) ion (an ion is any atom that has lost or gained one or more electrons and, therefore, has a positive or negative electrical charge) react in water solution, producing copper metal and an aqueous (denoted by aq) zinc ion according to the equation:

$$\underset{\substack{\text{zinc}\\\text{metal}}}{Zn} + \underset{\substack{\text{aqueous}\\\text{copper(II)}\\\text{ion}}}{Cu^{2+}(aq)} \longrightarrow \underset{\substack{\text{aqueous}\\\text{zinc(II)}\\\text{ion}}}{Zn^{2+}(aq)} + \underset{\substack{\text{copper}\\\text{metal}}}{Cu}\ .$$

With the transfer of two of its electrons, the zinc metal is oxidized, becoming an aqueous zinc ion, while the copper(II) ion, gaining electrons, is reduced to copper metal. Net change is the transfer of two electrons, lost by zinc and acquired by copper.

Because of their complementary nature, the oxidation and reduction processes together are referred to as redox reactions. The reactant that brings about the oxidation is called the oxidizing agent, and that reagent is itself reduced by the reducing agent. In the examples given, mercury(II) oxide, oxygen, and the copper(II) ion are oxidizing agents, and carbon, hydrazine, and zinc are the reducing agents.

General theory. *Stoichiometric basis.* Describing the redox processes as above conveys no information about the mechanism by which change takes place. A complete description of the net chemical change for a process is known as the stoichiometry of the reaction, which provides the characteristic combining proportions of elements and compounds. (Stoichiometry [from the Greek *stoicheion*, "component," and *metron*, "measure"] deals with methods of determining the characteristic combining proportions of reactions from formulas, equations, atomic weights, and molecular weights and with the practical use of the information to determine quickly and easily what and how much is used and produced in chemical processes.) Reactions are classified as redox and nonredox on the basis of stoichiometry; oxygen-atom, hydrogen-atom, and electron transfer are stoichiometric categories.

Oxidation-state change. Comprehensive definitions of oxidation and reduction have been made possible by modern molecular structure theory. Every atom consists of a positive nucleus, surrounded by negative electrons, which determine the bonding characteristics of each element. In forming chemical bonds, atoms donate, acquire, or share electrons. This makes it possible to assign every atom an oxidation number, which specifies the number of its electrons that can be involved in forming bonds with other atoms. From the particular atoms in a molecule and their known bonding capacities, the bonding pattern within a molecule is determined, and each atom is regarded as being in a specific oxidation state, expressed by an oxidation number.

Redox processes defined

Redox processes are defined as reactions accompanied by oxidation-state changes: an increase in an atom's oxidation number corresponds to an oxidation; a decrease, to a reduction. In this generalized theory, three examples of ways in which oxidation-state changes can occur are by oxygen-atom (gain, oxidation; loss, reduction), hydrogen-atom (loss, oxidation; gain, reduction), and electron (loss, oxidation; gain, reduction) transfer. The oxidation-state change definition is usually compatible with the above rules for applying the oxygen-atom-transfer and hydrogen-atom-transfer criteria and always compatible with the electron-transfer criterion when it is applicable. The oxidation state of any atom is indicated by a roman numeral following the name or symbol for the element. Thus: iron(III), or Fe(III), means iron in an oxidation state of +3. The uncombined Fe(III) ion is simply Fe^{3+}.

Historical origins of the redox concept. Of the chemical processes now regarded as redox reactions, combustion was the earliest focus of philosophical and scientific attention. The Greek scientific philosopher Empedocles listed fire as one of the four elements of matter. In more modern times the phlogiston theory enjoyed scientific popularity. First articulated in 1697 by Georg Ernst Stahl, a German physician, the theory asserted that matter releases an elementary constituent, phlogiston, during combustion. Thus, the burning of charcoal was interpreted as the loss of phlogiston from carbon to the air. The theory was also applied to processes other than combustion; in the recovery of a metal from its oxide by heating with charcoal, for example, phlogiston was regarded as being transferred from carbon to the oxide.

Phlogiston saturation was believed to be responsible for the limited ability of air in a closed container to support combustion. A notable consequence of the phlogiston theory was the view that an oxide of a metal, such as mercury(II) oxide (HgO), was a chemically simpler substance than the metal itself: the metal could be obtained from the oxide only by the addition of phlogiston. The theory, however, could provide no acceptable explanation of the gain in weight when an oxide is formed from a metal.

The work of Priestley and Lavoisier

Combustion and oxide formation. Late in the 18th century, the interrelated work of the English chemist Joseph Priestley and his French colleague Antoine Lavoisier led to the overthrow of the phlogiston theory. Lavoisier saw Priestley's discovery of oxygen in 1774 as the key to the weight gains known to accompany the burning of sulfur and phosphorus and the calcination of metals (oxide formation). In his *Traité élémentaire de chimie* (*Elements of Chemistry*), which set forth the systematic foundations of modern chemistry, Lavoisier clearly established that combustion consists of a chemical combination between oxygen from the atmosphere and combustible matter. By the end of the century, his ideas were widely accepted and had been successfully applied to the more complex processes of respiration and photosynthesis. Reactions in which oxygen was consumed were classified as oxidations, while those in which oxygen was lost termed reductions.

Electrochemical reactions. During the 19th century, the evolving field of electrochemistry led to a broadened view of oxidation. It was possible, for instance, to produce the ferric, or iron(III), ion from the ferrous, or iron(II), ion at the anode (positive electrode, where electrons are absorbed from solution) of an electrochemical cell (a device in which chemical energy is converted to electrical energy), according to the equation:

$$Fe^{2+}(aq) \longrightarrow Fe^{3+}(aq) + e^-$$

iron(II) ion — iron(III) ion — electron

Molecular oxygen could effect a similar transformation, according to the equation:

$$4Fe^{2+}(aq) + O_2 + 4H^+ \longrightarrow 4Fe^{3+}(aq) + 2H_2O$$

iron(II) ion — oxygen — hydrogen ion — iron(III) ion — water

The similarity of the two processes led to a precursor of the electron-transfer explanation for redox reactions. After the discovery of the electron, the conviction that oxidation and reduction are accomplished through electron loss and gain became firmly entrenched. Thus, early in the 20th century chemists tended to attribute all redox reactions to the transfer of electrons. Later work on chemical bonding, however, demonstrated the incorrectness of that description. An electronegativity scale (listing of elements in descending order of their tendency to attract and hold bonding electrons) provided a firm basis for the oxidation-state assignments on which oxidation–reduction definitions have become based.

Examples of oxidation–reduction reactions. Molecular oxygen is a conspicuously important oxidizing agent. It will directly oxidize all but a few of the metals and most of the nonmetals as well. Often these direct oxidations lead to normal oxides such as those of lithium (Li), zinc (Zn), phosphorus (P), and sulfur (S).

$$4Li + O_2 \longrightarrow 2Li_2O \text{ (lithium oxide)}$$

$$2Zn + O_2 \longrightarrow 2ZnO \text{ (zinc oxide)}$$

$$4P + 5O_2 \longrightarrow P_4O_{10} \text{ (phosphorus pentoxide)}$$

$$S + O_2 \longrightarrow SO_2 \text{ (sulfur dioxide)}$$

Oxidation of organic foodstuffs

Organic foodstuffs are oxidized to carbon dioxide and water in respiration. The reaction stoichiometry can be illustrated for glucose, a simple sugar:

$$C_6H_{12}O_6 + 6O_2 \longrightarrow 6CO_2 + 6H_2O$$

glucose — oxygen — carbon dioxide — water

Although the oxygen–glucose reaction is very slow at ambient temperatures outside the living cell, it proceeds quickly under the influence of enzymatic catalysis within the body. Essentially all organic compounds react with oxygen under appropriate conditions, but the rates of the reactions at ordinary temperatures and pressures vary greatly.

Many other oxidizing agents serve as oxygen-atom sources. Hydrogen peroxide (H_2O_2), acid chromate ion ($HCrO_4^-$), and hypochlorous acid (HClO) are reagents often used in oxygen-atom-transfer reactions, for example in the following reactions:

$$H_2O_2 + Cl^- \longrightarrow OCl^- + H_2O$$

hydrogen peroxide — chloride ion — hypochlorite ion — water

$$2HCrO_4^- + 3H_3C\overset{\overset{O}{\|}}{C}H + 8H^+$$

acid chromate ion — acetaldehyde — hydrogen ion

$$\longrightarrow 3H_3C\overset{\overset{O}{\|}}{C}OH + 2Cr^{3+}(aq) + 5H_2O$$

acetic acid — chromium(III) ion — water

$$5HClO + I_2 + H_2O \longrightarrow 5HCl + 2HIO_3$$

hypochlorous acid — iodine — water — hydrogen chloride — iodic acid

In the simplest hydrogen-atom transfers, molecular hydrogen serves as the hydrogen-atom source. The hydrogenations (hydrogenation is the adding of hydrogen atoms to a molecule) of ethylene and of molecular nitrogen are illustrative in the following equations:

$$H_2C{=}CH_2 + H_2 \longrightarrow H_3CCH_3$$

ethylene — hydrogen — ethane

$$N_2 + 3H_2 \longrightarrow 2NH_3$$

nitrogen — hydrogen — ammonia

Reactions of molecular hydrogen are characteristically slow at ordinary temperatures. The hydrogenation of molecular nitrogen and of olefins such as ethylene (an olefin is an unsaturated hydrocarbon compound; it has at least two adjacent carbon atoms joined by a double bond to which other atoms or groups of atoms can be joined directly) is a process of extraordinary commercial importance and requires catalysts to occur at useful rates.

Hydrogen-atom transfer in organic oxidation

Hydrogen-atom transfer from an organic molecule to a suitable acceptor is a common mode of organic oxidation. The oxidation of formic acid by permanganate and that of ethanol by acid chromate share stoichiometry that features hydrogen-atom loss by the organic species, as shown in the following equations:

$$3\underset{\text{formic acid}}{\overset{O}{\overset{\|}{HCOH}}} + 2\underset{\text{permanganate ion}}{MnO_4^-} + 2\underset{\text{hydrogen ion}}{H^+} \longrightarrow 3\underset{\text{carbon dioxide}}{CO_2} + 2\underset{\text{manganese dioxide}}{MnO_2} + 4\underset{\text{water}}{H_2O}$$

$$3\underset{\text{ethanol}}{CH_3CH_2OH} + 2\underset{\text{acid chromate ion}}{HCrO_4^-} + 8\underset{\text{hydrogen ion}}{H^+} \longrightarrow 8\underset{\text{water}}{H_2O} + 3\underset{\text{acetaldehyde}}{CH_3CHO} + 2\underset{\text{aqueous chromium(III) ion}}{Cr^{3+}(aq)}$$

The oxidizing agents permanganate and acid chromate, typical of many hydrogen-atom acceptors, undergo complicated changes rather than simple hydrogen-atom addition.

Electron-transfer stoichiometry is usually associated with metal ions in aqueous solution, as shown in the following equations:

$$\underset{\text{iron(II) ion}}{Fe^{2+}(aq)} + \underset{\text{cobalt(III) ion}}{Co^{3+}(aq)} \longrightarrow \underset{\text{iron(III) ion}}{Fe^{3+}(aq)} + \underset{\text{cobalt(II) ion}}{Co^{2+}(aq)}$$

$$\underset{\text{thallium(I) ion}}{Tl^{+}(aq)} + 2\underset{\text{cerium(IV) ion}}{Ce^{4+}(aq)} \longrightarrow \underset{\text{thallium(III) ion}}{Tl^{3+}(aq)} + 2\underset{\text{cerium(III) ion}}{Ce^{3+}(aq)}$$

Many positively charged metal ions have been shown to be bonded to water molecules, so that their electron-transfer reaction occurs between rather complex molecular groups. The iron ion formulas above, for example, are more properly written as $[Fe(H_2O)_6]^{2+}$ and $[Fe(H_2O)_6]^{3+}$ to reflect the presence of six water molecules bonded to the metal ion. Simple electron transfer between free ions is known only in the gas phase, as in this argon–sodium reaction:

$$\underset{\text{argon ion}}{Ar^+(g)} + \underset{\text{sodium}}{Na(g)} \longrightarrow \underset{\text{sodium ion}}{Na^+(g)} + \underset{\text{argon}}{Ar(g)} .$$

Several other types of redox reactions do not fall in the oxygen-atom, hydrogen-atom, or electron-transfer categories. Important among these are reactions of fluorine, chlorine, bromine, and iodine. These four elements known as the halogens, all form diatomic (two-atom) molecules, which are versatile oxidizing agents. The following examples are typical:

$$3F_2 + S \longrightarrow \underset{\text{sulfur hexafluoride}}{SF_6}$$

$$\underset{\text{chlorine}}{Cl_2} + 2\underset{\text{iron(II) ion}}{Fe^{2+}(aq)} \longrightarrow 2\underset{\text{chloride ion}}{Cl^-} + 2\underset{\text{iron(III) ion}}{Fe^{3+}(aq)}$$

$$\underset{\text{bromine}}{Br_2} + \underset{\text{ethylene}}{H_2C{=}CH_2} \longrightarrow \underset{\text{ethylene dibromide}}{BrCH_2CH_2Br}$$

$$\underset{\text{iodine}}{I_2} + 2\underset{\text{thiosulfate ion}}{S_2O_3^{2-}} \longrightarrow 2\underset{\text{iodide ion}}{I^-} + \underset{\text{polythionate ion}}{S_4O_6^{2-}}.$$

Such reactions often qualify as redox processes only in the broad sense that oxidation-state changes occur. The oxidation-state characterization extends oxidation–reduction chemistry to include examples from the reactions of all the chemical elements.

Significance of redox reactions. Oxidation–reduction reactions have vast importance not only in chemistry but in geology and biology as well. The surface of the Earth is a redox boundary between the planet's reduced metallic core and an oxidizing atmosphere. The Earth's crust is largely composed of metal oxides, and the oceans are filled with water, an oxide of hydrogen. The tendency of nearly all surface materials to be oxidized by the atmosphere is reversed by the life process of photosynthesis. Because they are constantly renewed by the photosynthetic reduction of carbon dioxide, life's complex compounds can continue to exist on the Earth's surface.

The Earth's surface as a redox boundary

For similar reasons, much of chemical technology hinges on the reduction of materials to oxidation states lower than those that occur in nature. Such basic chemical products as ammonia, hydrogen, and nearly all the metals are produced by reductive industrial processes. When not used as structural materials, these products are reoxidized in their commercial applications. The weathering of materials, including wood, metals, and plastics, is oxidative, since, as the products of technological or photosynthetic reductions, they are in oxidation states lower than those stable in the atmosphere.

Solar radiation is converted to useful energy by a redox cycle that operates continually on a global scale. Photosynthesis converts radiant energy into chemical potential energy by reducing carbon compounds to low oxidation states, and this chemical energy is recovered either through enzymatic oxidations at ambient temperatures or during combustion at elevated temperatures.

THEORETICAL ASPECTS OF OXIDATION REACTIONS

Oxidation states. The idea of assigning an oxidation state to each of the atoms in a molecule evolved from the electron-pair concept of the chemical bond. Atoms within a molecule are held together by the force of attraction that the nuclei of two or more of them exert on electrons in the space between them. In many cases this sharing of electrons can be regarded as involving electron pair bonds between adjacent nuclei. Electron pair bonding is often diagrammed so as to show all the bonding and nonbonding valence electrons; *e.g.*, the structures of atomic hydrogen, atomic chlorine, and hydrogen chloride shown below (each dot represents one valence electron):

Diagramming electron pair bonding

$$\underset{\text{hydrogen atom}}{H\cdot} + \underset{\text{chlorine atom}}{:\ddot{\underset{\cdot\cdot}{Cl}}\cdot} \longrightarrow \underset{\text{hydrogen chloride molecule}}{H:\ddot{\underset{\cdot\cdot}{Cl}}:}$$

The hydrogen chloride diagram reflects the presence, in the internuclear region, of two electrons that are under the mutual attractive influence of both the hydrogen and chlorine nuclei. Oxidation states for the hydrogen and chlorine in HCl are assigned according to the net charges that remain on H and Cl when the shared electrons are assigned to the atom that has the greater attraction for them. Through physical measurements on isolated atoms and simple molecules, these relative attractive powers have been determined. Table 1 lists the electronegativity values for some important elements.

In the hydrogen chloride molecule the chlorine is more electronegative than hydrogen and is, therefore, assigned both shared electrons. Chlorine has seven valence electrons in its neutral state; having acquired an eighth electron in its reaction with hydrogen, it is considered to have

Table 1: Pauling Electronegativities of Selected Elements

Fluorine	4.0
Oxygen	3.5
Nitrogen	3.0
Chlorine	3.0
Bromine	2.8
Sulfur	2.5
Iodine	2.5
Carbon	2.5
Hydrogen	2.1
Phosphorus	2.1
Iron	1.8
Sodium	0.9

Source: L. Pauling, *The Nature of the Chemical Bond.*

an oxidation state of -1, while hydrogen is assigned $+1$, having lost the single valence electron it has in its neutral state. Charges arrived at in this way are the basis for oxidation-state assignments, conventionally represented by roman numerals, as in H(I) and Cl($-$I) for the constituents of HCl. Since determination of oxidation states is simply a method of conceptually distributing shared electrons to individual atoms, the same number of electrons must be accounted for, before and after such assignment. Table 2 includes examples of molecules with multiple bonds. The oxidation states of the atoms involved are added up algebraically in the table, and their sum must always equal the net charge on the molecule. There is no physical reality to oxidation states; they simply represent the results of calculations based on a formal rule.

Table 2: The Oxidation States of the Atoms in Typical Small Molecules

molecular species	oxidation-state assignments	algebraic sums
	H(I), Cl($-$I)	1 − 1 = 0
	H(I), O($-$II)	2(1) − 2 = 0
	Cl(I), O($-$II)	1 − 2 = −1
	C(IV), O($-$II)	4 − 2(2) = 0
	C($-$II), O($-$II), H(I)	4(1) − 2 − 2 = 0
	N(V), O($-$II)	5 − 3(2) = −1
	H(I), N($-$III)	4(1) − 3 = +1

Guidelines for assigning oxidation states

Oxidation states can be assigned for most common molecules with the help of a few guidelines. First, electrons shared by two atoms of the same element are divided equally; accordingly, elements are always in oxidation state of 0, regardless of their allotropic form (allotropic refers to the phenomenon of an element's having two or more forms; *e.g.*, carbon can exist as diamond or graphite and in both cases is in the 0 oxidation state). Second, only fluorine is more electronegative than oxygen. Therefore, except in compounds containing oxygen–oxygen or oxygen–fluorine bonds, oxygen can be reliably assigned the oxidation state -2. Similarly, hydrogen is less electronegative than fluorine, oxygen, nitrogen, chlorine, sulfur, and carbon (F, O, N, Cl, S, and C), so it is in the $+1$ oxidation state in its combinations with those elements. For many common compounds containing only hydrogen, oxygen, and a third element, the third element's oxidation state can be calculated, assuming oxidation numbers of $+1$ for hydrogen and -2 for oxygen. When bonds are present between two elements that differ little in electronegativity, however, oxidation-state assignments become doubtful, and the distinction between redox and nonredox processes is not evident.

There is a general reluctance, particularly regarding organic systems, to assume oxidation-state changes when the reaction results can be accounted for by the transfer or addition of water (H_2O), ammonia (NH_3), the hydroxide ion (OH^-), or the ions of hydrogen (H^+), chlorine (Cl^-), bromine (Br^-), or iodine (I^-), or combinations of these species; *e.g.*, the ammonium ion (NH_4^+), hydrogen chloride (HCl). The reason is that, in these molecules and ions, the elements are present in their most typical oxidation states: hydrogen(I), chlorine($-$I), oxygen($-$II), bromine($-$I), iodine($-$I), and nitrogen($-$III).

Example of oxygen-atom-transfer reaction

The oxidation-state concept clarifies the relationship between oxygen-atom, hydrogen-atom, and electron transfer. The oxygen- and hydrogen-transfer criteria apply only when oxygen and hydrogen occur in their typical oxidation states. An example of an appropriate reaction involving oxygen-atom transfer is the reduction of ferrous oxide by carbon monoxide:

$$\underset{\substack{\text{iron(II) oxide}\\\text{(ferrous oxide)}}}{FeO} + \underset{\substack{\text{carbon}\\\text{monoxide}}}{CO} \longrightarrow \underset{\substack{\text{carbon}\\\text{dioxide}}}{CO_2} + \underset{\text{iron}}{Fe}\,.$$

In terms of oxidation-state changes, this oxygen-atom transfer is equivalent to the two-electron reduction of iron and complementary two-electron oxidation of carbon:

$$Fe(II) + C(II) \longrightarrow C(IV) + Fe(0)\,.$$

Oxygen, which occurs in the oxidation state -2 in both reactants and products in the first equation, is not shown in the second. In transferring, the oxygen atom leaves two electrons behind, causing the reduction of iron, and acquires two electrons from carbon, oxidizing the carbon.

In a similar way, the hydrogenation of ethylene corresponds to a two-electron reduction of the two-carbon skeleton:

$$\underset{\text{hydrogen}}{H_2} + \underset{\text{ethylene}}{H_2C{=}CH_2} \longrightarrow \underset{\text{ethane}}{H_3CCH_3}$$

$$\underset{\substack{\text{hydrogen in}\\\text{oxidation state zero}}}{2H(0)} + \underset{\substack{\text{carbon in}\\\text{oxidation state }-2}}{2C(-II)}$$

$$\longrightarrow \underset{\substack{\text{hydrogen in}\\\text{oxidation state }+1}}{2H(I)} + \underset{\substack{\text{carbon in}\\\text{oxidation state }-3}}{2C(-III)}\,.$$

In this example also, the second equation includes only the atoms that change oxidation states: the four hydrogen atoms initially present in ethylene are in the $+1$ oxidation state in both reactants and products and are therefore omitted. Each of the two neutral hydrogen atoms can be regarded as giving up an electron to, and thereby reducing, one of the carbons. This example also shows that the oxidation that complements the reduction of ethylene is that of the two hydrogen atoms in H_2, from the 0 to the $+1$ oxidation state. General application of the oxidation-state concept leads to a formal viewpoint toward all redox reactions as electron-transfer reactions.

Half reactions. One of the basic reasons that the concept of oxidation–reduction reactions helps to correlate chemical knowledge is that a particular oxidation or reduction can often be carried out by a wide variety of oxidizing or reducing agents. Reduction of the iron(III) ion to the iron(II) ion by four different reducing agents provides an example:

$$\underset{\substack{\text{iron(III)}\\\text{ion}}}{Fe^{3+}(aq)} + \underset{\substack{\text{vanadium(II)}\\\text{ion}}}{V^{2+}(aq)} \longrightarrow \underset{\substack{\text{iron(II)}\\\text{ion}}}{Fe^{2+}(aq)} + \underset{\substack{\text{vanadium(III)}\\\text{ion}}}{V^{3+}(aq)}$$

$$\underset{\substack{\text{iron(III)}\\\text{ion}}}{2Fe^{3+}(aq)} + \underset{\substack{\text{zinc}\\\text{metal}}}{Zn(s)} \longrightarrow \underset{\substack{\text{iron(II)}\\\text{ion}}}{2Fe^{2+}(aq)} + \underset{\substack{\text{zinc(II)}\\\text{ion}}}{Zn^{2+}(aq)}$$

$$2Fe^{3+}(aq) + 2I^- \longrightarrow 2Fe^{2+}(aq) + I_2$$

iron(III) ion; iodide ion; iron(II) ion; iodine

$$2Fe^{3+}(aq) + C_6H_4(OH)_2 \longrightarrow 2Fe^{2+}(aq) + C_6H_4O_2 + 2H^+.$$

iron(III) ion; hydroquinone; iron(II) ion; quinone; hydrogen ion

Production of the same change in the aqueous iron(III) ion by different reductants emphasizes the fact that the reduction is a characteristic reaction of the iron system itself, and, therefore, the process may be written without specifying the identity of the reducing agent in the following way:

$$Fe^{3+}(aq) + e^- \longrightarrow Fe^{2+}(aq) .$$

iron(III) ion; electron; iron(II) ion

Hypothetical equations of this type are known as half reactions. The symbol e^-, which stands for an electron, serves as a reminder that an unspecified reducing agent is required to bring about the change. Half reactions can be written, equally, for the reducing agents in the four reactions with ferric ion:

$$V^{2+}(aq) \longrightarrow V^{3+}(aq) + e^-$$

vanadium(II) ion; vanadium(III) ion; electron

$$Zn(s) \longrightarrow Zn^{2+}(aq) + 2e^-$$

zinc(0) metal; zinc(II) ion; electron

$$2I^- \longrightarrow I_2 + 2e^-$$

iodide ion; iodine; electron

$$C_6H_4(OH)_2 \longrightarrow C_6H_4O_2 + 2e^- + 2H^+$$

hydroquinone; quinone; electron; hydrogen ion

Although hypothetical, half reactions are properly balanced chemical processes. Since $V^{2+}(aq)$ increases its oxidation number by one, from +2 to +3, in the first half reaction, an electron is shown as a product of the change. Similarly, two electrons are produced when the oxidation number of zinc increases from 0 to +2 in the second half reaction. When half reactions for hypothetical isolated oxidations and reductions are combined, the electrons must cancel if the equation for a possible overall chemical reaction is to result.

The use of half reactions is a natural outgrowth of the application of the electron-transfer concept to redox reactions. Since the oxidation-state principle allows any redox reaction to be analyzed in terms of electron transfer, it follows that all redox reactions can be broken down into a complementary pair of hypothetical half reactions. Electrochemical cells (in which chemical energy can be converted to electrical energy, and vice versa) provide some physical reality to the half-reaction idea. Oxidation and reduction half reactions can be carried out in separate compartments of electrochemical cells, with the electrons flowing through a connecting wire and the circuit completed by some arrangement for ion migration between the two compartments (but the migration need not involve any of the materials of the oxidation–reduction reactions themselves).

Redox potentials for common half reactions. Analysis of the electrical potential, or voltage, developed by pairing various half reactions in electrochemical cells has led to the determination of redox potentials for many common half reactions. While a detailed description of redox potentials requires the methods of thermodynamics (the branch of physics concerned with the role of heat in transformation of matter or energy), much useful information can be obtained from redox potentials with minimal recourse to formal theory. Basically, a table of half-cell potentials is a summary of the relative tendencies of different oxidations and reductions to occur. Table 3 lists selected half reactions and their corresponding reduction potentials (symbolized by $E°$).

Table 3: Selected Values of Standard Reduction Potentials

half reactions*	$E°$ (volts)
$F_2(g) + 2e^- \rightarrow 2F^-$ fluorine(0) electrons fluoride(−I) ion	2.87
$MnO_4^- + 8H^+ + 5e^- \rightarrow Mn^{2+}(aq) + 4H_2O$ permanganate ion; hydrogen(I) ion; electrons; manganese(II) ion; water	1.51
$Cl_2(g) + 2e^- \rightarrow 2Cl^-$ chlorine(0) electrons chloride(−I) ions	1.36
$O_2(g) + 4H^+ + 4e^- \rightarrow 2H_2O$ oxygen(0) hydrogen(I) ions electrons water	1.23
$Fe^{3+}(aq) + e^- \rightarrow Fe^{2+}(aq)$ iron(III) ion electron iron(II) ion	0.77
$Cu^{2+}(aq) + 2e^- \rightarrow Cu(s)$ copper(II) ion electrons copper(0)	0.34
$2H^+ + 2e^- \rightarrow H_2(g)$ hydrogen(I) ion electrons hydrogen(0)	0.00
$Zn^{2+}(aq) + 2e^- \rightarrow Zn(s)$ zinc(II) ion electrons zinc(0)	−0.76
$Na^+ + e^- \rightarrow Na(s)$ sodium(I) ion electron sodium(0)	−2.71

*The identifications in parentheses refer to the physical state of the substance: (g), gas; (aq), as a hydrated positive ion in water; (s), as the pure solid.
Source: W. Latimer, *Oxidation Potentials.*

The physical significance of the values is directly linked to several agreements about their use. First, the greater the value of $E°$ (the reduction potential), the greater the tendency of a half reaction to proceed from left to right (as written). The half reactions in Table 3 are listed from top to bottom in order of decreasing $E°$: the higher a reaction's position on the list, the greater the tendency of the reactants to accept electrons. In other words, reagents high on the list, such as fluorine gas (F_2) and permanganate ion (MnO_4^-), are strong oxidizing agents. Second, the reduction of hydrogen ions (H^+) to hydrogen gas (H_2) is arbitrarily assigned the value 0 volts. Half cells with positive reduction potentials involve reactants more easily reduced than H^+; conversely, those with negative potentials, reactants more difficult to reduce than hydrogen ions.

Use of reduction potentials to predict reactions

With the aid of reduction potentials, it is possible to predict whether a particular oxidation–reduction reaction can occur. The predictions require breaking down the overall reaction into two half reactions of known reduction potentials. For example, if a strip of zinc metal is dipped into a solution containing copper(II) ion, the possibility exists for a redox process, which can be regarded as the sum of the half reactions aqueous zinc ion (Zn^{2+}[aq]) to zinc metal (Zn[s]) and aqueous copper ion (Cu^{2+}[aq]) to copper metal (Cu[s]), as follows:

$$Zn(s) + Cu^{2+}(aq) \longrightarrow Zn^{2+}(aq) + Cu(s) .$$

zinc(0) metal; copper(II) ion; zinc(II) ion; copper(0) metal

Combining these two half reactions requires writing the zinc ion to zinc metal half reaction the reverse of the way it appears in Table 3. When the direction of a half reaction is reversed, so that it can be added to another half reaction, the sign of its redox potential is also reversed (in this case, from negative to positive), and the two reduction potential values are then added.

$$Cu^{2+}(aq) + 2e^- \longrightarrow Cu(s) \qquad +0.34 \text{ volt}$$

$$Zn(s) \longrightarrow Zn^{2+}(aq) + 2e^- \qquad +0.76$$

$$Cu^{2+}(aq) + Zn(s) \xrightarrow{\text{spontaneous}} Cu(s) + Zn^{2+}(aq) \qquad +1.10$$

copper(II) ion; zinc metal; copper metal; zinc(II) ion

The resulting $E°$ value for the net reaction, +1.10 volts, measures the tendency of the net reaction to occur. If $E°$ for a particular net reaction is positive, the process may be expected to occur spontaneously when the reactants are mixed at specified concentrations (one mole per litre;

see below *Oxidation–reduction equilibria*). Therefore, it is predicted that copper metal should be deposited on a strip of zinc metal when the latter is immersed in a solution of a copper(II) salt. This reaction is, in fact, readily observed in the laboratory. A more specific physical interpretation of the +1.10 volt value is that it represents the voltage that would be produced by an ideal electrochemical cell based on the copper(II) ion to copper metal and zinc(II) ion to zinc metal half reactions with all the reagents at specified concentrations.

When the same two half cells are combined, with both their directions (and therefore the signs of their redox potentials) reversed, it is predicted that the reverse reaction, the depositing of zinc metal from a zinc(II) ion solution onto a copper strip, will not occur spontaneously. As in the case of $E°$ values for half reactions, those for net redox reactions also change sign when the direction of the reaction is reversed.

$$\begin{array}{lll} \mathrm{Cu(s)} \longrightarrow \mathrm{Cu^{2+}(aq)} + 2e^- & & -0.34 \text{ volt} \\ \mathrm{Zn^{2+}(aq)} + 2e^- \longrightarrow \mathrm{Zn(s)} & & -0.76 \\ \hline \mathrm{Zn^{2+}(aq)} + \mathrm{Cu(s)} \xrightarrow{\text{nonspontaneous}} \mathrm{Cu^{2+}(aq)} + \mathrm{Zn(s)} & & -1.10 \end{array}$$

The results of the copper–zinc system can be applied more generally to the half reactions in Table 3. For example, copper(II) ion in water (Cu^{2+}[aq]) is an oxidant strong enough to force a half reaction lower on the table to proceed spontaneously in the opposite direction of that written. Therefore, not only is copper(II) ion expected to oxidize zinc metal (Zn[s]) to zinc(II) ion (Zn^{2+}[aq]); it is also predicted to oxidize hydrogen gas (H_2[g]) to hydrogen ion (H^+) and sodium metal (Na[s]) to sodium ion (Na^+). Similarly, fluorine gas (F_2[g]), the strongest oxidant listed in Table 3, is predicted to oxidize spontaneously the products of all the other half reactions in the table. In contrast, the strongest reducing agent is solid sodium metal (Na[s]), and it is expected spontaneously to reduce the reactants of all the other half cells.

Oxidation–reduction equilibria. In practice many chemical reactions can be carried out in either direction, depending on the conditions. The spontaneous direction predicted for a particular redox reaction by half-cell potentials is appropriate to a standard set of reaction conditions. Specifically, the temperature is assumed to be 25° C (77° F) with reagents at specified concentrations. Gases are present at one atmosphere pressure and solutes at one mole per litre (one molecular weight in grams dissolved in one litre of solution) concentration (1M). Solids are assumed to be in contact with the reaction solution in their normal stable forms, and water is always taken to be present as the solvent. Many practical problems can be solved directly with standard reduction potentials.

Role of the Nernst equation

The usefulness of reduction potentials is greatly extended, however, by a thermodynamic relationship known as the Nernst equation, which makes it possible to calculate changes in half-cell potentials that will be produced by deviations from standard concentration conditions. In the reaction between zinc metal and copper(II) ion, standard conditions for zinc and copper metal require simply that both solids be present in contact with the solution; the $E°$ values are not affected by either the total or proportionate amounts of the two metals. The calculation that the overall reaction is spontaneous by +1.10 volts is based on standard one mole per litre (1M) concentrations for aqueous zinc(II) ion (Zn^{2+}[aq]) and aqueous copper(II) ion (Cu^{2+}[aq]). Using the Nernst equation it is found that $E°$ for the overall reaction will be +1.10 volts as long as both ions are present in equal concentrations, regardless of the concentration level.

On the other hand, if the ratio of the zinc(II) to copper(II) ion concentrations is increased, the reduction potential ($E°$) falls until, at a very high preponderance of zinc ion, $E°$ becomes 0 volt. At this point, there is no net tendency for the reaction to proceed spontaneously in either direction. If the zinc(II) to copper(II) ion ratio is increased further, the direction of spontaneity reverses, and zinc ion spontaneously oxidizes copper metal. In practice, such high zinc(II) to copper(II) ion concentration ratios are unattainable, which means that the reaction can only be carried out spontaneously with copper(II) ion oxidizing zinc metal. Many reactions with $E°$ values smaller than +1.10 volts under standard conditions can be carried out in either direction by adjusting the ratio of product and reactant concentrations. The point at which $E° = 0$ volt represents a state of chemical equilibrium. When chemical reactions are at equilibrium, the concentrations of the reagents do not change with time, since net reaction is not spontaneous in either direction. Measurements of half-cell potentials combined with Nernst-equation calculations are a powerful technique for determining the concentration conditions that correspond to chemical equilibrium.

Reaction rates. *Predictability.* There are practical limitations on predictions of the direction of spontaneity for a chemical reaction, the most important arising from the problem of reaction rates. An analogy can be made with the simple physical system of a block on a sloping plane. Because of the favourable energy change, the block tends spontaneously to slide down, rather than up, the slope, and, at mechanical equilibrium, it will be at the bottom of the slope, since that is the position of lowest gravitational energy. How rapidly the block slides down is a more complex question, since it depends on the amount and kind of friction present. The direction of spontaneity for a chemical reaction is analogous to the downhill direction for a sliding block, and chemical equilibrium is analogous to the position at the bottom of the slope; the rate at which equilibrium is approached depends on the efficiency of the available reaction processes. Between zinc metal and aqueous copper(II) ion, the reaction proceeds without observable delay, but various other spontaneous redox processes proceed at imperceptibly slow rates under ordinary conditions.

Biological processes. A particularly significant illustration of the role of mechanisms in determining the rates of redox reactions concerns respiration, the central energy-producing process of life. Foodstuffs that are oxidized by molecular oxygen during respiration are quite unreactive with oxygen before ingestion. Such high-energy foods as grains and sugar can resist the atmosphere indefinitely but are rapidly converted to carbon dioxide and water through combination with oxygen during respiratory metabolism. The situation is exemplified by the behaviour of glucose at ambient temperatures.

The significance of the different rate behaviour of high-energy foods inside and outside the cell has been dramatized by Albert Szent-Györgyi, a Hungarian biochemist resident in the United States, a pioneering researcher into the chemical mechanism of respiration:

> You remember the exciting story of the grave of the Egyptian emperor. At its opening the breakfast of the emperor was found unburned though it had been exposed to the action of oxygen during several thousand years at a temperature that was not very different from 37° C [98.6° F]. Had the king risen and consumed his breakfast, as he had anticipated doing, the food would have been oxidized in no time, that is to say the cells of the emperor would have made reactions take place that would not run spontaneously (from Albert V. Szent-Györgyi, *On Oxidation, Fermentation, Vitamins, Health and Disease;* the Williams and Wilkins Company, 1939).

Living systems are able to use respiratory oxidation as an energy source only because the same reactions are slow outside the cell. In return for providing an efficient mechanism for the oxidation of foods, the cell gains control over the disposition of the liberated chemical energy.

Examples such as the chemistry of respiration make clear the importance of determining the rates and mechanisms of redox reactions. Often questions are difficult to answer even in regard to relatively simple reactions. It has been pointed out that many redox processes can be categorized as oxygen-atom-, hydrogen-atom-, or electron-transfer processes. These categories describe the net changes that are involved but provide no insight into the mechanisms of the reactions.

Mechanisms of redox reactions. Some of the problems associated with formulating descriptions of the mechanisms are illustrated by the reaction between two metal

ions that undergo complementary, one-unit changes in oxidation state:

$$M(\text{III}) + N(\text{II}) \longrightarrow M(\text{II}) + N(\text{III}) .$$

There are many different metal ions, designated with the letters M and N, which participate in redox reactions with this basic stoichiometry. To define the possible mechanisms with any precision, it is necessary to identify the groups that are directly bonded to the metals, as well as to specify which particular metals take part in the reactions. One relatively simple example is the chromium(II)–iron(III) reaction. Both chromium and iron aquo ions are surrounded by six water molecules in both the +2 and +3 oxidation states.

$$\underset{\substack{\text{hexaaquoiron(III)}\\\text{ion}}}{Fe(H_2O)_6^{3+}} + \underset{\substack{\text{hexaaquochromium(II)}\\\text{ion}}}{Cr(H_2O)_6^{2+}} \longrightarrow \underset{\substack{\text{hexaaquoiron(II)}\\\text{ion}}}{Fe(H_2O)_6^{2+}} + \underset{\substack{\text{hexaaquochromium(III)}\\\text{ion}}}{Cr(H_2O)_6^{3+}}$$

The reaction appears from its stoichiometry to entail simple electron transfer from Cr(II) to Fe(III). There are, however, other possibilities. Their variety is most evident if it is assumed that the oxidizing agent, hexaaquoiron(III) ($Fe[H_2O]_6^{3+}$), dissociates a hydrogen ion before reacting with hexaaquochromium(II) ($Cr[H_2O]_6^{2+}$). The hexaaquoiron(III) ion is then converted to a hydroxopentaaquoiron(III) ion, known to be an important reactant in the Fe(III)–Cr(II) reaction. Its formation requires no change in the oxidation state of iron and should be regarded as a simple acid–base reaction. With hydroxopentaaquoiron(III) ion, $(H_2O)_5FeOH^{2+}$, as the oxidizing agent, simple electron transfer does provide one plausible means for the reaction. All the steps in the mechanism must add up to give the overall reaction. Intermediate species such as hydroxopentaaquoiron(III) must cancel out in the addition process by occurring as products in one step and reactants in another:

$$\underset{\substack{\text{hexaaquoiron(III)}\\\text{ion}}}{Fe(H_2O)_6^{3+}} \longrightarrow \underset{\substack{\text{hydroxopenta-}\\\text{aquoiron(III)}\\\text{ion}}}{(H_2O)_5FeOH^{2+}} + \underset{\substack{\text{hydrogen}\\\text{ion}}}{H^+}$$

$$\underset{\substack{\text{hydroxopenta-}\\\text{aquoiron(III)}\\\text{ion}}}{(H_2O)_5FeOH^{2+}} + \underset{\substack{\text{hexaaquo-}\\\text{chromium(II)}\\\text{ion}}}{Cr(H_2O)_6^{2+}} \xrightarrow[\text{transfer}]{\text{electron}} \underset{\substack{\text{hydroxopenta-}\\\text{aquoiron(II)}\\\text{ion}}}{(H_2O)_5FeOH^{+}} + \underset{\substack{\text{hexaaquo-}\\\text{chromium(III)}\\\text{ion}}}{Cr(H_2O)_6^{3+}}$$

$$\underset{\substack{\text{hydroxopenta-}\\\text{aquoiron(II)}\\\text{ion}}}{(H_2O)_5FeOH^{+}} + \underset{\substack{\text{hydrogen}\\\text{ion}}}{H^+} \longrightarrow \underset{\substack{\text{hexaaquoiron(II)}\\\text{ion}}}{Fe(H_2O)_6^{2+}}$$

$$Fe(H_2O)_6^{3+} + Cr(H_2O)_6^{2+} \longrightarrow Fe(H_2O)_6^{2+} + Cr(H_2O)_6^{3+}$$

An alternative to simple electron transfer is the transfer of a hydrogen atom from a water molecule bound to chromium(II) to the hydroxide ion (OH^-) bound to iron(III). A third important possibility is the transfer of a neutral OH group (called a hydroxyl radical) from iron(III) to chromium(II). Oxygen and hydrogen occur as oxygen(−II) and hydrogen(I) in both reactants and products. These oxidation states correspond to those present in the hydroxide ion OH^-. Therefore, when an OH group transfers, it must leave an electron behind, reducing the iron, and then reaccept an electron from chromium, oxidizing it. Since both the aqueous iron and chromium ions have a strong tendency to remain surrounded by six oxygen molecules, the most likely method of OH transfer would be the sharing of the transferred oxygen between the two metals at an intermediate stage of the reaction. But iron(III) is not a strong enough oxidizing agent to produce a significant concentration of neutral OH groups from OH^- ions. A more acceptable description of the OH transfer mechanism, therefore, is to regard OH^- as a bridging group through which electron transfer is accomplished as the two metal ion groups share a bonded oxygen atom.

$$[(H_2O)_5\overset{3+}{Fe}-\underset{\displaystyle H}{\underset{|}{O}}-\overset{2+}{Cr}(H_2O)_5]^{4+} \longrightarrow [(H_2O)_5\overset{2+}{Fe}-\underset{\displaystyle H}{\underset{|}{O}}-\overset{3+}{Cr}(H_2O)_5]^{4+}$$

Experimentally, it is difficult to distinguish between the alternative mechanisms posed above. Classification schemes for reaction mechanisms are of little value unless they offer alternatives that can be experimentally verified. For that reason the most successful system for classifying the mechanisms of redox reactions between metal ions has been the inner sphere–outer sphere dichotomy. Outer-sphere reactions are those that take place without breaking any bonds between a metal and a group such as water or hydroxide ion bound to it. Both the simple electron- and hydrogen-atom-transfer mechanisms are outer-sphere processes. If, on the other hand, the oxidation-state changes take place within an intermediate product in which the two metals are directly bonded to a common bridging group (such as shown in the equation above), the mechanism is inner-sphere. Formation of the intermediate requires loss of a bound water molecule by one of the metals. The inner sphere–outer sphere distinction can be tested experimentally in some redox systems.

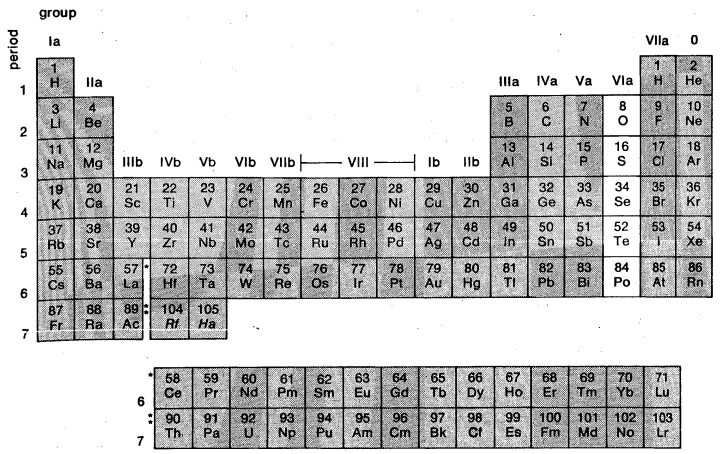
Oxygen Group Elements and Their Compounds

Oxygen, sulfur, selenium, tellurium, and polonium comprise the family referred to in the periodic classification of the chemical elements as Group VIa, or the chalcogens (see the Figure). A relationship among the first three members of the group was recognized as early as 1829; tellurium was assigned its place by 1865, and the discovery of polonium in 1898 completed the group. By the early 1970s, the possibility of finding element 116, the next member of Group VIa, in nature appeared to be negligible.

I. General considerations

OCCURRENCE IN NATURE

Estimates of the proportions of the various kinds of atoms in the universe put oxygen fourth in abundance, after hydrogen, helium, and neon, but the importance of such a ranking is slight since hydrogen atoms account for almost 94 percent of the total and helium for most of the rest. About three atoms out of 10,000 are oxygen, but because the mass of an oxygen atom is approximately 16 times that of a hydrogen atom, oxygen constitutes a larger fraction of the mass of the universe, though still only about 0.5 percent. In the regions ordinarily accessi-



Oxygen group elements in the periodic table.

ble to man, however—*i.e.*, within a few kilometres of the surface of the Earth—oxygen is the most abundant element: in mass, it makes up about 20 percent of the air, about 46 percent of the solid crust of the Earth, and about 89 percent of the water.

Oxygen is represented by the chemical symbol O. In the air, it exists mostly as molecules each made up of two atoms (O_2), although small amounts of ozone (O_3), in which three atoms of oxygen make up each molecule, are present in the atmosphere. Oxygen is a colourless, odourless, tasteless gas essential to living organisms, being taken up by animals, which convert it to carbon dioxide; plants, in turn, utilize carbon dioxide as a source of carbon and return the oxygen to the atmosphere. Oxygen forms compounds by reaction with practically any other element, as well as by reactions that displace elements from their combinations with each other; in many cases, these processes are accompanied by the evolution of heat and light and in such cases are called combustions.

In cosmic abundance, sulfur ranks ninth among the elements, accounting for only one atom of every 20,000–30,000. Sulfur occurs in the uncombined state as well as in combination with other elements in rocks and minerals that are widely distributed, although it is classified among the minor constituents of the Earth's crust, in which its proportion is estimated to be between 0.03 and 0.06 percent. On the basis of the finding that certain meteorites contain about 12 percent sulfur, it has been suggested that deeper layers of the Earth contain a much larger proportion. Seawater contains about 0.09 percent sulfur in the form of sulfate. The most important source is underground deposits of very pure sulfur present in domelike geologic structures where the sulfur is believed to have been formed by the action of bacteria upon the mineral anhydrite, in which sulfur is combined with oxygen and calcium. Deposits of sulfur in volcanic regions probably originated from gaseous hydrogen sulfide generated below the surface of the Earth and transformed into sulfur by reaction with the oxygen in the air.

Sulfur exists under ordinary conditions as a pale yellow, crystalline, nonmetallic solid; it is odourless and tasteless, combustible, and insoluble in water. Its chemical symbol is S. It reacts with all metals except gold and platinum, forming sulfides; it also forms compounds with several of the nonmetallic elements. Several million tons of sulfur are produced each year, mostly for the manufacture of sulfuric acid, which is widely used in industry.

The element selenium (symbol Se) is much rarer than oxygen or sulfur, comprising approximately 90 parts per billion of the crust of the Earth. It is occasionally found uncombined, accompanying native sulfur, but is more often found in combination with heavy metals (as copper, mercury, lead, or silver) in a few minerals. The principal commercial source of selenium is as a by-product of copper refining; its major uses are in the manufacture of electronic equipment, in pigments, and in making glass. The gray, metallic form of the element is the most stable under ordinary conditions; this form has the unusual property of greatly increasing in electrical conductivity when exposed to light. Selenium compounds are toxic to animals; plants grown in seleniferous soils may concentrate the element and become poisonous.

Tellurium is a silvery-white element (symbol Te) with properties intermediate between those of metals and nonmetals; it makes up approximately one part per billion of the Earth's crust. Like selenium, it is less often found uncombined than as compounds of metals such as copper, lead, silver, or gold, and is obtained chiefly as a by-product of the refining of copper or lead. No large use for tellurium has been found.

Polonium (symbol Po) is an extremely rare, radioactive element found in minerals containing uranium. It has some scientific applications as a source of alpha radiation.

HISTORICAL SURVEY

Oxygen. Although several substances now recognized as elements were known in their uncombined states in ancient times, the presently accepted idea of chemical elements dates from 1661, when the English natural philosopher Robert Boyle set forth their nature as simple, primitive, perfectly unmixed bodies, not formed from each other nor from any other bodies. Despite its terrestrial abundance, oxygen was not recognized as belonging to this class before the 1770s. Two chemists, Carl Wilhelm Scheele, in about 1772, and Joseph Priestley, in 1774, both obtained oxygen by heating certain metal oxides. Antoine-Laurent Lavoisier, with remarkable insight, interpreted the role of oxygen in respiration as well as combustion, discarding the phlogiston theory, which had been accepted up to that time; he noted its tendency to form acids by combining with many different substances and accordingly named the element *oxygen* (*oxygène*) from the Greek words for "acid former."

Boyle's definition of chemical elements

Sulfur. The history of sulfur is part of antiquity. The name itself probably found its way into Latin from the language of the Oscans, an ancient people who inhabited the region including Vesuvius, where sulfur deposits are widespread. Prehistoric man used sulfur as a pigment for cave painting; one of the first recorded instances of the art of medication is in the use of sulfur as a tonic.

The combustion of sulfur had a role in Egyptian religious ceremonials as long as 4,000 years ago. "Fire and brimstone" references in the Bible are related to sulfur, suggesting that "hell's fires" are fuelled by sulfur. The beginnings of practical and industrial uses of sulfur are credited to the Egyptians, who used sulfur dioxide for bleaching cotton as early as 1600 BC. Greek mythology includes sulfur chemistry: Homer tells of Odysseus' use of sulfur dioxide to fumigate a chamber in which he had slain his wife's suitors. The use of sulfur in explosives and fire displays dates to about 500 BC in China, and flame-producing agents used in warfare (Greek fire) were prepared with sulfur in the Middle Ages. Pliny the Elder in AD 50 reported a number of individual uses of sulfur and ironically was himself killed, in all probability by sulfur fumes, at the time of the great Vesuvius eruption (AD 79). Sulfur was regarded by the alchemists as the principle of combustibility. Lavoisier recognized it as an element in 1777, although it was considered by some to be a compound of hydrogen and oxygen; its elemental nature was established by the French chemists Joseph Gay-Lussac and Louis Thenard.

Selenium. In 1817 a Swedish chemist named Jöns Jacob Berzelius noted a red substance resulting from sulfide ores from mines of Fahlun (Falun), Sweden. When this red material was investigated in the following year, it proved to be an element and was named after the moon or the moon goddess Selene. An ore of unusually high selenium content was discovered by Berzelius only days before he made his report to the scientific societies of the world on selenium. His sense of humour is evident in the name he gave the ore, *eucairite*, meaning "just in time."

Tellurium. The element tellurium was isolated before it was actually known to be an elemental species. About 1782 Franz Joseph Müller von Reichenstein, an Austrian

mineralogist, worked with an ore referred to as German gold. From this ore he obtained a material that defied his attempts at analysis and was called by him *metallum problematicum*. In 1798 Martin Heinrich Klaproth confirmed Müller's observations and established the elemental nature of the substance. He named the element after man's "heavenly body" Tellus, or Earth.

Polonium. The fifth member of Group VIa, polonium, was the first to be found by taking advantage of the phenomenon of radioactivity, discovered by Henri Becquerel in the last part of the 19th century. Pierre and Marie Curie isolated the element while carrying out analyses on a uranium ore, pitchblende. The very intense radioactivity not attributable to uranium was ascribed to a new element, named by them after Mme Curie's homeland, Poland. The discovery was announced in July 1898.

OXYGEN GROUP ELEMENTS IN THE PERIODIC TABLE

Atomic and molecular nature of matter. *Atoms, nuclei, and electrons.* Of the millions of forms in which matter is known to exist, all are composed of one or more of only about 100 different kinds of tiny particles called atoms. These 100-odd basic varieties of matter are the chemical elements, each of which has distinctive properties that are systematically related to the way in which their atoms are, in turn, built up from even smaller, more fundamental particles. Practically the entire mass of every atom is concentrated in its nucleus, which is made up of protons, each possessing a positive electrical charge, and neutrons, which possess no charge. The number of protons in the nucleus of an atom is called the atomic number and determines the chemical identity of that atom: an atom with eight protons in its nucleus is an oxygen atom; one with 16 protons is a sulfur atom; one with 34 is a selenium atom. The number of neutrons in the nucleus is approximately the same as the number of protons, but for every element, more than one combination of protons and neutrons is possible. Oxygen nuclei, for example, always contain eight protons but may contain from five to 12 neutrons; these different forms of a single element are called isotopes. Some isotopes are unstable, spontaneously changing into others, but of the known elements, 88 have at least one stable isotope, and many have several. Of the eight isotopes of oxygen, for example, those with eight, nine, or ten neutrons are stable, and the one with eight comprises more than 99 percent of the oxygen found in nature.

Protons and neutrons

The nucleus is surrounded by a cloud of electrons, particles each having a single negative electrical charge but very little mass. The number of electrons in an atom is the same as the number of protons in its nucleus, so that the entire atom is electrically neutral. The electrons are distributed in regions of space called orbitals, each with a capacity of two electrons, arranged in shells of increasing distance from the nucleus. Each successive shell contains a larger number of orbitals that differ in shape and orientation. Each electron is attracted to the nucleus but repelled by all the other electrons in the atom, and, as a result of the variations between orbitals, the sum of all these interactions is different for every electron. The particular set of orbitals occupied by electrons, called the configuration of the atom, is determined by the tendency of the total energy involved in the interactions to assume a minimum value.

The electrons in the outermost shell are least strongly bound to the atom and are the only ones affected in ordinary chemical processes; these, called the valence electrons, determine the tendency of an atom to take part in chemical reactions leading to formation of compounds.

Reactions and chemical bonds. A configuration of eight electrons in the outermost shell is an especially stable one, as shown by the extremely small tendency of the noble gases neon, argon, krypton, xenon, and radon, which have this configuration, to take part in chemical reactions. To achieve this condition, atoms that have seven electrons outermost have a strong tendency to gain one more; this gain makes the number of electrons larger than the number of protons, and the resulting negatively charged particle is called an ion. Atoms with six or five valence electrons show the same tendency, but not to the same extent, because each additional electron is increasingly repelled by the negative charge introduced by the first.

Ions and molecules

Atoms that have one electron outermost and eight electrons in the next lower shell have a strong tendency to lose their lone outer electron, forming a positive ion that has a noble gas configuration. Loss of two or three electrons occurs progressively less readily, because in these cases each electron is being removed from the attractive positive charge resulting from loss of the first.

Both these processes are illustrated by the exchange of an electron between atoms of chlorine and potassium. A chlorine atom has two electrons in its first shell, eight in its second, and seven in its third; a potassium atom has two, eight, and eight, respectively, and one in the fourth shell. Loss of the single electron from the fourth shell of the potassium atom leaves the third shell, with eight electrons, outermost, and addition of this electron to the third shell of the chlorine atom gives it eight. Therefore, when potassium and chlorine atoms approach one another, an electron is transferred, resulting in the formation of a positive potassium ion and a negative chloride ion, with each ion having the electron configuration of the noble gas argon.

The attraction between opposite charges constitutes a chemical bond—called ionic or electrovalent—that causes large numbers of these ions to cling together in an orderly array. The formula of the compound is written KCl, which indicates that there is one chloride ion for each potassium ion, but should not be taken to mean that there are molecules—that is, discrete particles in which one potassium ion is specifically associated with one of chlorine. The transfer of electrons between atoms is the feature underlying oxidation and reduction processes. Oxidation was originally defined as the reaction of oxygen with another element, such as hydrogen, carbon, or zinc. Recognition that many other elements reacted in the same general way as oxygen led to extension of the term oxidation to reactions of those elements, such as the oxidation of zinc by chlorine or the oxidation of iron by sulfur. Establishment of the fact that all these oxidation reactions are accompanied by transfer of electrons to the oxidizing agent allowed the generalization that oxidation is any process in which one atom removes electrons from another; the atom that contributes these electrons to the oxidizing agent is called the reducing agent.

Oxidation and reduction

The number of electrons lost in the oxidation or reduction of an element is called the oxidation number. For example, in the oxidation of potassium by chlorine, an atom of potassium loses one electron, and its oxidation number changes from zero to plus one. At the same time, a chlorine atom gains one electron, and its oxidation number changes from zero to minus one. In electrovalent compounds, the oxidation number of an ion is the same as its electrical charge and often is referred to as the valence of the element.

The name of a compound of an element that may assume different oxidation states often specifies the oxidation state by a roman numeral following the name of the element, as in iron(II) oxide, FeO, or tin(IV) chloride, $SnCl_4$.

Atoms in which the outermost electron shell is occupied by three, four, or five electrons do not form ions readily because the gain or loss of the large number of electrons requires too much energy. Such atoms achieve a condition in which the valence shell interacts with eight electrons—without gaining sole possession of them—by sharing electrons with other atoms. Bonds formed in this way are called covalent, and the shared electrons remain in the region of space between the nuclei of the two atoms bonded together. Two atoms may each contribute one, two, or three electrons, forming single, double, or triple covalent bonds, and one atom may share electrons with several other atoms at the same time, linking whole groups of atoms together into molecules as simple as that of hydrogen or as complicated as those of proteins and nucleic acids, in which many thousands of atoms are linked together.

Covalent bonds

General similarities and differences. The elements belonging to Group VIa of the periodic table are characterized by electron configurations in which six electrons occupy the outermost shell. An atom having such an electronic structure tends to form a stable shell of eight electrons by adding two more, producing an ion that has a double negative charge. This tendency to form negatively charged ions, typical of nonmetallic elements, is quantitatively expressed in the properties of electronegativity (the assumption of partial negative charge when present in covalent combination) and electron affinity (the ability of a neutral atom to take up an electron, forming a negative ion). Both these properties decrease in intensity as the elements increase in atomic number and mass proceeding down column VIa of the periodic table. Oxygen has, except for fluorine, the highest electronegativity and electron affinity of any element; the values of these properties then decrease sharply for the remaining members of the group to the extent that tellurium and polonium are regarded as predominantly metallic in nature, tending to lose rather than gain electrons in compound formation.

As is the case within all groups of the table, the lightest element—the one of smallest atomic number—has extreme or exaggerated properties. Oxygen, because of the small size of its atom, the small number of electrons in its underlying shell, and the large number of protons in the nucleus relative to the atomic radius, has properties uniquely different from those of sulfur and the remaining chalcogens. Those elements behave in a reasonably predictable and periodic fashion, as will be shown.

Although even polonium exhibits the oxidation state −2 in forming a few binary compounds of the type MPo (in which M is a metal), the heavier chalcogens do not form the negative state readily, favouring positive states such as +2 and +4. All the elements in the group except oxygen may assume positive oxidation states, with the even values predominating, but the highest value, +6, is not a very stable one for the heaviest members. When this state is achieved, there is a strong driving force for the atom to return to a lower state, quite often to the elemental form. This tendency makes compounds containing Se(VI) and Te(VI) more powerful oxidizing agents than S(VI) compounds. Conversely, sulfides, selenides, and tellurides, in which the oxidation state is −2, are strong reducing agents, easily oxidized to the free elements.

Neither sulfur nor selenium, and most certainly not oxygen, forms purely ionic bonds to a nonmetal atom. Tellurium and polonium form a few compounds that are somewhat ionic; tellurium(IV) sulfate, $Te(SO_4)_2$, and polonium(II) sulfate, $PoSO_4$, are examples.

Stability of compounds

Another feature of the Group VIa elements that parallels trends generally shown in columns of the periodic table is the increasing stability of molecules having the composition $X(OH)_n$ as the size of the central atom, X, increases. There is no compound HO—O—OH, in which the central oxygen atom would have a positive oxidation state, a condition that it resists. The analogous sulfur compound HO—S—OH, although not known in the pure state, does have a few stable derivatives in the form of metal salts, the sulfoxylates. More highly hydroxylated compounds of sulfur, $S(OH)_4$ and $S(OH)_6$, also do not exist, not because of sulfur's resistance to a positive oxidation state but rather because of the high charge density of the S(IV) and S(VI) states (the large number of positive charges relative to the small diameter of the atom), which repels the electropositive hydrogen atoms, and the crowding that attends covalent bonding of six oxygen atoms to sulfur, favouring loss of water:

$$S(OH)_6 \longrightarrow (HO)_2SO_2 + 2H_2O.$$

orthosulfuric acid — sulfuric acid — water

As the size of the chalcogen atom increases, the stability of the hydroxylated compounds increases: the compound orthotelluric acid, $Te(OH)_6$, is capable of existence.

Catenation

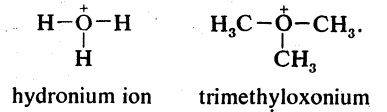
One of the most unusual properties of this family of elements is that of catenation (from Latin *catena*, "chain") or the bonding of an atom to another identical atom. Although oxygen shows this property only in the existence of ozone, sulfur is second only to carbon in exhibiting this mode of combination; the chalcogens beyond sulfur show it to diminishing degrees, polonium having no tendency to catenate. This type of bonding is found in the many ring systems of sulfur and selenium as well as in long zigzag chain structures. Catenation also occurs in the sulfanes and the metal polysulfides, compounds that have the formulas H_2S_x and M_2S_x, in which x may take the values of 2, 3, 4, or more, and M represents a singly charged metal ion. In comparing the catenation of sulfur atoms with that of carbon atoms, it may be noted that the number of molecular species having $(-S-)_x$ structures is very large, as is that of the analogous hydrocarbon compounds $(-CH_2-)_x$. The analogy between molecules containing rings of sulfur atoms and cyclic hydrocarbons is limited because only S_6 and S_8 have sufficient stability to permit proper comparison to be made. The general similarity extends to molecules of the form $Z(-S-)_xZ$ and $Z(-CH_2-)_xZ$, which are represented by compounds in which Z is H, SO_3H, and CF_3.

Covalent links between sulfur atoms have some of the character of multiple bonds—that is, more than one pair of electrons is shared, at least to some extent. Such interactions may involve overlap of p orbitals of one sulfur atom with d orbitals of another. Although not all investigators feel alike on the subject of d-orbital participation in the bonding of sulfur compounds, partial occupation of these orbitals is consistent with certain properties such as the colours of S_8 and S_2 molecules, the rigidity of chains and rings of sulfur atoms, and other features of the chemistry of sulfur compounds.

Similarities of sulfur and oxygen are exhibited in certain compounds in which these elements interchange for one another. Examples include sulfates and thiosulfates (such as Na_2SO_4 and $Na_2S_2O_3$), phosphates and thiophosphates (containing the ions PO_4^{3-}, PO_3S^{3-}, $PO_2S_2^{3-}$, POS_3^{3-}, and PS_4^{3-}), and a similar series of arsenates and thioarsenates.

Ores of heavy metals often are found as both sulfides, MS, and selenides, MSe, or even with MS_xSe_y structures. The similarity in structures as well as properties accounts for the chalcogens' being found together in nature.

The number of atoms to which an element of Group VIa can form covalent bonds increases from oxygen to sulfur. An oxygen atom usually combines with two other atoms, as in the compounds water (H_2O), oxygen fluoride (OF_2), or dimethyl ether ($H_3C-O-CH_3$); the unshared pairs of electrons and the partial negative charge on the oxygen atom in most of these compounds allows bonding to another atom, as in the hydronium ion or trimethyloxonium ion:



hydronium ion — trimethyloxonium ion

Heavier members of the group associate or coordinate with other atoms or groups of atoms in numbers commensurate with the size of both the chalcogen and the coordinating group. Thus, sulfur tetrafluoride (SF_4) and sulfur hexafluoride (SF_6) are stable compounds, although sulfur hexaiodide (SI_6) is not known because of the very large size of the iodine atom. A closely related property is that of anionic complex formation: there is little evidence for the ion SF_6^{2-}, but there are ions such as $TeCl_6^{2-}$, TeF_6^{2-}, and PoI_6^{2-}.

Isotopes

The known isotopes of each of the Group VIa elements are listed in Table 1. Consistent with a generality observed throughout the periodic system, isotopes of even mass number are more abundant than those of odd mass number. Each member of the group except polonium has several stable isotopes; oxygen-18 and sulfur-35 have been used as tracers in chemical analysis, and polonium-210 serves as a convenient source of alpha particles (nuclei of helium atoms) for nuclear reactors and nuclear batteries.

Table 1: Isotopes of the Group VIa Elements

	stable isotopes		unstable isotopes	
	mass	abundance (percentage)	mass	half-life
Oxygen	16	99.759	14	71 seconds
	17	0.037	15	2.07 minutes
	18	0.204	19	29 seconds

			217	less than 10 seconds
			218	3.05 minutes

*No stable isotopes. †Two isotopes.

II. The chalcogens and their compounds

OXYGEN

Natural occurrence and distribution. As mentioned earlier, oxygen makes up about 46 percent of the mass of the crust of the Earth. In rocks, it is combined with metals and nonmetals in the form of oxides that are acidic (such as those of sulfur, carbon, aluminum, and phosphorus) or basic (such as those of calcium, magnesium, and iron) and as saltlike compounds that may be regarded as formed from the acidic and basic oxides, as sulfates, carbonates, silicates, aluminates, and phosphates. Plentiful as they are, these solid compounds are not useful as sources of oxygen, because separation of the element from its tight combinations with the metal atoms is too expensive.

Allotropy. Oxygen has two allotropic forms, diatomic (O_2) and triatomic (O_3, ozone). The properties of the diatomic form suggest that six electrons bond the atoms and two electrons remain unpaired, accounting for the paramagnetism of oxygen. The three atoms in the ozone molecule do not lie along a straight line.

Ozone may be produced from oxygen according to the equation:

$$3O_2 \longrightarrow 2O_3.$$

oxygen ozone

Production of ozone

The process, as written, is endothermic (energy must be provided to make it proceed); conversion of ozone back into diatomic oxygen is promoted by the presence of transition metals or their oxides. Pure oxygen is partly transformed into ozone by a silent electrical discharge; the reaction is also brought about by absorption of ultraviolet light of wavelengths around 250 nanometres (nm, the nanometre, equal to 10^{-9} metre); occurrence of this process in the upper atmosphere removes radiation that would be harmful to life on the surface of the Earth. The pungent odour of ozone is noticeable in confined areas in which there is sparking of electrical equipment, as in generator rooms. Ozone is light blue; its density is 1.658 times that of air, and it has a boiling point of −112° C at atmospheric pressure.

Ozone is a powerful oxidizing agent, capable of converting sulfur dioxide to sulfur trioxide, sulfides to sulfates, iodides to iodine (providing an analytical method for its estimation), and many organic compounds to oxygenated derivatives such as aldehydes and acids. The conversion by ozone of hydrocarbons from automotive exhaust gases to these acids and aldehydes contributes to the irritating nature of smog. Commercially, ozone has been used as a chemical reagent, as a disinfectant, in sewage treatment, water purification, and bleaching textiles.

Preparative methods. Production methods chosen for oxygen depend upon the quantity of the element desired. Laboratory procedures include the following:

1. Thermal decomposition of certain salts, such as potassium chlorate or potassium nitrate:

$$2KClO_3 \longrightarrow 2KCl + 3O_2$$

potassium chlorate — potassium chloride — oxygen

$$2KNO_3 \longrightarrow 2KNO_2 + O_2.$$

potassium nitrate — potassium nitrite — oxygen

The decomposition of potassium chlorate is catalyzed by oxides of transition metals; manganese dioxide (pyrolusite, MnO_2) is frequently used. The temperature necessary to effect the evolution of oxygen is reduced from 400°C to 250° by the catalyst.

2. Thermal decomposition of oxides of heavy metals:

$$2HgO \longrightarrow 2Hg + O_2$$

mercury(II) oxide — mercury — oxygen

$$2Ag_2O \longrightarrow 4Ag + O_2.$$

silver(I) oxide — silver — oxygen

Scheele and Priestley used mercury(II) oxide in their preparations of oxygen.

3. Thermal decomposition of metal peroxides or of hydrogen peroxide:

$$2BaO + O_2 \xrightarrow{\text{heat}} 2BaO_2$$

barium oxide — oxygen (from air) — barium peroxide

$$\underset{\text{barium peroxide}}{2BaO_2} \xrightarrow{\text{heat}} \underset{\text{barium oxide}}{2BaO} + \underset{\text{oxygen}}{O_2}$$

$$\underset{\text{barium peroxide}}{BaO_2} + \underset{\text{sulfuric acid}}{H_2SO_4} \longrightarrow \underset{\text{hydrogen peroxide}}{H_2O_2} + \underset{\text{barium sulfate}}{BaSO_4}$$

$$\underset{\text{hydrogen peroxide}}{2H_2O_2} \xrightarrow[\text{catalyst}]{\text{heat or}} \underset{\text{water}}{2H_2O} + \underset{\text{oxygen}}{O_2}$$

An early commercial procedure for isolating oxygen from the atmosphere or for manufacture of hydrogen peroxide depended on the formation of barium peroxide from the oxide as shown in the equations.

4. Electrolysis of water containing small proportions of salts or acids to allow conduction of the electric current:

$$\underset{\text{water}}{2H_2O}. \xrightarrow[\text{electric current}]{H_2SO_4} \underset{\text{hydrogen}}{2H_2} + \underset{\text{oxygen}}{O_2}.$$

Oxygen from the air

Commercial production and use. When required in tonnage quantities, oxygen is prepared by the fractional distillation of liquid air. The process takes advantage of the fact that when a compressed gas is allowed to expand, it cools. Major steps in the operation include the following: (1) Air is filtered to remove particulates; (2) moisture and carbon dioxide are removed by absorption in alkali; (3) the air is compressed and the heat of compression removed by ordinary cooling procedures; (4) the compressed and cooled air is passed into coils contained in a chamber; (5) a portion of the compressed air (at about 200 atmospheres pressure) is allowed to expand in the chamber, cooling the coils; (6) the expanded gas is returned to the compressor with multiple subsequent expansion and compression steps resulting finally in liquefaction of the compressed air at a temperature of −196° C; (7) the liquid air is allowed to warm to distill first the light rare gases, then the nitrogen, leaving liquid oxygen. Multiple fractionations will produce a product pure enough (99.5 percent) for most industrial purposes.

The steel industry is the largest consumer of pure oxygen in "blowing" high carbon steel—that is, volatilizing carbon dioxide as well as other nonmetal impurities in a more rapid and more easily controlled process than if air were used. The treatment of sewage by oxygen holds promise for more efficient treatment of liquid effluents than other chemical processes. Incineration of wastes in closed systems using pure oxygen had become important by the early 1970s. The so-called LOX of rocket oxidizer fuels is liquid oxygen; the consumption of the element in this way depends upon the activity of space programs. One Saturn V engine consumes 590,000 gallons (2,200,000 litres) of liquid oxygen in launching a 6.5-million-pound rocket. Pure oxygen is used in a multitude of breathing devices, submarines, diving bells, and in hospitals.

Chemical properties and reactions. The large values of the electronegativity and the electron affinity of oxygen are typical of elements that show only nonmetallic behaviour. In all of its compounds, oxygen assumes a negative oxidation state as is expected from the two half-filled outer orbitals. When these orbitals are filled by electron transfer, the oxide ion O^{2-} is created. In peroxides (species containing the ion O_2^{2-}) it is assumed that each oxygen has a charge of −1. This property of accepting electrons by complete or partial transfer defines an oxidizing agent. When such an agent reacts with an electron-donating substance, its own oxidation state is lowered. The change (lowering), from the zero to the −2 state in the case of oxygen, is called a reduction. Oxygen may be thought of as the "original" oxidizing agent, the nomenclature used to describe oxidation and reduction being based upon this behaviour typical of oxygen.

Oxygen in combination with itself. As described in the section on allotropy, oxygen forms the diatomic species, O_2, under normal conditions and, as well, the triatomic species ozone, O_3. There is some evidence for a very unstable tetratomic species, O_4. In the molecular diatomic form there are two unpaired electrons that lie in antibonding orbitals. The paramagnetic behaviour of oxygen confirms the presence of such electrons.

The intense reactivity of ozone is sometimes explained by suggesting that one of the three oxygen atoms is in an "atomic" state; on reacting, this atom is dissociated from the O_3 molecule, leaving molecular oxygen.

The molecular species, O_2, is not especially reactive at normal (ambient) temperatures and pressures. The atomic species, O, is far more reactive. The energy of dissociation ($O_2 \rightarrow 2O$) is large at 117.2 kilocalories per mole. The reduction of the molecular species is a one-electron process in nonaqueous solutions but a two-electron process in aqueous solutions:

$$\underset{\text{oxygen}}{O_2} + \underset{\text{electron}}{e^-} \rightleftharpoons \underset{\text{superoxide ion}}{O_2^-}$$

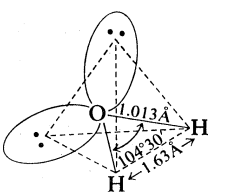
$$\underset{\text{oxygen}}{O_2} + \underset{\text{water}}{H_2O} + \underset{\text{electrons}}{2e^-} \rightleftharpoons \underset{\text{hydroperoxide ion}}{HO_2^-} + \underset{\text{hydroxide ion}}{OH^-}.$$

Reactions of oxygen forming oxides, peroxides, and superoxides may be broadly classified according to periodic table relationships. The strong metals, or those with relatively small ionization energies and large oxidation potentials (Groups Ia and IIa) form ionic oxides (M_xO_y) in which electrons are transferred from the metal to the oxygen. The most active of these metals form peroxides (*e.g.*, Na_2O_2) and superoxides (*e.g.*, KO_2). The metalloids, such as beryllium, silicon, arsenic, antimony, and tellurium, form polymeric oxide species, while the nonmetallic elements (those of Groups VIa and VIIa) form gaseous covalent molecules.

Compounds with hydrogen. The principal compounds containing hydrogen and oxygen are water, H_2O, and hydrogen peroxide, H_2O_2; the hydroxyl radical, OH, is an unstable species that can exist in certain circumstances (see also the article WATER).

Formation of water

The reaction between hydrogen and oxygen takes place extremely slowly at ordinary temperatures and in the absence of catalysts. The reaction may be accelerated by certain catalysts such as the metals of Group VIII. The molecule of water is nonlinear, the angle between the two covalent bonds being 104° 30′. The high electronegativity of oxygen induces a strong negative electrical charge on the oxygen atom with a corresponding positive charge distributed between the two hydrogen atoms. The bent molecule is described in the following diagram, showing the two lone (unshared) pairs of electrons extending in space toward the apices of a tetrahedron.



This model correctly implies that water should possess a dipole moment—*i.e.*, that the centres of positive and negative electrical charge are separated in space. This property, coupled with a large dielectric constant (the ability to decrease the attraction between oppositely charged particles), makes water an effective solvent for substances that are ionic or that themselves possess dipole moments. The ability of water to interact with other molecules in this way is important in understanding biological reactions as well as the structures of large polymer molecules in nature.

Water serves as a medium for characterizing metal and nonmetal oxides. Metal oxides react with water to liberate hydroxide ion, OH^-:

$$MO + H_2O \longrightarrow M^{2+} + 2OH^-.$$

metal oxide — water — metal ion — hydroxide ion

If the final concentration of the hydroxide ion in the solution is greater than the hydrogen ion concentration, the solution is said to be basic. The more soluble the metal oxide, the stronger its basic behaviour.

Nonmetal oxides in general react with water to provide an excess of hydrogen ions, H^+, over hydroxide ions, OH^-:

$$XO + H_2O \longrightarrow XO_2^{2-} + 2H^+.$$

nonmetal oxide — water — oxyanion — hydrogen ion

In addition to its reactions with metal oxides and nonmetal oxides, water also reacts with some metals and nonmetals themselves. The strongly metallic elements (the oxides of which form strong bases) in general react directly with water to liberate hydrogen and form the metal hydroxide as shown by the reaction with the element calcium:

$$Ca + 2H_2O \longrightarrow Ca(OH)_2 + H_2.$$

calcium — water — calcium hydroxide — hydrogen

Nonmetals dissolve, forming acids as illustrated by the nonmetal chlorine:

$$Cl_2 + H_2O \longrightarrow HCl + HOCl.$$

chlorine — water — hydrochloric acid — hypochlorous acid

Less active metals and some nonmetals, such as carbon, react with steam to form hydrogen:

$$C + H_2O \longrightarrow CO + H_2.$$

carbon — water (steam) — carbon monoxide — hydrogen

Hydrogen peroxide

The direct combination of oxygen and hydrogen does not provide a satisfactory method of preparing hydrogen peroxide. Commercial preparation is accomplished through the reaction of water with peroxy salts or peroxides. The following equations represent the electrolytic formation of peroxydisulfuric acid and its hydrolysis to hydrogen peroxide:

$$2H_2SO_4 \xrightarrow[\text{current}]{\text{electric}} H_2S_2O_8 + H_2$$

sulfuric acid — peroxydisulfuric acid — hydrogen

$$H_2S_2O_8 + H_2O \longrightarrow H_2SO_4 + H_2SO_5$$

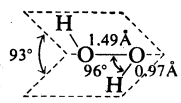
water — peroxymonosulfuric acid

$$H_2SO_5 + H_2O \longrightarrow H_2O_2 + H_2SO_4.$$

hydrogen peroxide

Concentration is accomplished by distillation of the H_2O_2 from the solution of sulfuric acid and then to the pure or nearly pure state by multistage vacuum fractionation. At high purity the compound is sensitive to decomposition by transition metal ions. A nonelectrolytic procedure involves the reaction of anthraquinone with oxygen to form a peroxide that undergoes decomposition to form hydrogen peroxide. The hydrogen peroxide formed is extracted by water from the organic solution containing the anthraquinone.

The structure of hydrogen peroxide is best represented by a twisted H—O—O—H molecule, some 93° out of planarity and with an O—O—H angle of 96°:



Chemically, the compound is both an oxidizing and a reducing agent. With strong oxidizing agents, such as permanganate ion, it is converted to oxygen:

$$5H_2O_2 + 2MnO_4^- + 6H^+ \longrightarrow 2Mn^{2+} + 5O_2 + 8H_2O.$$

hydrogen peroxide — permanganate ion — hydrogen ion — manganese(II) ion — oxygen — water

The more usual behaviour of hydrogen peroxide is as an oxidizing agent. As such it has commercial application in water purification and bleaching. In the pure form it has been used as a rocket propellant fuel. The 30 percent solution is caustic enough to burn skin severely.

Metal oxides

Reactions with metals. The nature of the oxide formed when a metal reacts with oxygen depends upon such factors as the concentration of the oxygen, the ionization energy of the metal, the temperature, and the electron configuration of the metal (*e.g.*, the possibility of polyvalency).

Group Ia metals (lithium, sodium, potassium, rubidium, cesium) all react at room temperature with oxygen to form ionic oxides having the general formula M_2O.

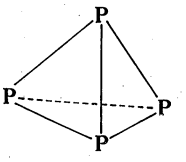
Certain strong metals also form peroxides and superoxides in which oxygen exists in the form of the ions O_2^{2-} and O_2^-. Examples of peroxides are those of sodium and barium, Na_2O_2 and BaO_2, respectively; the superoxides of potassium and cesium, KO_2 and CsO_2, are typical of that group. Acids react with these peroxy species (*i.e.*, compounds containing O—O bonds) to give hydrogen peroxide, H_2O_2, and a superoxide, HO_2, respectively.

Still another of the "poly-oxy" derivative of metals is potassium ozonide, KO_3, formed from ozone and solid potassium hydroxide.

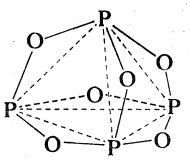
Oxides of the less active metals typified by those of Groups IIIa (aluminum, gallium, indium, thallium), IVa (germanium, tin, lead), Va (arsenic, antimony, bismuth), and VIa (tellurium, polonium) are far less ionic and often variable in their formulation or stoichiometry because of the possibility of more than one valence state. If more than one oxide of a metal is possible, the oxide of the lower oxidation state will be the more ionic, the more soluble in water, the stronger base, and less likely to be soluble in excess of a strong base, such as sodium hydroxide solution. Oxides of such metals as lead, tin, and antimony are likely to be nonstoichiometric, that is, have atomic ratios of metal to oxygen, not those of small whole numbers. Such also is the case for many transition metal oxides. Unique electrical properties may accompany the nonstoichiometric composition. When small amounts of certain metals are added to oxides of transition metals such as tungsten, molybdenum, chromium, or tantalum, unique electrical conducting properties are found, which make the substances useful in the electronics field; the tungsten bronzes, composed of tungsten trioxide, WO_3, and sodium, are examples of such materials.

Reactions with nonmetals. Because atoms of nonmetals have very little tendency to give up electrons in the formation of chemical bonds, the bonding between nonmetals is likely to be covalent as the result of sharing of electrons. Nonmetals of low atomic number, such as oxygen, form multiple bonds with other nonmetals as noted in such oxides as carbon monoxide (CO), nitric oxide (NO), chlorine monoxide (Cl_2O), sulfur dioxide (SO_2), and sulfur trioxide (SO_3). When the number of electrons in a compound is odd, the molecule will of necessity have a lone or unshared electron. Such a molecule is referred to as a radical or odd molecule.

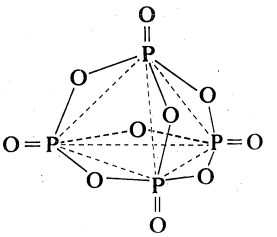
There is little tendency for oxides of light nonmetals to form solid or polymeric systems, in which many small molecules join together to form a very large one. The oxides of the heavier nonmetals and metalloids (*e.g.*, boron, silicon, arsenic, antimony, tellurium, and polonium) are solids and usually polymeric. Each of them attempts to form bonds to four surrounding atoms (fulfill a coordination number of four), often by forming networks or chains in which each metal atom is bonded to four oxygen atoms arranged in a tetrahedron. Although the element phosphorus is strongly nonmetallic, it forms oxides that are solid and in which the tetrahedral orientation of the phosphorus atoms is maintained as shown:



phosphorus, P_4



phosphorus (III) oxide, P_4O_6



phosphorus (V) oxide, P_4O_{10}

Oxides of nonmetals react with water to form acids, as previously mentioned. Certain of the oxides have very strong affinities for water and thus serve as dehydrating agents, rapidly removing water from combination with other substances. Phosphorus(V) oxide, P_4O_{10}, and sulfur(VI) oxide, SO_3, are outstanding examples.

Oxides of the noble gases. The fact that the heavy rare gases (*e.g.*, xenon, radon) will form compounds was definitely established in 1962.

Although only fluorine reacts directly with xenon, oxides form when the fluorides react with water:

$$3XeF_4 + 6H_2O \longrightarrow XeO_3 + 2Xe + \tfrac{3}{2}O_2 + 12HF$$

xenon tetrafluoride — water — xenon trioxide — xenon — oxygen — hydrogen fluoride

$$XeF_6 + 3H_2O \longrightarrow XeO_3 + 6HF.$$

xenon hexafluoride — water — xenon trioxide — hydrogen fluoride

SULFUR

Natural occurrence and distribution. Many important metal ores are compounds of sulfur, either sulfides or sulfates. Some important examples are galena (lead sulfide, PbS), blende (zinc sulfide, ZnS), pyrite (iron disulfide, FeS_2), chalcopyrite (copper iron sulfide, $CuFeS_2$), gypsum (calcium sulfate dihydrate, $CaSO_4 \cdot 2H_2O$) and barite (barium sulfate, $BaSO_4$). The sulfide ores are valued chiefly for their metal content, although a process developed in the 18th century for making sulfuric acid utilized sulfur dioxide obtained by burning pyrite.

Allotropy. In sulfur, allotropy arises from two sources: (1) the different modes of bonding atoms into a single molecule and (2) packing of polyatomic sulfur molecules into different crystalline and amorphous forms. Some 30 allotropic forms of sulfur have been reported, but some of these probably represent mixtures. Only eight of the 30 seem to be unique; five contain rings of sulfur atoms and the others contain chains.

In the rhombohedral allotrope, designated ρ-sulfur, the molecules are composed of rings of six sulfur atoms. This form is prepared by treating sodium thiosulfate with cold, concentrated hydrochloric acid, extracting the residue with toluene, and evaporating the solution to give hexagonal crystals. ρ-sulfur is unstable, eventually reverting to orthorhombic sulfur (α-sulfur).

A second general allotropic class of sulfur is that of the eight-membered ring molecules, three crystalline forms of which have been well characterized. One is the orthorhombic (often improperly called rhombic) form, α-sulfur. It is stable at temperatures below 96° C (205° F). Another of the crystalline S_8 ring allotropes is the monoclinic or β-form, in which two of the axes of the crystal are perpendicular, but the third forms an oblique angle with the first two. There are still some uncertainties concerning its structure; this modification is stable from 96° C to the melting point, 118.9° C (246° F). A second monoclinic cyclooctasulfur allotrope is the γ-form, unstable at all temperatures, quickly transforming to α-sulfur.

An orthorhombic modification, S_{12} ring molecules, and still another unstable S_{10} ring allotrope are reported. The latter reverts to polymeric sulfur and S_8. At temperatures above 96° C, the α-allotrope changes into the β-allotrope. If enough time is allowed for this transition to occur completely, further heating causes melting to occur at 118.9° C; but if the α-form is heated so rapidly that the transformation to β-form does not have time to occur, the α-form melts at 112.8° C (235° F).

Effects of heating sulfur

Just above its melting point, sulfur is a yellow, transparent, mobile liquid. Upon further heating, the viscosity of the liquid decreases gradually to a minimum at about 157° C (315° F), but then rapidly increases, reaching a maximum value at about 187° C (369° F); between this temperature and the boiling point of 444.6° C (832° F), the viscosity decreases. The colour also changes, deepening from yellow through dark red, and, finally, to black at about 250° C (280° F). The variations in both colour and viscosity are considered to result from changes in the molecular structure. A decrease in viscosity as temperature increases is typical of liquids, but the increase in the viscosity of sulfur above 157° C probably is caused by rupturing of the eight-membered rings of sulfur atoms to form reactive S_8 units that join together in long chains containing many thousands of atoms. The liquid then assumes the high viscosity characteristic of such structures. At a sufficiently high temperature, all of the cyclic molecules are broken, and the length of the chains reaches a maximum. Beyond that temperature, the chains break down into small fragments. Upon vaporization, cyclic molecules (S_8 and S_6) are formed again; at about 900° C (1,650° F), S_2 is the predominant form; finally, monatomic sulfur is formed at temperatures above 1,800° C (3,300° F).

Commercial production and use. Elemental sulfur is found in volcanic regions as a deposit formed by the emission of hydrogen sulfide, followed by aerial oxidation to the element. Underground deposits of sulfur associated with salt domes in limestone rock provide a substantial portion of the world's supply of the element. These domes are located in the Louisiana swamplands of the United States and offshore in the Gulf of Mexico.

Frasch process. Herman Frasch, a German-born U.S. chemist, developed a process, known by his name, for extracting and raising pure sulfur from these deposits, which may be anywhere from a few hundred feet to thousands of feet below the surface. Usual underground mining procedures are inapplicable since highly poisonous hydrogen sulfide gas accompanies the element in the domes.

The Frasch process takes advantage of the low melting point of sulfur, about 112° C (234° F). Water heated above this temperature (under pressure) is pumped down one of three concentric pipes, melting the sulfur. Compressed air is then forced down an inner pipe forming a froth of the molten sulfur, which is then forced up through the middle concentric pipe to the surface, where it is either pumped into bins for storage or into barges or ships for transporting to industrial areas for conversion, for the most part, to sulfuric acid. The availability of cheap, very pure sulfur from this process eliminated much of the need to mine sulfur from sulfides and volcanic sulfur-bearing rock for many years. By the mid-20th century the purification of sour (high sulfur-content) petroleum and improved methods for obtaining sulfur from metal sulfides had increased sulfur production from non-Frasch sources.

Other recovery processes. A few of the non-Frasch processes for sulfur production may be mentioned.

(1) Sulfur-bearing rock is piled into mounds. Shafts are bored vertically and fires set at the top of the shafts. The burning sulfur provides sufficient heat to melt the elemental sulfur in the rock layers below, and it flows out at the bottom of the pile. This is an old process, still used to some extent in Sicily. The product is of low purity and must be refined by distillation. The air pollution in the area of the process is so great that its operation is limited

to certain times of the year when prevailing winds will carry the fumes away from populated areas.

(2) Rock bearing sulfur is treated with superheated water in retorts, melting the sulfur, which flows out. This process is a modification of the Frasch method.

(3) Sulfates (such as gypsum or barite) may be treated with carbon at high temperatures, forming the metal sulfides, CaS or BaS (the Chance–Claus process). The metal sulfides can be treated with acid, generating hydrogen sulfide, which in turn can be burned to give elemental sulfur.

(4) Tremendous tonnages of sulfur are available from smelter operations and from power production by combustion of fossil and sour petroleum fuels, some of which contain as much as 4 percent sulfur. Thus, generation of electrical power and heat represent a major source of atmospheric pollution by sulfur dioxide. Unfortunately, recovery and purification of sulfur dioxide from stack gases are expensive operations.

Wherever such metals as lead, zinc, copper, cadmium, or nickel (among others) are processed, much of the sulfuric acid needed in the metallurgical operations may be obtained on the site by converting sulfur dioxide, produced by roasting the ores, to sulfur trioxide, SO_3, and thence to sulfuric acid.

Sulfur available in bulk from commercial production usually is more than 99 percent pure, and some grades contain 99.9 percent sulfur. For research purposes, the proportion of impurities has been reduced to as little as one part in 10,000,000 by the application of procedures such as zone melting, column chromatography, electrolysis, or fractional distillation.

Uses of sulfur. Sulfur is so widely used in industrial processes that its consumption often is regarded as a reliable indicator of industrial activity and the state of the national economy. Approximately six-sevenths of all the sulfur produced is converted into sulfuric acid, for which the largest single use is in the manufacture of fertilizers (phosphates and ammonium sulfate). Other important uses include the production of pigments, detergents, fibres, petroleum products, sheet metal, explosives, and storage batteries; hundreds of other applications are known. Sulfur not converted to sulfuric acid is used in making paper, insecticides, fungicides, dyestuffs, carbon disulfide (a solvent employed in making rayon, cellophane, and industrial chemicals), and numerous other products.

SELENIUM

Occurrence and distribution. The proportion of selenium in the Earth's crust is about 10^{-5} to 10^{-6} percent. It has been obtained mainly from the anode slimes (deposits and residual materials from the anode) in electrolytic refining of copper and nickel. Other sources are the flue dusts in copper and lead production and the gases formed in roasting pyrites. Selenium accompanies copper in the refining of that metal: about 40 percent of the selenium present in the original ore may concentrate in copper deposited in electrolytic processes. About 1.5 kilograms of selenium can be obtained from a ton of smelted copper.

Allotropy. The allotropy of selenium is not as extensive as that of sulfur, and the allotropes have not been studied as thoroughly. Only two crystalline varieties of selenium are composed of cyclic Se_8 molecules: designated α and β, both exist as red monoclinic crystals. A gray allotrope having metallic properties is formed by keeping any of the other forms at 200° –220° C (400°–430° F).

An amorphous (noncrystalline), red, powdery form of selenium results when a solution of selenious acid or one of its salts is treated with sulfur dioxide. If the solutions are very dilute, extremely fine particles of this variety yield a transparent red colloidal suspension. Clear red glass results from a similar process that occurs when molten glass containing selenites is treated with carbon. A glassy, almost black variety of selenium is formed by rapid cooling of other modifications from temperatures above 200° C. Conversion of this vitreous form to the red, crystalline allotropes takes place upon heating it above 90° C (195° F) or upon keeping it in contact with organic solvents, such as chloroform, ethanol, or benzene.

Preparation. Pure selenium is obtained from the slimes and sludges formed in producing sulfuric acid. The impure red selenium is dissolved in sulfuric acid in the presence of an oxidizing agent, such as potassium nitrate or certain manganese compounds. Both selenious acid, H_2SeO_3, and selenic acid, H_2SeO_4, are formed and can be leached from residual insoluble material. Other methods utilize oxidation by air (roasting) and heating with sodium carbonate to give soluble sodium selenite, $Na_2SeO_3 \cdot 5H_2O$, and sodium selenate, Na_2SeO_4. Chlorine may also be employed: its action upon metal selenides produces volatile compounds including selenium dichloride, $SeCl_2$; selenium tetrachloride, $SeCl_4$; diselenium dichloride, Se_2Cl_2; and selenium oxychloride, $SeOCl_2$. In one process, these selenium compounds are converted by water to selenious acid. The selenium is finally recovered by treating the selenious acid with sulfur dioxide.

Selenium is a common component of ores valued for their content of silver or copper; it becomes concentrated in the slimes deposited during electrolytic purification of the metals. Methods have been developed to separate selenium from these slimes, which also contain some silver and copper. Melting the slime forms silver selenide, Ag_2Se, and copper(I) selenide, Cu_2Se. Treatment of these selenides with hypochlorous acid, HOCl, gives soluble selenites and selenates, which can be reduced with sulfur dioxide. Final purification of selenium is accomplished by repeated distillation.

Physical–electrical properties. The most outstanding physical property of crystalline selenium is its photoconductivity: on illumination, the electrical conductivity increases more than 1,000-fold. This phenomenon results from the promotion or excitation of relatively loosely held electrons by light to higher energy states (called the conduction levels), permitting electron migration and, thus, electrical conductivity. In contrast the electrons of typical metals are already in conduction levels or bands, able to flow under the influence of an electromotive force.

Photoconductivity of selenium

The electrical resistivity of selenium varies over a tremendous range, depending upon such variables as the nature of the allotrope, impurities, the method of refining, temperature, and pressure. Most metals are insoluble in selenium, and nonmetallic impurities increase the resistivity.

Illumination of crystalline selenium for 0.001 second increases its conductivity by a factor of 10 to 15 times. Red light is more effective than light of shorter wave length.

Advantage is taken of these photoelectric and photosensitivity properties of selenium in the construction of a variety of devices that can translate variations in light intensity into electric current and thence to visual, magnetic, or mechanical effects. Alarm devices, mechanical opening and closing devices, safety systems, television, sound films, and xerography depend upon the semiconducting property and photosensitivity of selenium. Rectification of alternating electrical current (conversion into direct current) has for years been accomplished by selenium-controlled devices. Many photocell applications using selenium have been replaced by other devices using materials more sensitive, more readily available, and more easily fabricated than selenium.

TELLURIUM

Occurrence and preparation. The demand for tellurium does not match that for selenium. The two elements are found together in many ores; they may be isolated by employing the processes described in connection with selenium, obtaining solutions containing salts of both selenious and tellurous acids, H_2SeO_3 and H_2TeO_3. Upon treatment of these solutions with sulfuric acid, tellurium dioxide, TeO_2, separates because of its low solubility, while the selenious acid remains dissolved. The tellurium dioxide can be converted into elemental tellurium by treatment with sulfur dioxide; an electrolytic process is used to purify the product.

Physical and chemical properties. In tellurium, the covalent bonding necessary to provide large ring- and chain-molecules by catenation is almost nonexistent. The element crystallizes in the rhombohedral form. It is silvery white and isomorphous with gray selenium—that is, the structure and dimensions of the crystals are very similar. It is brittle but not very hard. The tellurium atoms form spiral chains in the crystal with Te–Te distances of 3.74 angstroms. (One angstrom [Å] equals 10^{-10} metre.) There are no good solvents for tellurium, although certain compounds oxidize or reduce the element to soluble substances. The photoconductivity of tellurium is not as pronounced as that of selenium, and tellurium does not have major industrial uses.

POLONIUM

The existence of polonium in pitchblende, an ore of uranium, was noted by the Curies. Polonium is extremely rare, even in pitchblende: 1,000 tons of the ore must be processed to obtain 40 milligrams of polonium. In the chemical isolation, the ore is treated with hydrochloric acid, and the resulting solution is heated with hydrogen sulfide to precipitate polonium monosulfide, PoS, along with other metal sulfides, such as that of bismuth, Bi_2S_3, which resembles polonium monosulfide closely in chemical behaviour, though it is less soluble. Because of the difference in solubility, repeated partial precipitation of the mixture of sulfides concentrates the polonium in the more soluble fraction, while the bismuth accumulates in the less soluble portions. The difference in solubility is small, however, and the process must be repeated many times to achieve a complete separation. Purification is accomplished by electrolytic deposition.

Two modifications of polonium are known, an α- and a β-form, both of which are stable at room temperature and possess metallic character. The fact that its electrical conductivity decreases as the temperature increases places polonium among the metals rather than the metalloids or nonmetals.

COMPOUNDS OF THE CHALCOGENS

The hydrogen chalcogenides. Hydrogen sulfide, H_2S; hydrogen selenide, H_2Se; and hydrogen telluride, H_2Te; are all colourless, evil-smelling, intensely poisonous gases. Their physiological action is one of interference with enzymes that facilitate biologically essential processes, such as respiration. The selenide is a cumulative poison, even in small concentrations, and causes body and respiratory odours that persist for long periods. Table 2 lists some numerical data on these compounds, including water for comparison.

Table 2: Properties of the Hydrogen Chalcogenides

	H_2O	H_2S	H_2Se	H_2Te
Solubility, moles/l 760 mm, 25° C		0.102	0.08415	~0.09

Hydrogen sulfide

Hydrogen sulfide is preparable by direct combination of the elements, although the reaction is slow. Sulfides of active metals (such as those of small atomic number in Groups Ia, IIa, and IIIa of the periodic table) react vigorously with acids to liberate hydrogen sufide. Iron(II) sulfide, FeS also reacts with nonoxidizing acids such as hydrochloric to form hydrogen sulfide. Hydrogen selenide and telluride are formed similarly.

Aqueous solutions of hydrogen chalcogenides are weak acids; the acidity increases as the atomic number of the chalcogen increases.

Reactions with metals. Metal chalcogenides, though bearing some structural resemblance to oxides, are less ionic. They are also less water-soluble and in general more intensely coloured. Sulfides of the strong metals (Groups Ia and IIa) are somewhat water-soluble, though the process of solution is likely to be slow and accompanied by hydrolysis, a competition between the sulfide ion and the hydroxide ion for the proton:

$$\underset{\text{metal sulfide}}{MS} \rightleftharpoons \underset{\text{metal ion}}{M^{2+}} + \underset{\text{sulfide ion}}{S^{2-}}$$

$$\underset{\text{sulfide ion}}{S^{2-}} + \underset{\text{water}}{H_2O} \rightleftharpoons \underset{\text{hydrosulfide ion}}{HS^-} + \underset{\text{hydroxide ion}}{HO^-}.$$

A solution of an alkali metal sulfide is, therefore, quite strongly basic. These sulfides have the capacity of dissolving powdered elemental sulfur to form polysulfides: $MS + xS \rightarrow MS_{1+x}$, in which x may be a large number, although in the well-characterized polysulfides the value is usually less than 6. When these polysulfides are treated with strong nonoxidizing acids (as mentioned), hydrogen sulfide forms as well as the hydrogen polysulfides (sulfanes), H_2S_x:

$$\underset{\substack{\text{sodium}\\\text{monosulfide}}}{Na_2S} + \underset{\text{sulfur}}{3S} \longrightarrow \underset{\substack{\text{sodium}\\\text{tetrasulfide}}}{Na_2S_4}$$

$$\underset{\substack{\text{sodium}\\\text{tetrasulfide}}}{Na_2S_4} + \underset{\substack{\text{hydrogen}\\\text{ion}}}{2H^+} \longrightarrow \underset{\text{sodium ion}}{2Na^+} + \underset{\substack{\text{hydrogen}\\\text{tetrasulfide}}}{H_2S_4}.$$

The disulfide H_2S_2 has some resemblance to hydrogen peroxide, H_2O_2, in being both an oxidizing and a reducing agent and having a bent or twisted structure. The higher sulfanes are reddish or yellow-red liquids.

Ores of such metals as iron, nickel, copper, cobalt, zinc, and lead often occur as sulfides and occasionally as mixed chalcogenides, having the general formula MS_xSe_y. Their metallurgy provides a considerable fraction of the world sulfur supply through the recovery of sulfur dioxide formed in the process of roasting.

Iron(II) sulfide occurs frequently as both the simple sulfide, FeS, and the disulfide, FeS_2 (pyrite). Just as the atoms in certain metal oxides do not occur in stoichiometric (small whole number) ratios, the sulfides have deficiencies in their structures, leading to nonstoichiometric ratios. Examples are found in the chromium–sulfur system with values ranging from 0.69 to 0.67 atom chromium to 1 of sulfur (close to Cr_2S_3) and in iron(II) sulfide with an Fe:S atomic ratio of 0.858:1.

Oxides of the chalcogens. The only reactions between elements in Group VIa are those of oxygen with the remaining members of the group.

Suboxides. The suboxides of sulfur are disulfur monoxide, S_2O; sulfur monoxide, SO; and sulfur sesquioxide, S_2O_3. The first of these is said to form from sulfur and sulfur dioxide in a glow discharge or from sulfur vapour and active oxygen. The sulfur(II) oxide (sulfur monoxide), SO, is not well characterized and may be merely a mixture of sulfur and sulfur dioxide or of disulfur monoxide, S_2O, and sulfur dioxide, SO_2. There is some evidence for the existence of the sesquioxide, S_2O_3, in mixtures of sulfur powder and anhydrous sulfur trioxide, SO_3. There appear to be no suboxides of selenium or tellurium. A black "oxide," possibly TeO, is reported but is likely to be a mixture of tellurium dioxide, TeO_2, and tellurium, Te.

Dioxides. There are examples of all the chalcogen dioxides; in fact, sulfur dioxide is produced in greater

quantity than almost any other chemical as a precursor of sulfur trioxide and thence sulfuric acid. As an air pollutant it ranks, with carbon monoxide, very high on the list of undesirable species.

Sulfur dioxide is a colourless, pungent gas, boiling at −10° C (14° F) and melting at −72.7° C (−98.9° F). The geometry of the molecule is "bent" with an O—S—O angle of 120° and a sulfur–oxygen bond distance of 1.43 Å. Even at its freezing temperature, the compound exists as discrete molecules.

Selenium dioxide, SeO_2, is a white, solid, chainlike polymeric substance, subliming (passing directly from the solid to the vapour state without melting) readily at 315° C. Both tellurium dioxide, TeO_2, and polonium dioxide, PoO_2, are solid polymeric crystalline materials of which the structures probably contain tetrahedral units. Sulfur burns with a bright blue flame, intensifying in colour as the concentration of oxygen increases, yielding sulfur dioxide. A small percentage of the trioxide is formed at the same time. To make commercial quantities of the trioxide, the dioxide must be oxidized in the presence of a catalyst at elevated temperatures. A major problem in manufacturing sulfur dioxide to be used for further chemical combination is disposal of the large amount of heat evolved in the reaction.

A major source of sulfur dioxide for production of sulfuric acid is the roasting of sulfides of such metals as iron, copper, zinc, nickel, cobalt, and lead. The oxidation of pyrite (FeS_2) is illustrative:

$$4FeS_2 + 11O_2 \longrightarrow 2Fe_2O_3 + 8SO_2.$$

pyrite; oxygen; iron(III) oxide; sulfur dioxide

The pollution of the atmosphere by gases resulting from the combustion of sour (high sulfur content) fossil fuels is a very serious environmental problem.

Sulfur dioxide is easily produced in the laboratory by the reaction of acids with sulfites or the reduction of sulfuric acid with metals. The following reactions are illustrative.

$$2NaHSO_3 + H_2SO_4 \xrightarrow{\text{heat}} Na_2SO_4 + 2H_2O + 2SO_2$$

sodium hydrogen sulfite; sulfuric acid; sodium sulfate; water; sulfur dioxide

$$2H_2SO_4 + Cu \longrightarrow SO_2 + CuSO_4 + 2H_2O$$

sulfuric acid; copper; sulfur dioxide; copper(II) sulfate; water

Uses of the dioxides

In addition to its production for conversion to sulfuric acid, sulfur dioxide is produced as a bleaching agent, as an industrial reducing agent (as for chlorine elimination), for food preservation, and fruit ripening. Sulfur dioxide can be liquefied easily; the liquid has been employed as a solvent in petroleum refining and in organic laboratory operations.

Selenium dioxide, SeO_2, an important reagent in organic chemistry, may be formed by direct union of the elements but is more conveniently prepared by treatment of the red form of the element (as an impure sludge, for instance) with nitric acid, HNO_3. The selenium is first converted to selenious acid, H_2SeO_3, which can be dehydrated to SeO_2. Under similar conditions, tellurium forms a compound formulated $2TeO_3 \cdot HNO_3$, which on heating and neutralization gives tellurium dioxide, TeO_2. Metaperiodic acid, HIO_4, behaves like nitric acid, giving $2TeO_3 \cdot HIO_4$ and then TeO_2 on heating.

Trioxides. Sulfur trioxide is formed only in very small amounts on direct combination of the elements ($S + 3/2O_2 \rightarrow SO_3$). Among the most important catalysts for the formation of SO_3 is vanadium pentoxide, V_2O_5, which is relatively insensitive to such poisons as arsenic oxides and hydrocarbons. Though now of little interest commercially, oxygen and iron(II) ions will convert sulfurous acid or sulfites to sulfuric acid (or sulfates). Oxides of nitrogen such as dinitrogen trioxide, N_2O_3, or nitrogen dioxide, NO_2, have been used for centuries as catalysts.

The so-called chamber process for making sulfuric acid dates from 1746 and uses a mixture of nitric oxide, NO, and NO_2 to accomplish the oxidation in a reaction generally represented by:

$$SO_2 + N_2O_3 + nH_2O \longrightarrow H_2SO_4 + (n-1)H_2O + 2NO.$$

sulfur dioxide; dinitrogen trioxide; water; sulfuric acid; water; nitric oxide

The nitric oxide (NO) is reconverted to N_2O_3 by air oxidation:

$$2NO + \tfrac{1}{2}O_2 \longrightarrow N_2O_3.$$

nitric oxide; oxygen; dinitrogen trioxide

As mentioned in the section describing general properties, the heavier chalcogens resist oxidation to the highest state (VI), but once this state is formed it reverts readily to the lower (IV) state or to the elemental (0) state. Thus, Te(VI) and Se(VI) compounds are strong oxidizing agents. Se(VI) oxide, SeO_3, is difficult to form in the pure state but may be formed in a glow discharge with oxygen and SeO_2. Although the acid H_2SeO_4 is preparable, dehydration to SeO_3, its anhydride, does not occur. Conversely, orthotelluric acid, H_6TeO_6, does exist and is dehydrated to TeO_3 at temperatures above 300° C.

Sulfur trioxide exists in three allotropic forms. Liquid sulfur trioxide can be stabilized by adding a small proportion of boric acid to prevent the asbestos-like or icelike modifications from forming.

Reactions with the halogens. The chalcogens react directly with all the halogens to form a wide variety of compounds. The fluorides are the most abundant and in general the most stable. Table 3 summarizes some of the data on these compounds.

Table 3: The Chalcogen Halides

compound	preparation and some properties
S_2F_2, disulfur difluoride	from sulfur and AgF, mp = −120.5° C, bp = −38.4° C
SF_4, sulfur tetrafluoride	direct combination of SCl_2 and NaF in CH_3CN; very reactive, used in synthesis of fluorides; mp = −124° C, bp = −40° C
SF_6, sulfur hexafluoride	kinetically inert to alkalies and oxygen but reacts with sodium; mp = −50.5° C and bp = 63.8° C
S_2F_{10}, disulfur decafluoride	from SF_5Cl and H_2 or direct combination; reactive and poisonous; mp = −92° C, bp = 29° C
SF_5Cl, sulfur pentafluoride chloride	from SF_4, Cl_2 and CsF; a partially ionic compound, $SF_5^-Cl^+$
SeF_4, selenium tetrafluoride	direct combination or from $SeCl_4$ and AgF; very reactive and thermally unstable
TeF_4, tellurium tetrafluoride	direct combination or from TeF_6 and Te, very reactive and thermally unstable; mp = 130° C
$TeCl_4$, tellurium tetrachloride	direct combination; mp = 224° C, bp = 380° C
TeI_4, tellurium tetraiodide	direct combination in sealed tube; decomposes 100° C
Te_2F_{10}, ditellurium decafluoride	direct combination; mp = −34° C, bp = 53° C
SeF_6 and TeF_6, selenium and tellurium hexafluorides	direct combination; stable but more reactive than SF_6; bp and mp of SeF_6, −34.5° C and −39° C respectively; bp and mp TeF_6, 35.5° C and −36° C respectively
S_2Cl_2, disulfur dichloride	direct combination in excess of S; good solvent for S_8; hydrolyzes; orange-yellow; mp = −80° C, bp = 135.6° C
S_2Br_2, disulfur dibromide	direct combination in excess S; deep red; mp = −40° C; only S–Br compound well known
SCl_2, sulfur dichloride	direct combination in excess Cl_2 or S_2Cl_2 with Cl_2; red liquid; bp = 59° C
SCl_4, sulfur tetrachloride	from SCl_2 and Cl_2; stable only as solid, probably $SCl_3^+Cl^-$; pale yellow; mp = −30° C
Se_2X_2, diselenium dihalides	all from Se and SeX_4, quite unstable
$SeCl_2$, selenium dichloride	from decomposition of $SeCl_4$
$SeBr_2$, selenium dibromide	from Se_2Br_2 decomposition
$TeCl_2$, tellurium dichloride	direct combination or reaction of Te and $TeCl_4$; very reactive, in water forms Te and H_2TeO_3; mp = 209° C, bp = 327° C
$SeBr_4$ and $TeBr_4$, selenium and tellurium tetrabromides	direct combination; thermally unstable; form ionic salts such as $K^+[SeBr_6^-]$; decompose to Br_2 and $SeBr_2$ or $TeBr_2$; relative hydrolysis rates: $SX_4 < SeX_4 < TeX_4$

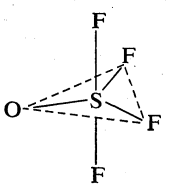
Polonium forms a volatile fluoride; a red dichloride, $PoCl_2$; a red tetrabromide, $PoBr_4$; and a black tetraiodide, PoI_4. The general chemistry of polonium resembles that of tellurium and bismuth.

Chalcogen oxyhalides. There are a large number of compounds in which a chalcogen atom is bonded to both oxygen and halogen atoms. In naming these compounds, the term thionyl is used to designate the unit $>SO$ and sulfuryl to designate the unit $>SO_2$; examples are thionyl chloride, $SOCl_2$, and sulfuryl bromide, SO_2Br_2. Table 4 summarizes some of the properties of the best known oxyhalides.

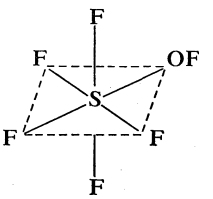
Table 4: Oxyhalides of the Chalcogens

compound	preparation and properties
Thionyl halides or chalcogen(IV) oxyhalides	
SOF_2, thionyl fluoride	from $SOCl_2$ and SbF_3; more stable than $SOCl_2$; hydrolyzes slowly; mp = −110.5° C, bp = −43.8° C
$SOCl_2$, thionyl chloride	from PCl_5 and SO_2; hydrolyzes readily to H_2SO_3; bp = 78.8° C
SOFCl, thionyl chloride fluoride	from $SOCl_2$ and SbF_3
$SOBr_2$, thionyl bromide	from $SOCl_2$ and HBr; red-yellow liquid, unstable when heated
$SeOF_2$, selenyl fluoride	from $SeOCl_2$ and AgF; very reactive, good fluorinating agent
$SeOCl_2$, selenyl chloride	distillation of $SeO_2 \cdot 2HCl$ in presence of P_4O_{10}
$SeOBr_2$, selenyl bromide	action of bromine on Se or SeO_2
Sulfuryl or chalcogen(VI) oxyhalides	
SO_2F_2, sulfuryl fluoride	combination of SO_2 and fluorine or by thermal decomposition of $Ba(SO_3F)_2$; mp = −136.7° C, bp = −55.4° C; thermally stable and chemically inert
SO_2Cl_2, sulfuryl chloride	direct union of Cl_2 and SO_2 in presence of camphor; more reactive than SO_2F_2; bp = 69.1° C
SO_2ClF, sulfuryl chloride fluoride	from SO_2Cl_2 and SbF_3
SeO_2Cl_2, selenium(VI) oxychloride	from $BaSeO_4$ and HSO_3Cl

A number of other oxyhalides are known, not in either of the thionyl or sulfuryl general classes. Two fluorides (formulated SOF_4 and SOF_6) have the structures shown below:



SOF_4



SOF_6

Both compounds result from the fluorination of thionyl fluoride (SOF_2); the presence of cesium fluoride favours formation of SOF_6. The ion SF_5O^- exists as a salt $SF_5O^-Cs^+$; by analogy SF_5OF might be one of the few compounds with a partially positive fluorine atom.

Other complex oxy-species are the highly poisonous $S_2O_5F_2$ (which melts at −48° C and boils at 51° C), $S_2O_5Cl_2$, and the mixed halide, S_2O_5ClF. The fluoride and chloride form from the reaction of sulfur trioxide and the appropriate halogen. The mixed chloride fluoride is formed from $S_2O_5Cl_2$ and antimony trifluoride, SbF_3. They all have an S—O—S structural unit. A trisulfoxy compound, $S_3O_8F_2$, is formed from the action of boron trifluoride (BF_3) and sulfur trioxide. Two peroxo halides are reported: $S_2O_6F_2$ and SO_3F.

Nitrogen compounds of the chalcogens. The molecular structures of sulfur—and to some extent those of selenium and tellurium—in the eight-membered ring systems have a number of analogues in which the sulfur atoms are replaced by one or more nitrogen atoms. These compounds are thought of as nitrides rather than sulfides (or selenides) because, on hydrolysis by acids, ammonium salts are formed rather than hydrogen sulfide.

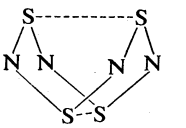
Cyclotetrasulfur tetranitride. The compound cyclotetrasulfur tetranitride, S_4N_4, is preparable using the following procedures:

1. The action of sulfur dichloride or disulfur dichloride on ammonia in solvents such as carbon disulfide, benzene, chloroform, or dimethylformamide. The chloride S_4N_3Cl, a canary-yellow solid, is also formed.
2. The direct action of dry ammonia on sulfur with removal of the by-product, hydrogen sulfide.

$$10S + 4NH_3 \longrightarrow 6H_2S + S_4N_4$$

sulfur — ammonia — hydrogen sulfide — cyclotetrasulfur tetranitride

The structure of the molecule is best described by a plane of nitrogen atoms with a pair of sulfur atoms above and another pair below this plane:

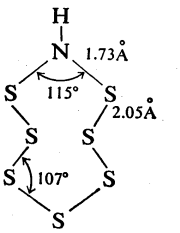


All the S—N distances are equal, with lengths between those expected for single and double bonds. The short S—S distance of 2.58 angstroms suggests that there are weak bonds between these pairs of atoms. If such is the case, the sulfur atoms may be tetravalent and the nitrogen atoms trivalent.

Cyclotetrasulfur tetranitride forms orange crystals, insoluble in water but soluble in benzene, carbon disulfide, or liquid ammonia. Its melting point is 187° C. It is a convenient starting material for other sulfur–nitrogen compounds. It is said to facilitate the starting action of diesel fuel and to serve as a repellent for birds when placed on grain before planting.

Treatment of the compound with tin and hydrochloric acid reduces the nitrogen atoms to imido groups ($>NH$), forming the compound cyclotetrasulfur tetraimide, $S_4N_4H_4$.

Heptasulfurimide. Heptasulfurimide (S_7NH) usually is formed along with S_4N_4 in reaction of disulfur dichloride (S_2Cl_2) and ammonia. If the reaction temperature is lowered to −10° C and dimethylformamide is used as solvent, the yield of S_7NH increases. When highly purified, the material is nearly pure white and has a melting point of 113.5° C, very near that of orthorhombic sulfur. The molecule contains an eight-membered ring closely resembling in its dimensions the S_8 ring with an imide group ($>NH$) replacing one sulfur atom:



cycloheptasulfurimide

The hydrogen atom is reactive and salts may be prepared. Alkalies convert S_7NH to intensely blue species thought to contain free radicals and the ion S_7N^-. Variations of these ring compounds are possible, with smaller rings being formed as well as those with more than one NH group present in either a six- or eight-membered ring.

The only analogous compounds of nitrogen with selenium or tellurium are cyclotetraselenium tetranitride, Se_4N_4, and cyclotetratellurium tetranitride, Te_4N_4. They are formed from ammonia and the elemental chalcogens or their so-called monohalides. They are unstable and easily revert to the free chalcogen.

The chalcogen oxyacids. The number of oxychalcogen acids, especially those of sulfur, is large, as is their importance to the chemical industry, especially sulfuric acid, H_2SO_4. Of the some 16 oxyacids of sulfur (including only the most common polythionic acids) reported, no

*Pure compounds. †$n \geq 2$. ‡$n \geq 3$.

more than four or five have been prepared in the pure state. The others are known only in dilute aqueous acid form or as salts or esters. Table 5 includes the most important of the oxyacids, including those of selenium and tellurium. No completely satisfactory system of categorization exists. In this table they are arbitrarily listed in order of increasing apparent oxidation number of the chalcogen followed by increasing chalcogen complexity. In the polychalcogen acids all the chalcogen atoms need not be, and in many cases certainly are not, in the same oxidation state. There are no examples of polyselenium or polytellurium acids, in conformance with the decreasing tendency of catenation in the Group VIa family with increasing atomic number. Examples of polythio acids are numerous, as expected from the strong catenation tendency of sulfur.

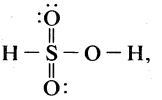
Sulfoxylic acid. This acid does not exist in the free state, nor can it be prepared from its hypothetical anhydride, SO. Its zinc salt results from the reaction of sulfuryl chloride and zinc:

$$SO_2Cl_2 + 2Zn \longrightarrow ZnSO_2 + ZnCl_2$$

sulfuryl chloride; zinc; zinc sulfoxylate; zinc chloride

Thiosulfurous acid. The prefix "thio" in the name of this compound implies that an oxygen atom in sulfurous acid, H_2SO_3, has been replaced by a sulfur atom. Only esters of this acid (compounds in which the hydrogen atoms have been replaced by atomic groups derived from organic substances) are known, having structures $(RO)_2S_2$. Hydrolysis of such esters gives a product that behaves as a very weak acid, as expected of a molecule in which a sulfur atom has a zero formal charge and hydrogen atoms are attached to the oxygen atoms: H—O—S—S—O—H.

Sulfurous acid, selenious acid, and tellurous acid. When sulfur dioxide is added to water, sulfurous acid, H_2SO_3, is but one of several species present. Much of the sulfur dioxide remains in the molecular form with water molecules attached essentially by dipole–dipole interaction. Some of the acid is in a form



in which one of the hydrogen atoms is bonded to the sulfur. In addition to $(HO)_2S{=}O$, there are also ionic species from partially and completely dissociated H_2SO_3:

$$H_2SO_3 \rightleftharpoons H^+ + HSO_3^-$$

sulfurous acid; hydrogen ion; hydrogen sulfite ion

$$HSO_3^- \rightleftharpoons H^+ + SO_3^{2-}$$

hydrogen sulfite ion; hydrogen ion; sulfite ion

Sulfurous acid is considered to be a moderately weak acid. The free acid has never been prepared. On concentration of the aqueous solution, sulfur dioxide is liberated.

Sulfites and bisulfites

Both normal and acid salts of sulfurous acid are preparable either by neutralization of the aqueous solution of the acid and the normal salts or by direct action of sulfur dioxide on metal oxides. The formation of potassium salts is representative.

$$H_2SO_3 + KOH \rightleftharpoons KHSO_3 + H_2O$$

sulfurous acid; potassium hydroxide; potassium hydrogen sulfite; water

$$KHSO_3 + KOH \rightleftharpoons K_2SO_3 + H_2O$$

potassium hydrogen sulfite; potassium hydroxide; potassium sulfite; water

$$K_2O + SO_2 \rightleftharpoons K_2SO_3$$

potassium oxide; sulfur dioxide; potassium sulfite

Acidification of sulfites, especially the acid sulfites (*e.g.*, $KHSO_3$), liberates sulfur dioxide after first forming sulfurous acid:

$$KHSO_3 + HCl \rightleftharpoons H_2SO_3 + KCl$$

potassium hydrogen sulfite; hydrochloric acid; sulfurous acid; potassium chloride

$$H_2SO_3 \rightleftharpoons SO_2 + H_2O.$$

sulfurous acid; sulfur dioxide; water

Thermal treatment of alkali metal acid sulfites forms pyrosulfites:

$$2KHSO_3 \xrightarrow{\text{heat}} K_2S_2O_5 + H_2O.$$

Metal sulfites are used in the paper and pulp industries in the formation of a fibre free of lignin. The disposal of the sulfite wastes presents a major environmental problem for the paper industry.

Selenium dioxide, SeO_2, reacts with water to form selenious acid, H_2SeO_3, a white solid. There does not appear to be a pure tellurous acid, H_2TeO_3. Selenious and

tellurous acids are both somewhat weaker than sulfurous acid.

Sulfites are easily converted to sulfates, thus sulfurous acid is a better reducing agent than oxidizing agent. Only with strong reducing agents (*e.g.*, hydrogen iodide) does it serve in the latter capacity:

$$6HI + H_2SO_3 \longrightarrow H_2S + 3I_2 + 3H_2O$$

hydrogen iodide; sulfurous acid; hydrogen sulfide; iodine; water

On the other hand, H_2SeO_3 and H_2TeO_3 in solution are more likely to function as oxidizing than reducing agents, themselves being reduced to the free chalcogen as illustrated by H_2SeO_3:

$$H_2O + H_2SeO_3 + 2SO_2 \longrightarrow 2H_2SO_4 + Se$$

water; selenious acid; sulfur dioxide; sulfuric acid; selenium

Sulfuric acid, selenic acid, and telluric acid. Sulfuric acid is the most abundantly produced chemical in the world. It is made industrially from its anhydride, sulfur trioxide, SO_3.

The process of dissolving sulfur trioxide in water to form sulfuric acid is not a trivial one. The reaction is very exothermic, with one water molecule interacting strongly with SO_3, to form a monohydrate $O_3S \cdot OH_2$, which is relatively inert, resisting solution. Introduction of gaseous SO_3 into a moist atmosphere produces a dense fog composed of this material. Dihydrates and tetrahydrates are also stable. Sulfur trioxide dissolves readily in concentrated sulfuric acid to form an acid represented as $H_2SO_4 \cdot xSO_3$. When $x = 1$ the compound is called pyrosulfuric acid, $H_2S_2O_7$. A product containing 30 percent or more SO_3 is marketed as oleum. Dilution of concentrated sulfuric acid may generate enough heat to cause vigorous boiling of the water, resulting in the expulsion of steam and spattering. Any dilution process of a strong acid is carried out by adding acid to water (rather than the reverse) with rapid stirring.

Sulfuric acid dissociates in aqueous solution in two steps:

$$H_2SO_4 \rightleftharpoons H^+ + HSO_4^- \text{ and } HSO_4^- \rightleftharpoons H^+ + SO_4^{2-}.$$

Acid and normal salts as well as the pyrosalts (see above) are easily formed:

$$H_2SO_4 + KOH \longrightarrow KHSO_4 + H_2O$$

sulfuric acid; potassium hydroxide; potassium hydrogen sulfate; water

$$KHSO_4 + KOH \longrightarrow K_2SO_4 + H_2O$$

potassium hydrogen sulfate; potassium hydroxide; potassium sulfate; water

$$2KHSO_4 \xrightarrow{\text{heat}} K_2S_2O_7 + H_2O$$

potassium hydrogen sulfate; potassium pyrosulfate; water

The acid and pyrosalts have use in preparing intractable metal oxide ores for solution metallurgy.

Production of sulfuric acid

Two processes have been responsible for the major output of commercial sulfuric acid over the past century and a half: (1) the chamber process and (2) the contact process. The two processes are discussed only briefly here.

In the mid-18th century the importance of oxidizing sulfur dioxide catalytically to sulfur trioxide by oxides of nitrogen or by nitric acid (and thence the formation of sulfuric acid) was recognized. All of the reactions in the oxidation of SO_2 to H_2SO_4 are not, even today, fully understood, but the formation of nitrosylsulfuric acid (lead chamber crystals) is of primary importance in the chamber process. The overall process may be described by the following reactions:

$$SO_2 + H_2O \rightleftharpoons H_2SO_3$$

sulfur dioxide; water; sulfurous acid

$$H_2SO_3 + NO_2 \longrightarrow H_2SNO_5$$

nitrogen dioxide; nitrosylsulfuric acid

$$H_2SNO_5 \longrightarrow H_2SO_4 + NO$$

sulfuric acid; nitric oxide

$$NO + \tfrac{1}{2}O_2 \longrightarrow NO_2$$

oxygen

The use of platinum metal catalysts to convert sulfur dioxide to sulfur trioxide was known as early as 1831. This metal is sensitive to such materials as arsenic and hydrocarbons, which poison the catalytic action. Vanadium pentoxide, V_2O_5, is less sensitive than platinum metals to poisons and is presently the most commonly used catalyst in industrial production of sulfuric acid. The essential reactions are much simpler than those noted earlier for the chamber process.

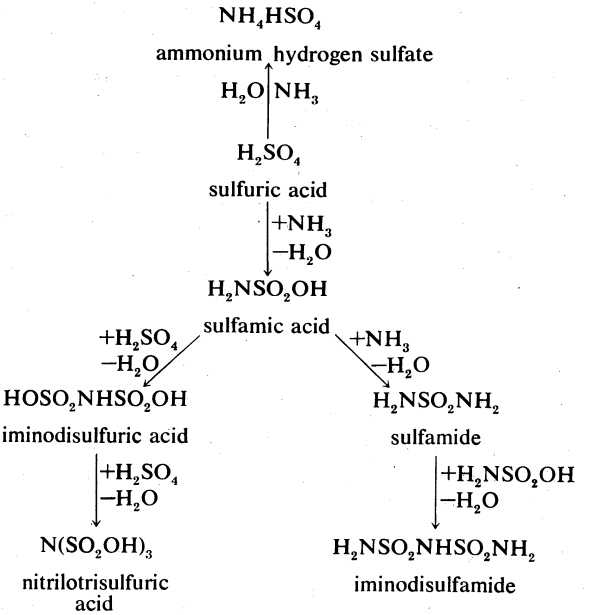
$$S + O_2 \longrightarrow SO_2 \qquad (1)$$

sulfur; oxygen; sulfur dioxide

$$SO_2 + \tfrac{1}{2}O_2 \xrightleftharpoons[\text{(vanadium pentoxide catalyst)}]{V_2O_5} SO_3 \qquad (2)$$

sulfur trioxide

Optimum conditions of temperature, contact time of the gases on the catalyst surface, ratio of the reacting and product gases (SO_2, SO_3, O_2 and N_2 from air), pressure as well as purity (freedom from poisons) must be experimentally determined. Too high a temperature (above about 425° C) is unfavourable for the formation of SO_3, since reaction (2) above is reversed. Too low a temperature (below about 400° C) does not allow reactions (1) and (2) to proceed rapidly enough even in the presence of the catalyst. Multiple chambers for catalytic oxidation may be used for a more efficient conversion of SO_2 to SO_3. The sulfur trioxide is absorbed in concentrated sulfuric acid. In addition to its strongly acidic nature, sulfuric acid is an oxidizing agent, especially when concen-



Some compounds derived from ammonia and sulfuric acid.

trated and warmed. Iodide and bromide ions are oxidized to the elemental halogens while reducing sulfuric acid to hydrogen sulfide, H_2S. This property prevents H_2SO_4 from being used in generating hydriodic or hydrobromic acids, HI and HBr, from their salts, NaI and NaBr. Certain metals (such as copper and silver) will reduce sulfuric acid to sulfur dioxide. The pure acid, 100 percent H_2SO_4, serves as a solvent for some organic reactions.

A number of compounds derived from both ammonia and sulfuric acid are known (see scheme, above).

Sulfamic acid

One of the most important of these compounds in sulfamic acid, NH_2SO_2OH, a versatile chemical produced in very large quantities. It is more conveniently and economically produced by the interaction of sulfur trioxide (or oleum) with urea, NH_2CONH_2. It is a white, solid, nonhygroscopic, strong acid useful as a primary standard for bases. It is also a reagent for the analysis of the nitrite ion, NO_2^- because it reacts rapidly and quantitatively with it to give nitrogen gas:

$$\underset{\text{sulfamic acid}}{H_2NSO_2OH} + \underset{\text{nitrite ion}}{NO_2^-} \longrightarrow \underset{\text{nitrogen}}{N_2} + \underset{\text{hydrogen sulfate ion}}{HSO_4^-} + \underset{\text{water}}{H_2O}.$$

Salts of sulfamic acid are used as herbicides and as flame retardants. The dairy industry uses large amounts of the acid in removing "milkstone" formed in pasteurization and evaporation of milk.

Selenic acid, H_2SeO_4, is formed as an oxidation product of selenium dioxide with halogens such as chlorine and bromine. Heavy metal selenites such as silver selenite, Ag_2SeO_3, are good sources of selenic acid because upon oxidation by a halogen the resulting halide ion is precipitated leaving a relatively pure form of the acid:

$$\underset{\text{silver selenite}}{Ag_2SeO_3} + \underset{\text{bromine}}{Br_2} + \underset{\text{water}}{H_2O} \longrightarrow \underset{\text{selenic acid}}{H_2SeO_4} + \underset{\text{silver bromide}}{2AgBr}$$

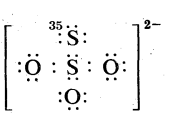
The anhydrous acid can be isolated but is less stable than sulfuric acid at elevated temperatures. Oxygen is evolved from selenic acid at about 210° C. The acid strength of H_2SeO_4 is comparable to that of sulfuric acid.

There are marked differences between tellurium and its two predecessors in Group VIa in the formation of oxyacids. The large size of the atom, even in a high oxidation state (VI), and its resistance to forming multiple bonds favour a highly hydroxylated acid of the form $(OH)_6Te$. When strong oxidizing agents, such as hydrogen peroxide or chromic acid, CrO_3, in nitric acid react with tellurium dioxide this hexahydroxytelluric(VI) acid is formed. Although it is a very weak acid, in a strongly basic environment two protons can be removed, forming the ions $[OTe(OH)_5]^-$ and $[O_2Te(OH)_4]^{2-}$. Telluric acid is an oxidizing agent, but its reactions usually are slow.

Thiosulfuric acid. This acid is known as its salts and in aqueous solution but not in the pure state. Sulfur dissolved in alkali sulfites forms the thiosulfate ion:

$$S_8 + 8Na_2SO_3 \longrightarrow 8Na_2S_2O_3.$$

The structure of the thiosulfate ion suggests a replacement of an oxygen atom in the sulfate ion by a sulfur atom. When radioactive sulfur (^{35}S) is used in the above preparation, it can be proved that the added sulfur has no oxygen attached to it:



since acidification of the thiosulfuric acid regenerates the radioactive sulfur:

$$\underset{\substack{\text{thiosulfate ion made from sulfur-35 and sulfite}}}{S_2O_3^{2-}} + \underset{\text{hydrogen ion}}{2H^+} \longrightarrow \underset{\text{sulfur-35}}{^{35}S} + \underset{\text{sulfurous acid}}{H_2SO_3}.$$

A mechanism has been postulated for the formation of thiosulfurous acid by attack of sulfurous acid (or sulfites) on the S_8 ring:

$$\underset{\text{sulfur}}{S_8} + \underset{\text{sulfurous acid}}{H_2SO_3} \longrightarrow \underset{\text{a sulfanesulfonic acid}}{HOSO_2S{-}S_6{-}SH}$$

$$HOSO_2S{-}S_6{-}SH + H_2SO_3 \longrightarrow HOSO_2S{-}S_5{-}SH + H_2S_2O_3$$

$$HOSO_2S{-}S_5{-}SH + H_2SO_3 \longrightarrow HOSO_2S{-}S_4{-}SH + H_2S_2O_3$$

(etc.)

Eventually, eight molecules of thiosulfurous acid form.

Alkali metal thiosulfates are important industrially as solubilizing agents for silver halides in the photographic industry. The portion of silver bromide, AgBr, unaffected by light on exposure of the emulsion in the camera is dissolved by the thiosulfate ion:

$$AgBr + S_2O_3^{2-} \longrightarrow AgS_2O_3^- + Br^-.$$

This is called the fixing process and the sodium salt, $Na_2S_2O_3$, is called hypo from an improper but often used name, sodium "hyposulfate."

Dithionous, hyposulfurous, or hydrosulfurous acid. All these names are or have been used to describe the acid that results from the reduction of sulfur dioxide by such agents as sodium amalgam (a solution of sodium in mercury) or zinc metal. The free acid is unknown, but the salts are stable enough to be used as reducing agents. A unique feature of the $S_2O_4^{2-}$ ion is the long S—S bond of 2.39 Å, which suggests a ready dissociation of the ion to an active radical:

$$\underset{\text{dithionite ion}}{S_2O_4^{2-}} \rightleftharpoons \underset{\text{a radical anion}}{2 \cdot SO_2^-}.$$

Dithionic acid. Pure dithionic acid, $H_2S_2O_6$, is too unstable to be isolated. When sulfur dioxide reacts with MnO_2, manganese dioxide, the manganous salt of dithionic acid, MnS_2O_6, is formed. Treatment with barium carbonate or barium hydroxide forms the barium salt, which in turn can be converted to sodium dithionate, $Na_2S_2O_6$. Solutions of the acid $H_2S_2O_6$ are strong proton providers. The geometry shows a tetrahedral orientation of oxygen atoms about each sulfur atom and a normal S—S distance of about 2.0 Å. There are no analogous compounds of tellurium or selenium.

The polythionic acids. The polythionic acids $H_2S_nO_6$ ($n = 3$ to 6) are unique in that they contain S—S—S units in which there is at least one sulfur atom between two tetrahedra of $-SO_3H$. Polythionic acids may be thought of as sulfanedisulfonic acids. No acid salts of the polythionates are known (*e.g.*, KHS_4O_6 does not exist), and the acids are unstable.

A general method of preparation of these acids is the action of sulfites, sulfurous acid, or thiosulfates on sulfur chlorides or iodine, as illustrated in the following equations:

$$\underset{\substack{\text{potassium hydrogen sulfite}}}{2KHSO_3} + \underset{\substack{\text{sulfur dichloride}}}{SCl_2} \longrightarrow \underset{\text{hydrochloric acid}}{2HCl} + \underset{\text{potassium trithionate}}{K_2S_3O_6}$$

$$\underset{\text{sulfurous acid}}{2H_2SO_3} + \underset{\text{disulfur dichloride}}{S_2Cl_2} \longrightarrow \underset{\text{hydrochloric acid}}{2HCl} + \underset{\text{tetrathionic acid}}{H_2S_4O_6}$$

$$\underset{\text{thiosulfate ion}}{S_2O_3^{2-}} + \underset{\text{iodine}}{I_2} \longrightarrow \underset{\text{iodide ion}}{2I^-} + \underset{\text{tetrathionate ion}}{S_4O_6^{2-}}$$

$$\underset{\text{thiosulfate ion}}{2S_2O_3^{2-}} + \underset{\text{sulfur dichloride}}{SCl_2} \longrightarrow \underset{\text{chloride ion}}{2Cl^-} + \underset{\text{pentathionate ion}}{S_5O_6^{2-}}$$

$$2S_2O_3^{2-} + S_2Cl_2 \longrightarrow 2Cl^- + S_6O_6^{2-}$$

thiosulfate ion; disulfur dichloride; chloride ion; hexathionate ion

A solution of sulfur dioxide saturated with hydrogen sulfide (Wackenroder's solution) contains a mixture of polythionic acids, especially $H_2S_4O_6$ and $H_2S_6O_6$.

Sulfur–nitrogen oxides. A few S—N—O compounds are known, with chain or zigzag structures. Ammonia and thionyl chloride, $SOCl_2$, react to give one of these compounds, $S_3N_2O_2$, a bright yellow substance also formed from ammonium chloride and either thionyl chloride or disulfur dichloride, S_2Cl_2. Sulfur trioxide reacts with S_4N_4 to give this same oxide and also another with the formula $S_3N_2O_5$. $S_3N_2O_2$ is stable in the absence of moisture and soluble in benzene. Two of the sulfur atoms in this compound appear to be in the S(VI) state and one in the S(IV) state.

Analysis of polythionates may be accomplished by the action of cyanide ion, CN^-, on the —S—S—S— chain, giving the thiocyanate ion, SCN^-, in a quantity of three moles less than the total S-atom number in the polythionate compound. Thus, in the analysis of $S_5O_6^{2-}$ two moles of SCN^-, one mole of $S_2O_3^{2-}$, and one mole of SO_4^{2-} are formed. The thiocyanate ion and the thiosulfate ion are easily determined by standard procedures.

Total sulfur in any sulfur-containing species is usually determined by oxidation to sulfate ion, precipitation as barium sulfate, and weighing. Peroxides and perchloric acid are used in the oxidation as well as for the destruction of any organic material present.

The thiosulfate ion is readily estimated by titration with a standard solution of iodine.

Pacific Coast Ranges

The Pacific Coast mountain ranges run parallel to the coastline of the states of California, Washington, and Oregon, and they extend into Canada and Mexico. In their fastness stand the giant redwood forests and the magnificent coastal scenery of California and Oregon. Also lying within the ranges are several sprawling urban regions, the largest of which are those centred on San Francisco and on the megalopolis of Los Angeles. The effort to preserve the beauty of the coastline, together with the ever-present threat of earthquakes and forest fires and the growth of the region's cities, has brought the ranges into national focus in the 1970s, because of the continuing debate over the nature and quality of the United States environment.

History of scientific study. The first generation of students to make thorough investigations into the complex geology of the Coast Ranges came from local universities in the late 19th century. Their studies were continued by an active second generation working for state and federal geological surveys and for petroleum-exploration companies. The great San Francisco earthquake of 1906 precipitated a thorough investigation of the earthquake problem, especially of epicentres (focuses of seismic activity) in the Californian Coast Ranges; once it was recognized that earthquakes start from movements along faults, or fractures, the fault system of the ranges was mapped with care, and an intensive seismological program developed in major Pacific coast universities. With the great influx of population into the region from the mid-20th century onward, investigations produced internationally significant work on problems ranging from highway construction to various manifestations of environmental pollution (see below). The ranges are also of considerable interest to geologists exploring new concepts relating ocean-floor spreading to the evolution of mountains at the continental margins.

Seismographic investigation

Major relief divisions. The Coast Ranges are separated from the lofty Sierra Nevada and Cascade mountains, to the east, by broad depressions known in Oregon and Washington as the Willamette Valley–Puget Sound region and in California as the Great Valley. On the west, there is virtually no coastal plain, for deep water sets in within 25 miles of the coast.

The ranges themselves have six major divisions. The unit stretching from San Francisco north to the Klamath Mountains of the Oregon–California boundary is known as the northern Coast Ranges; the coastal ranges of Oregon and Washington have similar geological features and form a separate division north of the Klamath Mountains. The Klamath Mountains, however, although fronting on the Pacific and topographically part of the marginal Coast Ranges, are made up of older rock structures resembling those of the Sierra Nevada (*q.v.*). Hence, they are not usually included as a subdivision. The coast ranges of British Columbia are also of the Sierra Nevada type and decidedly different from those of Oregon or Washington. South of San Francisco, the central Coast Ranges extend to the vicinity of Santa Maria, at latitude 35° N; beyond, they are succeeded by a sector that includes the Santa Barbara, Ventura, and Los Angeles areas. The sector's name—the Transverse Ranges—derives from a marked east–west topographic and geologic trend. The ocean bed south of the Transverse Ranges consists of basins and platforms belonging to the continental margin, rather than to the Pacific deep, and it can be counted as an extension of the Coast Ranges. Finally, the southern tip of the great formation is formed by the Peninsular Ranges extending down the fingerlike protrusion of Baja California.

The Coast Ranges for the most part exhibit a subdued and soft relief of below about 3,300 feet, but some peaks and ridges stand above 6,600 feet or even 11,500 feet (3,506 metres) at San Gorgonio in the eastern Transverse Ranges.

Geological history. *The basic rock structures.* Although the Coast Ranges were molded into their present shape in the geologically recent Cenozoic Era (beginning about 65,000,000 years ago), an important element in their composition dates from as far back as the Jurassic period (190,000,000 years ago). The rocks concerned in this underlying, or basement, complex have been called the Franciscan Group. These sedimentary and volcanic rocks were subsequently changed by great pressures, sheared, intricately folded, and invaded by granite, then molten. Many of the rock layers making up the rest of the Coast Ranges are composed of sediment washed out by erosion from the then-existing margin of the North American continent to the east. These deposits accumulated in local structural basins and along the continental shelf and its slope.

The Franciscan rock basement

The emergence of the Coast Ranges. The subsidence of the sediment-filled basins and related processes of structural uplift and subsequent erosion provide the key to the complex evolution of the Coast Ranges. The trend of the basins and the associated uplifts generally paralleled the coast, but in the Transverse Range sector the basins took an east–west trend, subsided rapidly and deeply, and received very thick layers of sediment that eventually formed the rich petroleum source beds of southern California. The uplifts, on the other hand, often brought older Franciscan and Upper Cretaceous rocks to a new surface exposure.

This process of mountain building took place in two clear-cut phases. In the first, the Early Cenozoic rock layers were folded and thrust up as a result of earth movements in mid-Miocene time (about 20,000,000 years ago), and this process of deformation spread all the way from the Peninsular Ranges in the south to the Coast Ranges of Oregon and Washington in the north. The upfolded layers of the central and Transverse ranges were subsequently eroded almost to a plain and were then covered by additional layers of younger sedimentary rocks washed down from the east. This latter development set the stage for a second mountain-building movement, which began in Quaternary time, possibly 1,000,000 years ago, and has continued to the present, for the central and Transverse ranges are still being built up, deformed, and eroded.

Farther north, however, the Coast Ranges of Oregon and Washington participated only in the first of the two mountain-building movements, when their Early Cenozoic rock layers were most affected by folding. Sediments and lava flows accumulated to great thicknesses in a large arc-shaped basin lying between the Klamath Mountains on the south and the British Columbian Coast Ranges on the north. The first mountain-building movement caused a notable structural uplift in the north in the form of a dome, the site of the present Olympic Mountains of Washington. Since this region escaped a second mountain-building phase, the forces of erosion were able to cut away much of the uplifted rock, revealing the great upward folds, or anticlines, and their downfolded equivalents, the synclines. The summits in the Olympic Mountains exceed 6,500 feet, and the relief has been scoured and molded by the action of extensive Ice Age glaciers, portions of which remain to enhance the scenic attractions of the area.

The San Andreas Fault system. A major feature of the Coast Range system is the San Andreas Fault, a line of structural weakness extending from the Gulf of California northwestward to the Transverse Range and then westward to the central Coast Ranges. It has been traced northward to the San Francisco peninsula and beyond, to Cape Mendocino, where it appears to join the structurally weak submarine Mendocino Ridge. It sends out a number of associated faults, notably in southern California and the San Francisco area. The great fault marks the splitting of a huge sliver of the North American continental margin. The land west of the fault line is being forced, or, in geological terms, translated, to the northwest. Over the past 15,000,000 years, it has travelled some 200 miles. The translation has occurred in short, violent movements best illustrated by the 1906 San Francisco earthquake, when the land west of the fault moved about 21 feet horizontally northwestward along the fault line. An intensive program of seismic investigation is underway, aimed at predicting the almost inevitable future dislocations along the fault, which runs through areas of dense population.

Movement of the San Andreas Fault

The continental shelf. The underwater fringe of the Coast Ranges is also of exceptional geological interest. The bold, sea-pounded coast has few natural harbours, but San Francisco Bay provides an exception: through the narrow 360-foot-deep trench spanned by the soaring Golden Gate Bridge, it opens into one of the most magnificent harbours in the world.

Beyond the coastline, from Santa Barbara to Vancouver Island, the underwater shelf juts out above the Pacific abyss. It has a width of 15–30 miles and a maximum depth of about 650 feet, at which point it begins to slope down to its base. The shelf and slope are fairly regular in submarine relief, except where indented by such fissures as the Monterey Canyon. Where the sliver of continental crust is being pushed into the Pacific Basin, an underwater headland or projection of the shelf and slope is prominent, such as Cape Mendocino, latitude 40° 30′ N.

South of the Transverse Ranges the underwater topography changes from a narrow shelf to a wider basin and platform region about 150 miles wide. From measurements made of crustal thickness, this is believed to have once been a portion of the North American continent that subsided in separate blocks between a series of faults.

The Coast Ranges and sea-floor-spreading theory. In the 1960s and 1970s the new and popular theory of sea-floor spreading provided a framework into which the origin of the San Andreas Fault and the entire evolution of the Coast Ranges could be quite plausibly fitted.

The ocean bed is now held to be cracking into great trenches. These fissures are constantly healed by eruptions of new lava from the earth's core that form mid-oceanic ridges. The East Pacific Ridge is of great significance in the evolution of the Coast Ranges: it has been charted northeastward along the Pacific floor as far as the Gulf of California, where it is deflected westward a number of times by a series of faults. The San Andreas Fault further deflects the ridge as far as the ocean floor off Oregon. This slow process of sea-floor spreading is responsible for the northwesterly movements associated with the San Andreas Fault. The rate of movement is about one inch per year.

Climate and vegetation. The northern sections of the Coast Ranges experience a climate known as humid mesothermal; *i.e.*, with cool summers and mild winters. South of San Francisco the climate becomes mesothermal subtropical, with dryer summers. Water is plentiful to the north but scarce—as needs increase—further south.

The rain forests of the northern Coast Ranges are among the finest in the world. Coniferous stands make up all but 10 percent of the wooded area, and there are no fewer than 50 species of trees, including the famed giant redwoods, which are found mostly on the westward facing slopes.

Economic development. Nature has provided the Coast Ranges, particularly the California section, with diversified climate, scenery, and economic potential. Resources include gold, petroleum, vineyards, and a supply of fruits, nuts, and vegetables sufficient for half the American nation. These resources help to explain the westward population movement that has made California the most populous state in the Union. Settlement there is concentrated in the Coast Ranges and the adjacent Great Valley.

Apart from the social problems of the great urban complexes centred on Los Angeles and San Francisco, this expansion of settlement has had a deleterious effect on the natural environment of the Coast Ranges. Landslides, caused by the removal of vegetation, and barren and eroding scars have become an eyesore in many places, while atmospheric pollution, brought about chiefly by the automobile, adds a host of problems. Even the offshore areas have been affected: by the early 1970s the region adjoining Santa Barbara was the scene of much oil-leasing activity, and, as drilling got underway in 1969, a serious oil leak occurred at one offshore site. All these factors helped to make the Coast Ranges area a focus of great ecological and conservationist discussion in the 1970s.

Pollution problems

(A.J.E.)

Pacific Islands

The Pacific Islands is an expression commonly accepted as including all of those islands in the Pacific Ocean that are collectively referred to as Melanesia, Micronesia, and Polynesia. This usage rules out the Australian island continent, the Asia-related Indonesian, Philippine, and Japanese archipelagoes, and the Ryukyuan, Bonin-Volcano, and Kuril island arcs that project seaward from Japan. Neither does the term encompass the Aleutian chain connecting Kamchatka and Alaska nor such isolated islands as Cocos, Galápagos, and Juan Fernandez off the coasts of Central and South America.

Although the Pacific Ocean makes up nearly one-third of the Earth's surface, the Pacific Islands discussed in this article add up to a little less than 500,000 square miles (1,300,000 square kilometres) of territory. New Guinea, the largest island in the world after Greenland, represents 60 percent of this total, and New Zealand accounts for 20 percent. The remaining one-fifth of the land area in the Pacific is divided among more than 10,000 islands. The Pacific Islands exist mainly in the area bounded by latitudes 12° north and 25° south and longitudes 130° east and 130° west. Exceptions to this are the Mariana Islands, which extend northward toward the Bonin-Volcano chain; the Hawaiian Islands, which straddle the Tropic of Cancer; New Zealand, which lies in the southern temperate zone; and Easter Island, which stands in isolation almost halfway to South America. (For a detailed discussion of the Pacific Ocean see the article PACIFIC OCEAN; for a detailed consideration of individual islands, see the articles BIKINI; EASTER ISLAND; FIJI; FRENCH POLYNESIA; HAWAII; NEW ZEALAND; and SAMOA; as well as the articles AUSTRALIAN EXTERNAL TERRITORIES; and UNITED STATES OUTLYING TERRITORIES. For historical aspects, see the articles NEW ZEALAND, HISTORY OF; and OCEANIA, HISTORY OF.)

Melanesia, Micronesia, and Polynesia

For convenient reference, the Pacific Islands are customarily divided into three ethnogeographic groupings. The great arc of islands located north and east of Australia and south of the Equator is called Melanesia (from the Greek words *melas*, "black," and *nēsos*, "island") after the predominantly dark-skinned peoples of New Guinea, the Bismarcks, the Solomons, the New Hebrides, New Caledonia, and Fiji. North of the Equator and east of the Philippines is another island arc that ranges from Palau and the Marianas in the west through the Caroline and Marshall clusters all the way to the Gilbert Islands. This is Micronesia, named in recognition of the smaller size of these islands and atolls. In the central Pacific, and largely enclosed within a huge triangle formed by Hawaii in the north, New Zealand to the south, and Easter Island far to the east, are the "many" (poly) islands of Polynesia. Other components of this widely scattered collection are Samoa, Tonga, and the Society, Tuamotu, Marquesas, and Cook Islands. In this, the last section of the Pacific Ocean to be occupied by man, the islanders share a cultural tradition that relates them closely to many Fijians. Fiji, indeed, is actually a transitional territory between Melanesia and Polynesia.

From the 16th century onward the Western world has shown an interest in the Pacific Islands that has been expressed in the activities of explorers, scientists, poets, missionaries, commercial entrepreneurs, and imperialistic statesmen. The endless variety of the Pacific's environments, both physical and biotic, has been, and still is, a laboratory for experimenting in social and cultural adaptation. Though insularity has often dominated this process, the effect of this has been offset by the opportunities for human contact and exchange in many directions across the ocean's expanse. In the 20th century the islands and their inhabitants continue to attract international interest, although for new reasons, such as their strategic significance in the balancing of power between East and West, and the problems created by nature's limitation of land and resources in the face of expanding populations and accelerating living standards.

THE ISLAND ECOSYSTEM

To know what it is like to live on a Pacific island, the intermixture of physical and biological characteristics of the particular island must be considered. Each of the myriad ecological systems in the Pacific is a unique complex of living organisms and their nonliving environment. Each is a functional system of interacting components that tends toward an equilibrium that is never quite achieved. The limited size of most Pacific islands makes almost any change, whether by the hand of man or by some natural agency, capable of repercussions elsewhere within the ecosystem. The landform, climate, soils, vegetation, and animal life—all are elements to which people who live on an island must relate themselves and their behaviour, for they, too, occupy a niche in the total ecological scheme.

Island types. The islands may be classified as either continental or oceanic. The former are associated with the ancient continental platforms of Asia and Australia, now partially submerged. Oceanic islands, located eastward in the deeper Pacific basin, are differentiated as high volcanic or low coral islands. A coral island may be single, or two or more coral islets may form an atoll if connected by a reef ringing a lagoon. The "high–low" distinction is misleading as the two types occur in many combinations, and some coral islands have been elevated considerably by changes in the ocean level.

Continental and oceanic islands

Continental islands. Faulted and folded in mountainous arcs that parallel deep ocean trenches, the islands of the broad western Pacific margin are formed mainly of metamorphosed sediments and of intrusive volcanic materials with a high content of silica and alumina. These islands are separated from the deeper Pacific basin—along the eastern borders of Kamchatka, Japan, the Marianas, New Guinea, the Solomons, Fiji, and New Zealand—by a geological demarcation known as the andesite or sial line. (These names refer to distinguishing features: the volcanic rock andesite is distinguished from basalt, the principal lava rock within the basin; the sial rock layer—composed principally of silica and alumina—underlies all continents.) This line marks the eastern limits of the earth's greatest volcanic activity and earthquake disturbance. Continental islands are generally larger, and more numerous, and have richer mineral-bearing soils that support almost every kind of vegetation. New Guinea, 1,300 miles long and with a maximum width of nearly 500 miles, is a good example. Its snow-capped mountains rise to 16,400 feet, its interior is dissected by high plateaus and extensive river systems, and its slopes and coastal margins are covered with dense forests and vast swamps.

High volcanic islands. Extensive mountain ranges in the Pacific basin proper rise abruptly from the ocean deep, their cores of dense black basalt built up from lava flows from the fractured sea floor. Where summits stand above sea level, they represent most of Polynesia and Micronesia. Small to intermediate in land area, nowhere do they match the extent of continental islands. Hawaii can boast a snow-topped peak 13,796 feet high, though most oceanic islands have peaks of somewhat less than 5,000 feet. Topography is extremely rugged, with sharp peaks and ridges, deep canyons, cliffs, and waterfalls abounding. Human communities occupy the more congenial lower slopes, floodplains, and wide strands. The islands, rich in iron and magnesium oxides, are densely forested but lack the metallic mineral wealth of continental islands.

Coral islands. Most Pacific islands are coral formations, although all have volcanic or other cores. In the shallow waters of the tropics, both continental and oceanic islands attract coral growth in the form of *fringing reefs*, partially submerged platforms of consolidated limestone, with coral organisms at the ocean edge feeding

on materials carried in by sea waves and currents. Coral-building polyps and algae secrete calcium carbonate (lime) from seawater, forming skeletal frameworks that adhere to land surfaces, or the rock remains of coralline ancestors. The gradual submergence of some islands, and a continuing coral growth outward, produce a *barrier reef* formation farther from shore and separated from it by a narrow lagoon.

Coral atolls

A coral *atoll* results when further subsidence reduces an island to a submarine condition. The usually irregular reef continues to flourish in the warm shallows: it encircles a clear-surfaced lagoon of moderate depth, and in time supports a number of islets, known as motus, built up from reef debris to 20 or 30 feet above sea level. Atolls of all shapes and sizes may be formed. Kwajalein Atoll in the Marshalls is the world's largest, being about 90 miles long and 20 miles wide, with a lagoon area of 839 square miles, and 38 islets totalling just over 6 square miles of land. Openings, or passes, which commonly occur on the leeward side of atoll reefs, permit access to the lagoon from the sea. The only source of fresh water is rain.

Successive elevations of an island above sea level create a variety of "raised" coral formations. Raised fringing reefs on Guam, for example, have become coastal limestone cliffs that rise to nearly 600 feet. Nauru and Ocean Island, as raised atolls, stand at an elevation of about 200 feet, and possess deeper soil and a more adequate water supply than other types of atoll, as well as refined guano deposits from which phosphate is mined commercially.

Climate. To describe the climate as tropical and oceanic is to stress the influence of the lower latitudes and the tremendous expanse of the sea. Humidity and temperature tend to be high and are generally uniform throughout the year. Regional differentiation in climate is linked principally to rainfall patterns. Here, factors of altitude and longitude, as well as latitude, come into play as they relate to the various systems of air circulation that prevail in the Pacific. The climate of New Zealand, which lies well outside the tropics, constitutes an exception.

Across the eastern and central Pacific, air currents flow south and north from the midlatitudes toward the Equator and, trending westward, form the northeast and southeast trade winds. These brisk winds bring light to moderate showers interspersed with brief rainy spells or clear skies. The windward sides of high islands are cloudy and wet, in contrast to the relatively dry leeward coasts. Short seasonal shifts in wind direction often presage stormy weather. Where the trade winds meet near the Equator lie the doldrums, a region of little or no wind, considerable cloud, and high humidity. The trade winds merge or give way to the monsoon winds in the far western Pacific, where the alternate cooling and heating of continental Asia produces a seasonal reversal of winds. From about November to March, the northwest monsoon from Asia brings rain to the northerly slopes of the western Carolines, New Guinea, and the Solomons. In summer the southeast monsoon reverses the process.

Typhoons, or hurricanes, occur frequently in western Micronesia from July to November, and are active south of the Equator from Australia to the Society Islands four to six months later. These winds of gale force are accompanied by torrential rains and tidal waves, and cause extensive damage to crops and buildings, especially on low-lying coral islands.

Soils. Pacific island soils develop through the action of temperature, rainfall, and organic matter on the original rock materials. This process is further influenced by factors of time and land relief. Coral island soils are the least mature, and are deficient in organic materials, low in fertility, and too porous to ensure proper soil moisture. The mineral-bearing continental islands are geologically more complex and, being also favoured by a longer period of weathering, possess richer and more varied soils than the volcanic islands. The most productive soils on high islands occur in the lower slopes and valleys, in the form of alluvial floodplains and deltas, and of recent volcanic ash deposits. Tropical temperatures and rainfall have produced a series of soils (laterites) from which nutrients have been leached. These soils, of only moderate fertility, decline rapidly after two or three years of crop use; fertilizers must then be added, or else the soil must be abandoned, and fresh land cleared and planted.

Vegetation. Most island vegetations reveal Asian ancestries stemming from Indonesia and New Guinea. Generic variety declines eastward across the Pacific, providing evidence that transient seeds and fruits carried by ocean currents, birds, winds, and early man, encountered mounting obstacles to acceptance. New Zealand was host to plant dispersal movements from South America via Antarctica. Plant adaptation to local differences in moisture, soil, salinity, and temperature has resulted in countless new, endemic species. Plant introductions from other world sources during the past century have, however, markedly altered island vegetations.

Seacoast vegetation

The seacoast, or strand, vegetation is the most widespread of Pacific zonal types. Depending on the availability of moisture, this relatively unfavourable setting supports shrubs, herbs, and woody vines, as well as such trees as coconut, casuarina (which takes its name from the resemblance of its twigs to the feathers of the cassowary bird), pandanus (screw pine), and hibiscus. Mangrove thickets proliferate in brackish swamps. Breadfruit, banana, papaya, and tubers resembling the taro (a plant with an edible starchy rootstock) are cultivated either in moist locations or in pits enriched with plant debris. On high islands, primary forests still survive in valley bottoms, as well as on lowland plains and on intermediate slopes. The prevalent rain forest constitutes a community of huge trees that overlook smaller trees and a ground growth of shade-tolerant ferns, vines, and shrubs. Species differentiate enormously. Yam, cassava, taro, and sweet potato are important staples in high island economies. Secondary forests and savannas (grasslands) have replaced virgin forests destroyed by fire, or by shifting cultivation practices. Grasslands are also associated with areas of poor soil and little rain, as on leeward slopes.

Animal life. Bats, rats, and, in New Guinea, marsupials such as tree kangaroos, flying opossums, and bandicoots were the only mammals to precede man into the Pacific, after which pigs, dogs, poultry, goats, deer, and cattle were introduced. Most islands have some snakes and lizards, but crocodiles are restricted to the west. Sea birds, such as terns, frigates, albatrosses, petrels, and boobies, supplemented by migratory ducks, plovers, and curlews, are found almost everywhere. While oceanic islands support only a few land birds, New Guinea has exotic species such as the cockatoo, hornbill, bird of paradise, and cassowary, while New Zealand is the home of the kiwi.

The abundant marine life is infinitely valuable for human subsistence. Reefs and lagoons provide lobsters, shrimps, clams, crabs, oysters, snails, eels, octopus, turtles, and innumerable fish species. In deeper waters are tuna, bonito, swordfish, and many other sport fishes. Sharks are prominent predators, and whales have been commercially fished. Insects are unquestionably the most numerous of island fauna. The more pestiferous include centipedes, cockroaches, lice, houseflies, and the malaria-carrying *Anopheles* mosquito, which exists in Melanesia from coastal New Guinea to the New Hebrides. Scorpions are also found.

HUMAN OCCUPANCY

Man's adaptation to island environments

Occupying a niche in the food chain, man in the Pacific has had to adapt to island environments just as other species have done. The technologies and organizational systems introduced into the Pacific by migrants had earlier been established in environments that varied from receptive to hostile. The earliest arrivals, as food-gathering peoples, probably provoked little disruption of the ecological balance (*i.e.*, the balance between organisms and their environment). Their aboriginal successors, practiced in horticulture and skilled in transporting themselves across the sea, were able in limited degree to fashion and control physical habitats after their own custom. Later, Western man with his advanced technology and civilization often threatened the balance of the inherently

unstable ecosystems (complexes of ecological community and environment forming a functioning whole in nature).

Aboriginal groupings. Natives of the Pacific tend to identify themselves by their home island or mother tongue, saying, for example, that they are from Nauru, or that they speak Fijian. Occasionally, however, they may invoke another, and larger, identity, claiming to be Polynesian, Micronesian, or Melanesian. As a geographic designation this practice has value, but as a mark of racial, linguistic, or cultural affiliation it is misleading. While Melanesians appear to be more Negroid and Micronesians more Mongoloid, a great deal of racial mixture throughout the Pacific has taken place since the first immigrants arrived in the southwest. The linguistic pattern is also complex. Some valid generalizations about traditional practices and institutions in the three areas may nevertheless be made, although it must be remembered that overlap between the areas is common, and that there are exceptions to every statement.

Polynesia. Polynesians are strikingly homogeneous in speech, custom, and physical appearance, although western Polynesians are moderately distinct from the rest. Accomplished as gardeners and fishermen, they have directed their principal energies to nonmaterial pursuits. Epic mythology, copious genealogies, sophisticated social etiquettes, hereditary aristocracies, and elaborated religious formalism, characterized society in pre-European Polynesia, receiving varying degrees of emphasis. A kinship system that accepted the worth of both maternal and paternal family ties supported group solidarity in community enterprises. Secular leaders, as lineal descendants of deified ancestors, served gods and humans alike. The social-religious-political hierarchies encouraged and rewarded aesthetic creativity in wood and stone sculpture, featherwork, tapa (barkcloth), and tattooing, according privileges to the artist, commensurate with those accorded the warrior, navigator, herbalist, and seer.

Micronesia. Eight or ten cultural-linguistic areas in Micronesia attest to its greater heterogeneity. The Palau Islands, the Yap Islands, and the Marianas suggest affinities with Melanesia and Indonesia. The habitual placing of island farmsteads and hamlets near the shore reflects the prevailing interest in fishing, canoeing, and overseas trade. Except in the Gilbert Islands, matrilineal clans and lineages characterized by marriage outside each group influence property inheritance, succession to traditional titles, and intracommunity competition. Local political autonomy was formerly overshadowed by loose confederations and tribute arrangements in western Micronesia, as well as in the area of Ponape Island, Kusaie Island, and the Marshall Islands, where class stratification still exists today. Indigenous religions lack formality, and are largely of personal or family concern. Art is mainly decorative, and is manifest in matwork, shell ornament, loom weaving, tattooing, and functionally crafted wood and stone artifacts.

Melanesia. This is a region of unending contrast. "Beach" natives, who have acquired advantages from coastal trading and cultural exchanges, may be compared with more isolated and traditional "bush" (unwesternized) populations inland. Polynesian influence touches Fiji and outlying islands to the northwest. The massive extent of New Guinea, with its thousands of indigenous groups, requires separate consideration. Melanesians are gardeners, with a penchant for pig raising, who promote social mobility by accumulating wealth through trading and competitive feasting; *i.e.*, local notables acquire more influence by giving more feasts than their rivals. Unilateral descent groups (*i.e.*, those that trace descent through either the maternal or paternal line only), usually patrilineal, are the essence of community organization. Leadership depends on the local "big man," whose personally acquired power gives him authority in his own village and influence in nearby villages. Headhunting and raiding of neighbouring tribes continue in remote parts of New Guinea. The animistic religion, a mixture of magic, sorcery, totemism, and ancestor worship, is dominated by men's clubhouses, secret societies, and elaborate initiations. Art forms associated with these activities include dance masks, sculptured figures, body scarification, and carved mortuary standards.

The indigenous heritage. The earliest humans entered Oceania after 20,000 BC, drifting into New Guinea from the Indies as small groups of migratory hunter-gatherers. Representing a genetic intermixture of Negrito and ancient Caucasian, they spoke languages ancestral to those nowadays termed "Papuan." Between about 3000 and 2000 BC, other migrants from Indonesia had begun to move into Melanesia in sailing canoes. These were traders, skilled in root and tree crop cultivation. Of Mongoloid provenance, and speaking Austronesian (Malayo-Polynesian) languages, they introduced their genes and customs to the simpler habitants of New Guinea and in time occupied all of Melanesia. Similar peoples entered western Micronesia from the west between about 2500 and 2000 BC. Later, in a continuing pattern of accidental voyaging, some natives of the New Hebrides region sailed northward to the Carolines, while others sailed eastward to Tonga and Samoa. This movement out of eastern Melanesia, between about 1500 and 1000 BC, was linked with the diversification of the Malayo-Polynesian languages, the largest group in the Austronesian phylum (a category of language stocks considered likely to have a common origin). All of Polynesia was settled by AD 1000, following migrations from the Marquesas and Society islands. Some Polynesians travelled westward and established outlying settlements in Melanesia and Micronesia. Polynesians were also in contact with South America, but American Indian influence was only nominal.

Early migratory movements

The alien heritage. More than five centuries passed before Balboa viewed the Pacific Ocean in 1513, and Magellan sailed across it in 1521. Other Europeans who pioneered in rediscovering the islands included the 16th-century Spanish explorer Álvaro de Mendaña de Neira, the 17th-century Dutch explorer Abel Janszoon Tasman, Louis Antoine de Bougainville, the French navigator, and the English explorer Captain James Cook, whose 1778 landfall in Hawaii ended the era of exploration. During the next seven decades, American and British whalers often wintered in the tropical isles, while shipwrecked sailors and fortune hunters settled in the region, as also did traders, who imported Western manufactures in exchange for sandalwood, coconut oil, and pearls. In 1797 the London Missionary Society became active in southern Polynesia. Other Protestant groups also entered the region, the Boston Mission working in Hawaii and eastern Micronesia, and the Anglican Mission in Melanesia. Though Spanish priests had built a mission in the Marianas in 1668, Catholicism was established on other Pacific islands only after French missionaries based on Tahiti became active in 1836.

Between 1850 and World War I, political and economic imperial interests were furthered when the governments of Germany, the United Kingdom, France, Spain, and the United States claimed island groups as colonies and protectorates. Corporate businesses, such as those of Godeffroy of Hamburg and Burns Philp of Sydney, extended their jurisdictions over shipping, trade, and plantation development. Large-scale production of sugar and copra encouraged the illegal recruitment of local labourers, although more satisfactory contract systems later brought shiploads of Indian workers to Fiji; Javanese and Tonkinese workers to New Caledonia; and Chinese, Japanese, and Filipino labourers to Hawaii. Many of these workers later settled, establishing their own commercial enterprises. Australia and New Zealand, areas of British colonialization, gained dominion status after 1900, subsequently strengthening their own spheres of influence by occupying offshore territories. Hawaii, annexed by the United States in 1898, like the two dominions began to play a role as a self-conscious agent of westernization in Oceania. Spain's withdrawal from the Pacific followed the Spanish-American War of 1898, and the onset of World War I ended Germany's regime as a colonial power.

Battle operations in World War I barely affected the Pacific. Japan, Australia, and New Zealand were mandated responsibility for the former German colonies by the

League of Nations. In violation of the mandate, Japan in the 1930s annexed Micronesian territories. During World War II administering authorities in the South Pacific were taken unaware when Japanese forces crossed the Equator in 1941. In the next three years Western superiority faltered but then was recovered as the tide of war turned.

From trusteeship to independence

Following Japan's surrender, territorial administrations accorded greater recognition to the islanders' welfare in the spirit of trusteeship pledged to the United Nations. By 1970 some island groups had won political independence. Meanwhile, tourists have been visiting the South Sea islands in increasing numbers.

Interaction and reaction. During the past four and a half centuries of culture contact there has been a constant flux between change and disorganization on the one hand, and stability and reintegration on the other. Relatively balanced ecosystems of prehistory were disrupted when islanders, reacting to the novelty and authority of Western civilization, discarded traditional crafts, directed their skills to serve new economies, and, under pressure from missions and alien governments, at least nominally adopted practices and beliefs that were strange to them. From this initial confusion there emerged reasonably stabilized island societies that, while preserving the native ethos, reflected a fusion of elements from both cultures. European, American, and Asian residents continued to conserve their own identities in cultural enclaves. Meanwhile, increasing influence was exercised by a population of mixed blood, formed of culturally marginal individuals.

The direct impact of World War II on island communities stimulated many islanders to seek a greater participation in Western society. Their efforts were expressed in two ways. The first was in a proliferation of mystical cults. Occurring principally in Melanesia, these cults blended traditional and Western practices but provided solutions only in fantasy. The second, the way of economic and political nationalism, was supported mainly by native and part-native residents in urbanized port towns and island capitals who had benefitted by travel and higher education. Opposed to assimilation, the latter held pride in their island origins and negotiated for more equal treatment within the framework of Western civilization.

Population dynamics. Almost 7,500,000 people are estimated to inhabit the Pacific islands. Continental islands are thinly settled with five to 17 persons per square mile. Many smaller islands, in Micronesia and Polynesia, have high population densities. On Nauru, for example, the density is 863 per square mile. New Zealand excluded, the tropical Pacific population is 81 percent native, 13 percent Asian (mainly Indian, Japanese, Filipino, and Chinese), and 6 percent Caucasian of whom three-fourths live in Hawaii. Most of New Zealand's 2,900,000 people are white, only 8 percent claiming to be half or more of Maori descent. Other anomalies are the Indian preponderance over native Fijians in Fiji, and Hawaii's mixture of Japanese, Caucasian, Filipino, and Chinese.

Killing epidemics of Western-introduced disease contributed to population decline until around 1900 when they were checked by modern medicine, health education, and improved diet, which allowed a high native fertility to re-assert itself. Many island populations almost trebled in the next five decades, with crude birth rates for 1956 being estimated at 36 to 45 per 1,000 population, as opposed to recorded death rates of 7 to 16. Family planning and economic pressures have not helped to retard the fast rate of population growth. The resettlement of individuals and of whole communities from coral atolls, as in the Gilberts and Carolines, has only momentarily relieved the crowded condition.

Emigration to port towns

Voluntary emigrants to such port towns as Papeete in Tahiti, Agaña in Guam, Suva in the Fiji Islands, and Port Moresby in Papua have responded in part to overcrowding at home but more often seek employment, entertainment, or further education. As such towns are built around trade, mission, hospital, school, and administration facilities, they service hinterland populations and link them to the outside world by sea, air, and tourism networks. Almost universally these heterogeneous, multiracial communities suffer from poor housing, underemployment, and juvenile delinquency; gambling and drinking are widespread. Native and part-native residents, growing in numbers and more vociferous in their demands, still do not fulfill their aspirations to participate more fully in these artificial societies.

POLITICAL AND ECONOMIC SYSTEMS

During the 20th century's third quarter, overpopulation in a region of fragmented land areas, widely scattered populations, poor communications, inadequate resources, and rising costs of living posed a fundamental dilemma. Political responsibility for the situation rested largely with the five metropolitan nations administering the possessions, protectorates, and trusteeships that perpetuated a no longer popular colonial heritage. Amelioration of social and economic conditions seemed to await changes in the political environment, while the question of the five nations' willingness to share their territorial commitments through international cooperation and with the emerging native elites remained undecided.

Administrative groupings. Two United Nations trust territories have achieved independence—Western Samoa in 1962, and Nauru in 1968. The first continued to depend on New Zealand in foreign affairs, while Nauru ended its ties with Australia, New Zealand, and the United Kingdom. When British Fiji and Tonga became independent in 1970, both elected to remain within the Commonwealth of Nations.

New Zealand, a Commonwealth member with a Maori Polynesian population surviving on its territory, maintains close relations with Polynesian territories to the northeast—the Cook Islands, Niue, and the Tokelaus. Cook Islanders in 1965 became self-governing in a free association with New Zealand, from which they required only support in external affairs, defense, and finances. The people of Niue and the Tokelaus are administered more directly from the metropolitan nation. Like the Cook Islanders, they have migrated in great numbers to New Zealand. Australia, a Commonwealth country with exclusively Melanesian interests, created the Territory of Papua and New Guinea in 1949. It combines its administration of Papua, which was acquired from the British in 1906, with its United Nations trusteeship administration of northeast New Guinea, which it was granted in 1946. British territories include the Solomon Islands protectorate, the Gilbert and Ellice Islands colony, and the British portion of the New Hebrides condominium. These territories are scattered throughout the South Pacific, and are all administered from Honiara, on the island of Guadalcanal in the Solomons, by the British High Commission for the Western Pacific.

The United States dominates the island region north of the Equator. Hawaii, formerly a territory, became the 50th U.S. state in 1959. Other territories, under civilian control after 1950–1951, are American (eastern) Samoa; the Trust Territory of the Pacific Islands, a strategic area trusteeship under the United Nations, formerly a Japanese mandate, in Micronesia; and Guam, a U.S. outlying territory whose people are U.S. citizens. France is represented in the Pacific by three overseas territories—French Polynesia, New Caledonia, and Wallis and Futuna Islands—as well as in the New Hebrides condominium shared with the United Kingdom. The New Caledonian governor, as High Commissioner, is responsible for French interests in the condominium. Each French overseas territory has a degree of local autonomy and is represented in the French parliament by an elected deputy and senator.

Two territories are politically and geographically peripheral to contemporary Oceania. Western New Guinea, a former Dutch colony, became a province of the Republic of Indonesia in 1963, and was renamed West Irian (Irian Barat). Easter Island was acquired by Chile in 1888, and is leased to a Chilean stock-raising company.

The international coordination of health, social, economic, and educational development is organized by the South Pacific Commission, established in 1947 to advise island governments. A research council advises the commission in its work. Commissioners meet annually at

Administrative Groupings of Pacific Islands

territory	area (sq mi)	population (1970 estimate)	capital	political status and remarks
American (eastern) Samoa	76	29,000	Pago Pago	U.S. unincorporated territory
British Solomon Islands	11,500	163,000	Honiara	U.K. protectorate
Cook Islands	93	24,000	Avarua, Rarotonga	N.Z. self-governing territory
Easter Island	45	1,200	—	Chilean dependency
Fiji	7,055	531,000	Suva	independent parliamentary state (1970), former U.K. colony; includes Rotuma Island
French Polynesia	1,544	109,000	Papeete	French overseas territory; includes Clipperton Island, Marquesas Islands, Society Islands, Tuamotu and Gambier Islands, and Tubuai (or Austral) Islands
Gilbert and Ellice Islands	376	56,000	Bairiki, Tarawa	U.K. colony; includes Central and Southern Line Islands (also claimed by U.S.), Northern Line Islands (except Jarvis, Palmyra, and Kingman Reef), Ocean Island, and Phoenix Islands
Guam	206	100,000	Agana	U.S. organized unincorporated territory
Hawaii	6,424	769,000	Honolulu	U.S. state
Nauru	9	7,000	Domaneab	independent republic (1968)
New Caledonia	7,082	109,000	Nouméa	French overseas territory; includes Bélep, Chesterfield, Huon, Loyalty, and Walpole Islands, and Isle of Pines
New Guinea, Northeastern	93,000	1,752,000	Port Moresby	U.N. trust territory, administered by Australia as part of Territory of Papua and New Guinea; includes Bismarck Archipelago, northeastern New Guinea, and Bougainville, Buka, and adjacent islands
New Guinea, Western (Irian Barat)	160,000	907,000	Djajapura	province of Indonesia
New Hebrides	5,700	86,000	Vila	Anglo-French condominium
New Zealand	103,736	2,853,000	Wellington	parliamentary state
Niue Island	100	5,000	Alofi	N.Z. territory
Papua	90,540	669,000	Port Moresby	Australian territory, administered as part of Territory of Papua and New Guinea; includes D'Entrecasteaux, Louisiade, Trobriand, and Woodlark islands, and the southeastern part of the island of New Guinea
Pitcairn Island	2	82	Adamstown (defacto)	U.K. colony
Tokelau Islands	4	2,000	—	N.Z. territory
Tonga	259	86,000	Nukualofa	independent state (1970)
Trust Territory of the Pacific Islands (American Micronesia)	706	107,000	Saipan	U.N. trust territory, administered by U.S.; includes Caroline, Marshall, and Mariana islands (except Guam)
Wallis and Futuna	60	9,000	Mata Utu	French overseas territory
Western Samoa	1,140	143,000	Apia	independent state (1962)

International coordination of development

headquarters in Nouméa, following the South Pacific Conference attended by island delegates, and which has been held in Nouméa in New Caledonia, Suva in Fiji, Lae in New Guinea, Rabaul on the Australian-administered island of New Britain, and Pago Pago in American Samoa. Proposals to add a political dimension to the commission's work have not been accepted. Commission membership includes Australia, France, New Zealand, Nauru, the United Kingdom, the United States, and Western Samoa.

Communication networks. Most islanders in the 1970s, by resorting to some combination of track, road, canoe, interisland freighter, local air service, or international airline, can travel within a week or two to such distant cities as Sydney, Auckland, San Francisco, Vancouver, Tokyo, or Singapore. Inhabitants of remote islands may need two months more to make such a journey, owing to less frequent or irregular travel schedules. More than a score of shipping and airline companies ensure the movement of inbound and outbound cargo and passengers through such island centres as Honolulu, Agana, Port Moresby, Honiara, Vila (in the New Hebrides), Nouméa, Suva, Pago Pago, and Papeete, thus bringing hinterland populations into closer touch with countries on the Pacific rim. This readier access, in both directions, has developed partly because World War II created new traffic patterns and facilities, partly because islanders have demanded better transport, trade, and mail services, and partly because of the growth of the tourist industry.

Communication by radio, radiotelephone, cable, and news services has also improved. Two-way radio transmission can inform territorial service centres of emergencies and needs in even the most distant locations. Local broadcasts and news releases in English, French, pidgin English (in western Melanesia), and indigenous tongues, inform the island public about world events.

Economic development. Pacific islanders, as producers of agricultural, mineral, and marine commodities, face problems of market demand, labour supply, development planning, and transportation that relegate them to an insignificant role in world trade. Their small and scattered populations do not constitute an attractive consumer market. Present aims are to achieve more self-sufficiency, and to export selectively so as to cover the cost of importing essential machinery, petroleum products, motor vehicles, textiles, and other manufactures.

Economic handicaps

Coconut products, principally copra from which the oil is extracted overseas, form the principal export in nearly every territory. Production, which depends as much on native family enterprise as it does, for example, on the plantation system that predominates in Melanesia, is likely to continue as the mainstay of most island economies. Sugar, exported mainly from Hawaii and Fiji, requires careful management, costly machinery, and specialized labour for its production. Perishable fruits, such as pineapples and bananas, demand markets close at hand unless locally processed. Experiments in growing coffee, cacao, and other cash crops have been undertaken with a view to stimulating economic diversification, so as to avoid the hazards of a one-crop economy. Grassland areas support

the production of beef cattle and sheep as subsidiary exports. Timber is processed commercially on the larger Melanesian islands.

New Caledonia is rich in nickel, chrome, and other metallic ores, New Guinea and Fiji have profited from gold discoveries, and oil dominates West Irian's export production. Reserves of natural phosphates on Nauru and Ocean Island are expected to last for 30 years before they become depleted. Marine resources, although almost unlimited, require skilled labour and capital facilities for commercial exploitation. Deep-sea fishing for tuna and bonito is practiced, mostly by Japanese crews. Canneries in Hawaii, American Samoa, Fiji, and the Carolines are in operation. Local island cooperatives have also successfully marketed fresh fish.

About half of the Pacific Islands' exports are sent to Australia and New Zealand, Japan, Canada, and the United States; most of the rest go to northwestern Europe. Traders based in Australia control most of the import commerce south of the Equator. Government grants and training programs, many promoted by the South Pacific Commission, have developed native experience in labour, marketing, and management. To some extent this has discouraged foreign, profit-seeking enterprise, although outside capital is needed. In the 1970s tourism opened up new income opportunities for islanders. Tahiti, American Samoa, and Fiji followed Hawaii's earlier lead in developing the tourist industry. Other territories are also attracting visitors by improving transport and accommodation, while at the same time endeavouring to safeguard local custom against excessive commercialization.

(L.E.M.)

Pacific Islands, Trust Territory of the

The Trust Territory of the Pacific Islands, a United Nations strategic-area trusteeship administered by the United States, consists of more than 2,000 islands, 96 of them populated, scattered over about 3,000,000 square miles (7,770,000 square kilometres) of the tropical western Pacific Ocean. The area lies north of the Equator between latitudes 1° and 22° N and longitudes 130° and 172° E. The total land area of the islands is about 700 square miles. The population of the group numbered 107,054 in 1971.

The territory generally covers the ethnic area known as Micronesia ("tiny islands") and is composed of three major island groups—the Marianas, Carolines, and Marshalls. The Micronesian Gilbert Islands to the southeast and Guam in the Marianas are politically excluded, while the islands of Kapingamarangi and Nukuoro, which are Polynesian instead of Micronesian in language and culture, are included. The political definition of the area was inherited from the Japanese, who governed it before World War II. (For articles on the region, see PACIFIC ISLANDS; PACIFIC OCEAN; and BIKINI. For historical aspects, see OCEANIA, HISTORY OF.)

Three types of islands

The natural environment. Three basic types of islands exist in the trust territory—low coral islands, or atolls; high islands of volcanic origin; and islands that represent a combination of coral limestone and volcanic uplift. The Marshalls and the eastern Carolines are generally of the coral variety, with elevations seldom exceeding 30 feet above sea level. In the western Carolines and Marianas are volcanic "high" islands, built upon a range of submarine mountains. The largest, Babelthuap in the Palau group, has 143 square miles of land area. Ponape, the second largest, has approximately 129, while Saipan, site of the administrative capital, has 47. The highest elevation, 3,166 feet, occurs on Agrihan, in the northern Marianas.

Coral platforms built on submerged peaks form an atoll's base. On these platforms, shell, broken coral, and floating debris build up narrow islands with the open ocean on one side and the more or less sheltered waters of a lagoon on the inside. Around this lagoon, which may cover more than a hundred square miles, as in Ulithi, many small islands dot the reef, with few or no deep passages connecting open sea and lagoon.

Climate, soil, and vegetation. The climate of the entire area is generally warm and humid. Daily or seasonal changes in temperature are slight, ranging usually from about 75° to 85° F (24° to 29° C). Rainfall on larger volcanic islands may reach 300 to 400 inches a year, but on atolls in the northern Marshalls annual rainfall may be as low as 20 to 30 inches, with prolonged periods of drought.

The soil of coral islands is sandy and lacking in important minerals, so that only limited and specialized vegetation can grow. Wind and sea erosion are a constant threat to atoll soils, and major typhoons have been known to completely wash over even sizable islands of this type, extinguishing both plant and human life. Smaller islets have sometimes been simply washed away.

Along the coral-sand beaches, coconut palms are the most visible and important form of vegetation, although pandanus (the screw pine) is also found. On less favoured islands these trees, together with a few ground creepers, may be the only land vegetation. On larger islands breadfruit and even bananas grow, as well as taro, a starchy root with a buried stem; the marsh taro (*Cyrtosperma chamissonis*), an edible member of the arum family, is grown in swampy areas or man-made compost pits.

High islands frequently have steep, heavily forested areas in the interior, as in Ponape or Babelthuap. Heavy rainfall leaches minerals from the volcanic soil and causes severe erosion when the vegetative cover is destroyed. Excessive timber removal and slash-and-burn farming have left badly eroded areas. Soils are generally shallow and low in fertility.

In the northern Marianas, where rainfall is less abundant, there occur level or gently sloping areas suitable for grazing. Areas resembling savanna (grassy parklands) also appear, intermingled with dense forests where local differences in soil or rainfall occur. Comparatively little use is made of the interiors of the steep volcanic islands, and settlement and economic activity cling close to the shore. Along the ocean fringe, steep, rocky cliffs, sandy beaches, or swampy areas overgrown with mangrove thickets may occur. Here, with ample rainfall, coconut, breadfruit, and pandanus thrive, together with a wider variety of native and introduced food crops than is found on the atolls.

Animal life. The original animal life on the islands was usually extremely limited, probably being confined to one or two species of bats. Pigs, small dogs, and a species of rat were introduced before the European era. Begin-

ning with the Spaniards in the 17th century, other varieties of rats, some fowl, and the water buffalo were introduced, followed by horses, cattle, goats, and cats. Deer were introduced into the Marianas by the Germans in the early 20th century and were later carried to Palau and Ponape. The larger animals were able to thrive only on the larger, high islands.

Marine and shore birds are more common throughout the trust territory than land birds. There are local variations in prevailing species. The albatross, frigate bird, shearwater, tern, and other birds of passage are widespread. Parrots, cockatoos, owls, white-eyes, finches, and other land birds are limited chiefly to the larger volcanic islands in the west. Two species of crocodile and two species of poisonous sea snakes are found in the Palau group. Other harmless snakes and lizards are fairly widespread. More than 7,000 species of insects are known.

Life in the lagoons

In contrast to the relatively few kinds of land animals, life on the shores and in the lagoons is varied and rich. Many types of reef fish, shellfish, and edible algae are found in the shallow waters of lagoons or fringing reefs. Deeper waters between islands or atoll groups offer tuna, barracuda, sharks, and other large species.

The landscape under human settlement. Variations in life-style make it impossible to speak of a typical Micronesian village or pattern of life. The simple, scattered, generally rectangular shelters of remote atolls still house Marshallese and eastern and central Carolinians as they have for centuries. Yet each area has distinctive patterns of design. Roofs and walls of traditional structures are thatched or plaited with pandanus, coconut-palm, or nipa-palm leaves, with supporting timbers of whatever wood is available. Yet, even in remote villages, modern additions in the form of boards, corrugated sheet metal, or concrete blocks have begun to come into use. Houses are built on the ground or occasionally are elevated on stone platforms, pillars, or wooden posts. The elevated houses have bamboo or board floors.

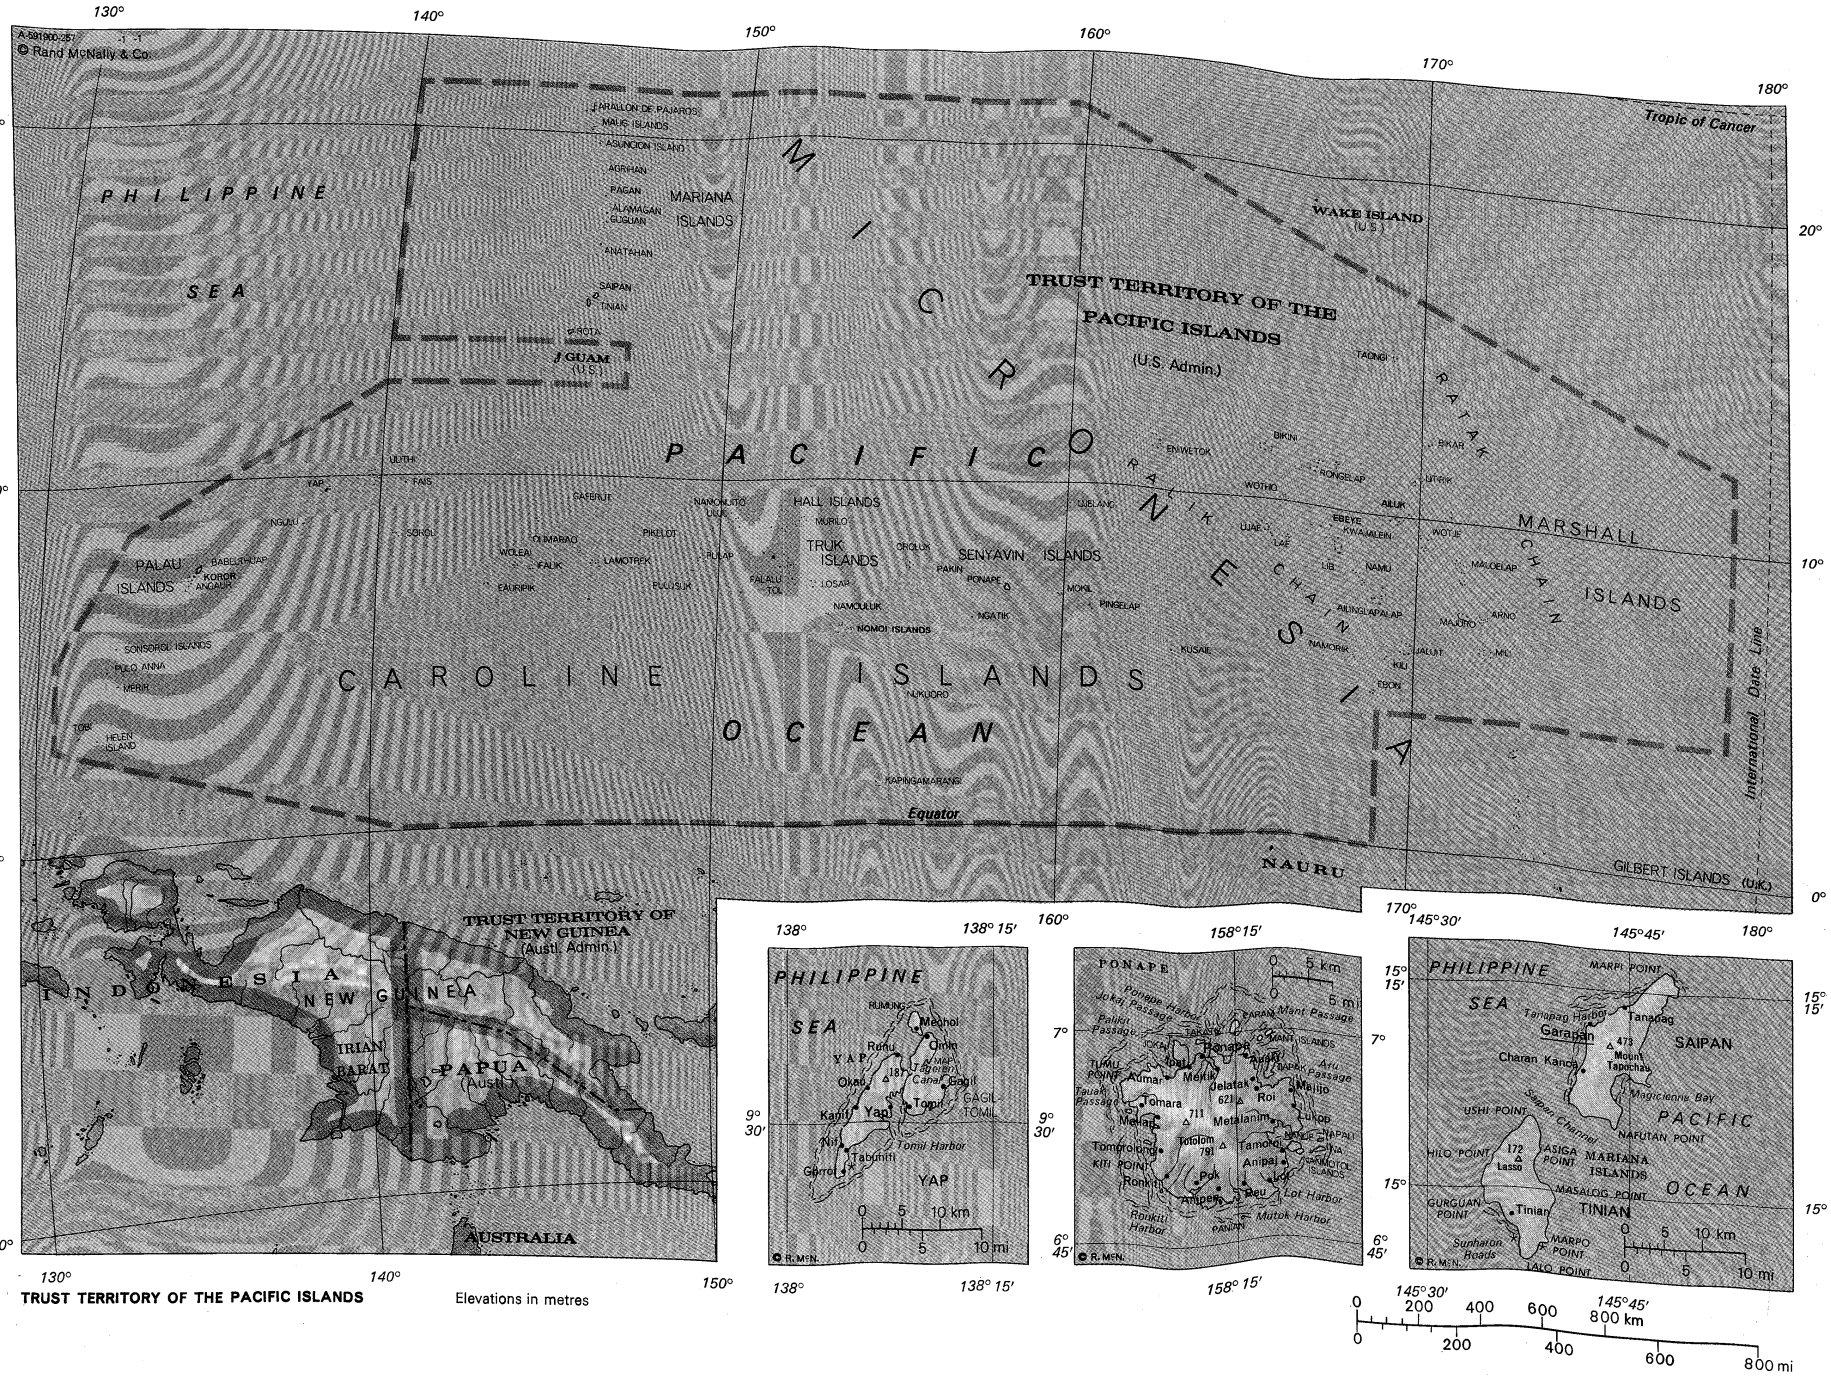
Individual dwellings are scattered among the trees near the shores of the islands, joined together by footpaths made of sand or smooth stones. When the buildings themselves are not unsightly shacks of rusting, salvaged materials, the villages thus loosely clustered make an attractive sight. In high islands where extensive mangrove swamps occur along the shore, as in Ponape, villages are usually farther back from the water's edge, with access to the sea being gained by means of water passages at the mouths of streams. In the small communities most influenced by outside contact and commerce, more tightly clustered groups of buildings along a more definitely marked main street or road have appeared.

In most villages, often in a central location, is a larger structure, which is the dwelling of the chief, a communal meetinghouse, or men's clubhouse. Schoolhouses, clinics, administrative housing, or community centres of modern construction may constitute the largest, if not the most beautiful, buildings. Substantial wooden or concrete buildings of Japanese construction may still be found, particularly in the Marianas and western Carolines. Concrete construction has become increasingly common during the recent period of American rule, particularly where exposure to devastating typhoons has made lighter construction appear impractical.

Major settlements

The principal towns of the trust territory are the district centres, which form the main focusses of foreign influence. Some of them, notably Koror in the Palau group and Truk in the Carolines, were much larger communities in the Japanese period and still have an air of decline, despite recent building.

The district-centre towns are usually built of wood or of corrugated iron. Power and water supplies are found only in the district centres and, even there, are often unreliable. Capitol Hill on Saipan, the administrative centre of the territory, is exceptionally efficient in this respect. Among the largest of the district centres are Majuro, an unplanned and struggling town on a long coral island in the Marshalls, and Koror, on a green volcanic island in the western Carolines. Their populations each numbered about 6,000 in 1970. Residents have been attracted to



TRUST TERRITORY OF THE PACIFIC ISLANDS Elevations in metres

these communities by the concentration of administrative- and commercial-employment opportunities there.

A special type of community has developed at Kwajalein, the American missile-testing base, where a replica of a typical town in the southwestern United States has been built for American personnel. Another type of town has been allowed to develop on the tiny nearby island of Ebeye, where Micronesians who also work on Kwajalein are huddled into crowded quarters quite unlike anything to be found in their native islands.

Life in the more remote villages continues to revolve about subsistence economic activities: the cultivating of small garden plots, the gathering of seafood on the reef, or fishing there or in the sea beyond. The traditional economy is supplemented by the gathering and preparing of copra for sale through a government-controlled system of cooperatives. In the larger towns and district centres, the administration itself is a major contributor to economic life; there, however, modern education and the availability of comparatively highly paid positions place new strains upon traditional patterns of authority.

People and population. *Ethnic groups.* The inhabitants of the trust territory belong to an ethnic stock generally known as Micronesian, with the exception of the Polynesians of Kapingamarangi and Nukuoro. Micronesians are usually described as of Malayan origin and are characterized by medium stature, brown skin, and straight or wavy hair. Mongoloid features are more common in the western part of the territory, suggesting a degree of mixture with other people to the west.

Perhaps the most distinctive ethnic group among the Micronesians consists of the Chamorro of the Marianas. They represent a mixture of the aboriginal inhabitants and a variety of European and Asian groups with whom they have intermarried over a period of some four centuries. The term Micronesian, however, refers to a variety of differing cultures, separately influenced by geographic isolation and—in recent times—by contact with foreigners.

Linguistic groups. Nine major languages exist among the people of the territory, though all of them belong to the Malayo-Polynesian family. Within the individual language groups there are variations in dialects that may result in mutual unintelligibility at first contact. Two of the languages, Chamorro and Palauan, have been described as Indonesian in type. Yapese, Ulithi, Trukese, Ponapean, Kusaiean, and Marshallese are classed as Micronesian languages. A type of Polynesian is spoken by the inhabitants of Kapingamarangi and Nukuoro.

Religious groups. The original religions of Micronesia were not marked by a highly developed set of institutions or by priestcraft. Religion was a pervasive part of the way of life, however, and religious and political power were and still are often ceremonially combined in a chief or shaman.

Christianity was introduced early to the Marianas by the Spanish. Widespread mission work began only in the second half of the 19th century, however, when Spanish Catholics vied with American and, later, German Protestants in an effort that eventually influenced most of the people of the territory. Today, the missions play a vital role in the educational system. Christian services are held regularly in all the major island groups.

Oriental farmers

Demography. During the 1920s thousands of Japanese and Korean workers were brought into the area to provide labour for intensive agriculture, as well as for phosphate mining on the island of Angaur and for commercial fishing. The Marianas and western Carolines were the islands mainly affected. There the Micronesians were often displaced from their lands and resettled by order or by choice on the fringes of the Japanese communities. After World War II nearly all the Japanese and Koreans were repatriated, creating serious economic and social dislocations among Micronesians who had come to rely on the Japanese-built economy and who had intermarried with Japanese. A strong trace of Japanese influence on life patterns remains.

Though the total population was drastically reduced by repatriation, the number of Micronesians more than doubled between 1945 and 1970, rising from an estimated 48,000 to about 100,000. This pattern of growth continues. The 1967 United Nations Visiting Mission reported the population density of the trust territory as 130 persons per square mile, and by 1970 this figure had risen to 140. Yet there are places where the land available is sparsely settled and little cultivated, while district centres and the atolls of the Truk group in general face problems of population pressure upon the resources available.

Trust Territory of the Pacific Islands (Carolines, Marshalls, Marianas), Area and Population

	area		population	
	sq mi	sq km	1967 census	1971 estimate
Districts				
Mariana	184	475	11,000	13,000
Marshall	69	181	19,000	23,000
Palau	179	465	11,000	13,000
Ponape	176	455	18,000	21,000
Truk	46	118	25,000	29,000
Yap	46	119	7,000	7,000
Total Trust Territory of the Pacific Islands	700	1,813	91,000	107,000*

*Figures do not add to total given because of rounding.
Source: Official government figures.

One reason for the uneven distribution of population lies in the greater economic opportunities available at the administrative centres. Another may be found in the unevenness of communications and transportation. Many outlying islands have been visited only rarely by supply ships bringing medical aid. Schools, particularly at the secondary level, also draw residents to the islands on which they are located, sometimes from hundreds of miles away. The outlook for a redistribution of population that would be in closer harmony with the subsistence base is clouded by these factors as well as by landholding traditions and strong ties of association with home islands.

In most of the islands, the introduction of modern medicine has been accompanied by a rising rate of population growth. While this trend points to possible future overcrowding on islands with limited soil and resources, the danger point does not seem to lie in the immediate future, except in some islands in the Truk and Marshall districts. Pre-European population levels in most of the islands were greater than they are today. Ponape, for example, with 20,093 inhabitants in 1969, had less than half the population estimated to have existed two centuries ago. The northern Marianas, the large Palauan island of Babelthuap, and Yap have abundant evidence of settlements in areas now left untilled.

Given the greater productive power resulting from modern scientific methods, the islands in general can support a growing population of indigenous peoples for some time, though at a limited standard of living.

The economy. The traditional subsistence economy of the Micronesians was varied by interisland trading traditions. Production of copra for sale to Western traders was introduced in the late 19th century and continues to be a mainstay of commerce. From the proceeds of copra sales, islanders in the remotest atolls have purchased supplies of Western cloth, kerosene, metal implements, and fishhooks and even tinned food to supplement the regular diet of fish and island vegetable products.

The copra trade

Attempts are being made to diversify the economy and to reduce the dependence upon copra. Cacao and pepper have been introduced experimentally in Ponape with some success. Grazing has been expanded and improved in the northern Marianas, but the number of livestock is still below that kept by the Japanese in the 1930s. The high cost of imported feed and fertilizer forms a barrier to development of dairying, large-scale poultry production, or diversified commercial farming. Sugar production was practiced by the Japanese on lands now largely untilled, but imported labour was required.

If good agricultural soil and minerals are scarce in the trust territory, there are both abundance and variety of

marine resources. Fishing is still chiefly a subsistence activity for the Micronesians, and they lack the technological equipment for a modern commercial fishing industry. Young men are being trained in Japanese and Hawaiian methods, and boats are being built; but fuel will still have to be imported for modern vessels and for machinery to be used in canning or refrigerating plants. Japanese competition and American tariff policies offer additional obstacles in this field.

Some income has been secured from sales of Micronesian handicrafts. Here again, potential expansion is hampered by the amount of time and hand labour required. Another supplement to the economy has been the salvaging of scrap metal left from World War II activities, carried on chiefly by Japanese teams under contract; by the 1970s, however, the richest sources had become exhausted.

One of the most promising economic possibilities for Micronesia appears to lie in tourism. The beauty of the islands, the year-round mildness of the climate, and the exotic nature of island cultures all offer attractions to visitors. Improved transportation and accommodations are being developed in parts of the territory. In parts of the Marshalls and in conservative Yap, however, resistance to the growth of tourism and its inevitable intrusion into traditional ways of life appears likely to limit the industry.

By far the largest economic enterprise in the trust territory is the administration itself. Salaries paid to Micronesians and Americans in the employ of the government compose a major part of the money economy.

Taxation

Levels of taxation are generally low, being hampered by the difficulty of levying property taxes where land titles are still so uncertain. Absence of adequate tax revenues is viewed by administration officials as an obstacle to early self-government. For the immediate future it appears clear that economic support from outside will be needed to maintain the economy. Some young Micronesian leaders, however, feel that most of the money now used to support the administration goes to a bureaucracy of American and Micronesians that would not be needed under self-government. They foresee a much simpler political structure that Micronesians could support with only minimal foreign aid.

Transportation. The vast open ocean spaces between islands make transportation and communication a major problem. Canoes are inadequate to meet the freight needs of today, and the Micronesians generally lack the capital to purchase modern motor ships or the skills required to operate them. Fuel, also, must be imported.

The administration operates motor ships in each district to provide interisland freight and passenger service. Two additional ships are operated on a territory-wide basis to meet educational, medical, and community needs. Private local concerns handle lading and ship-agency work at district ports. On outlying islands the whole population may turn out to help bring imports in over the reef or through difficult waters.

In 1968, Micronesian Interocean Line, Inc., began operating between the trust territory and ports in the United States and the Far East, on a ten-year contract with the government. It is hoped that Micronesian labour and capital will play an increasingly important role in this enterprise and in intraterritory shipping.

Air Micronesia, a combination of the United Micronesia Development Association (which owns a 40 percent interest) and two American airlines, began regular air-transport service in 1968. Airfields at the six district centres can handle jet aircraft, and plans have been made to build hotels nearby for American and Japanese tourists. Charter airlines carry some local freight and passenger traffic among Guam, Saipan, and major centres in the Carolines.

Land transportation throughout the territory is limited in extent and is hampered by poor roads outside the main population centres. Heavy rainfall and sea erosion make road maintenance difficult and costly, and it is seldom possible to maintain roads circling larger islands to connect their shoreline settlements.

Bus services exist in the largest towns, extending to a few outlying communities. By the 1970s, other vehicles, including trucks and motor scooters, numbered about 7,000. Radiotelephone and teletype stations connect the district centres, and some form of radio contact is maintained with the outlying populated islands. A telephone link from Saipan to Guam and thence to the outside world was completed in 1970. Ship-to-shore communications and navigational aids are maintained at the district centres.

Administration and social conditions. In accordance with the provisions of the 1947 United Nations Trusteeship Agreement, the legal basis for government within the area was laid down in the Code of the Trust Territory, enacted December 22, 1952. Later amended, the code defined citizenship, provided a formal law code, and created six administrative districts, centred at Saipan (northern Marianas), Moen (Truk), Colonia (Yap), Koror (western Carolines), Kolonia (on Ponape in the eastern Carolines), and Majuro (Marshalls). The Code recognizes local customary law, but in many cases, especially on land tenure, formal codification of customary law has not been completed. The administrative officials of the trust territory are appointed, not elected. A high commissioner is appointed by the president of the United States, and he, in turn, appoints the six district administrators, their deputies, and the heads of administrative departments at Saipan, under authority from the secretary of the interior. The judicial system consists of a High Court, six district courts, and community courts throughout the islands. Only the High Court justices, appointed by the secretary of the interior, are Americans. The law applied by the courts is a mixture of United States and Trust Territory codes, together with local customary law.

During the 1950s criticism of administration policies in the trust territory was expressed by Micronesians, in the Trusteeship Council of the United Nations, and within the United States. Specific complaints concerned inadequate budgets for education and health services, the slow pace of economic development, and an apparent absence of American plans for future self-government. Following this criticism, trust-territory budgets were markedly increased, particularly after 1960.

Early in the 1960s, an advisory Council of Micronesia was created as a step toward representation of the inhabitants of the trust territory, and in 1965 this body was succeeded by an elected Congress of Micronesia with legislative powers. These powers are subject to approval by the high commissioner or, on appeal, by the secretary of the interior of the United States. The 12 senators and 24 representatives of the Congress are elected in even-numbered years. The former serve four-year terms and the latter, two. There are two senators for each district, while the representatives are apportioned on the basis of population. Six district legislatures are also elected, each under its own charter. Agitation for increased self-government grew among Micronesian leaders and subsequently found support both in the United Nations and in the United States.

Medical care in the trust territory is entirely a public service. There are hospitals at all six district centres, three sub-district hospitals, and rural dispensaries. Doctors and nurses visit the remoter islands on field trip ships, and Peace Corps physicians and medical aides supplement their work. Cases requiring special treatment are still referred to Guam or Honolulu hospitals, though a larger, new hospital with modern equipment opened at Truk in 1971. Micronesians have been trained as nurses, technicians, and medical practitioners, but not yet as qualified physicians. Micronesian students are sent outside, mostly in Guam, Hawaii, and the mainland United States. By 1971 there were public high schools in all district centres and five additional ones on outer islands. At Ponape a community college offers training, primarily to teachers.

Prospects for the future. In 1968 Pres. Lyndon B. Johnson suggested 1972 as a possible date for a plebiscite on the future political status of the trust territory. In 1970 the Congress of Micronesia sent a committee to the United States and to various self-governing island groups to

Movements toward self-government

examine other systems. A resulting report led the Congress to vote in favour of self-government in free association with the United States. When the U.S. Department of the Interior offered the Micronesians a commonwealth status under United States supervision, members of their Congress voted to reject the offer and to seek either "free association" status or complete independence from the United States. The question remains unsettled, subject to further negotiations.

In contemplating the future, U.S. administrators see in the existence of different traditional systems an obstacle to unified government. Micronesian leaders, on the other hand, tend to minimize this difficulty and to place a higher value on maintenance of local custom than on foreign tutelary dominance. The problem of balancing the need for unity in administration against cultural diversity is also marked in the field of language. Micronesian sentiment appears divided between the need for a modern common language of administration on the one hand and pride in local dialects on the other. Leaders with modern education appear more attuned to change than are tradition-oriented Micronesians, and they are also more determined to secure self-government on a unified basis.

An independent Micronesia would require economic support from abroad until a viable economy combining the traditional and modern sectors could be developed. Military protection from without also appears likely to be needed, for the trust territory still occupies an area that is of potential strategic importance in the relations between major powers. If neutralization through international agreement cannot be arranged, then some form of major-power protectorate appears certain.

Pacific Ocean

Of the three oceans that extend northward from the Antarctic continent, the Pacific, occupying about a third of the surface of the terrestrial globe, is by far the largest. Its area, excluding adjacent seas, encompasses about 64,000,000 square miles (166,000,000 square kilometres). It has double the area and more than double the water volume of the Atlantic—the next largest division of the hydrosphere. Its area exceeds that of the whole land surface of the globe, Antarctica included, with Africa counted twice. The Pacific stretches from the shores of Antarctica to the Bering Strait through 135° of latitude, or for 8,350 nautical miles (9,600 miles or 15,500 kilometres). Its greatest longitudinal extent measures 11,500 nautical miles along the parallel of 5° N, between the coasts of Colombia in South America and the Malay Peninsula in Asia. The mean depth of the Pacific (excluding adjacent seas) is 14,050 feet (4,280 metres). Its greatest known depth is 36,198 feet or 11,033 metres (in the Mariana Trench).

Extent of the Pacific

The Pacific and Arctic systems mingle their waters in the Northern Hemisphere at the shallow Bering Strait—whose width is a mere 55 nautical miles—and in the Southern Hemisphere the Pacific and Atlantic mix in the relatively narrow Drake Passage between Tierra del Fuego in South America and Graham Land in Antarctica. The separation between the Pacific and Indian oceans is less distinct; in this article, it is considered to lie along the line of islands extending eastward from Sumatra, through Java to Timor, thence across the Timor Sea to Cape Londonderry in Australia. To the south of Australia the boundary extends across the Bass Strait and thence from Tasmania to Antarctica.

Because of the pattern of major mountain systems of the globe, a relatively small proportion (one-seventh) of the total continental drainage enters the Pacific—*i.e.*, a total drainage area of not more than about three times that of Australia. Of the rivers that drain into the Pacific, those of China and Southeast Asia are of the greatest importance; the basins of these rivers support more than one-quarter of the world's population.

The eastern boundary of the Pacific is associated with the American Cordilleran mountain system, which stretches from Alaska in the north to Tierra del Fuego in the south. Except for its extreme northern and southern sections, which are characterized by fjords (narrow arms of the sea bordered by steep cliffs) and their numerous off-lying islands, and except for the deeply indented Gulf of California, the coastal boundary is relatively regular and the continental shelf narrow. The western, or Asiatic, coastal boundary, in contrast, is irregular. Although the mountain systems there lie roughly parallel to the coast, as they do on the eastern Pacific coastlands, the western Pacific is noted for its many peripheral seas. From north to south they include the Bering Sea, Sea of Okhotsk, the Sea of Japan, the Yellow Sea, the East China Sea, and the South China Sea. Their eastern boundaries are formed by southward-jutting peninsulas or by island arcs or both. It is of oceanographic significance that the great rivers of eastern Asia—including the Amur, the Yellow River, the Yangtze, the Hsi Chiang, and the Mekong—enter the Pacific indirectly by way of peripheral seas. (For associated physical features, see BERING SEA AND STRAIT; BIKINI; CHINA SEA; DRAKE PASSAGE; EASTER ISLAND; GALAPAGOS ISLANDS; JAPAN, SEA OF; PACIFIC ISLANDS; and YELLOW SEA; for historical background see OCEANIA, HISTORY OF; see also CONTINENTAL DRIFT; CONTINENTAL SHELF AND SLOPE; OCEAN BASINS; OCEAN CURRENTS; OCEANIC RIDGES; OCEANS AND SEAS; and OCEANS, DEVELOPMENT OF.)

THE NATURAL ENVIRONMENT

Relief. The Pacific Basin may conveniently be divided into three major physiographic regions, the eastern, western, and central Pacific regions.

Eastern region. The eastern region, which extends southward from Alaska to Tierra del Fuego, is relatively narrow and is associated with the American Cordilleran system of almost unbroken mountain chains, the coastal ranges of which rise steeply from the western American shores. The continental shelf, which runs parallel to it, is steep and comparatively narrow. Significant oceanic trenches in this region are the Acapulco and Guatemala trenches in the North Pacific and the Peru–Chile Trench in the South Pacific.

Oceanic trenches

Western region. The second physiographic province is the western region, the seaward boundary of which is marked by a broken line of oceanic trenches, extending from the Aleutian Trench in the north through the Kuril and Japan trenches and southward to the Tonga and Kermadec trenches, terminating close to the southeast of North Island, New Zealand. The western region has a structure more complex than that of the eastern region. Characteristically associated with the ocean trenches of the western region are festoons either of peninsulas or islands or both. The islands, which include those of Japan as well as numerous small islands, represent the upper parts of mountain systems that rise abruptly from the deep ocean floor. The island clusters of the western Pacific form the boundaries of the several wide and deep continental seas of the region.

Central Pacific region. The third province is the central Pacific region lying between the boundaries of the eastern and western regions. The largest and the most geologically stable of the structural provinces of the earth's crust, it is characterized by expansive areas of low

relief, lying at a general depth of about 15,000 feet below the surface.

Principal ridges and basins. To the east of the meridian of 150° W the relief of the ocean floor is considerably less pronounced than it is to the west. In the eastern Pacific the Cocos Ridge extends southwestward from the Central American isthmus to the Galápagos Islands. To the southwest of the Galápagos lies the Southeast Pacific Basin, which is separated by the extensive Southeastern Pacific Plateau from the Pacific-Antarctic Basin, which, in turn, is separated from the Southwest Pacific Basin by the indeterminate Pacific-Antarctic Ridge, which runs from the Southeastern Pacific Plateau to Antarctica in the vicinity of 150° W.

Extending southward from the Tasman Basin (between New Zealand and East Australia) is the Macquarie Ridge, which forms a significant boundary between the deep waters of the Pacific and Indian oceans. The Hawaiian Ridge extends westward from Hawaii to the meridian of 180°.

The submerged parts of the series of ridges that are capped by the island archipelagoes of the western Pacific are continuous and are to be found at depths of less than about 2,000 feet. These ridges include the Aleutian ridge in the northwest Pacific; the series of ridges extending southward through the Kurils, Bonin, Marianas, Yap, and Patou; those extending eastward from Patou including the Bismarck, Solomons, and Santa Cruz ridges; and finally the ridges extending southward from which rise the Samoan islands, Tonga, Kermadec, Chatham, and Macquarie.

Islands. The islands of the western region—including the Aleutians, Kurils, Ryukyus, Taiwan, the Philippines, Indonesia, New Guinea, and New Zealand—are continental in character. Geologically they consist, in part, of sedimentary rocks, and their structures are not dissimilar to those of the coastal mountain ranges of the adjacent continent. Most are sufficiently large for oceanic climatic influences not to be pervasive.

"High" islands and "low" islands

A geologically important boundary between the continental, or "high" islands, and the numerous truly oceanic, or "low" islands, of the Pacific is the Andesite Line. (Andesite is a fine-grained rock typical of the geologic boundary line separating the basic igneous rock of the ocean basins from the acid igneous rock characteristic of continental areas.) In the north and west Pacific the Andesite Line follows close to seaward the trend of the island arcs from the Aleutians southward to the Yap and Patou arcs, thence eastward through the Bismarcks, Solomons, and Santa Cruz, and thence southward through Samoa, Tonga, Chatham, and Macquarie to Antarctica. Within that boundary, islands are essentially of basalt, a basic igneous rock characteristic of ocean basins; basalt contrasts with the more acid igneous rocks associated with volcanic activity in continental areas.

The numerous "oceanic" islands of the Pacific are unevenly distributed. They lie, in the main, between the Tropics of Cancer and of Capricorn and occur in great numbers in the western Pacific. The northernmost chain of oceanic islands is associated with the Hawaiian Ridge. The Hawaiian archipelago consists of about 2,000 islands, although the term Hawaiian Islands is usually applied to the small group that lies at the eastern end of the archipelago.

The numerous small islands of Micronesia lie mainly north of the Equator and to the west of the 180th meridian. Nearly all are coralline; the principal groups are the Marianas, the Marshalls, the Carolines, and the Gilbert and Ellice Islands.

To the south of Micronesia lie the islands of Melanesia, most of which are small coral islands. The region's physiography is dominated by a group of large continental islands, however, including New Guinea. The principal groups of the Melanesian islands are the Bismarck Archipelago, the Solomons, the New Hebrides, New Caledonia, and Fiji.

The immense triangular area, with Hawaii in the north, Easter Island in the southeast, and New Zealand in the southwest is peppered with the multitude of islands known as Polynesia. The main Polynesian groups are the Phoenix Islands, Samoa, Tonga, the Cook Islands, Society Islands, Tuamotu, and the Marquesas.

Geology. Corroboratory evidence drawn from various geophysical fields—seismology, vulcanology, gravimetry (the measurement of weight or density), and paleomagnetism (the study of the traces of magnetic polarization of rocks from previous eras)—points to the general validity of the theory of continental drift (see CONTINENTAL DRIFT).

Origin of island arcs

The Pacific island arcs, or epicontinental (*i.e.*, near-continental) islands as they are sometimes called, are believed to have originated in the lateral thrusting of the Asian continental crust toward and over the Pacific floor, the shapes of the island arcs corresponding to the intersections of the thrust planes with the spherical earth's surface. The intense folding and faulting along the volcanic zone of the western Pacific provide unmistakable evidence of orogenic (mountain-building) forces at work. The deep basins that lie between the Asian continent and the island arcs were evidently caused by the local downfolding of the earth's crust; the island arcs themselves, along the line of which volcanic and seismic activity are pronounced, are the result of weakening of crustal strata by strong upfolding. On the oceanic side of the island arcs, intense downfolding has resulted in the formation of the deep trenches that fringe the line of the island arcs.

The character of the eastern marginal physiographic region of the Pacific suggests a lateral movement of the North American and South American continents westward over the Pacific floor. The floor of the northeastern Pacific is remarkable for its several major fracture zones, which extend east and west and which, in some instances, are identifiable over distances of thousands of miles.

Of great geological interest are the seamounts (called guyots) and the oceanic islands of the Pacific. The numerous tropical islands of the Pacific are mainly coralline. The three principal types of coral reef—fringing, barrier, and atoll, as well as the flat-topped guyots, which are abundant on the ocean floor in extratropical latitudes within the Pacific—are explained by the slow subsidence theory advanced by the English naturalist Charles Darwin during the 19th century. (According to this theory, the ocean floor in the vicinity of a submarine volcano or volcanic island sinks slowly in response to gravitational and other forces; coral reefs are assumed to grow upward and outward on tropical islands that are submerging, taking the form first of a fringing reef, then of a barrier reef, then of an atoll. Outside the tropics, where reef-building corals are not found, the tops of oceanic volcanic islands would be expected ultimately to be truncated by the erosive action of sea waves. The submergence of the island would then give rise to a guyot.)

Climate. The wind and pressure systems of the Pacific conform closely with the so-called planetary system—*i.e.*, the pattern of air pressure and the consequent wind pattern that develops when the earth's surface (land or sea) is smooth. This conformity is partly a consequence of the great extent of the Pacific and the comparative uniformity of its surface. Climatic conditions in the South and East Pacific, where the steadiness of the trade winds and the westerlies is remarkable, are the most uniform on the globe. In the North Pacific, however, conditions are not so uniform, particularly the considerable climatic differences between the eastern and western regions in the same latitude. The rigour of the winters off the east coast of the Soviet Union, for instance, contrasts sharply with the relative mildness of winters in the region of British Columbia.

Uniformity of climate

The trade winds. The trade winds of the Pacific represent the eastern and equatorial parts of the air-circulation system; they move around the subtropical high-pressure zones centred, respectively, over the northeast and southeast Pacific between the 30th and 40th parallels N and S. The obliquity of the ecliptic (the term used to denote the angle, approximately 23½°, contained between the planes of the earth's rotation on its axis and its revolution around the sun) limits the seasonal shifting of

WESTERN PACIFIC OCEAN

Depths in metres

Colours used are thought to be those of the various rocks and sediments on the sea floors. Differences in relief are shown by relief shading.

0 400 800 1200 km

0 400 800 1200 mi

the Pacific trade-wind belts to about 5° of latitude. The easterly winds in between the two subtropical zones form the intertropical air flow, which is most pronounced in the eastern Pacific.

The trade winds, especially in the eastern Pacific, convey relatively cool air toward the Equator; in moving, the air comes in contact with the sea and thus becomes increasingly humid and warm, and high lapse rates (the term used to denote the rate of change of air temperature with increasing height above sea or land surface) result. The average wind speed of the Pacific trade winds is about 13 knots (nautical miles per hour). The weather in the trade-wind belts is normally fine, with relatively little cloud; such cloud as there is characteristically takes the form of broken cumulus (small piles of cloud with flat bases) at about 2,000 feet above sea level. Precipitation, usually in the form of light showers, is slight; visibility is generally excellent.

Off the west coasts of the American continent in the trade-wind belts, upwelling of cold, subsurface water results in the overlying air being cooled below its dew point (the air temperature below which vapour condenses as dew), with the consequent formation of widespread and low, thick clouds. Fog in these regions is not uncommon.

The equatorial region, in which the trade winds of the Northern and Southern hemispheres converge, is the region of calms or light variable breezes and is known as the doldrums.

Tropical storms. Although, in general, the climatic conditions of the trade-wind belts are characteristically regular and uniform, storms of great violence do originate there. In such storms, winds of exceptionally great force blow around a centre of exceedingly low sea-level air pressure. These are the tropical storms known in the western Pacific as typhoons. The mechanism that operates to trigger a tropical storm is not understood completely, but the energy required to engender and sustain a storm is undoubtedly related to the enormous quantity of latent heat associated with tropical maritime air.

Typhoons of the western Pacific

Ideal conditions for the development of tropical storms occur in the western Pacific between the parallels of 5° and 25° N during late summer and early autumn. The regions to the east of the Philippines and in the South and East China seas are notorious for these storms, which imperil shipping and often cause severe coastal flooding, accompanied by loss of life and property.

The westerlies. Within the belts of the westerly winds, cold easterly winds from polar regions meet the warm westerly winds of the middle latitudes, causing the formation of the travelling depressions characteristic of middle latitudes. The zone of convergence, or polar front, is most strongly developed in winter when the contrast in temperature and humidity of the air between the converging flows is greatest.

The westerlies in the Southern Hemisphere are steady and strong, and "brave west winds" is an apt name. The gales that accompany the depressions have led to the term roaring forties named for the latitudinal zone in which the storm winds are of greatest frequency.

The monsoon regime. The western Pacific is subject to a seasonal climatic regime, which replaces the planetary system. This is the regime of the monsoon (rain-bearing winds), which is associated with the heating of the Asian landmass in summer and its intense cooling in winter. The heating of tropical Asia in summer initiates a low-pressure system, which becomes the focal point of the trade winds of both hemispheres. The doldrums, therefore, do not exist in the western Pacific during northern summer because of the large-scale flow of maritime air into the Asian low-pressure zone. The cooling of the continent in winter results in the development of the Asian high-pressure system, which leads to a strengthening of the trade winds of the Northern Hemisphere.

As a result of seasonal changes in pressure and wind circulation, marked seasonal contrast between continental and maritime influences—the first associated with drought and cold and the second with moisture and heat—is to be found in the whole of the western Pacific from the Sea of Japan southward.

Temperature and salinity. Temperature and salinity of sea water are the principal determinants of density; and density differences play an important role in relation to the circulation of the ocean.

Density and water circulation

Temperature. The oceans tend to be stratified, with the densest water lying at the bottom and the least dense at the surface. The principal factor in establishing this pattern is temperature; the bottom waters of the deep parts of the ocean are intensely cold, with temperatures only slightly above freezing.

Ocean temperatures in the North Pacific tend to be higher than those experienced in the South Pacific because the ratio of land to sea areas is larger in the Northern Hemisphere than it is in the Southern Hemisphere and because the ice continent of Antarctica also influences water temperature.

The mean position of the thermal Equator (the line on the earth on which the highest average air temperatures are found; the line migrates latitudinally with the changing angular distance from the equator of the sun) in the Pacific, although it lies in the Northern Hemisphere, is nearer to the geographical Equator than in the Atlantic and Indian oceans.

Salinity. The waters within the belt of calms and variable winds near the Equator have lower salinities than those in the trade-wind belts. In the equatorial belt, relatively large amounts of rain fall and little evaporation occurs both because of low windspeeds and because of the generally cloudy skies; salinity in the equatorial belt runs as low as 34 parts per thousand.

The highest surface salinities in the open Pacific occur in the southeastern area, where they reach 37 parts per thousand; in the corresponding trade-wind belt in the North Pacific the maximum salinity seldom reaches 36 parts per thousand. Pacific waters near Antarctica have salinities of less than about 34 parts; the lowest salinities—less than about 32 parts—occur in the extreme northern zone of the Pacific.

The heavy rainfall of the western Pacific, associated with the monsoons of the region, gives rise to relatively low salinities. Seasonal variations there, as well as in the eastern Pacific where seasonal changes in surface currents occur, are significant.

Hydrology. *Surface currents.* Pacific trade winds drive surface waters toward the west to form the North and South Equatorial currents, whose axes coincide, respectively, with the parallel of 15° N and the Equator. Squeezed between the Equatorial currents is a well-defined countercurrent, the axis of which is always north of the Equator and which extends from the Philippines to the shores of Ecuador.

The major part of the North Equatorial Current swings northward in the vicinity of the Philippines to form the warm Kuroshio Current. To the east of Japan the Kuroshio swings eastward to form the Kuroshio Extension. The branching of this current in the region of 160° E results in the movement known as the North Pacific Drift. A branch of the warm Kuroshio Current passes through the Tsushima Strait to form the Tsushima Current, which flows in a northward direction on the eastern side of the Sea of Japan.

The North Equatorial Current

The surface waters of the Bering Sea circulate in an anticlockwise direction. The southward extension of the Kamchatka Current forms the cold Oya-shio, which flows to the east of Honshu to meet the warm Kuroshio waters in the vicinity of 36° N.

The California Current forms the eastern branch of the main circulation system of the North Pacific. Having a great east–west extent, its surface-water movement is very slow.

The South Equatorial Current, on reaching the Solomon Islands, swings southward to form the East Australian Current, which links with the southern line of the main South Pacific circulation system, which, in turn, reaches the South American coast in the region of 45° S. One branch flows northward to form the Peru (Humboldt) Current, and a second branch flows southward to pass through the Drake Passage.

Between January and February—but sometimes as late

as March, or even April—the axis of the Equatorial Countercurrent is displaced southward of its mean position, north of the Equator, so that warm saline waters reaching the coast of Ecuador swing southward to merge with the relatively cold northward-flowing waters of the Peru Current south of the Equator. The warm south-flowing current is called El Niño ("The Child")—a reference to the infant Christ. The strong development of El Niño, which may extend to 14° S, causes destruction (due to changes in temperature and salinity) of vast numbers of marine planktonic life and of fish and other higher marine life-forms that feed on the plankton. Mass starvation of birds that rely on the fish of these waters for food follows.

Effects of El Niño Current

Deepwater circulation. Observations of temperature and salinity at different levels in the ocean reveal well-defined layers, each forming a water mass distinguished by its own temperature and salinity characteristics.

It appears that the most important influence on the vertical circulation of the Pacific is the cold water generated around the Antarctic continent. This dense circumpolar water sinks and then spreads northward to form the bottom layer of the greater part of the Pacific. It has been suggested that cold, deep water flows northward in the western Pacific in a relatively well-defined current from the vicinity of Antarctica to Japan. Branches from this deep main stream convey cold water eastward and then poleward in both hemispheres.

Deepwater circulation is influenced by the descent of surface water at zones of convergence of neighbouring water flows. In the zone known as the Pacific Tropical Convergence, which coincides with the Equatorial Countercurrent, water sinks to a depth of about 300 feet before it spreads laterally. The Pacific Sub-Tropical Convergences are located between the parallels of 35° and 40° N and S. Water that sinks at the convergences spreads laterally at increasing depths as the distance from the Equator increases. The most important convergence in the Pacific is the Antarctic Convergence, which lies in the zone of the brave west winds. A corresponding Arctic Convergence is prominent in the northeastern Pacific.

The Antarctic Convergence

To compensate for downward-moving water, some water rises at zones of divergence, particularly along the so-called cold water coasts of both North and South America, where upwelling of cold water is a well-marked phenomenon.

Tides. In contrast to the tides of the Atlantic, those of the Pacific include many examples of diurnal and mixed tides. In the diurnal type of tidal oscillation, only a single high water and a single low water occur each tidal day (which lasts for about 24 hours and 50 minutes). Tides of this type occur in the Gulf of Tonkin in Southeast Asia, Vancouver Island (Canada), and the Torres Strait (between Australia and the island of New Guinea). Mixed tides, in which both diurnal and semidiurnal oscillations appear, are characterized by large inequalities in successive high (or low) water heights. This type of tide is prevalent along the Pacific coast of the United States. At certain places in the South Pacific the natural period of oscillation of the sea accentuates the solar tidal oscillation. At these places the time of the AM (or PM) high (or low) water, instead of getting later each day by about 50 minutes (as is generally the case), occurs at about the same time for several days in succession. The tide at Tahiti, for example, follows the sun and not the moon—the time of high water occurring, day after day, at about midnight and noon, and that of low water at about 6 AM and 6 PM.

In general, tidal ranges within the Pacific are small. That at Tahiti is about one foot; at Honolulu it is about two feet; at Yokohama, the port for Tokyo, it seldom exceeds five feet; and at Cape Horn it is never more than about five feet. In the upper reaches of the Gulf of California and the Gulf of Korea, however, large tidal ranges of over 40 feet are common.

Marine life. The most abundant plant forms of the ocean are the microscopic phytoplankton that favour regions where upwelling or mixing of waters brings plant nutrients from deep levels to the euphotic zone (the upper layers of water where light penetrates). Diatoms (unicellular algae) occur in vast numbers in Arctic and Antarctic waters and along the cold-water coasts of both North and South America. Other important phytoplankton include numerous species of flagellates (species of algae having antennae). The phytoplankton provide for the needs of zooplankton (animal forms of plankton), important among which are the radiolarians (microscopic unicellular marine animals, most species of which secrete shells of silica), which are abundant in tropical waters of the Pacific. Foraminifera of the genus *Globigerina* (a minute form of shell-building acellular animal life) are widespread in the South Pacific but are conspicuously absent in the North Pacific.

An important marine animal in the Pacific is the reef-building coral. Some of these animals have the ability to secrete calcareous (chalky) material and construct compound limestone skeletons, which form the major elements of coral reefs. Reef-building corals are sensitive to changes in temperature and salinity. They flourish on firm foundations in clear and shallow water in the Central Pacific between about 30° N and 30° S. The numerous coral atolls of this region are characteristic of this type of formation.

Bottom deposits. The surface waters of the sea form one wide nursery for forms of life. The sea bed, correspondingly, forms one vast burial ground. Apart from the narrow coastal zone of the eastern region and the broad continental seas of the western region, the Pacific is floored with pelagic (*i.e.*, oceanic) material derived from the remains of marine organisms that once inhabited the waters lying above. Red or brown radiolarian ooze is found along the zone of the North Equatorial Current, east of the meridian of 170° W, and on the floors of some deep Indonesian basins. A belt of diatom ooze occurs between the parallels of 45° and 60° S and across the northern Pacific, between Japan and Alaska. *Globigerina* ooze occurs in the shallower parts of the South Pacific, the dissolving power of the sea water at great depths being sufficient to dissolve calcareous material to such an extent that calcareous oozes are not generally found at depths in excess of about 15,000 feet. Silica-containing material, such as radiolarian and diatom ooze, is found at greater depths, but even these siliceous remains are dissolved at very great depths, where the characteristic deposit is red clay. Red clay, which covers no less than half the Pacific floor, is believed to be formed of colloidal (very finely divided) clays derived essentially from the land.

Occurrences of ocean-floor ooze

Among the many different forms of land-derived muds (formed by the erosive action of rivers, tides, and currents) that floor the continental shelves and slopes of the Pacific, the yellow mud of the Yellow Sea is of particular interest. The mud is conveyed to the sea bed by the Huang Ho that drains a vast area of North China blanketed with loess, a fine-grained soil.

THE IMPRINT OF MAN

Economic resources. *Fisheries.* The resources of the Pacific include large quantities of fish, mammals, crustaceans, and mollusks. The northeast Pacific is noted for its salmon fisheries based on the Skeena, Fraser, and Columbia rivers. The fisheries of the northwest Pacific, especially in the seas of Japan and Okhotsk, harvest great quantities of herring, cod, tunny, bonita, crab, lobster, shrimp, and prawn. More fishermen find employment in these waters than in any other fishing ground, and the annual catch of Japan exceeds in value that of any other nation. The waters off the South American coasts are rich in marine life; the growth of the Peruvian anchoveta fishery—anchoveta are a species similar to anchovy—has been phenomenally rapid since 1957. In the early 1970s the quantity—but not the value—of Peru's annual catch was the world's largest. The greater proportion of Peru's catch is converted into fishmeal for cattle and other domestic animals.

Minerals. The mineral resources of the waters of the ocean are vast and virtually inexhaustible. But apart from the extraction of sea salt, magnesium, and bromine, the

Pacific's mineral resources for economic reasons remain untapped. The mineral deposits of the sea beds, especially on the continental shelves, however, are being increasingly exploited. Sea-bed oil prospecting started as far back as 1891 when a well was drilled beneath the shallow waters off the southern California coast. Sea-bed surveys in the Yellow Sea and East China Sea in the 1960s indicated that the continental shelf there may contain one of the most extensive and richest petroleum reserves in the world. Petroleum and natural gas exist in continental shelves adjacent to Alaska, Washington, Oregon, California, Central America, Ecuador, and Peru, as well as in the western Pacific off Japan, Indonesia, Southeast Australia, and New Zealand.

Minerals of the ocean floor

During the scientific voyage of the British naval vessel HMS "Challenger" in the 1870s, nodules or concretions of manganese compounds and minerals were discovered on the floors of the ocean basins. Considerable economic interest was aroused during the International Geophysical Year (1957 to 1958) when scientists discovered huge quantities of nodules on the Pacific floor, off the coast of California as well as in other localities. Research into economical methods of dredging and extracting the valuable metallic nodules continues.

Resource exploitation. In exploiting the resources of the sea, men require knowledge as well as tools and machines. Prospects for making optimum use of the resources of the sea, therefore, depend upon improved technology. No Pacific nation is more aware of this need than Japan, which dominates the commercial fishing of the Pacific.

The sophisticated oceangoing factories of the Japanese fishing fleet are capable of remaining at sea for long periods of time and thus are taking an increasingly important role in Pacific fishing. Fish canneries have been established in American Samoa, the New Hebrides, and Fiji; and these, together with older established factories in Hawaii and the Galápagos Islands, are supplied with tuna and bonita caught by Japanese fishermen.

The formerly prosperous whaling and pearling industries of the Pacific have dwindled to negligible proportions. Pearling for pearls and shell used to be important in many parts of Micronesia and Polynesia, but overgathering has reduced production to insignificance. Fishpond culture and oyster farming are practiced, techniques that may grow in economic importance.

It is worthy of note that the sea and lagoons play a relatively important role in Pacific island life; Polynesian food gatherers learned long ago the art of tending reef "gardens" in order to obtain food from the sea.

History. *Exploration and mapping.* Although the peoples of the western Pacific coastlands formed flourishing civilizations in very early times, they appear to have made no attempt to explore the Pacific beyond their coastal waters. Direct contact between Europe and the Pacific dates from the 16th century, when the exploration of the Pacific began in earnest. The initial European explorations of the Pacific were designed to open up oceanic trade routes to link Europe with the spiceries of the Far East. Later, attention was given to the discovery of Terra Australis. These explorations brought the peoples of western Europe into direct contact with the world of the Pacific islands.

Eight years after the Spanish conquistador Vasco Núñez de Balboa had sighted the "peaceful sea" from a peak in Darien in the Isthmus of Panama in 1513, the ship of Ferdinand Magellan, the Portuguese navigator, voyaged across the Pacific. Subsequent Spanish voyages led to the European discovery of the Moluccas, the Carolines, Papua, the Hawaiian Islands, and the Solomons. From the beginning of the 17th century, Pacific voyages of discovery were dominated by the Dutch, and credit is due to the Dutch navigator Abel Tasman for his significant discoveries of Tasmania, New Zealand, and Fiji.

Dutch voyages of discovery

A later major period of Pacific exploration is marked by the 18th-century voyages of the English navigator James Cook, the French navigator Louis-Antoine de Bougainville, and others who made possible the accurate mapping of the whole of the Pacific.

In the 19th century, the English naturalist Charles Darwin sailed on the British naval vessel HMS "Beagle," which circumnavigated the globe between 1831 and 1836. Growing interest, at that time, in the physical and biological problems of the ocean paved the way for the many oceanographic voyages made later in that century. These were initiated by the previously mentioned "Challenger" expedition.

The voyage of USS "Tuscarora," from 1874 to 1875, contributed significantly to oceanographic discovery in the northern Pacific; scientists aboard the German research vessel "Gazelle" in its 1874–76 voyage added considerably to knowledge of oceanic physics. During the International Geophysical Year the Soviet vessel "Vityaz" carried out detailed soundings of the deep trenches of the western Pacific. In the same year the United States bathysphere "Trieste" descended to the bottom of the Mariana Trench, reaching the greatest known depth of 36,198 feet.

Eras of naval predominance. The European intrusion into the Pacific resulted in the establishment of the first Spanish colony in the Philippines, in 1564. The 17th century witnessed the rise of Dutch naval power in the East Indies. From the beginning of the 19th century onward, the Pacific became the scene of a struggle for colonies and coaling stations by the maritime powers of western Europe.

The history of modern naval strategy in the Pacific dates from 1894, when Japan eliminated the Chinese navy. Ten years later Japan destroyed the Russian Far East fleet and became ruler of the western Pacific, from its own shores to the Philippines. To safeguard British interests in the Pacific an alliance between Great Britain and Japan was concluded in 1902.

The rise of Japan's naval dominance

After World War I Japan acquired former German Pacific islands, thus strengthening its naval influence. Although the opening of the Panama Canal (*q.v.*) in 1914 allowed the United States to operate its fleet in the Pacific, Japanese control of the western Pacific remained unchallenged. World War II committed the major part of the British fleet to the Atlantic, and in 1941 significant U.S. naval forces were transferred to the Atlantic from the Pacific. Nevertheless, Japan, despite its military successes in Asia, failed to establish control of the eastern Pacific. By degrees the United States wrested command of the western Pacific from Japan and, since World War II, has been master of the whole of the Pacific. The South Pacific remains a sphere of influence in which Great Britain, Australia, and New Zealand are important naval powers.

Trade and communications. Although Thor Heyerdahl, the Norwegian author and anthropologist, has amply demonstrated the possibility that at least some Pacific islands may first have been inhabited by peoples from South America, the weight of anthropological evidence suggests that the indigenous peoples of the Pacific islands originated in Asia and that the peninsulas of Southeast Asia were the principal centres from which Polynesian, Micronesian, and Melanesian settlement spread out. The European impact on the Pacific, which began in the early 16th century when the Spanish entered Central America, did not become significant until about 1800, when local Pacific economies were severely disrupted by European exploitation of the resources of the Pacific islands. This epoch was marked by the arrival of numerous planters, traders, and missionaries, and the introduction into the Pacific islands of relatively large numbers of Indian, Chinese, and Japanese labourers. The native populations decreased sharply as a result of diseases introduced by Europeans, the introduction of slavery, and the more lethal local warfare caused by the availability of guns.

The development of the North American west coast during the early 19th century, and the concomitant extension of United States trade into the Pacific, ushered in a period of profitable trading in which manufactures were exported from North America in exchange ultimately for silks, spices, and other products of the Far East and Oceania.

Since the beginning of the 20th century, Japan's influ-

ence in the Pacific has increased. After World War II, when Japan's economic power was temporarily eclipsed, Australia, New Zealand, France, The Netherlands, the United States, and the United Kingdom were instrumental in establishing the South Pacific Commission, with headquarters in Australia, which aims to encourage and coordinate research into the economic and social problems of the region.

The South Pacific Commission

The major trading patterns of the Pacific are essentially determined by political factors. Strong trading links have long existed between Hawaii (which achieved statehood in 1959) and the United States; between Great Britain and France and their respective scattered colonial Pacific islands; and between Australia and New Zealand and their dependent territories.

Communications. Communications across the Pacific are better than they are between island communities within the Pacific. Regular ocean-freight and passenger services connect North America with Japan and the Philippines; and Honolulu, the capital of Hawaii, serves as an important port of call. The Panama Canal provides a sea-trade route linking Atlantic and Pacific ports. The principal focal point of air and shipping services in the Far East is Japan; from there, routes lead southward to Australasia and, by way of the Strait of Malacca, to the Indian and Atlantic oceans. Important airports providing calling points in an increasingly complex network of air services include Honolulu (Hawaii), Papeete (Tahiti), Pago Pago (American Samoa), and Nandi (Fiji).

Prospects for the future. The peoples of the colonial island territories of Melanesia, Micronesia, and Polynesia are becoming increasingly responsible for their own political affairs, and self-government appears to be inevitable for them all. The rising birthrate in the Pacific islands, especially in the low-lying islands where land resources are severely restricted, is resulting in overpopulation. Mixed populations, in which the indigenous peoples in many instances have been, or are being, rapidly outnumbered by people of Indian, Chinese, Japanese, and European origin, give rise to complex social problems.

Population problems of the islands

Jet airplanes and modern airports have marked the beginning of a new epoch for many Pacific islands. Tourism, doubtless, will boom in numerous hitherto remote Pacific areas.

It appears that the comparatively new states of Indonesia and the Philippines, as well as China and Japan, will become increasingly important in the western Pacific, politically as well as economically. The vast populations of the countries of eastern Asia represent an enormous demand for food and manufactures. Japan, the United States, and the Soviet Union, with their advanced technologies, are capable of producing enough manufactured goods to meet this demand. The mineral wealth of the Pacific rimlands is, moreover, substantial. Pacific sea trade may consequently be expected to increase.

There can be no doubt that the recent devastating wars in Korea and the Indochina peninsula have retarded economic and social progress and have had far-reaching effects in the whole of the Pacific region. Were it not for these hostilities, Theodore Roosevelt's prophecy of 1905 that "The 20th century will be the century of the Pacific," might well already have come to pass.

OSBORN (ed.), *The Pacific World* (1944), an excellent collection of articles concerning the peoples and lands of the Pacific; H.U. SVERDRUP, M.W. JOHNSON, and R.H. FLEMING, *The Oceans* (1942), a general text embracing physical, chemical, and biological oceanography; C.R.H. TAYLOR, *A Pacific Bibliography*, 2nd ed. (1965), a valuable work relating to the native peoples of Polynesia, Melanesia, and Micronesia.

(C.H.C.)

Pacifism and Nonviolent Movements

Pacifism is taken in this article to embrace the sum of all endeavours and programs for the realization of a lasting or, if possible, a perpetual peace between peoples in the belief that this goal is of positive value and can be attained within the historically foreseeable future. This is a broader definition, of course, than that of common usage, which refers to movements for the total abolition of war. The term nonviolent movements refers to what have been, as a rule, sects or movements of small minorities that share a fundamental conviction that it is possible to transmit the individual ethic of "negative actions" (nonresistance, sufferance, and nonviolence) to the collective arena.

NATURE AND RELATIONS OF THE MOVEMENTS

In its general form as just defined, pacifism can be found to exist in all higher cultures and in all historical times, as a more or less distinct and vivid idea, often supported by (1) religious and philosophical or ethical demands for the abandonment of violence, (2) the postulate of tolerance, and (3) programs aimed at the improvement of relations between nations, the limitation of armaments, the moderation and rational discussion of conflicts, and the institution of neutral courts of arbitration. As a rule, the basis for such programs lies in the conception of an organic social ethic and a harmonious human society. Yet, there are different degrees of rigour among pacifist conceptions and ambitions. Whereas there is an integral pacifism that eschews, under all circumstances, the violent settlement of conflicts and rejects war unconditionally, there is also a less severe, or compromising, semipacifism that permits wars under certain conditions, as, for instance, when they are "just" or decidedly wars of "defense" or wars against "unbelievers" or "rebels." Naturally, the conception of pacifism becomes problematic in this case. Furthermore, there exists a conception of a positive peace, which connects the abandonment of armed force with religious or cryptoreligious sanctions on the one hand and demands of social justice and inner peace on the other. There can, in addition, be distinguished a conception of a negative peace, which considers that the mere renunciation of armed force is the most that can be attained through intelligent politics.

Types of pacifism and peace

Social and religious movements with the renunciation of violence on their banners have often been the germ cells of pacifistic challenges, for which, on the basis of religious doctrines, they could provide a more or less precise ideological foundation. Among groups exemplifying nonviolent movements (as earlier defined) are those of Chinese Taoism, of Buddhism, of the Shīʿite branch of Islām, of medieval Christianity, and of certain Protestant sects. In its methodical application, however, the principle of negative actions espoused by these groups always turns out to be a procedure tenable only for minorities or elite cadres and this often causes the nonviolent movements to separate themselves from pacifism. The nonviolent movement of Mahatma Gandhi, for instance, is to be explicitly understood as a method of constitutional opposition within an existing governmental system aimed at relieving its own tensions and not at the solution of international conflicts; thus, Gandhi was not an integral pacifist. Nevertheless, besides certain emotional suppositions, the nonviolent movements generally share with pacifism an emphasis on the peaceful solution of conflicts through the renunciation of violence—though the nonviolent movements and pacificism do not always apply these principles in the same sphere.

GENESIS AND DYNAMICS OF WAR AND PEACE

It is impossible to consider peacemaking tendencies without taking into account the empirical evidence regarding the dynamic relation that exists between peace and war. Peace between different ethnic groups is held by many historical and ethnographic studies to be not a natural situation but a conscious creation, as Immanuel Kant proclaimed in his essay "Zum ewigen Frieden" (1795; "Toward Eternal Peace").

Causes of combat among primitives

Inherent conflict and its control. Among primitive tribes there is always present the possibility of a latent hostility, which does not always break out, however, into actual combat. This possibility is based on an ethnocentric conception of the world as comprised of simple kinship alliances, clans, tribes, and confederacies. An ingroup and an outgroup ("we" and "they"), with their corresponding inward and outward moralities, are strictly distinguished, so that friendship, solidarity, and peace exist, for the most part, only inside the ingroup, whereas xenophobia and readiness for battle prevail in attitudes directed outward. Whoever belongs to the outgroup is essentially an alien; friendly and peaceful relations with him are not excluded but have to be purposely established through certain rituals. Among these groups, military conflicts arise less from the wanton urge to attack than they do from a readiness for aggression issuing from an atmosphere of fear, tension, feelings of injury, frustration, and offense to their complex of honour and prestige. Well-defined causes and goals for war are seldom encountered—with the exception of blood revenge, with its goal of mere reprisal, which in its turn is answered by reprisal, and so on (theoretically) *ad infinitum*. An actual redemption from the feud becomes functionally possible when an authority that encroaches upon the parties obtains recognition; this authority is the root of the primitive state. Higher primitive races formulate more precise war goals: plunder, slaves, or the extension of the power of their own group by the incorporation of prisoners of war. There is a great reluctance, however, about annexing foreign areas, because the hostile foreign land is thought to be occupied by strange demons and, therefore, dangerous. But the adoption of strangers into their own group already prefigures the higher organized nations of the old Orient, the Sudan, and both Americas.

Methods of combat and peace-making

Methods of combat among primitive tribes are of two main types: first, an unprepared invasion of a hostile settlement at dawn with the aim of destroying it and, if possible, killing many inhabitants, including women and children; or, second, an open combat, announced in advance and carried out in an arena upon which both adversaries have agreed. Such combat is generally connected with certain further regulations and moderations—for instance, the prohibition of certain dangerous weapons, settlement of the combat through a match between duelists, sanctuary for cult places and channels of commerce, exemption from injury of women, children, and respected persons (older persons, priests, guests), which in practice means asylum for civil persons and a distinction between combatants and noncombatants. These regulations mark the genetic beginnings of the laws of arms with moderating and disciplining effects. It is especially the second type of combat, as practiced between traditionally hostile groups, that leads to a real and established peace. Such a peace is never amorphous but is confirmed in ceremonies and often strengthened by an exchange of women for intermarriage and the establishment of hospitable relations. In the case of primitive tribes, this created peace is perceived not as "eternal" but as having its place in a general rhythm of war and peace. It is usually ephemeral. Gauged by the ideal of positive peace, such interludes may seem trivial; but in human history they have meant much. The ethnology of war and peace suggests that relative stages of peace must be distinguished, and in reality the moderations and regulations of combat are already significant as elements of peaceful achievement.

Effect of religious sanctions

Efforts to confirm a lasting peace through religious sanctions have had little effect. Among primitive races (in parts of Polynesia, Melanesia, Africa, and North America), cultic alliances and confederations existed between different tribes whose members temporarily shunned hostilities with each other at times of a "truce of God." Such combines date far back into historical time (compare the amphictyons of the Hellenes and Israelites, associations initiated to defend a common shrine). Yet, the peace-creating effect of the common cult was never very strong. Genetically, the cult unions were the germinal forms of later supranational authoritative courts organized to try to establish a lasting peace. To sanction peace, however, involves the danger that war, if it does break out, will be marked by an additional element of quasireligious fanaticism. But if sanction systems cannot really eliminate armed conflicts, it is also true that the actual carrying out of conflicts can take place only within such a combine system, in which the adversary is no longer regarded as sovereign but as deserting or rebellious, and the struggle against him is then no longer war but federal execution, punishment, excommunication, or collective outlawing, so that the restrictions normally imposed against such an adversary by the articles of war are inoperative. This internalization is a setback in the development of martial and international law and is detrimental to the creation of a situation for a real peace. The holy wars of the Hellenic amphictyons, the religious wars of late antiquity (since Constantine the Great) between paganism and blossoming Christianity, the Crusades, and the later religious wars in West and East have always been waged with singular brutality and cruelty. Terminologically, moreover, they provide a broad opening for the perversion of language, which occupies such an important place in the semantics of "peace" rhetoric. This happens, in particular, when an element of fanaticism present in the competing religions can break in and, independent of the dogmatic content of the respective religions, announce "tolerance" and "peace."

Limiting the scope of war. There is, nevertheless, a kind of progress in the conditions for peace through the history of mankind, which is the achievement of politics with religion playing an important, though ancillary, role. Peace and security have gained ground through both the broadening of the geographical areas of peace and the expansion of the class of noncombatants.

Expansion of peace zones. By expanding smaller sovereign political units into larger ones, armed conflicts have been suspended within larger units. Naturally, this broadening has always stemmed from earlier peaceful—or, more often, military—annexations. As a consequence of such processes, a kind of imperialistic pacifism could easily be proclaimed. After many wars of conquest and annexations, for example, the emperor Aśoka of India (*c.* 265–238 BC) announced numerous edicts of tolerance, by which he made use of the Buddhistic ethics as a means of domesticating robber castes and rebellious and uncertain tribes. The same was done by Prince Shōtoku of Japan in the 6th century; the universal ethic of Buddhism aided him in shattering the traditional clan units and welding together a centralized state. The Achaemenid rulers in Iran made use of the religion of Zarathushtra for the same purpose, and Darius I wrote inscriptions comparable to the edicts of Aśoka. Such manifestations, however, are a matter of religiopolitical decrees and not of tolerance in the sense of the 18th-century Enlightenment. The regulations of the Christianized ruler Constantine the Great were also religiopolitical: a warfare of Christ and a Pax Christiana (Christian Peace) of the young church had to help confirm the Pax Romana. The fact that this process is always one of domesticating and taming of competing inner groups, parties, sects, castes, tribes, and small nations and a process of subduing or silencing the opposition within is illustrated by the epithet of the Oriental rulers, "Shepherds of the Nations"; by the comparison of pacified tribes with tamed beasts or the hope that they will be miraculously tamed in a future state (in the Old Testament); and by the Buddhist term *purisadamma* ("the human animal who can be tamed").

Imperialistic pacifism

All of these symbols suggest that a peaceful behaviour of man does not arise by itself but requires regulating and compulsory forces. This fact in no way impugns the religious sincerity of the rulers who employed such edicts and symbols, nor does it question the reality of the legal security that was guaranteed within the limits of peace of these realms. But this reality was created by war and force. The paradox of "imperial pacifism" is revealed by the insight of the philosopher Max Scheler, an early-20th-century Phenomenologist, who said during a time of declining imperialism that "the pure idea of law has no power in itself" but that right requires a power that guarantees it while it nevertheless remains right. This

Paradox of forceful pacification

principle, expressed earlier by Aristotle (and then by St. Augustine) in the formula that peace is the aim of war, is a genuine *aporia*, leading to insoluble logical difficulties; and politically seen, the principle has time and again been expressed in the paradoxical concept of pacification, which means exactly those violent actions through which an expanded area of peace shall be won and maintained. This phraseology first occurred among the Romans but was later taken over by other empires and most expressively by the Spaniards in their New World colonies, where the term *conquista* was replaced by *pacificación*. Characterizations of the imperial peace that correspond with this notion are, for instance, Pax Romana, Pax Christiana, Pax Hispanica, and Pax Britannica. In all of this terminology the heritage of the Roman conception of justice is reflected. In the case of the Romans, the terms *securitas pacis* and Pax Romana encompassed the whole area of authority of Roman laws—laws that, by their introduction among the subjugated peoples, resulted also in the introduction of the values of Roman civilization. Since Cicero and Julius Caesar, at the latest, *pacare* and *pacificatio* have been expressions denoting the military subjugation of a foreign nation and its incorporation into the jurisdiction of Rome. In this terminology, which still has aftereffects in the West, there is an inextricable interlacing of the reality of the territorially expanded peace and its security, the force and violence through which this situation was set up, and the ideological proclamation of peace and mutual tolerance as a means of domination. The opposition of those who are deprived of their political independence in the enforcement of this peace is not expressed in this terminology but is nonetheless implicitly contained in it.

Expansion of noncombatant classes. Next to the expansion of zones of peace, the recognition and expansion of the class of noncombatants during times of war is the most important step toward the goal of maintaining a relative degree of security for the life and property of the largest possible part of the population, even though it is not possible to protect the people completely from the actions of war. A privileged noncombatant class was found among primitive tribes and, indeed, existed among the Western nations as long as wars were conducted with mercenaries—*i.e.*, with minorities of combatants. It was lost in modern times by four paramount factors: (1) During the French Revolution, the principle of the equality of all citizens led to a general levy into military service and to the creation of enormous national armies. As long as the armies were small and operated with baggage-train and reinforcement columns, the largest part of the population could live in relative peace even in the midst of war. When the Napoleonic armies, however, changed over to living off the land itself, an important step was taken toward making war "total." (2) In military technology powerful mass weapons were developed that did not discriminate between combatants and noncombatants. (3) Psychological warfare was instituted to propagandize the population behind the enemy's lines and break down its resistance—the psychological equivalent of long-distance bombers. (4) And, faced with guerrilla tactics that dissolve the distinction between combatants and noncombatants (*e.g.*, by dispensing with uniforms and terrorizing populations), Western nations devised countermeasures that were similarly nondiscriminatory. Through these (and other) factors, structurally interwoven with one another, the traditional concept of a military "front" was antiquated: it became a general structural feature of modern military conflicts that the "front lines" were no longer clearly defined but were disarranged and confused. In addition, there arose a new element of national and revolutionary fanaticism, which replaced that of the earlier religious wars and was and is no less potent than the latter. The culminating point of this development is reached at the present time by the modern principles of the "revolutionary people's war."

PACIFISM IN THE HISTORY OF MAN

In ancient times. Classical antiquity knew no pacifism. The Hellenic poets complained about the evil and destruction of war; but the idea that things could be fundamentally different did not arise. The so-called pacifism of certain intellectuals of the 4th and 3rd centuries BC (such as Xenophon, a Greek essayist and soldier, and the Athenian orator Isocrates) was of an opportunistic, rather than a fundamental, nature. Protracted wars such as the Peloponnesian War, waged among the Greeks late in the 5th century BC, left an atmosphere of war weariness behind and possibly stimulated the idea that philanthrōpia ("humanity," "benevolence") and related conceptions are authentic values not only for private but for public conduct as well. Yet, the Hellenistic rulers—in particular, the Ptolemies in Egypt in their peace proclamations (*philanthrōpa*)—were the first to make amnesty a repeatedly practiced institution for rebels, emigrants, and persecuted people. The thought of a general peace presupposes a change of consciousness that would make the concept of unitary humanity possible. This consciousness had not been possible on the basis of the Hellenic polis (or city-state) but required an expansion of the horizons to the Hellenistic cosmopolis. Thus, the first timid stirrings of pacifism can be seen to emerge after the expansion of the peaceful zone in the Hellenistic states. Several intellectuals early grasped the idea of a world state without courts of justice, temples, or a monetary system. The Stoic Law of Nature showed certain very modest tendencies toward the idea of a lasting peace. The Stoic ethic, nevertheless, remained essentially a private ethic that embraced the ideals of an inner peace composed of apathy, nonaction, and strength of mind for the single individual but did not carry over such ideas to the community. The same observation can be made regarding the religiophilosophical systems of the East, where conceptions of a Law of Nature were never entirely awakened: the Taoist idea of *wu-wei* ("nonaction") and the Jainist and Buddhist demand for *ahiṃsā* ("noninjury") were demands made upon individuals and served their inner peace but remained irrelevant for political action. Gandhi was the first to interpret *ahiṃsā* positively and in the sense of a social obligation.

Greek approaches to peace

Roman juridical pax

In contrast with the Hellenistic conception of peace, which simply meant a peaceful situation, the Roman conception (pax) had from the outset a judicial character: pax is a covenant that creates a just situation, which rests upon bilateral recognition. The Roman conception of peace is therefore more political than the Greek conception, and insofar as pacifist ideas in Europe took the form of international law, they go back to the tradition of the Roman law. Additionally, near the beginning of the Christian Era there arose another complex of pacifist aspirations: "eschatological" pacifism, closely related with the conceptions of a revived "Golden Age," which was destined later to permeate all other forms of pacifism, whether humanistic, juridical, or illuminative, as a strong, emotionally resounding, messianic, and prophetically inclined undercurrent. A strong longing for peace spread abroad in the Roman Empire toward the end of the republic as a consequence of uninterrupted civil and foreign wars, a longing reflected, for example, in the myth of a divine, sunlike child who would redeem the world from the "eternal horror" (Virgil) and, as saviour and prince of peace, would lead to an era of world peace.

It was natural that in the principate of Augustus, the Pax Augusta would be interpreted with the aid of this prophecy. In Virgil, however, the renaissance of the era is portrayed as being at least as important as peace itself, which is thus not absolute because it is said that later there will be wars yet again. Clearly, these messianic-prophetic ideas were admitted into the legend of the Christian birth of the Messiah. The Pax Romana, however, was not really universal, because it was always regarded as a world peace for the civilized world, and it thus excluded barbarians; and obviously the peace would have to be defended against these barbarians. Accordingly, the peoples that were not integrated into the Roman Empire were always excluded from the peace, just as the pagans, unbelievers, and heretics were later to be excluded during the Christian Era. When, late in the 3rd century, Emperor Aurelius Probus could finally say that he no

longer needed soldiers and could demobilize his troops, this alleged pacifism was the luxurious product of a saturated imperialism. Because the threat to the frontiers of the civilized world by the barbarians and pagans never ceased, this pacifism could never become integral. When this was connected with the religious sanction, it always remained in the guise of an eschatological pacifism and cultivated the idea of a last war, which must be conducted in order to make the world ripe for an empire of eternal peace ("the war to end war"). This conception of an integral pacification through an ultimate war has also in its secularized form remained tempting through all later centuries and, in particular, in its world-revolutionary–Communistic version.

In medieval Christendom. Christianity, with its evangelical message, offered considerations in support of individual nonviolence as well as of collective peacefulness. It is questionable, however, whether the ethics of Jesus reflect the apolitical and pietistic pacifism of the Essene sect, a strict monastic brotherhood that had numerous followers in Palestine. There are words in the evangelical message that lend themselves to an interpretation of "peace" as the peace of mind of the individual ("My peace I give unto you: not as the world giveth, give I unto you"), but this unworldliness is counterbalanced by other sayings praising those who are ready for peace ("On earth peace, goodwill among men" and "Blessed are the peacemakers," in which the Greek *eirēnopoios* may be equated with the Latin *pacificus*), which can be interpreted in the sense of an integral pacifism and is, in fact, so interpreted by the many radical followers of Christ. As a rule, however, this peace was only open to minorities, or sects that practiced a rigorous ethic, while the church had to compromise with worldly necessities. Since Marcus Aurelius and Commodus, in the era of the Roman emperors, the "question of soldiers" (*i.e.*, the question whether a Christian could be or remain a soldier) had continued to perplex the faithful. The Church Father Tertullian answered the question unambiguously in the negative but testified at the same time that there were many Christians in the Roman Army and that his conception was therefore not generally shared. Though it seems that Christian soldiers who suffered a martyr's death are an exception, desertions from the army after inner or outward conflicts were, in contrast, more frequent. In consequence, to practice the Gospel strictly within the military profession was, naturally, hopeless. On the other hand, there were not only the Old Testament sources with their warlike authorities to which one could refer but also passages in the Gospels, such as those citing the centurion of Capernaum and the centurion of Caesarea, with the help of which attempts have been made to prove that the military profession could not be completely non-Christian. Subsequent to Tertullian (early 3rd century), the symbols of the military service, discipline, and combat even break into the Christian sermon, so that a Christian became understood as *miles Christi* ("soldier of Christ") or even as *miles gloriosus*, who had to fight the demons; the church became the camp of God, and the schismatics were called the gang of Korah—in reference to an ancient rebellion against Moses. Military language, in fact, became a fashion, as it did again later in the order of the Jesuits.

The "question of soldiers"

In the beginning of the 5th century, St. Augustine, bishop of Hippo, in his work *De civitate Dei* (*The City of God*), created a reconciliation between the ideas of a worldly and a supraworldly state and built some thoughts on peace into this counterpoised system, which reflects his enthusiasm about the church's victory in the world but also his impression of the threat to this world posed by the invasions of the barbarians—in particular, the invasion of the Goths (AD 410). Augustine saw the empire of a thousand years, of which the Apocalypse had spoken, as already realized in his own present epoch—but only insofar as the state is spiritually penetrated and ruled by the church. Without such influence the state is no better than a band of robbers or a city of the devil; for worldly states, taken by themselves, arose out of sin, even though this sin is called virtue. They can establish, though with the greatest of difficulty, the worldly peace, Augustine held, but not the heavenly peace, which is the greatest good and, indeed, the eternal harmony itself—a standard by which all worldly achievements are measured, including worldly peace. This worldly peace, which Augustine also called the Pax Babylonis, is in fact only a pseudo-peace, which, nonetheless, need not be despised; for, even in this disfigured form, the peace is still worth striving for, and a pious man may seek it as long as he must live in community with impious men—though only insofar as it allows him to consider the heavenly peace as well. Beyond this, in Augustine's view, the devout man does not have to take part in the worldly peace and, indeed, must even destroy it when it is contrary to God. The same applies to nations. Consequently, a war against evil men is as surely justified as the combat of the martyrs against the demons. Admittedly, such a just war is not a happy thing, and the most incomplete worldly peace remains a relative good and is, in fact, according to the interpretation of Augustine, all that can be attained for mankind on this earth. Nonetheless, this worldly state should always be interlaced with the spiritual reality of the heavenly state, by the image of which, alone, does the earthly state have a right to exist. Moreover, it is above all necessary that the worldly state shall serve the church and stand up against all peacebreakers from within and without and especially against heretics and schismatics. Thus, for Augustine, the state that is ruled by the church is a magnificent, comprehensive, and powerful sanction system.

This idea, which is that of the Catholic Church, was maintained throughout the Middle Ages. Charlemagne added the epithet *pacificus* to his emperor's title, and the German kings called themselves *Friedensfürsten* ("peace princes"). Behind these claims lay the popular millenarian expectation of an eschatological emperor, which, since the 13th century, was more closely related with the sects and orders than with the official dogma of the church. The Sibylline oracles, some of whose prophecies, though pagan, were at times taken seriously by Christian writers, reduced the doctrine of an eschatological emperor to the plane of history and saw him as a saving warrior of God who suppresses the power of the Antichrist and introduces an era of peace. Taken wholly in the sense of Augustine, however, this peace was not absolute but included the possibility and even the obligation of combatting unbelievers, heretics, and rebels; the true peace entails the just war in the name of Christ. Thus, it could happen that the reigns of several kings were praised by chroniclers as times of peace whereas in reality they were filled with war. Thus, medieval pacifism, by excluding certain categories of persons, groups, and nations, was always incomplete; and the background for this exclusion was always quite real because there were always heretics, schismatics, and, at the borders—as successors of the barbarian tribes of the Roman era—unbelievers: Arabs, Mongols, or Turks. This world view was described in terms of a dualism, or dichotomy, of good and evil spirits, Christians and non-Christians, and, as the latter were poorly known, the world view was strongly demonological. Thus, the sphere of the real as well as of the ideal and sanctioned peace was always limited, leaving outside of its province a very large part of mankind as demonic and doomed to hell. The conceptions of Dante Alighieri were also governed by this dichotomy, for he conceived of the peaceful state as one that must be outwardly defended. Moreover, the attempts to limit internal wars by a truce of God (*treuga Dei*) met with only trifling success.

The eschatological emperor

Probably the first attempt to overcome the dualistic concept was made in the late Middle Ages by Cardinal Nicholas of Cusa (Cusanus), a scholar in many fields, whose book *De pace fidei* ("On the Peace of Faith") reflects the impressions made upon him by the conquest of Constantinople by the Turks (1453). Cusanus abhorred "holy wars" and believed that the different religions should tolerate each other. He caught the vision of a kind of League of Nations, which would have to accept his philosophy of the coincidence of opposites and derive from this a peace in religious faith.

In the modern world. Since the time of the Renaissance, the possibility of a world free from wars has been considered by several intellectuals, who had very different relations, however, to the realities of politics. The humanist theologian Erasmus of Rotterdam (died in 1536), whose thought was permeated by the idea of a renewal of mankind by a deepened understanding of the Holy Scriptures, was cosmopolitan in his sentiments and an adversary of wars; he taught that the highest ideal of mankind would be peace and concord (*tranquillitas orbis Christiani*). The 17th-century French monk Émeric Crucé is important because he was the first of a series of thinkers who saw the main cause for the outbreak of wars in the strong-handed, dynastic power politics of the princes. Crucé perceived the remedy to lie in an appeal to the moderating reason of the sovereigns and in the improvement of the judicial relations between states. He thought that a transfer of the political pretensions of the rulers to the public would improve the situation. Moreover, the later legal pacifists shared, for the most part, the conviction that the public's power of reasoning was greater than that of the sovereigns. At the beginning of the 17th century, Maximilien, duc de Sully, who was a minister under King Henry IV of France, conceived a plan of European federation that was supposed to re-establish the religious unity of Christendom and to expel the unbelievers from Europe. The plan remained unrealized, notwithstanding attempts to bring about negotiations on it between the European royal courts. One hundred years later, after the Peace of Utrecht (1713), Charles, abbé de Saint-Pierre, a French social critic, again demanded the establishment of a confederation of states that would guarantee an eternal peace; but it too, was in vain. The great teachers of international law of the 17th century, the broadly learned Dutch scholar Hugo Grotius and the German publicist and jurist Samuel von Pufendorf, were not as much pacifists as they were designers of the just war, and only the presumption that the latter was considered an exception moves them toward semipacifism. The conceptions of Natural Law held by these and other thinkers reveal more and more in the following period the features of a revolutionary ideology reflecting the interests of the rising bourgeoisie as against the postfeudal or absolutistic relations of constitutional law. The abbé de Saint-Pierre had already demanded that, if necessary, the confederation to be founded had to fight those sovereigns who refused to join the new order.

Diverse peace proposals

The culminating point against the sovereigns became even more evident after the outbreak of the French Revolution. Even Kant, in his work *Vom ewigen Frieden* (1795, 1796; "Of Eternal Peace"), which contains many realistic insights, defended the claim that the monarchies tended toward wars only because the sovereigns regarded their states as their personal property and that, compared to this, a republic would be peaceful. This illusion had a long-lasting aftereffect. In the 19th century Sully's and Saint-Pierre's ideas were realized in an alliance of the great powers (1815–18), which thereupon became identified with the autocratic system of Metternich, known for its abhorrence of any essential change. This was an alliance of the sovereigns, however, not of republics. Other supranational organizations also existed after 1815; many voluntary pacifist associations were founded (New York, 1815; London, 1816; Geneva, 1830; Paris, 1841; and other cities), which organized congresses (Brussels, 1848; Paris, 1849; Frankfurt am Main, 1850; and London, 1851). The theme of pacifism thereby caught the public interest and inspired an extensive literature. General disarmament, the establishment of referees' courts to consider international conflicts, and the placing of moral stigmata on loans for purposes of war were all proposed. Some of these ideas were later realized in the Court of Arbitration in The Hague, in the League of Nations, and in the United Nations, as well as in temporary disarmament conferences. Nevertheless, these proposals remained without effective response during that time. The real maintenance of a relative peace in the 19th century was accomplished through the statesmanlike political establishment of a balance of power among the five great European states. The peace was also upheld by the grace of the Pax Britannica, which lasted as long as a British naval force existed and British finance retained its dominating position. These factors did not accomplish universal peace, but they created a certain control and localization of military conflicts. Those who fostered the system of free trade and expanding capitalism were not desirous of war, but they created the mentality of what was known as the bourgeois-liberal "Manchester Pacifism," based not on altruistic motives but on a utilitarian system of values that generally opposed an expansion in armed conflicts. The champions of this system wanted to rule but were against armed conflicts of imperial form.

Peace organizations

There is no particular correlation between Communism and pacifism. The chief theoreticians of the former, Friedrich Engels, Karl Marx, and Lenin, were influenced by the military philosophy of the Prussian strategist Gen. Carl von Clausewitz, and they nourished the idea of a world revolutionary war. For Marx, "war" and "revolution" were interchangeable terms. Lenin explicitly rejected pacifism. The idea, however, of justifiable wars against the capitalistic classes moves the ideological system of revolutionary Communism toward eschatological modes of thought, which indulge in dreams of universal peace in a classless society following the world-revolutionary victory of the international proletariat. But the accent falls less on this finality than it does on the justifiable war that will lead in this direction. Thus, the idea of national war has been accused of creating a sentiment not for universal peace but for war, pugnacity, and hate.

Marx and Communism

NONVIOLENT MOVEMENTS IN MODERN TIMES

While endeavours, valuations, ideologies, and programs are involved in pacifism, the device of nonviolence is an immediate method for the action of individuals or small but determined and convinced groups. Though chiefly a modern phenomenon, the method was understood by the Chinese Taoist wise men (such as Lao-tzu and Chuang-Tzu—in the 6th and 4th centuries BC) as negative action, nonaction, or nonresisting. In this case the method was completely apolitical and escapist. In practice, it was a course of withdrawal and elastic evasiveness. Yet, it also displayed a positive accent—"the soft water, if moving," will in the course of time "wear away the hard stone"—an accent by which this method is correlated with the virtue of patience and adapted to a sense of time that is more in accordance with Eastern religions than with Western activism. When the philosophy of nonresistance is connected with a positive goal and is practiced by an organized plurality, it becomes a nonviolent action. Nevertheless, if it preserves the terminology and ideology of negative action, as in Gandhi's philosophy of suffering, it becomes especially effective through the action that publicly interprets itself, paradoxically, as a nonaction.

Specific modern movements. In the past four centuries, nonviolent action has been proclaimed and practiced in exemplary fashion by certain Protestant sects, most convincingly by the Anabaptists, the Quakers, and the Mennonites. Theologically speaking, the purely unworldly demands and rigorous ethical principles of the Sermon on the Mount, and the religious natural law derived from them, were mobilized in radical religious groups who, esteeming themselves to be especially qualified, embraced the idea of a purely spiritual, "invisible church" and thus separated from "the world" and refused to become involved in state offices, legal courts, the oath, and military service. These refusals were partly a consequence of the ethics of the Sermon on the Mount (taken literally) and partly an offshoot from the general anti-institutionalism characteristic of this type of religious group from early Christian times. Therefore, for the English spiritualistic sects of the 16th century (for example), war was as serious a problem as the legal coercion of the government. Theologically, Calvinism, more than any other creed, found war to be a problem: if at all, only defensive war was to be allowed. Especially with the Calvinists, and above all, with the sects, a humanitarian movement grew up directed against war and in favour of its compensation by a system of covenants and arbitrations; but it was

Nonviolence as practiced by Christian religious sects

always in conflict with the belligerent and imperialistic inclinations of the majorities. Alongside the secularization and superficialization of the religious impulses, however, all of these groups and movements had to adjust to the worldly powers, which alone were able to safeguard the domination of the "right" creed from without—thus re-enacting the situation of the late Roman Empire. The Quaker community in Pennsylvania (1683 to *c.* 1770) provides a good example: it was decidedly nonviolent and pacifistic, but was entangled in the quarrels between England and France, in which it sided in warlike manner with the mother country; thus the colony lost its Quakerish stamp. While the Quakers were present in England and North America, Mennonite sectarian colonies flourished in The Netherlands, Germany, and Russia, until their recent migration to Canada. They were highly esteemed by the rulers in former times because of their industrial skill; hence their refusal of military service was tolerated. On the whole, their "pacifism," like that of many other sectarian manifestations, remained without any radiating diffusion into the broader society.

Gandhi's nonviolent activism. The most massive, comprehensive, and historically effective example of nonviolent activism is that of the movements unchained and organized by Mahatma Gandhi. Though Gandhi was not a theorist, he gave, throughout four decades, the most precise and ideal justification for nonviolence. He collected the richest experiences about practical successes and failures and designed a systematization of nonviolent campaigns, in which the methods of noncooperation and civil disobedience were conceptually and practically differentiated and graded. The religious philosophy of nonviolence has stronger Western roots than those of which Gandhi himself was conscious—in the examples, for instance, of the Puritan sects, the British spiritualists, the Quakers, the British suffragette movement, the Irish boycott practices (Sinn Féin), and in the reading of the Bible (especially the Sermon on the Mount), and such authors as Henry Thoreau, John Ruskin, and Tolstoy—although Gandhi also joined in with the methods of the Indian *dharma sitting* and the Islāmic *hijrah*. The expression *satyāgraha* (the force that is born of truth and love) was coined by him in an attempt to tie the practice of nonviolent procedures to ethical principles. While speaking as a rigorist, Gandhi declared that nonviolent actions were worthless when not related to the sentiment of love for one's enemy; but, while acting as a political practitioner, he was principally satisfied with effective action. He always attempted to control the campaigns of noncooperation and civil disobedience in their organizational phase and repeatedly interrupted them when violence occurred. Limited political goals were connected with the general goal of educating and emancipating the Indian masses for their political independence. Inner freedom and salvation were seen together with the economic deliverance from imported goods, emancipation of the untouchables, rural self-sufficiency, and political self-determination. Gandhi attempted to act in exemplary fashion as a charismatic leader—authoritative and, in practice, often authoritarian. His many visible symbolic actions, including numerous hunger strikes "unto death," were demonstrative actions employed to enforce certain political compromises. The fascinating effect that Gandhi had on his disciples and on a worldwide public of Western propagandists lay, in part, in its presentation of a doctrine that was at the same time an order for action and, in part, in its connection with mysticism and activism. This doctrine offered salvation (*mokṣa*) but simultaneously was interpreted as a revolutionary "direct action" in the sense of the French Syndicalist Georges Sorel, who envisioned an uncompromising elite who would lead the proletariat—with the only difference being that the action should be nonviolent, in contrast with the examples set in the West. Gandhi was not a pacifist in the strict sense of the word. During World War I, for example, he agreed to send Indian troops away to the European seats of war, and in World War II he agreed to set up an armed resistance in case the Japanese threatened the Indian borders.

Civil disobedience and *satyāgraha*

As far as the political effectiveness of nonviolent campaigns is concerned, it is necessary to distinguish between the limited results of single actions and the analysis of the historical results of whole chains of actions with far-reaching goals. Gandhi's single actions were often rather successful, at least as long as the British had not yet learned to adjust to these unexpected methods. The campaigns, as a whole, that were led in India from 1919–20 are to be judged with respect to the end result: the independence of India in 1947. Yet this result was not exclusively nor even predominantly produced by nonviolent actions. Since it was combined with the partition into two states, India and Pakistan, and since one of Gandhi's chief goals had been to reconcile Hindus and Muslims, this division by religions signified a serious failure. The separation of India from Great Britain was also hastened, in fact, by World War II and came at a time of general decolonization all over the world.

The pariah ethic

A more important aspect of Gandhi's policies was his identification with the role of the untouchables, such as those of the low-caste pariahs, which was part of his tendency to confound political emancipation with personal salvation and thus to make external politics an emanation from the activities of the soul. He declared that Great Britain's subjugation of India was a punishment for the treatment accorded by orthodox Hindu society, with their rigorous taboos, to the untouchables and that consequently the liberation of the untouchables (whose name he changed to Harijan, God's Children) would be a condition and a symbol for the national liberation of India. This identification illuminates the ethic of nonviolence, which is (in the words of the German sociologist Max Weber) a "pariah ethic"; for, notwithstanding Gandhi's assurances to the contrary, it is a weapon of the weak. It appeals to the situation of the underdog and the rejected while it cultivates a philosophy of suffering. It attempts to overpower the rulers by patience, love, conversion, transformation of hearts, and (speaking in modern terms) change of consciousness, especially by bewitching the adversary with a feeling of guilt or wrong. In the case of Gandhi, this was all highly sublimated, but this has not always been so. Nevertheless, these features of the pariah ethic explain, for the most part, the enormous response that the exemplary effect of nonviolent movements inspired in many countries, especially in those countries of the Third World, in which the social situation of the underdog or the "external proletariat" was similar to that of India and therefore could evoke a psychic situation similar to that of Gandhi's South Africa and India. Consequently, nonviolent direct action is a watchword for many spokesmen and demagogues of the Third World. The readiness for action heightens also the consciousness of the groups and accomplishes a turn of the pariah consciousness into the consciousness of the mission of an elite.

Gandhi's subsequent movements could not all maintain the unity of political and religious purposes. While official India built a myth around the name of Gandhi, his actual aftereffect was politically largely neutralized.

U.S. civil rights and other movements. Besides the smaller movements of Albert Luthuli, a South African tribal chief who was awarded the Nobel Peace Prize in 1960, and of Danilo Dolci in Sicily, the civil rights movement in the U.S. became the most important manifestation of nonviolent principles. Its best known leader, Martin Luther King, Jr., was strongly influenced by the doctrine and example of Gandhi. Nevertheless, the civil rights movement is grounded in a more general tradition in which the impulse of Protestant sects, especially the pacifist Quakers, and the works of the romantic nature writer Henry Thoreau and other nonconformists were just as effective as the religious ecstatic spirit of the Negro churches and sects and the pariah-elite consciousness developed among these groups, which is connected with their conviction that they are the true apostles of Christ on this earth. King was also influenced by the semipacifist and critical pacifist doctrines of A.J. Muste, of Walter Rauschenbusch, a proponent of the social gospel, of the moral philosopher Reinhold Niebuhr, and of Mordecai

Influences on Martin Luther King, Jr.

Johnson, formerly president of Howard University, who was the first one to refer him to Gandhi. The whole movement favoured, like Gandhi, symbolic actions—walks, marches, and pilgrimages; the millenaristic spirit of a departure was always nourished. Yet the element of demonstration was undoubtedly a more important factor in the public eye for awakening the democratic consciousness, even when the immediate purpose of the demonstrative actions was not always attained; the effects of the civil rights movement are, in any case, obvious. If, on the other hand, the symbolic character of actions is overly accentuated, the danger exists that the political goals will be defined at the outset by the limit of what can be attained by nonviolent methods. (This objection was posed against Gandhi by Jawaharlal Nehru, at the time of their joint nonviolent campaigns.)

In recent history there have been actions of passive resistance or obstructionism in Western countries completely without any foundation in religion, philosophy of life, or ideology. The so-called Ruhr Battle against the French occupation in Germany in 1923 was a failure. In contrast, a certain success has been attributed to the Fabian tactics of some population groups in the Western countries (The Netherlands, Denmark, Norway) that were occupied by German troops during World War II. Nonviolent resistance against the massive terror of totalitarian regimes (the German Democratic Republic, 1953; Hungary, 1956; Czechoslovakia, 1968) has been completely ineffective or impossible from the beginning. When Gandhi recommended *satyāgraha* to the Jews in Hitler's Germany in the '30s, this proposal was rejected with good reason by Martin Buber, a Jewish Existential philosopher. In cases of intelligent application, however, the nonviolent method can function if there is at least still some remnant of a joint base of reciprocally recognized game-rules—as was the case with Gandhi and the British bargainers in South Africa and India.

Tendency to turn to violence. Many movements that begin with a program of nonviolence and an irenic ideal turn to violent actions in the course of events. This fact can be established in respect to nonviolent movements in their end results as well as to the processes of single actions. Some nativistic movements, as, for example, those of certain messianic North American Indian tribes within the complex of the ghost-dance movements (which envisioned an apocalyptic cataclysm at which the dead would rise to announce the vanishing of the white man and the regeneration of pristine Indian life) started with pacifistic ideals but later became violent. The same can be observed among nativistic movements in New Guinea This was seen, too, in the case of the dualistic sects of the Bogomils and Cathari that arose in the Balkans after AD 1000, in some messianic Islāmic Mahdist movements dedicated to restoring primitive Islām, and in Gandhi's and King's campaigns.

Specific instances of the turn to violence

The turn to violence is partly caused by the reaction of the surrounding world or the adversary; but there may also be an inner trend or real dialectic in the movement of nonviolence into violence. Since many leaders of nonviolent movements are pure idealists fostering the conviction that "from good only good can arise" as "from evil only evil," they may be unable to see through a dynamic that conjures evil actions from good intentions. The idea of a "last war to end all wars"—*i.e.*, eschatological pacifism—is another great allurement; and, besides, it is difficult to keep a great multitude of people in an attitude of mere adventism when at the same time great hopes are being generated in them. It is also seldom possible to discipline the members within a nonviolent movement so that it remains throughout as mild as it was at the beginning: some leaders lose the helm while it is in their hands and cannot prevent bloody transgressions; others are manoeuvred out by a second set of leaders who take the helm and again precipitate bloody actions; and in still other cases the leader himself, at first a partisan of principles and a prophet of nonviolence, may turn into a millenarian prophet and apostle of terror. This type of leader then throws off his Gandhism and returns to the position of the authentic ideologists of violent direct action, as Georges Sorel and, presently, Frantz Fanon and the Existentialist philosopher Jean-Paul Sartre. This development is especially confirmed in the case of demagogues of the revolutionary rebellion in the Third World. There are smooth transitions from nonviolent resistance (with the use of pacifist language) to civilian defense (rural and urban guerrilla warfare) and to revolutionary people's war. This seems particularly to be a development in the poor countries and indeed a promising one—from the viewpoint of the revolutionary activists—because the combination is simple, whereas a modern military machine set against it is vulnerable. In recent times some intellectuals have also discussed the possibility of employing this new method of combat in the industrial countries. They urge that the nonviolent, political, psychological, civil, and social elements of the guerrilla war be maximized and the militaristic and territorial elements be minimized. In such a process the quantitative process of change in the guerrilla war turns at a certain point into a qualitative change, giving rise to the new quality of social defense, of which the active supporter is no longer some sort of partial organization but the total civil population.

CRITICAL EVALUATION OF THE MOVEMENTS

Ethical questions. Critics often issue warnings against simplistic views of the ethics of peace and conflict:

Relevance, scope, and misuse of ethics

1. Some critics have argued that it is difficult to correlate the practice of a certain peaceful and nonviolent behaviour with any definite, ethically positive viewpoint (as Gandhi, King, and all ethical partisans desire). As experience teaches, the results and effects of nonviolent methods are independent of their foundation in any religion or view of life; nor is there any guarantee that the representatives of peaceful ideals will personally represent these ideals. Thus pacifism and nonviolence are, from the ethical standpoint, neutral.

2. The advocates of pacifism and nonviolence, it is said, take the change from individual to collective (or social) ethics too lightly, or they do not see at all the problem of this change. According to Max Weber, this is the main problem of the ethics of the Sermon on the Mount. Thoreau acknowledged that only an individual, not a collective body, has a conscience, but he thought that this inconsistency could be resolved by merely summing up sheer individuals with a conscience. But this is a short circuit, since an organized society includes not only idealistic and ethically notable activists but also half-hearted fellow-travellers, partially resisting, or half- or totally-compelled members; in short, a sum of persons with different motives. In the actual war, guilty people and nonguilty people can be at the same front. Reinhold Niebuhr, an American moralist and theologian, has criticized as naive the democratic belief in the identity of personal and general interest.

3. Critics have charged that the methods of making a display of suffering that put an adversary in a morally bad light pose ethical problems. The formal quiet submission and suffering is supposed to evoke a readiness in the adversary to lay down his "false convictions" and be converted, an intention that is different only by degrees from the methods of brainwashing. The renunciation of physical means of combat and the moralizing of combat do not make it nonviolent but possibly only more malicious. Besides, it is difficult to draw a line between morally allowable pressure and unallowable moral extortion. The tendency to moral destruction can take the place of physical destruction. Particularly suspect is the spiritualizing of combat that turns a normal conflict, as King has said, into a combat of the powers of light against the powers of darkness instead of acknowledging the reality of the objects of group conflicts. Because of this interspersion of religious terminology, the adversary is demonized and is treated worse than he was before. Thus, a religiously founded dualism does not moderate the combat; it justifies, in principle, the total liquidation of the adversary.

4. As highly as a man may appraise the value of peace, it is wrong, according to many moralists, to make this value absolute; peace may not necessarily be a positive value in every case. As Reinhold Niebuhr showed, there

Peace as a relative value

is no peace without coercion, but there are different degrees of coercion. In nations that are pacified by too much coercion, the value of peace is not unconditionally negative, but it is disputable. There can be a "peace of the grave," which is of a dubious value. No one knows how much suffering, misery, and frustration have been accumulated among the people under despotism and dictatorships, both in the past and the present, who were condemned to remain "peacefully" still and silent. Man's world is one of conflicting values, not only between different cultures but also within the same culture. Thus, a relevant political ethic may not succumb to what Nicolai Hartmann, a dominant philosopher in Germany between the world wars, called the "tyranny of values." This ethic, therefore, may not absolutize the value of peace but has to counterbalance it with other values—in particular, with the value of personal freedom.

Pragmatic and other questions. Some critics have argued that the proponents of pacifism and nonviolence have not faced up to the realities of the human situation:

1. It has been claimed that man sometimes overestimates the goodness of human nature and overlooks the fact that an element of coercion exists in every society, that there are gradations of this coercion, and that it is therefore a question not of abolishing coercion but of favouring the gradations that are felt the least. In this view, peace is, as Niebuhr argued, always a coerced peace. Coercion, as it is, is ethically neutral and can be used either to commit or to suppress injustice. This problem cannot be precluded by moralistic claims, appeals to reason and conscience, and frontal attacks on prejudices—approaches that are useless and even dangerous because they arouse the illusion that something is being done, whereas in reality everything remains the same.

2. The demarcation of nonviolence from violence is clearly debatable. As a rule, nonviolence is understood merely as avoidance of physical attacks on an adversary. On the other hand, as Weber has charged, the theoreticians of nonviolence have overlooked the unintended indirect results of formal nonviolent actions, which can be more destructive than physical violence (among which are the destruction of life and property as a consequence of a commercial strike or boycott or the interruption of food supplies or medical care). According to this view, the supporters of nonviolent methods simply cover themselves with the language, the outer form, and visibility of nondamaging behaviour; they use a peaceful and passive terminology to achieve results that in fact are as destructive "as an earthquake" (as King himself has expressed it); and they connect a negative action that has destructive effects with a semantics of suffering.

3. It is not certain that human aggression can be abolished merely by the suppression of violent impulses, even if it is connected with a peaceful and friendly terminology. In India, the decades of Gandhi's nonviolent campaigns were followed by a wave of bloody reciprocal mass persecution of Hindus and Muslims that took the lives of hundreds of thousands. Some authors, in fact, have asserted that to intentionally dam aggression could cause even more violent outbursts of aggression in the future, a thesis that is still under discussion.

Depth of human differences

4. The spokesmen of pacifism and nonviolent movements, it is claimed, often fail to comprehend the depth of the gap that divides human groups through religion, nation, caste, and class. Consequently, they fail to grasp correctly the reality of the group conflicts, which they therefore overlook or consider more tractable than they actually are. When Nicholas of Cusa dreamed of a reconciliation of the different religions of mankind, he had no idea of the differences and the antitheses in the doctrines and in the existential sentiments of these religions. The same simplistic approach was taken by many optimistic, pacifistic, and enlightened men in later centuries. The "mankind" that was to be peacefully united was actually an unreal concept for many centuries. It was not until the 19th and 20th centuries, with their researches in comparative religions and cultural sciences, ethnology, psychology, and sociology, that it became possible to look into the depth of the differences in motivations and senses of life in various nations and societies. Conflict theories that are based on this research are still in process. Many of the attempts that have so far been made to account for group conflicts out of prejudices and to do away with these prejudices through better adjustments, edicts of toleration, and attempts to persuade may not take the reality of these conflicts seriously. Pacifistic proposals, such as the improvement of communication and information, that are suggested by many theoreticians cannot really solve such conflicts, but they can create new ones. Many forms of nonresistance and nonviolence, too, are more capable of miscarrying group conflicts than of solving them.

Besides, the attitude toward the problems of war and peace, pacifism, and violence and nonviolence might depend largely upon the personal perspective and group membership of the critic. It makes a difference whether the critic is personally involved in such problems in his own country or whether he sees them only from a distance. The activist, the simple follower, the resister, and the armchair theoretician all have different perspectives. It is often those who have not experienced dictatorship who preach nonviolent resistance against it.

Semantics of peace and war

5. The most difficult problem lies in the manipulation of the language. It has been pointed out that a falsification of peaceful language is usually established in the dynamics of war and peace itself and particularly in the course and conception of "pacification." Since peace applies to "good" and war to "evil," the political powers like to adopt an irenic and pacifistic language. They attempt to usurp the role of the attacked party in the case of conflicts by making an effort to interpret their actions as peaceful in the eyes of the world, even when they do (or have in mind) the opposite. In modern times this practice has improved through dialectic and has caused a babelized bewilderment, not only in the case of listeners and readers but also in the case of the speakers of that language themselves, who no longer know when they deceive others or when they deceive themselves. The language no longer has the function only of communication but has also that of an ideological means of combat. One and the same action can be an action of peace or an action of war, depending upon whether one or the other of the combatants is speaking. The meanings of words are no longer firmly fixed, but have become more relative in respect to the ingroup or outgroup. One can talk of peaceful coexistence when military aggression is planned and is being prepared. The nonviolent terminology is just as popular as this instrumental pacifism. A revolutionary programmatic can be draped as peace research, guerrilla war can be called civilian defense. Moreover, perfectionist pacifists are encountered who define peace so broadly that it includes social justifications that could be made to sanction armed intervention in every country. This ideological usage has evoked great uncertainty among the people.

PERSPECTIVES ON THE PROBLEM OF VIOLENCE

The technical development in the violent means of warfare had reached such a point in the decades prior to 1970 that no political goal is imaginable that would be commensurate with the potential for mutual annihilation. It does not necessarily follow, however, that a turn in human reason for the abandonment of all wars will now occur; but there exists only a certain probability that the means employed to solve international conflicts can remain below these potentials. The conflicts themselves may remain for as long as the national interests that can be conceived as realities exist; and these may prevail for as long as the idea of national sovereignty exists—an idea that, since the historical phase of decolonization, has expanded to include ever more political units.

Idealism, meliorism, and realism

Historically, there are no noticeable signs that the practice of violence has diminished among mankind. There were some short periods during Gandhi's nonviolent revolution in the '20s and the civil rights movement in the '60s when some enthusiastic people and idealists believed that at last the right method had been found to bring the settlement of group conflicts to a greater perfection. But the further development of these and other movements

did not encourage such hopes. In recent times, as violent acts within the nation's borders seem to be increasing, some observers claim to discern a certain tendency for violence to shift from foreign to domestic politics. This tendency provides no encouragement for the pacifists, however, who cannot be satisfied by the substitution of civil for foreign wars.

It may be that the perspective for pacifism would become more encouraging if it would renounce the perfectionist illusions of a positive peace and be satisfied, in a realistic way, with the intelligent planning of possibilities for a negative peace; *i.e.*, for the greatest possible reduction in the extermination of human life, the infliction of suffering, and the destruction of property. The problems that man now faces and will face in the following decades are overpopulation of the earth and pollution of the surrounding world. These problems will demand the total power of mankind to adapt plans to the remaining possibilities of the closed system that is the earth. The program calls for a hierarchy of planning, of which the reduction and moderation of armed conflicts (on the national and international planes) are an important point, but only one among others. What man can do for peace is evaluated through a consciousness of the limitations that are drawn for human endeavour. These limitations are more restrictive than most enthusiasts and idealists have assumed. The discoveries of individual and social psychology, of anthropology and sociology, are interpreted by many as demonstrating that man is not as free as the enlightened Rationalists had believed since the 18th century. The terminology of modern futurologists and decision-makers seems to suggest these limitations as well. The idea of a maximum peace that connects the abandonment of armed force with the demand in every country for the creation of institutions for social justice resuscitates, in truth, ancient millenarian hopes for an eternal peace combined with an empire of harmony and justice. In fact, this idea may not guarantee peace so much as it endangers peace to the extent that it calls for an intervention in every place where this combination does not exist as envisioned. If a maximum or integral peace cannot be attained, it is at least conceivable that, in many cases, by intelligent planning, a minimal peace can be reached, that armed conflicts can be localized and kept on a small scale, that the grossest mistreatment of civilians can be prevented, and that the belligerents can find their way back to the conclusion of peace.

REGAMEY, *Non-violence et conscience chrétienne* (1958; Eng. trans., *Non-Violence and the Christian Conscience*, 1966), an unusually perceptive analysis; LEYTON RICHARDS, *Christian Pacifism After Two World Wars* (1948); E.A. RYAN, "The Rejection of Military Service by the Early Christians," *Theological Studies*, 13:1–32 (1952), an excellent historical exposition; ABBE CASTEL SAINT-PIERRE, *Projet pour rendre la paix perpétuelle en Europe* (1713; Eng. trans., *A Project for Settling an Everlasting Peace in Europe*, 1714) and *Projet de traité pour rendre la paix perpétuelle entre les souverains chrétiens* (1717), two interesting treatises from the early 18th century demanding a sort of league of European nations; MAX SCHELER, *Die Idee des Friedens und der Pazifismus* (1931), a posthumously published treatise by a great German Phenomenological philosopher; GEORGES SOREL, *Réflexions sur la violence*, 3rd ed. (1912; Eng. trans., *Reflections on Violence*, 1914, reprinted 1941), a pre-World War I treatise by the great French syndicalist author; S. RUDOLF STEINMETZ, *Soziologie des Krieges* (1929), a realistic treatment by a famous Dutch sociologist—still pertinent today; WILLIAM TEMPLE, *A Conditional Justification of War* (1940); RALPH T. TEMPLIN, *Democracy and Nonviolence* (1965); NORMAN M. THOMAS, *The Conscientious Objector in America* (1923), the first major study of this subject in the United States; LEO TOLSTOY, *The Law of Love and the Law of Violence* (Eng. trans. 1948, reprinted 1970), a classic by the world-famed Russian author; ARTHUR and LILA WEINBERG (eds.), *Instead of Violence: Writings by the Great Advocates of Peace and Nonviolence Throughout History* (1963); CARL F. VON WEIZSACKER (ed.), *Kriegsfolgen und Kriegsverhütung* (1971), an analysis of the consequences as well as of the prevention of war by a contemporary German scholar; L.S. WITTNER, *Rebels Against War: the American Peace Movement, 1941–1960* (1969); QUINCY WRIGHT, *A Study of War*, 2nd ed., 2 vol. (1965), a comprehensive historical treatment of the subject.

(W.E.Mü.)

Packaging

From the beginning of commerce, packaging has been indispensable in the movement of many kinds of products. Animal skins, baskets woven from reeds, and earthenware vessels may be considered the packages of prehistoric man. The ancient world contributed glass bottles, clay amphorae, and leather bags. The cask was probably an invention of the Middle Ages. But it was not until the Industrial Revolution, which created a need for packaging great numbers of similar items for shipping, that the packaging industry became economically important.

Virtually all modern manufactured and processed goods require packaging at some stage in their production and distribution. Fresh foods need the protection and convenience that packaging gives. Specialized knowledge and skills, as well as specific machinery and facilities, are required to produce packages that meet one or more of five basic demands: protection from the environment; containment as a handleable unit; machine performance in the packaging process (such as on filling machines); communication to identify contents and to aid in marketing; and convenience to everyone concerned with the making, distribution, and use of the product; in addition, disposal of the package must be easy.

Table 1: Cost of Packages in Relation to Product Cost

product	percent of packages on the market costing		
	less than 3 percent of product cost	3–10 percent of product cost	more than 10 percent of product cost
Sugar	100	—	—
Margarine	—	100	—
Butter	38	25	37
Flour	—	50	50
Tea	33	17	50
Cocoa	—	50	50
Biscuits	—	50	50
Chocolate	33	—	67
Toilet soap	18	41	41
Detergents	4	65	31
Tobacco	17	50	33
Cement	6	79	15
Electric light bulbs	23	40	37

These basic requirements must be provided at a cost related to the selling price of the goods. Apart from certain luxury items such as cosmetics and perfumes, packaging is not an essential part of what is to be sold but only the means of conveying it. Consequently, packaging costs must be kept to the minimum necessary to do the job required. Table 1 lists approximate packaging costs in relation to typical product costs. The labour content and the machinery required are not included. For some products, *e.g.*, sugar, the packaging is at a minimum; for others (*e.g.*, butter) there is great variability according to the job the package has to do.

PACKAGING MATERIALS: THEIR CHARACTERISTICS AND MAJOR APPLICATIONS

The main packaging materials and their share of the total packaging used are shown in Table 2.

Table 2: Main Packaging Materials and Their Share of Total Packaging Used

material	percent of total value
Paper and paperboard	45
Metal	25
Plastics, moldings, and film (including cellulose)	12½
Glass	8½
Wood	3½
Textiles	2½
Miscellaneous	3

These figures relate to the United Kingdom in 1969, but similar proportions of the market will be applicable in almost all the developed countries.

The forms in which the main packaging materials are employed are shown in Table 3, which also gives some idea of the wide variety available.

Shipping containers. The principal shipping-container materials are wood, fibreboard, and metal. Glass is used for carboys of corrosive liquids such as acids, etchants, and other chemicals, but the quantities are small. Usually wood is used whenever the package is large or the product is of high density. Thus timber cases and crates are used extensively for weights above 100 kilograms (220 pounds) while below this weight fibreboard, both solid and corrugated, is the favoured material. Timber is also used for casks for wine and beer, but there is a trend toward its replacement by metal (stainless steel or aluminum) either alone or with inner liners of plastic.

Table 3: Applications of Various Packaging Materials

material	package type
Paper and board	paper wrappers, sacks, labels, etc.; fibreboard cases; boxes and folding cartons; paper bags and carrier bags
Metal	tinplate containers (cans and boxes); aluminum foil; aerosols; collapsible tubes; steel drums, boxes and crates
Glass	bottles; jars; carboys
Plastics	films; bottles, pots, jars, etc.; thermoformed trays, etc., from plain or expanded sheet; cushioning materials
Wood	boxes and crates; casks and kegs; pallets and containers
Textiles	sacks and bags; bales

There is some use of plastic for shipping containers, and these are returnable because the basic material cost is high. Plastic crates are well established in the dairy industry and are spreading to the more exacting use for bottled beers, minerals, and soft drinks. Beer crates are usually stacked higher and for longer periods than those for milk, and polypropylene is, therefore, preferred for beer, while high-density polythene has proved adequate for milk crates. Polythene is also used for carboys for many liquids, eliminating the protection required for glass. Some polythene casks (barrels) are also used.

Advantages of plastic crates

Expanded polystyrene is employed as a shipping container for tomatoes and grapes and also for both cured and fresh fish; the heat insulation properties are useful in keeping the product cold with a minimum of solid coolant. Solid and corrugated fibreboard cases are probably the most widely used, convenient, and economical shipping containers.

Solid fibreboard is made of paperboard (often waste pulp board) lined on one or both sides with kraft (strong paper, usually brown, made from sulfate pulp) or similar material of between 0.1 and 0.3 millimetres thick. The total thickness of the combined board ranges from 1 to 3 millimetres.

Corrugated fibreboard includes both double-faced board and double-wall board. Double-faced board consists of two flat sheets separated by a fluted sheet made from straw or a special hardwood pulp; different grades and types of board can be produced by varying the materials, the thickness, and the weight of the liners and the fluting medium. Double-wall board is made from two fluted sheets separated by a flat sheet and faced on both sides with a further flat sheet. Flute configurations vary in number of corrugations to the metre and hence in thickness of the combined board.

The conventional case is the one-piece, or regular slotted container, although open-tray and wrap-around styles are used extensively. The normal range of weight that corrugated and solid fibreboard cases can carry lies between five and 20 kilograms, but fibreboard cases can be made to hold loads of up to 50 kilograms (110 pounds) without any special fittings being used, and reinforced containers are capable of carrying loads of powdered or granular material of up to 500 kilograms.

In the 1960s important innovations in the movement of goods appeared, including palletization, modular packaging, and freight containers. In some instances the pallet

has superseded the wooden case or crate, and in others the shipping container has been eliminated since the goods are loaded directly into a freight container and secured. This is particularly applicable to heavy machinery.

Retail containers. Folding cartons and paperboard boxes are used extensively in the food industry (about 45 percent of all types). The second largest use is in the chemical field, particularly for pharmaceuticals, cosmetics, and detergents (about 20 percent). The cigarette and tobacco industry account for the third largest use, and the remaining use is divided among electrical equipment, clothing, toys, and other goods. In most instances where little climatic protection is needed, a carton provides the cheapest and best physical protection against crushing; it can be supplemented with a barrier against moisture by adding an inner film bag or an outer wrapper. Despite advances in printing technology for other materials, paperboard and paper remain more easily and cheaply printed to high graphic standards than most of their competitors.

Basic shapes: tube and tray

Cartons are made in a great variety of shapes and sizes. Originally cut and creased on converted printing presses, they are now produced on more efficient and sophisticated machinery. All of the hundreds of different types and styles of cartons in use are descended from two primary constructions: the tube and the tray.

A tubular carton consists of a sheet of paperboard folded over and glued at the edges to produce a rectangular tube, the ends of which can be closed or locked together. A tray-type carton consists of a sheet of board all of whose edges, usually four, have been folded up at right angles to the main sheet and secured at the corners. The tray may, in fact, be joined along one edge with another sheet of board similarly folded to form a lid. The most commonly used style of tubular carton is the glue-end carton. This is particularly suitable for automatic packaging of powdered materials, including foods and detergents. The tuck-in style of carton is often used if the package needs to be reclosed after it has been opened for the first time.

The main advantage of the tray style of carton, whether fitted with a lid or not, is the greater area initially available for filling the box; trays are preferred for applications in which the contents would be difficult to load through the narrow ends of a tube. They are used widely for biscuit assortments, cakes, and pies and are easily adapted to both semi-automatic and fully automatic packaging systems.

Although most carton styles are based on folds and creases produced from straight lines and possess four major faces, it is possible to handle curved creases and shapes based on triangles or hexagons, to improve display. Complications can arise, however, in the packing of such cartons for delivery in bulk, particularly where triangular, tetrahedral, or seven-, eight-, or ten-face constructions are produced, even if these are based on regular figures.

Tinplate containers can be divided into two classes: the cylindrical open-top variety, of which some 80 to 90 percent are in use for processed-food cans or canned beverages; and general line cans that have replaceable lids; nearly half of these are also used in food packaging, about a quarter for paints and varnishes, and most of the remainder in the tobacco, medical, and cosmetic fields.

The tin can is fabricated of steel with a thin coating of tin on each side of the sheet. For some products, it is advantageous to have a thicker coating on one or both sides, or a lacquer coat to prevent the product from attacking the metal.

Three basic styles of can are the seamless-body can, the locked-corner-body can, and the rolled-body can.

The seamless, or solid-drawn can is pressed into shape and has no joints. The body is usually finished at the open mouth by trimming, beading, or curling to receive the lid, which is frequently of a slip-on variety. The tinplate can be formed into a seamless-body can of only relatively small depth, otherwise the material will tend to pucker or wrinkle during the pressing. Limitations are imposed by the sharpness of curvature of the finished container, the thickness of the container material, and the ability of the surface finish to remain anchored to the base metal. It is possible to make round, oblong, and square shapes, but beyond about 100-millimetre (4-inch) diameter the round, seamless can tends to become uneconomic and functionally poor. The locked-corner can has, essentially, the ability to form an almost square corner, permitting efficient storage.

The rolled, built-up can must have at least two components, the side wall and the base. (It may have a third, or even a fourth component.) The side wall is often referred to as the body and the base is called the bottom, or end. A two-piece body has two joints; the side seam of the wall, and the joint between this wall and the bottom or end. Both are produced by interlocking folds. The side seam is formed by interlocking the fold on each edge and "bumping" the interlock. The bottom joint is made by a process called double seaming. The common food can is produced by securing a third component, the end, by double seaming after the can has been filled.

Aluminum is used to produce seamless body cans by impact extrusion. If the can depth required is large relative to the diameter, aluminum is the only material for producing such a container, because tinplate cannot be formed to great depths. To achieve adequate rigidity, an alloy of aluminum with about 1 percent manganese is commonly used. Aluminum does not rust and is light and pleasant to handle, but its resistance to chemical attack, particularly that of alkalies, is limited. Its application must, therefore, be carefully considered in relation to the properties of the product.

Most aerosol (pressurized) containers are based on metal cans. This package must dispense the product in the right form and quantity. Hairsprays, air fresheners, insecticides, wax polishes, deodorizers, cleaners, and coatings are among the products so packaged.

Collapsible metal, and more recently, plastic tubes are used in the cosmetics, toiletry, and pharmaceutical fields, with toothpaste accounting for the highest single use.

Aluminum is used principally as foil: in a thin form as a barrier to gases and vapours of all kinds, either alone or as a component of a laminate; or in a thicker form as a lightweight container (basins, trays, dishes) for food that must be heated before consumption. It also provides bottle caps and closures and easy-open tops for cans.

Advantages of glass

Glass is a highly inert material of great cleanliness and hence is used mainly for food and drink (about 70 percent) and for drugs, cosmetics, and toiletries. A material easily formed into almost any shape, with exceptional aesthetic potential, it is widely used to package products dispensed at intervals, over a relatively long period; *e.g.*, perfumes and toilet water. Glass containers, both bottles and jars, are mainly produced on fully automatic machines at speeds up to over a hundred a minute in a continuous process; once started, the furnace containing the molten glass remains in operation for two or three years. The furnaces operate at temperatures of up to 1,500° C (2,700° F) and hold up to 400 tons of glass. The molten glass passes from a melting chamber into the working chamber of the furnace where it cools slightly before passing into the molds of the forming machines. The molten glass is then either sucked up or, more frequently, extruded into preliminary molds where an initial or "parison" shape is formed. It then passes into the second stage where the container is blown to its final shape. After forming, the hot containers are annealed in a long tunnel to eliminate undesirable stresses.

The majority of glass containers sold today are discarded when they are empty, with the exception of milk bottles, some beer bottles, and certain carbonated-drink bottles. Successful re-use of returnable bottles depends on the control of the packer over the distribution system. Most modern developments in glass-container manufacture are related to the weight of the finished container and its strength. New production methods promise to bring considerable changes in the form of containers that will be light, strong, and shaped like an electric-light bulb, with a plastic base and a simple closure.

Of the large number of plastic materials available in the

Table 4: Comparison of Properties of Common Flexible Packaging Materials*

Uses of plastic in packaging

early 1970s, only a few have made a substantial impact on packaging: polyethylene (often referred to as polythene), polystyrene, polyvinyl chloride, and polypropylene. Others, such as thermosetting resins and saran, have limited applications as closures and coatings. More than half the polythene is used in film form and much is converted into shrink film, liners, sacks, and bags. Some is used in the form of bottles, a little for larger specialized containers, and the remainder for coatings or laminates. Polystyrene is principally made into tubs for ice cream, packs for eggs, sausages, and small pots or jars for butter, jam, and cheese; or used in expanded form for packaging typewriters, record players, and other delicate machinery; or formed from expanded sheet into trays for fresh foods, cameras, or other lighter weight goods needing attractive protection against shock damage. Polyvinyl chloride is used typically for bottles for soft drinks, cooking oil, and vinegar, and as trays for chocolates. The use of polypropylene is growing rapidly, especially as a transparent overwrap, in which it has strength advantages over cellulose film.

Molded thermoplastic containers are produced by blow-molding, injection molding, or thermoforming. They generally have no special names but are given the same description as the traditional containers that they emulate. The same type of container can often be made by more than one method. Thus, bottles are produced by either blowing or injection molding, and tubs can be produced by all three processes.

One of the most important problems in the early use of plastics for the food industry was the possibility of taint, but special grades of several plastics now ensure the safe packaging of a wide range of foods.

Polystyrene is the main plastic used for injection-molded containers, but polypropylene is beginning to be employed in this field. Both are available in special grades for food. Such containers are light in weight and chemically inert, and those from polystyrene can be produced in glass-clear form if required. Polystyrene and polyvinyl chloride may also be formed by vacuum into containers for a variety of foods, including fresh fruits and vegetables. Polystyrene frequently is toughened by the addition of a small percentage of synthetic rubber, allowing it to be vacuum-formed into deep containers. Other polystyrene grades with good flow properties are used for thin-walled, injection-molded tubs for such commodities as cream or yoghurt.

The thermoforming process is suitable for making trays and fittings, as well as tubs, particularly where weight, and thus cost, must be kept to a minimum. Cellulose acetate, polystyrene, polyvinyl chloride, high density polythene, and polypropylene are all thermoformed in this way, and polystyrene can be thermoformed both from clear film and, more recently, from foamed sheet. These fittings and trays find considerable application in reducing shock and separating lighter fragile items from each other. They also provide more decorative fittings than the previously used paperboard for such items as cameras, cosmetics, and toiletries.

Plastic packaging films in very large variety have considerable uses in all fields of barrier packaging (see below). There is no single material that is equally suitable for all purposes, and the most suitable film must be chosen for the greatest advantage. Information on the properties of common flexible materials is given in Table 4.

Packaging of hazardous materials. Many chemical products have obnoxious or hazardous properties. Explosives, poisonous materials, and liquids that are corrosive or produce dermatitic or skin irritant effects, inflammable goods, materials that react either with air or water, radioactive materials, and materials that are likely to cause spontaneous combustion all require special selection of materials for packaging. In general, regulations are laid down in handbooks of road, rail, and sea transport authorities. Where export is involved, it is also necessary to comply not only with the regulations of the country of destination, but also with the regulations of countries through which the goods may have to pass.

Labels must indicate the hazardous nature of the contents.

Packaging fragile articles. The selection of materials and design of cushions and fittings for fragile products is

one of the most important problems of packaging design. Frequently a high proportion of the total packing costs must be allocated to protect against shock and vibration. Since over-packing can be expensive, it is necessary to choose the right material, use it efficiently, and provide only sufficient protection for the product. To do this requires information on the fragility of the product, the cushioning materials available, and the shocks likely to be experienced in distribution.

There are, essentially, six steps that must be taken in producing a pack for a fragile article, whether it be electronic equipment or decorative glass. First, the hazards of the transport system are assessed, and the height and the number of drops to guard against decided. Second, the fragility of the product is assessed. Third, cushioning materials are selected and their positioning calculated. Fourth, the total cost of each material is determined. Fifth, a prototype package is produced using the most economical material. And sixth, the package is tested to assess defects or deficiencies. The steps are repeated until the package is satisfactory.

Barrier packages. To maintain favourable climatic environment around goods subject to deterioration from moisture, oxygen, light, or heat, any of several barrier materials are employed, such as waxed paper, metal foil, plastic films, and flexible materials listed in Table 4. Most are good barriers to moisture and moisture vapour, some are good barriers to oxygen and other atmospheric gases. The opaque materials are barriers to light, and in some instances, for relatively short periods of time, a certain degree of heat insulation can be provided for some products.

There are four principal mechanisms by which gases and vapours penetrate flexible packaging materials: closure failure; passage through the pores and channels in the material itself, especially paper; diffusion through such material as cellulose film or polythene, and transmission of gases or vapours through pinholes in metal foils, such as aluminum. The rate at which gases or vapours are transmitted by the activated diffusion process increases as the temperature rises, but the other mechanisms are hardly affected by temperature at all.

The light transmission qualities of flexible barrier materials can be controlled by their colour, by their opacity, and by their thickness. Almost all plastic films may be treated in some way to change their light-transmission capabilities, while materials such as paper are generally opaque. Light can cause problems in the packaging of foods, particularly frozen foods, if the lighting in cool and cold display cabinets is intense. Heat insulation is possible for periods of up to 48 hours. Products sensitive to temperature need to be packed in temperature-controlled vehicles, either refrigerated or insulated.

RETAIL PACKAGE DESIGN

Four major considerations are involved in package design: the product, its market, the package production problem, and the economics of the packaging operation.

Under product considerations come such questions as susceptibility to damage or deterioration, the need for protection against temperature changes, moisture changes, oxygen, light, mold, or insects, and whether the product will interact with the potential container.

Market considerations

Market considerations include the characteristics of the customer, such as age group and income level, the unit quantities required, aspects of the retail and wholesale operations, and probable methods of handling, warehousing, and distribution. The graphics considered include brand name; whether the product is part of a range; whether there are colours that may not, or must be, used; any pertinent government regulations; and the economic effect of all these factors.

Food packages. In the food industry the processes of canning and bottling tend to be differentiated from other methods of packaging. To some extent this is a distinction between methods of food processing; *e.g.*, sterilization or pasteurization as against dehydration and quick freezing, which are much more demanding with respect to packaging.

All foods are perishable, but some ripen or mature after being packed and improve for a short period. The deterioration that inevitably occurs is hastened by unfavourable environmental conditions; much of food packaging is designed to intervene between a food and its surroundings to delay the processes of deterioration beyond the time needed for transportation, marketing, and consumption.

Factors controllable by packaging that lead to spoilage include mechanical damage, changes in moisture content, interaction with oxygen, and intrusion of foreign odours. Most spoilage involves more than one of these factors; *e.g.*, mechanical damage, in addition to physically damaging the food, may permit entry of moisture, oxygen, or foreign odours.

In addition to providing a barrier against dirt and other contamination, and protecting against physical damage, moisture, oxygen, and light, a food package is designed to function smoothly, efficiently, and economically on the production line during the packaging operation, and to supply convenience not only to the consumer but during storage and distribution. Finally, it must provide identification, information, and sales appeal.

Food packaging always involves quality control, whether through government regulation or other means. Laboratory techniques are often used, followed by field trials, in which the food is packed and stored under specified conditions for specified periods. Once the basic suitability of the package is established, some method of rapidly checking incoming packaging materials and completed packages of food is provided.

The quality of many foodstuffs (as well as other products) has reached such uniformity in standards that there is often little difference among brands. Under such circumstances, convenience of the packaging becomes paramount, at least in countries where economic competition flourishes. Provision of individual portions, such as boil-in-bag preparations, without materially affecting cost, is an important marketing factor. The flexibility of pouch packages permits remixing components that separate during storage, or, alternatively, for mixing materials packed in separate compartments. Some food products can be sold dry in a flexible package to which the requisite quantity of water, or other liquid, is added, and the mixture kneaded in the pack, eliminating the need for mixing bowls.

Consumer convenience

Convenience for the consumer, once virtually limited to easy opening and reclosing, has thus broadened in scope. Convenience for the distribution chain involves such considerations as the right size and shape for outer containers, the ease of disposing of unwanted packaging materials, and the breakdown of larger packs into simpler and more convenient units. Large savings can accrue from packaging that facilitates warehousing.

Closures. Glass containers always require a closure, and closures are produced in a great number of sizes with the precision necessary to ensure complete sealing. The majority are made of metal or plastics, although paper, rubber, glass, or combinations of these are also used. Tinplate, aluminum, and aluminum alloy are the most common metals, while Bakelite, polythene, polyvinyl chloride, and polystyrene are the most widely used plastics. Both metal and plastic closures may be rigid or semirigid, sealing by compressing an interposing wad of rubber, paper, cork, or synthetic material against the edge of the glass. Designs vary widely, including external screw caps, lug caps, internal screw stoppers, lever and snap-on caps, vacuum seals, and corks. Metal-foil caps, as used for milk and other dairy products where both the product and the pouring lip of the container are protected, and special rubber closures that can be pierced by a hypodermic syringe are also used.

Metal-can closures operate by one of five basic methods: frictional engagement, screw-thread engagement, plastic closures, vacuum seals (which rely on atmospheric pressure on the lid), and permanent mechanical interlocking of lid and body. This last is the most widely used form of tin-box closure, as used in the food can. The joint, usually called a double-seam, is ideal

in its simplicity and reliability for the exacting chemical and microbiological requirements of food canning.

Plastic containers such as bottles and jars may be closed with screw caps similar to those used on glass. Rigid and hard tubes made in polystyrene can be effectively closed with injection-molded polythene plugs, sometimes ribbed to improve the seal. Another type of closure is the push-on cover, which can be made in paperboard, plastic, or foil. Vacuum-formed plastic containers are sometimes closed by a heat-sealed flat or recessed lid. The seal is commonly made on a heated jig.

Most closures of film packages rely on the heat-seal characteristics of the film. Some films, such as regenerated cellulose, cannot be sealed with heat unless they are coated with a special heat-sealable coating, usually based on a thermoplastic lacquer. Polythene and polypropylene can be sealed by electrical-resistance heating; most of the machines currently available employ electrically heated jaws or resistance tapes pressure-closed onto the film to effect the seal. Some plastic film bags are closed by tying.

Fibreboard shipping cases may be closed successfully with cold adhesives, usually based on sodium silicate, hot-melt adhesives applied by special methods, gummed paper tape, self-adhesive plastic tapes, and stapling.

Opening devices. Despite much ingenuity used in designing opening devices, results have often been unreliable. One problem is that the easier a package is to open, the greater the chance of accidental opening. Cans, particularly for beverages, received considerable attention in the 1960s, and the easy-open beer can, not requiring an opener, became highly successful in Germany, the U.K., the U.S., France, and other Western countries. Such cans have opening tabs of aluminum, which has lower resistance to tear than tinplate. The "crown cork" for bottles also eliminates the need for a special tool and makes opening possible by tearing. In the early 1970s, a number of plastic and aluminum-foil closures of this type showed promise.

Tear-tapes for packages made of film and paper, however, have often proved unreliable, either because of poor adjustment of the machine applying the tape, or because of variations in the dimensions of the packaged product. The latter has often been the case with the film-wrapped biscuit packs. Some success has been obtained in tearing devices to convert corrugated cases into display units. Considerable further development is probable in this area.

Dispensing packages. Aerosols, or pressurized containers, are a leading example of dispensing packages. Although in theory anything that can be made into a liquid or paste form can be dispensed from an aerosol, in practice only products that derive some practical advantage from spray dispensing are so packaged.

Materials for boil-in-bag packages, besides being resistant to boiling water, must have a degree of impermeability to odours and resistance to grease. High-density polythene or polypropylene films are very suitable. Another convenience package is the bake-in tray that doubles as cooking utensil, and in one form, as serving dish. Such trays are made from foil-lined paperboard, lacquered boards coated with heat-resistant plastic, or aluminum foil.

Labelling and decoration. Plain labels, applied by adhesive spread on the machine, are used for bottles, cans, and boxes of all kinds. Pre-gummed labels are precoated on the back with a water-activated adhesive just before application. Thermoplastic backed labels have a resin adhesive that is activated by heat just before applying to the container. Pressure-sensitive or self-adhesive labels have their backs precoated with an adhesive substance that is protected by a separate backing removed just before applying the label. Pressure-sensitive labels are of two types; one remains permanently bonded, and the other may be removed without marking the surface. Thermoplastic and pressure-sensitive labels are used for plastic containers because most gummed labels will not adhere to plastic.

All printing processes are used for package decoration; the choice is determined by the package material and the type of decoration required. The principal problems are odour transfer from inks, rubbing and smearing of ink, fading by light, and colour variation.

Printing on metal

Although the most widely used form of decoration for a can is a printed paper label, both tinplate and aluminum can be printed; in fact there is little difference between printing paper or board by offset lithography and printing tinplate. Paper and board, however, are absorbent, and tinplate is not. Hence each colour printed on tinplate must be baked at a high temperature to dry it and key it to the metal. Since it is also necessary to use a base coat, a six-colour printing with a final overprint varnish requires baking eight times. Similar problems are associated with fired-on print for glass bottles.

PACKAGING MACHINERY AND TECHNIQUES

Filling and sealing bottles. Bottle-filling machines for liquids can be divided into four basic types: vacuum filling, measured dosing, gravity filling, and pressure filling.

Filling by vacuum is the cleanest and most economical way to handle many products. In spite of the care that is taken in making bottles and cleaning them, there is always a percentage with holes, chips, or cracks. Vacuum-filling machines automatically avoid such bottles. Vacuum filling is neat and efficient, and it is unnecessary to wash or wipe the bottles before the labelling. The vacuum system requires a supply tank that is below the level of the bottles to be filled; from the supply tank run pipes or lines to which are attached filling nozzles. Also connected with the supply tank is an airtight overflow receptacle. When the machine is started, vacuum is created in the overflow receptacle, and in turn in the lower end of the air line or at the suction ends of the nozzles. When the bottle is pushed into close contact with the gasket of the suction nozzle, making an airtight seal, a vacuum is created in the bottle (unless the bottle is imperfect). The vacuum draws the liquid from the supply tank, through the tube and into the bottle. When the liquid reaches the end of the overflow or suction airlines, it automatically breaks the vacuum, causing a cessation of the flow of liquid into the bottle. The filling stem is then withdrawn and the bottle passes to the closure plant.

In measured dosing, the height of fill is not constant. Each filling unit consists of a calibrated cylinder and a piston. As the piston begins its down stroke a valve opens, allowing free passage of liquid into the cylinder. At the end of the stroke the cylinder is charged with a measured quantity, and when a container is correctly positioned, a delivery valve opens and the supply valve closes. The piston discharges the liquid into the container on its return stroke, and the sequence repeats.

Gravity filling

There are two types of gravity-filling machines, one of which fills on a controlled-time cycle and the other by using a measuring chamber. In the first, the presentation of the container to the filling head opens a valve that permits the liquid to flow for a predetermined time. The valve then closes and the container is taken away. The open time is determined by the viscosity of the product and the diameter of the filling orifice; control may be mechanical, by time clock, or electronic. In the second type of gravity filler, a supply valve opens to admit liquid to a calibrated chamber. When a container is correctly positioned at the filling head the supply valve closes and a delivery valve opens, thus charging the container with the measured amount.

Pressure filling is basically similar to time-cycle gravity filling. An artificial head pressure is induced to the liquid by a pump or by air pressure within a closed tank. Gravity and pressure filling are appropriate to moderately fast filling of low viscosity liquids, such as fruit juices, but they are considerably slower than vacuum filling.

Dry goods in powdered and granular form. Granules or tablets are sometimes counted by sorting equipment with electronic counters, but more usually they are simply loaded into containers by one of two basic methods, volumetric filling, and filling after weighing. The nature of the product usually determines which method is used. Volumetric filling may be by vacuum, by the

use of an auger (screw), or the use of a flask. The vacuum method is similar to that described for liquids. In auger fillers, the quantity delivered is controlled by turning the auger a certain number of cycles. And, in flask fillers, the volume of the flask determines the quantity delivered.

Weight filling is the best way to meet the requirements of weights and measures regulations. In all the different weighing techniques (scale beams, compressed-air, or electronic measurement systems), the basic principle is to divide the supply of product into a bulk feed and a fine feed. At the beginning of the weighing cycle both the bulk and the fine feed operate to fill the weighing pan until 80 or 90 percent of the required material has been added; at this point the bulk feed stops and the fine feed continues until the exact balance is reached; as the fine feed is cut off the load is discharged, usually by tipping into the container.

Cartoning systems. A cartoning system combines a special carton with the machinery to erect it from a flat condition, fill it with a product, and close it. The machinery varies from simple hand-fed machines to automatic stations coupled with means for packing the cartons directly into cases for dispatch. Whatever the system employed, three main operations are performed.

First, forming or erecting the container. Material may be fed to the carton erection point as a continuous web, as a flat carton blank, or as a folded carton flat with a manufacturer's joint secured.

Second, loading or filling the container. In the continuous web fed and the top-loading systems the container has only one face open at the moment of filling; with an end-loading system it is possible with certain products to load the carton and close both ends afterwards.

Third, closing or sealing.

In addition to these main operations cartoning systems may be required to carry out secondary operations such as handling paper liners, embossing codes, and inserting leaflets.

All these can be performed along with the three main operations on manual, semi-automatic, or fully automatic lines.

When forming, filling, and closing must be carried out on one machine in a single operation, fully automatic machinery is usually used. The division between semi-automatic or fully automatic machines relates principally to how the filling or loading of the carton is carried out. If loading is done directly into the carton, even though an operator inserts it into the infeed conveyor by hand, the system is classed as automatic. If the rest of the operation is automatic but the load is inserted directly into the carton by hand, however, the system is described as semi-automatic. Most systems requiring higher speeds use continuous-motion machines; lower-speed systems usually use intermittent-motion machines. The latter can also be of advantage where the nature of the product demands a stationary carton at the moment of filling.

Automatic and semi-automatic loading

Film forming, filling, and closing machines. These machines use a reel of flexible material (paper, film, or foil laminate) and either form it into a tube and seal and fill it at regular intervals, or fold it lengthwise, and pinch and seal it at right angles to the fold to form a series of pockets that are filled and closed.

In high-speed operations the tolerances both in the machine and the packaging material are critical. Containers may also be produced from reels of material by thermoforming a series of trays in a web, filling them with the product, and feeding another web over the open trays to cover exactly their flanges, permitting heat-seal closures. The web of filled and closed packages is either punched out to form individual packages or slit at intervals to give a number of units joined together.

Bag manufacture, filling, and closing. A bag is a prefabricated wrapper that only needs the product and closure to complete the pack. Bags have always been useful in hand-filling operations; and recent developments in automatic bagging machines, coupled with the wider choice of materials, notably polythene, have increased their value even further.

Paper bags are available in four standard styles: flat, gusseted, self-opening satchel, and rose bottom. They are made in various types and weights of paper according to the size, weight, and nature of the contents, and other functional factors. Sulfite papers, particularly the machine-glazed variety, are used for general purposes, and kraftpapers (made from sulfate pulp) are used where strength is essential. If resistance to grease or fatty foods is necessary, bags are made in greaseproof paper, vegetable parchment, or glassine, all of which can provide some resistance to loss of flavour. Paper bags are also available in wet-strength or waxed papers; such materials give resistance to the passage of water vapour if special attention is given to the closure and seams.

Film bags offer more protection than a paper bag and also provide visibility to the product. Film-fronted or windowed bags using both film and paper are also common. Films such as polyethylene, which may be extruded in tubular form, can be produced both with or without gussets and contain no seam in the length direction of the bag. The great improvement in resistance to moisture and grease of this type of bag, and its efficient closure, have led to its wide adoption for food packaging. The principal film materials used are cellulose (in plain, moisture-proof, and heat-sealing moisture-proof grades) and low-density polyethylene, although polypropylene, polyester, vinyl- and rubber-hydrochloride, and saran films are all used.

Cotton bags also have limited uses for packaging larger quantities of some products, notably foods. They are manufactured in bleached and unbleached qualities and may be printed.

Open mesh bags are frequently used to pack products such as fresh vegetables that require complete ventilation in transport and storage. In smaller quantities, up to about 2 kilograms (5 pounds) weight, polythene film bags with perforations may be used for the same produce; but above this weight, film bags lack strength. Open mesh bags were first made in hessian (burlap), but they are now produced in yarn twisted from special paper or in mesh of tough resilient plastics.

Bag-filling and closing equipment performs four operations: feeding the flat bag to the loading point; opening the bag and keeping it open; loading the product; and making the closure.

The initial opening is usually achieved by an air-blowing device, often assisted by the incorporation of lips on the bag. Mechanical fingers are also used either alone or to assist the air-opening device. The bag may be held open and the product guided into it by a scoop or other means, or, for certain products, the scoop is inserted into the bag, and the bag pulled over the product. The principle of moving the bag rather than the product enables bagging to be performed on products with little resistance to distortion or crushing, such as sliced bread. Ties, clips, staples, tapes, and heat seals are all widely employed as closures.

Bag-in-box packages are used for protection of dried and powdered foods and also for liquid packaging such as fruit juices and even wines, in quantities up to a gallon or more. Given a wrapping material inherently water-vapour resistant and heat-sealable (whether the seal is a weld or a surface seal) it is always possible to make a bag more efficient than an overwrap for a box of a given size. Moreover, many film materials are also odour-resistant and by their immediate contact can avoid locking in potential sources of odour. Cheaper grades of boxboard may be used for cartons when an inner bag is employed.

TESTING

The three main reasons for testing packages, containers, and packaging materials are: first, to predict their performance in practice, second, to control quality, and third, to plan improvements. A single test applied repetitively, or at an increasing level of intensity, can show exactly the strengths and the weaknesses of a packaging material or container.

There are two basic ways to evaluate test performance of a new package. The first is to compare it with the

known performance of a package already in existence. The second method attempts to reproduce the actual events that are experienced by the package or the material in use, and from the results deduce what will occur in practice.

The first semiscientific test was the drum tumbler, which replaced the earlier method of rolling a package down a flight of stairs. More accurate tests are now available. The principal ones attempt to reproduce the effects of the main hazards of distribution, including impacts, vibration, and compression loads (such as are experienced in stacks) as well as climatic effects, principally the effects of moisture and temperature changes. Such tests are either put together in schedules or used alone to evaluate particular aspects of performance.

Pagan

The modern village of Pagan lies on the Irrawaddy River about 90 miles (145 kilometres) southwest of Mandalay in Burma. Its population in 1970 was only about 3,000. The site of an old capital city of Burma, Pagan is unique in preserving the largest extant group of examples of a superb brick-building architecture that once stood in many parts of Southeast Asia. Its structures date from between the 9th and 13th centuries. Some, which are Buddhist shrines, have remained in use to the present day, continuously restored and redecorated; the majority, however, are shells, some well preserved but others less so. Pagan's importance lies in its heritage rather than its present. It was first built probably in AD 849 and, from the 11th century to the end of the 13th, was the capital of a region roughly the size of modern Burma. Only once, *c.* 1160–65, did it fall victim to a surprise attack. In 1287 it was overrun by the Mongols in the course of their wide-ranging conquests and never recovered its position thereafter, although a little desultory building continued on Buddhist shrines.

Topography

Old Pagan was a walled city, its western flank resting on the Irrawaddy River. It was the focus of a network of highroads by means of which its rulers could command a large region of fertile plains. They were able to dominate the other major Burmese dynastic cities, such as Pegu, Prome, Taungdwingyi, Thaton, and Tagaung, while the small Shan and Arakanese kingdoms gave allegiance. From the port of Thiripyissaya, further down the river, important overseas trade was conducted with India, Ceylon, and other regions of Southeast Asia. Studies so far undertaken suggest that the walls of the old city, within which lies a substantial area of the modern town, originally contained only royal, aristocratic, religious, and administrative buildings. The populace is thought to have lived outside in homes of light construction closely resembling those occupied by the present-day Burmese. The walled city, whose moats were fed by the Irrawaddy, was thus a sacred dynastic fortress. Although it was never as large as old Śrī Kṣetra (modern Hmawza), the circuit of its walls and river frontage is some two and a half miles, and there is evidence that perhaps as much as a third of the old city has been washed away by the river. Since building was principally in brick, decoration was carried out in carved brick, in stucco, and in terra-cotta. The earliest surviving structure is probably the 10th-century Nat Hlaung Gyaung. The shrines that stand by the Sarabha Gate in the eastern wall, although later than the wall they adjoin, are also early. These are shrines of protecting *nats*—the traditional spirit deities of the animist ethnically Burmese. Pagan lies near Mount Popa, sacred to the Burmese as the dwelling of the brother and sister spirits called the Mahagiri Nats.

Settlement

Between *c.* 500 and 950, people of the Burmese ethnic group had been infiltrating from the north into a region occupied by other peoples; these people already had been converted to Indian religion, especially the Mahāyāna Buddhism of Bihār and Bengal. Under King Anawrahta (reigned 1044–77) the ethnically Burmese finally conquered the other peoples of the region, including a people called the Mon, who were previously dominant in the south. They transported the Mon royal family and their scholars and craftsmen to Pagan, making it the capital and centre of an official, fundamentalist form of Hīnayāna (Theravāda) Buddhism adopted from Ceylon (*c.* 1056). This initiated the period of Pagan's greatness, which was sustained at first by Mon artistic traditions. The construction and existence of the enormous number of monasteries and shrines built during the next 200 years was made possible both by the enormous wealth of the royal exchequer and by the large numbers of slaves, skilled and unskilled, whose working lives were dedicated to the support of each institution. The city became one of the most important centres of Buddhist learning in the East.

Architecture

Lesser buildings are grouped around the more important pagodas and temples. Scattered around these are smaller pagodas and buildings, some of which may once have been aristocratic palaces and pavilions later adapted to monastic uses; *e.g.*, as libraries and preaching halls. All are based on Indian prototypes, modified during subsequent development by the Mon. The principal architectural themes are the Buddhist stupa, a tall bell dome, designed originally to contain near its apex the sacred relics of Buddhist saints. The other is the high, terraced plinth, which may be supplemented by stairs, gateways, extra stupas, and pinnacles and symbolizes a sacred mountain. Interior arches and vaults, both rounded and pointed, are, however, constructed by a true radiating-arch technique that was not used in India. During the course of artistic evolution the themes were frequently combined, and the combination developed into a complex rectangular hall with porticos extended from the sides, crowned by a stupa or, in some cases, by a rectangular tower of curved outline reminiscent of the contemporary Indian Hindu shrine tower. A vista across the site of Pagan shows a series of variations and combinations of the themes. Many buildings, especially those no longer in use and hence unrestored, bear substantial remains of external, decorative stucco and terra-cotta, adding flamboyance to the finely proportioned rectilinear structures,

and internal paintings and terra-cottas recording Buddhist legend and history.

Anawrahta constructed the Shwezigon pagoda. Nearby he built a *nat* shrine with images. The Shwezigon is a huge, terraced pyramid, square below, circular above, crowned by a bell-shaped stupa of traditional Mon shape and adorned with stairways, gates, and decorative spires. It is still much revered and famous for its huge golden umbrella finial encrusted with jewels. Also revered are the late-12th-century pyramidal Mahābodhi, built as a copy of the temple at the site of the Buddha's enlightenment at Bodh Gayā, in India, and the Ananda temple mountain just beyond the east gate, founded in 1091 under King Kyanzittha. By the time the Thatpyinnyu temple was built (1144), Mon influence was waning, and a Burmese architecture had evolved. Its four stories, resembling a two-staged pyramid, and its orientation are new. Its interior rooms are spacious halls, rather than sparsely lit openings within a mountain mass, as in the earlier style. This building combined the functions of stupa, temple, and monastery. The Burmese style was further developed in the great Sulamani temple and culminated in the Gawdawpalin, dedicated to the ancestral spirits of the dynasty (late 12th century), whose exterior is decorated with miniature pagodas, the interior with extremely lavish, coloured surface ornament.

BIBLIOGRAPHY. The physical and geographical characteristics, with plans of the city, are discussed by DAW THIN KYI, "The Old City of Pagan," in *Essays Offered to G.H. Luce . . .*, vol. 2, pp. 179–188 (1966). WIM SWAAN, "Pagan," in *The Lost Cities of Asia*, pp. 90–120 (1966), gives an account of the architectural and artistic history. These are set into broader historical perspective and related to the arts of the rest of Southeast Asia by A.B. GRISWOLD in the "Burma" section of *Art of Burma, Korea, Tibet* (1964).

(P.S.R.)

Pageant and Parade

Pageants and parades are related phenomena, often one and the same thing, although a pageant may include events other than processions or omit them altogether. Basically both are entertainments, often in the open air, involving spectacle that is sometimes extravagantly devised; they are usually used as a means of expressing national, communal, or other kinds of group purpose or identity. The word pageant is derived from the Latin *pagina*, "page," and the form is, especially in its premodern manifestations, essentially a kind of illustration.

Three early usages of the word in English are recorded to denote (1) the individual episodes of a mystery or miracle play cycle, (2) the wagons upon which these plays were performed in the streets of certain English towns, and (3) any piece of stage scenery or machinery used to produce spectacular effects in the indoor court masques. Later, the word came to have broader implications, and parades or processions, even those solemn in nature, partake of the essence of pageantry.

ORIGIN AND DEVELOPMENT

Communal celebrations. In a primitive society a procession is one of the most basic demonstrations of communal unity. The occasions for such demonstrations vary greatly—fertility rites, the casting out of evil spirits, or a display of military strength are but a few—as do the formations the paraders may adopt. The simplest of these is for a whole tribe or community to form the procession. A more sophisticated variant is to include only selected individuals such as priests, witch doctors, warriors, or rulers who in their persons represent vicariously the interests of the community at large or their own particular status and function. It is characteristic of pageantry, as it is of heraldry, to represent in symbolic form the various classes and castes of society. Thus the common people will develop forms of pageantry that proclaim their own interests, whereas the religious, merchant, and ruling classes will produce other, but equally characteristic, forms. Occasions of national rejoicing, such as religious feasts or patriotic celebrations, tend to bring these various manifestations together into a more or less prolonged period of rejoicing.

Processions

Once such periods of festivity have been established, they and the customs and processions connected with them tend to pass easily from one culture to another with little regard to the purposes for which they were instituted. Thus, for example, the carnival processions that precede Lent in many Roman Catholic countries are probably derived from the heathen feasts of Saturnalia, Lupercalia, and Bacchanalia. In the same way, Communist countries adopted May 1 as the occasion for great military parades, though May Day had been the occasion for fertility rites and processions since the dawn of history. The history of pageants and parades, therefore, is essentially one of eclecticism and adaptation. Any large modern parade, indeed, comprises items and floats that appear at first sight to have no necessary connection with one another: the origin and significance of some will lie in primitive history, that of others in more recent tradition, and that of still others in the demands of commercial advertising. Giants, dragons, Arabs, Indians, professional soldiers, drum majorettes, and wagons advertising milk and beer may follow one another in mystifying assortment. Moreover, the features of one procession may be taken over by another and their original significance either reinterpreted or lost altogether.

Pageant drama. The eclecticism of pageantry in general becomes even more pronounced in pageant drama. Music of one kind or another was an easily arranged adjunct to a simple procession. When it did not serve to express such spontaneous communal emotion as grief or bellicosity, it was probably intended to frighten off evil spirits. Once the theme of the procession came to be illustrated with spoken words or simple dramatic action, however, the parade had, of necessity, to be halted. "Stations" would be adopted and ceremonies or short scenes enacted at given points along the route. But such scenes and ceremonies would not necessarily be any more self-explanatory than the individual emblems and items that made up the parade. They would tend to remain enacted illustrations of a wider theme or story, the significance of which was usually apparent only to those in the group or community, who would already be fully conversant with the matter in hand.

Herein lies the difficult distinction to be made between drama proper and what in Western civilization has come to be the subdivision known as pageant drama. All forms of drama, of course, may be regarded as originating in religious rites—more particularly, and usually, in the desire to illustrate a particular theme or point as a kind of gloss to the rite itself. Thus, in the Christian Church, there arose the so-called tropes or additions to the mass; some of these were originally simple dialogues, based on the Gospel text, that were sung antiphonally

Relation to other drama

by the choir. Illustrative properties, such as the wooden ass, or *Palmesel,* used on Palm Sunday, were introduced, and a number of pageant-like ceremonies were evolved that eventually grew into complete mystery and miracle cycles. As such, they developed such fully rounded characters as Noah's wife in some English plays, a fact indicative of their tendency toward a more self-contained form of drama than that of the pageant episode. Certainly Western drama, once it had passed beyond the influence of the church and, more especially, as it was influenced by later Neoclassical scholarship in the 16th and 17th centuries, rapidly adopted the Aristotelian characteristic of having "a beginning, a middle, and an end." Strict pageant drama, on the other hand, differs from other dramatic forms in lacking this structure, since it is made up of loosely connected episodes.

Analogies in the East

This distinction between pageant drama and other forms is a peculiarly Western one. In Japanese Nō theatre, for example, and in its descendant jōruri and kabuki forms, it is customary for a performance to comprise individual scenes from several plays rather than a single, unified play. Although each incident, like the episode of a sophisticated Western pageant drama, may be more or less complete in itself, the full significance of the action is clear only to those well versed in Eastern myth or legend. The jōruri theatre, performances of which are still occasionally given, takes the form of the singing of dramatic ballads, the action of which is illustrated by puppets whose manipulators are always visible to the audience. Indeed, the frankly stylized nature of the puppet stage, with its conventionalized movements and often fragmentary narrative, communicated itself everywhere to other forms of Eastern theatre, not only in Japan but also in China and India. Thus the classical dramas of these countries have much in common with what Western theatregoers would class as pageants.

The pageant dramas of the West have tended to be largely open-air performances given in front of mass audiences, and hence they have stressed spectacle and broad effects at the expense of subtlety of characterization. The idea of a pageant as a collection of spectacular historical episodes illustrating a given theme or tradition is a modern one; it probably dates from the work of Louis Napoleon Parker in England, who produced a number of such entertainments in the first two decades of the 20th century.

TYPES AND OCCASIONS

Fertility rites. Fertility rites and military demonstrations must be counted among the earliest occasions for the holding of a parade. An instance of fertility procession has been recorded in the practice of a Snake tribe in the Punjab: an effigy of the snake god made of dough was carried from dwelling to dwelling and finally laid in the earth and worshipped. Similar processions have been recorded in all parts of the world, though sometimes a live animal was substituted for the effigy. Even as late as the 19th century, travelers to eastern Siberia witnessed such a procession, in this case with a bear who was subsequently sacrificed, among the Gilyaks, a Tunguzian people. In Paris a fat ox was paraded through the streets on Mardi Gras (Shrove Tuesday) in imitation of a Roman sacrificial procession. The ancient Chinese made wood and paper effigies of their dragon gods and carried them through the streets to procure rain, and until modern times the peasants of Sicily carried the effigy of St. Francis of Paolo through the market gardens with a similar intention.

Contests. A more sophisticated development of processions designed to influence the will of heaven can be found in a ceremonial race or contest in which the outcome is uncertain, presumably awaiting the decision of a supernatural power. It has even been suggested that the game of English football, or soccer, is derived from such a contest: after the sacrifice of the divine animal, teams or tribes contended with each other to obtain the sacred head, which would then be buried in their own territory to ensure its fertility for another year. If this is so, the processions of victorious football teams, returning to their home grounds with their trophy high over the heads of their exultant supporters, have an ancient history behind them. Certainly many modern forms of pageantry have the form of a contest, notable among them being the dragon-boat races of Hong Kong and the *palio* of Siena, Italy. The former takes place on the fifth day of the fifth month, when boats 80 to 100 feet in length, decorated to resemble dragons and crewed by up to 50 highly trained oarsmen, compete in an atmosphere of general festivity. The origin of the practice is said to be an attempt to stimulate the dragon gods to fight in heaven and hence produce rain.

Sporting events

The *palio* is an annual horse race held in the centre of Siena on July 2, the Feast of the Madonna of the Province, and on August 16, the day following the Feast of Our Lady's Assumption. It is remarkable for its colourful medieval costumes. Each *contrada,* or ward, of the city enters a horse, and the prize given to the winner is the *palio,* or banner, that invariably depicts a religious subject. The victors carry their prize home and keep it safely until the next contest. It is then taken in solemn procession to church on the day preceding the race and placed near the high altar during mass as a sign of its sacred significance.

Certain aspects of pageantry are also to be found in the *tauromaquia,* or bullfight, which has become a national sport of Spain and other Spanish-speaking countries. Both the parade of the brilliantly clad toreadors, matadors, and civic officials that precedes the fight itself, and the ceremonies that lead up to the releasing of the bull into the ring, are occasions of great splendour. Unlike the dragon-boat races and the *palio,* however, the bullfight is not chiefly popular today because it re-enacts a traditional ceremony. Its pageantry is essentially subservient to its importance as a contest, and although any popular sporting event may attract to itself elements of pageantry, as in the parades preceding football bowl games in the U.S., it is important to distinguish between contests that take place for their own sake and those that are staged for a more specifically mimetic or illustrative purpose.

A clear and extreme example of the latter type of contest, of a contest turned into a pageant, is the game of dice, played by Richard II of England when a procession of 130 citizens of London greeted him at Kennington at Christmas 1377. The procession itself was a mumming or disguising, words that in 14th-century vocabulary did not denote anything specifically dramatic but merely implied the wearing of colourful costumes for the Christmas revelry. When the mummers—dressed as knights and squires, "24 arrayed like cardinals," one dressed like an emperor, another like a pope—reached the King, they invited him to play at dice with them, a common feature of a mumming procession since those so disguised were popularly held to bring good luck with them. On this occasion, however, to ensure this good fortune the dice had been loaded so that Richard and other members of his party might be sure of winning the rich gifts the mummers had brought with them. The line dividing contest from pageant cannot always be so sharply drawn and depends ultimately on whether the contest or its attendant decoration is the main attraction.

Mumming

Particularly illustrative of the connection between contests and pageants were the jousts and tournaments of medieval Europe. Originally the tournament was nothing more than a means of training warriors, but as it evolved into a bloody and brutal exercise it encouraged the maintenance of private armies by the nobility, which was likely to lead to sedition. The consequent disapproval of both the church and heads of state led gradually to the adoption of literary and decorative elements, thus prolonging the existence of tournaments under the guise of civilized and harmless ornament. No longer might one end in the death of a contestant: artificial barriers, elaborately decorated, were set up in the streets, and the presence of the ladies as spectators led to the development of allegory of the kind encouraged by the cults of courtly love and chivalric honour. Knights would arrive in pageant cars decked out to pay fanciful compliments to the ladies of their choice, and such emphasis came to be put upon sheer equestrian skill that by the end of the 16th

Tournaments

century jousts and tournaments had disappeared altogether, their place being taken by the carrousel or horse ballet. This entertainment has at least three descendant forms in the modern world: the horse ballet of the circus; the carrousel or merry-go-round of the fair ground, whose wooden horses represent the live originals; and the displays of equestrian art given in the Spanish Riding School of Vienna.

Gymkhanas and tattoos. Equestrian skill is also much in evidence in gymkhanas and tattoos. The former originated under the British rule in India, combining displays of horsemanship with general athletics. The latter are a form of military display highly developed in Great Britain, at Aldershot and as part of the Edinburgh Festival, during the 20th century. The word tattoo, in this sense, is said to be derived from the Dutch phrase *doe den tap toe* ("turn the tap off"), which was used by the innkeepers of Flanders when the British were fighting there in the 17th century: as a sign of the closing of the taverns, it sent processions of soldiery through the streets on the way back to quarters.

State occasions. As a modern phenomenon, however, the spectacular tattoo must be considered in conjunction with other manifestations of pageantry on occasions of state celebration, which have always generated parades and lavish display. One of the earliest examples of this was the Roman triumph, with its procession of prisoners and victorious soldiers. Modern examples include the victory parades held in the Allied capitals after World Wars I and II and the many parades to celebrate national independence, such as those held in the United States on July 4, since 1950 in India on January 26, and in other nations. Such parades, like those of the various "old comrades" associations throughout the world (*e.g.*, the American Legion), serve to commemorate occasions of general national importance. Others, however, may celebrate only the interests of one section or ethnic group within the larger community—*e.g.*, the St. Patrick's Day parades or the ceremonial "piping in" of the haggis on "Burns's night," a tradition maintained by Scottish communities throughout the world.

Victory parades

Coronations, royal weddings, and state visits have been the occasion for pageantry since the dawn of history and were enhanced in medieval Europe by the development of spectacular pageant machines and devices. In 1481, for example, Isabella of Spain was greeted at Barcelona by a pageant wagon of St. Eulalia, remarkable for its device of three revolving spheres. In 1514, when Louis XII of France was married to Mary Tudor, sister of Henry VIII of England, a pageant was erected outside the Church of the Holy Innocents in Paris to represent the occasion in allegorical form. The pageant had two levels: on the lower stage a rose representing England, on the upper a lily for France. The rose had a bud that grew until it reached the second level, where it opened to reveal a girl representing Mary herself. At the same time the lily opened to show a youth who symbolized the French king.

Double pageant stage with operating medieval stage machinery. The rosebud grew, opened its petals and ascended to the height of the upper stage. Illumination from a medieval manuscript in the British Museum (Cot. Vesp. B. II).

Such pageantry was frequent in the major cities of Europe during the 16th century, but thereafter it declined in frequency. The machinery involved could stand little comparison with the effects that were obtained in the court masques or even, perhaps, the public theatres, and hence static pageantry in the streets tended to give way to moving processions. Samuel Pepys, for example, found the pageants offered for the Lord Mayor's procession of 1660 "good for such kind of things, but in themselves but poor and absurd." The Lord Mayor of London still has his "show" at the commencement of his year of office, but the use of mechanical devices at given stations has vanished. A procession connected with merchant guilds, that of Sächselauten (literally, "ringing of the bell at six o'clock"), persists in Zürich, Switzerland, but does not reach a station until its end in the heart of the city, where the figure of winter is ceremonially burned.

Court masques. Court masques, an example of pageantry confined to one section of the populace, became increasingly elaborate during the 17th century. Essentially they were entertainments that led up to a dance or masked ball: the masquers would conclude their display by inviting the spectators to dance with them, and it was therefore essential that they themselves be of high birth. The names of Ben Jonson and Inigo Jones are closely connected with this form of display in England, which illustrated a simple theme with lavish embellishments of music, poetry, costumes, and ever-changing scenery. In Italy, where stage machinery was first devised in the West, the masque reached even more spectacular heights. At Parma, on the occasion of the marriage of Ranuccio II to Margherita of Tuscany in 1628, an entertainment was given in the ducal theatre that combined opera, tournament, ballet, and regatta. Its climax was the flooding of the floor of the Teatro Farnese and the entry of several pageant cars representing sea monsters and islands, each propelled by men who guided them from beneath. After the display the waters were drained away as miraculously as they had appeared.

In Austria, too, such pageants were popular: when the emperor Leopold I welcomed the Spanish infanta Margaretha Elisabeth as his bride in 1666, the "Contest between Air and Water" was staged at the Hofburg. This display, which included a carrousel that had taken months to rehearse, reached its climax when the Temple of Eternity descended from the skies to reveal within itself a cupbearer, 8 live guardsmen, 16 grooms, 12 trumpeters, and the monarch himself, dressed like a Roman emperor and on horseback. The entire spectacle comprised numerous pageant cars, much music, and over 1,300 performers.

"Contest between Air and Water"

Carnival. The use of such lavish pageantry by a single privileged class of society has necessarily disappeared in the modern world. Where much money is devoted to display, all sections of the community demand equal rights to enjoyment of the splendour. Nowhere can the democratic tendencies of modern pageantry be seen more clearly than in carnival processions. In the West, carnival originated in Italy, sharing characteristics with ancient Roman feasts. The Roman Saturnalia permitted slaves to treat their masters as equals, a license that recurred in both the Feast of Fools and carnival itself. Each occasion has its unique procession. On the Feast of Fools, observed by the subdeacons in great cathedrals during January, it was the custom in 13th-century France for a girl carrying a baby to ride into church on an ass, in imitation of the flight into Egypt. In the ensuing mass,

celebrant and choir mimicked the braying of an ass, and the proceedings were sometimes concluded by the throwing of buckets of water. Carnival processions at first exhibited equal disorder but soon acquired elaborate artistic display. In modern Italy the processions at Rome and Venice are especially famous, the Venetian ones inevitably being held on the canals. An equally renowned carnival is held at Nice, whose culture is predominantly Italian. One of Nice's main attractions is the Battle of Flowers at carnival and other occasions. Floats are lavishly decorated, and spectators and paraders pelt one another with blossoms. The origin of the custom may lie in the ancient habit of exchanging gifts of foliage at fertility festivals, but the throwing of flowers, bonbons, confetti, rice, and ticker tape is common to many parades, and too much stress must not be laid on its having primitive origins. Like the ubiquitous balloon—in origin, possibly the bladder taken from a sacrificial animal—such features endure by the simple pleasure they afford, a reminder of the ease with which features of one kind of parade are incorporated into another without preexistent rites or traditions to support their new presence. The Battle of Flowers, for example, has been copied in the Tournament of Roses parade at Pasadena, California, since 1890, though it has acquired a more distinctly American flavour by association, since 1916, with the Rose Bowl football game. Students returning from Paris in 1827 introduced a Mardi Gras parade to New Orleans; decorated floats were added in 1837, and annual parades there date from 1857. In Rio de Janeiro, a similar pre-Lent carnival has long been customary. In Germany, too, the carnival, known as Fasching, with its attendant processions, was re-established in the 19th century in both the Rhineland and Bavaria, especially in Munich and Cologne.

Eastern carnivals

Carnival parades also occur in the East. Hindus observe the feast of Holī in March, originally a fertility celebration, when revellers set out in groups to squirt coloured water at everyone they meet or to smear their faces with coloured powders, customs recalling the throwing of water at the Feast of Fools and the blackening of the face in European parades. In China and in Chinese communities such as that in San Francisco, the New Year is observed with parades distinguished by elaborate dragon masks. In Hong Kong the festival of Tin Hau, Queen of Heaven, sees a procession of "lion dancers" accompanied by hooters and drums. Such dances originated in religious ritual and elsewhere have developed into dramatic form, as in Japanese Nō theatre. But Japan is also rich in pageantry of a less specifically dramatic kind. At the Gion festival in July enormous floats and magnificent costumes are exhibited, and at Miyazu Toro Nagahi in August thousands of lanterns are set floating on the sea in honour of the dead. The anthropologist Sir James Frazer suggested that carnival giants like those once popular at Douai and Dunkirk, France, and Antwerp, Belgium, originated in the sacrifice to the nature god of human beings, carried along in huge osier frames decorated with greenery, much in the fashion of the basket-clad figure of Jack-in-the-Green in English May Day parades. But not all parades originated in fertility rites. Some arose from practical necessity, like the British "trooping of the colour," which came from the need to familiarize mercenaries with the flag they were to follow. And the trooping ceremony, held in London on the sovereign's official birthday, uses mounted soldiers to give the tall effects essential to any parade.

By courtesy of the Japan National Tourist Organization

Decorated shrine car in the Gion Matsuri festival in Kyoto, Japan, 1968. The festival originated in the 9th century as a religious procession.

Such height is interestingly met at the annual Bun festival in Hong Kong by bandaging children to supporting frames and carrying them above the procession. Most contemporary giants are, however, very tall and often mechanized figures, long serpents and dragons, perhaps belching smoke, or are enormous balloons in the form of a traditional or comic-strip character.

Historical re-enactments. Many modern forms of pageantry unite parades with some form of drama. The Calgary Stampede in Alberta includes not only a procession, competitions, and a carnival atmosphere but also re-enactments of battle between cowboys and Indians. A similar historical re-enactment was presented for Queen Elizabeth II of England at Waitiang, New Zealand, in 1963, when she was greeted by a "Maori challenge." In India the parade at the autumn festival of Dussera culminates in plays based on incidents in the life of Rāma, the prince of Hindu mythology. In Delhi the performances are especially spectacular, and one incident of the prince's life is dramatized each day. As a culmination of these celebrations in northern India, the effigy of the demon-king Rāvaṇa is packed with fireworks and burned.

Christian themes

In the Christian religion simple plays and tableaux, such as the procession of the Magi at Limoges in the 11th century and the introduction of the Christmas crib three centuries earlier, were incorporated into church services. Like the Hindu Rāma plays and the Islāmic plays of Ḥusayn (a grandson of Muḥammad) still performed in Shīʿah towns, such Christian manifestations show the essential pageant characteristic of being fully understood only in relation to a wider context that is not itself dramatized. Even when Christian drama left the church proper and became, in such English cities as York and Coventry, part of a miracle cycle ranging from the Creation to the Day of Judgment, this characteristic remained: although one episode might have dramatic connection with the next, the different episodes were performed in different parts of the town.

Pageant in modern drama. In recent times distinguished dramatists have contributed to pageant drama, notably T.S. Eliot, who wrote the choruses for *The Rock*, a religious pageant staged in England in 1934. Other dramatists have written dialogue and commentary for *son et lumière*, the most modern development of pageant form. In the U.S., outdoor dramas on historical themes are staged annually. Notable among these are Paul Green's *The Lost Colony* on Roanoke Island; *The Common Glory* at Williamsburg, Virginia; and *Unto These Hills*, dealing with the Cherokee Indian tribe, at Cherokee, North Carolina. Such entertainments are sometimes termed epic dramas, but the designation is misleading, implying as it does a connection with the work and theories of the German playwright Bertolt Brecht. Although Brecht's own plays were deliberately episodic and eschewed Aristotelian precepts of unity, their basic intention was opposite to that of most pageantry. Brecht used a fragmentary method to provoke his audience into critical thought, whereas the usual aim of a pageant is to awaken nostalgic and uncritical identification with past glories.

Reinhardt's contributions

Not Brecht but Max Reinhardt must be seen as the essential figure behind modern pageant drama. From the beginning of the present century Reinhardt was advocating *Sprengung des Bühnenrahmens* ("exploding the confines of the stage") and experimenting with performances on such unusual stages as the circus ring and the exhibition hall. These experiments led others to realize that drama could indeed be staged, as it had been before the advent of the proscenium arch in the 17th century, in many different locales. Reinhardt's production of *Jedermann*, the adaptation by Hugo von Hofmannsthal of the medieval morality play *Everyman*, has been performed in front of Salzburg Cathedral annually since 1920; it is distinguished by elaborate crowd movement and audacious dramatic effects. His staging of *The Miracle* in London, in 1911, with music by Engelbert Humperdinck, was one of the most elaborate and successful examples of modern pageantry.

Restaged classics. Not all modern pageant drama, of course, is especially written or composed for the occasion. Works that are so written tend by their very nature to be of only local or temporal interest, although Mozart's music for student parades in Salzburg and Handel's *Water Music* and *Music for the Royal Fireworks* show that individual contributions to pageantry can enter the repertory of the classics.

An interesting modern development of pageantry is the restaging of classical works in open-air theatres of countries closely connected with the genre or theme presented. The operas of Verdi and other composers are given annually during the summer in the Arena at Verona and in the other Roman monuments throughout Italy. In Greece, classical plays are staged in the ancient theatres with a maximum of spectacular effect. At Bregenz in Austria, operettas are performed on a stage that stands in the waters of Lake Constance, transforming them, as it were, into water pageants. In Switzerland annual open-air performances are given of Schiller's *Wilhelm Tell*. Although all these works lend themselves to such spectacular production, it is significant that none was originally conceived as a pageant in the strict sense of the word. The nature of the presentation alone makes them so, coupled with the fact that they seem uniquely representative of the national spirit of the country concerned.

Oberammergau

A similar manifestation of local feeling is represented by the famous passion play (*Passionsspiel*) that is presented every ten years at Oberammergau in Bavaria. This custom dates from 1634, originating in a pledge made by the villagers in gratitude for the ending of the plague, in 1633. The actors are all local amateurs, about 500 in number; the action of the play lasts more than seven hours; and the entire proceeding is informed by a strong sense of religious devotion. In the intervening years other plays are presented, usually on Old Testament subjects, to give the actors training and experience. The *Passionsspiel* is given in a modern open-air theatre that is reserved for it alone. Since 1680 it has been presented in decimal years.

It will be seen, therefore, that pageantry is by no means a dead art nor a mere relic of things past. The instincts that created it in the past—religious belief, superstition and fear, militarism, great national occasions, the desire of a particular community to demonstrate its traditions and ethos—are still central forces in human existence and will doubtless continue to develop and adapt pageantry. Although many of the forms they take may be ephemeral, pageants and parades must be regarded as an abiding part of man's artistic endeavour.

BIBLIOGRAPHY. Major works on theatre history that discuss pageants and parades include E.K. CHAMBERS, *The Medieval Stage*, 2 vol. (1903), *The Elizabethan Stage*, 4 vol. (1923); G.W.G. WICKHAM, *Early English Stages, 1300 to 1660*, 2 vol. (1959–63); and A. NICOLL, *World Drama* (1949). E.J. STERN, *My Life, My Stage*, trans. from German by E. FITZGERALD (1951), covers the work of Max Reinhardt, theatrical producer; J.W. GASSNER, "Outdoor Pageant-Drama: Symphony of Sight and Sound," *Theatre Arts*, 38:80–83 (1954), considers modern U.S. pageant drama.

Pain, Theories of

Pain is the experience one associates with injury or some type of damage to the body: blows, bangs, cuts, and so forth. It is described in this way because the experience of pain is psychological and subjective. A good deal is known about the anatomical and physiological basis for pain, however. A minimal effective condition for the experience of pain is any stimulus that can cause tissue damage, slight and easily reversible, perhaps, but nevertheless damage. There is evidence that persons learn to discriminate the experience of pain as a result of events in infancy. Withdrawal from damaging stimuli occurs readily and early both in man and other animals. There are indications, however, that undue protection from the experience of damage reduces the ability to feel pain or to discriminate the stimuli that give rise to it. Not only does the unburned child not fear the fire, he may less readily have pain or know what it is when he is ultimately burned.

There are upward of 65 reports of persons who were born without the ability to feel pain at all, or else very little. Although they may survive without disability, they are at greater risk of suffering, or neglecting, burns, fractures, or infections. A similar effect has been produced in one recorded case by accidental damage to part of the midbrain. The life expectancy in these cases is shorter than average.

Even in people without this disability severe injury quite often does not cause pain; on the other hand, pain in adults often occurs for psychological reasons, in circumstances such that a physical basis for this bodily experience is, apparently, either absent or secondary. Thus an important proportion of persons with pain have their pain not because of any physical disease but because of emotional disorders. Nevertheless, pain is primarily associated with injury. To allow for this, for the learning of pain, for its usual subjective patterns, and for the frequent lack of evidence of a physical basis, pain has been defined operationally as an unpleasant experience, primarily associated with injury to tissue, and described in terms of such damage.

Pain without physical disease

Pain helps to preserve the organism by securing withdrawal from harmful agents. Alternatively, in sick people, pain may secure the rest that is needed for healing. Nature often is overabundant, however, and pain at times appears unnecessarily severe. This happens especially in some cases of damage to the nervous system.

MANIFESTATIONS OF PAIN

Pain is presumed to occur when a person takes avoiding action after stimulation from a potentially damaging source or when he gives signs of distress suggesting the effects of pain. The external signs of pain thus include avoidance behaviour, verbal complaints, cries, yelps, and so on. Another reaction to damaging stimuli is not avoidance but attack on neighbouring organisms; this may happen among rats that are subjected to electric shock. None of these signs is exclusive to pain. For many pur-

The private nature of pain

poses pharmacologists and other experimenters can work with laboratory animals, testing analgesics (pain-relieving drugs) on the assumption that their cries represent painful experience. But there can never be any certainty of this since inevitably the supposed experiences of others are private; only their unreliable external activities are public. One is only able to feel directly his own headache. Thus in human research, pain can only be inferred or assessed from what the sufferer does or says about it. After allowing for some discrepancies, it can be shown that people may grade their pains approximately as mild, moderate, or severe and that these descriptions tend broadly to conform to the degree of disorder, physical or psychological, from which it may be ascertained that they are suffering. Further, the measures required to relieve pain (*e.g.*, by analgesics) tend to conform to what would be predicted from the descriptions obtained.

The introspective report of pain is most consistent with regard to severity. The quality of pain is extremely hard to describe. Usually, its site can be denoted, then its intensity (*e.g.*, mild or very bad), and, with somewhat more difficulty, whether it is dull, throbbing, piercing, stabbing, and so forth. When the sufferer offers many descriptions of his unpleasant subjective state, it seems to be an indication of the severity that he attributes to the pain.

An indirect or inferential measurement of someone else's pain may be made by means of so-called pain thresholds. All techniques available for measuring these are open to criticism. They require the individual to undergo a safe stimulus that is varied in intensity until it just begins to feel painful; critics observe this to be a very different matter from spontaneous pain (as in cancer) in which the potential harm may be unclear and the feared risk very alarming. A popular technique for measuring pain thresholds employs a device (dolorimeter) that consists of a lamp as a source of heat, focussed onto the skin, and operated by a timing mechanism. An even safer device is a pressure algometer, a rod with a flat end loaded against a calibrated spring. Pressure is applied with this rod against a flat bony surface (*e.g.*, the shin) and increased steadily until pain is reported. Thresholds simply specify the directly observable degree of stimulation (intensity of heat or pressure) reported as pain. Under controlled conditions it has been shown that women are more sensitive (have lower thresholds) than men, office workers more than manual workers, and anxious people more than calm people. Thresholds tend to increase (sensitivity diminishes) somewhat in old age, although spontaneous pain at that time of life is relatively frequent.

NEUROPHYSIOLOGICAL BASES

Before the 19th century, theorists, physicians, and others tended to think of pain as an emotion (*q.v.*) rather than as a sensory experience. Anatomical and neurophysiological discoveries overwhelmingly resulted in its later classification as a sensory activity. More recent work, however, does not sustain such a limited sensory classification, although the neurophysiological basis remains extremely important. Pain is generally reported after injurious stimuli (or others, such as electric shock, which are not always damaging) are applied to normal skin or other tissues that contain microscopic structures called free nerve endings (see MECHANORECEPTION; NERVES AND NERVOUS SYSTEMS). Free nerve endings seem to subserve other experiences besides pain and are widely distributed to internal and external body surfaces; from them nerve fibres conduct impulses to the spinal cord. A stimulated point on the skin that is supplied by free nerve endings can, under varying circumstances, give rise to reports of other experiences (*e.g.*, heat, cold) as well as pain. Thus it can be argued that pain can best be related to variable anatomic and physiological *patterns* rather than to specific, unchanging neural pathways, each resembling the tract of an isolated single railway line. Nevertheless, there is also evidence that some nerve fibres in the vicinity of their receptors (*i.e.*, near such peripheral parts of the body as the skin) do respond in a fairly specific way to noxious stimulation. Accordingly, even at the most peripheral level it seems that there are some fixed elements that contribute to the physiological basis for the experience of pain. Their effects, however, seem to be modified by other concomitant patterns of activity deeper within the nervous system. In general, the nerve fibres that respond in a fixed way to noxious stimulation belong to the smaller myelinated and to the unmyelinated groups of fibres. (Myelinated fibres are those covered with a fatty sheath that seems to have an insulating function.) These conduct impulses more slowly than the larger fibres, which have been related to such sensory experiences as touch and pressure. Some of the so-called pain fibres are distributed to what is named (from its appearance) the posterior horn of gray matter in the spinal cord. Here they appear to be in close relationship to the substantia gelatinosa, an area lying at the tip of the posterior horn. Additional fibres cross from the two posterior horns to the opposite side of the spinal cord where they run in an area of white matter known as the anterolateral column. Several tracts run in this column, including a spino-thalamic tract that goes to the thalamus, which serves as a kind of relay centre in the brain. There is a wealth of evidence that interruption of this tract either by injury or disease (sometimes very highly localized damage) results in loss of the ability to feel pain from stimuli applied to the opposite side of the body in parts below the level of interruption.

The role of free nerve endings

Such loss is found to be an invariable consequence of full interruption of the pathways mentioned; more spatially restricted loss occurs after injuries to individual nerves. In a small proportion of cases, damage to the pathways may result in the spontaneous occurrence of pain, referred to the area supplied by the pathway, as well as a loss of sensory input. When this pain follows from damage to peripheral nerves, it is usually reported as burning in character and is called causalgia. After a limb is lost, the amputee normally still experiences the impression that it remains; this effect of a phantom limb is also sometimes accompanied by phantom pain (often very unpleasant). Spontaneous discomfort similar to causalgia can occur when there is damage to more centrally located structures (such as the spinal cord or the thalamus) and is known as central pain. It is convenient to call central pain, phantom-limb pain, and causalgia, jointly, neurogenic pain.

The sensation of pain in a missing leg

Neurogenic pains usually occur together with some general loss of sensory activity in the affected part of the body, thresholds for touch being raised particularly, a circumstance known as anaesthesia dolorosa. Study of such cases has led to the development of a theory that pain results from an imbalance of input between large, rapidly conducting myelinated ("fast") fibres and smaller, slower conducting myelinated and unmyelinated ("slow") fibres. If the slow fibres are heavily stimulated or the fast fibres are not stimulated enough, pain is believed to develop. Physiological evidence suggests that the balance is controlled by certain cells in the spinal cord that operate a "gating" mechanism that modulates, or regulates, the fast and slow input. These cells in turn appear susceptible to the influence of higher level structures (*i.e.*, cells farther up in the nervous system) that may increase or reduce their activity.

A coherent theory is thus available to account for experienced variations in pain by invoking the influence both of local peripheral events and of higher levels in the nervous system. Stated in neurophysiological language, this theory accounts for many of the observed phenomena. While it allows for fixed peripheral input, it also places particular weight on the pattern of input and on the possibility of psychological influence associated with relevant brain processes.

PSYCHOLOGICAL THEORIES

Some theories of pain are given primarily in psychological terms without specifying possible neural bases for them. As noted above, pain frequently is attributed to psychological (*e.g.*, emotional) factors. Secondly, an emotional state (*e.g.*, anxiety) often can enhance or abate pain that arises from observable physical sources. In consequence it is often convenient to talk of pain in

introspective terms whenever its possible neurophysiological basis remains incompletely explained.

Limited evidence indicates that persistent muscle tension will give rise to pain, as in holding an unfamiliar posture on a long journey. Similarly, there may be contraction of muscles as a result of anxiety, particularly in the neck and scalp. Tension in these muscles produces pain, notably headache, which generates further anxiety and alarm; this makes the pain even worse, in what seems to be a vicious circle. Relaxation and the easing of anxiety frequently bring relief. Such pain may be called psychosomatic; *i.e.*, it seems to be a bodily effect stemming from a psychological disturbance.

Sometimes pain seems to arise from an idea. The psychoanalyst Sigmund Freud reported the case of a man who attended an operation in which his brother's hip joint was to be straightened under an anesthetic. The joint was frozen in place by some abnormal adhesions that had to be broken; when a loud crack was heard, the man said he felt a pain in his own hip at the same moment, in what might be interpreted as sympathetic identification. Another physician reported a patient who imagined a nail or hammer at the back of his head and who experienced pain whenever he thought of the nail. Pain can arise as a hallucination as well; this may happen among people who are severely depressed and occasionally among those who suffer from schizophrenia or epilepsy.

All of these examples represent psychological routes for the production of pain. A psychological theory of pain that allows both for the physical and psychological description of events has been offered by the Hungarian-U.S. psychoanalyst Thomas Stephen Szasz. According to Szasz, pain functions as a danger signal and arises when a threat appears to the integrity of the body. Pain is held to arise as a consequence of the individual's awareness of a specific threat of loss in terms of bodily function. While it is wholly psychological, this theory seems to account for the apparent discrepancies between the intensity of pain and the extent of bodily lesions observed in people who report pain. Pain is regarded as "organic" or as "neurotic" according to the observer's opinion of the reality of the threat to the body. The actual presence or absence of structural disturbance is considered not to be relevant to the psychological mechanism but only to the individual's assessment of the reality of the threat.

MODIFICATION OF PAIN

It has been indicated that, in addition to physical lesions in the body generally and in the nervous system especially, the factors related to pain include age, sex, occupation, social circumstances, learning effects, and anxiety. There is much evidence that pain can be alleviated by drugs and psychiatric techniques designed to reduce anxiety. It is probable that analgesics such as acetylsalicylic acid (aspirin) have a special pharmacological effect in the relief of pain. But any drug or other measure that increases confidence and abates fear also will ease pain.

Effects of trance states, hypnosis, and drugs

The abolition of pain by trance states, including hypnosis, has long been accepted. Without taking all claims at their face value (which is probably inflated), it can be accepted that the modification of attitudes does at times abate pain. While this holds for moderate and slowly rising intensities of pain, it seems much less effective for sudden or severe pain. Nevertheless, under special circumstances (as in battle), severe wounds may not be noticed until later. As the French writer Michel de Montaigne put it, one feels a single cut from the surgeon's scalpel more than ten strokes of the sword in the heat of battle.

When drugs work by altering mood, their effect is partly attributable to the effects of suggestion and the expectation that relief will occur. This commonplace placebo effect (*e.g.*, relief by swallowing sugar pills) seems actually to result in less pain to the extent that the sufferer believes he will improve, becomes more confident, has more hope, and less anxiety. With such drugs as aspirin, part of the benefit is attributable to direct pharmacological effects on anxiety and hence on pain.

In one study, wounded soldiers were compared with civilians who had surgical wounds of comparable size. To the soldiers, their incapacitating wounds apparently meant an honourable release from danger. At any rate, their demands for analgesics were much more modest than those of the civilians for whom surgery had brought no comparable advantages, only serving to interrupt their lives. This shows how circumstances can alter pain. Pain seems alleviated to a very similar extent by hypnosis, placebos, suggestion, psychotherapy, and other means that relieve anxiety, including sedatives and the milder analgesics. For effective relief, more severe pain with a mainly organic basis tends to require potent drugs, local anesthesia, or neurosurgery. Treatments for depression also relieve chronic pain in many cases. Among current treatments available, some surgical operations on selected portions of the brain may be effective in pain relief; their application remains a matter for very careful consideration, however, and is certainly not routine.

MASOCHISM

Feelings of pain and pleasure are not simple opposites; but a surprising mixture of the two has often been suggested as occurring in masochism. By one definition, masochists are people who find sexual gratification in being humiliated or physically injured. Among many who seek injury or humiliation, however, the goal certainly does not seem to be immediately sexual. This is not to say that physical trauma in sexual activity is uncommon; indeed, among some animals (*e.g.*, the mink) it seems essential for normal arousal and orgasm. Among humans, it is most abnormal to require such injury for full sexual arousal, although acceptance of mild pain in sexual encounters may be normal. In addition, the term masochism may be extended to self-damaging behaviour, as among people who pursue martyrdom. Some psychiatric patients appear to experience pain as a result of such broadly defined masochistic motives. Whatever such behaviour represents, to some students of behaviour it seems a contradiction in terms; *i.e.*, the enjoyment of the unenjoyable.

Most often it is the humiliation or subservient sexual role that is sought by the extreme masochist, rather than any actual physical damage. It is thus possible to consider many manifestations of masochism as relatively normal (or at least harmless) in relation to the biological economy. Insofar as females do experience pain in such activities as defloration and childbirth, it would seem advantageous to the survival of species that they should have evolved to some experience of pain as rewarding.

NOORDENBOS, *Pain: Problems Pertaining to the Transmission of Nerve Impulses Which Give Rise to Pain* (1959), a penetrating and original consideration of pain mechanisms, based upon clinical data of neurological investigations; R. MELZACK and P.D. WALL, "Pain Mechanisms: A New Theory," *Science*, 150:971–979 (1965), a paper presenting a new theory, partly derived from that of Noordenbos but taking into account additional physiological observations and the relationship of pain to psychological factors; J.D. HARDY, H.G. WOLFF, and H. GOODELL, *Pain Sensations and Reactions* (1952), the classic report of investigations conducted during the period 1940–50; K.D. KEELE, *Anatomies of Pain* (1957), a scholarly and valuable source book dealing with the history of pain and its mechanisms; W.H. SWEET, "Pain," in J. FIELD (ed.), *Handbook of Physiology*, vol. 1 (1959), a standard account of the physiology of the subject; R.S. KNIGHTON and P.R. DUMKE (eds.), *Pain* (1966), a symposium —good in parts; T.S. SZASZ, *Pain and Pleasure: A Study of Bodily Feelings* (1957), an original, thoughtful book by a psychoanalyst, very clear on the conceptual and semantic problems of pain.

(H.Me.)

Paine, Thomas

Thomas Paine, political journalist, patriot, and champion of the rights of the common man, first achieved fame with the pamphlet "Common Sense," a stirring plea for American independence. Other works that gained him his

reputation as one of the greatest political pamphleteers in history were "The American Crises" papers, which rejuvenated the dispirited Continental Army; *Rights of Man*, a defense of the French Revolution and of republican principles; and *The Age of Reason*, an exposition of the place of religion in society.

Paine, portrait by John Wesley Jarvis. In the Thomas Paine Memorial House, New Rochelle, New York.

Life in England and America. Paine was born at Thetford, Norfolk, on January 29, 1737, of a Quaker father and an Anglican mother. His formal education was meagre, just enough to enable him to master reading, writing, and arithmetic. At 13 he began work with his father as a corset maker and then tried various other occupations unsuccessfully, finally becoming an officer of the excise. His duties were to hunt for smugglers and collect the excise taxes on liquor and tobacco. The pay was insufficient to cover living costs, but he used part of his earnings to purchase books and scientific apparatus.

Paine's life in England was marked by repeated failures. He had two brief marriages. He was unsuccessful or unhappy in every job he tried. He was dismissed from the excise office after he published a strong argument in 1772 for a raise in pay as the only way to end corruption in the service. Just when his situation appeared hopeless, he met Benjamin Franklin in London, who advised him to seek his fortune in America and gave him letters of introduction.

Arrival in Philadelphia

Paine arrived in Philadelphia on November 30, 1774. His first regular employment was helping to edit the *Pennsylvania Magazine*. In addition Paine published numerous articles and some poetry, anonymously or under pseudonyms. One such article was "African Slavery in America," a scathing denunciation of the African slave trade, which he signed "Justice and Humanity."

Paine had arrived in America when the conflict between the colonists and England was reaching its height. After blood was spilled at the Battle of Lexington and Concord, April 19, 1775, Paine argued that the cause of America should not be just a revolt against taxation but a demand for independence. He put this idea into "Common Sense," which came off the press on January 10, 1776. The 50-page pamphlet sold more than 500,000 copies within a few months. More than any other single publication, "Common Sense" paved the way for the Declaration of Independence, unanimously ratified July 4, 1776.

During the war that followed, Paine served as volunteer aide-de-camp to General Nathanael Greene. His great contribution to the patriot cause was the 16 "Crisis" papers issued between 1776 and 1783, each one signed "Common Sense." "The American Crisis. Number I," published on December 19, 1776, when George Washington's army was on the verge of disintegration, opened with the flaming words: "These are the times that try men's souls." Washington ordered the pamphlet read to all the troops at Valley Forge.

In 1777 Congress appointed Paine secretary to the Committee for Foreign Affairs. He held the post until early in 1779, when he became involved in a controversy with Silas Deane, a member of the Continental Congress, whom he accused of seeking to profit personally from French aid to the United States. But in revealing Deane's machinations, Paine was forced to quote from secret documents to which he had access as secretary of the Committee for Foreign Affairs. As a result, despite the truth of his accusations, he was forced to resign his post.

Paine's desperate need of employment was relieved when he was appointed clerk of the General Assembly of Pennsylvania on November 2, 1779. In this capacity he had frequent opportunity to observe that American troops were at the end of their patience because of lack of pay and scarcity of supplies. Paine took $500 from his salary and started a subscription for the relief of the soldiers. In 1781, pursuing the same goal, he accompanied John Laurens to France. The money, clothing, and ammunition they brought back with them were important to the final success of the Revolution. Paine also appealed to the separate states to cooperate for the well-being of the entire nation. In "Public Good" (1780) he included a call for a national convention to remedy the ineffectual Articles of Confederation and establish a strong central government under "a continental constitution."

Efforts to aid the American troops

At the end of the American Revolution, Paine again found himself poverty stricken. His patriotic writings had sold by the hundreds of thousands, but he had refused to accept any profits in order that cheap editions might be widely circulated. In a petition to Congress endorsed by Washington, he pleaded for financial assistance. It was buried by Paine's opponents in Congress, but Pennsylvania gave him £500 and New York a farm in New Rochelle. Here Paine devoted his time to inventions, concentrating on an iron bridge without piers and a smokeless candle.

In Europe: "Rights of Man." In April 1787 Paine left for Europe to promote his plan to build a single-arch bridge across the wide Schuylkill River near Philadelphia. But in England he was soon diverted from his engineering project. In December 1789 he published anonymously a warning against the attempt of Prime Minister William Pitt to involve England in a war with France over Holland, reminding the British people that war had "but one thing certain and that is increase of taxes." But it was the French Revolution that now filled Paine's thoughts. He was enraged by Edmund Burke's attack on the uprising of the French people in his *Reflections on the Revolution in France*; and, though Paine admired Burke's stand in favour of the American Revolution, he rushed into print with his celebrated answer, *Rights of Man* (March 13, 1791). The book immediately created a sensation. At least eight editions were published in 1791, and the work was quickly reprinted in America, where it was widely distributed by the Jeffersonian societies. When Burke replied, Paine came back with *Rights of Man, Part II*, published on February 17, 1792.

What began as a defense of the French Revolution evolved into an analysis of the basic reasons for discontent in European society and a remedy for the evils of arbitrary government, poverty, illiteracy, unemployment, and war. Paine spoke out effectively in favour of republicanism as against monarchy, and went on to outline a plan for popular education, relief of the poor, pensions for aged people, and public works for the unemployed, all to be financed by the levying of a progressive income tax. To the ruling class Paine's proposals spelled "bloody revolution," and the government ordered the book banned and the publisher jailed. Paine himself was indicted for treason, and an order went out for his arrest. But he was en route to France, having been elected to a seat in the National Convention, before the order for his arrest could be delivered. Paine was tried in absence, found guilty of seditious libel, and declared an outlaw; and *Rights of Man* was ordered permanently suppressed.

Paine's support of Republicanism

In France Paine hailed the abolition of the monarchy but deplored the terror against the royalists, and fought unsuccessfully to save the life of King Louis XVI, favour-

ing banishment rather than execution. He was to pay for his efforts to save the King's life when the radicals under Robespierre took power. Paine was imprisoned from December 28, 1793, to November 4, 1794, when, with the fall of Robespierre, he was released and, though seriously ill, readmitted to the National Convention.

Imprisonment in France

While in prison, the first part of Paine's *Age of Reason* was published (1794), and it was followed by Part II after his release (1796). Although Paine made it clear that he believed in a Supreme Being and as a deist opposed only organized religion, the work won him a reputation as an atheist among the orthodox. The publication of his last great pamphlet, "Agrarian Justice" (1797), with its attack on inequalities in property ownership, added to his many enemies in establishment circles.

Paine remained in France until September 1, 1802, when he sailed for the United States. He quickly discovered that his services to the country had been all but forgotten and that he was widely regarded only as the world's greatest infidel. Despite his poverty and his physical condition, worsened by occasional drunkenness, Paine continued his attacks on privilege and religious superstitions. He died in New York City on June 8, 1809, and was buried in New Rochelle on the farm given to him by the state of New York as a reward for his Revolutionary writings. Ten years later, William Cobbett, the political journalist, exhumed the bones and took them to England, where he hoped to give Paine a funeral worthy of his great contributions to humanity. But the plan misfired, and the bones were lost, never to be recovered.

Assessment

At Paine's death most American newspapers reprinted the obituary notice from the *New York Citizen*, which read in part: "He had lived long, did some good and much harm." This remained the verdict of history for over a century following his death, but in recent years the tide has turned: on January 30, 1937, *The Times* of London referred to him as "the English Voltaire," and on May 18, 1952, Paine's bust was placed in the New York University Hall of Fame.

MAJOR WORKS

POLITICAL AND RELIGIOUS: "Common Sense" (1776); "The American Crisis," 15 pt. (1776–83); "Prospects on the Rubicon" (1787); *Rights of Man*, 2 pt. (1791–92); "Letter Addressed to the Addressers on the Late Proclamation" (1792); *The Age of Reason*, 2 pt. (1794–95); "Dissertation on the First Principles of Government" (1795); "Letter to George Washington, President of the United States of America, on Affairs Public and Private" (1796); "Atheism Refuted" (1798); "Letters to the Citizens of the United States," 4 letters (dated 1802).

ECONOMIC AND FINANCIAL: "Dissertation on the Affairs of the Bank" (1786); *The Decline and Fall of the English System of Finance* (1796); "Agrarian Justice" (1797).

BIBLIOGRAPHY. The first comprehensive edition of Paine's works is that of MONCURE D. CONWAY, *The Writings of Thomas Paine*, 4 vol. (1894–96). This has been replaced by PHILIP S. FONER, *The Complete Writings of Thomas Paine*, 2 vol. (1945). Several later discoveries of Paine's writings are in A.O. ALDRIDGE, "Some Writings of Thomas Paine in Pennsylvania Newspapers," *American Historical Review*, 56:832–838 (1951). RICHARD GIMBEL, *Thomas Paine Fights for Freedom in Three Worlds* (1961), offers the best annotated bibliography of Paine's works. The first worthwhile biography, though entirely uncritical, was MONCURE D. CONWAY, *The Life of Thomas Paine*, 2 vol. (1892). There is still no full-length study of Paine that replaces Conway's biography, but a number of brief studies of the man are more valuable in terms of an overall evaluation of his contributions. Worth consulting are VERNON L. PARRINGTON, "Tom Paine: Republican Pamphleteer," in *Main Currents in American Thought*, pp. 327–341 (1927); HARRY H. CLARK'S Introduction to *Thomas Paine: Representative Selections*, rev. ed. (1961); and PHILIP S. FONER'S Introduction to *The Complete Writings*. A recent book that helps break down the tradition of the religious infidel and political demagogue is ROBIN MCKOWN, *Thomas Paine* (1962).

(P.S.F.)

Painting, Art of

The art of painting is the expression of ideas and emotions, with the creation of certain aesthetic qualities, in a two-dimensional visual language. The elements of this language—its shapes, lines, colours, tones, and textures—are used in various ways to produce sensations of volume, space, movement, and light on a flat surface. These elements are combined into expressive patterns in order to represent real or supernatural phenomena, to interpret a narrative theme, or to create wholly abstract visual relationships. The artist communicates his visual message in terms of the sensuous qualities and expressive possibilities and limitations of a particular medium, technique, and form.

Earlier cultural traditions—of tribes, religions, guilds, royal courts, and states—largely controlled the craft, form, imagery, and subject matter of painting and determined its function, whether ritualistic, devotional, decorative, entertaining, or educational. Painters were employed more as skilled artisans than as creative artists. Later, the Far East and Renaissance Europe saw the emergence of the fine artist, with the social status of scholar and courtier, who signed his work, who decided its design and often its subject and imagery, and who established a more personal, if not always amicable, relationship with his patron.

The painter as skilled artisan and fine artist

During the 19th century the painter in Western societies began to lose his social position and secure patronage. Generally, he can now reach an audience only through commercial galleries and public museums, although his work may be occasionally reproduced in art periodicals. He may be also assisted by financial awards or commissions from industry and the state. He has, however, gained the freedom to invent his own visual language and to experiment with new forms and unconventional materials and techniques. The restless endeavour to extend the boundaries of expression in Western art produces continuous international stylistic changes. The often bewildering succession of new movements in painting is further stimulated by the swift interchange of ideas by means of international art journals, travelling exhibitions, and art centres.

This article is concerned with the elements and principles of design in painting and with the various mediums, forms, imagery, subject matter, and symbolism employed or adopted or created by the painter.

This article is divided into the following sections:

ELEMENTS AND PRINCIPLES OF DESIGN

The design of a painting is its visual format: the arrangement of its lines, shapes, colours, tones, and textures into an expressive pattern. It is the sense of inevitability in this formal organization that gives a great painting its self-sufficiency and presence.

The colours and placing of the principal images in a

Formal interplay of colours and shapes

design may be sometimes largely decided by representational and symbolic considerations. Yet, it is the formal interplay of colours and shapes that alone is capable of communicating a particular mood, producing optical sensations of space, volume, movement, and light and creating forces of both harmony and tension, even when a painting's narrative symbolism is obscure.

Elements of design. *Line.* Each of the design elements has special expressive qualities. Line, for example, is an intuitive, primeval convention for representing things; the simple linear imagery of young children's drawings and prehistoric rock paintings is universally understood. The formal relationships of thick with thin lines, of broken with continuous, and of sinuous with jagged are forces of contrast and repetition in the design of many paintings in all periods of history. Variations in the painted contours of images also provide a direct method of describing the volume, weight, spatial position, and textural characteristics of things. The finest examples of this pictorial shorthand are found in Japanese ink painting, where an expressive economy and vitality of line is closely linked to a traditional mastery of calligraphy.

In addition to painted contours, a linear design is composed of all the edges of tone and colour masses, the axial directions of images, and the lines implied by alignments of shapes across the picture. The manner in which these various kinds of line are echoed and repeated animates the design (Figure 1). The artist, consciously or intuitively, also places them in relationship to one another across the picture, so that they weave a unifying rhythmic network throughout the painting (Figure 1).

Apart from the obvious associations of some linear patterns with particular actions—undulating lines suggesting buoyant movement, for instance—emotive sensations are produced by certain linear relationships. Thus, lines moving upward express feelings of joy and aspiration, those directing the eye downward evoke moods of sadness or defeat, while lines at angles opening to the right of a design are more agreeable and welcoming than those spreading outward to the left.

Shape and mass. Shape and mass, as elements of design, include all areas of different colour, tone, and texture, as well as individual and grouped images.

Children instinctively represent the things they see by geometrical symbols. Not only have sophisticated modern artists, such as Paul Klee and Jean Dubuffet, borrowed this primitive imagery, but the more arresting and expressive shapes and masses in most styles of painting and those to which most people intuitively respond will generally be found to have been clearly based on such archetypal forms. A square or a circle will tend to dominate a design and will therefore often be found at its focal

Response to archetypal forms

centre—the square window framing Christ in Leonardo da Vinci's "Last Supper," for example, the hovering "sun" in an Adolph Gottlieb abstract, or the halo encircling a Christian or Buddhist deity. A firmly based triangular image or group of shapes seems reassuring, even uplifting, while the precarious balance implied by an inverted triangular shape or mass produces feelings of tension. Oval, lozenge, and rectangular forms suggest stability and protection and often surround vulnerable figures in narrative paintings.

There is generally a cellular unity, or "family likeness," between the shapes and masses in a design similar to the visual harmony of all units to the whole observed in natural forms—the gills, fins, and scales in character with the overall shape of a fish, for example.

The negative spaces between shapes and masses are also carefully considered by the artist, since they can be so adjusted as to enhance the action and character of the positive images. They can be as important to the design as time intervals in music or the voids of an architectural facade.

Colour. In many styles and periods of painting, the functions of colour are primarily decorative and descriptive, often serving merely to reinforce the expression of an idea or subject communicated essentially in terms of line and tone. In much of 20th-century painting, however, colour has gained in importance and is the primary expressive element.

The principal dimensions of colour in painting are the variables or attributes of hue, tone, and intensity. Red, yellow, and blue are the basic hues from which all others on the chromatic scale can be made by mixtures. These three opaque hues are the subtractive pigment primaries and should not be confused with the behaviour of the additive triads and mixtures of transparent, coloured light. Mixtures of primary pairs produce the secondary hues of orange, violet, and green. By increasing the amount of one primary in each of these mixtures, the tertiary colours of yellow-orange, orange-red, red-violet, violet-blue, blue-green, and green-yellow, respectively, are made. The primary colours, with their basic secondary and tertiary mixtures, can be usefully notated as the 12 segments of a circle (Figure 2). The secondary and tertiary colour segments between a pair of parent primaries can then be seen to share a harmonious family relationship with one another—the yellow-orange, orange, and orange-red hues that lie between yellow and red, for example.

Local hues are the inherent and associative colours of things. In everyday life, familiar things are described by particular colours, and these often are identified by reference to familiar things; the green of grass and the grass green of paint, for instance. Although, as the Impressionists demonstrated, the inherent colours of forms in the real world are usually changed by effects of light and atmosphere, many of the great primitive and classical styles of representational painting are expressed in terms of local hues.

Tone is a colour's relative degree, or value, of lightness or darkness. The tonal pattern of a painting is shown in a monochrome reproduction. A painting dominated by dark colours, such as a Rembrandt, is in a low tonal key, while one painted in the pale range of a late Claude Monet is said to be high keyed. The tonal range of pigments is too narrow for the painter to be able to match the brightest lights and deepest darks of nature. Therefore, in order to express effects of illumination and dense shadow, he must lower the overall tonal key of his design, thus intensifying the brightness value of his lightest pigment colours.

Tonal pattern of a painting

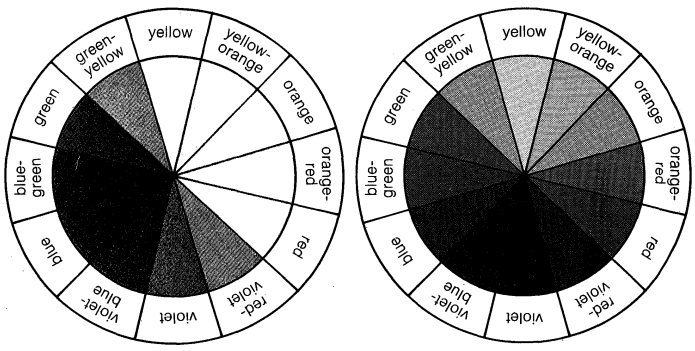

Figure 2: *Colour.*
(Left) Colour wheel made up of the primary colours and their basic secondary and tertiary mixtures. (Right) Colour wheel with approximate, inherent tonal values.

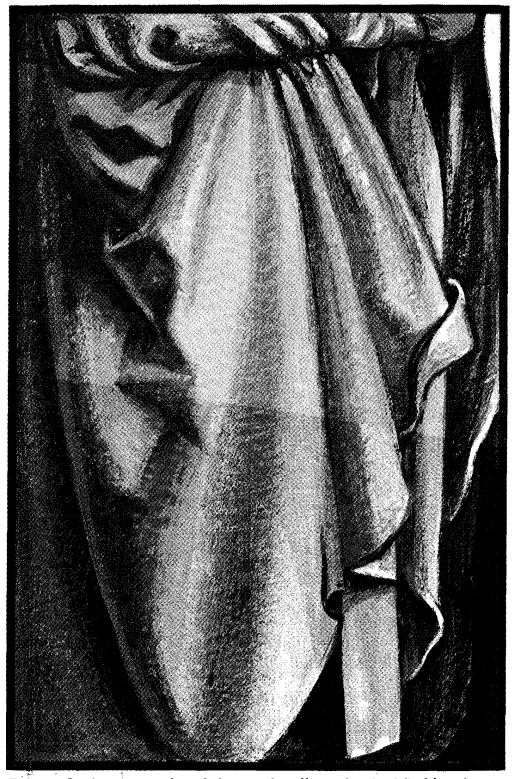

Figure 3: An example of the early oil method of (left) colour glazing a (right) monochrome painting.

The Greco-Roman, Renaissance, and Neoclassical method of representing volume and space in painting was by a system of notated tonal values, the direction of each plane in the design being indicated by a particular degree of lightness or darkness. Each tonal value was determined by the angle at which a plane was meant to appear to turn away from an imaginary source of light. The tonal modelling, or shading, of forms was often first completed in a monochrome underpainting. This was then coloured with transparent washes of local hues, a technique similar to that of colour tinting a black-and-white photograph (Figure 3).

Each hue has an intrinsic tonal value in relation to others on the chromatic scale; orange is inherently lighter than red, for instance, and violet is darker than green (Figure 2). Any reversal of this natural tonal order creates a colour discord. An optical shock is therefore produced when orange is juxtaposed with pink (a lighter tone of red) or pale violet is placed against dark green. Such contrasts as these are deliberately created in paintings for the purpose of achieving these dramatic and disturbing effects.

The intensity of a colour is its degree of purity or hue saturation. The colour of a geranium, therefore, is said to be more intense, more highly saturated with pure orange-red than is mahogany. The pigment vermilion is orange-red at maximum intensity; the brown earth pigment burnt sienna is grayer and has a lower degree of orange-red saturation.

Intense hues are termed chromatic colours. The achromatic range is made up of hues reduced in intensity by the addition of white, making the tints, or pastel colours, such as cream and pink; or of black, producing the shades, or earth colours, such as mustard and moss green; or of both

white and black, creating the neutralized hues, or colour-tinged grays, such as oatmeal and charcoal.

An achromatic colour will seem more intense if it is surrounded by neutralized hues or juxtaposed with its complementary colour. Complementaries are colour opposites. The complementary colour to one of the primary hues is the mixture of the other two; the complementary to red pigment, for example, is green—that is, blue mixed with yellow. The colour wheel (Figure 2) shows that the tertiaries also have their colour opposites, the complementary to orange-red, for instance, being blue-green. Under clear light the complementary to any chroma, shade, or tint can be seen if one "fixates," or stares at one colour intently for a few seconds then looks at a neutral, preferably white, surface. The colour afterimage will appear to glow on the neutral surface (Figure 4). Mutual

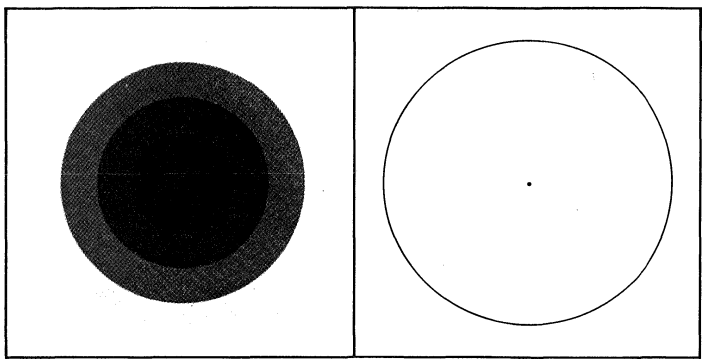

Figure 4: Coloured afterimages: if a person stares for about 30 seconds at the coloured disk under a clear light and then fixes upon the empty space of the adjacent circle, coloured afterimages will appear.

Enhancement of colour intensity

enhancement of colour intensity results from juxtaposing a complementary pair, red becoming more intensely red, for instance, and green more fiercely green when these are contiguous than either would appear if surrounded by harmonious hues. The 19th-century physicist Michel-Eugène Chevreul referred to this mutual exaltation of opposites as the law of simultaneous contrast. Chevreul's second law, of successive contrast, referred to the optical sensation that a complementary colour halo appears gradually to surround an intense hue. This complementary glow is superimposed on surrounding weaker colours, a gray becoming greenish when juxtaposed with red, reddish in close relationship with green, yellowish against violet, and so on (Figure 5).

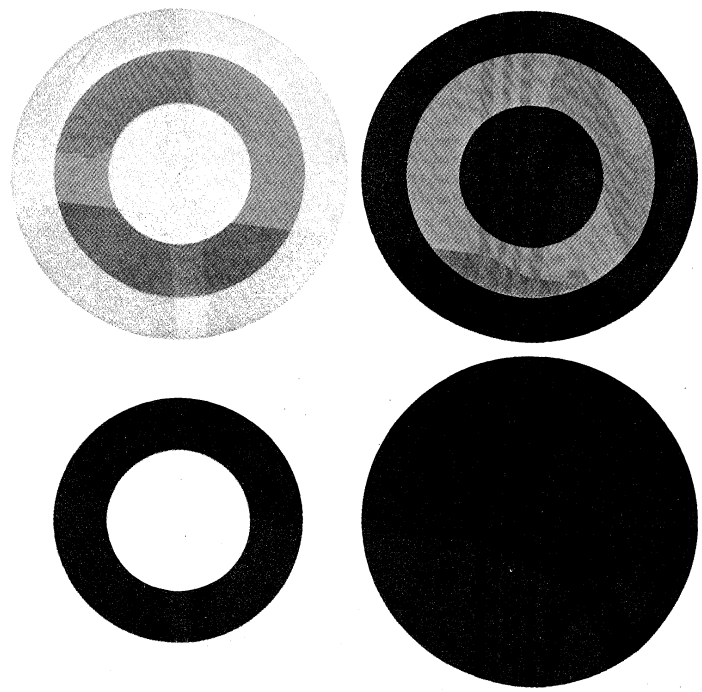

Figure 5: *Optical colour change.*
(Top) By complementary action, the same gray pigment will appear greenish when adjacent to red but reddish if adjacent to green. (Bottom) A green hue will seem cool if surrounded by yellow, but warm when surrounded by blue-green.

Hues containing a high proportion of blue (the violet to green range) appear cooler than those with a high content of yellow or red (the green-yellow to red-violet range). This difference in the temperature of hues in a particular painting is, of course, relative to the range and juxtaposition of colours in the design. A green will appear cool if surrounded by intense yellow, while it will seem warm against blue-green (Figure 5). The optical tendency for warm colours to advance before cold had been long exploited by European and Oriental painters as a method of suggesting spatial depth. Changes in temperature and intensity can be observed in the atmospheric effects of nature, where the colours of distant forms become cooler, grayer, and bluish, while foreground planes and features appear more intense and usually warmer in colour.

The apparent changes in a hue as it passes through zones of different colour has enabled painters in many periods to create the illusion of having employed a wide range of pigment hues with, in fact, the use of very few. And, although painters had applied many of the optical principles of colour behaviour intuitively in the past, the publication of research findings by Chevreul and others stimulated the Neo-Impressionists and Post-Impressionists and the later Orphist and Op Art painters to extend systematically the expressive possibilities of these principles in order to create illusions of volume and space and vibrating sensations of light and movement. Paul Cézanne, for example, demonstrated that subtle changes in the surface of a form and in its spatial relationship to others could be expressed primarily in facets of colour, modulated by varying degrees of tone, intensity, and temperature and by the introduction of complementary colour accents.

While the often-complex religious and cultural colour symbologies may be understood by very few, the emotional response to certain colour combinations appears to be almost universal. Optical harmonies and discords seem to affect everyone in the same way, if in varying degrees. Thus, an image repeated in different schemes of colour will express a different mood in each change (Figure 6).

Texture. Pointillism was a term given to the Neo-Impressionist system of representing the shimmer of atmospheric light with spots of coloured pigment. This technique produced an overall granular texture. As an element of design, texture includes all areas of a painting enriched or animated by vibrating patterns of lines, shapes, tones, and colours, in addition to the tactile textures created by the plastic qualities of certain mediums. Decorative textures may be of geometrical repeat patterns, as in much of Indian, Islāmic, and medieval European painting and other art, or of representations of patterns in nature, such as scattered leaves, falling snow, and flights of birds.

Perceptual and conceptual levels of understanding spatial relationships

Volume and space. The perceptual and conceptual methods of representing volume and space on the flat surface of a painting are related to the two levels of understanding spatial relationships in everyday life.

Perceptual space is the view of things at a particular time and from a fixed position. This is the stationary window view recorded by the camera and represented in the later periods of ancient Greek and Roman paintings and in most Western schools of painting since the Renaissance. Illusions of perceptual space are generally created by use of the linear perspectival system, based on the observations that objects appear to the eye to shrink and parallel lines and planes to converge as they approach the horizon, or viewer's eye level (Figure 7).

Young children and primitive artists, however, do not understand space in this way and represent it conceptually. Their paintings, therefore, show objects and surroundings independently of one another and from the views that best present their most characteristic features. The notion of scale in their pictures is also subjective, the

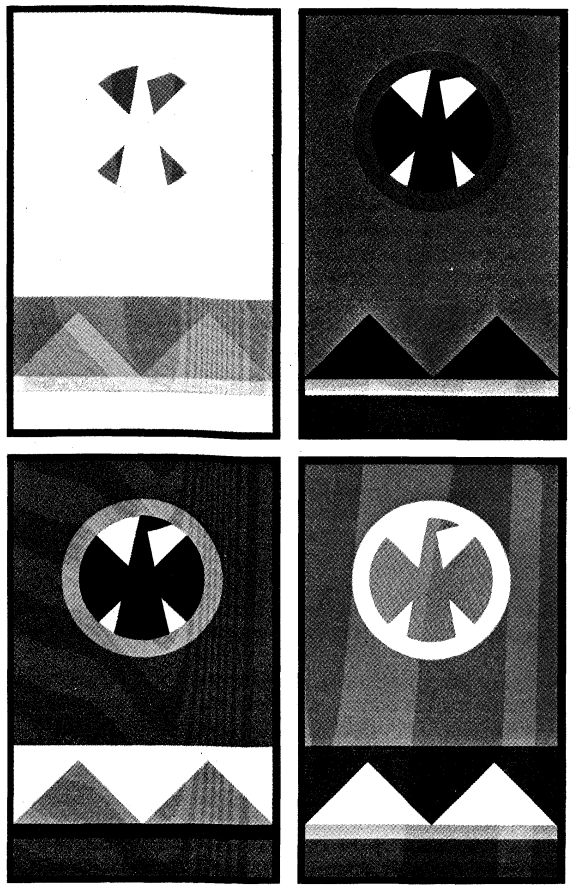

Figure 6: Emotive colour relationships: an identical pattern of shapes may express a different emotional mood through each colour variation.

relative size of things being decided by the artist either by their degree of emotional significance for him or by their narrative importance in the picture (interest perspective).

The conceptual, polydimensional representation of space has been used at some period in most cultures. In much of ancient Egyptian and Cretan painting, for example, the head and legs of a figure were shown in profile, but the eye and torso were drawn frontally. And in Indian, Islāmic, and pre-Renaissance European painting, vertical forms and surfaces were represented by their most informative elevation view (as if seen from ground level), while the horizontal planes on which they stood were shown in isometric plan (as if viewed from above) (Figure 7). This system produces the overall effect that objects and their surroundings have been compressed within a shallow space behind the picture plane.

By the end of the 19th century Cézanne had flattened the conventional Renaissance picture space (Figure 7), tilting horizontal planes so that they appeared to push vertical forms and surfaces forward from the picture plane and toward the spectator (Figure 8). This illusion of the picture surface as an integrated structure in projecting low relief was developed further in the early 20th century by the Cubists. The conceptual, rotary perspective of a Cubist painting shows not only the components of things from different viewpoints but presents every plane of an object and its immediate surroundings simultaneously. This gives the composite impression of things in space that is gained by having examined their surfaces and construction from every angle.

In Pop Art painting, both conceptual and perceptual methods of representing space are often combined. And, where the orbital movement of forms in European design since the Renaissance was intended to hold the spectator's attention within the frame (Figure 7), the expanding picture space in recent mural-size abstract paintings directs his eye outward to the surrounding wall, and their shapes and colours seem about to invade his own territory (Figure 9).

Time and movement. Time and movement in painting are not restricted to representations of physical energy but are elements of all design. Part of the viewer's full experience of a great painting is to allow the arrangement of lines, shapes, and accents of tone or colour to guide him across the picture surface at controlled tempos and rhythmic directions that contribute to the expression of a particular mood, vision, and idea.

Kinetic sensations on a flat surface

Centuries before cinematography, painters attempted to produce kinetic sensations on a flat surface. A mural of 2000 BC in an Egyptian tomb at Beni Hasan, for instance, is designed as a continuous strip sequence of wrestling holds and throws, so accurately articulated and notated that it might be photographed as an animated film cartoon. The gradual unrolling of a 12th-century Japanese hand scroll produces the visual sensation of a helicopter flight along a river valley, while the experience of walking to the end of a long, processional Renaissance mural by Andrea Mantegna or Benozzo Gozzoli is similar to that of having witnessed a passing pageant as a standing spectator.

In the Eastern and Western narrative convention of continuous representation, various incidents in a story were depicted together within one design, the chief characters

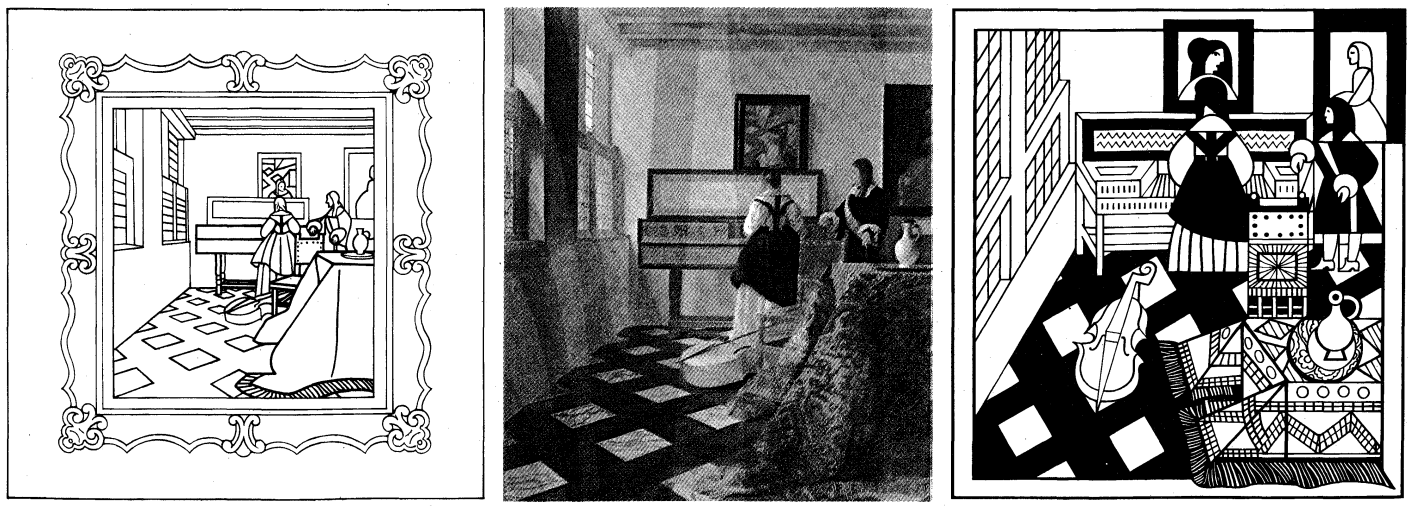

Figure 7: *Perceptual and conceptual space.*

in the drama easily identified as they reappeared in different situations and settings throughout the painting. In Byzantine murals and in Indian and medieval manuscript paintings, narrative sequences were depicted in grid patterns, each "compartment" of the design representing a visual chapter in a religious story or a mythological or historical epic.

The Cubists aimed to give the viewer the time experience of moving around static forms in order to examine their volume and structure and their relationships to the space surrounding them. In paintings such as "Nude Descending a Staircase," "Girl Running on a Balcony," and "Dog on Leash," Marcel Duchamp and Giacomo Balla combined the Cubist technique of projected, interlocking planes with the superimposed time–motion sequences of cinematography. This technique enabled the artists to analyze the structural mechanics of forms, which are represented as moving in space past the viewer.

Principles of design. Because painting is a two-dimensional art, the flat pattern of lines and shapes is an important aspect of design, even for those painters concerned with creating illusions of great depth. And, since any mark made on the painting surface can be perceived as a spatial statement—for it rests upon it—there are also qualities of three-dimensional design in paintings composed primarily of flat shapes. Shapes in a painting, therefore, may be balanced with one another as units of a flat pattern and considered at the same time as components in a spatial design, balanced one behind another. A symmetrical balance of tone and colour masses of equal weight creates a serene and sometimes monumental design, while a more dynamic effect is created by an asymmetrical balance.

Geometrical shapes and masses are often the basic units in the design of both "flat patterns," such as Byzantine and Islāmic paintings, and "sculptural compositions," such as Baroque and Neoclassical figure tableaux. The flat, overlapping squares, circles, and triangles that create the pattern of a Romanesque mural, for example, become the interlocking cubic, spherical, and pyramidal components that enclose the grouped figures and surrounding features in a Renaissance or a Neoclassical composition (Figure 10).

An emphasis upon the proportion of the parts to the whole is a characteristic of Classical styles of painting. The Golden Mean, or Section, has been used as an ideal proportion on which to base the framework of lines and shapes in the design of a painting. The Renaissance mathematician Lucas Pacioli defined this aesthetically satisfying ratio as the division of a line so that the shorter part is to the longer as the longer is to the whole (approximately 8 to 13). His treatise (*Divina proportione*) influenced Leonardo da Vinci and Albrecht Dürer. The Neo-Impressionists Georges Seurat (Figure 1) and Paul Signac based the linear pattern of many of their compositions upon the principle of this "divine proportion." Golden Mean proportions can be discovered in the design of many other styles of painting, although often they may have been created more by intuitive judgment than by calculated measurement.

Tension in paintings

Tension is created in paintings, as it is experienced in everyday life, by the anticipation of an event or by an unexpected change in the order of things. Optical and psychological tensions occur in passages of a design, therefore, when lines or shapes almost touch or seem about to collide, when a harmonious colour progression is interrupted by a sudden discord, or when an asymmetrical balance of lines, shapes, tones, or colours is barely held.

Contrasts in line, shape, tone, and colour create vitality; rectilinear shapes played against curvilinear, for instance, or warm colours against cool. Or a painting may be composed in contrasted overall patterns, superimposed in counterpoint to one another—a colour scheme laid across contrasting patterns of lines and tones, for example (Figure 11).

Design relationships between painting and other visual arts. The philosophy and spirit of a particular period in painting usually have been reflected in many of its other visual arts. The ideas and aspirations of the ancient cul-

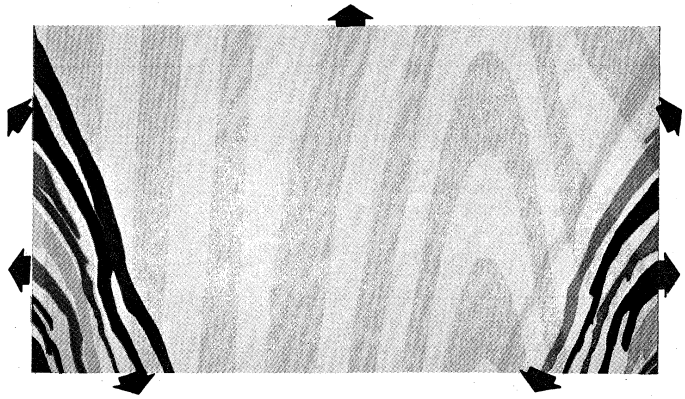

Figure 9: Opening out the picture space: the movement of shapes in Morris Louis' acrylic painting "Alpha-Phi," 1961, directs the spectator's eye outside the picture surface. In the Tate Gallery, London. 2.59 m × 4.58 m. In contrast, Vermeer's design (Figure 7) is contrived to hold the spectator's attention within the frame.

tures, of the Renaissance, Baroque, Rococo, and Neoclassical periods of Western art and, more recently, of the 19th-century Art Nouveau and Secessionist movements were expressed in much of the architecture, interior design, furniture, textiles, ceramics, dress design, and handicrafts, as well as in the fine arts, of their times. Following the Industrial Revolution, with the redundancy of handcraftmanship and the loss of direct communication between the fine artist and society, idealistic efforts to unite the arts and crafts in service to the community were made by William Morris in Victorian England and by the Bauhaus in 20th-century Germany. Although their aims were not fully realized, their influences, like those of the short-lived de Stijl and Constructivist movements, have been far-reaching, particularly in architectural, furniture, and typographic design.

Michelangelo and Leonardo da Vinci were painters, sculptors, and architects. Although no artists since have excelled in so wide a range of creative design, leading 20th-century painters have expressed their ideas in many other mediums. In graphic design, for example, Pierre Bonnard, Henri Matisse, and Raoul Dufy produced posters and illustrated books; André Derain, Fernand Léger, Marc Chagall, Mikhail Larionov, and Kazimir Malevich designed for the theatre; Joan Miró, Georges Braque, and Chagall worked in ceramics; Braque and Salvador Dalí designed jewelry; and Dalí, Hans Richter, and Andy Warhol have made films. Many of these, with other modern painters, have also been sculptors and printmakers and have designed for textiles, tapestries, mosaics, and stained glass, while there are few mediums of the visual arts that Pablo Picasso has not worked in and revitalized.

In turn, painters have been stimulated by the imagery, techniques, and design of other visual arts. One of the earliest of these influences was possibly from the theatre, where the ancient Greeks are thought to have been the first to employ the illusions of optical perspective. The discovery or reappraisal of design techniques and imagery in the art forms and processes of other cultures has been an important stimulus to the development of more recent styles of Western painting, whether or not their traditional significance have been fully understood. The influence of Japanese woodcut prints on Synthetism and the Nabis, for example, and of African sculpture on Cubism and the German Expressionists helped to create visual vocabularies and syntax with which to express new visions and ideas. The invention of photography introduced painters to new aspects of nature, while eventually prompting others to abandon representational painting altogether. Painters of everyday life, such as Edgar Degas, Henri de Toulouse-Lautrec, Edouard Vuillard, and Bonnard, exploited the design innovations of camera cutoffs, close-ups, and unconventional viewpoints in order to give the spectator the sensation of sharing an intimate picture space with the figures and objects in the painting.

Influence of photography

TECHNIQUES AND METHODS

Whether a painting reached completion by careful stages or was executed directly by a hit or miss alla prima method (in which pigments are laid on in a single application) was once largely determined by the ideals and established techniques of its cultural tradition. For example, the medieval European illuminator's painstaking procedure, by which a complex linear pattern was gradually enriched with gold leaf and precious pigments, was contemporary with the Sung Chinese Zen practice of immediate, calligraphic brush painting, following a contemplative period of spiritual self-preparation. More recently, the artist has himself decided the technique and working method best suited to his aims and temperament. In France in the 1880s, for instance, Seurat might be working in his studio on innumerable drawings, tone studies, and colour schemes in preparation for a large composition at the same time that, outdoors, Monet would be endeavouring to capture directly the transitory effects of afternoon light and atmosphere, while Cézanne analyzed the structure of the Montagne (mountain) Sainte-Victoire with deliberated brush strokes, laid as irrevocably as mosaic tesserae (small pieces, such as marble or tile).

The kind of relationship established between artist and patron, the site and subject matter of a painting commission, and the physical properties of the medium employed may also dictate working procedure. Peter Paul Rubens, for example, followed the business-like 17th-century custom of submitting a small oil sketch, or *modella*, for his client's approval before carrying out a large-scale com-

mission. Siting problems peculiar to mural painting, such as spectator eye level and the scale, style, and function of a building interior, had first to be solved in preparatory drawings and sometimes with the use of wax figurines or scale models of the interior. Scale working drawings are essential to the speed and precision of execution demanded by quick-drying mediums, such as buon' fresco (see below *Mediums*: *Fresco*) on wet plaster and acrylic resin on canvas. The drawings traditionally are covered with a network of squares, or "squared-up," for enlarging on the surface of the support. Some modern painters prefer to outline the enlargement of a sketch projected directly onto the support by epidiascope (a projector for images of both opaque and transparent objects).

In Renaissance painters' workshops, pupil assistants not only ground and mixed the pigments and prepared the supports and painting surfaces but often laid in the outlines and broad masses of the painting from the master's design and studies.

Preservation of a painting

The inherent properties of its medium or the atmospheric conditions of its site may themselves preserve a painting. The wax solvent binder of encaustic paintings (in which after application, the paint is fixed by heat [see below *Mediums*], for example) both retains the intensity and tonality of the original colours and protects the surface from damp. And, while prehistoric rock paintings and buon' frescoes are preserved by natural chemical action, the tempera pigments thought to be bound only with water on many ancient Egyptian murals are protected by the dry atmosphere and unvarying temperature of the tombs. It has, however, been customary to varnish oil paintings, both to protect the surface against damage by dirt and handling and to restore the tonality lost when some darker pigments dry out into a higher key. Unfortunately, varnish tends to darken and yellow with time into the sometimes disastrously imitated, "Old Masters' mellow patina." Once cherished, this amber-gravy film is now generally removed to reveal the colours in their original intensity. Glass began to replace varnish toward the end of the 19th century, when painters wished to retain the fresh, luminous finish of pigments applied directly to a pure white ground. The air-conditioning and temperature-control systems of modern museums make both varnishing and glazing unnecessary, except for older and more fragile exhibits.

The frames surrounding early altarpieces, icons, and cassone panels (painted panels on the chest used for a bride's household linen) were often structural parts of the support. With the introduction of portable easel pictures, heavy frames not only provided some protection against theft and damage but were considered an aesthetic enhancement to a painting, and frame making became a specialized craft. Gilded gesso moldings (consisting of plaster of paris and sizing that forms the surface for low relief) in extravagant swags of fruit and flowers certainly seem almost an extension of the restless, exuberant design of a Baroque or Rococo painting. A substantial frame also provided a proscenium (in a theatre, the area between the orchestra and the curtain) in which the picture was isolated from its immediate surroundings, thus adding to the window view illusion intended by the artist. Deep, ornate frames are unsuitable for many modern paintings, where the artist's intention is for his forms to appear to advance toward the spectator rather than be viewed by him as if through a wall aperture. In contemporary Minimal paintings, no effects of spatial illusionism are intended; and, in order to emphasize the physical shape of the support itself and to stress its flatness, these abstract, geometrical designs are displayed without frames or are merely edged with thin protective strips of wood or metal.

MEDIUMS

By technical definition, mediums are the liquids added to paints to bind them and make them workable. They are discussed here, however, in the wider meaning of all the various paints, tools, supports, surfaces, and techniques employed by painters. The basis of all paints is variously coloured pigment, ground to a fine powder. The different expressive capacities and characteristic final surface texture of each medium are determined by the vehicle with which it is bound and thinned, the nature and surface preparation of the support, and the tools and technique with which it is handled.

Sources of pigments

Pigments are derived from various natural and artificial sources. The oldest and most permanent pigments are the blacks, prepared from bone and charcoal, and the clay earths, such as raw umber and raw sienna, which can be changed by heating into darker, warmer browns. In early periods of painting, readily available pigments were few. Certain intense hues were obtainable only from the rarer minerals, such as cinnabar (orange-red vermilion), lapis lazuli (violet-blue ultramarine), and malachite (green). These were expensive and therefore reserved for focal accents and important symbolic features in the design. The opening of trade routes and the manufacture of synthetic substitutes gradually extended the range of colours available to painters.

Tempera. A tempera medium is dry pigment tempered with an emulsion and thinned with water. It is a very ancient medium, having been in constant use in most world cultures, until in Europe it was gradually superseded, during the Renaissance, by oil paints. Tempera was the original mural medium in the ancient dynasties of

Egypt, Babylonia, Mycenean Greece, and China and was used to decorate the early Christian catacombs. It was employed on a variety of supports, from the stone stelae (or commemorative pillars), mummy cases, and papyrus rolls of ancient Egypt to the wood panels of Byzantine icons and altarpieces and the vellum leaves of medieval illuminated manuscripts.

True tempera is made by mixture with the yolk of fresh eggs, although manuscript illuminators often used egg white and some easel painters added the whole egg. Other emulsions have been used, such as casein glue with linseed oil, egg yolk with gum and linseed oil, and egg white with linseed or poppy oil. Individual painters have experimented with other recipes, but few of these have proved successful; all but William Blake's later tempera paintings on copper sheets, for instance, have darkened and decayed, and it is thought that he mixed his pigment with carpenter's glue.

Distemper is a crude form of tempera made by mixing dry pigment into a paste with water, which is thinned with heated glue in working or by adding pigment to whiting, a mixture of fine-ground chalk and size. It is used for stage scenery and full-size preparatory cartoons for murals and tapestries. When dry, its colours have the pale, mat, powdery quality of pastels, with a similar tendency to smudge. Indeed, damaged cartoons have been retouched with pastel chalks.

Egg tempera is the most durable form of the medium, being generally unaffected by humidity and temperature. It dries quickly to form a tough film that acts as a protective skin to the support. In handling, in its diversity of transparent and opaque effects, and in the satin sheen of its finish, it resembles the modern acrylic resin emulsion paints.

Traditional process of tempera painting

Traditional tempera painting is a lengthy process. Its supports are smooth surfaces, such as planed wood, fine set plaster, stone, paper, vellum, canvas, and modern composition boards of compressed wood or paper. Linen is generally glued to the surface of panel supports, additional strips masking the seams between braced wood planks. Gesso, a mixture of plaster of paris (or gypsum) with size, is the traditional ground. The first layer is of gesso grosso, a mixture of coarse, unslaked plaster and size. This provides a rough, absorbent surface for ten or more thin coats of gesso sotile, a smooth mixture of size and fine plaster previously slaked in water to retard drying. This laborious preparation results, however, in an opaque, brilliant white, light-reflecting surface, similar in texture to hard, flat icing sugar.

The design for a large tempera painting traditionally was executed in distemper on a thick paper cartoon. The outlines were pricked with a perforating wheel so that when the cartoon was laid on the surface of the support, the linear pattern was transferred by dabbing, or "pouncing," the perforations with a muslin bag of powdered charcoal. The dotted contours traced through were then fixed in paint. Medieval tempera painters of panels and manuscripts made lavish use of gold leaf on backgrounds and for symbolic features, such as haloes and beams of heavenly light. Areas of the pounced design intended for gilding were first built up into low relief with gesso duro, the harder, less absorbent gesso compound used also for elaborate frame moldings. Background fields were often textured by impressing the gesso duro, before it set, with small, carved, intaglio wood blocks, to create raised, pimpled, and quilted repeat patterns that glittered when gilded. Leaves of finely beaten gold were pressed onto a tacky mordant (adhesive compound) or over wet bole (reddish-brown earth pigment) that gave greater warmth and depth when the gilded areas were burnished.

Colours were applied with sable brushes in successive broad sweeps or washes of semitransparent tempera. These dried quickly, preventing the subtle tonal gradations possible with watercolour washes or oil paint; effects of shaded modelling had therefore to be obtained by a crosshatching technique of fine brush strokes. According to the Italian painter Cennino Cennini, the early Renaissance tempera painters laid the colour washes across a fully modelled monochrome underpainting in terre vert (olive-green pigment), a method developed later into the mixed mediums technique of tempera underpainting followed by transparent oil glazes.

The luminous gesso base of a tempera painting, combined with the accumulative effect of overlaid colour washes, produces a unique depth and intensity of colour. Tempera paints dry lighter in value, but their original tonality can be restored by subsequent waxing or varnishing. Other characteristic qualities of a tempera painting, resulting from its fast drying property and disciplined technique, are its steely lines and crisp edges, its meticulous detail and rich linear textures, and its overall emphasis upon a decorative flat pattern of bold colour masses.

The great Byzantine tradition of tempera painting was developed in Italy in the 13th and 14th centuries by Duccio di Buoninsegna and Giotto. Their flattened picture space, generously enriched by fields and textures of gold leaf, was extended by the Renaissance depth perspectives in the paintings of Giovanni Bellini, Piero della Francesca, Carlo Crivelli, Sandro Botticelli, and Vittore Carpaccio. By that time, oil painting was already challenging the primacy of tempera, Botticelli and some of his contemporaries apparently adding oil to the tempera emulsion or overglazing it in oil colour.

20th-century revival of tempera techniques

Following the supremacy of the oil medium during succeeding periods of Western painting, the 20th century saw a revival of tempera techniques by such U.S. artists as Ben Shahn, Andrew Wyeth, and George McNeil and by the British painter Edward Wadsworth. It would probably have been the medium also of the later hard-edge abstract painters had the new acrylic resin paints not proved more easily and quickly handled.

Fresco. Fresco (Italian: "fresh") is the traditional medium for painting directly onto a wall or ceiling. It is the oldest known painting medium, surviving in the prehistoric mural decorations and perfected in 16th-century Italy in the buon' fresco method.

The cave paintings are thought to date from 13,000–20,000 BC. Their pigments probably have been preserved by a natural sinter process of rainwater seeping through the limestone rocks to produce saturated bicarbonate. The colours were rubbed across rock walls and ceilings with sharpened solid lumps of the natural earths, (yellow, red, and brown ochre). Outlines were drawn with black sticks of wood charcoal. The discovery of mixing dishes suggests that liquid pigment mixed with fat was also used and smeared with the hand. The subtle tonal gradations of colour on animals painted in the Altamira and Lascaux caves appear to have been dabbed in two stages with fur pads, natural variations on the rock surface being exploited to assist in creating effects of volume. Feathers and frayed twigs may have been used in painting manes and tails.

These were not composite designs but separate scenes and individual studies that, like graffiti drawings, were added at different times, often one above another, by various artists. Paintings from the Magdalenian period (*c.* 10,000 BC) exhibit astonishing powers of accurate observation and ability to represent movement. Women, warriors, horses, bison, bulls, boars, and ibex are depicted in scenes of ritual ceremony, battle, and hunting. Among the earliest images are imprinted and stencilled hands. Vigorous meanders, or "macaroni" linear designs, were traced with fingers dipped in liquid pigment.

Fresco secco. In the fresco secco, or lime-painting, method, the plastered surface of a wall is soaked with slaked lime. Lime-resistant pigments are applied swiftly before the plaster sets. Secco colours dry lighter than their tone at the time of application, producing the pale, mat, chalky quality of a distempered wall. Although the pigments are fused with the surface, they are not completely absorbed and may flake in time, as in sections of Giotto's 14th-century S. Francesco murals at Assisi. Secco painting was the prevailing medieval and early Renaissance medium and was revived in 18th-century Europe by artists such as Giovanni Battista Tiepolo, François Boucher, and Jean-Honoré Fragonard.

Buon' fresco. Buon', or "true," fresco is the most durable method of painting murals, since the pigments are

completely fused with a damp plaster ground to become an integral part of the wall surface. The stone or brick wall is first prepared with a brown trullisatio scratch coat, or rough-cast plaster layer. This is then covered by the arricciato coat, on which the linear design of the preparatory cartoon is pounced (see above *Tempera*) or engraved by impressing the outlines into the moist, soft plaster with a bone or metal stylus. These lines were usually overworked in reddish sinopia pigment. A thin layer of fine plaster is then evenly spread, allowing the linear design to show through. Before this final intonaco ground sets, pigments thinned with water or slaked lime are applied rapidly with calf-hair and hog-bristle brushes; depth of colour is achieved by a succession of quick-drying glazes. Being prepared with slaked lime, the plaster becomes saturated with an aqueous solution of hydrate of lime, which takes up carbonic acid from the air as it soaks into the paint. Carbonate of lime is produced and acts as a permanent pigment binder. Pigment particles crystallize in the plaster, fusing it with the surface to produce the characteristic lustre of buon' fresco colours. When dry, these are mat and lighter in tone. Colours are restricted to the range of lime-resistant pigments.

Arricciato coat

The intonaco coat is laid only across an area sufficient for painting before the plaster sets. The joins between each successive "day piece" are sometimes visible. Alterations must be made by immediate washing or scraping; minor retouching to set plaster is possible with casein or egg tempera, but major corrections necessitate breaking away the intonaco and replastering. The swift execution demanded stimulates bold designs in broad masses of colour with a calligraphic vitality of flecked, spotted, and scribbled brush marks.

No ancient Greek buon' frescoes now exist, but forms of the technique survive in the Pompeian villas of the 2nd century AD, in Chinese tombs at Liao-yang, Manchuria, and in the 6th-century Indian caves at Ajantā. Among the finest buon' fresco murals are those by Michelangelo in the Sistine Chapel and by Raphael in the Stanze of the Vatican. Other notable examples from the Italian Renaissance can be seen in Florence: painted by Andrea Orcagna in the Museo dell'Opera di Sta. Croce, by Gozzoli in the chapel of the Palazzo Medici-Riccardi, and by Domenico Ghirlandajo in the church of Sta. Maria Novella. Buon' fresco painting is unsuited to the damp, cold climate of northern countries, and there is now some concern for the preservation of frescoes in the sulfurous atmosphere of even many southern cities. In recent times, buon' fresco has been successfully revived by the Mexican mural painters Diego Rivera, José Orozco, and Rufino Tamayo.

Sgraffito. Sgraffito (Italian *graffiare*, "to scratch") is a form of fresco painting for exterior walls. A rough plaster undercoat is followed by thin plaster layers, each stained with a different lime-fast colour. These coats are covered by a fine-grain mortar finishing surface, about two inches thick (five centimetres). The plaster is then engraved with knives and gouges at different levels to reveal the various coloured layers beneath. The sintered-lime process binds the colours. The surface of modern sgraffito frescoes is often enriched with textures made by impressing nails and machine parts, combined with mosaics of stone, glass, plastic, and metal tesserae.

Sgraffito has been a traditional folk art in Europe since the Middle Ages and was practiced as a fine art in 13th-century Germany. It has been recently revived in northern Europe.

Oil. Oil paints are made by mixing dry pigment powder with refined linseed oil to a paste, which is then milled in order to disperse the pigment particles throughout the oil vehicle. According to the 1st-century Roman scholar Pliny the Elder, whose writings the Flemish painters Hubert and Jan van Eyck are thought to have studied, the Romans used oil colours for shield painting. The earliest use of oil as a fine-art medium is generally attributed to 15th-century European painters, such as Giovanni Bellini and the van Eycks, who glazed oil colour over a tempera underpainting. It is also thought probable, however, that medieval manuscript illuminators had been using oil glazes in order to achieve greater depth of colour and more subtle tonal transitions than their tempera medium allowed.

Earliest use as a fine-art medium

Oils have been used on linen, burlap, cotton, wood, hide, rock, stone, concrete, paper, cardboard, aluminum, copper, plywood, and processed boards, such as masonite, pressed wood, and hardboard. The surface of rigid panels is traditionally prepared with gesso and that of canvas with one or more coats of white acrylic resin emulsion or with a coat of animal glue followed by thin layers of white-lead oil primer. Oil paints can be applied undiluted to these prepared surfaces or can be used thinned with pure gum turpentine or its substitute, white mineral spirit. The colours are slow drying; the safest dryer to speed the process is cobalt siccative.

An oil glaze is a transparent wash of pigment, traditionally thinned with stand oil (a concentrate of linseed oil). Glazes can be used to create deep, glowing shadows and to bring contrasted colours into closer harmony beneath a unifying tinted film. Scumbling is the technique of scrubbing an undiluted, opaque, and generally pale pigment across others for special textural effects or to raise the key of a dark-coloured area.

Hog-bristle brushes are used for much of the painting, with pointed, red sable-hair brushes generally preferred for outlines and fine details. Oils, however, are the most plastic and responsive of all painting mediums and can be handled with all manner of tools. The later works of Titian and Rembrandt, for example, appear to have been executed with thumbs, fingers, rags, spatulas, and brush handles. With these and other unconventional tools and techniques, oil painters create pigment textures ranging from delicate tonal modulations to unvarying, mechanical finishes and from clotted, impasto ridges of paint to barely perceptible stains.

The tempera-underpainting–oil-glaze technique was practiced into the 17th century. Artists such as Titian, El Greco, Rubens, and Diego Velázquez, however, used oil pigments alone and, employing a method similar to pastel painting, applied them directly to the brownish ground with which they had tinted the white priming. Contours and shadows were stained in streaks and washes of diluted paint, while lighter areas were created with dry, opaque scumbles, the tinted ground meanwhile providing the halftones and often remaining untouched for passages of local or reflected colour in the completed picture. This use of oil paint was particularly suited to expressing atmospheric effects and to creating chiaroscuro, or light and dark, patterns. It also encouraged a bravura handling of paint, where stabs, flourishes, lifts, and pressures of the brush economically described the most subtle changes of form, texture, and colour according to the influence exerted by the tinted ground through the varying thicknesses of overlaid pigment. This method was still practiced by the 19th-century painters such as John Constable, J.M.W. Turner, Eugène Delacroix, and Honoré Daumier. The Impressionists, however, found the luminosity of a brilliant white ground essential to the alla prima technique with which they represented the colour intensities and shifting lights of their plein air (open air) subjects. Most oil paintings since then have been executed on white surfaces.

Deterioration of Leonardo's "Last Supper"

The rapid deterioration of Leonardo's 15th-century "Last Supper," which was painted in oils on plaster, probably deterred artists from using the medium directly on a wall surface. And the likelihood of eventual warping also prohibited using the large number of braced wood panels required to make an alternative support for an extensive mural painting in oils. Canvas, however, can be woven to any length, and, since an oil-painted surface is elastic, mural paintings could be executed in the studio and rolled and restretched on a wooden framework at the site or marouflaged (fastened with an adhesive) directly onto the wall surface. In addition to the immense studio canvases painted for particular sites by artists such as Jacopo Tintoretto, Paolo Veronese, Delacroix, Pierre-Cécile Puvis de Chavannes, and Monet, the use of canvas has made it possible for mural-size, modern oil paintings to be transported for exhibition to all parts of the world.

Tempera

"Wind from the Sea," tempera painting by Andrew Wyeth, 1947. In a private collection. 47 × 70 cm.

"Christ Discovered in the Temple," panel painting by Simone Martini, 1342. In the Walker Art Gallery, Liverpool. 49.5 × 35 cm.

"King Khusrau Seated Upon his Throne," Persian miniature from the *Khamsa of Nizami*, 1524–25. In the Metropolitan Museum of Art, New York City. 32 × 23 cm.

A leaf from the *Calendar of a Book of Hours (April)*, manuscript illumination by Simon Bennick, early 16th century. In the Victoria and Albert Museum, London. 14 × 9.6 cm.

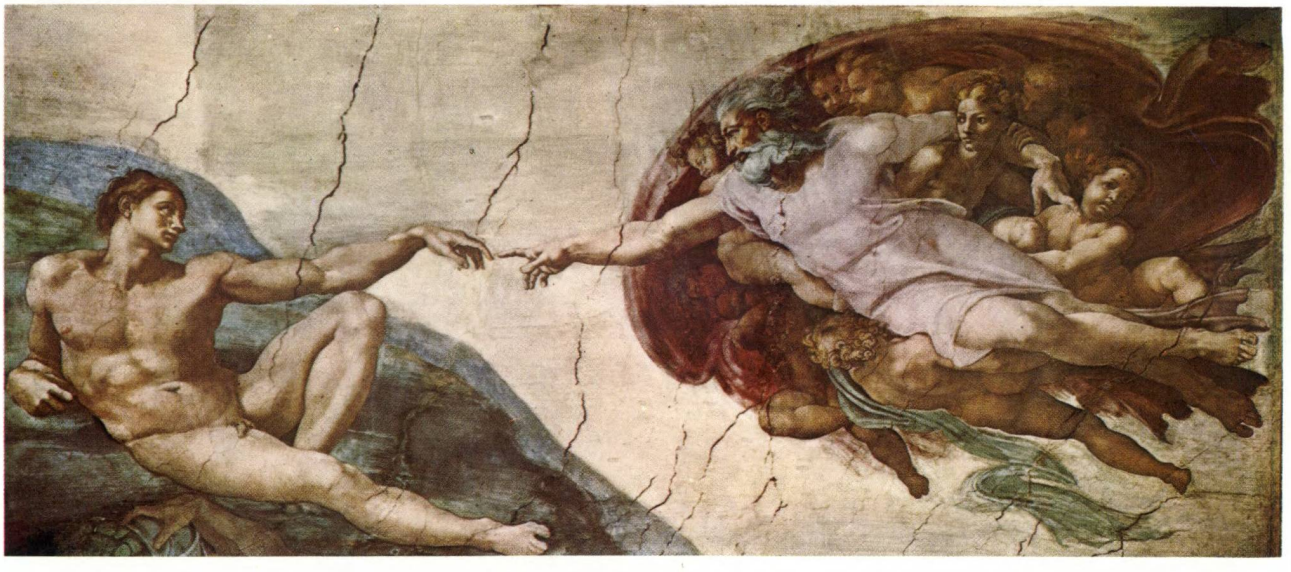
Plate 1: By courtesy of (top right) the Walker Art Gallery, Liverpool, (bottom left) the Metropolitan Museum of Art, New York, gift of Alexander Smith Cochran, 1913, (bottom right) the Victoria and Albert Museum, London; photograph, (bottom right) John Webb

Fresco of a court scene from the *Mahājanaka Jataka*, Cave I, Ajantā, India, 600–700.

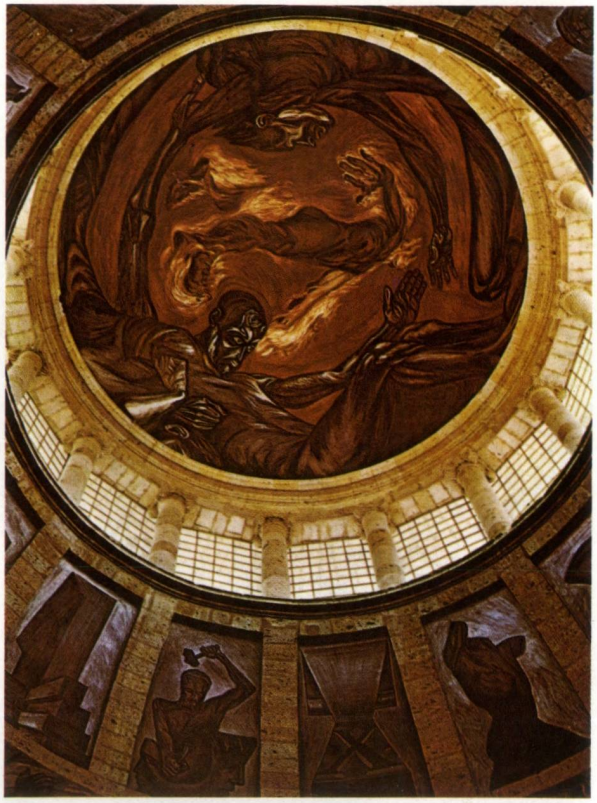
Frescoes by Giovanni Battista Tiepolo, 1750–52, decorating the Kaisersaal Residenz, Würzburg, West Germany, designed by Balthasar Neumann, 1719–44.

"Fowling in the Marshes," detail of a wall painting from the tomb of Amenemhab, Thebes, Egypt, *c.* 1450 BC, XVIII dynasty. In the British Museum.

"The Creation of Adam," detail of the ceiling fresco in the Sistine Chapel, Vatican, by Michelangelo, 1508–12.



Wall painting



Frescoes by José Clemente Orozco, 1938–39, decorating the ceiling and drum of the dome of the Hospicio Cabañas, Guadalajara, Mexico.

Fresco cycle depicting scenes from the life of the Virgin and the life of Christ by Giotto in the Arena Chapel, Padua, Italy, *c.* 1305–09.

Folk art fresco on the Adam and Eve house, Ardez, Switzerland, 1647.

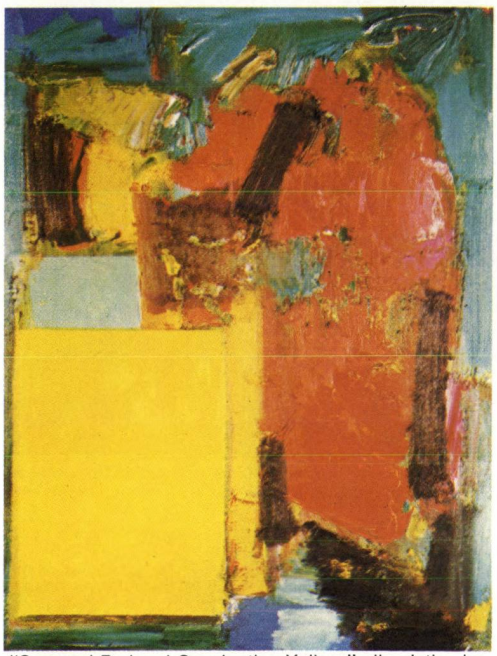
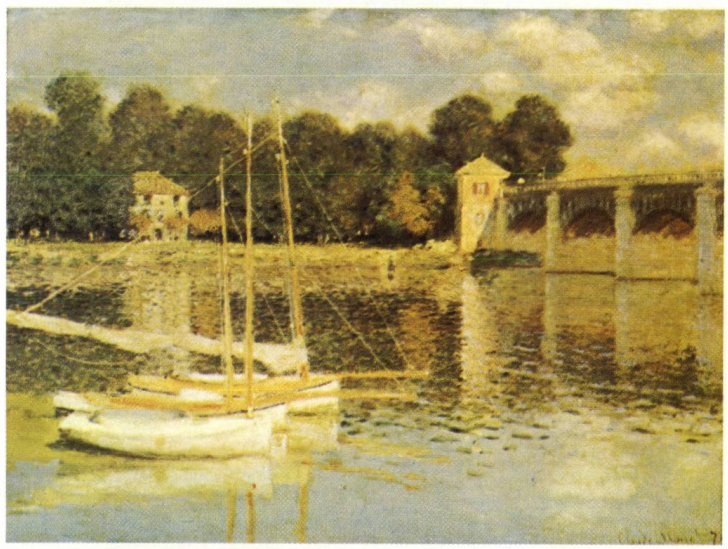
Oil and encaustic

"Salisbury Cathedral," oil painting by John Constable, *c.* 1825. In the National Gallery, London. 53 × 77 cm.



"Smaragd Red and Germinating Yellow," oil painting by Hans Hofmann, 1959. In the Cleveland Museum of Art. 1.4 × 1 m.



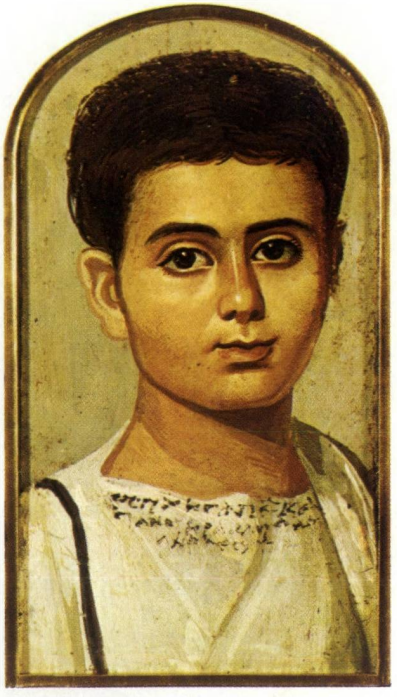
"The Bridge at Argenteuil," oil painting by Claude Monet, 1874. In the Louvre, Paris. 60 × 80 cm.

"Venus and the Lute Player," oil painting by Titian, *c.* 1560. In the Metropolitan Museum of Art, New York City. 1.7 × 2.1 m.

Plate 4: By courtesy of (top left) the Contemporary Collection of the Cleveland Museum of Art, (top right) the trustees of the National Gallery, London, (bottom) the Metropolitan Museum of Art, New York, Munsey Fund, 1936; photograph, (centre right) Cliche Musees Nationaux

Plate 5: By courtesy of (top left) the Rijksmuseum, Amsterdam, (top right) the Metropolitan Museum of Art, New York, gift of Edward S. Harkness, 1917–18, (bottom left) the National Gallery of Art, Washington, D.C., Andrew W. Mellon Collection, 1937; photograph, (bottom right) Joseph Martin—SCALA, N.Y.

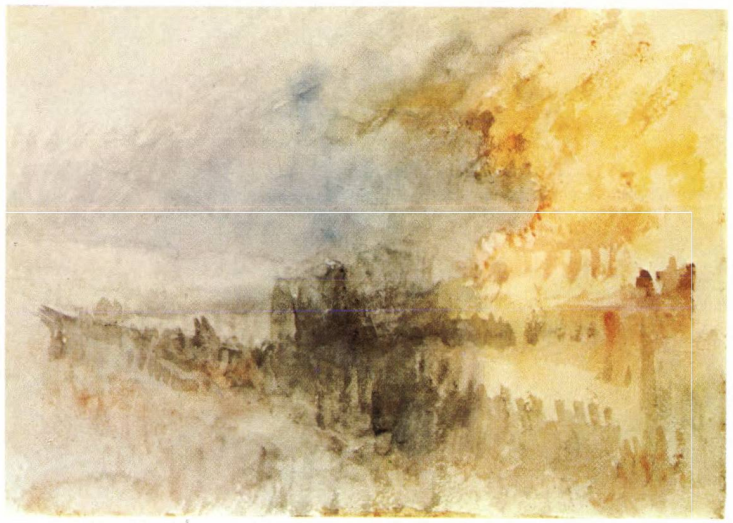
"The Bridal Couple," oil painting by Rembrandt, *c.* 1665. In the Rijksmuseum, Amsterdam. 1.2 × 1.7 m.



Portrait of a boy, encaustic painting from al-Fayyūm, Egypt, probably 2nd century. In the Metropolitan Museum of Art, New York City. 33 × 18.5 cm.

"The Annunciation," oil painting by Jan van Eyck, *c.* 1434. In the National Gallery of Art, Washington, D.C. 93 × 36.5 cm.

"Mystic Marriage of St. Catherine," oil painting by Peter Paul Rubens, 1627–28. In St. Augustine Church, Antwerp. 5.7 × 4 m.



"The Burning of the Houses of Parliament," watercolour painting by J.M.W. Turner, 1834. In the British Museum. 23.4 × 32.4 cm.

"A Young Man Among Roses," watercolour miniature by Nicholas Hilliard, *c.* 1588. In the Victoria and Albert Museum, London. 13.4 × 7.4 cm.

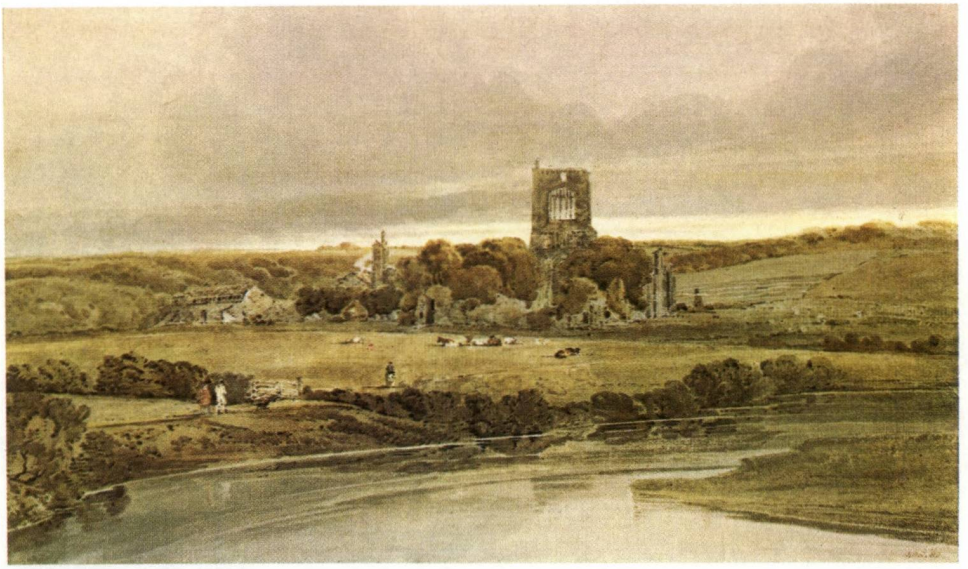
Ink, gouache, and watercolour

"The Annunciation," anonymous Austrian or Swabian woodcut, hand-coloured with watercolour, 1450–70. In the National Gallery of Art, Washington, D.C. 27.3 × 19.2 cm.

"The Monumental Turf," watercolour painting by Albrecht Dürer, 1503. In the Albertina, Vienna. 41 × 31.5 cm.

Plate 6: By courtesy of (top left) the Victoria and Albert Museum, London, (bottom left) the National Gallery of Art, Washington, D.C., Rosenwald Collection, (bottom right) the Albertina, Vienna; photograph, (top right) Hans Hinz, Basel

Plate 7: By courtesy of (top, centre right) the Victoria and A'bert Museum, London, (bottom) the Museum of Fine Arts, Boston, Ross Collection; photographs, (top, centre right) John Webb, (centre left) Holle Bildarchiv, Baden-Baden

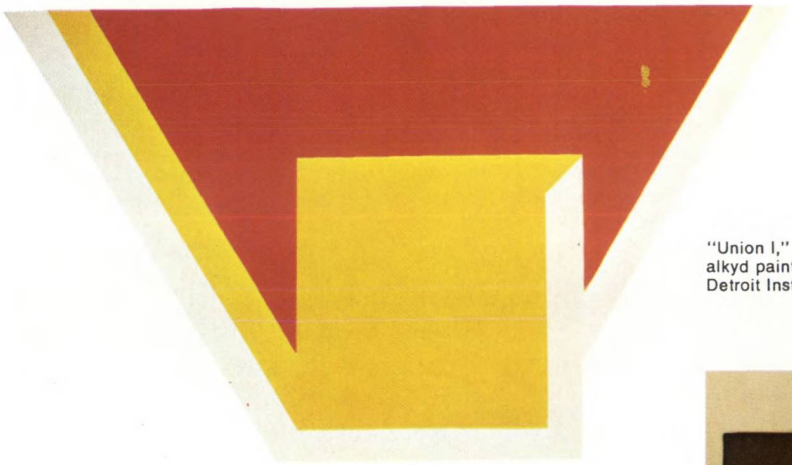


"Kirkstall Abbey, Yorkshire—Evening," watercolour painting by Thomas Girtin, 1801. In the Victoria and Albert Museum, London. 30.4 × 51 cm.

"Landscape," detail of a Japanese handscroll, ink on paper by Sesshū (1420–1506). In the National Museum, Tokyo. Dimensions of entire scroll 147.3 × 35.6 cm.

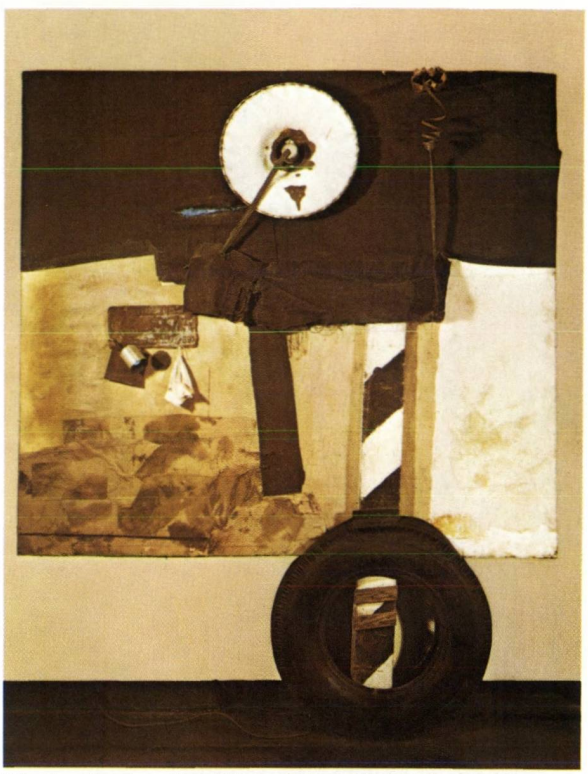
French fan, gouache on paper, sticks of carved mother-of-pearl inlaid with gilt and set with pastes, *c.* 1750. In the Victoria and Albert Museum, London.

"The Return of Wen-chi to Ying-chuan," scene from the Chinese handscroll "The Life of Lady Ts'ai-chi," anonymous, ink and colour on silk, 12th century, Sung dynasty. In the Museum of Fine Arts, Boston. Detail of the scroll 25 × 55.8 cm.

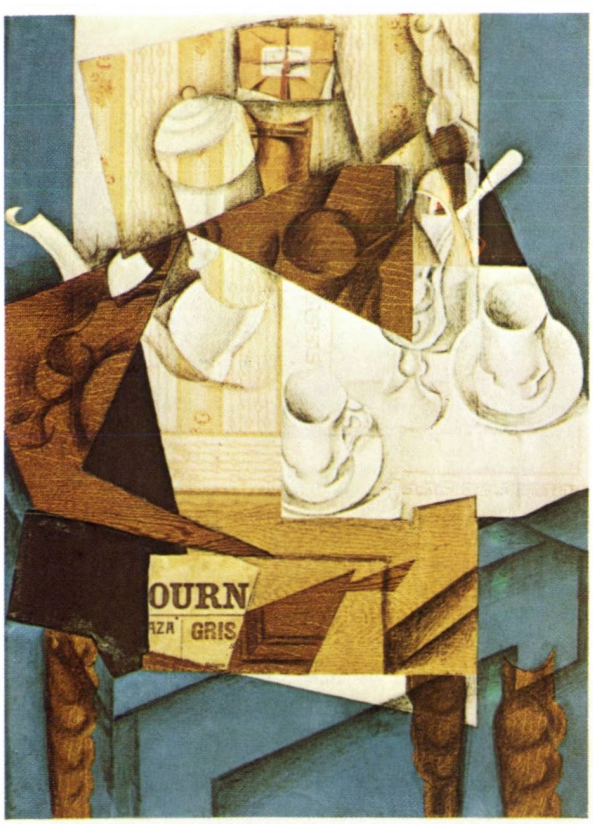


"Union I," epoxy paint and fluorescent alkyd painting by Frank Stella, 1966. In the Detroit Institute of Arts. 2.6 × 4.5 m.

Synthetic and mixed media



"First Landing Jump," combine painting by Robert Rauschenberg, 1961. In the Museum of Modern Art, New York City. 2.3 × 1.8 m.



"Breakfast," pasted paper, crayon, and oil paint collage by Juan Gris, 1914. In the Museum of Modern Art, New York City. 81 × 60 cm.

"Oh, Jeff . . . I Love You, Too . . . But . . .," acrylic painting by Roy Lichtenstein, 1964. In the Harry N. Abrams Family Collection, New York City. 1.2 × 1.2 m.

Plate 8: By courtesy of (top left) the Detroit Institute of Arts, gift of Friends of Modern Art, (top right) the Leo Castelli Gallery, New York, (bottom left) the Museum of Modern Art, New York, acquired through the Lillie P. Bliss Bequest, (bottom right) the Harry N. Abrams Family Collection, New York City

The tractable nature of the oil medium has sometimes encouraged slipshod craftsmanship. Working over partly dry pigment or priming may produce a wrinkled surface. The excessive use of oil as a vehicle causes colours to yellow and darken, while cracking, blooming, powdering, and flaking can result from poor priming, overthinning with turpentine, or the use of varnish dryers and other spirits. Colour changes may also occur through the use of chemically incompatible pigment mixtures or from the fading of fugitive synthetic hues, such as the crimson lakes used by Pierre-Auguste Renoir.

Watercolour. Watercolours are pigments ground with gum arabic and gall and thinned with water in use. Sable and squirrel ("camel") hair brushes are used on white or tinted paper.

Three hundred years before the late 18th-century English watercolorists, Albrecht Dürer had anticipated their technique of transparent colour washes in a remarkable series of plant studies and panoramic landscapes. Until the emergence of the English school, however, watercolour became a medium merely for colour tinting outlined drawings or, combined with opaque body colour to produce effects similar to gouache (see below) or tempera, was used in preparatory studies for oil paintings.

The chief exponents of the English method were Thomas Girtin, John Sell Cotman, John Robert Cozens, Richard Parkes Bonington, David Cox, and Constable. Their contemporary J.M.W. Turner, however, true to his unorthodox genius, added white to his watercolour and used rags, sponges, and knives to obtain unique effects of light and texture. Victorian watercolorists, such as Birket Foster, used a laborious method of colour washing a monochrome underpainting, similar in principle to the tempera–oil technique. Following the direct, vigorous watercolours of the French Impressionists and Postimpressionists, however, the medium has been established in Europe and America as an expressive picture medium in its own right. Notable 20th-century watercolorists have been Wassily Kandinsky, Klee, Dufy, and Georges Rouault; the U.S. artists Thomas Eakins, Maurice Prendergast, Charles Burchfield, John Marin, Lyonel Feininger, and Jim Dine; and the English painters John and Paul Nash, Eric Ravilious, Edward Bawden, Edward Burra, and Patrick Procktor.

The "pure" watercolour technique

In the "pure" watercolour technique, often referred to as the English method, no white or other opaque pigment is applied, colour intensity and tonal depth being built up by successive, transparent washes on damp paper. Patches of white paper are left unpainted to represent white objects and to create effects of reflected light. These flecks of bare paper produce the sparkle characteristic of pure watercolour. Tonal gradations and soft, atmospheric qualities are rendered by staining the paper when it is very wet with varying proportions of pigment. Sharp accents, lines, and coarse textures are introduced when the paper has dried. The paper should be of the type sold as "handmade from rags"; this is generally thick and grained. Cockling is avoided when the surface dries out if the dampened paper has been first stretched across a special frame or held in position during painting by an edging of adhesive tape.

Ink. Ink is the traditional painting medium of China and Japan, where it has been used with long-haired brushes of wolf, goat, or badger on silk or absorbent paper. Oriental black ink is a gum-bound carbon stick that is ground on rough stone and mixed with varying amounts of water to create a wide range of modulated tones or applied almost dry, with lightly brushed strokes, to produce coarser textures. The calligraphic brush technique is expressive of Zen Buddhist and Confucian philosophies, brushstroke formulas for the spiritual interpretation of nature in painting dictating the use of the lifted brush tip for the "bone," or "lean," structure of things and the spreading belly of the hairs for their "flesh," or "fat," volumes. The Far Eastern artist poises the brush vertically above the paper and controls its rhythmic movements from the shoulder. Distant forms represented in landscapes painted on silk were sometimes brushed on from the reverse side in order to create a mysterious illusion of depth.

In the Western world, ink has been used rather more for preparatory studies and topographical and literary illustrations than as a medium for easel paintings. Western artists have generally combined ink washes with contours and textures in quill or steel pen. Among the finest of these are by Rembrandt, Nicolas Poussin, Tiepolo, Samuel Palmer, Constable, and Edouard Manet. Claude Lorrain, Turner, and Daumier and, in the 20th century, Braque, Picasso, Reginald Marsh, Henri Michaux, and John Piper are some of those who have exploited its unique qualities.

Gouache. Gouache is opaque watercolour, known also as poster paint and designer's colour. It is thinned with water for applying, with sable- and hog-hair brushes, to white or tinted paper and card and, occasionally, to silk. Honey or starch is sometimes added to retard its quick-drying property. Liquid glue is preferred as a thinner by painters wishing to retain the tonality of colours (which otherwise dry slightly lighter in key) and to prevent thick paint from flaking. Gouache paints have the advantages that they dry out almost immediately to a mat finish and, if required, without visible brushmarks. These qualities, with the capacities to be washed thinly or applied in thick impasto and a wide colour range that now includes fluorescent and metallic pigments, make the medium particularly suited to preparatory studies for oil and acrylic paintings. It is the medium that produces the suede finish and crisp lines characteristic of many Indian and Islāmic miniatures, and it had been used in Western screen and fan decoration and by modern artists such as Rouault, Klee, Dubuffet, and Morris Graves.

Medium particularly suited to preparatory studies

Encaustic. Encaustic painting (from the Greek: "burnt in") was the ancient method, recorded by Pliny, of fixing pigments with heated wax. It was probably first practiced in Egypt about 3000 BC and is thought to have reached its peak in Classical Greece, although no examples from that period survive. Pigments, mixed with melted beeswax, were brushed onto stone or plaster, smoothed with a metal spatula, and then blended and driven into the wall with a heated iron. The surface was later polished with a cloth. Leonardo and others attempted unsuccessfully to revive the technique. North American Indians used an encaustic method, whereby pigments mixed with hot animal fat were pressed into a design engraved on smoothed buffalo hide.

A simplified encaustic technique uses a spatula to apply wax mixed with solvent and pigment to wood or canvas, producing a ridged, impasto surface. This is an ancient and most durable medium, Coptic mummy portraits from the 1st and 2nd centuries AD retaining the softly blended, translucent colouring typical of waxwork effigies. In the 19th century, Vincent van Gogh also used this method to give body to his oil pigment; the Neo-Impressionist artist Louis Hayet applied encaustic to paper, and it was used by the U.S. Pop Art painter Jasper Johns for his "Flag" canvases. Coloured wax crayons, also, have been used by modern painters such as Picasso, Klee, Arshile Gorky, and David Hockney (see above *Mediums: Fresco*).

Casein. Casein, or "cheese painting," is a medium in which pigments are tempered with the gluey curd of cheese or milk precipitate. For handling, an emulsion of casein and lime is thinned with water. The active element of casein contains nitrogen, which forms a soluble caseate of calcium in the presence of lime. It is applied in thin washes to rigid surfaces, such as cardboard, wood, and plastered walls.

Casein colours dry quickly, although lighter in tone than when first applied. Since they have more body than egg-tempera paints, they can be applied with bristle brushes to create impasto textures not unlike those of oils. Casein paints were used in ancient Rome. They are now available ready-made in tubes and have been used by such modern artists as Robert Motherwell and Claes Oldenburg.

Casein is also an ingredient of some charcoal and pastel fixatives and was a traditional primer for walls and panels.

Synthetic mediums. Synthetic mediums, developed by industrial research, range from the Liquitex fabric dyes

used on canvas by the U.S. abstract painter Larry Poons to the house enamel paints employed at times by Picasso and Jackson Pollock.

Acrylic resin emulsion

The most popular medium and the first to challenge the supremacy of oils is acrylic resin emulsion, since this plastic paint combines most of the expressive capabilities of oils with the quick-drying properties of tempera and gouache. It is made by mixing pigments with a synthetic resin and thinning with water. It can be applied to any sufficiently toothed surface with brush, roller, spray gun, spatula, sponge, or rag. Acrylic paints dry quickly, without brush marks, to form a mat, waterproof film that is also elastic, durable, and easily cleaned. They show little colour change in drying, nor do they darken in time. While they lack the surface textural richness of oil or encaustic, they can be built up with a spatula into opaque impastos or thinned immediately into transparent colour glazes. Polyvinyl acetate (PVA) is applied for priming, although it is claimed that acrylic paints can be safely applied directly onto unprepared raw canvas or cotton. The wide range of intense hues is extended by fluorescent and metallic pigments. Polymer paints are particularly suitable for the precise, immaculate finish demanded by Op Art and Minimal painters, such as Bridget Riley, Morris Louis, Kenneth Noland, and Frank Stella.

Other mediums. *French pastels.* French pastels, with the sharpened lumps of pigment used by Ice Age artists, are the purest and most direct painting materials. Pastel pigments are mixed only with sufficient gum to bind them for drying into stick molds. Generally, they are used on raw strawboard or on coarse-grained tinted paper, although vellum, wood, and canvas have been also employed. These colours will not fade or darken, but, since they are not absorbed by the surface of the support, they lie as pigment powder and are easily smudged. Unfortunately, pastel colours lose their luminosity and tonality if fixed with a varnish and so are best preserved in deep mounts behind glass. Degas often overcame the fragile nature of true pastel painting by the unorthodox method of working on turpentine-soaked paper, which absorbed the powdery pigment.

Eighteenth-century portrait pastellists, such as Maurice-Quentin de La Tour, Jean-Baptiste Peronneau. Jean-Étienne Liotard, and Anton Raphael Mengs, blended the pigment with coiled paper stumps into the surface appearance of a smooth oil painting. Later pastel painters such as Degas, Toulouse-Lautrec, Mary Cassatt, Everett Shinn, Klee, and Arthur Dove, contrasted broad masses of granular colour, spread with the side of the stick, with broken contours and passages of loose cross-hatching. They often used the tinted ground as a half-tone, and, according to the amount of manual pressure exerted on the chalk, they varied the degree of pigment opacity to extract a wide range of tints and shades from each pastel colour.

Oil pastels. Oil pastels are pigments ground in mastic with oil of turpentine, spermaceti, and poppy oil. They are used in a similar way to that of French pastels but are already fixed and harder, producing a permanent, waxy finish. Oil-pastel paintings are generally executed on white paper, card, or canvas. The colours can be blended if the surface of the support is dampened with turpentine or if they are overworked with a brush and turpentine. They are popular for small preparatory studies for oil and acrylic paintings.

Folk art tradition

Glass paintings. Glass paintings are executed with oil and hard resin or with watercolour and gum on glass sheets. These have been a folk art tradition in Europe and North America and, from the 15th to the 18th centuries, were regarded as a fine art in northern Europe, where they have been more recently revived by such painters as Willi Dirx, Ida Kerkovius, Lily Hildebrandt, Klee, Oskar Schlemmer, and Heinrich Camperdonck. Colours are applied from the back in reverse order. Unpainted areas of glass are often coated with mercury, providing a mirror background to the coloured images; this creates the kind of illusionary, bizarre spatial relationship between the viewer and picture space sought by the modern artist Michelangelo Pistoletto with his use of photographic images fixed to a polished steel sheet. The colours seen through glass appear translucent, jewel-like, and, since they cannot be touched, even magical.

Ivory painting. Ivory painting was practiced in the 18th and 19th centuries in Europe and America for portrait miniatures. These were generally oval shaped and designed as keepsakes, lockets, and mantle pictures. They were painted under a magnifying glass in fairly dry watercolour or tempera stippling, with sable- or marten-hair brushes on thin, semitranslucent ivory pieces. Corrections were made with a needle. The velvet quality of their colours was enhanced, on the thinner ivories, by the glow produced by a gold leaf or tinted backing (see below *Forms of painting: Miniature painting*).

Lacquer. Lacquer has been a traditional Chinese medium for over 2,000 years. It combines painting with intaglio relief. Linen-covered wood panels are coated with chalk or clay, followed by many thin layers of black or red lacquer-tree resin. The surface is polished and a design engraved, which is then coloured and gilded or inset with mother-of-pearl. Layers of compressed paper or molded papier-mâché have also provided supports. In China and Japan, lacquer has been used principally for decorating shrine panels, screens, caskets, panniers (large baskets), and musical instruments.

Sand, or dry, painting. Sand, or dry, painting is a traditional magic art of the North American Indians; it is still practiced in healing ceremonies among the Navajos of New Mexico and Arizona. Ground sandstone, natural ochres, mineral earths, and powdered charcoal are sprinkled onto a pattern marked into an area covered with yellow-white sand. The patient sits in the centre of this vivid symbolic design of coloured figurative and geometrical shapes. Following the ritual, the painting is destroyed. These "floor" pictures influenced Jackson Pollock in his horizontally spread "action paintings."

Paper. From the end of the 18th century profiles and full-length group portraits were cut in black paper, mounted on white card, and often highlighted in gold or white. A silhouette ("shade") might be first outlined from the sitter's cast shadow with the aid of a physionotrace.

Collage. Collage was the Dada and Synthetic Cubist technique of combining labels, tickets, newspaper cuttings, wallpaper scraps, and other "found" surfaces with painted textures simulating wood graining and marbling. Frottage was Max Ernst's method of taking paper rubbings from surfaces, unrelated to one another in real life, and combining them to create fantasy landscapes. Cut paper shapes, hand coloured in gouache, were used by Matisse for his monumental last paintings; Piet Mondrian composed his famous "Victory Boogie Woogie" (1942–43) in coloured-paper cutouts.

Mechanical mediums. The use of mechanical mediums in painting has run parallel to similar developments in modern music and drama. In the field of cybernetics, painters have programmed computers to permutate drawings, photographs, diagrams, and symbols through sequences of progressive distortion; and light patterns are produced on television screens by deliberate magnetic interference and by sound-wave oscillations. Artists have also explored the expressive and aesthetic possibilities of linear holograms, in which all sides of an object can be shown by superimposed light images. Painters are among those who have extended the boundaries of film making as an art form. Following the Surrealist film fantasies created by Berthold Bartosch, Jean Cocteau, Hans Richter, and Salvador Dalí, by Schlemmer's filmed ballets and Norman McLaren's hand-painted abstract animations, some artists are now experimenting with video cassettes for television, intending to distribute them in the manner of limited or multiple editions of prints.

For some Conceptual artists the typewriter is the only equipment used when visual ideas are expressed in the form of instruction sheets alone. For example, typed proposals for defining the real space of an exhibition area with painted lines might invite the active participation of visitors (see below *Forms of painting: Modern forms*).

Mixed mediums. Some pictures are first painted in one medium and corrected or enriched with colour and tex-

ture in another. Examples of this kind of mixed mediums are the Renaissance tempera–oil technique, William Blake's relief etchings colour-printed in glue tempera and hand-finished in watercolour, and Degas's overpainted monotypes and his combinations of pastel, gouache, and oil. More recent examples are Richard Hamilton's photographs overpainted in oil colour, Dubuffet's patchwork assemblages of painted canvas and paper, and Klee's alchemy in mixing ingredients such as oil and distemper on chalk over jute and watercolour and wax on muslin stuck on wood.

FORMS OF PAINTING

Mural painting. Mural painting has its roots in the primeval instincts of people to decorate their surroundings and to use wall surfaces as a form for expressing ideas, emotions, and beliefs. In their universal manifestation in graffiti and in ancient murals, such as Ice Age cave paintings and protodynastic Egyptian frescoes, symbols and representational images have been spread freely and indiscriminately across walls, ceilings, and floors. But, in more disciplined attempts to symbolize the importance and function of particular buildings through their interior decoration, murals have been designed for the restricted framework of specific surface areas. They therefore have to be painted in close relationship to the scale, style, and mood of the interior and with regard to such siting considerations as light sources, eye levels, the spectators' lines of sight and means of approach, and the emotive scale relationship between spectators and the painted images.

Early mural decorations

Early mural decorations for tombs, temples, sanctuaries, and catacombs were generally designed in horizontal divisions and vertical axes. These grid patterns were in harmony with the austere character of the interiors, and their geometrical plan enabled the artist to depict clearly the various episodes and symbols of a narrative subject. In these early traditions of mural design, in China, India, Mexico, Egypt, Crete, and Byzantium, no illusionary devices were used to deny the true flatness of the wall surface; images were silhouetted against a flatly painted ground framed by decorative dadoes (the decoration adorning the lower part of an interior wall) of stylized motifs in repeat patterns. By the early Renaissance, however, innovators such as Giotto, Masaccio, and Fra Angelico were placing figures within architectural and landscape settings, painted as if extensions to the real dimensions of the interior. The peak of technical skill and artistic expression was reached in the 15th and 16th centuries with the frescoes of Piero della Francesca, Michelangelo, and Raphael. The irregular shapes of wall areas and the distortions produced by convex surfaces were inventively exploited in the design. Intruding doors and windows, for example, were skillfully circumvented by sweeping pattern rhythms or were incorporated as features in the painting, and figures were foreshortened so as to appear to float across or to rise into cupolas (rounded vaults that form ceilings), lunettes (rounded spaces over doors or windows), and apses (domed projections of a church, usually at the east end or altar), the curving surfaces of which might be painted to simulate celestial skies. Existing structural wall features provided the divisions between narrative episodes. These were often supplemented by trompe l'oeil ("deceive the eye") columns, pilasters, arcading, balustrading, steps, and other architectural forms that also served to fuse the painted setting with the real interior.

With the increasing dependence upon tapestry hangings and stained glass as primary forms of interior decoration, mural painting suffered a decline in the Western world. Except for those given to Rubens, Tiepolo, Delacroix, and Puvis de Chavannes, there were relatively few important mural commissions in the period following the High Renaissance. In the 20th century, however, enlightened patronage has occasionally enabled leading modern artists to execute paintings for specific sites: Monet's "Water-lilies" series for the Paris Orangerie, for example, and other murals in France by Vuillard, Matisse, Léger, Chagall, and Picasso; in Mexico and the United States by Orozco, Rivera, Tamayo, and David Siqueiros and also in the U.S. by Matisse, Shahn, and Willem de Kooning; in Britain by Sir Stanley Spencer and Bawden; in Norway by Edvard Munch; in Holland by Karel Appel; and in Italy by Afro Basaldella.

Easel and panel painting. The easel, or studio, picture was a form developed during the Renaissance with the establishment of the painter as an individual artist. Its scale and portability enabled European artists to extend the range of themes, previously restricted to those suitable to mural decoration. Easel and panel forms include still life, portraiture, landscape, and genre subjects and permit the representation of ephemeral effects of light and atmosphere that the more intimate forms of Oriental art had already allowed the painters of scrolls, screens, and fans to express. Although easel paintings are occasionally commissioned for a special purpose, they are generally bought as independent art objects and used as decorative focal features or illusionary window views in private homes. They are also collected as financial investments, for social prestige, for the therapeutic escapism their subject may provide, or purely for the aesthetic pleasure they afford.

Panel paintings

Panel paintings, by strict definition, are small pictures designed for specific sacred or secular purposes or as part of a functional object. Although these wooden boards are sometimes categorized as a form of "decorative" rather than "fine" art, the best examples justify their place in museums alongside great easel paintings. Among the functions they originally served were as predellas (the facings to altar-step risers); devotional and ceremonial icons; portable, folding diptych and triptych altarpieces; shop and tavern signboards; mummy cases; and for the panels of carriages, musical instruments, and cassoni. Many of them were painted by acknowledged masters, such as Fra Angelico, Paolo Uccello, and Antoine Watteau, as well as by anonymous folk artists.

Miniature painting. Miniature painting is a term applied both to Western portrait miniatures and to the Indian and Islāmic forms of manuscript painting discussed below. Portrait miniatures, or limnings, were originally painted in watercolour with body colour on vellum and card. They were often worn in jewelled, enamelled lockets. Sixteenth-century miniaturists, such as Hans Holbein, Jean Clouet, Nicholas Hilliard, and Isaac Oliver, painted them in the tradition of medieval illuminators. Their flat designs, richly textured and minutely detailed, often incorporated allegorical and gilded heraldic motifs. In 17th- and 18th-century Western portrait miniatures, the two-dimensional pattern of rich colours was developed by atmospheric tonal modelling into more naturalistic representations; these were sometimes in pastel and pencil or painted in oils on a metal base. Pantographs (reducing and enlarging copying instruments made on the lazy-tongs lever principle) might be used to transfer a drawing. Among the exponents of this naturalistic style were Francisco Goya, Fragonard, Samuel Cooper, John Hoskins, François Dumont, and the U.S. miniaturists Robert Field and Edward Green Malbone. The introduction of painted ivory miniatures was followed, in the 19th century, by a decline in aesthetic standards, although a classical simplicity was achieved by unsophisticated itinerant limners and by the German miniaturist Patricius Kittner. The painted miniature was eventually superseded by the small, hand-tinted photograph (see above *Mediums: Ivory painting*).

Manuscript illumination and related forms. Among the earliest surviving forms of manuscript painting are the papyrus rolls of the ancient Egyptian Book of the Dead, the scrolls of Classical Greece and Rome, Aztec pictorial maps, and Mayan and Chinese codices, or manuscript books. European illuminated manuscripts were painted in egg-white tempera on vellum and card. Their subjects included religious, historical, mythological, and allegorical narratives, medical treatises, psalters, and calendars depicting seasonal occupations. In contrast to the formalized imagery of Byzantine and early Gothic manuscript painters, Celtic illuminators developed a unique, abstract style of elaborate decoration, the written

Abstract style of Celtic illuminators

text being overwhelmed by intricate latticework borders, with full-page initial letters embraced by interlacing scrolls. The medieval Gothic style of illumination, in sinuous, linear patterns of flattened forms isolated against white or gilded grounds, had developed, by the end of the 15th century, into exquisitely detailed, jewel-like miniatures of shaded figures and spatial landscapes. These were often framed by gilded initial letters as vignettes or by margin borders in simulated half relief. With the advent of printing in the 15th century and a final, brilliant period of Flemish and Italian illumination, European manuscript painting survived only in official documents, maps, and in the form of hand-coloured, block-printed pages. Pennsylvanian-German birth and baptismal certificates in the U.S. and William Blake's hand-coloured engravings to the Bible and to his own poems were isolated revivals of those forms.

Indian and Islāmic miniature painting, however, was practiced into the 19th century; and 11th-century Oriental albums of poem paintings in ink, on leaves of silk or paper, represent a tradition that was continued into modern times. The subjects of Near Eastern miniatures included religious and historical narrative, cosmic maps, and medical, palmistry and astrological charts, as well as illustrations to poems, songs, and romantic epics. These were generally painted in gouache on paper, with occasional gold- or silver-leaf embellishment. The linear design was first drawn with a brush in delicate contours and soft shading. Landscape and architectural detail was as well observed as in that of the principal figures.

The rapprochement established between text, painted borders, margin spaces, and illustration is characteristic of both Eastern and Western manuscript paintings. In Indian and Islāmic miniatures, for example, the panels of decorative script are integrated within the overall pattern as areas of textural enrichment; and, with the margin and inset frames, these panels serve also as concrete screens and prosceniums to the action depicted, the participants in the narrative episode making their exits and entrances across or behind them.

Scroll painting. Hand scrolls, traditional to China and Japan, are ink paintings on continuous lengths of paper or silk. They are unrolled at arms' width and viewed from right to left. These generally represent panoramic views of rivers, mountain and urban landscapes and domestic interiors. They also illustrate romantic novels, Taoist and Buddhist themes, and historical and genre subjects. Narrative poetic commentaries were included as integral textures in the flowing design. The scrolls are remarkable for their vitality, the lyrical representation of atmospheric space, and for the rising and dipping viewpoints that anticipate the zooming motion-picture camera. The earliest surviving scrolls, such as Ku K'ai-chih's "Admonitions of the Imperial Perceptions," date from the 4th century AD. Oriental hanging scrolls and Indian and Tibetan temple banners are forms similar to those of Western easel and panel paintings. Their subjects range from the seasons (symbolized in bird, fruit, and tree motifs), domestic interiors, landscapes, and portraits to Vishnu epics, mandalas (a circle enclosing a square with a deity on each side), and temple icons. They are painted in ink or gouache on silk and paper and are usually mounted on embroidered or block-printed silk. The dramatic interplay of bold, flattened images against the open space of an unpainted or gilded ground influenced 19th-century Western Art Nouveau decoration.

Hanging scrolls and temple banners

Screen and fan painting. Folding screens and screen doors originated in China and Japan, probably during the 12th century, and continued as a traditional form into the 20th. They are in ink or gouache on plain or gilded paper and silk. Their vivid rendering of animals, birds, and flowers and their atmospheric landscapes brought nature indoors. In some screens each panel was designed as an individual painting, while in others a continuous pattern flowed freely across the divisions. Japanese screens were often painted in complementary Yin and Yang pairs. Large 12-panel Chinese coromandel lacquer screens were imported into Europe during the 17th and 18th centuries. French Rococo boudoir screens depicting *fêtes champêtres* (townspeople enjoying rural surroundings) and toile de Jouy (landscape or floral) pastoral themes were painted on silk or on wood panels in a flamboyantly scrolled, gilded framework. The designs of Art Nouveau screens were inspired by the Japanese tradition. Sidney Nolan's screens on Greek themes and the pastiches of Victorian paper-scrap screens by Pop Art painters are recent Western revivals. Traditional to the Greek and Russian Orthodox churches is the iconostasis screen, which stands between the nave (central part of the church) and sanctuary and displays icon panel paintings in rows representing the Virgin, the saints, and narrative subjects.

Rigid fans are depicted in the paintings and reliefs of ancient Egypt, Assyria, Greece, and Rome, but the oldest surviving specimens are the round and folding fans from Japan and China. These were painted in India ink and colour on paper, card, and silk, the ground often sprinkled with gold dust or laid with gold or silver leaf. Spread freely across the mount, a calligraphic design depicted seasonal landscapes, genre scenes, and bird, flower, and animal motifs, with accompanying poems and commentaries. Leading Oriental painters produced much of their finest work in this form. In Europe, however, where fan painting had been rarely practiced until the 17th century, it was considered a minor art, and designs were often based on frescoes and easel paintings. The richest and most elegant of these were painted in France and Italy during the 18th century. Watercolour and gouache paintings and hand-coloured engraved designs were made on paper, card, kid, and gauze. Allegories and romantic pastoral landscapes were frequently designed as separate vignettes, linked by floral swags and border scrolls. Both sides of the mount might be painted. The guards and sticks of the spoke framework were in delicately carved wood or ivory, inlaid with gold leaf or mother-of-pearl. Round hand-screens of parchment, mounted on handles like lollipops, were popular in early 19th-century English society. Charles Conder was a notable fin de siècle ("end of the century," characterized by effete sophistication) fan painter and, more recently, Oskar Kokoschka decorated a lively set of fans on an autobiographical narrative theme.

Round hand-screens

Panoramas. Panoramas were intended to simulate the sensation of scanning an extensive urban or country view or seascape. This form of painting was popular at the end of the 18th century. Notable examples are "The Battle of Agincourt" (1805), by R.K. Porter, and "Scheveningen," by Hendrik Willem Mesdag. Panoramas might be compared to cinerama films and enjoyed as a stimulating optical entertainment, along with cyclorama drums (large pictorial representations encircling the spectator), trompe l'oeil diorama peep shows, and the show box for which Thomas Gainsborough painted glass transparencies. More serious forms of panoramic painting are exemplified in Chinese Buddhist sanctuary frescoes, Oriental hand scrolls, Dürer's watercolour townscapes, Andrey Rublyov's 14th-century mural of Moscow, and Uccello's original sequence of three panels depicting the Battle of San Romano.

Modern forms. The concept of painting as a medium for creating illusions of space, volume, texture, light, and movement on a flat, stationary support has been challenged by many modern artists. Some recent forms, for example, have blurred the conventional distinctions between the mediums of sculpture and painting. Sculptors such as David Smith, Eduardo Paolozzi, and Philip Sutton have made multicoloured constructions; painters such as Jean Arp and Ben Nicholson have created abstract designs in painted wood relief, and Richard Smith has painted on three-dimensional canvas structures the surfaces of which curl and thrust towards the spectator. And, rather than deny the essential flatness of the painting support by using traditional methods of representing volume and texture, Robert Rauschenberg and Jim Dine have attached real objects and textures to the painted surface, and Frank Stella and Kenneth Noland have designed their irregularly shaped canvases to be seen as explicitly flat art objects. Rejecting earlier painting methods of reproducing effects of light with tonal con-

trasts and broken, pigment colour, some artists have made use of neon tubes and mirrors. Instead of simulating sensations of movement by optical illusion, others have designed kinetic panels and boxes in which coloured shapes revolve under electric power. The traditional definition of painting as a visual, concrete art form has been questioned by recent aspects of Conceptual art, in which the painter's idea might be expressed only in the form of documented proposals for unrealized and often unrealizable projects.

IMAGERY AND SUBJECT MATTER

The imagery and subject matter of paintings in early cultures were generally prescribed by tribal, religious, or dynastic authorities. In some Eastern countries, traditional models survived into the 18th century and even later. With the Renaissance, however, images and themes in Western painting, reflecting the new spirit of Humanistic, objective curiosity and scientific research, came to be decided by the artist and his patron and, in more recent periods, by the artist alone.

Kinds of imagery. Within the various cultures the art of representing things by painted images has rarely shown a continuously developing pattern toward greater realism. More often, religious and philosophical precepts have determined the degree of naturalism permitted. Rules governing portrayals of the human figure have been particularly stringent in certain traditions of representational painting, reflecting different attitudes to the cosmic significance of man. For example, a belief in the inferiority of man in relation to an almighty deity is expressed in the faceless figures in early Jewish painting and in the dehumanized stylizations of Byzantine imagery; and his insignificance against the dynamic forces of nature is symbolized in Chinese landscape paintings by his puny scale within a monumental setting. An earlier view, which instead sought to glorify the spiritual, intellectual, and physical attributes of mankind, is typified in the noble figures of Greco-Roman art and in the renewed celebration of human physical beauty in the Renaissance and subsequent Neoclassical styles. The uniqueness of man among living things and the expression of his individual physical and emotional characteristics is exemplified in Japanese and northern European narrative and genre painting. Concomitant with the antipathy toward figurative representation in some cultures was a general distaste for the portrayal of all things of the exterior world, animals, landscape features, and other natural forms rarely appearing except as stylized images signifying spiritual forces of good and evil. The representational imagery of modern painting borrows freely from ancient and contemporary sources such as primitive and child art, Classical mythology, commercial advertising, press photography, and the allegories and fantasies of the motion picture and the comic strip. Nonrepresentational imagery is not restricted to modern painting but appears also in earlier forms such as Aurignacian (Paleolithic) decorative meanders, the scrollwork of Celtic illuminations, and the patterns of Islāmic Kūfic calligraphy (an angular variety of the Arabic alphabet). And the abstraction of natural forms into rudimentary symbols, characteristic of modern painting, is echoed in the "pin-men" conventions of Magdalenian caves, in Aztec pictograms, and Indian and Tibetan cosmic-diagram paintings.

Attitudes toward the cosmic significance of man

Kinds of subject matter. *Devotional.* The range and interpretation of subjects in different forms of devotional painting express a particular attitude to the relationship between man and his deity. Early Christian and Buddhist murals, for example, portrayed an all-powerful, remote, and mysterious being, painted as a flat, formalized head or figure whose stern gaze dominated the interiors of temples, churches, and sanctuaries. Christian Last Judgments and Oriental hell paintings were intended to frighten the believer, while subjects such as the Virgin enthroned, the Assumption, and Buddha descending from Paradise sustained his faith with hopes for salvation and rewards of blissful immortality.

Narrative. When the autocratic ecclesiastical control over Western painting weakened under Renaissance Humanism, the religious narrative picture became a window onto a terrestial rather than a celestial world. Both emotional and physical relationships between the figures depicted were realistically expressed, and the spectator was able to identify himself with the lifelike representation of a worldly space inhabited by Christ, his disciples, and saints, wearing updated dress and moving naturally within contemporary settings. This kind of narrative interpretation persists in the modern religious paintings of Sir Stanley Spencer, where biblical environments are represented by the clipped hedgerows, the churchyards, and the front parlours of his neat, native English village of Cookham.

Allegorical narrative subjects

Allegorical narrative subjects might exalt the sensuous arts, as in the symbolic muses portrayed by Poussin and Luca Signorelli and the paradisiac gardens of 15th-century French illuminated manuscripts. But they might also carry warnings. In the 16th century, Pieter Bruegel, for example, combined overt and often grotesque symbols with subtle visual metaphors to point stern morals in such paintings as "The Triumph of Death" (alluding to the "wages of sin"), "The Land of Cockaigne" (attacking gluttony and sloth), and "Mad Meg" (ridiculing covetousness). Even Bruegel's apparently straightforward genre subjects, such as "The Peasant Dance" and the festival of "The Fight between Carnival and Lent," conceal parables on man's follies and sins, while Hieronymus Bosch introduced abstruse, allegorical phantasmagoria into such traditional narratives as "The Temptation of St. Antony" and "The Prodigal Son" and made his "Garden of Delights" an expression of disgust rather than of joy. Botticelli's late paintings, probably produced under the influence of the 15th-century Italian monk and reformer Girolamo Savonarola, are other savagely pessimistic allegories: "The Story of Virginia Romana" and "The Tragedy of Lucretia" representing virtue upheld only by death and "The Calumny of Apelles," in which envy, suspicion, deceit, guile, repentance, and truth are identified, like medieval mummers, by their costume, pose, and gesture. Rubens, however, found in allegorical symbolism a means of dramatizing mundane state commissions, such as "The Union of Scotland and Ireland" and "The Bounty of James I (Triumphing Over Avarice)." Among famous 19th-century allegories are Delacroix's "Liberty Leading the People" and Pierre-Paul Prud'hon's "Crime Pursued by Vengeance and Justice."

Possibly the highest achievements in narrative illustrations to poetry and literature are found in Eastern miniatures and Oriental scrolls, such as the Persian paintings of Ferdowsī's 11th-century national epic poem, the *Shāh-nāmeh*, and the 12th-century Japanese scrolls of the *Genji monogatari* and the *Story of Ben Dainagon*. An example of modern literary painting is Sidney Nolan's narrative series portraying the Australian folklore hero Ned Kelly.

Ancient Greek and Roman mythologies have provided Western artists with rich sources of imagery and subject matter and with opportunities for painting the nude. Historical narrative painting includes Classical mythology and heroic legend, as well as the representation of contemporary events; examples include Benjamin West's "Death of Wolfe," Théodore Géricault's "Raft of the Medusa," and Goya's "The 3rd of May in Madrid."

Portraiture. The earliest surviving portraits of particular persons are probably the serene, idealized faces painted on the front and inside surfaces of dynastic Egyptian sarcophagi. The human individuality of the Roman mummy portraits of the 1st and 2nd century AD, however, suggests more authentic likenesses. Although portraits are among the highest achievements in painting, the subject poses special problems for the artist commissioned to paint a notable contemporary. The portraits of patrons by artists such as Raphael, Rubens, Hyacinthe Rigaud, Antoine-Jean Gros, Jacques-Louis David, and Sir Thomas Lawrence were required to express nobility, grace, and authority, just as the sultans and rajahs portrayed on frontispieces to Persian and Indian illuminated books and albums had understandably to be flattered as benevolent despots. Such concessions to the sitter's vanity and social position seem to have been disregarded, how-

ever, in the convincing likenesses by more objective realists such as Robert Campin, Dürer, Jan van Eyck, Velázquez, Goya, and Gustave Courbet. Probably the finest are the self-portraits and studies of ordinary people by Rembrandt and Van Gogh, where psychological insight, emotional empathy, and aesthetic values are fused. A more decorative approach to the subject is seen in the flattened portraits by Holbein, the Elizabethan and itinerant naïve U.S. limners, and the Far Eastern paintings of ancestors, poets, priests, and emperors. Like these paintings, the full-length portraits by Boucher, Gainsborough, Kees van Dongen, and Matisse display as much regard for the texture and form of their sitters' dress as for their facial features.

Photographs and painted portraits

Since the development of photography, however, portraiture has been rarely practiced for its own sake as a serious art form, except where artists such as Cézanne and Braque have used it as a subject for structural research or—like Amedeo Modigliani, Chaim Soutine, and Francis Bacon—for the expression of a personal vision beyond the scope of the camera.

Genre. Genre subjects are scenes from everyday life. Hunting expeditions and tribal rituals figure in prehistoric rock paintings. Domestic and agricultural occupations, with banquet scenes of feasting, dancing, and music, were traditional subjects for ancient Egyptian tomb murals. Far Eastern hand scrolls, albums, and screens brilliantly describe court ceremonies, the bustle of towns, and the hardships of the countryside. The depiction of earthly pursuits was forbidden under the strict inconography prescribed by the early Christian Church, but the later illuminated Books of Hours provide enchanting records of the festivals and occupations of northern European communities. In Renaissance painting, genre subjects were generally restricted to background features of portraits and historical narratives. Domestic scenes, however, not only provided Bruegel with subjects for moral allegories but, as with Rembrandt, were used to counterpoint the emotional intensity of a dramatic religious theme. The withdrawal of religious patronage in northern Europe directed painters towards secular subjects. The rich period of genre painting in 17th-century Holland is represented by the interiors, conversation pieces, and scenes of work and play by David Teniers the Younger, Frans Hals, Jan Steen, Gerard Terborch, Pieter de Hooch, Adriaen van Ostade and, the finest, by Jan Vermeer. Pictures of rustic life had a special appeal for collectors in 18th-century France and England; these were the somewhat picturesque representations of peasant life painted by Jean-Baptiste Greuze, Boucher, George Morland, and Gainsborough. Jean-Baptiste-Siméon Chardin's paintings of servants and children, however, exhibit a timeless dignity and grandeur. The harsher realities of working life were depicted by Jean-François Millet, Daumier, Courbet, Van Gogh, and Degas; the robust gaiety of cafés and music halls was captured by Toulouse-Lautrec, John Sloan, Everett Shinn, and Walter Richard Sickert; and intimate domestic scenes were recorded by Bonnard and Vuillard. Modern genre movements have included the American Scene painters, the Ashcan and Kitchen Sink schools (represented by such painters as George Wesley Bellows, Jack Smith, and Derrick Greaves), the Camden Town and Euston Road groups (Frederick Spencer Gore, Sir William Coldstream, and Victor Pasmore), and the Social Realists in England and in the United States (Robert Henri, Stuart Davis, and Maurice Prendergast).

Landscape. Idealized landscapes were common subjects for fresco decoration in Roman villas. Landscape painting (as exemplified by a Chinese landscape scroll by Ku K'ai-chih dating from the 4th century) was an established tradition in the Far East, where themes such as the seasons and the elements held a spiritual significance. In Europe, imaginary landscapes decorated 15th-century Books of Hours. The first naturalistic landscapes were painted by Dürer and Bruegel. Landscapes appeared in most Renaissance paintings, however, only as settings to portraits and figure compositions. It was not until the 17th-century Dutch and Flemish schools—of Rembrandt, Jacob van Ruisdael, Meindert Hobbema, Aelbert Cuyp, Rubens, and Hercules Seghers—that they were accepted in the West as independent subjects. The most significant developments in 19th-century painting, however, were made through the landscapes of the Impressionists and the Neo-Impressionists and Postimpressionists. Styles in landscape painting range from the tranquil, classically idealized world of Poussin and Claude, the precise, canal topography of Francesco Guardi and Canaletto, and the structural analyses of Cézanne to the poetic romanticism of Samuel Palmer and the later Constables and Turners and the exultant pantheism of Rubens and Van Gogh. Modern landscapes vary in approach from the Expressionism of Oskar Kokoschka's cities and rivers, Maurice de Vlaminck's wintry countrysides, and John Marin's crystalline seascapes to the metaphysical country of Ernst, Dalí, and René Magritte and the semi-abstract coastlines of Nicolas de Staël, Marie Hélène Vieira da Silva, and Richard Diebenkorn.

Still life. The earliest European still-life painting is usually attributed to Jacopo de'Barbari (*i.e.*, "Dead Bird," 1504). In Western paintings, still life often appears as a minor feature of the design; but until the 17th century it was not generally painted for its own sake, although it was already traditional to Far Eastern art. The subject is particularly associated with northern European painting, and the choice of objects very often has a religious or literary significance: wine, water, and bread symbolizing the Passion; skulls, hourglasses, and candles, the transience of life; and selected flowers and fruits, the seasons. Flower painting, especially, held a spiritual and emotional meaning for Japanese artists and for 19th-century European painters, such as Odilon Redon, Paul Gauguin, and Van Gogh. Still life has been expressed in many different ways: Giuseppe Arcimboldo's witty arrangements of fruit, flowers, and vegetables made into fantastic allegorical heads and figures; the sensuous representation of food by Frans Snyders, Goya, and William Merritt Chase; the trompe l'oeil illusionism of François Desportes and William Harnett; the formal decoration of folk artists or primitives such as Henri Rousseau and Séraphine and of modern painters such as Matisse, Dufy, and Pat Caulfield; the semi-abstract designs of Picasso, Gris, and William Scott; and, probably at its highest level of expression, the majestic still lifes of Chardin, Cézanne, and Giorgio Morandi.

Subject matter of still lifes

Other subjects. Since ancient times, animals and birds have provided the primary subject matter of a painting or have been included in a design for their symbolic importance. In the paintings of prehistoric caves and dynastic Egyptian tombs, for example, animals are portrayed with a higher degree of naturalism than human figures. Their texture, movement, and structure have provided some artists with a primary source of inspiration: the classical, anatomical grace of a George Stubbs' racehorse and a more romantic interpretation in the ferocious energy of a Rubens and Géricault stallion; the vivid expression of rhythmically co-ordinated movements of deer by Tawaraya Sotatsu and Antonio Pisanello; the weight and volume of George Morland's pigs and Paul Potter's cows; the humanized creatures of Gothic bestiaries and of Edward Hicks' "Peaceable Kingdom"; and, finally, Dürer's "The Hare," which is possibly as famous as Leonardo's "Mona Lisa."

Increasing interest is shown in notable painters' versions of other artists' works. These are not academic copies (such as the study made by Matisse, when a student, of Chardin's "La Raie"), but creative transcriptions. Examples that can be appreciated as original paintings are those by Miró of Sorgh's "Lute Player"; by Watteau of Rubens' "Apotheosis of James I"; by Degas of Bellini's "Jealous Husband"; by Caulfield of Delacroix's "Greece Expiring on the Ruins of Missolonghi"; by Larry Rivers of Jean-Auguste-Dominique Ingres's "Mlle Rivière"; and by Picasso of Manet's "Déjeuner sur l'herbe," Velázquez's "Las Meñinas," and Delacroix's "Woman of Algiers" (which produced Roy Lichtenstein's "Femmes d'Alger, After Picasso, After Delacroix"). Picasso has also painted free versions of works by El Greco, Lucas

Cranach, Poussin, and Courbet, as Rubens had of Mantegna and Titian, Rembrandt of Persian and Indian miniatures, Cézanne of Rubens and El Greco, and Van Gogh of Millet, Gustave Doré, and Delacroix.

The subject of an abstract painting

In an abstract painting, ideas, emotions, and visual sensations are communicated solely through lines, shapes, colours, and textures that have no representational significance. The subject of an abstract painting may be therefore a proposition about the creative painting process itself or exclusively about the formal elements of painting, demonstrating the behaviour of juxtaposed colours and shapes and the movements and tensions between them, their optical metamorphosis and spatial ambiguities. Many abstracts, however, are more than visual formal exercises and produce physical and emotional reactions in the spectator to illusions of shapes and colours that appear to rise and fall, recede and advance, balance and float, disintegrate and re-form; or of moods created of joy, sadness, peace, or foreboding; or of effects produced by light or by flickering or throbbing movement. Some abstracts evoke the atmosphere of a particular time, place, or event; and then their titles may be significant: "Pancho Villa, Dead and Alive" (Robert Motherwell); "Late Morning" (Bridget Riley); "Broadway Boogie Woogie" (Mondrian); "Gold of Venice" (Lucio Fontana); "Capricious Forms" (Kandinsky).

SYMBOLISM

Most early cultures developed iconographic systems that included prescriptions for the site, design, function, form, medium, subject matter, and imagery of their painting. The siting of early Byzantine murals, for instance, echoed the symbolic, architectural planning of the basilica. Thus, a stylized, linear image of Christ, surrounded by heavenly hosts, occupied the central dome; the Virgin was represented in the apse; and stiff figures of apostles, prophets, martyrs, and patriarchs occupied the aisle walls. The format of early devotional paintings was also prescribed, Christian and Buddhist deities being placed in the focal centre of the design, above the eye level of the audience and larger than surrounding figures. And, in the conventional arrangement of a Christian subject such as the Holy Trinity, a central, bearded, patriarchal God, flanked by archangels, presented Christ on the cross; between them was a dove, representing the Holy Spirit. In a rendering of the risen Christ, the Son faced the audience, with the Virgin Mother on the left and St. John on the right of the design. In the Far East a traditional format depicted Buddha on a lotus throne or in a high chariot drawn by oxen across clouds, surrounded by figures representing the planets. Deities generally appear against undefined grounds of white (signifying eternity or nothingness), blue (the celestial vaults), or gold (representing heavenly light by radiating lines or the spiritual aura by a nimbus). The elaborate surface preparation of supports and the painstaking execution with the finest materials symbolized the intention that paintings dedicated to a deity should last forever. The imagery, subject matter, and form might also have a mystical function: the realistic rendering of animals in contrast to the perfunctory human representations in Ice Age rock paintings, thought to signify a wishful guarantee for success in hunting; the earthly pleasures depicted on ancient Egyptian tomb murals intended to secure their continuance for the deceased; and the North American Indian sand paintings designed for magic healing ceremonies and the Tantrik (relating to Tantrism, a school of Mahāyāna Buddhism) mandalas used for meditation and enlightenment.

Symbolism in Eastern painting—intended to deepen the experience of a picture's mood and spirituality—is more generalized and poetic than in Western art. Both the execution and the subject matter of Buddhist Chinese and Japanese painting have a religious or metaphysical significance: the artist's intuitive, calligraphic brush movements symbolizing his mystical empathy with nature and his cyclic landscape and flower subjects expressing his belief in the spiritual harmony of natural forms and forces. Much of Indian symbolism is visually emotive, images such as snakes, plantain leaves, twining creepers, and rippling water being overtly sexual. And, although symbolic attributes and colour codes identify Indian mythological characters (for example, the four arms of the terrible goddess Kālī and the blue skin of the divine lover Kṛṣṇa [Krishna]), the formal character and colour scheme of settings generally reflect the narrative's emotional mood (for example, vibrant, dark-blue, cloudy skies and embracing, purple-black glades evoking amourous anticipation and red grounds expressing the passions of love or war).

Western symbolic systems

Western symbolic systems, however, are more intellectually directed, their imagery having precise literary meanings and their colour codes intended primarily for narrative or devotional identification. The iconographic programs of the early Christian churches, for example, laid down complex formulas for the viewpoints, gestures, facial expressions, and positions of arms, hands, and feet for religious figures. An elaborate Ethiopian Christian iconographic system was followed until very recently, and elsewhere traditional methods survive of identifying archangels and saints by their attributes and by the symbols of martyrdom that they display: distinguishing white-bearded St. Peter from black-bearded St. Paul, for example, and portraying St. Catherine with a wheel and St. Bartholomew with a knife and skin. Christian iconography adopted and elaborated Greco-Roman and Jewish symbolic imagery: the pagan signs of the vine and the fish, for example, and the image of Christ as the Good Shepherd based on the Greek Hermes Kriophoros. Medieval and Renaissance writings define an immense vocabulary of symbolic images, such as the crescent, sea urchin, and owl signifying heresy, the toad and jug representing the devil, and the egg and bagpipes as erotic symbols (all of which appear in Hieronymus Bosch's 15th-century narrative moralities). Angels and devils, hell fire and golden paradise, heavenly skies and birds in flight representing spirituality and rebirth are examples of the similarity of symbolic meaning for many religious, mythological, and allegorical traditions. The significance of images common to several cultures, however, may also be very different: the dragon representing avarice in European medieval allegory symbolizes friendliness in Japanese Zen painting; and the snake, symbol of temptation and eroticism in the West, signifies, by its skin shedding, the renewal of life in Far Eastern iconography.

(P.D.O.)

Paints, Varnishes, and Allied Products

Paint, a fluid suspension spread in thin coats to decorate and protect surfaces, consists of pigment or colouring matter, and the vehicle in which the pigment is suspended. The function of the vehicle is to form a tough film when applied to a surface and to bind the pigment to the surface. Paint may be applied to metal, wood, stone, paper, leather, cloth, or other surfaces.

Varnish is a liquid coating material containing a resin that dries to a hard transparent film. Though usually clear, varnishes occasionally may contain pigment. Lacquer is a varnish that solidifies by evaporation of the solvents contained within it rather than by one of the more complicated processes of film formation described later in this article. Lacquers may be clear and tinted, or opaque and coloured.

Certain types of surface coatings not ordinarily considered paints, though they have some characteristics in common with paints, are described in the articles PRINTING; PAPER AND PAPER PRODUCTS; ADHESIVES; and TEXTILE INDUSTRY.

HISTORICAL DEVELOPMENT

Origins. Paints were in use for representational and decorative purposes for thousands of years before the idea of using them as protective coatings appeared. The earliest known paintings, found in the caves of Lascaux, France, and Altamira, Spain, made with iron oxide and applied without binder, date from as early as 15,000 BC. Early peoples of Africa, Oceania, and the Americas also used paints to decorate temples and dwellings. The Egyptians prepared colours from soil and by 1500 BC imported such dyes as indigo and madder to make blue and red pigments. By 1000 BC they had developed a varnish from

First known paintings

the gum of the acacia tree (gum arabic) that contributed to the permanence of their art.

Asian art appears to have begun independently, with coloured crayons as pigment and clay as a binder. Natural ores served as sources of the first pigment, but calcined (fired) mixtures and organic pigments were developed at least before 6000 BC. Vehicles were prepared from gum arabic, egg white, gelatin, and beeswax. The use of lacquer in China goes back to prehistoric times. During the Chou dynasty (*c.* 1122–221 BC), it served for the decoration of carriages, harnesses, and weapons. By the 2nd century BC, Chinese buildings were decorated with lacquer both inside and outside; lacquer was also extensively used in Korea and Japan.

The first use of protective coatings was by the Egyptians, who employed pitches and balsams to seal ships, a practice followed by other peoples of the ancient world.

Not until the Middle Ages did paint as a preservative for exposed wood surfaces have considerable use. The paints developed then were handmade, using such costly raw materials as egg white; the craftsmen kept their formulas secret and their products were expensive. Medieval city streets, nevertheless, bore considerable evidence of the painters' art, with colourful tradesmen's signs and shop facades painted red or blue. In the 17th century white lead paint became widely available; yet ordinary houses and even such important structures as bridges remained unpainted for the most part until the 18th century, when there was an increased availability of both vehicles and pigments. Extensive exploitation of linseed oil from the flax plant and pigment-grade zinc oxide produced a rapid expansion of the paint-manufacturing industry. In the 19th century for the first time the two ingredients, pigment and vehicle, were brought together before the paint was marketed.

Emergence of paint science and technology. The 20th century brought an enormous proliferation of articles requiring protective coating; a corresponding proliferation of paint products was achieved by intensive research efforts. The dye industry contributed the knowledge needed to upgrade and evaluate pigments, and the plastics industry contributed the development of polymers, the giant molecules containing many repeating basic molecules.

The study of heat energy, or thermodynamics, begun in the 19th century, proved a useful tool for understanding chemical reactions of paint components and the more subtle interactions leading to compatibility and pigment wetting. A newer discipline, rheology—the science of the deformation and flow of matter—had a great impact; chemists and engineers appeared in paint-industry laboratories.

New coating materials

Many new types of coating materials have evolved: resins, solvents, plasticizers, pigments, driers, foam-control agents, and adhesion promoters. Fire retardancy, corrosion resistance, and heat stability have been achieved with selected new materials and new methods of application. The art of paint making has become a science.

The most significant change in paint technology in this century is the return to aqueous systems (water-base paints) at a level of sophistication and complexity never conceived by the Egyptians. The industry is stable; the raw materials are virtually unlimited; and the future portends a small but steady growth rate, notwithstanding competition from plastics, decorator fabrics, and ceramic tile.

PAINT MANUFACTURE

Composition. Paint is composed of a pigment, that hides the substrate (base on which it is applied) and imparts colour, and a vehicle, or binder, that carries the pigment onto the substrate and binds it there. Inorganic pigments are insoluble, metallic compounds the colours of which depend mainly on the electronic energy levels of the metal. Organic pigments are compounds containing colour-producing (chromophoric) groups of atoms within their molecules. Manufactured in batches of up to 2,500 gallons (9,500 litres), binders are composed of polymeric resins, usually dissolved in a solvent. A resin is a high molecular weight organic compound, soluble in organic solvents but not in water.

Dispersion. Paint manufacture involves bringing pigment particles and vehicle into close contact and achieving a thorough dispersion of the particles throughout the binder. Dispersion is in fact the most important operation in a paint factory; the economics of plant operation are keyed to it. The design of dispersion mills depends on the type of paint manufactured and on the formulations and colours the equipment must handle. The most popular types are so-called ball mills, which grind by tumbling heavy metal or ceramic balls through the paint in a cylindrical container, and sand grinders, which circulate a suspension of sand in paint through a rotor assembly at high speed. A fine grind can be achieved with ball mills operating for eight or more hours on single batches or with sand grinders delivering a nearly continuous output.

Paints are no longer hand mixed. Most of the important properties of a paint depend on the nature and extent of the interfaces (boundary surfaces) between the pigment particles and the vehicle. If the particles are not completely dispersed, with all the pigment particles wetted by vehicle, they link together in a reticulated structure that leads to poor brushability, low gloss, and the appearance of oversize particles in the film.

Oil absorption of a pigment

Oil absorption of a pigment, the volume of oil per unit weight of dry pigment needed to form a stiff coherent paste, indicates how well the pigment will disperse. Oil absorption is determined experimentally.

For each paint, there is an optimum ratio between the amount of pigment and the amount of binder. In the industry, this ratio is called critical pigment volume concentration (CPVC). As this critical figure is approached by adding more binder, gloss and blistering tendency decrease markedly, whereas permeation (penetration) of water and oxygen increase.

Control. Paint is usually made in batches. But there is a trend toward automation, especially in plants that make one product on a given line, even though continuous manufacture of paint is difficult (see illustration). If a large variety of colours or types must be made, the scheduling and control of the various operations become more important than the convenience of automation.

Colour adjustment. Paint products must be uniform in colour, flow, and other physical properties. Driers, fungicides, and tint bases are added during the process of thinning, and the paint is checked against a previously established colour standard. Skilled colour matchers have never been replaced in this phase of manufacture, although instruments are used to quantify the colour values of hue, brightness, and chroma (purity). As a rule, white pigments and extenders are used to provide hiding power by scattering light (see below), and the hue is provided by coloured pigments and toners that absorb light of certain wavelengths. By contrast, tint base used in the adjustment stage is a neutral colour that possesses good hiding qualities.

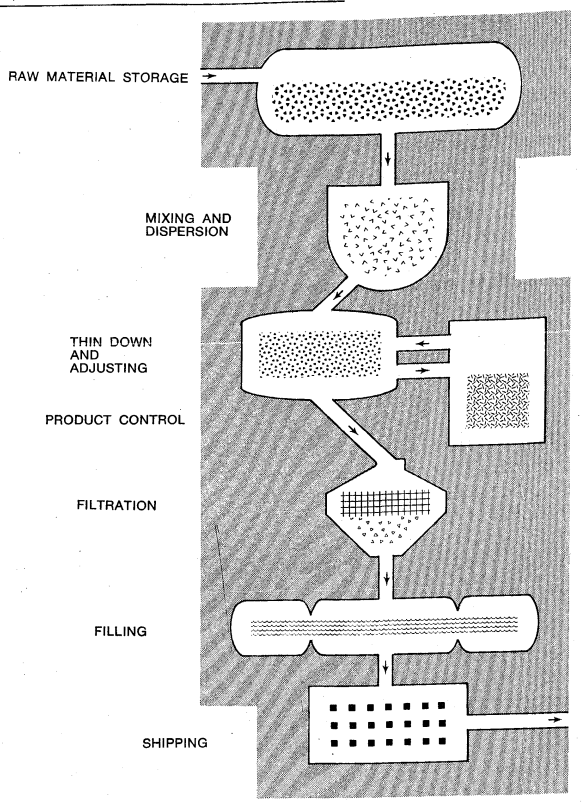
The purely technical aspects of the film are established instrumentally insofar as possible, and the observations are recorded instrumentally; but the final check is made by eye.

PIGMENTS AND OTHER COLORANTS

Pigment is the universally accepted term for the particulate matter dispersed in liquid or solid binders. Its two main functions are to impart colour and hiding and to improve hardness and durability.

Colour and hiding. The absorption of certain wavelengths of light gives rise to colour. The colour is the complement of the wavelengths absorbed.

When light strikes a pigment particle, the portions that are not absorbed are diverted in two ways, both of which result in hiding or obscuring the substrate. The light not absorbed may be reflected from the pigment surface or refracted as it passes through the pigment. Reflected light does not reach the substrate and hence cannot illuminate it at all. Refracted light, on the other



Stages in the paint manufacturing process.
Drawing by D. Meighan based on material courtesy of E.F. Wahl

hand, may reach the substrate, but at such an angle, and over such a tortuous path, that the diffuse reflection does not reach the eye. Reflection and refraction depend on a mismatch of refractive index between the pigment and the binder to scatter the light. Absorption is a characteristic that is present in dyes as well as pigments and that does not rely on light scattering. Hiding power has often been referred to the difference in refractive index between pigment and vehicle, but this difference plays a role in scattering.

Colour-defining systems

Colour is difficult to quantify. The best known colour-order system, the Munsell system, complete with ordered collections of colour chips, was originated in 1915 by an American artist, Albert Henry Munsell, and has since been refined. Another system in wide use that does not depend on collections of physical samples and is most often used in connection with instruments is the CIE (Commission internationale de l'éclairage) system, based on the matching of colours by mixing coloured lights from standard sources and providing a standard observer. In reducing the colour description to a set of quantitative terms, suitable for use in a computer, this system employs a set of standard coordinates, called tristimulus values. These values are used to match and guarantee the uniformity from batch to batch of one of the most important properties of a paint—its colour.

Pigments. Pigments are classified according to type or colour. Early classifications distinguished between mineral, or natural, pigments, which came from the earth and were either ground directly, or refined to a certain extent; and chemical pigments, which required a conversion of one sort or another. It is more convenient to classify pigments by colour, starting with the whites, then listing the blacks, and following with the more popular primary hues.

White pigments. White lead, the basic carbonate ($2PbCO_3 \cdot Pb[OH]_2$), has been manufactured for over 300 years by subjecting lead sheet to acetic acid fumes and carbon dioxide. The process takes several months.

Basic sulfate of lead ($PbSO_4 \cdot PbO$) is manufactured by heating lead in contact with sulfur. Reaction occurs when both the lead and the sulfur are vapourized. The basic silicate ($PbO \cdot SiO_2$) is formed as a coating on silica. Zinc oxide (ZnO) is the product of the reaction of zinc vapour with oxygen. Zinc sulfide (ZnS) is formed by precipitation out of aqueous solution and heating to a high temperature.

Lithopone ($ZnS + BaSO_4$) is a composite material, formed by precipitating zinc sulfate ($ZnSO_4$) and barium sulfide (BaS) together. Antimony trioxide (Sb_2O_3) is an exceptionally white pigment obtained by roasting antimony ore in air.

Titania, or titanium dioxide (TiO_2), is the superior pigment from the standpoint of hiding capability. Its preparation requires the removal of iron from the ilmenite ore $FeTiO_3$ (see also TITANIUM PRODUCTS AND PRODUCTION). Titanium dioxide is heated to a high temperature with small amounts of aluminum, antimony, silicon, or zinc oxide to produce white pigments with improved texture, resistance to light and moisture, and ease of dispersion in specific paint vehicles.

Black pigments. Most black pigments are made of elemental carbon. Carbon blacks are formed by allowing a smoking flame of natural gas to impinge onto a metal surface, usually iron. In the furnace process, the flame is not made to impinge on a surface but simply burns freely; the carbon is precipitated from the cooled gases. Lampblacks are obtained by burning oils in regulated amounts of air and allowing the carbon to fall by gravity from the combustion gases. Their blackness is inferior to carbon blacks, and they produce finishes of lower gloss. Bone blacks are made by charring bones. The char, which forms in the absence of air, consists of only about 10 to 20 percent carbon. Bone blacks are used principally in tinting when compatibility with other pigments is required. Graphite occurs naturally or can be prepared from coal in electric furnaces. It is an inferior pigment used only for specialty finishes. Amorphous graphite occurs in nature and is available at low cost. Mineral blacks derived from shale, peat, and coal dust are used as inexpensive pigments in undercoats.

Obtaining carbon black and lampblack

In addition to the carbon-containing black pigments, there exist iron oxide blacks found in nature or prepared. Blue basic lead sulfate, called blue lead, is a gray pigment that is used in the priming (*i.e.*, first coating) of structural steel.

Coloured pigments. It is convenient to group coloured pigments according to their position in the visible spectrum. Mineral varieties predominate at the red and blue ends and organic varieties in the centre.

Among the most common red pigments are red lead, iron oxide, cadmium reds, cuprous oxide, and various organics. Red lead (Pb_3O_4) is usually applied to steel for its protective value and is not used for tinting. This pigment is usually made by heating lead monoxide, or burning metallic lead. Iron oxide earth pigments (Fe_2O_3) are naturally occurring end products of the weathering of silicate rocks and were used in prehistoric times. The more important of these earth pigments are classified as ochres, the colorant of which is exclusively iron oxide and which tend toward the yellow part of the spectrum; siennas, which contain from 30 to 75 percent iron oxide and range from yellow-brown to reddish-orange depending on the variety and the degree of calcination; and umbers, which have a high manganese content in the form of manganese dioxide and tend toward brown coloration. Iron oxide ores, some of which can be ground directly to produce bright-coloured red pigments, include hematite ores, such as Spanish oxide and Persian Gulf oxide; magnetite (black); limonite (yellow); siderite (brown); and pyrites (dark brown). Synthetic iron oxide can be derived from ferrous sulfate ($FeSO_4$) by means of: calcination (heating to high temperatures) to produce grades ranging from light Turkey reds to dark Indian reds; calcination in the presence of lime (CaO), which produces a mixture of ferric oxide and calcium sulfate ($CaSO_4$) known as Venetian red; and precipitation from aqueous solution, which can produce any of three iron oxides of different hue.

Miscellaneous inorganic red pigments include cadmium reds, which rely on the mixture of cadmium sulfide (CdS) and selenide (CdSe) to produce colours ranging from

light red to maroon, and cuprous oxide (Cu_2O), which starts out as a bright red pigment but gradually oxidizes to the cupric form (CuO), which is black. Because cuprous oxide is a fungicide, this pigment is used in spite of its inherent chemical instability.

Organic red pigments include naturally occurring organic pigments, such as carmine and madder (mainly of historical interest, though still used as artists' colours), and synthetics. Synthetics are high-cost items, used because of the infinite variety of hues that can be achieved by minor changes in molecular structure.

Yellow and orange pigments

Yellow and orange pigments are obtained from metallic salts and from organic compounds. Chrome yellows and oranges are low-cost, bright, and stable pigments that display a considerable range of hues. Consisting of various proportions of lead chromate ($PbCrO_4$), lead sulfate ($PbSO_4$), and lead monoxide (PbO), all turn brown on exposure to sulfide gases in the air because of the formation of lead sulfide (PbS). Molybdate oranges, inclining toward the red, are made from lead chromate precipitated together with lead molybdate ($PbMoO_4$) and lead sulfate ($PbSO_4$). These also darken on exposure. Zinc yellow has a greenish cast because of a high content of chromic oxide. It is lightfast, rust inhibitive, and sulfide resistant. Basic zinc chromate ($5ZnO \cdot CrO_3$) is widely used as an undercoat. Cadmium yellow and oranges are formed by diluting yellow cadmium sulfide (CdS) with white zinc sulfide (ZnS) and barium sulfate ($BaSO_4$), using small amounts of red cadmium selenide (CdSe) to impart the orange coloration. Yellow-tinted titanium dioxide is produced by calcining it in the presence of nickel. The resulting product is very lightfast. Organic yellows and oranges are high-cost compounds (see DYES AND DYEING).

Blue and green pigments are mostly synthetic today. The natural blues and greens such as lapis lazuli have disappeared from coatings technology. In their place are synthetic ultramarines, produced by fusing china clay in a mixture of sulfur, sodium sulfate, and an organic reducing agent such as rosin. The glassy product is pulverized, leached free of sodium sulfate, and size-separated by sedimentation.

The most widely used blue pigments are the iron blues that contain various amounts of iron, ammonium and sodium ions (electrically charged particles), and water of crystallization (water trapped in the molecular structure as the pigment crystallizes). Two versions of iron blue are produced. Chinese blue has a greenish-blue tint; Milori blue tends toward the red. Hiding power of iron blue is good. Phthalocyanine pigments have a rather complicated organic structure; are reproducible, lightfast, brilliant; and make excellent tinting pigments but are expensive to produce.

The anthraquinone molecule ($C_{14}H_8O_2$), also used in dyes, can be made to form a permanent strong blue pigment that can be obtained in green hues by substituting chlorine atoms for most of the hydrogen atoms. It is an expensive pigment that withstands baking.

Iron blues mixed with chrome yellows in various proportions produce a popular class of chrome greens. Except for the darkening inherent in these lead-containing compounds (and the growing objections in many places to lead in coatings on grounds of health hazard), chrome greens offer the best combination of features for indoor and outdoor applications. Chromic oxide (Cr_2O_3) is a heat resistant, lightfast pigment.

Miscellaneous pigments. Finely divided aluminum, copper, bronze, and zinc are used to create a metallic or bronzing effect in coatings, particularly on metal panels, and also to impart corrosion resistance. The metals are produced in the form of powders or flakes that align themselves in the finished coating roughly parallel with the substrate. The flakes have good hiding power and are highly reflective, whereas spherical particles produce a less brilliant, sometimes milky, effect, with somewhat less protective value.

Fluorescent pigments include materials that absorb short wavelength radiation and re-emit light of longer wavelength. These are exceptionally brilliant if the emitted radiation falls in the same wavelength range as the reflected radiation. The molecular structure of the dyes responsible for this reinforcement must be such that electronic energy levels for the reflected and emitted light lie near each other. Phosphorescent pigments, which glow in the dark, are made from radioactive materials. Pearlescent pigments create a pearly, or nacreous, effect by diffraction of visible light.

Fluorescent pigments

Extenders. Certain inorganic salts that have little hiding power by themselves can be used to extend or conserve the more expensive hiding pigments; these are called extenders, or fillers. Extenders are also used to control the flow properties of paint, improving brushability and mechanical strength of the dried film. They sometimes decrease gloss and increase the resistance of a film to vapour transmission.

The main types of extenders are sulfates, which include natural or precipitated calcium or barium salts; carbonates, which comprise calcium or a mixture of calcium and magnesium salts; oxides, which include silica, either natural, precipitated, or hydrolyzed; and silicates, among which are clay, talc, mica, and calcium silicate. The types of coating that employ large volumes of extenders are architectural and maintenance finishes, particularly interior flat wall paints where hiding is not as critical as uniform coverage.

VARNISHES AND OTHER PAINT BINDERS

A surface coating protects the substrate against external influences such as moisture, light, and corrosive elements in the atmosphere. Thus, the binder for the pigment and whatever extenders are present are characterized by fluidity before application to the surface and rigidity soon afterward. This metamorphosis requires that a surface coating be either a solution from which the solids can be smoothly deposited on the substrate, a solution from which the binder will evaporate, or a liquid capable of solidifying or polymerizing to a rigid mass.

Natural binders. Originally, pigments were suspended in water, with and without binders. As binders the Persians used gum arabic; the Chinese, weak glue; the Asiatic Indians, boiled rice; the East Indians, shellac; and the Japanese, the sap from the wood-oil tree (which they called the varnish tree), possibly the first drying oil. The American Indians used a mixture of salmon eggs and fish oil.

Oil, wax, egg albumen, and glue were used in medieval Europe. During the Renaissance each artist developed his own formula for incorporating resins in drying oils. With the Industrial Revolution, copals and amber became the principal resins, and five classes of varnish were in use, only one of which contained linseed oil, which was to become the backbone of the industry in its formative stage.

Early varnishes

The first varnishes were solutions of natural resins, characterized by transparency, hardness, amorphous (noncrystalline) structure, and virtually no long-lasting integrity. They developed cracks on aging, even when used indoors; the utility of an outside coating relied largely on the natural tendency of pigments to adhere to the substrate by mechanical means.

Versatility is a characteristic of natural resins. They vary not only in solubility but also in transparency, brittleness, and crystallinity. Many are formed as natural secretions of plants or insects. Those resins that are compatible with oils (rosin, copals, amber) generally require heating. By contrast, the spirit-soluble resins (balsams, turpentine, lacs) usually dissolve without application of heat, but the danger of fire was a hazard in preparing their solutions with the highly volatile solvents.

Modern vehicles. Synthetic resins are now the heart of the paint industry. Not subject to variations in availability or quality as were their natural predecessors, these substances can be adapted with great chemical precision to various end uses and can be formed in many different suspending media.

There are two main types of synthetic resin: condensation polymers and addition polymers. Condensation polymers, formed by condensation of like or unlike molecules into a new more complex compound, include polyesters,

phenolics, amino resins, polyurethanes, and epoxies. Addition polymers, formed by direct chemical combination of substances into a single large molecule consisting of repeated units of the simpler original substance, include polyvinyl acetate, polyvinyl chloride, and the acrylates. (See also POLYMERS; PLASTICS AND RESINS.)

Condensation polymer resins. Alkyds (any of several common condensation polymer resins) are the most widely used protective-coating vehicles. Almost 1,000,000,000 pounds (450,000,000 kilograms) of these substances are consumed annually throughout the world. Brittle and insoluble in common solvents, they are always manufactured along with an agent (plasticizer) that makes them soluble and plastic. By manipulating their molecular structure in various ways, manufacturers can make alkyds more or less viscous, more or less hard as a coating, soluble in water or other substances, adherent, and capable of mixing successfully with various pigments.

Phenolic resins

Phenol (C_6H_5OH) reacts readily with aldehydes (any of various compounds containing the group —CHO, composed of carbon, hydrogen, and oxygen) to form oil-soluble compounds called phenolic resins, which are rapid drying, hard, chemically resistant, and abrasion resistant. The outdoor life of phenolic resins is not long, however, and they tend to yellow on aging.

Condensation of urea (H_2NCONH_2) or melamine ($C_3H_6N_6$) with formaldehyde (HCHO) produces compounds called amino resins, which are non-yellowing and alkali resistant and have good adhesive properties. When used in coatings, these amino resins contain an alcohol as a third component.

Both polyurethanes and epoxy resins are produced by means of complex organic reactions. Polyurethane coatings dry hard and inert on a substrate; epoxy resins have the qualities of toughness, adhesion, chemical resistance, rigidity, and thermal resistance.

Silicones are produced when various organic groups are attached to the silicon atom. They are hard and tough, with clarity and high gloss. They resist heat, weathering, and chemical attack and can be modified by blending or by chemical combination with other resins.

Addition polymers. Ethylene ($CH_2 = CH_2$), one of the simplest unsaturated organic molecules, can be made into translucent, inert, waxy polymers (called polyethylenes) at high pressures. Though the low-molecular-weight resins lack toughness and the higher are insoluble and unworkable, the inertness of the polymers gives them special interest in paint applications. When polyethylenes are applied to substrates, the resulting film is resilient and resistant to acids and oxidizers.

Polyvinyl acetate resin

One of the synthetic addition polymers that has largely replaced natural resins is polyvinyl acetate. This substance is a clear transparent resin that softens below the boiling point of water. It is sensitive to water and decomposes in acids and bases. Its solubility in a wide variety of organic solvents is good. It also has excellent adhesion properties.

Vinyl resins are marketed either dissolved or suspended in an organic medium like the natural resins or polymerized and marketed as aqueous emulsions called latexes.

Polyvinyl chlorides, though related to the compounds discussed above, lack desirable qualities as coatings. Acrylic compounds, on the other hand, which are clear, non-yellowing and heat stable, are used in the production of acrylic emulsion paints. Slight variation in the chemical composition of acrylic esters can produce wide variations in the physical properties of the polymer. Manufacture of acrylic emulsion paints consists of dispersing the pigment in water and adding the latex with only moderate agitation.

Solvents. Except for the solventless coatings (linseed oil and unsaturated polyesters) and the aqueous dispersions (vinyls and acrylics), it is necessary to dissolve solid resinous binders. Sometimes solvents are referred to as thinners because their inevitable effect is to reduce the viscosity of the resin solution. Plasticizers belong to the same category except that their volatility is not as pronounced as that expected of a solvent.

FILMS

Film formation. In the sense used by paint scientists, film formation involves conversion of a fluid coating, such as paint, into one with considerable rigidity.

Colloid chemical basis. Before the development of coatings science, little was known about the process of film formation except that a successful conversion required the film to maintain both integrity and adherence. Much of the modern thrust of paint science has been devoted to upgrading appearance and durability of materials that were known from the start to be film formers; little attention was paid to promising materials of good stability and desirable mechanical properties that did not form films.

The process of film formation is still not thoroughly understood. It is a far more complicated phenomenon than simple hardening or freezing. It involves transient and nonreversible conversions that are subject to many interdependent variables such as temperature, humidity, and the nature of the substrate. Film drying involves orientation of molecules at interfaces. Matter with thicknesses in the colloid range of dimensions is involved (see COLLOIDS).

Many of the test methods used by the paint industry are pragmatic: they are supposed to indicate when the coating is dry enough to be put in service. In effect they measure changes in the mechanical properties of the film and signify when they cross a particular threshold. All matter can be characterized by certain physical constants such as viscosity, modulus of rigidity, free volume, and density. Values of these constants, together with such basic chemical properties as bond strength, determine whether a film will form.

Types of film formation. There are two recognized ways to produce a rigid film on a substrate: continued growth of the polymer until it crosses the threshold between liquid and solid, and coalescence of finely dispersed polymer that has already terminated its growth as a molecule. The former method is chemical and the latter, physical. Combinations exist wherein the initial stage is physical and curing is effected chemically.

Physical and chemical film formation

The evolution of new concepts and new materials has broadened the number of variations of the film-forming process. Three strictly physical means of film-forming are: (1) from solution, in which evaporation of solvent leaves a deposit of polymer on the substrate; (2) from dispersions, in which evaporation of nonsolvent results in a deposit of particulate matter that coalesces into a continuous film; and (3) from melts, in which cooling of a supported fluid or plastic mass produces a rigid coating. Three strictly chemical means of film formation are: (1) by reaction with a component of the atmosphere in which the molecule combines with oxygen or water in the atmosphere; (2) by interaction of components already present in formulation, in which heat or radiation induce a reaction between species that coexist in the container without reacting; and (3) by reaction with a reagent or in the presence of a catalyst added just before application.

It is possible for solvent evaporation to accompany any of the three chemical means of film formation in a combination of physical and chemical drying. A combination of the two processes is provided by oil in the form of extended latexes, the initial rapid set of which is provided by evaporation and coalescence but the ultimate development of high rigidity of which is chemical.

Film formation by physical means. A solid resin or synthetic high polymer may be dissolved in a volatile solvent and converted by evaporation from a mobile fluid into a rigid film. Lacquer is an example of a coating that dries exclusively by this mechanism.

One of the standard polymerization techniques uses an emulsion directly as a film former, providing that the particles are deformable and hence are able to pack closely on drying. Only if the interstices and particle interfaces (points of contact) are obliterated will a clear, continuous film result. Acrylic ester emulsions may be formulated at extremely high molecular weights (up to 1,000,000), resulting in a polymer highly resistant to attacks by solvents.

Film formation by chemical means. Chemical reactions that occur during drying and hardening may lead to the formation of molecules of elongated or branched shape. When linseed oil dries and when epoxy resin hardens, the molecules link up and become elongated. In the case of some triglycerides and epoxies, elongation and cross-linking take place indefinitely, converting liquid films to a solid comprising one giant macromolecule. The greater the frequency of cross-links in the molecule, the more rigid the dried film.

Characteristics. Coatings are measured and characterized with instruments, ranging from the spatula of the craftsman and the penknife (or thumbnail) of the early development chemist to highly complex and expensive modern instruments.

Polymer properties. The properties of any substance depend on the size, shape, and composition of the molecules and on the magnitude and nature of the bonding forces within each molecule. Polymer structures are either open-chain or cross-linked; the former are generally thermoplastic and soluble, whereas the latter remain rigid at all temperatures below decomposition and merely swell in the presence of solvents.

Polymer properties and film formation

The properties of polymers that influence the quality of the ultimate film include the strength of bonding between atoms and between repeating groups of atoms in the chain of the polymer molecule; the crystallinity of the polymer—that is, the geometric arrangement of repeating atoms with the chain; and the manner in which polymers mix with various solvents. Measurement of these properties and determination of the exact means by which they influence film quality is complex and even controversial. Many difficult questions remain to be answered.

Paint properties. A paint should be applicable while liquid; on application all surface irregularities should smooth out, and paint film should flow into cracks and crevices before it develops appreciable rigidity. If a fluid condition is maintained too long, the coating will sag on vertical surfaces; consequently, most paints are so formulated that the time of hardening is kept short. This is done by adding what are called thixotropic agents to the paint that cause the binder to lose its structural rigidity as it is brushed onto the surface and to regain it shortly thereafter.

PAINT APPLICATION

Coatings have been applied for decades by brushing, rolling, spraying, and scraping. Techniques of deposition by means of an electrical charge and fluidized beds (finely divided pigments made to act as a fluid by passing air through them) recently have been introduced on a commercial scale.

Surface preparation. Wood, masonry, and other porous substrates must be treated to develop a surface capable of permanent and strong adhesion of the coating. Old loose paint and nonadherent weathering products, chalk, and dirt must be removed by abrasion. Metal surfaces require removal of scale and grease or pretreatment with phosphoric acid solutions.

Combating corrosion

The two main reasons for careful preparation of a surface are to maintain adhesion and combat corrosion. Corrosion of metals cannot be stopped simply by covering the surface with a thin film; corrosion is electrochemical in nature and can arise from irregularities in composition, aggravated by the slow diffusion of water and oxidants through the film. Thus, for complete protection, a first, or primer, coat is needed, followed by a second, or finishing, coat.

Application methods. Brushing and rolling are two very common methods of application. Brush marks are not simply indentations made by the bristles but arise from the unstable flow pattern of paint from brush to wall in addition to a profile produced by groups of bristles and substrate irregularities.

A common method for the application of primers, topcoat enamels, and lacquers is spraying, which minimizes the stress on the primer coat, formulated more for its chemical than for its mechanical properties. Whereas brushing creates a sizable stress on the undercoat, spraying largely avoids stresses at the interface.

In coating an object by spraying, much of the coating material may be lost by missing the target. One arrangement designed to overcome this waste is the provision of a high-voltage electrostatic field as the workpiece and then inducing a charge in the spray; its particles are then attracted to the workpiece.

Small objects are coated by a slow-dip process characterized by drying of the lacquer to a stable film as rapidly as the object is withdrawn. This procedure avoids the drainage problem that leads to sagging, and it is particularly suitable for the application of thick coatings. Curing may require subsequent baking.

Fast-dip application is used in coating large objects such as machinery. The piece is withdrawn and hung on a rack to drain and dry. In this version of dipping, the solvent is of a slow-evaporating nature, and the coating formulation has a low viscosity.

Electrophoretic coating

Electrophoretic coating, which involves movement of suspended particles through a fluid under the action of a voltage applied to electrodes in contact with the suspension, and electrocoating, which involves electrical attraction of the coating to the substrate, are modern developments carried out in fast-dip tanks. Charged resin particles are attracted only to bare, uninsulated metallic areas and therefore ensure complete, even coverage.

Flat stock ranging from metallic coils to porous paper can be coated at high speed by equipment that resembles a printing press. Printing of decorative patterns is performed in this manner.

Tumbling is employed in the coating of small objects such as hardware and buttons. The coating forms evenly if the objects are fairly smooth and have no sharp projections.

Fluidized-bed coating provides a solventless way of depositing an even coating of resin on surfaces that can be heated, thereby relying on fusion to provide the levelling and adhesion. A current of air is blown through a bed of resin beads, which impinge on the heated surface lowered into the heated fluid. The hot metal entraps particles that reach its surface. Flame spraying is employed in applying ceramic or refractory coatings to metallic surfaces.

Baking or stoving. The ultimate cure or final drying of many organic coatings is provided by baking. In general, the aim is to have this final step occur evenly throughout the thickness of the film in order to minimize residual stresses that would adversely affect the adhesion. Baking is used to level out buffed coatings to provide extremely high gloss.

Elevated curing temperatures are obtained by convective heating and infrared heat radiation. Some attempts have been made to use induction heating, and this method is likely to grow in popularity. Radiation is occasionally provided by a beam of electrons or by ultraviolet radiation.

ECONOMICS

The paint industry of the world enjoyed a steady growth through the 1960s and early 1970s, notably in western Europe, Japan, and the United States. The number of paint producers in any country is typically large because of the competitive advantage enjoyed by producers in the immediate geographic area in which the paint is marketed and used. Demand is met by many small producers as well as by branches of large companies; the consumers' requirements for small specialty batches and his call upon technical service staffs are based on many subjective factors requiring local contacts. It is estimated that 1,700 companies make paint in the United States; 480 in the United Kingdom; 350 each in Italy and France; 200 in West Germany; and 100 in The Netherlands. The bulk of the sales volume, however, is handled nearly everywhere by a few large manufacturers. Three manufacturers dominate the United Kingdom, and 15 firms in the United States account for 50 percent of the sales.

Half of the paint market involves industrial firms, that sell the coating as an integral part of the finished product, and only half involves over-the-counter sales to final users.

Nevertheless, the small paint manufacturer exerts a profound effect on the overall industry; it is common for the leading paint company in any given metropolitan area to be a local firm. To compete with the research efforts of the large companies, small companies often band together to form cooperative research groups.

Over one-third of the cost of paint is the cost of resins and other chemical raw materials; another third is for manufacturing costs and the remainder for packaging and marketing.

Technical societies

Technical developments are disseminated largely by federations of local paint societies made up of individual rather than corporate memberships. The Oil and Colour Chemist's Association in London, the Federation of Scandinavian Paint and Varnish Technicians, and the Federation of Societies for Paint Technology (FSPT) in Philadelphia are continuously active. The countries of western Europe and North America hold a biennial conference under the auspices of a loose international federation known as Fatipec (Federation of Associations of Technicians in the Paint, Varnish, and Printing Ink Industries of Continental Europe).

FUTURE OF THE COATINGS INDUSTRY

The surface-coating industry promises to continue to grow in the future as a result of overall world economic growth, technology that will widen the application of surface coatings, and finally, the important role foreseeable for paints, varnishes and allied products in the struggle to improve the environment.

Electrocoating methods and coil coating (described above) will grow, and curing methods requiring high energy radiation will be the preferred means of developing desirable mechanical properties within a brief time span after application. Powder coatings are on the threshold. New resin systems will be developed.

In order to minimize pollution and safety hazards, the trade will turn more to aqueous (water-base) systems. The chemistry of film formation from latexes will be thoroughly probed so that the limitations of latex application will be understood.

Paints will perform more varied functions than decoration and protection against degradation. Sacrificial coatings that protect surfaces from fire by swelling and bubbling are expected to double in volume; their use may be required for certain types of installations. Conductive coatings will serve a variety of uses ranging from panel heating to undercoats for electrodeposited finishes. Coatings that change hue on demand will provide a new dimension in decoration. Sound-absorbing coatings may be developed.

One of the most rapidly growing markets for coatings is floor coverings. Having lost much of the market for ceilings, the paint industry has turned to seamless flooring, a liquid system possessing decorative, high-build, and abrasion-resistant qualities. Because of the need for high-impact resistance, seamless flooring must be applied at least 35 mils (35 thousandths of an inch) thick.

Biodegradable plastics, which break down when exposed to sunlight, then decompose like natural substances, may serve as protective coatings for base metals or other degradable stock. After use, the article will be exposed to sunlight, which will destroy the integrity of the coating and allow degradation of the substrate to occur.

Pollution control

As a derivative industry dealing with conversions of raw materials into finished products, the paint industry is concerned more with pollution by its product and related hazards associated with coatings than with pollution during the process of paint manufacture. Research has already been brought to bear effectively on the solution of the production problem. Pollution by the product after application is more difficult to estimate or even to identify. Lead has been removed from coating formulations that are liable to come within the reach of children; it may come under more sweeping prohibition. Mercury salts were the best fungicides for preventing mildew growth on surfaces until that metal was ruled out of house paint.

Hiding without pigments is an attainable goal. The bloom on fruit, the opacity of flower petals, and blush films all result from the scattering of light at the interface of minute voids in the film. The low refractive index of such voids provides an optical mismatch with the film, as does high-index pigment, so that hiding is just as effective with voids as with solid pigments. Inferior mechanical properties of pigmentless paints, particularly as manifested by loss of hiding power when voids are crushed, must be overcome if these materials are to make deep inroads into paint markets.

Industry-wide basic research is supported by the Paint Research Institute of the FSPT. Through its program of awarding fellowships in chemistry, physics, and engineering the institute maintains contact with the latest developments in colloid and macromolecular science.

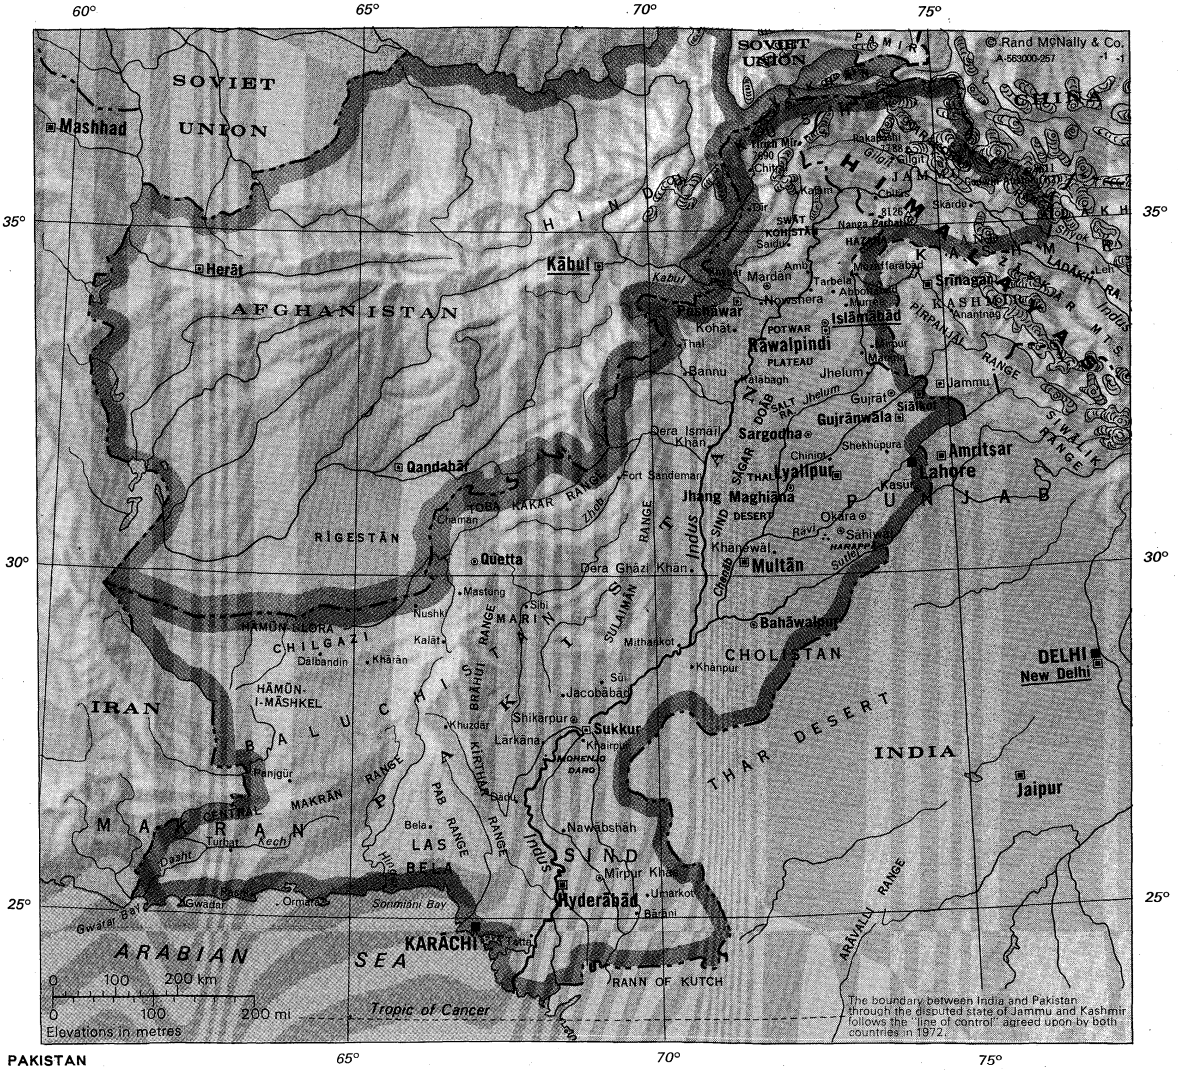
Pakistan

Pakistan (the Islāmic Republic of Pakistan) is a country in South Asia. It is bounded to the west by Iran, to the north by Afghanistan and the U.S.S.R., to the northeast by China, to the east and southeast by India, and to the south by the Arabian Sea. The territory has an area (excluding the Pakistani-held part of Jammu and Kashmir) of 307,374 square miles (796,095 square kilometres) and at the 1972 census had a population of 64,892,000. The capital of the country is Islāmābād.

Pakistan was brought into being at the time of the Partition of British India in 1947 in order to create a separate homeland for India's Muslims in response to the demands of Muslim nationalists. From independence in 1947 until 1971, Pakistan (both de facto and in law) consisted of two regions—West Pakistan in the Indus River Basin, and East Pakistan, located more than 1,000 miles away in the Ganges River Delta. In response to grave internal political problems, however, an independent state of Bangladesh was proclaimed in East Pakistan in 1971.

Economic development has been concentrated in two of Pakistan's four provinces—Punjab and Sind—which, with about 75 percent of the rural population, produce more than 90 percent of the country's wheat, more than 95 percent of its rice, and 100 percent of its cotton. The remaining two provinces—Baluchistan and the Northwest Frontier Province—are, by comparison, poor, for industrial development is also largely concentrated in Punjab and Sind.

Throughout the republic of Pakistan there is a high degree of concentration of landownership, although successive governments have pledged themselves to land reform. There is an even greater concentration of ownership of industry among a few. (See the city articles on KARACHI and LAHORE, as well as the articles on Pakistan's four provinces, BALUCHISTAN; NORTHWEST FRONTIER PROVINCE; PUNJAB [PAKISTAN]; and SIND; see also the articles on BANGLADESH [formerly East Pakistan] and on JAM-



PAKISTAN

MAP INDEX

MU AND KASHMIR. For associated physical features, see ARABIAN SEA; HIMALAYAN MOUNTAIN RANGES; HINDU KUSH [MOUNTAINS]; INDUS RIVER; KARAKORAM RANGE; SALT RANGE; and THAR DESERT. For historical aspects, see INDIAN SUBCONTINENT, HISTORY OF THE.)

This article is divided into the following sections:

I. Landscape and environment

RELIEF AND DRAINAGE

Pakistan is situated at the western end of the Indo-Gangetic Plain, which is bounded to the north by the mountain wall of the Great Himalayan mountain ranges and their offshoots. It is situated in the northwestern part of the southern Asian subcontinent and may be subdivided into six natural regions—the northern mountains, the submontane plateau, the Indus Plain, the Baluchistan Plateau, the western bordering mountains, and the desert areas.

The Himalayan sector

The northern mountains. The Himalayan and Trans-Himalayan mountains occupy the entire northern end of Pakistan, to a depth of about 200 miles; they are among the youngest mountains on Earth, having attained their present elevation only within the last 1,000,000 years. They rise to an average height of more than 20,000 feet and include such towering peaks as Nānga Parbat (26,660 feet, or 8,126 metres, high) and K2, also called Godwin Austen (28,251 feet, or 8,611 metres, high). Beyond the Karakoram Range in the extreme north lies the Chinese province of Sinkiang; to the northwest, beyond the Hindu Kush, are the Pamirs—the "Roof of the World"—where only a narrow strip of Afghan territory separates Pakistan from the Soviet Union. The Himalayan massif (mountainous mass) that isolates the South Asian subcontinent from Soviet and Chinese Central Asia was pierced in 1970 when a road was completed across the Karakoram Range, linking the town of Gilgit in Pakistan with Kashgar in Sinkiang, China.

The northern mountain barrier influences the rainfall pattern in Pakistan by intercepting monsoon (rain-bearing) winds from the south. Melting snow from the mountains also feeds rivers, including the mighty Indus, which cut across the east–west aligned mountain ranges to flow southward.

The population in this inhospitable region is generally sparse, although in a few favoured places it is dense. In most of the tiny settlements of this region, the usual crop is barley; fruit culture, especially of apricots, is of special importance. Timber, mainly pine, is found in some parts, but its occurrence varies with rainfall and altitude. Many slopes have been denuded of cover by excessive timber felling and overgrazing. The whole region in itself is of less significance than in its relation to the plains to the south.

The submontane plateau. Lying below the Himalayas, the submontane plateau has four distinct divisions—the Trans-Indus plains, the Potwar Plateau, the Salt Range, and Siālkot district.

The Trans-Indus plains. The Trans-Indus plains, west of the Indus, comprise the hill-girt plateaus of the Vale of Peshāwar, Kohāt, and Bannu, which are oases in the arid, scrub-covered landscape of the Northwest Frontier Province. Of these, the Vale of Peshāwar (consisting of Peshāwar and Mardān districts) is the most fertile. It was once a flourishing centre of Greco-Buddhist culture; with a territory of only 2,500 square miles, it has nearly half of the population of the entire Northwest Frontier Province, which has a total area of 39,000 square miles. Much of the area is covered by gravelly or clayey alluvial detritus. Rainfall is generally only between 10 and 15 inches but is higher in Mardān district. About 65 percent of the net sown area in Peshāwar Vale is irrigated from canals. Kohāt is, comparatively, little developed. Rainfall is about 16 inches. Only 12 percent of the sown area is canal irrigated. Nor is its groundwater adequately exploited, although the water table is generally high. Much of the area consists of scrub and poor grazing land. The region is much broken by limestone ridges, and the uneven limestone floor is variously filled with lacustrine clays, gravel, or boulders. In Bannu, soils are in general sandy or gravelly, except for rich silts that occur in places. About 23 percent of the net sown area is irrigated. Rainfall is low, amounting to about 11 inches. In both Kohāt and Bannu fat-tailed sheep, camels, and donkeys are extensively reared; wool is an important cash crop.

The Vale of Peshāwar

The Potwar Plateau. The Potwar Plateau lies at a height of 1,200 to 1,900 feet and covers an area of about 5,000 square miles east of the Indus, in the Punjab. It is an open, undulating country developed on the Siwālik Range, which is mainly of sandstone and is covered by varying thicknesses of loess (a loamy deposit formed by the wind), which erodes easily. Rainfall is between 15 and 20 inches (380 to 510 millimetres), being higher in the northwest; the southwest is very arid. The landscape is dissected and eroded by streams that, during the rains, cut into the land and wash away the soil. The streams are generally deep set and are of little or no use for irrigation. It is generally a poor agricultural area, with an excessive pressure of population upon its resources.

The Salt Range. The Salt Range lies at the southern edge of the Potwar Plateau and has an average height of 2,200 feet, the highest peak being at Sakesar (5,000 feet, or 1,500 metres); it is an extremely arid territory that sharply marks the boundary between the submontane region and the Indus Plain to the south. The Salt Range is of interest to geologists, as it contains the most complete

geologic sequence in the world, in which rocks from the Cambrian Period (from 500,000,000 to 570,000,000 years old) to the Pleistocene Epoch (from 10,000 to 2,500,000 years old) are represented.

Siālkot district. Siālkot district is a narrow submontane region in the northeast; unlike the Potwar Plateau, it is a rich agricultural region. Rainfall varies from 25 to 35 inches (650 to 900 millimetres), and the water table is high, facilitating well (and tube-well) irrigation; the soil is heavy and very fertile. Population is dense (about 1,100 per square mile); the land is divided into small farms on which intensive cultivation is practiced.

The Indus Plain. The Indus Plain, which covers an area of about 200,000 square miles, is the most prosperous agricultural region in Pakistan. It is an unrelieved featureless plain of fertile alluvium extending for 650 to 700 miles from the rim of the Potwar Plateau southward to the Arabian Sea. Its northern zone comprises the province of Punjab (literally, Five Waters) and is enclosed by the Indus and its five tributaries—the tributaries converging to their confluence with the Indus at Mithankot. It is divided into several interfluves (lands situated between streams) called *doābs*, the largest but the poorest of them being the Sind Sāgar Doāb, situated between the Indus and the Chenāb rivers, which is mostly a desert. The *doābs* that lie to the east of it, however, are the richest agricultural lands in the country. Until the advent of irrigation, at the end of the 19th century, much of the area was a desolate waste, for there is little rainfall. But irrigation has not been an unmixed blessing; it has also caused waterlogging and salinity in some places.

The *doābs*

In the southern zone of the Indus Plain lies the province of Sind, which is named after Sindhu (the Indus River). There, the size of the Indus—its waters augmented by the contribution of its five tributaries—is very great; its average annual discharge at Sukkur, in northern Sind, is more than 5,000,000,000,000 cubic feet (140,000,000,000 cubic metres), including nearly 10,000,000,000 cubic feet of water-borne silt. The land in Sind, consisting of alluvial sands and clays, tends to give way before the Indus flood, and the river frequently changes course. Manchhar, a marshy lake west of the Indus, has an area of 14 square miles at low water but extends for no less than 200 square miles when full; on such occasions, it is the largest freshwater lake in South Asia. The quality of groundwater in the Indus Plain varies, that in the southern zone (Sind) being mostly saline and unfit for agricultural use. Extensive areas in both the northern and southern zones of the Indus Plain have been affected by waterlogging and salinity. In the south the Indus Delta (in marked contrast to the Ganges Delta) is a wild waste. When high tides and Indus floods coincide, the littoral is flooded for 20 miles inland.

The Baluchistan Plateau. The Baluchistan Plateau extends westward, 1,000 feet high, with many ridges running across it from northeast to southwest; it is separated from the Indus Plain by the Sulaimān and Kīrthar ranges. It has a remarkable indigenous method of irrigation called the *kārez*, which consists of underground channels and galleries that collect subsoil water at the foot of hills and carry it to the fields and villages. The water is drawn from the channels through shafts that are sunk into the ground, at suitable intervals, in the fields. Because the channels are under ground, the loss of water by evaporation is minimized. The plateau is an extremely arid country and is the most sparsely populated region in Pakistan, with an average density of nine persons per square mile. Pastoral activity supplements a primitive form of agriculture. True pastoral nomadism survives in the northwest. Goats and fat-tailed sheep account for about 80 percent of the stock, and much of the local traffic consists of camels and donkeys, although trucks and buses are in use on the new roads.

The western bordering mountains. These mountains run south from the Hindu Kush, in several parallel ranges, outside the path of the monsoons. Rainfall is low, and there is little vegetation. Occasional heavy rain in the mountains results in destructive torrents, washing away the soil. Some cultivation is practiced beside streams and along riverbanks or (wherever conditions permit) by terracing hillsides. Three minor ranges run south from the Hindu Kush to the Kābul River, south of which lies the famous Khyber Pass, at the frontier with Afghanistan. Further south the Sulaimān Range runs southward for about 300 miles, after which the lower Kīrthar Range runs down to the coast. These hills separate the Indus Plain from Baluchistan. The population of these arid hills is tribal. The area in general is extremely poor; only a minimum of crops are grown in favoured valleys—which, however, are generally malarial. Large numbers of sheep and goats are kept. The mule is the main beast of burden in this broken country.

The desert areas. The desert areas include firstly the dreary steppes of the Sind Sāgar Doāb (at the centre of it the Thal, which has true desert conditions) and secondly Cholistan in Bahāwalpur (Punjab), which is known as the Nāra or Registān in Khairpur (Sind) and further south as the Thar Desert in the Thar Parkar District of Sind. These areas are extensions of the Thar Desert of western India.

SOILS AND CLIMATE

Soils. The soils of Pakistan are classified as pedocals, which comprise a dry soil group having a high content of calcium carbonate and a low content of organic matter; they are characteristic of a land with low and erratic rainfall. The soils of the Indus Plain consist of alluvium, old and new, whereas in the desert areas and most of Baluchistan they consist either of windblown deposits known as loess or else of loess mixed with alluvium. The soils of the Thar Desert area are, for the most part, sandy loams with patches of clay and larger areas of pure sand. Some of the virgin soils respond generously to irrigation, and an extensive reclamation scheme has made much progress in the Thal region.

Climate. As Pakistan is located on a great landmass, north of the Tropic of Cancer (between latitudes 24° and 37° N), it has a continental type of climate characterized by extreme variations of temperature, both seasonally and daily. Very high altitudes modify the climate in the cold snow-covered northern mountains; temperatures on the Baluchistan Plateau are somewhat higher. Along the coastal strip, the climate is modified by sea breezes. In the rest of the country, temperatures reach great heights in the summer; the highest temperature in the entire Indian subcontinent—126° F (52° C)—was recorded at Jacobābād, in Sind. In the summer, hot winds called *loo* blow across the plains during the day. Trees shed their leaves to avoid loss of moisture. The dry, hot weather is broken occasionally by dust storms and thunderstorms that temporarily lower the temperature. Evenings are cool; the diurnal variation in temperature may be as much as 20° to 30° F (11° to 17° C). Winters are cold, with minimum mean temperatures of about 40° F (4° C) in January.

Summer and winter temperatures

The characteristics of different regions are determined by variations in rainfall and irrigation rather than by temperature. Although the country is dominated by monsoon winds, it is extremely arid, except for the southern slopes of the Himalayas and the submontane tract, which have a rainfall of from 30 to 35 inches (750 to 900 millimetres). The 20-inch (500-centimetre) precipitation line, which runs northwest from near Lahore, marks off the Potwar Plateau and a part of the Indus Plain in the northeast; these areas receive enough rainfall for dry cropping (farming without irrigation by taking measures to conserve water). South of this region, cultivation was confined mainly to riverine strips until the advent of irrigation.

VEGETATION AND ANIMAL LIFE

Vegetation. Natural vegetation, except for wooded mountain slopes, is largely limited to tough wiry grass and stunted bushes, with only a few scattered trees, except for a few plantations in forest reservations and ubiquitous orchards of fruit trees. In Baluchistan the Salt Range and the western-bordering-mountains vegetation is mostly limited to xerophytic plants (plants adapted for growth under dry conditions). The deserts are virtually devoid of

vegetation. The Indus Plain when watered, however, is very fertile. Wheat is the principal winter crop, the main summer crops being cotton and rice. Widespread installation of tube wells, especially in the Punjab, is bringing about substantial changes in cropping patterns, encouraging substitution of wheat for less valuable drought-resisting crops, such as gram (chickpea).

Animal life. Wildlife abounds in the northern mountains and includes brown bear, black Himalayan bear, leopard, the rare snow leopard, Siberian ibex, and varieties of wild sheep. Buffalo rather than cows are kept as milch cattle, and bullocks are employed for plowing, although occasionally camels are also used for that purpose. Donkeys are the beasts of burden. The Manchhar Lake in Sind has an abundance of water birds, including mallards, teals, shovellers, spot bills, geese, pochards, and wood ducks; desert gazelles are also found in the region. Crocodiles, pythons, and wild boars are found in the delta area. Jackals, foxes, wild cats, and a variety of rodents and reptiles are found throughout the country.

TRADITIONAL REGIONS

The traditional regions of Pakistan, shaped by ecological factors and historical evolution, are reflected in the administrative division of country into the four provinces of Sind, Punjab, the Northwest Frontier Province, and Baluchistan. The encroachment of the Cholistan Desert and of the western bordering mountains narrows down the Indus Plain below Mithankot, thus separating the destinies of Sind and Punjab, each of which has a distinct language, culture, and history. Until 1937 Sind was a part of the Bombay Presidency, and it had no administrative links with the Punjab. Baluchistan and the Northwest Frontier Province are separate, both linguistically and culturally; they are distinguished by tribal societies subsisting on precarious agriculture, supplemented by pastoralism. In the Punjab, until the advent of irrigation, the bulk of the population was restricted to the *bārānī* ("land dependent on rainfall for cultivation") region—the Potwar Plateau and the Upper Indus Plain—which receives more than 20 inches of rainfall.

The Canal Colony districts of southern Punjab were large tracts of uncultivated land in the Indus Plain that were irrigated by canals and populated by colonists drawn from every part of the Punjab. They now form the richest agricultural region of the country. Agricultural wealth is concentrated in districts of Lahore Division (in the *bārānī* region) that have benefitted from irrigation, together with the Canal Colony districts and Sind. These areas contain 65 percent of the rural population of Pakistan and produce well over three-quarters of its wheat production and virtually all of its cotton and rice production. Landholdings are comparatively larger in the Canal Colony districts of the Punjab and in Sind.

Land-holding patterns

Elsewhere, in the overpopulated and poor districts of the *bārānī* region, which moreover do not benefit from irrigation, holdings are exceedingly small and fragmented. In these districts there is a great pressure to migrate from the villages to find employment in towns or in the armed forces. Consequently, unlike the richer agricultural areas, this impoverished and overpopulated region maintains a close symbiotic relationship with urban economy and society. Educational levels in these districts are higher than they are in the richer agricultural areas.

THE LANDSCAPE UNDER HUMAN SETTLEMENT

Rural settlement. The vast majority of the rural population of Pakistan lives in nucleated villages or hamlets (*i.e.*, in compact groups of dwellings). Sometimes, as is generally the case in the Northwest Frontier Province, the houses are placed in a ring with blank outer walls, so that each complex resembles a protected fortress with a few guarded entrances. Dispersed habitation patterns in the form of isolated single homesteads are rare, occurring only in a few mountainous areas. But it is not uncommon to find numerous satellite hamlets of varying sizes near larger villages; such hamlets are occupied either by a landlord, with his servants and sharecroppers, or else by members of a lineage living together in adjoining houses. The spread of tube wells in the Punjab has increased the tendency for such dispersal, for people often prefer to live near their tube wells in order to guard the valuable machinery. The concept of village, therefore, often tends to be equivalent to that of the *mawzaʿ* (an area of land that, together with a village and its satellite hamlets, forms a unit in land-revenue records). It is difficult to speak of an average size of village, for patterns of habitation are complex. Most groups of dwellings have a minimum of a dozen or a score of houses, and there are usually a few hundred dwellings in each "village." Large villages rarely have a population exceeding 2,500 persons.

Three basic types of village layout are to be found. Most of the older villages are of the "spider-web" form, having at least one focal point, such as the village mosque, some shops, or a well from which lanes radiate. A few villages follow the contours of hill slopes and other natural features. Finally, in the Canal Colony areas, villages are of a regular rectangular pattern, with a well, a mosque, and a school, as well as the house of the village headman, at the centre, and with the houses being arranged in a series of concentric rectangles. Houses are built from available local materials; the vast majority are of mud, a material that is not only cheap and reasonably durable in the dry climate but also provides better insulation from extremes of heat and cold than brick or stone. Houses usually have walled courtyards where animals are tethered and where people sleep in the open in the hot summer.

Urban settlement. The urban population of Pakistan represents about a quarter of the total. Two cities have a dominating position—Karāchi, which in 1961 had nearly a fifth of the urban population, and Lahore, which had 13 percent of it. By 1972 there were 18 cities with a population of more than 100,000, compared with seven such cities in 1941. During the 1960s government policy was directed toward the dispersal of industry, which had become heavily concentrated in Karāchi. As a consequence, since the 1961 census, urban growth has been more evenly distributed among several cities. Karāchi, the principal port and centre of commerce and industry, was also the national capital until 1966, when the new capital at Islāmābād, 750 miles away, began to function.

Rapid and unplanned urban expansion has been paralleled by a deterioration in living conditions, particularly in the housing conditions of lower income groups. According to one official estimate in 1969, about 72 percent of urban households are unable to pay rent for the cheapest form of available housing and live in makeshift shacks. Water supply and sewerage systems are inadequate, and in many areas residents have to share communal water taps. Inadequate urban transport is also a major problem. After Karāchi and Lahore, the principal cities (in order of size as of the 1972 census) were Lyallpur, Hyderābād, Rāwalpindi, Multān, Gujrānwāla, Peshāwar, Siālkot, Sargodha, Sukkur, Quetta, Jhang, Bāhāwalpur, Sahiwal, Mardān, Wah, and Kasur. Karāchi is the provincial capital of Sind, Lahore of Punjab, Peshāwar of the Northwest Frontier Province, and Quetta of Baluchistan. The new capital city of Islāmābād adjoins Rāwalpindi, where the army's general headquarters and the offices of the president of Pakistan are located.

Urban living conditions

II. People and population

ETHNIC GROUPS

Race as such plays little part in defining regional or group identity in Pakistan, and no ideal racial type is accepted by all Pakistanis. The population is a complex mixture of indigenous peoples, many racial types having been introduced by successive waves of migrations from the northwest, as well as by internal migrations across the subcontinent of India. Aryans, Persians, Greeks, Pashtuns (Pathans), and Mughals came from the northwest and spread across the Indo-Gangetic Plain, while the Arabs conquered Sind. All left their mark on the population and culture of the land. During the long period of Muslim rule, immigrants from the Middle East were brought in and installed as members of the ruling oligarchy. It became prestigious to claim descent from them, and many

members of the landed gentry and of upper class families are either actually or putatively descended from such immigrants. In 1947, when Pakistan and India became independent, there was another massive migration, of a different character, when millions of Muslim refugees were uprooted from different parts of India and settled in Pakistan; an equal number of Hindus were uprooted from Pakistan and driven across to India. This development further complicated the racial mixture of the population of the various regions of Pakistan.

Ethnic antecedents

Of the earlier people, almost the only known skeletal remains of much significance are those associated with the Indus civilization that flourished 5,000 years ago. Human skeletons and skulls found among the ruins at Mohenjo-daro in Sind reveal firstly that at least four racial types were present in that area in about 2500 BC—Mediterranean and Alpinoid (both Europoid), Proto-Australoid (Veddoid), and Mongoloid—and secondly that there was much racial mixture. The Indo-Aryans, who predominate in contemporary Pakistan, arrived between about 1500 and 1200 BC. In the 6th century BC the Persian Empire was extended to the Indus Valley, and in the 4th century BC Alexander the Great and his armies passed through the region. The region subsequently became a melting pot for diverse races and cultures that came not only from outside the Indian subcontinent but also as a result of internal movements, such as the expansion of the Mauryan Empire over northern India. These variegated influences and associated migrations render any attempt to identify racial origins of people in different parts of Pakistan somewhat arbitrary.

Racial types to be seen in Pakistan include the tall, fair-skinned, and blue-eyed type; the olive-skinned, fine-boned, hawk-nosed "Iranian" type; smaller, dark-skinned types of "Dravidian" and "Australoid" origin; wheaten-skinned, dark-eyed "Indo-Aryan" types; short-headed and long-headed Mongoloid peoples; and, in Baluchistan, the broad-headed Europoid type of stocky build, reminiscent of the Alpine type in Europe.

Regionally, the population is sometimes grouped into four types by racial origin as follows—(1) the "true" Mediterranean type, found in the Punjab; (2) the "Oriental" Mediterranean type, found in the Punjab and Sind, characterized by an unusually long and often convex nose and lighter skin colour but otherwise similar to the first type; (3) the Pashtuns of the Northwest Frontier Province; (4) the brachycephalic (short-headed) Baluchi type, which derives from Iranian stock.

Attitudes to racial types vary. In Baluchistan, the short Iranian head is admired, so that the three major tribes of the region sometimes bind their daughters' heads. In other areas, longheadedness is valued. Elsewhere, again, the shape of the head is a matter of indifference. There is, however, a general prejudice in favour of fair rather than dark skin colour.

LINGUISTIC GROUPS

Pakistan is in general linguistically heterogeneous, and no single language can be said to be common to the whole population. Each of its principal languages has a strong regional focus, although statistics show some languages to be distributed between various provinces because administrative boundaries cut across linguistic regions. The picture is also complicated by the fact that, especially in Sind, there are substantial numbers of Urdu- and Punjabi-speaking immigrants who have moved from the place of their origin and have settled on the land or taken up urban employment. The distribution of languages claimed as mother tongue at the time of the 1961 census was as follows: Punjabi, 66 percent; Sindhi, 13 percent; Pashto, 8 percent; Urdu, 8 percent; Baluchi, 2 percent; and Brahui, 1 percent.

The language distribution pattern

The provincial distribution of languages spoken (whether as mother tongue or as an additional language) was as follows: in Punjab, Punjabi is the principal language, although Urdu is also spoken by about 16 percent of the people, though of these only one-third speak it as their mother tongue; in Sind (excluding Karāchi), about 80 percent speak Sindhi, 14 percent Urdu, and 10 percent Baluchi; in the Northwest Frontier Province, about 84 percent speak Pashto and about 23 percent Punjabi; in Baluchistan, 41 percent speak Baluchi, 25 percent Pashto, and 20 percent Sindhi. In Karāchi, about 68 percent speak Urdu, 17 percent Sindhi, about 9 percent Punjabi, about 9 percent Baluchi, and about 9 percent English.

The languages of Pakistan are written in modified forms of the Arabic–Persian script, which is written from right to left. Punjabi has its own script called Gurmukhi, but this is mainly used in India. In Pakistan, Punjabi is mainly spoken rather than written; it is also a predominantly rural rather than an urban language. Urdu, rather than Punjabi, is the first language taught in schools in Punjab, so that every educated Punjabi reads and writes Urdu. There is, however, a movement for the promotion of the Punjabi language, and some Punjabi literature is being published using the Urdu script; among the works published are Punjabi classics that have hitherto been available in Gurmukhi script or preserved in oral tradition.

Sindhi is derived from the Virachada dialect of Prākrit; it has fewer dialects than Punjabi. It is written in a special variant of the Arabic script. Most of the educated middle class in Sind were Hindu, and their departure to India in 1947 had a traumatic effect on Sindhi culture. Vigorous efforts are therefore directed toward a recovery and preservation of the rich Sindhi literary and cultural heritage. Large numbers of Urdu-speaking refugees have settled down in Sind and constitute the majority of the population of its larger towns. As a consequence, the movement for promotion of Sindhi language and culture sometimes finds expression in hostility toward Urdu. Unlike Punjabis, who learn Urdu at school, in Sind, Sindhi children are taught Sindhi as their first language.

Pashto

Pashto, the language of the Pashtuns (Pakhtuns or Pathans) of the Northwest Frontier Province, has no written literary traditions although it has a rich oral tradition that is being put into a written form using a modified version of the Persian script. There are two major dialect patterns within which the various individual dialects may be classified; these are Pakhto, which is the northern (Peshāwar) variety, and the softer Pashto spoken in southern areas. As in the Punjab, Urdu is the language taught in schools, and educated Pashtuns read and write Urdu. Again, as in the case of Punjabi, there is a movement for developing the written language and increasing the usage of Pashto.

The two main spoken languages of Baluchistan are Baluchi and Brahui. Makrani is an important dialect of Baluchi; it is spoken in Makran, the southern region of Baluchistan, bordering on Iran.

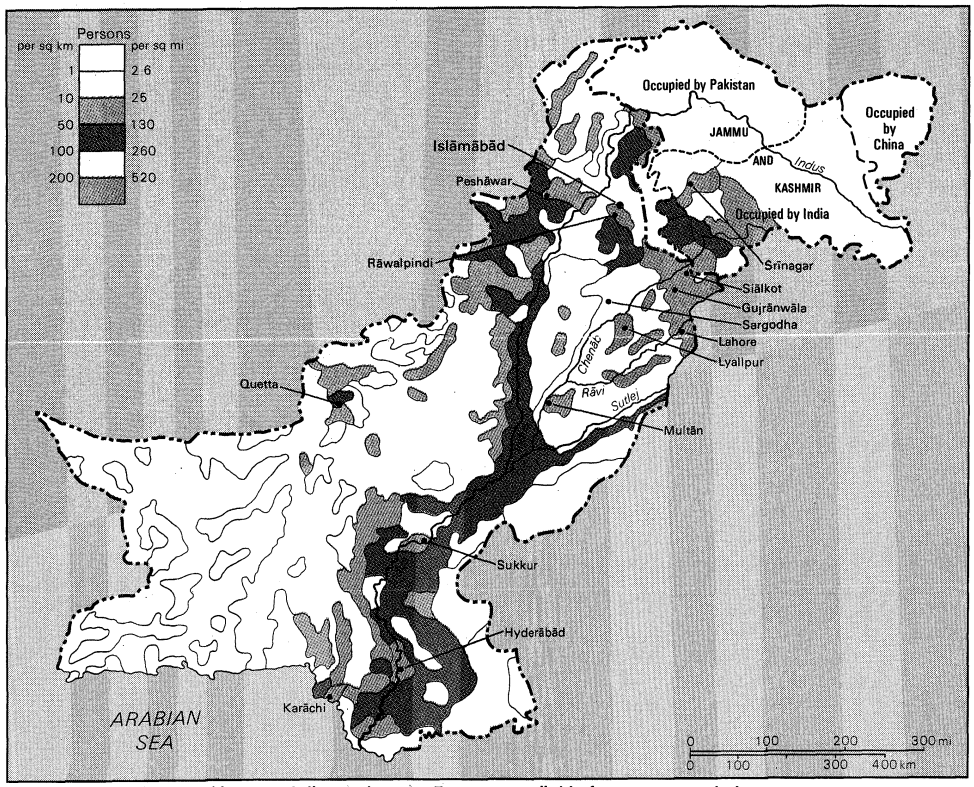
Urdu is the youngest of the nation's languages, and is not indigenous to Pakistan; it is very similar to Hindi, the official language of India. Although the two languages have a common base, in its literary form Urdu emphasizes words of Persian and Arabic origin, whereas Hindi emphasizes words of Sanskrit origin. Urdu is written in a modified version of the Persian script (written from right to left), whereas Hindi is written in Devānagari script from left to right. Because it is pre-eminently the language of the educated Muslims of northern India, including the Punjab, Urdu has strong associations with Muslim nationalism; hence the ideological significance of Urdu in Pakistan politics. Urdu was the mother tongue of only about 7.6 percent of the population of Pakistan in 1961; it was a minority language in every province.

English is used for official purposes except in local administration, where the local vernacular is used. English is the de facto official language; the 1956 Constitution prescribed its use for 20 years, and the 1962 Constitution made the period indefinite. It is spoken by only about 2 percent of the people of Pakistan.

RELIGIOUS GROUPS

About 97 percent of the people of Pakistan are Muslims. Most of them belong to the Sunnī, the major branch of Islām, with a significant representation among the small but equally important Shīʿī branch. There is also a very small, though influential, sect called Ahmadis, or Qadianis, which does not regard the prophet Muḥammad as

Muslim sects



Population density of Pakistan and disputed areas. Data not available for areas occupied by China and Pakistan.

being the final prophet, a basic tenet of Islām. The majority of Pakistani Sunnīs belong to the orthodox Ḥanafī school, which is one of four schools or subsects of Sunnīs. Shīʿites are also divided into numerous subsects; among them are Ismāʿīlīs (the followers of the Aga Khan), as well as The Twelvers (Ithnā ʿAsharīs) and Bohrās, which are prominent communities in commerce and industry. The principal business communities among Sunnīs are Gujarati Memons and Chiniotis from Punjab.

With the exception of some sects, such as Dawoodi Bohrās, there is generally no ordained priesthood among Pakistan's Muslims. Anyone may be appointed *imām* who leads prayers in mosques. Those who are trained in theology are given the title of mullah or *mawlānās* or, collectively, *ʿulamā'*. There are, however, powerful networks of "holy men" called *pīr*s, who receive great reverence, as well as gifts in cash or kind from a multitude of followers. They constitute a hierarchy in one of four Ṣūfī (Muslim mystic) orders. An established *pīr* may pass on his spiritual powers and sanctified authority to one or more of his *murīds* ("disciples"), who may then operate as a *pīr* in his own right. There are also many self-appointed *pīr*s who practice locally without being properly inducted into one of the four orders. *Pīr*s who occupy high positions in the *pīr* hierarchy wield great power and play an influential role in public affairs.

The number of Hindus in Pakistan was greatly reduced as a consequence of the exodus of refugees to India in 1947; in 1961 they formed only 0.5 percent of the population of present-day Pakistan (then West Pakistan). Christians constituted 1.4 percent.

DEMOGRAPHY

The population of Pakistan (then West Pakistan), excluding non-Pakistanis, at the 1961 census was 42,880,000, representing a density of 140 persons per square mile (54 per square kilometre). At the 1972 census the population had reached 64,892,000.

The rate of population growth is phenomenal. Between 1901 and 1961, the population of West Pakistan (as it then was) increased by about 158 percent. From 1951 to 1961, the population increased by 27 percent, and from 1961 to 1972 by 51 percent.

The growth of population was primarily caused by natural increase. As mentioned, the 1947 influx of Muslim refugees from India was balanced by an exodus of Hindu refugees to India. Refugees entering what was then West Pakistan numbered about 6,500,000, or about 20 percent of the population of the territory at that time.

Regional population distribution

Regional distribution of the population is uneven, being dense in the fertile Indus Valley, especially in the extreme northeast. In 1972, it was the highest in Lahore district, with 1,698 persons per square mile, the average for the whole of the Lahore division being 1,086. By contrast, in the vast expanse of Baluchistan, the population densities were only 26 in Quetta division and 15 in Kalāt division.

Estimates of fertility levels (and changes) vary widely and are unreliable. In the early 1970s it was generally believed, however, that the birth rate would remain almost constant for some time, whereas the death rate would decline because of improving health facilities, and that growth in population would persist unless the fertility rate could be brought down drastically. But the achievements of the family-planning program were not yet commensurate with the scale on which it was being operated; by 1968 the family-planning program was be-

lieved to be the third largest employer in the country, after the military and the railway system.

Urban population represented about 22 percent of the total in 1961; it grew by 60 percent during the decade 1951 to 1961. The trend toward greater urbanization has been accompanied by a relatively faster growth of the larger cities as compared to smaller ones; this has reflected the influence of industrial location as a new factor in the pattern of urban growth. In 1961 in what was then West Pakistan, there were 37 towns and cities with populations of over 25,000, having altogether a total population of 7,000,000. (H.A.A.)

III. The national economy

A COMPARATIVE VIEW

Pakistan, like neighbouring India and Afghanistan, is among the 20 poorest nations in the world. Output per head of population in the early 1970s was less than U.S. $140. The relative prosperity of the industrialized regions around Karāchi and Lahore contrasts sharply with the poverty of the semi-arid Baluchistan province and the Northwest Frontier. The economy still relies heavily on the agricultural sector, mainly cotton. The combination of crop failures because of unfavourable weather and weak trends in world commodity prices was a major problem in the early 1970s. At the same time, there has been a relentless increase in population, so that, notwithstanding a real growth in the economy, output per head rose slowly. Nevertheless, Pakistan's economic performance compares favourably with that of many other developing countries. Real progress has been made in reducing the dependence on agriculture and in the diversification of the manufacturing sector. In this, foreign aid has played an important part. During the 1960s, aid receipts per head of population were high compared with many other developing countries and double those received by India.

The gradual structural change in the economy is reflected in the composition of foreign trade. Although as a trading nation Pakistan is among the ten nations with the lowest imports and exports per head, it is among the ten principal raw cotton exporters. Pakistan also managed to become a leading world exporter of cotton yarn and cloth during the 1960s. Since the separation from India in 1947, Pakistan has evolved from an area supplying raw materials to the processing industries situated in what is now India into a more integrated economy processing and manufacturing its own raw materials both for export and for the home market. Meanwhile, the agreement on Regional Cooperation for Development (RCD) with Iran and Turkey and the trade from aid deals has strengthened ties with the Middle East, Europe, and the United States.

RESOURCES

Mineral resources. The exploration of Pakistan's mineral wealth is far from complete, but by the early 1970s some 20 different types of minerals had been located. Coal mining is one of the country's oldest industries. The quality of the coal is poor, and the mines are working below capacity because of the lack of demand. Estimated reserves are about 400,000,000 metric tons. Iron-ore deposits are also mostly of poor quality. The most extensive known reserves are situated in the Kālābāgh region in western Punjab, amounting to some 300,000,000 metric tons. There are plans to develop these in an effort to set up a local iron-and-steel industry. Other low-grade ore reserves have been found in Hazāra in the Northwest Frontier Province. Small reserves of high-grade iron ore have been identified in Chitrāl and in the Chilghāzi area (located in the Chagai district of Baluchistan province), also in the Northwest Frontier Province. Total known iron-ore reserves in Pakistan are estimated at about 520,000,000 metric tons. There are enormous reserves of easily exploited limestone that form the basis of a growing cement industry. Other minerals that are being exploited include chromite (mostly for export), barite (a white, yellow, or colourless mineral resembling marble), and celestite (strontium sulphate), antimony, aragonite (a mineral resembling calcite [calcium carbonate]), gypsum, rock salt, and marble. Radioactive minerals have been found in the Dera Ghāzi Khān district in the Punjab.

Oil and natural gas

Pakistan also has small quantities of oil and some very large natural-gas fields. The first oil discovery was made in 1915. By the early 1970s, several more fields had been found, none of them very important. The largest natural-gas deposits are at Sūi (on the border between Baluchistan and the Punjab), discovered in 1953. Reserves have been estimated at 6,300,000,000,000 cubic feet (180,000,000,000 cubic metres) and rank among the world's largest. A smaller field, at Māri, in the northwest of Sind province, was found in 1957 with estimated reserves of 3,900,000,000,000 cubic feet. Overall, the region's natural-gas reserves amounted to some 16,000,000,000,000 cubic feet. A network of gas pipelines links the fields with the main consumption areas: Karāchi, Lahore, Multān, Lyallpur, and Islāmābād.

Biological resources. The variety of climates and soils has given rise to a wide diversity in biological resources. As Baluchistan is mostly desert, only in the small areas of intensive cultivation do crops and orchards thrive. In Sind and Punjab, where the annual rainfall is also low, most of the vegetation is basically xerophilous, except for the riverine forests along the Indus and its tributaries. The coastal region has mangrove forests. Regular rain and snow in the Himalayan foothills of the north have given them a variety of vegetation and animal life ranging from the Mediterranean to the Alpine types. There is a fishing industry centred on Karāchi, and part of the lobster and other shellfish catch is exported.

Pakistan's wildlife, already described, is varied. There are no game reserves, and indiscriminate hunting is threatening the survival of several animal species.

Hydroelectric and other power resources. Although Pakistan is poorly endowed with water resources, great progress has been made with the development of its hydroelectric potential. The biggest hydroelectric plant in operation at the beginning of the 1970s was the Mangla Dam on the Jhelum River in Āzād Kashmir, which had a generating capacity of 650,000 kilowatts. This is to be raised first to 1,000,000 kilowatts and then to 3,000,000 kilowatts by 1980. Work on the giant Tarbela Dam on the Indus River started in 1968 and was expected to be completed in 1975; the power plant will have a final capacity of 2,100,000 kilowatts. Notwithstanding the heavy investment in hydropower, most of Pakistan's power needs are met by thermal plants, most of which are coal burning, although some of the newer ones use natural gas. A 137,000-kilowatt nuclear power plant has been built outside Karāchi. By the early 1970s, total electricity generating capacity amounted to about 1,900,000 kilowatts; the share of natural gas in total power consumption was rising steadily as new reserves were discovered and as the distribution system improved.

SOURCES OF NATIONAL INCOME

Agriculture, forestry, and fishing. In 1971–72, agriculture, forestry, and fishing accounted for 41 percent of the gross domestic product. Although the average annual growth rate during the second half of the 1960s was almost 6 percent, compared with 4 percent in 1960–65, its share of total output was declining by the early 1970s. This sector provides employment for at least two-thirds of the official labour force and a livelihood for more than 80 percent of the population. Of the total land area of 199,000,000 acres, only about 25 percent was under cultivation at the beginning of the 1970s. A land-reform program has dealt with the dual problem of large-scale, often absentee ownership and the excessive fragmentation of small holdings by introducing maximum and minimum area limits.

Changes in agricultural techniques

The priority given to the agricultural sector in the development plans during the 1960s brought about some radical changes in centuries-old farming techniques. The construction of tube wells for irrigation and salinity control, the use of chemical fertilizers and scientifically selected seeds, and the gradual introduction of farm machinery—all contributed to the notable increase in pro-

ductivity compared with the 1950s. One of the prime objectives of agricultural development programs was self-sufficiency in wheat; this was so successful that by the early 1970s Pakistan was disposing of surpluses.

During the year 1969 to 1970, agricultural output amounted to 11,000,000 metric tons of food crops, of which 7,000,000 tons were wheat and 2,000,000 tons rice; 26,000,000 tons of sugarcane made up the bulk of the 26,500,000 tons of cash crops produced.

Pakistan experienced a "green revolution" during the 1960s and early 1970s. In this period wheat production increased from 4,000,000 to 6,400,000 metric tons, leaving a surplus over domestic consumption that was partly shipped to East Pakistan (now Bangladesh) and partly exported. Cotton production rose from 2,000,000 to 4,000,000 bales in the course of the 1960s and early 1970s, but yields remain low by international standards. More and more of the crop is being locally processed, with a corresponding decline in exports, although foreign sales of manufactured cotton have been rising rapidly. Large domestic sugar subsidies were the main cause for the increase in sugarcane production from 15,000,000 to 23,000,000 tons in the second half of the 1960s and early 1970s.

Animal husbandry accounted for 12 percent of the gross domestic product in 1971 to 1972, or about 30 percent of the agricultural sector's total contribution. Apart from the supply of meat and dairy products for local consumption, it includes production of wool for the carpet industry and for export and of hides and skins for the leather industry.

The contribution of forestry to national income remains negligible, but that of fisheries has been rising. In 1969 the total catch of what was then West Pakistan amounted to 180,000 tons.

Mining and manufacturing. Mining and quarrying account for less than 1 percent of gross domestic product and of total employment. Production of natural gas has been by far the fastest growing sector of the industry: total output rose from 26,000,000 cubic feet (740,000 cubic metres) in 1959 to 1960 to 115,000,000 cubic feet (3,200,000 cubic metres) in 1970. Coal production amounted to just over 1,000,000 tons a year at the beginning of the 1970s, having grown at an average annual rate of 5 percent in the preceding decade. Output of limestone doubled during the 1960s to about 1,700,000 tons. It provides the basis for a growing cement industry.

By the early 1970s the manufacturing sector accounted for 17 percent of gross domestic product, compared with 12.5 percent ten years earlier. But it still employs only 10 percent of the official labour force. During the 1960s manufacturing output rose at an average annual rate of 9 percent. Most of the growth occurred in the large-scale industries, which represented 72 percent of total manufacturing output at the end of the 1960s.

Industrialization

The beginning of the main industrialization effort dates back to the Korean War boom and to the early 1950s. Initially, it was based on the processing of domestic agricultural raw materials for the home market and for export. This led to the setting up of cotton textile mills—an industry that accounts for 37 percent of the total employment in industry. Woollen textiles, sugar, paper, tobacco, and leather industries provided jobs for a further 20 percent of the industrial labour force. The growing trade deficit in the mid-1950s compelled the government to cut down on imports. This encouraged the implantation of a number of import-substitution industries. At first, they produced mainly consumer goods, but, gradually, they came to include intermediate goods and a range of capital goods, including chemicals, fertilizers, and light engineering products. Nevertheless, Pakistan still has to import a large proportion of the capital equipment and raw materials required by industry. Notwithstanding the diversification in the industrial sector during the 1960s, cotton textiles still account for a major share of total output.

The cotton mills account for about one-third of the manufacturing sector's contribution to Pakistan's total gross domestic product and with a labour force of 150,000 constitute the single largest sector of employment in the country. There has been a gradual diversification of the production mix, both in response to domestic demand and because of restrictions in export markets. Output of yarn amounted to nearly 670,000,000 pounds (300,000,000 kilograms) in 1970 to 1971, compared with 360,000,000 pounds (160,000,000 kilograms) ten years earlier; in the same period, output of cloth rose from 614,000,000 to 787,000,000 yards (560,000,000 to 720,000,000 metres).

Energy. Although energy production rose faster than the economy as a whole during the 1960s, it did not keep pace with demand, and consequent shortages of fuel and electric power inhibited industrial growth. The exploitation of domestic natural-gas resources was a major breakthrough, while heavy expenditure on thermal plants and hydroelectric resources increased electricity generating capacity more than fivefold during the 1960s.

Financial services. Pakistan has a fairly well developed system of financial services. The State Bank of Pakistan has overall control over the banking sector, which consists of a number of commercial banks and specialist credit institutions. The State Bank acts as banker to the central and provincial governments and administers official monetary and credit policies, including exchange controls. It has sole currency-issuing rights and has custody of the country's gold and foreign exchange reserves. In 1972 in Pakistan there were 25 scheduled banks subject to strict State Bank requirements as to paid-up capital and reserves. They accounted for the bulk of total deposits, collected through a network of about 2,400 branch offices. Four specialist financial institutions provided medium- and long-term credit for industrial, agricultural, and housing purposes. They were the Pakistan Industrial Credit and Investment Corporation (PICIC), the Industrial Development Bank of Pakistan (IDBP), the Agricultural Development Bank of Pakistan (ADBP), and the House Building Finance Corporation. The Karāchi stock exchange dealt in the stocks and shares of 220 registered companies in 1970. There is another stock exchange in Lahore, opened in 1971. The Investment Corporation of Pakistan (ICP), set up by the government in 1966, and the National Investment Trust have helped to channel domestic savings into the capital market. ICP mutual funds were heavily oversubscribed in the late 1960s.

Banking and credit

Foreign trade. Between 1961 and 1971 what was then West Pakistan's exports grew at an average annual rate of 5.2 percent to a total of $704,000,000. In the same period, imports increased by about 1.4 percent a year, reaching $730,000,000 in 1971–72. Although exports rose faster than imports in the 1960s, overall trade remained heavily in deficit, with total export earnings covering only about half of the import bill. The magnitude of these deficits began to decline during 1971, and for the first eight months of 1972, Pakistan actually showed a slight positive balance of trade. During the 1960s some important changes took place in the composition of foreign trade. In particular, while the proportion of total export from primary commodities, including raw cotton, fell, the share of manufactures almost doubled. But the bulk of the manufactured products coming into the export trade consisted of cotton goods, so that Pakistan remained as dependent as ever on its leading cash crop. The other manufactures exported came mostly from industries based on agriculture, such as leather and leather goods and carpets. The shift toward manufactured agricultural exports, which have a higher added value content than the primary commodities, has been strongly encouraged by the government. It is also because of government policies that the 1960s saw a gradual change in the composition of imports. The trade deficit and the shortage of foreign exchange made it necessary to cut down on all but the most essential purchases abroad. As a result, the proportion of the total import bill spent on consumer goods fell from 25 percent to 12 percent to about 23 percent in 1971–72. Capital goods accounted for 42 percent and industrial raw materials for the remaining 35 percent of total imports in 1971–72.

By the early 1970s Hong Kong was Pakistan's biggest single export market, followed by Japan and the United Kingdom. But the import markets were gradually being diversified, and, although the United States was still among the main suppliers, Japan and the European Economic Community (EEC) were gaining ground rapidly.

MANAGEMENT OF THE ECONOMY

The private sector. The government has traditionally supported a system of free enterprise and has encouraged private domestic and foreign capital investment within the framework of the development plans. The policy has been comparatively successful. At the time of partition, in 1947, numbers of Muslim businessmen from what was to become secular India moved to Lahore and Karāchi and set up the nucleus of a new industrial and financial society. They were helped by the strong bias in favour of the manufacturing sector maintained by the government in its foreign-exchange allocation policy, particularly in the early 1950s. The availability of imported machinery and raw materials helped to promote a process of fairly diversified industrialization. Overall, private enterprise in the manufacturing and financial sectors has been concentrated in the hands of a small number of family cartels. This was one of the big grievances nursed by the trade unions and left-wing political groups, which contributed to the social unrest of the late 1960s.

In an effort to remedy this situation, the government in 1972 introduced a program of economic reforms which placed control over a number of key industries, such as iron and steel, chemicals, and cement, as well as the insurance sector, in the hands of the state.

Foreign investment

Foreign private investors have been attracted to Pakistan by favourable investment incentive schemes, including tax holidays, long-term credit facilities from local industrial-financing institutions, and repatriation guarantees for capital and profits. By the end of the 1960s, before the secession of Bangladesh, foreign private investment in Pakistan was estimated at about $600,000,000. United Kingdom investors accounted for the largest share of the total as a result of their predominant pre-independence position; but United States, German, and Japanese investments were also gaining in importance.

The public sector and the role of government. Investment by the public sector has been concentrated on social programs (education, health, etc.) and on the infrastructure (transport, communications, and power), leaving agriculture and industry to the private sector. Even in these sectors, however, when private investment would not or could not fulfill the set development targets, the government has stepped in. The development targets themselves have been spelled out in a series of five-year plans that have given the economy its general direction, but the government has also made use of a number of other methods to make short-term changes. Thus, the biannual foreign-trade policy could liberalize or restrict imports at short notice, while manipulations of bonus rates proved to be a flexible way of promoting selected exports. Subsidies, price controls, and tariff protection have all been used with varying degrees of success.

Taxation. The overall tax burden was estimated at 12 percent of the gross national product in 1969 to 1970. Even though income tax rates rise to comparatively high levels—the top rate in 1972 was 70 percent—the tax base is so small that revenue from this source and from the 30 percent corporation tax has remained disappointingly low. The government has therefore had to rely on indirect taxes for most of its current income. It has not made much use of deficit financing, and the domestic public debt per head of population has been well below the world average. The government has been able to maintain heavy expenditure on development and defense because of the inflow of foreign aid. In doing this, however, the country has accumulated an enormous foreign debt, the financing of which was a major problem in the early 1970s.

The central-government budget is divided into a revenue budget, which deals with current expenditure, and a capital budget, covering development expenditure under the five-year plan. Taxation yields over 70 percent of revenue receipts. Excise duties alone accounted for more than 30 percent of revenue by the early 1970s. Customs duties provided a further 25 percent. Less than 10 percent of current revenue came from income and corporation taxes. Capital-budget receipts consisted of at least half of foreign aid. The provincial governments draw up their own budgets along lines similar to those adopted by the central government. Revenue consists of a share of the central government's tax receipts and of local taxes levied by the provincial governments themselves. Capital receipts are almost entirely made up of loans from the central government.

Sources of revenue

In the 1960s and early 1970s defense absorbed about half of the central government's current expenditure, but twice as much again was spent on development through the capital budget.

Trade unions and employer associations. The trade-union movement dates back to the late 19th century, but, because Pakistan's industrial sector (inherited at independence) was so small, organized labour as a proportion of total employment is still in a minority. This has not prevented it from becoming an important political force. The total union membership at the end of the 1960s (*i.e.*, before the secession of Bangladesh) was about 750,000, out of a labour force of some 30,000,000. There were well over 1,000 registered unions, most of them organized within individual establishments. Countrywide unions based on a common craft or industry are very few. Most of the unions are situated in the urban centres and are affiliated to one of three national labour confederations. These, in turn, are affiliated to the International Confederation of Free Trade Unions (ICFTU).

Many of the labour laws still in force in the early 1970s dated back to British colonial days. The extensive labour unrest in the late 1960s eventually led to a tripartite labour conference in 1969, attended by government, employer, and trade-union representatives. A new labour policy was agreed upon, dealing in particular with industrial relations, minimum-wage legislation, and workers' welfare. But, because of the high rates of unemployment, employers remained in a strong position, and many of them were able to bypass the new working conditions. Only the unions in the bigger industries (*e.g.*, cotton textiles) had the necessary coherence to fight back. The resulting wave of strikes and the rise in industrial costs slowed growth in the manufacturing sector.

Contemporary economic policies. The Pakistan government's economic strategy has been spelled out in the development plans. The first one was a six-year plan that came into operation in 1957 and was implemented through annual development programs. The projected expenditure targets were largely fulfilled, but production in agriculture particularly fell short of the expected levels. The first plan provided valuable experience for the formulation of the second plan, covering the period 1960 to 1965. This plan proved to be exceptionally successful: gross national product grew at an average annual rate of 5.5 percent, instead of the target rate of 4.7 percent, and agricultural output rose by 3.5 percent a year, compared with the 1.3 percent achieved during the first plan period. The manufacturing sector expanded by 10 percent a year, and the combined aims of import substitution and export promotion brought about a structural improvement in the foreign-trade sector.

The third plan (1965 to 1970) was introduced as the first five-year stage of a 20-year plan that would carry Pakistan through to 1985. The main objectives of this perspective plan were to quadruple the national product and to increase income per head from about $83 U.S. in 1965 to $200 U.S. in 1985, to achieve parity in incomes between East and West Pakistan, to eliminate the dependence on foreign aid, to provide full employment, and to achieve universal literacy. But the war with India in 1965, the falloff in foreign aid, setbacks in agriculture, the socio-political unrest in the late 1960s, and the secession of Bangladesh early in the 1970s all combined to make the third plan a period of disappointments. Exports grew by 7 percent a year compared with a 9.5 per-

cent target, imports of capital goods and raw materials declined, and foreign-aid receipts were lower than expected. The problems and imbalances that emerged during the third plan determined the guidelines for the fourth plan, which was to run from 1970 to 1975. The political disruption from 1970 to 1972, culminating in the secession of Bangladesh, left the plan in suspense, while annual development programs took its place.

The three major economic problems

Problems and prospects. Without entering into the political aspects of the secession of Bangladesh, it may be said that economic problems and prospects in Pakistan have not been essentially changed by this event. The three major economic problems that faced the government in the first half of the 1970s were those of slow overall growth, inequalities in income distribution, and the deterioration in the balance of payments (although much progress had been made with the latter by late 1972). The basic solution lies in a higher rate of investment. Although the planners had hoped that by 1970 investment expenditure would have risen to 20 percent of gross national product, it amounted to only 14 percent. This was partly because of the falloff in domestic savings and partly because of the reduction in foreign aid. The marginal rate of savings in the second half of the 1960s, instead of rising to the planned level of 20 percent, came down to less than 10 percent as a result of the political upheavals and declining profit levels in industry. Meanwhile, the contribution made to the economy by foreign aid had been smaller than expected, while at the same time foreign debt servicing was becoming more onerous, reducing the net inflow of new aid even further. The government tried to renegotiate its debt position, particularly with the Aid Pakistan Consortium (the group of countries and international organizations, including the World Bank, that underwrote the bulk of development spending in the 1960s). But debt servicing will remain a heavy burden on the economy and threatens to absorb up to one-fifth of Pakistan's export earnings during the 1970s.

A selective increase in investment expenditure would go a long way toward reducing the income inequalities that emerged so blatantly during the 1960s. Investment in the less developed regions of Baluchistan and the Northwest Frontier Province will also have to be raised if the income gap between them and the two better-off provinces, Sind and Punjab, is not to grow even wider. Finally, the government will have to take strong measures to combat the social concentration of wealth and the enormous income disparity between the rich and the poor. A start was made in the early 1970s with such a program, but the power of the big family cartels was difficult to break.

The third major problem facing Pakistan's economy during the 1970s concerned the balance of payments. Every effort will have to be made to increase earnings from traditional exports, such as cotton. At the same time, new exports will have to be developed if the country is to maintain its share of world trade. After export earnings, foreign aid is the most important balance-of-payments factor that will influence the economy during the 1970s. It is closely related to the problem of overall growth in that the availability of foreign credit will determine the level of new investment as well as the flow of imported raw materials and spare parts to maintain output. Even though Pakistan hopes to be able to do without foreign aid in the long term, during the 1970s external assistance will have to continue if only to make it possible to repay the outstanding debt without further reducing essential imports. (E.I.U.)

TRANSPORTATION AND COMMUNICATIONS

Component systems. *Roads and railways.* The dominant role of rail as the principal long-distance carrier has been displaced by the bus and truck; road transport now accounts for two-thirds of the total passenger miles and about one-half of the total freight. Motor trucks and tractor-drawn trailers are also displacing the traditional bullock cart for local transport of produce to markets. In 1970 there were about 12,700 miles (20,400 kilometres) of paved roads and, in 1969, 12,400 miles of unpaved roads. The main arterial road, which runs from Karāchi to Peshāwar via Lahore and Rāwalpindi, is 1,080 miles (1,740 kilometres) long. The rapid increase in road traffic had caused a rapid deterioration in road surfaces by the early 1970s. There are about 7,600 miles (12,000 kilometres) of railroad track for a total route mileage of 5,300 miles—a length that has changed little since independence. The main route runs more than 1,000 miles north from Karāchi to Peshāwar, via Lahore and Rāwalpindi. Another main line branches northwestward from Sukkur to Quetta.

Air transport. Pakistan International Airlines (PIA), established in 1955, is the sole carrier of internal air traffic. PIA also runs international flights to Europe, the Middle East, Africa, the Far East, and China, as well as to neighbouring Afghanistan. The principal airports are at Karāchi, Lahore, Rāwalpindi, and Peshāwar.

Shipping. Pakistan's merchant fleet in 1972 consisted of about 131 ships with a total tonnage of 739,000 deadweight tons. The semi-governmental National Shipping Corporation owns less than one-half of the ships. Karāchi is the principal port.

Postal services and telecommunications. There were over 8,000 post offices in 1970. The volume of mail carried has increased by 130 percent since independence. The service whereby remittance facilities are sent through the post office is of particular importance for the population in general. The total number of telephones in Pakistan was 207,000 in 1971; much of the equipment is manufactured locally. Teleprinter services connect Karāchi, Lahore, and Rāwalpindi. International communication is available by direct telephone and international radiotelegraph circuits, and a Telex service is available for many places abroad. A high-capacity microwave communications system, linking Pakistan, Iran, and Turkey, has been further extended to London, with links to the European network.

IV. Administration, social conditions, and cultural life

THE STRUCTURE OF GOVERNMENT

The political system of Pakistan has undergone several far-reaching changes since independence; in 1971, its turbulent politics culminated in the secession of its eastern region (having more than 54 percent of the total population at that time), which established itself as the independent state of Bangladesh. In the aftermath of that event, in 1972, Pakistan (now reduced to what was previously West Pakistan) was in the throes of political and economic crises and uncertainties about its future.

Political stresses

Three distinct sets of conflicts have left their mark on the politics of Pakistan. The first of these, initially obscured by the paraphernalia of a parliamentary form of government but later made manifest by overt seizure of power by men at the head of the military and bureaucratic establishment, is a continuing struggle between political leadership and a military–bureaucratic oligarchy for supremacy and authority in the state; ideologically, this struggle was expressed as a struggle for democracy. A second and a quite distinct conflict was a struggle between regional groups. Because it was directed against centralized authority, it merged with the democratic struggle. But its express aims were focussed on securing greater regional representation in the bureaucratic and military establishment, especially in the higher echelons, as well as achieving effective decentralization of powers within a federal governmental structure by emphasizing regional autonomy. A third set of conflicts concerned the allocation of economic resources and burdens and the distribution of a greater share of the benefits of development among the more deprived regions and strata of the population. In particular, a small number of business families control the bulk of the industrial wealth of the country. Agricultural wealth is concentrated in the hands of the landlords, especially of the Canal Colonies of the Punjab and of Sind. The incomes of the bulk of the rural as well as of the urban populations all over the country have been rapidly eroded by inflation and higher indirect taxes. This has resulted in spontaneous explosions of popular discontent in a leaderless form of revolt that has taken by

surprise not only the government but also the entire established political leadership ranging from the extreme right to the extreme left.

The constitutional framework. The task of framing a constitution for independent Pakistan was entrusted in 1947 to a Constituent Assembly that was also to function as the country's interim legislature under the Government of India Act (1935 [as adapted]), which was to be the interim constitution. It was federal in form, with the Constituent Assembly and a governor general at the centre and with provincial assemblies with governors of provinces on the regional level. Government was to be under Cabinets responsible to the central assembly and the provincial assemblies, respectively. Extraordinarily wide powers were, however, vested in the governor general, which were to prove decisive in establishing the power relationship between the bureaucratic and military establishment and the political leadership.

Pakistan's first constitution was enacted by the Constituent Assembly in 1956. It followed the form of the Government of India Act (1935), allowing the president far-reaching powers to suspend federal and provincial parliamentary government. The 1956 constitution also included the "parity formula," by which representation in the National Assembly for East and West Pakistan would be decided on a parity rather than population, basis. (A major factor in the political crisis of 1970–71 was abandonment of the "parity formula" and adoption of representation by population, giving East Pakistan an absolute majority in the new National Assembly.)

In 1958 the constitution was abrogated and martial law was instituted. A new constitution, promulgated in 1962 provided for the election of the president and National and provincial assemblies by an electoral college composed of 80,000 members of local councils.

Although a federal form of government was retained, the assemblies had little power, for, in effect, power was centralized through the authority of governors acting under the president. A massive revolt developed spontaneously in the winter of 1968–69, stimulated ironically by the regime's over-enthusiastic celebrations of its "Decade of Development." This led to the resignation of the President and the installation as president and chief martial-law administrator of the Commander in Chief of the army; the 1962 constitution was superseded by martial law. The government promised, however, to hold general elections on the basis of direct universal adult franchise and to convene a constitutional assembly.

Re-establishment of the four provinces

The popular demand to dissolve the One Unit—the single province of West Pakistan—and to reconstitute the provinces of the region was also conceded. The four existing provinces were, accordingly, re-established in 1970. Elections were held in the same year. In what was then West Pakistan, the Pakistan People's Party, which called for Islāmic socialism but enjoyed the support of powerful landowning groups, secured 60 percent of the West Pakistani seats, mainly from the two major provinces of the Punjab and Sind. The National Awami Party and the Jamīʿat-e ʿUlamā'-ye Islām (Hazarvi) secured strong positions in Baluchistan and the Northwest Frontier Province, where they drew support through regionalist sentiment. In East Pakistan, the electoral victory of the Awami League, which was committed to a program of regional autonomy, precipitated a political crisis that eventually led to the establishment of Bangladesh in 1971. As a consequence of the repercussions of the crisis. Zulfikar Ali Bhutto, the leader of Pakistan People's Party, was installed as president and chief martial-law administrator. He dismissed a large number of officers holding senior commands in the armed forces and also the military governors of the provinces, in whose place he installed his own party men as governors. The National Assembly, which was convened in April 1972, enacted an interim constitution and endorsed the presidential appointment. Martial law was then lifted. In April 1973 a new constitution, the third in Pakistan's 25-year history, was adopted by the National Assembly.

Political parties. The unity of Pakistan, it is sometimes argued, is premised on its Islāmic ideology, for that is the only cement that could bind together, it was supposed, its culturally diverse peoples. But it could be argued equally that it was the insistence on Islāmic ideology, in opposition to regional demands expressed in secular and cultural idiom, that progressively alienated regional groups and eroded national unity. The Muslim League, the party of Muslim nationalism in India, the aspirations of which were fulfilled by the creation of Pakistan, had by 1947 pushed all other political parties into insignificance. It had put forward the "two nation theory," which declared that Indian Muslims were a separate nation from other Indians. But its political idiom was not theological. It was the party of "Muslim modernists," the educated Muslim middle classes who aspired to more secure and more privileged positions in the worlds of government and public service and in business. The Muslim theocratic parties, however, such as the Jamīʿat-e Islāmī or the Jamīʿat-e ʿUlamā'e Hind, were opposed to the creation of Pakistan.

After independence the Muslim League was rapidly fragmented and the fragments developed into rival political parties. The rump of the Muslim League allied itself closely with the bureaucratic–military establishment, and, reluctant to face an electorate in elections, it was willing to submit to the bureaucratic–military establishment as a price for holding office. To oppose regionalist and democratic demands against centralized authority, the Muslim League, to an extent that it had never done before, began to stress Islāmic ideology, which it advocated as the only basis for the unity of Pakistan in opposition to regionalist secular politics, thus further alienating regional sentiment.

Comparative strength of political parties

At the time of the 1970 elections, the Pakistan People's Party was the largest, securing 81 out of West Pakistan's 144 seats in the National Assembly. The three factions of the Pakistan Muslim League—the Qayyum, the Convention, and the Council—won nine, one, and seven seats, respectively. Jamāʿat-e Islāmī won seven seats, Jamīʿat-e ʿUlamā'-ye Pakistan seven seats, and the National Awami Party (Wali Khan group), which was strong in Baluchistan and the Northwest Frontier Province, six seats.

Local government and administration. The basic administrative structure has remained virtually unchanged since the colonial period, despite all the constitutional upheavals and changes at the national and provincial levels. Provinces are subdivided into divisions, districts, and *tahsil*s (district subdivisions), which are run by a hierarchy of administrators, such as the divisional commissioner, the deputy commissioner (in the district), and the subdivisional magistrate, subdivisional officer, or *tahsildār* at the *tahsil* level. The key level is that of the district, where the deputy commissioner controls all branches of government, being directly in charge of the administration of revenue and having judicial functions as the district magistrate; he also controls the police.

District councils

Local self-government in the form of district boards has existed since colonial times. In 1959, however, these were transformed into district councils with the deputy commissioner as chairman instead of having an elected chairman; they were also made a part of a hierarchy of councils, which were set up at the divisional as well as at the *tahsil* level. The councils were subject to extremely close control and regulation by administrative officers. The system fell into disrepute because of corruption as well as because of authoritarian control, and there was a public demand to disband them; the system has been moribund since 1969 and was to be restructured drastically.

The administration itself is run by officials organized as a hierarchy at the top of which is the elite Civil Service of Pakistan (CSP). Below the CSP is the Provincial Civil Service (PCS) and several specialist departments, such as the Pakistan Police Service (PPS) and the departments of irrigation, agriculture, etc.

Justice. There is a division between the judiciary and the executive branches of government. The judiciary consists of the Supreme Court, the provincial high courts, and (under their jurisdiction and supervision) district courts that hear civil cases and sessions courts that hear criminal cases. There is also a magistracy that deals with

cases brought by the police. The district magistrate (who, as deputy commissioner, also controls the police) hears appeals from magistrates under him; appeals may go from him to the sessions judge. The Supreme Court is a court of record. It has original, appellate, and advisory jurisdictions and is the highest court in the land. At the time of independence, Pakistan inherited legal codes and acts that remain in force, subject to amendment.

Armed forces. The army is the senior service and had an estimated strength of 278,000 in the early 1970s; it consisted of one armoured brigade, with U.S. M-4 Sherman, M-47 Patton, and Chinese T-59 tanks; 10 infantry divisions; about 900 artillery pieces; and one air-defense brigade with anti-aircraft guns. At the same time, the total strength of the navy was 10,000 men; it had three submarines, two destroyers, three destroyer escorts, two frigates, six coastal minesweepers, and supporting units. The air force had a strength of 17,000 men, with another 2,000 as reservists. It was equipped with 200 combat aircraft, of which 140 were U.S. F-86 Sabre jet interceptor fighter bombers. The armed forces suffered heavy losses in East Pakistan during 1971, especially during the two-week war in December with Indian forces. The losses were estimated to be of the order of nearly half the navy, a quarter of the combat aircraft, and about 30 percent of the ground forces. One of the first acts of President Bhutto was to dismiss a large number of senior army generals and naval and air-force officers; this was not only because of their responsibility for the debacle in East Pakistan but also to reduce the top-heavy military establishment.

SOCIAL CONDITIONS

The literacy rate

Education. The literacy rate for persons over five years of age is over 16 percent. About 10 percent of the literates are without any formal education. Educational levels for women were much lower than those for men, the percentages of literates among the female population being about 7 percent. The share of females in educational levels progressively diminishes above the primary school level.

There are five multifaculty universities, as well as an agricultural university and an engineering university. There are also a number of colleges offering degrees, as well as some medical colleges.

Welfare. Welfare services are inadequately developed in relation to needs. In 1970, for a population of about 60,000,000, there were only 13,400 doctors and 4,700 nurses. Annual expenditure on education, health, and social welfare pales into insignificance beside the annual defense expenditure.

CULTURAL LIFE AND INSTITUTIONS

The cultural milieu. Pakistan shares influences that have shaped the cultures of the peoples of South Asia. There are thus wider regional similarities extending beyond the national boundaries. On the other hand, there are specific cultures of the various regions of Pakistan that present a picture of rich diversity. It would be difficult to speak of a culture of Pakistan in the singular.

The status of women

Family organization is strongly patriarchal, as in most agrarian societies, and most people live in large extended families. A woman's place in society is low, and she is restricted to the performance of domestic chores and to fulfilling the role of a dutiful wife and mother. Rich peasants and landowners and members of urban middle classes keep their women in seclusion (*pardah*); on the rare occasions on which they set foot outside their houses, they must be veiled. Among poor peasants, women have duties on the farm as well as in the house and do not observe *pardah*. In the Punjab, picking of cotton is exclusively a woman's job, and women keep the money thus earned for their own purposes. Houses of those who practice *pardah* have a men's section (*mardānah*) at the front of the house, so that visitors do not disturb the womenfolk, who are secluded in the *zanānah* (women's section).

Among the very rich, Western education and modes of living have eliminated *pardah*, but, in general, even among this group, attitudes toward women in society and the family are akin to those of Victorian England. Change is coming most rapidly among the urban lower middle income group, in which women are forced to seek employment under the pressure of economic necessity; *pardah* is then cast off and the education of women encouraged. In consequence, some women have gained distinction in the professions; significantly, some of the country's leading trade unionists are women.

Social organization revolves around kinship rather than caste. *Berādarī* (patrilineage) is the most important social institution. Marriage is preferably with the father's brother's daughter, and among many groups marriages are invariably within the *berādarī*. The lineage elders constitute a council that adjudicates disputes within the lineage and acts on behalf of the lineage with the outside world—for example, in determining electoral allegiances.

Pakistan claims a cultural heritage dating back more than 5,000 years, to the epoch of the Indus civilization. But the emphasis on Islāmic ideology has brought about a strong romantic identification with Islāmic culture—not only that of India but of the whole of the Islāmic world. *Qawwālī*, a form of devotional singing, is very popular. Poetry is also a popular rather than an esoteric art, and public poetry recitations called *mushā'irah*s are organized like musical concerts. Urdu, Sindhi, and Pashto poets are regional and national heroes. Literary tradition is the richest of all Pakistani art forms. Music and, especially, dancing are comparatively less developed arts. The visual arts, too, play little part in popular folk culture. In recent years, however, painting and sculpture have made considerable progress as expressions of a new sophisticated urban culture.

The cinema is now the most popular form of entertainment. About 50 feature films are produced each year, mostly in Urdu. The songs and music used in the films have a distinctive character and are often reproduced on phonograph records and broadcast on the radio.

Broadcasting and the press. During the 1960s radio and television attempted to harness folk cultural traditions (especially in song, music, and drama) for political and nonpolitical propaganda purposes. The ubiquitous transistor radio has brought broadcasts into every village. By 1970 it was expected that 65 percent of the area of West Pakistan and 85 percent of its population would be within the range of medium-wave broadcasting. Programs, including overseas broadcasts, are sent out in 17 languages. Television came to Pakistan in 1965, and its development is slow. There are three principal television broadcasting stations—at Karāchi, Lahore, and Rāwalpindi–Islāmābād.

Newspapers and periodicals

In 1965 there were about 450 English-language, 700 Urdu, 60 Sindhi, and two Bengali newspapers and periodicals in what was then West Pakistan. Among these, there were about 80 daily newspapers, of which only a handful had circulations between 20,000 and 160,000. In 1959 the government took over a major group of newspapers and in 1964 set up the Press Trust of Pakistan, which then took over most of the most important newspapers and periodicals. Censorship was subsequently imposed at various times, but it was replaced by what was euphemistically called a "press-advice" system by which the ministry of information gave guidance to the press.

PROSPECTS FOR THE FUTURE

The most significant fact about Pakistan is the rich diversity of its many regions and peoples. Its natural regions embrace a whole gamut of ecological variations, and its peoples are a mixture of many racial types speaking different languages and having different cultures.

But, throughout its short existence, Pakistan has been a nation in search of its identity and in search of national myths that could explain its existence and sustain its unity. Regionalist demands have been questions of a different order and related primarily to the allocation of resources and opportunities in the economy and the polity. But those who were concerned with the preservation of central authority and privilege resorted increasingly to opposing regionalist sentiment with an ideology of Islām-

ic unity. Paradoxically, instead of binding the nation more firmly together, the emphasis upon ideology appears to have convinced disgruntled regional groups that by that means their demands and needs were being ruled out of court. Ironically, therefore, the stress upon Islāmic unity and the ideological basis of Pakistan's existence strengthened centrifugal forces rather than cemented bonds. Both the emphasis upon ideology and the regionalist demand for autonomy made the constitution the central issue in political debate in Pakistan, virtually to the exclusion of most other issues. But, by the early 1970s, there had been a clear shift in emphasis to questions of equity and equality, both between regions and between different strata of the community. The secession of Bangladesh in 1971 was probably the culmination of that phase of Pakistan politics that was exclusively focussed on the regional issue and on its mirror image, the issue of a unifying Islāmic ideology. A new politics subsequently emerged in which economic, political, and social problems were projected in terms that transcended the regional perspective, while recognizing regional needs. Along with this shift of emphasis, there were indications of recognition that regional diversity of culture and language were not to be taken as signs of national weakness but as sources of national pride.

BIBLIOGRAPHY. M.L.P. PATTERSON and R.B. INDEN, *South Asia: An Introductory Bibliography* (1962), cites more than 4,000 entries on Pakistan with emphasis on history, culture, and politics. SHAUKAT ALI and GARTH N. JONES, *Pakistan Government and Administration: A Comprehensive Bibliography*, 2 vol. (1970–71), is exhaustive. O.H.K. SPATE and A.T.A. LEARMONTH, *India and Pakistan: A General and Regional Geography*, 3rd ed. (1967), is comprehensive and authoritative; KAZI S. AHMAD, *A Geography of Pakistan* (1964), is conveniently brief. ALOYS A. MICHEL, *The Indus Rivers* (1967), is concerned with development and with the dispute with India over allocation of river waters. W. CANTWELL SMITH, *Modern Islam in India* (1947), is as yet unsurpassed as an introductory account of the Muslim intellectual and political movements that culminated in the creation of Pakistan. KHALID B. SAYEED, *The Political System of Pakistan* (1967), is an excellent general work, and a worthy successor to his *Pakistan: The Formative Phase, 1857–1948*, 2nd ed. (1968). G.W. CHOUDHURY, *Constitutional Development in Pakistan* (1959) and *Democracy in Pakistan* (1963), is strongly oriented towards the "Muslim League" point of view, whereas TARIQ ALI, *Pakistan: Military Rule or People's Power?* (1970), offers a left-wing analysis. G.W. CHOUDHURY (ed.), *Documents and Speeches on the Constitution of Pakistan* (1967), is useful. RALPH BRAILBANTI, *Research on the Bureaucracy of Pakistan* (1966), is a comprehensive survey of the literature; and H.F. GOODNOW, *The Civil Service of Pakistan: Bureaucracy in a New Nation* (1964), is a valuable study of the structure of the bureaucracy and its role in public life. H.N. GARDEZI (comp.), *Sociology in Pakistan* (1966); and A.S. DIL (ed.), *Perspectives on Pakistan* (1965), contain essays by Pakistani scholars; STANLEY MARON (ed.), *Pakistan: Society and Culture* (1957), contains essays on history and rural social organization. FREDRIK BARTH, *Political Leadership Amongst Swat Pathans* (1959), is a classic study in political anthropology. S.K. CHATTERJI, *Languages and the Linguistic Problem*, 3rd ed. (1945), summarizes the *Linguistic Survey of India*, ed. by GEORGE A. GRIERSON, 11 vol. (1903–28); the *Census of Pakistan* (1951), but not that of 1961, briefly outlines the subject. B.S. GUHA, *Racial Elements in the Population* (1944), synthesizes the most widely accepted classifications of races of South Asia. V.G. KIERNAN, *Poems from Iqbal* (1955) and *Poems by Fraiz* (1971); H.T. SORLEY, *Shah Abdul Latif of Bhit* (1940, reprinted 1966); and G. ALLANA (ed.), *Presenting Pakistani Poetry* (1961), are some examples of poetry from Pakistan available in English translation.

Palamas, Saint Gregory

Gregory Palamas, a 14th-century Greek Orthodox monk and theologian, is acknowledged as the intellectual leader and apologist for a monastic school of mysticism called Hesychasm, from the Greek word *hesychia*, or state of quiet. This Byzantine contemplative movement, at one time controversial but now sanctioned by the Orthodox Church as a legitimate form of prayer, is an ascetical method that integrates repetitive prayer formulas with bodily postures and controlled breathing for the purpose of experiencing a state of inner peace and mystical union. Its history includes involvement in Byzantine political and ecclesiastical upheavals and sharp polemics with Greek and Latin theologians.

Born in 1296 at Constantinople of a distinguished family with ties to the imperial court, Palamas mastered the classical philosophies of antiquity at the imperial university. In 1316, however, he renounced a political career in order to become a monk at Mt. Athos in northeastern Greece, the spiritual centre of Greek Orthodoxy. For 25 years he immersed himself in study and reflection on the sacred Scriptures and the writings of the Church Fathers; he was introduced to contemplative prayer by a spiritual master and in turn became a master for other initiates. Raids by the Turks in about 1325 forced him to interrupt his monastic life on Mt. Athos and to flee to Thessalonica and Macedonia. He was ordained a priest in 1326 and later, with ten companions, retired to a hermitage in Macedonia.

Early monastic training and responsibilities

He returned to Mt. Athos in 1331 to the community of St. Sabas and *c.* 1335 was chosen a religious superior (*hēgoumenos*) of a neighbouring convent. Because of differences with the monks who considered his spiritual regimen too strict, he resigned after a short term and returned to St. Sabas.

In 1332, Palamas entered into a theological dispute that lasted for a quarter of a century and involved polemics with a series of Greek and Latin Scholastic theologians and certain rationalistic Humanists. His first adversary was Barlaam the Calabrian, a Greek monk residing in Italy who visited Constantinople and other Orthodox monastic centres to engage in philosophical disputation for intellectual prestige. Expounding a mode of theological agnosticism, Barlaam denied that any rational concepts could express mystical prayer and its divine–human communication even metaphorically. Subsequently, he composed a satirical work defaming Hesychasm by referring to its adherents as "men with their souls in their navel" (Greek *omphalopsychoi*). The image derived from the Hesychast meditative posture of focussing the eyes on a spot below the chest in order to heighten the mystical experience. Palamas responded to this attack by composing his "Apology for the Holy Hesychasts" (1338), also called the "Triad" because of its division into three parts.

Defense of Hesychasm

The "Apology" established the theological basis for mystical experience that involves not only the human spirit but the entire human person, body and soul. This doctrine attempts to articulate a prayer experience that devotees call "the deification of the entire man," a reference to the Hesychasts' claim of an inner transformation effected by a mystical illumination uniting man with God in the depths of his spirit. Hesychast spirituality strove to bridge the gulf between human and divine existence. It held the necessity of an intermediary relationship between man's world (immanence) and God's eternity (transcendence). Hesychast prayer aspires to attain the most intense form of God–man communion in the form of a vision of the "divine light," or "uncreated energy," analogous to the Gospel account of Christ's transfiguration on Mt. Tabor, as noted in Matt. 16:17 and Mark 8:9. The corporeal disposition for this contemplative state involves intense concentration and a methodical invocation of the name of Jesus (the Hesychastic "Jesus prayer"). Palamas emphasized the nonmaterialistic nature of Hesychast spirituality by explaining that the experience of inner light was not available to all but only to the "pure of heart" empowered by grace to perceive it.

After a succession of public confrontations with critical theologians and Humanists, and a politically motivated excommunication in 1344, Palamas had his teaching systematized in the *Hagioritic Tome* ("The Book of Holiness"), which became the fundamental textbook for Byzantine mysticism. The Hesychast controversy became part of a larger Byzantine political struggle that erupted in civil war. At its conclusion in 1347, Palamas, with support from the conservative, anti-Zealot party, was appointed bishop of Thessalonica. His administrative duties,

Excommunication and return to church administration

together with continued writings against his Humanist critics, occupied him for the rest of his life. He died in 1359.

In his fusion of Platonic and Aristotelian philosophy, used as a vehicle to express his own spiritual experience, Palamas set a definitive standard for Orthodox theological acumen. At the provincial Council of Constantinople in 1368, nine years after his death, he was acclaimed a saint and titled "Father and Doctor of the Orthodox Church," thus placing him among the ranks of those who determined the ideological shape of the Eastern Church.

BIBLIOGRAPHY. An English translation of selected Hesychast texts is in *Writings from the Philokalia on Prayer of the Heart*, trans. by EUGENIE KADLOUBOVSKY and G.E.H. PALMER (1951). See also the critical Greek text of Palamas' works, *Συγγραμματα*, ed. by B. BOBRINSKY *et al.* (1962–). JEAN MEYENDORFF, *Introduction à l'étude de Grégoire Palamas* (1959; Eng. trans., *A Study of Gregory Palamas*, 1964), is the principal biographical study in a Western language, with extensive bibliography. BASIL KRIVOSHEIN, "The Ascetic and Theological Teaching of Gregory Palamas," *The Eastern Churches Quarterly*, 3:26–33, 71–84, 138–156, 193–214 (1938), is the fullest exposition of Palamas' thought. Excellent surveys of Orthodox spirituality are VLADIMIR LOSSKY, *Essai sur la théologie mystique de l'Église d'Orient* (1944; Eng. trans., *The Mystical Theology of the Eastern Church*, 1957); and ERNST BENZ, *Geist und Leben der Ostkirche* (1957; Eng. trans., *The Eastern Orthodox Church: Its Thought and Life*, 1963). LE GUILLOU, *L'Esprit de l'orthodoxie grecque et russe* (1961; Eng. trans., *The Spirit of Eastern Orthodoxy*, 1962); A.J. PHILIPPOU (ed.), *The Orthodox Ethos* (1964).

(A.H.Ao.)

Paleogeography

Paleogeography is the geography of selected portions of the earth's surface at specific times in the geologic past. This geography consists of interpreted reconstructions, produced in map form, which represent visual summaries of a wide variety of complex geological information. The maps provide a series of relatively instantaneous views of the earth through geological time. Paleogeographic maps may be as simple as those that merely give the former distribution of ancient lands and seas. They may be extremely comprehensive, however, showing the occurrence and distribution of fossil, plant, and animal communities, environments of sedimentation (*e.g.*, deltas, reefs, deserts, or deep-sea basins), areas undergoing uplift and erosion or subsidence and deposition, and major climatic zones. The value and accuracy of such maps depend, of course, upon the extent and reliability of the basic data available for a given geographic area and time interval. Even when such data are available, various interpretations can often be made and these may lead to quite different paleogeographic syntheses. Despite the many difficulties and uncertainties inherent in paleogeographic reconstructions, they are viewed basically as useful summaries of the existing knowledge of earth history.

Virtually all the scientific specialties within the geological sciences contribute to paleogeography. The disciplines of stratigraphy and sedimentology, paleontology and paleoecology, structural geology and geophysics, and petrology and geochemistry are particularly important. In this article the discussion will focus on the interrelations of these fields and of the data that they supply for paleogeographic reconstruction. Illustrations are drawn from selected paleogeographic syntheses of the Middle Silurian of North America, the Jurassic of the world, and the Middle Tertiary of Europe. For additional information on the subject matter of these disciplines and on relevant aspects of earth history, see SEDIMENTARY FACIES; SEDIMENTARY ROCKS; STRATIGRAPHIC BOUNDARIES; EARTH, GEOLOGICAL HISTORY OF; MOUNTAIN-BUILDING PROCESSES; CONTINENTAL DRIFT; CLIMATIC CHANGE; OCEANS, DEVELOPMENT OF; FOSSIL RECORD; and the several pertinent geological period articles—*e.g.*, TERTIARY PERIOD.

FACTORS INVOLVED IN PALEOGEOGRAPHIC RECONSTRUCTIONS

Interpretations of the distant geologic past are based largely on observations of the rocks of the earth's crust in light of knowledge of present geological processes. In the late 18th and early 19th centuries, the explanation of the earth's history in terms of observable geologic processes was known as uniformitarianism (*q.v.*) and was expressed by the phrase, "the present is the key to the past." The intent of this phrase was not only to direct attention to existing geologic processes but to discourage appeals to mystical causes or unique special events to explain the geologic history of the earth. Since the latter half of the 19th century, geologists have sought to understand the past through knowledge of the present, and uniformitarianism is viewed as a guiding principle for interpretation of the past. Such interpretation, in the case of paleogeography, requires recognition of the earth's constantly changing character as well as the invariance of certain kinds of earth processes.

A fundamental consideration in any paleogeographic reconstruction is the length of time involved and the precision with which it is known. Ideally, a paleogeographic reconstruction should be developed for an instant in time, but this is impossible to achieve. Usually, a paleogeographic map covers a certain interval of time and thus represents the average geologic situation during that interval.

Should the time interval be too large, the average will be meaningless or misleading. For example, a paleogeographic map for the last 1,000,000 years, which approximates the second half of the Pleistocene Epoch, would have to span several glacial and interglacial stages of earth history. Ice sheets, glacial sediments, fluctuation of shorelines with sea level, and migrating animal and plant communities that parallel shifting climatic belts would all have to be superimposed on one map. In that case, two maps, one for a "typical" glacial stage and one depicting an interglacial stage, although not precisely accurate for each of the Pleistocene stages, would be infinitely more informative. Time intervals for any particular paleogeographic reconstruction should, therefore, be short, relative to the rates of geological change in the area. Thus, two reconstructions are the minimum requirement for the last 1,000,000 years of earth history, but a single map spanning a few tens of millions of years might reasonably portray North American paleogeography during the Early Silurian Period when large parts of the continent were covered by shallow seas with high-land areas and associated deltas located along the present Appalachian Mountain trend (Figure 1).

Relative and absolute age dating

Methods for determining geological time intervals are not sufficiently refined to permit resolution of instants in time in any case. The technique of dating rocks by measuring ratios of radioactive parent-to-daughter isotopes always involves certain intrinsic sources of error and the time of formation of a rock is given as a range of years rather than as a unique point in time. For example, the age of the Palisades Basalt, which crops out along the Hudson River opposite New York City, is given as 195,000,000, plus or minus 5,000,000 years.

The second technique for dating rocks is by correlating the similarity of fossil remains. Differing evolutionary stages of organisms provide a useful chronology for establishing the time equivalence of rocks in separate parts of the world. Rates of evolutionary change, however, usually are not sufficiently great to discriminate events of less than several million years' duration. Moreover, fossils from different geographic areas may be similar not because they occupy the same time interval of evolutionary history but because they prefer the same life habitats. In fact, it is sometimes difficult to determine if two similar but geographically separate fossil assemblages represent the same time period or whether they are derived from the same environment (which may have existed at two different times). Are the oysters in sedimentary rocks of the Gulf Coast the same age as the oysters in sedimentary rocks of the Atlantic Coast, for example, or do they simply record similar nearshore, shallow, brackish ma-

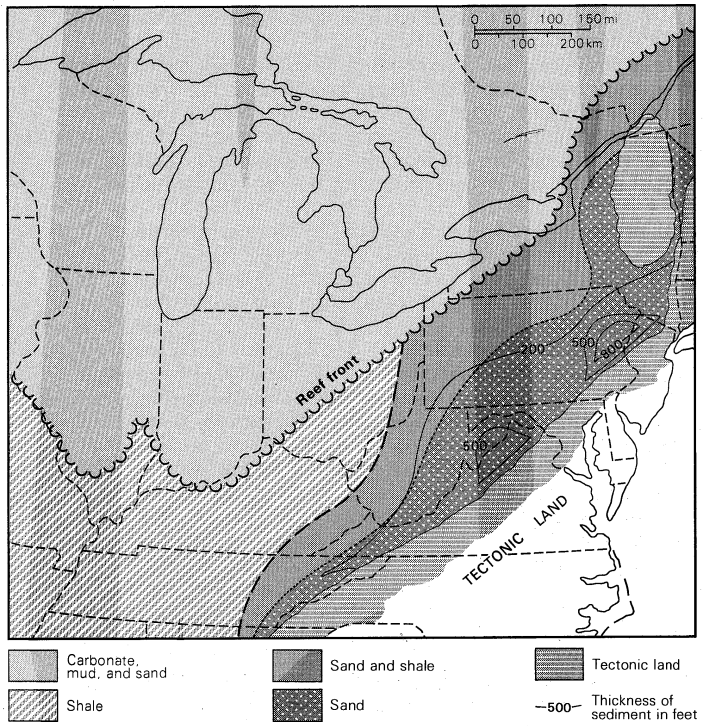

Figure 1: Paleogeographic structure of east central United States during Early Silurian time. Tectonic land raised during the Taconic orogeny provided a source for nonmarine and marine sandstones and shales, which were deposited along a broad shelf. Coral reefs formed along the shelf edge.

rine environments that existed at various times during the Tertiary Period in these two areas?

Paleomagnetic reversals

A relatively new technique for establishing instants in time is that provided by study of paleomagnetic reversals. At specific times in the past the polarity of the earth's magnetic field reversed and each reversal was essentially instantaneous. A sequence of reversals has been established for the last 4,000,000 years from the polarity and orientation of fine-grained iron oxides found in deep-sea sediments and terrestrial lava flows. There is some evidence that such reversals also occurred farther back in the geologic past. If used in conjunction with geochemical and paleontologic dating techniques, paleomagnetic reversals may ultimately provide the instant-time signatures so necessary for accurate reconstruction of the earth's geologic history.

Besides the importance of narrowing the time interval of a paleogeographic reconstruction to avoid blurring the results, it is also necessary that the geological data on which the reconstruction is based are, in fact, contemporaneous. Again, as previously mentioned, radiometric dating of rocks and paleontologic correlations cannot always guarantee the requisite time equivalency.

PALEOGEOGRAPHIC DATA AND THEIR APPLICATION

Biological information. The simplest kind of paleogeography is that showing the location of ancient lands and seas. The data which bear on such a reconstruction include the distribution of marine and nonmarine sedimentary rocks as defined by their fossil flora or fauna. Strata containing fossil corals or starfish, for example, would be interpreted as obviously marine, whereas rocks with the bones or teeth of hoofed herbivores would be considered definitely nonmarine or terrestrial. It should be pointed out that the present distribution of these rocks will only indicate the minimum limits of the former lands or seas, for it might be expected that erosion after the formation of the rocks would diminish their original areal extent.

Fossil organisms, however, can provide much more detailed information than whether their enclosing sedimentary rocks were deposited on land or in the sea. Terrestrial and marine environments include a wide range of habitats (*e.g.*, upland plains or plateaus, deserts, forests, river valleys, swamps and lakes, tidal flats, beaches, lagoons, reefs, deltas, or open ocean) in each of which there lives an assemblage of animals and plants especially adapted to the ecology of the particular habitat. Knowledge of the ecologic requirements of fossil organisms thus allows more refined interpretation of the paleogeography than simply designating "land" or "sea."

Fossil plants and their significance

Fossil land plants have long been used as climatic indicators in paleogeographic studies. In cases where the internal cellular structure is still preserved, it is possible to determine if the plant lived in an arid or wet climate and if there were marked seasonal changes in temperature or rainfall. In geologically younger rocks containing fossil plants that have living descendants one can define the past climate from the environmental preferences of the living form. For example, fossils of the genus *Artocarpus* (which includes the modern breadfruit plant, a native of the tropical Pacific) are found in Cretaceous rocks of Greenland; this clearly indicates the occurrence of a much warmer climate for that glacial land some 100,000,000 years ago.

More generally, however, it is the total assemblage of plant species that characterizes the local climate rather than any one single species. Thus, the assemblage of deciduous hardwoods, which includes maples, oaks, beeches, elms, and birches, occurs in temperate climates having warm summers, cold winters, and an average yearly rainfall of 92 centimetres (40 inches). Other assemblages occur from the northern tundra to the temperate grasslands and from the tropical desert to the rain forests. These individual assemblages parallel latitudinal gradients in temperature and precipitation; they also can be locally duplicated vertically as a consequence of variations in climate with altitude. Several fossil-plant assemblages, therefore, may suggest regional climate and local topographic elevation, thereby providing useful paleogeographic information.

Plants provide other fossil traces besides bits and pieces of leaves, stems, or fruits. In fact, most paleoclimatological interpretation is based upon the study of fossil spores and pollen, the microscopic reproductive bodies of plants that have extremely resistant outer coverings. Because of the great durability of spores and pollen, and their very great initial abundance (one flowering plant will produce more than 10^9 pollen grains), fossil spores and pollen can be obtained from many terrestrial or even marginal marine sedimentary deposits that may otherwise lack larger plant remains. Tracing spore and pollen assemblages across a broad geographic area or through a vertical sequence of rock strata will permit interpretation of areal or secular climatic variations.

Marine plants, especially the calcareous algae, are also found and recognized in the fossil state. Not only will they indicate the marine origin of the rocks in which they occur but because of the need for light for photosynthesis, the marine environment will be identified as being relatively shallow (solar radiation does not penetrate much beyond several hundred feet of seawater). One special group of marine algae, the soft-bodied, filamentous blue-green and green algae, thrives in tidal flat and very shallow marine waters. They form thin mats that trap and bind fine-grained sedimentary particles. Successive algal mats build up laminated sedimentary accumulations called stromatolites. Although the algae themselves are rarely preserved as fossils, their stromatolitic deposits are well-known. Because of their close association with the strandline environment, fossil stromatolites are extremely useful in delineating ancient shorelines.

Fossil vertebrates and land connections

Fossil vertebrates, whether fish, amphibians, reptiles, birds, or mammals, are also useful in paleogeography. Like plants, individual vertebrate species have characteristic adaptations to their environment so that their distribution in ancient rocks is a guide to the occurrence and extent of those environments. The presence of freshwater fish in the terrestrial rocks of Triassic age in eastern North America and those of Tertiary age in western North America provides evidence of inland freshwater

bodies in both of these regions during these geological periods.

One special value of fossil land vertebrates in paleogeography is their usefulness in defining migration routes across land bridges between continental landmasses. Fossil vertebrates from North and South America, for example, demonstrate that these two continents were connected by the Isthmus of Panama during early Tertiary time. During the Middle Tertiary the Panamanian land bridge became submerged and the two continents were separated for some 40,000,000 years. During this time the land mammals of South America evolved in isolation from the rest of the world, developing a number of types that paralleled those elsewhere. Toward the end of the Tertiary Period the vertebrate fossil record shows that the land bridge was again established and the faunas of the two Americas migrated northward and southward into the adjacent continental areas.

Similar evidence from land mammal fossils of the Pleistocene Epoch indicates periodic land connections and subsequent vertebrate migrations (including early man) between northeastern Asia and northwestern North America, across the Bering Strait. The presence of this land connection at different times also corroborates other independent evidence that the level of the world oceans periodically fluctuated several hundreds of feet with the waxing and waning of Pleistocene glaciers.

Some extremely interesting and significant finds of fossil terrestrial reptiles from Lower Triassic rocks of Antarctica that are practically identical to forms from South Africa have been used to substantiate the theory of drifting continents; in this instance, the paleogeography includes the former connection of Antarctica with Africa some 220,000,000 years ago. Furthermore, the climatic requirements of reptiles are such that the climate of Antarctica must surely have been much warmer then than now. Thus, the discovery of these reptile fossils indicates a very different paleogeography from that of today.

Marine invertebrates as environmental indicators

Shelly marine invertebrates, including microscopic calcareous and siliceous protists, sponges, corals, ectoproct bryozoans, brachiopods, mollusks, echinoderms, and arthropods, are used regularly by paleontologists to define environments within ancient seas. Foraminifera, for example, which are unicellular animals that secrete microscopic shells of calcium carbonate, include some forms that float in the upper surface waters of the sea. Upon death, these microscopic shells rain down on the sea floor where they are buried within the accumulating sediments. Certain varieties of the foraminiferans are restricted to water masses having a particular range of temperature and salinity. Examination of the foraminiferan assemblages in deep-sea cores raised from the oceans reveals significant water mass changes during the last 2,000,000 years. The changes correlate with continental evidence of glacial and interglacial stages during this time.

Other foraminiferans live directly on the sea floor rather than in the overlying water column, and different species are adapted to the varying conditions of temperature, salinity, sediment texture, and food content existing there. Since these ecologic conditions tend to vary more or less with changes in water depth, individual bottom-dwelling foraminiferan assemblages are used as indicators of depth when found in marine sedimentary rocks.

The larger shelly invertebrates are also bottom-dwelling forms for the most part. They, too, have certain environmental preferences with respect to water turbulence, grain size of the substrate, nutrients, temperature, salinity, and oxygen of the surrounding water. These characteristics of the sea floor and the immediately overlying waters are not, of course, everywhere the same but vary locally (from delta front and coastal marshes to the current-swept open shelf), as well as regionally (from the warm, shallow seas of tropical lagoons and reefs to the cold, iceberg-laden waters of the Arctic). Consequently, the composition of shelly marine assemblages varies systematically with changes in the marine environment.

Although not all assemblages are perfectly diagnostic of each different marine environment, certain marine assemblages are especially helpful in recognizing specific habitats. For example, coral-reef environments are characterized by a great diversity and abundance of shelly organisms, including massive, frame-building corals, encrusting calcareous algae, relatively large, bottom-dwelling foraminiferans, clams, snails, and sea urchins. Such reef environments are typical of warm, shallow waters protected from large run-off from the adjacent lands (silt and freshwater influx being unfavorable for good coral development). Usually the reefs lie next to low-lying land, or offshore, toward the edge of the continental shelf and marginal to the nutrient-rich waters of the open ocean. Clearly, recognition of an ancient reef tract would be extremely useful in reconstructing the paleogeography of an area.

Indirect organic information. Not all past evidence of life found in rocks is so direct as the presence of the hard skeletal remains of shelly invertebrates, calcareous algae, or plants. Indeed, much of the evidence is quite indirect. The occurrence of oil and gas whose organic constituents are derived from fossil marine life usually defines the origin of the containing strata as marine although, after formation in the source rock, oil and gas can migrate to the reservoir rocks whose origin might actually be nonmarine. Coprolites, which are the fossilized fecal remains of animals, can occasionally provide some paleogeographical data. For example, many marine sediments are pelleted by mud-ingesting bottom feeders, most of which are soft-bodied and therefore unpreserved as fossils. But the pellets may be preserved and there are many ancient limestones that are composed entirely of these pellets; such limestones are assumed to be marine. Human coprolites have been found in caves and their contents analyzed. Many ingested seeds, hair, feathers, and small animal bones within the coprolites may provide a reliable estimate of the paleoclimate of the time.

Other interesting indirect evidence of life is that of tracks, trails, and burrows made by ancient animals. For example, bottom-dwelling marine invertebrates living in the intertidal zone often make vertically directed burrows whereas those living in the subtidal parts of the sea make horizontally oriented ones. The purpose of burrowing vertically is to allow the organism to penetrate deeply enough in the sediment to escape the harmful effects of desiccation during exposure at low tide. The subtidal organisms, however, are continuously submerged and move parallel to the substrate, either on it or just below it, feeding on the accumulated organic matter. Geologists have recently come to realize the value of looking for vertical burrow traces in sedimentary rocks in order to define the position of the ancient strandline.

Biogeography and paleogeographic interpretations

From what has been discussed so far, it is clear that biogeography—that is, the geography of life—has great potential in interpreting and reconstructing the geography of the geologic past. Biogeography, however, can provide additional insights. For example, it is observed today that terrestrial and marine animal and plant communities are more diversified in the lower latitudes than toward the poles. This diversity, measured by the variety of species, is usually a maximum in the equatorial regions and decreases progressively poleward. Accompanying this decrease in variety is an increase in the abundance of individuals in the remaining species. This biogeographic trend has been studied in Permian marine rocks that occur on the present continents. The marine assemblages in these rocks have diversity trends that apparently parallel those of today, a conclusion that is contrary to current theories of continental drift, which claim significant changes in latitudinal position before drift (in the Permian) and after drift (today).

There are other biogeographic trends that have not, as yet, been as regularly applied to the fossil record for paleogeographic interpretation. They are the observations that the average size of a species tends to be smaller in warmer climates and larger in colder climates (Bergmann's rule, so called). A related observation is that the appendages or other protruding parts of a species are longer in warmer climates than in colder ones (Allen's rule). The biological significance of these two trends is

that heat is more easily conserved in organisms having a relatively higher body–mass to body–surface ratio.

Implicit throughout this discussion is the principle that the geography of life reflects the different distribution of organisms according to their adaptations to the various environments found across the Earth. Besides distributing themselves along ecological boundaries, organisms also are restricted in distribution by physical barriers, such as mountains, deserts, and seas. If the organisms were able to breach these barriers they often would adapt to the environmental conditions on the other side (consider the rapid spread of the English starling in North America after its transportation across the Atlantic Ocean). The barrier which separated South American mammals from the rest of the world during the Middle Tertiary Period is one example. Another barrier is that of the deep eastern Pacific Ocean, which prevents migration of shallow-water invertebrates from the Indo-Pacific to the shallow shores of the western Americas. The depths are too great for the adults, and the distances too large for the free-floating larval stages, for successful migration. In paleogeographic reconstructions, therefore, discontinuities among fossil assemblages may allow the inference of either ecological boundaries (regional climate or local environment) or physical barriers (water bodies, mountain ranges, deserts, etc.)

One final limitation of biological data used in paleogeography is that past biogeography cannot automatically be interpreted from the present distribution of life, for life has continuously evolved and changing adaptations may invalidate seemingly logical conclusions.

Petrological information. Paleogeographic data are not confined, of course, to fossil remains. Rocks of all sorts, fossiliferous or not, are used for paleogeographic reconstruction. Igneous, sedimentary, and metamorphic rocks are the products of a variety of processes occurring at the Earth's surface or within its crust and include phenomena as diverse as volcanism, erosion and deposition by streams and rivers, folding and faulting of strata, or the heating and recrystallization of earlier formed rocks. The environments in which rocks are made are distributed along geographic trends whether mountain belts, coastlines, earthquake zones, or volcanic-island arcs, and the composition, texture, and internal structures characteristic of these environments are often recorded within the individual rock types. Analysis of the rock record at a specific point in the geologic past allows definition and interpretation of these major rock-forming environments and indicates their geographic distribution.

Significance of sedimentary rocks

Sedimentary rocks are compacted and cemented mineral grains and rock fragments (with or without fossil debris) that have been eroded from older rocks and deposited by wind, water, or ice. The composition of the constituent grains varies as a function of the composition of the rocks in the source area from which the particles are initially eroded. The mineralogy of the sediments may thus reflect the mineralogy of the source. If the rates of erosion and sediment deposition are slow enough, however, the minerals may be broken down chemically and mechanically and only the most resistant (*e.g.*, quartz) will be left. Although the resulting mineralogy will differ considerably from the source rock, new paleogeographical clues may be obtained as to climatic conditions and relative rates of uplift in the source area and subsidence in the sedimentary basin. Sedimentary rocks may also contain grains formed directly within the area of sediment accumulation. Skeletal debris from organisms living in the depositional environment, for example, or chemical precipitates such as salt deposits or iron ores, may be incorporated with the transported sediments or even form entire strata by themselves. Such locally produced sediments will have their own paleogeographic implications.

The size of transported grains provides evidence of the strength of the transporting medium. The coarser the grains, the stronger the wind or water currents. Water-transported sediments will show decreasing grain size downstream, away from the source area, as the currents wane in strength near the area of deposition.

The roundness of individual grains as well as the size grades present provide a measure of erosional and depositional rates. Sediments with grains that are poorly sorted and angular in shape, with little or no rounding, are typical of areas undergoing relatively rapid erosion and sediment transport and deposition. There is little opportunity for size reduction through chemical or mechanical processes (solution or abrasion of grains); nor is there sufficient reworking by currents to size-sort the sediments.

The internal fabric, or geometry, of the grains within a sedimentary rock often contains environmental or geographic significance. The stratification, or layering, of the grains within the rock may be horizontal, inclined, or rippled, depending upon the character of the transporting currents. The direction of the inclination of stratification and the shape of the ripples will indicate current direction: the inclined layers and steep sides of the ripples point down current. Fine-grained sedimentary rocks that are water-laid will desiccate and shrink upon exposure to the air; the presence of mud-cracks in certain sedimentary rocks provides evidence, therefore, of periodic subaerial exposure during, perhaps, a drought (for terrestrial rocks) or a low tide (for marine rocks).

The analysis of individual sedimentary rocks, therefore, can be useful in paleogeography because it is often possible to identify the particular source area and its direction and distance from the depositional site, the nature of the transporting medium, the location of shorelines, and, perhaps, the general character of the climate. When these data are combined with knowledge of fossil assemblages, important and significant paleogeographic conclusions can be drawn (Figure 2).

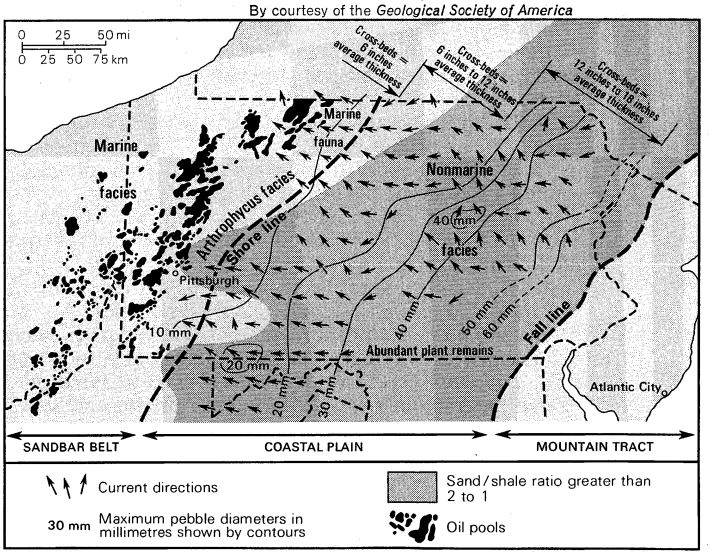

Figure 2: Paleogeography of the central Appalachians during the early Mississippian Period. Interpretation is based upon detailed analysis of the Pocono Sandstone Formation including grain size and composition, orientation of cross-stratification and plant remains, maximum size of quartz pebbles, sand/shale ratios, and fossil content. Sediment transport was to the west and northwest and the ancient shoreline trended northeast. The offshore parts of the Pocono are marine sandstones and shales with abundant burrows (*Arthrophycus*), and occasional marine fossils. Note relation of oil pools (black) to sediment type.

Igneous and metamorphic rocks

Igneous rocks are the cooled crystalline products of once-molten masses of viscous magma or lava that are derived from deep within the Earth's crust. These rocks may intrude overlying rocks higher in the crust or totally penetrate them and flow out upon the earth's surface. Igneous activity is usually associated with those parts of the Earth's crust that are subjected to stress. Around the rim of the Pacific today, for example, there are active zones of earthquakes and volcanoes within, or marginal to, geologically young mountain belts; the mid-oceanic ridges are interpreted as piles of submarine volcanic rocks formed during sea floor spreading and mid-oceanic rifting; and the exposed granitic cores of older moun-

tains were formerly buried deep within the crust during the subsidence and compression accompanying mountain building. Areas of the earth's crust that are structurally or tectonically quiet lack significant igneous activity.

The composition and grain size of igneous rocks are diverse and reflect many variables, including original composition of the molten material, rate of cooling, amount of water vapour and other dissolved gases, and depth of intrusion below the surface. Consequently, the paleogeographic significance of any specific igneous rock, beyond its recognition as a lava flow, granitic dike, or volcanic ash fall, is somewhat limited. This information alone, however, can indicate the presence of former mountain ranges, zones of tectonic activity, or areas of volcanism. The postulated existence of a mountain belt, for instance, will have paleogeographic implications, particularly because mountains influence climate. Climatic factors, in turn, affect the regional animal and plant communities and the volume of streamflow, rates of erosion, and other important variables. High mountain ranges provide large sources of erosional debris that build outward from the mountains as alluvial deposits and are carried down to the sea, where river deltas form. Offshore, the sediments will be distributed by longshore currents or slowly transported across the continental shelf into the deeper ocean basins.

Metamorphic rocks are the products of intense heat and pressure exerted upon pre-existing rocks or sediments so that new mineral assemblages recrystallize and new internal structures develop. Because the earth's crust is constantly undergoing stresses, the origins of which are still not entirely clear, earlier formed rocks are subjected to lateral or vertical increases in pressure and temperature. The minerals that initially had crystallized in equilibrium with the lower pressures and temperatures now become unstable, and new mineral suites recrystallize. Material also may be added or lost during metamorphism, which will alter the mineral assemblages still more. Like igneous rocks, metamorphic rocks can indicate former areas of regional deformation that are associated with mountain building or other movements of the earth's crust.

Because the focus of much modern effort is associated with the theory of continental drift, the value of igneous and metamorphic rock data in paleogeographic reconstruction has increased. Tectonic trends, linear-fold belts, metallogenic provinces, and exotic lithologies can be traced from one continent to another. These data provide evidence of the geologic and geographic configuration of the continents before drift occurred. The metamorphic trends and radiometric dates of South America and South Africa, for example, support a former joining of the two continental masses that accords to a fit suggested by other lines of evidence.

The dynamic activity of the earth's crust, as recorded by igneous and metamorphic rocks, is the fundamental mechanism underlying temporal changes in paleogeography. The uplift of mountains and the subsidence of sedimentary basins provide the topographic relief (and potential energy) by which other geologic phenomena occur; namely, changing patterns of sedimentation, shifting shorelines, varying climates, and migrating faunas and floras. It is these temporal variations in the distribution of land and sea, mountains and lowlands, and animals and plants that paleogeography attempts to depict (Figures 3 and 4).

Geophysical and geochemical information. Some of the most interesting problems in paleogeography relate to the question of whether the present distribution of the continents and ocean basins has remained more or less the same throughout geologic time. Opposed to the stability of continental position is the theory of continental drift, that the existing continents are fragmented portions of a once larger continent that have parted from each other and slowly moved into their present configuration. Recent revival of interest in continental drift was generated by the startling paleogeographic implications of geophysical measurements of paleomagnetism.

It has been observed that igneous and sedimentary rocks contain certain fine-grained minerals that become magnetized and aligned with the earth's magnetic field. When igneous rocks cool and crystallize, or sediments are compacted and lithified, the magnetic orientation of the minerals is "frozen" within the rocks. The individual grains act as small compass needles that not only point toward the poles but also have a dip from the horizontal that increases with latitude. Geophysicists have developed techniques for determining this remanent magnetic orientation in ancient rocks and this permits determination of the former geographic pole position and the latitude at the time a given rock formed. The interpretation is based on the assumption that the magnetic-pole positions approximate the position of the rotational, or geographic, poles and that the earth's magnetic field has been dipolar throughout geological time.

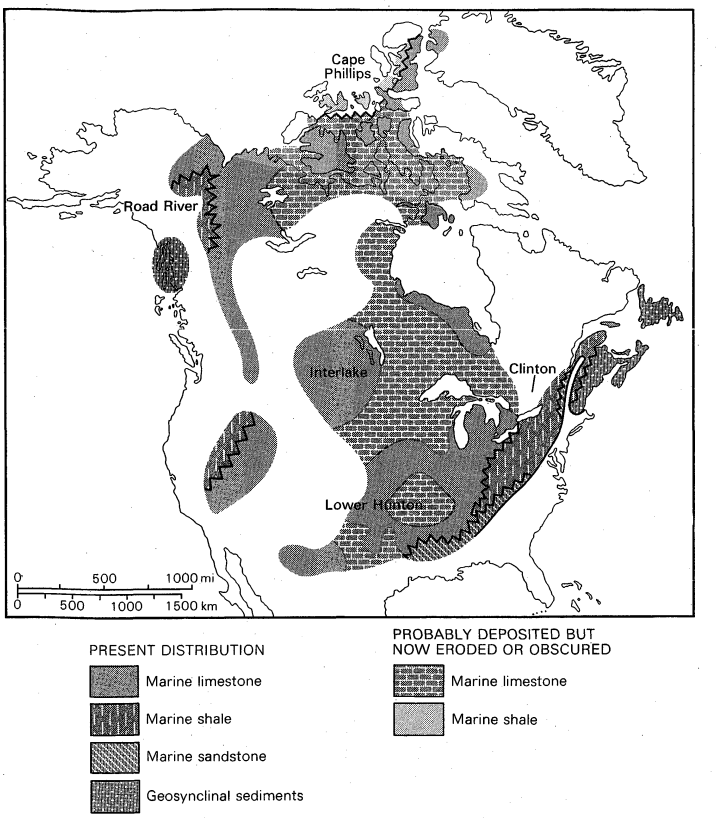

Figure 3: Paleogeography of North America during the Middle Silurian Period. Areas without rock pattern were either above sea level (as in southeastern U.S.) or lack definite paleogeographic indicators.

Polar wandering and continental drift

Paleomagnetic measurements have been made on many rocks of diverse ages from all the continents. It has been found that the magnetic and the geographic poles have wandered during the course of earth history, and that the observed path of polar migration, as recorded on an individual continent, becomes increasingly dissimilar with those of other continents going backward in time. Because there is only one pair of magnetic or rotational poles, the continents must have changed their spatial arrangement with respect to each other over the course of time. Paleogeographic reconstructions consistent with the paleomagnetic data, therefore, require some degree of continental drift. Although not all paleomagnetic results are fully consistent, this geophysical technique, together with measurements of paleomagnetic reversals, is extremely valuable for paleogeography.

Geochemical data are used to investigate paleogeographic interpretations based on the older and more traditional disciplines of paleontology, stratigraphy, and sedimentation. The chemistry of sediments, fossils, and rocks may record particular conditions of temperature, salinity, availability of water or carbon dioxide, or certain trace element abundances. These factors, in turn, may reflect past climates and environments. Although

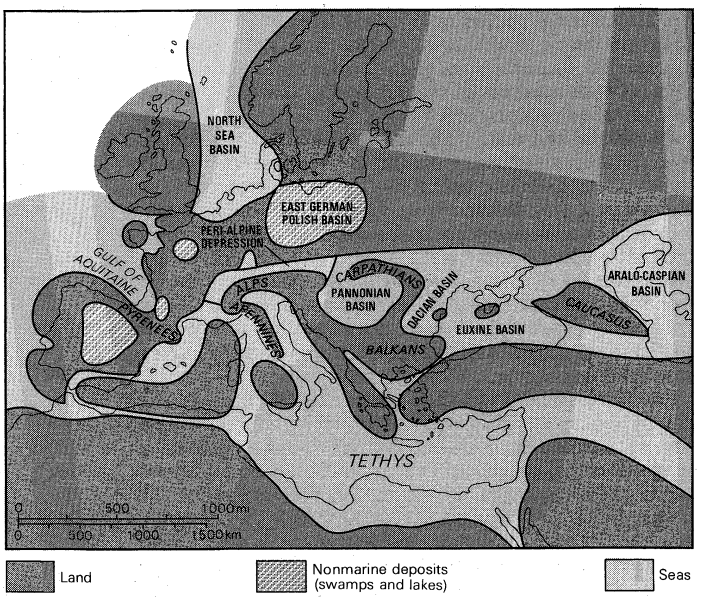

Figure 4: Distribution of land areas, nonmarine aquatic deposits, and marine sediments in Europe during the Miocene Epoch of Cenozoic Era. Complex arrangement of lands and surrounding basins in southern Europe reflects general tectonic instability of the area at that time.

Adapted from B. Kummel, *History of the Earth*, second edition, W.H. Freeman and Company; © 1970

sediments, fossils, and rocks may originally have been in delicate chemical equilibrium with their environments, their susceptibility to post-depositional alteration is very great and a large degree of uncertainty surrounds most paleogeographic conclusions that are based on geochemistry. Nevertheless, when used in conjunction with other independent evidence, geochemical techniques can make important contributions to paleogeography. The ratio of the stable oxygen isotopes O_{16} and O_{18} that occur in the shells of marine fossils, for example, is related to the temperature conditions at the time of their formation. This relationship has been used to document the cooling and warming of North Atlantic water masses during glacial and interglacial stages of the Pleistocene and the associated changes in oceanic circulation.

Oxygen isotope ratios

Trace element geochemistry has been used to determine the marine or freshwater origin of shales based on the relative abundances of gallium, rubidium, and boron. Empirically, it has been observed that freshwater shales have more gallium whereas marine shales contain relatively more rubidium and boron. Boron itself seems to have a special affinity for the clay mineral illite, and because boron in natural waters increases with overall salinity, some geologists have used boron-to-illite ratios as a measure of ancient salinities.

Other trace elements, particularly magnesium and strontium, have been observed in marine shells to vary directly in abundance with water temperature. Low-latitude, shallow-water, calcareous sediments, rich in the remains of shelly invertebrates, have relatively higher magnesium and strontium content than colder water sediments from higher latitudes or from deeper (and therefore colder) water at the same latitude. But this technique has proved difficult to apply to ancient shelly sediments because the mineral and chemical instability of most shell remains containing significant amounts of magnesium or strontium results in their very early post-depositional removal.

Red beds and weathering

The presence of "red bed" sedimentary rocks (sandstones and shales stained red by the iron-oxide mineral hematite) has been given paleoclimatological significance by a number of geologists. Although the details of formation may be disputed, there is a body of evidence suggesting that red beds accumulate in low latitudes (between 30° N and 30° S) and in relatively moist climates. Some red beds also may form in hot, dry climates as in the Recent alluvium of the Sonoran Desert of northwestern Mexico and southwestern United States. Thus, the ancient distribution of red beds, used in conjunction with other paleoclimatological data, may provide significant paleogeographic information.

A final example of how geochemical evidence can contribute to the interpretation of former climates and geography is that provided by the presence of bauxite in the geologic record. Bauxite is a rock rich in aluminum hydroxide that forms as a residual deposit under intense chemical weathering in tropical climates. Heavy rainfall, combined with the acidic conditions of tropical soils, causes the leaching of water-soluble ions and silica from the soil and weathered rock. The residual product, called bauxite, is an important aluminum-bearing ore and so has been extensively sought around the world. The occurrence of bauxite deposits helps to delineate the presence of tropical weathering conditions in the geologic past, and although these deposits are relatively thin and thus subject to removal by subsequent erosion, they are known to have formed as long ago as Cambrian time (500,000,000 to 570,000,000 years ago).

Paleography

Paleography (from Greek *palaios*, "old," and *graphein*, "to write") is the study of ancient and medieval handwriting. Precise boundaries for the study are hard to define. For example, epigraphy, the study of inscriptions cut on immovable objects for permanent public inspection, is related to paleography. Casual graffiti, sale or election notices as found on the walls of Pompeii, and Christian inscriptions in the Roman catacombs are likewise part of paleographical knowledge. In general, however, paleography embraces writing found principally on papyrus, parchment (vellum), and paper. Today, paleography is regarded as relating to Greek and Latin scripts with their derivatives, thus, as a rule, excluding Egyptian, Hebrew, and Middle and Far Eastern scripts. It is closely linked with diplomatic (*q.v.*), the study of forms in which official and private documents are drawn up.

The scientific study of Latin paleography (and diplomatic) dates from 1681, when the French monk Jean Mabillon published *De re diplomatica*, the first textbook on the subject, while his compatriot Bernard de Montfaucon performed a parallel service for Greek paleography in his *Palaeographia Graeca* in 1708.

The primary task of the paleographer is to read the writings of the past correctly and to assign a date and place of origin. Close acquaintance with the language of the text is a prerequisite. Help in dating is offered by changes in styles of handwriting and variations from area to area. Abbreviations in texts likewise help in dating and localization.

Writing materials. A paleographer must be familiar with writing materials. Any smooth surface able to accept writing has served in the past, notably, pottery fragments, animals' shoulder blades, slabs of wood, bark, cloth, and metal.

Papyrus

The great writing material of the ancient world was papyrus, in use by 3500 BC. In preparing the surface,

strips taken from the papyrus reed (*byblos*) growing in the Nile Delta were laid side by side, while other strips were laid across at right angles, and the whole impregnated with paste. After treatment a fine smooth surface was obtained. Much of the administration of the Roman Empire depended upon papyrus, in the same way that modern bureaucracies depend upon paper. Warfare and a damp climate resulted in an almost total disappearance of papyrus from Europe, though the dry (if war-scarred) sands of Egypt have preserved vast numbers of documents. Papyrus was imported into Europe from Egypt even after the fall of Rome. Chance survivals include charters of Merovingian kings in France (7th century) and business documents (5th–10th centuries) at Ravenna, the old administrative capital of the late Roman Empire.

The other great ancient writing material, still in occasional use today, is parchment, or vellum, the terms being often used interchangeably. Vellum is a term usually applied to skin from a calf (*cf.* veal, *veau*), while parchment is an expression often applied to sheepskin or goatskin. The word parchment is derived from Pergamum in Asia Minor, the ancient centre of its manufacture.

Both papyrus and parchment were expensive and were replaced for everyday use by wax tablets corresponding to today's notebook. Tablets made of wooden blocks were hollowed out and filled with melted, often black wax. Notes were made in the hardened surface. Even documents of permanent significance, such as property conveyances, were made on wax tablets.

Because ancient writing materials were expensive, they were often reused. Papyrus presented difficulties, for ink soon bonded itself firmly into the surface. Parchment could be more readily reused, because it is tougher and can be washed or scraped clean. Many medieval monks, when short of writing materials, took ancient books to pieces, cleaned off the leaves and used them again. The original script can often be brought out under ultraviolet light. Parchments thus cleaned and freshly inscribed are called palimpsests (Greek *palin*, "again"; *psēstos*, "scraped").

Paper is the third great writing material. In use in China at a remote period, it was employed extensively in the Arab world by the 9th century. Not in common use in Europe until the 14th century, it took over the name of the half-forgotten papyrus.

Form and binding of texts

In the early classical world the standard form of book was the papyrus roll, commonly called *biblion*, taking its name from the material of which it was made. It consisted of papyrus sheets pasted edge to edge with a slight overlap. The text was set out in columns, drawn up at right angles to the edge of the rolls, and started at the left. The reader unrolled as he went along and at the conclusion was obliged to reroll the book. The roll was an inconvenient form of book, difficult to consult, which probably accounts for the inaccurate quotations found in early literature, caused by an author relying on his memory rather than troubling to unwind a long roll. By the time of Christ, a new form of book was coming into fashion, the codex, or book in the shape in which it is known today. The codex is almost always of parchment, since papyrus cracks when folded. The codex seems first to have been used for notebooks or account books, the conservatism of booksellers and readers ensuring the survival of the roll for centuries. The Christians popularized the codex, using it for the Gospels.

Writing implements

Various instruments have been used for writing. The early Egyptians used a slender rush. From about 300 BC the thicker reed pen was used. The reed was in general use in the Romano-Greek world. Metal pens, copied from the reed, were also employed. For wax tablets a stylus was used, made of wood, bone, ivory, iron, or bronze. In many northern European areas, where reeds suitable for writing purposes are not indigenous, the feather (*penna*) became the main writing instrument. It was usually stripped of its vanes and the quill alone used.

Lead, used in classical times for ruling guidelines in manuscripts, was used extensively in the Middle Ages for rough notes and annotations in the margins of books.

Ink has been prepared in a variety of ways. In classical times the black discharge of cuttlefish was used, as well as concoctions of soot and gum. In the Middle Ages oak-apples were steeped in water with "vitriol" (ferrous sulphate) to produce ink.

Analysis of the text. The essential skill of a paleographer is the ability to recognize the numerous styles of handwriting prevalent in different ages and places. Most European scripts descend from Greek and Roman capital letters, but variations are enormous. It is a European convention that writing starts on the left at the top and works line by line down the page. An eccentricity known as boustrophedon (from Greek *boustrophēdon*, "following the ox furrow"), whereby alternate lines are written backward in mirror writing, occurs chiefly in very ancient inscriptions.

The Greek and Latin alphabets existed originally as capital, or majuscule, letters. The ancient Greek alphabet, as developed in chiselled inscriptions on stone or marble, served without much modification as the alphabet used in literary works written on papyrus rolls. This script, found in the oldest surviving Greek literary papyri of *c.* 300 BC or earlier, gave way to more rounded and elegant forms, probably developed in the Greek literary circles of Alexandria. Cursive scripts that were easier to write were developed for everyday use, for business, and to record the acts of the great bureaucracy of Egypt, where the Greeks settled in large numbers. The Greek cursive script and the formal book script greatly influenced each other, as can be seen from a vast series of cursive documents dating from the 4th century BC for about 1,000 years. Because so much material survived, early Greek cursive can be better studied than its Latin counterpart. In Greek cursive manuscripts the everyday life of ordinary people becomes a reality: they pay or fail to pay taxes, buy or sell houses, and harass civil servants with awkward demands.

A very rough division in Greek paleography may be made at around AD 300. The earlier age is called the papyrus period; and the later, the parchment or Byzantine (or Christian) period. The division, however, is imprecise, for parchment was used well before and papyrus long after this date. The change from papyrus to parchment is signalized by three great monuments of paleographical studies, the Vatican, Alexandrine, and Sinai Bibles, all on parchment and in codex form.

An alphabet of small, or minuscule, letters developed gradually and was in use by the 8th century. Numerous abbreviations exist in Greek manuscripts, though never so many as in Latin. Accents, an additional complexity, were not systematically applied before the 7th century AD.

Styles of writing

The ancient Latin alphabet of capitals (*quadrata*) is found in numberless inscriptions in stone and marble all over the Roman world. How far this alphabet was used for writing books is uncertain, because, though excellently adapted for incision, it is difficult to write. Some specimens of handwriting in *quadrata* do exist, such as 4th- or 5th-century copies of Virgil, but scholarly opinion largely regards these as abnormal productions. By the 1st century a handsome Latin alphabet existed, called rustic, based on the use of a broad pen or brush. Rustic was used for public inscriptions on walls, as in the sale and election notices found at Pompeii. Although specimens are scarce, it is likely that books were extensively written in this hand in classical times. By the 4th century another Latin alphabet existed, the script known as uncial, in the nature of a rounded form of *quadrata*. Uncial survived the fall of Rome and from it developed half-uncial, the ancestor of the small letters in use today.

The stately Roman scripts, *quadrata*, rustic, or uncial, were not used for everyday purposes, and, as in the case of Greek, a cursive, rapidly written hand arose in which letters and business documents were inscribed. This hand is found in graffiti on Pompeian walls and in wax tablets. After the disintegration of the empire, Roman cursive became the ancestor of regional hands in what are now Spain, France, and Italy.

During the flowering of Christianity and art in Ireland

(*c.* 500–*c.* 1000) a beautiful "insular" script developed, which found its way into England. There, two streams of influence commingled, for from 597 Christian missionaries arrived from Rome and brought in books in uncial script. Both scripts prospered in England, though insular gradually superseded uncial.

The most successful of all scripts proved to be Caroline minuscule, which takes its name from the emperor Charlemagne (died 814), patron of scholars and scribes, under whom the script was developed. Despite its inherent superiority and clarity, it did not predominate over regional scripts until the mid-12th century, and the local hand of southern Italy (Beneventan) maintained itself for much longer.

In the 12th century, Caroline minuscule, which had undergone moderate developments, started to display more obvious changes. It compressed laterally, while its rounded strokes became stiffer and straighter as it was converted into the so-called Gothic hands—very angular in northern Europe and more rounded in Italy. A revulsion against Gothic took place in scholarly circles in Italy in the 14th and 15th centuries, and a return to models based on Caroline minuscule took place. This revived hand, called Humanistic because humanist scholars used it, was adopted by 15th-century Italian printers, whose type faces ultimately triumphed over the Gothic. (This encyclopaedia is printed in a type scarcely modified from Caroline minuscule.) Meanwhile, Caroline and Gothic scripts had produced cursive hands for quick everyday use, as in the case of the ancient Greek and Latin alphabets. These cursive scripts were used for the vast mass of business documents written in the Middle Ages.

Cursive scripts

Abbreviations are the principal problem confronting paleographers. They were extensively used in Roman times by lawyers to avoid repetition of technical terms and formulas. Abbreviations fall into two classes, suspension and contraction. Suspension, omission of the end of a word and indication by a point or sign, was used extensively in Roman public inscriptions—*e.g.*, IMP.(ERATOR), CAES.(AR). Contraction, the omission of letters from the middle of a word and replacement by a sign or some other device, was common among Greek-speaking Jews, who contracted certain sacred or revered names, such as God, Lord, Israel, or David, as a mark of veneration. The Christians followed the practice by contracting their sacred names, such as Jesus and Christos. The great increase in use of abbreviation as a means of saving time and material dates from the 12th century, but some contraction signs are of high antiquity, such as the sign 7 for *et* (Latin, "and"). Some are quickly written versions of letter groups, such as "÷" for *est* (Latin, "is"), the top dot standing for e, the bottom dot for t, and the stroke being a long or f-shaped s, fallen on its side. The letter r is often omitted, the adjacent vowel being written above the line, as c^{a}ta for *carta* ("charter"). In works for semilearned readers, such as romances, abbreviations are often few, but books produced for the learned, such as university textbooks, are heavily loaded with abbreviations. The number of signs and devices in use by the end of the Middle Ages was enormous. More than 13,000 are listed in the standard work, Adriano Cappelli's *Lexicon Abbreviaturarum* (1912).

Abbreviations

Dating of books and documents also offers problems. Even when a precise date is given, the dating system of a given time and a given area must be checked because the year began at different times in different territories, and there were even variations in the same country. Calendar reforms initiated in 1582 by Pope Gregory XIII, for example, were not adopted in Protestant England until 1752. If a year of a monarch's reign is given as a date, it is necessary to determine whether the reign is counted from his accession or coronation. Moreover, few books were dated, the dated title page being nonexistent in medieval works, though sometimes a final paragraph, the colophon, supplies a date with the scribe's name and place of work. Important documents, such as English 12th-century royal charters, are undated.

In the absence of dates, inferences are drawn from handwriting, use of abbreviations, and internal evidence. Caution must be used, however; for an elderly scribe may be using a hand learned over half a century before, and work in the same scriptorium or office as a young clerk anxious to show off all the latest tricks and flourishes. Some styles lasted a long time: Caroline minuscule lasted for more than three centuries. Certain kinds of books, such as liturgical volumes, were produced in a highly stylized form for generations, and thus it is often difficult to provide a close date for a late medieval missal (with standard illustrations and marginal decorations) in a mechanical Gothic hand.

Internal evidence must be weighed carefully. A given historical event noted in a chronicle will provide an earliest possible date, unless the entry is an interpolation. Evidence for some legal practice or liturgical usage is no safe guide, for legislation on the subject by a king or a pope may merely be ratification of a long-standing practice.

A paleographer must get to know his scribes, for their mannerisms can be highly informative. Nearly 50 different scribes have been distinguished in the English royal chancery in the period 1100–89. First-rate scribes, such as notaries public, provide much information about themselves, giving their names, notarial signs, and information on their authority to act. Even anonymous clerks, who drew up innumerable property conveyances, can be identified by their script over a period of years, and their career can be traced through developing, mature, and deteriorating handwriting, thereby offering dating evidence.

Internal evidence

The provenance (origin) of many manuscripts can be immediately recognized because certain centres developed individual styles. Papal and royal chanceries issued documents of easily identifiable origin, while many monastic scriptoria—for example, that of Canterbury Cathedral in the earlier 12th century—had a virtually private handwriting.

Textual corruptions are another obstacle to correct elucidation. A legal document is certain to have been checked at the time of writing, but one cannot be sure in the case of a literary, philosophical, or theological text. Scribes were fallible, and, if there are no signs of any corrections in a text, then it probably embodies inaccuracies. A popular book, such as Chaucer's works, exists in large numbers of manuscripts, and many manuscripts produce variant readings. If a scribe made a mistake in copying, future scribes using his version are likely to reproduce the error and add others. Sometimes the same muddled passage in a group of manuscripts of a given author can be traced back to damage in an earlier copy, say a section eaten by rodents or impenetrably stained. Whenever copyists worked from different and faulty originals, various copies tend to fall into families. A paleographer must bring together various readings in families and decide which is the best reading.

Sometimes a scribe, set to work because he could write a fine hand, did not necessarily possess much knowledge of the language. Such a scribe faced with a text heavily loaded with abbreviations would usually make nonsense of it. Occasionally, a particularly stupid copyist, faced with a master copy in two columns of writing, would copy straight across the top line, then across the second. When he used a different number of words per line, the text was reduced to unintelligibility. In Greek and Roman times there was the difficulty that texts were written continuously, without space between the words. Copyists misread passages. For instance the historian Tacitus reported that some tribesmen went off to guard their own property: ADSVATVTANDA (*ad sua tutanda*). Some copyist thought "Suatutanda" was a place and this ghost name was perpetuated in geographical works. Later medieval Gothic hands presented a forest of vertical strokes called minims. The letter *v* rendered as *u* made two strokes, while *i* was often left without a dot or at best with a faint hairline, often misplaced. The group of letters *ium* could be read, as *uim, uiui, niui, mui, miu,* with many other variations. Accordingly, minim corruption, confusion of vertical strokes, is a term constantly heard in paleographical circles.

Latin and Greek are inflected languages in which the

same case and tense endings constantly occur, offering scope for error. Moreover, in biblical, theological, or philosophical texts, the same words abound. For example, in one place in the Gospel According to John there occurs the passage:

> Verba quae ego loquor
> vobis a me ipso non loquor
> pater autem in me manens . . .

("The words that I speak . . ."). The eye of a sleepy scribe might slip from the first *loquor* to the second, whereupon he would go on copying at *pater autem*, leaving out the second line altogether, a common type of error known as *homoioteleuton* ("like ending").

Because of the lack of surviving specimens, it is difficult to assess book decoration in classical times, but apparently it was very limited. In the later centuries of the Roman Empire, however, book illustrations were not infrequent.

Decorations

The narrative material in the Bible encouraged illustration. The Irish were foremost in applying decoration to the text in the form of elaboration of capital letters, producing such masterpieces as the Book of Kells (late 7th century), in which Celtic imagination and artistic sense ran riot in elevating the book to an object of outstanding beauty. Some of the greatest creative talent of the Middle Ages was lavished upon books, especially upon those used in worship, such as Bibles, psalters, and missals. When a book cannot be assigned either a date or provenance upon the appearance of the text alone, its style of illumination will often direct the paleographer to a certain monastery in which the carving on capitals or wall paintings may contain the same motifs.

Because of the immensely high prices of manuscripts, the question of forgery naturally arises, but it is safe to say that no modern forgery could survive for a moment. A convincing imitation of ancient script is virtually impossible, while the papyrus, parchment, or paper on which it would be written could not stand up to modern scientific inspection. Anything of recent vegetable or animal origin fluoresces brightly under ultraviolet light, to name but one test. William Henry Ireland (died 1835), the Shakespeare forger, used flyleaves from 16th-century books, but his handwriting and non-Shakespearean language gave him away. A modern would-be forger must either copy an existing work, which, in the present state of art history and paleographical study, would be immediately recognized, or be prepared to invent medieval subject matter.

Forgeries

There was fabrication of documents in medieval times on a considerable scale. A monastery might find itself in possession of estates held since remote antiquity but without any title deeds. When some powerful monarch made difficulties, there was a strong inducement to produce the required ancient-looking documents. The borderline between justifying legitimate possession and culpable attempts to gain extra territory or privileges, however, is ill-defined. Monks occasionally descended to falsifications of title deeds and charters of exemption. About 1125 a monk of Soissons on his deathbed confessed to a career of professional forgery for gain and admitted fabricating charters for various monasteries, including Westminster Abbey. Early forgeries, however, give themselves away through such inconsistencies as mentioning bishops of nonexistent sees or embodying legal phrases that came into use generations later or bearing seals when seals were not yet appended to documents.

The modern paleographer has great technical aids: photography since the 19th century and colour photography in the 20th. Ultraviolet light brings out faded handwriting. Microfilm makes the contents of a whole volume in a far-distant repository available quickly and cheaply.

BIBLIOGRAPHY. The most comprehensive work, certainly in English, is still E. MAUNDE THOMPSON, *An Introduction to Greek and Latin Palaeography* (1912). Also valuable, and in print, is his shorter version, *Handbook of Greek and Latin Palaeography* (1893, reprinted 1966). For Greek paleography, see B.A. VAN GRONINGEN, *Short Manual of Greek Palaeography*, 3rd rev. ed. (1963); and C.H. ROBERTS, *Greek Literary Hands, 350 B.C.–A.D. 400* (1956). The article "Handwriting" in C.G. CRUMP and E.F. JACOB (eds.), *The Legacy of the Middle Ages* (1926), is an important account of Latin book hands. Essential for the study of abbreviations in medieval Europe is ADRIANO CAPPELLI, *Lexicon abbreviaturarum: dizionario di abbreviature latine ed italiane*, 6th ed. (1961). A standard textbook for medieval English cursive hands is CHARLES JOHNSON and HILARY JENKINSON, *English Court Hand A.D. 1066 to 1500* (1915), continued in Jenkinson's *Later Court Hands in England from the Fifteenth to the Seventeenth Century* (1927). L.C. HECTOR, *The Handwriting of English Documents*, 2nd ed. (1966), contains a valuable introduction to the paleography of English administrative manuscripts. Very many classical, biblical, and liturgical texts have now been published in facsimile, often with colour plates. Large collections in facsimile comprise E.A. LOWE, *Codices latini antiquiores*, 12 vol. (1934–71); CHARLES SAMARAN and ROBERT MARICHAL, *Catalogue des manuscrits en écriture latine, portant des indications de date* (1959–); BERTRAM COLGRAVE (ed.), *Early English Manuscripts in Facsimile* (1951–); and the "Oxford Palaeographical Handbooks," a series designed to deal with various aspects of the subject, such as C.H. ROBERTS (see above); C.E. WRIGHT, *English Vernacular Hands from the Twelfth to the Fifteenth Centuries* (1960); M.B. PARKES, *English Cursive Book Hands, 1250–1500* (1969); and T.A.M. BISHOP, *English Caroline Minuscule* (1971).

(W.G.U.)

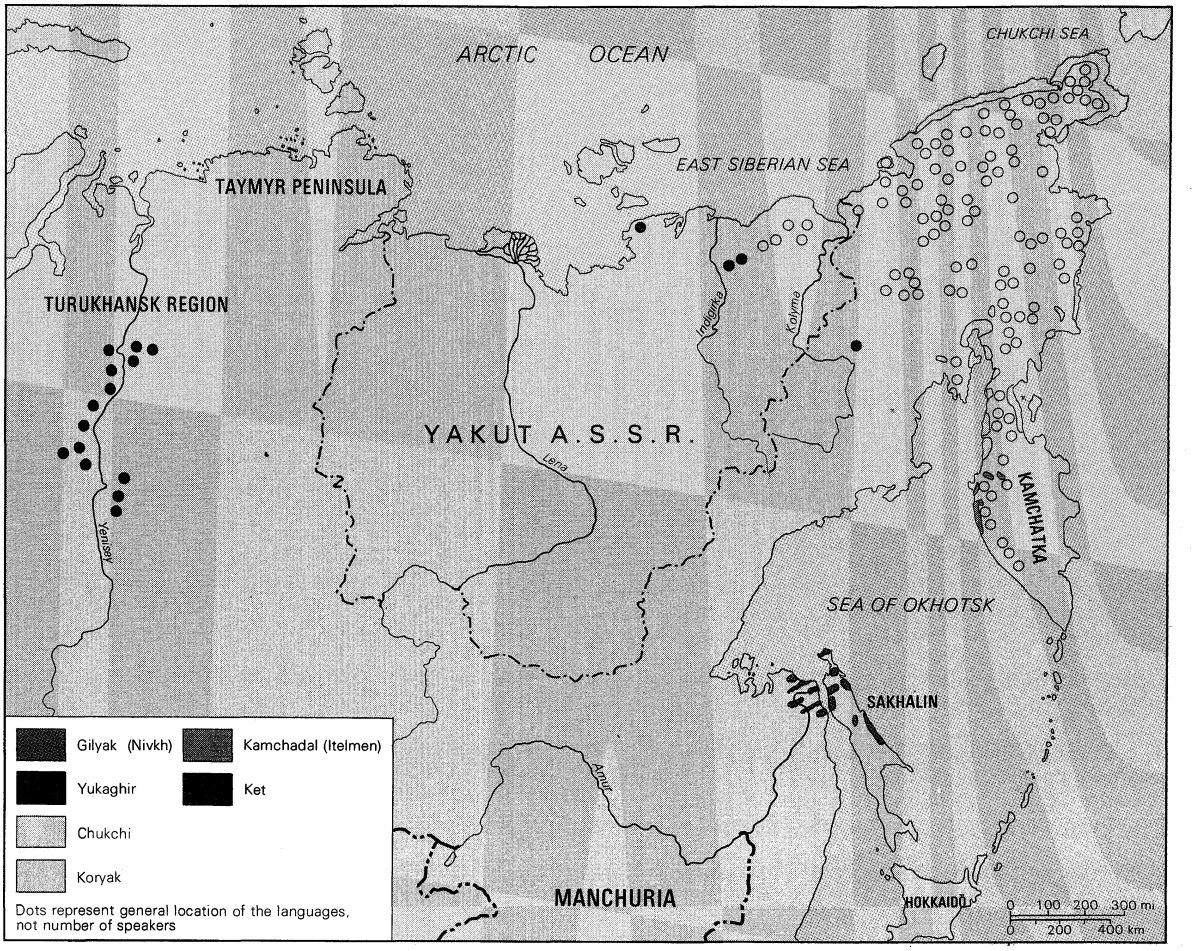
Paleosiberian Languages

The collective term Paleosiberian is applied to four genetically unrelated language groups situated in northern Asia—Yeniseian, Luorawetlan (Luoravetlan), Yukaghir (Yukagir), and Gilyak. The Yeniseian group, whose only living member is Ket (or Yenisey-Ostyak), is spoken by about 1,000 persons in the Turukhansk region along the Yenisey River. Kott (Kot), Arin, and Assan (Asan), now extinct members of this group, were spoken to the south of the present-day locus of Ket. The Luorawetlan family consists of (1) Chukchi, spoken by 12,000 people in the northeasternmost parts of Siberia, west of the small enclave of Siberian Eskimo; (2) Koryak, also called Nymylan, with approximately 8,000 speakers, found to the south of Chukchi; (3) the more remotely related Kamchadal (or Itelmen), with a bare remnant of 350 speakers in southern Kamchatka; (4) Aliutor, perhaps a Koryak dialect, with a small and unknown number of speakers; and (5) Kerek, with about 100 speakers. Some Soviet scholars list Aliutor and Kerek as being more closely related to Chukchi and Koryak than to Kamchadal.

The Yukaghir group, whose only living member is Yukaghir proper (or Odul), is spoken by about 450 persons in two enclaves in the Yakut A.S.S.R. (Yukutskaya A.S.S.R.), near the estuary of the Indigirka and along the bend of the Kolyma River. Extinct languages belonging to the Yukaghir group (or perhaps dialects of an earlier form of Yukaghir proper) are Omok and Chuvan (Chuvantsy); these were spoken south and southwest of Yukaghir proper. Gilyak (or Nivkh) has about 4,000 speakers, 2,500 of whom live in the estuary of the river Amur and 1,500 on the island of Sakhalin.

Classification of the languages. These four groups are *not* related to each other. They have been subsumed under the names Paleosiberian, Paleo-Asiatic, or, more rarely, Hyperborean, ever since the Baltic German zoologist and explorer Leopold von Schrenck surmised, in the middle of the 19th century, that they constituted the remnants of a formerly more widely dispersed language family that had been encroached upon by invading groups of Uralic, Turkic, and Tungus speakers. Schrenck's hypothesis is quite correct to the extent that as recently as the 17th century Yeniseian, Luorawetlan, and Yukaghir languages were spoken over much wider territories than they are today. For example, it is known that Samoyed languages (of the Uralic family) at one time in the past absorbed the languages of now extinct Yeniseian tribes, that Yukaghir was spoken as far west as the Taymyr Peninsula in the 17th century, and that the former domains of Chukchi and Koryak extended much further to the west. Little is known about the prehistory of Gilyak but it may be assumed that this language was also originally centred further to the west, perhaps in Manchuria. As far as can be determined with the help of methods of comparative linguistics, however, the four

Paleosiberian groups not genetically related



Distribution of Paleosiberian languages.

present-day Paleosiberian groups never formed a single family of languages in the accepted sense of that term. In fact, they may represent only a fragment of a possibly greater diversity of language families in prehistoric Siberia. Many of the languages spoken in the area during earlier periods may have been swallowed up by the more recent and culturally vigorous intruders in Siberia that are now the neighbours of the Paleosiberian enclaves: mainly the Yakut (whose domains stretch as far as the Chukchi and Yukaghir areas) and various Tungus tribes (one or another of which borders on each Paleosiberian language).

Comparisons with other language families

Nevertheless, many attempts have been made to show that the four Paleosiberian families are either related to each other or to adjacent (or more distant) language families. Thus, Ket has been compared with the Sino-Tibetan family (Chinese, Tibetan) and with some of the languages of the Caucasus, and Yukaghir has been compared with Uralic. Some of these comparisons are fanciful experiments or completely unfounded (*e.g.*, the comparisons of Ket with Caucasian languages). Others are more reasonable but not compelling (*e.g.*, the Yukaghir-Uralic hypothesis) because the evidence adduced so far has been too unsystematic and fragmentary. It is therefore safest, at present, to consider Ket, Yukaghir, and Gilyak as language isolates that are unrelated to any known language or language family and to regard Luorawetlan as a family in its own right that is also unrelated to any other family or isolated language. Further research on the internal history of these four groups will eventually enable comparatists to reconstruct hypothetical earlier stages of the languages and to make comparisons with non-Paleosiberian languages more cogent, if at all feasible. Mere resemblances in grammatical or phonological traits between Paleosiberian and adjacent languages (such as between Chukchi and Eskimo, or betweeen Gilyak and Korean or Japanese) are not indexes of genetic affinity, but are often the result of the diffusion of linguistic traits over large geographical areas. They may, however, provide clues to the linguistic prehistory of Siberia.

The cultures of the four Paleosiberian groups are, in general, similar in that they are all Arctic or subarctic. In detail, however, each group of speakers of a Paleosiberian language has its own characteristic cultural profile. These characteristics may on occasion even resemble the cultural profile of a non-Paleosiberian group very closely; *e.g.*, Ket culture resembles Selkup (Ostyak-Samoyed) culture more closely than it resembles that of any Paleosiberian group. (Selkup- and Ket-speaking groups are located in contiguous areas.)

Linguistic characteristics. *Grammar.* The grammatical structures of the four Paleosiberian groups differ considerably from each other. In a broad sense, Gilyak resembles Japanese in its grammatical categories and processes (in the word order, heavy inflection of verbs, and use of enclitics—words closely connected with the word that precedes), whereas Yukaghir shares certain grammatical categories with some Uralic languages (the objective conjugation—*e.g.*, "he shot it" versus "he shot"—and the negative conjugation—*e.g.*, Yukaghir *tet mer-ai-mek* "you shot" versus *tet el-ai-yek* "you did not shoot"). A typical feature of Luorawetlan is its strong tendency toward complex compounding, also called incorporation, and circumfixation; *e.g.*, in Chukchi *ga+mor-ïk+tor+orw-ïma* "in our new sleigh," the entire unit is surrounded by the circumfix *ga- . . . ïma* "in" (compare *ga+mor-ïk+orw-ïma* "in our sleigh," without *tor* "new," and *ga+tor+orw-ïma* "in the new sleigh," without *mor-ïk* "our"). A characteristic feature of the Ket verb is its succinct com-

Typological resemblances between Gilyak and Japanese

plexity, involving such categories as gender, animateness, and type of event; *e.g.*, *t-k-it-n-a* "I carved it up," which consists of *t-* "I," the verbal complex *k- . . . -a* "cut up (carve, split) into pieces once," *-it-* (feminine object marker "her, it"), and *-n-* (past-completed tense). All of the Paleosiberian languages are rich in devices for compounding words. In syntax, Luorawetlan favours ergative constructions in which markers indicate the agent or instrument of the action; *e.g.*, *Father* + agent marker, *bear* (subject), *shoot* (main verb), "Father is shooting a bear."

Phonology. Typical phonological features of the Paleosiberian languages are post-velar consonants (*i.e.*, sounds formed further back in the mouth than *k*, usually represented as *q*), vowel harmony of various kinds (*e.g.*, the alternation of *e* and *i* in the form for "my" in Gilyak *ñe-řla* "my harpoon" and *ñi-řly* "my sky"), consonant alternations (*e.g.*, the alternation between *b*, *v*, and *f* in Gilyak *bal* "mountain," *ñ-val* "my mountain," *c-fal* "thy mountain"), and rich consonant clusters in all but Yukaghir.

Vocabulary. In addition to the stock of native words inherited from its ancestral language, each Paleosiberian language also has numerous loanwords, some of which are recent and from adjacent or recently adjacent languages, and others of which are ancient, from languages with which it no longer has contact. Some of the loanwords from ancient times are, of course, more difficult to identify. In general, Tungus, a branch of the Altaic family, is the source of most loanwords, but the Turkic languages (including Yakut) have also served as the sources of loans, and Ket has some words from Selkup. There are also more complicated loan relationships, such as are found in the reindeer terminology of Gilyak, which is borrowed from a Tungus language but seemingly not from any of the Tungus languages with which Gilyak is now in contact. South Sakhalin Gilyak also contains a considerable number of loanwords from Ainu (a language of northern Japan) and was, during 1905–45, hospitable to potential loans from Japanese; the Japanese loanwords never became acculturated because the Japanese hegemony over South Sakhalin ceased after World War II. Chukchi has some Eskimo loans.

Loanwords in Paleosiberian languages

The most viable source of technical and all of the other modern vocabulary has been the Russian language, the influence of which began with the first contact and continues to be strong. Each Paleosiberian language adjusts the Russian loans according to the dictates of its phonology and grammar but the most recent borrowed words tend to retain their original Russian form or one closely resembling it.

Writing. The Yukaghir had a tradition of pictographic writing (incisions on fresh birch bark) used by men for route maps and by young women for a type of love letter. Limited use of such a system among the Koryak speakers has also been reported.

Since the 1920s and 1930s each Paleosiberian language has had a literary language and a script now based on the Cyrillic alphabet (and formerly based on the Latin script). Because at one time these native languages were used in part in elementary education, primers and arithmetic books for the lowest grades were available. Some natives continue their education and acquire a good knowledge of Russian and of Soviet culture. This has led to the rise of bilingualism but has also contributed to the growth of modern literatures in the native languages, based on Russian models, especially among the Koryak and the Chukchi.

The native traditions and folklore of the Paleosiberian peoples have been collected since the last century, mainly by Russians and Westerners. Work in these fields is still continuing and is attracting a slowly emerging corps of trained native specialists. Such trained natives are also beginning to collaborate in the compilation of dictionaries.

BIBLIOGRAPHY. ROMAN JAKOBSON, GERTA HUTTL-WORTH, and JOHN FRED BEEBE, *Paleosiberian Peoples and Languages: A Bibliographical Guide* (1957), very useful, with informative appendix; DEAN WORTH, "Paleosiberian," in T.A. SEBEOK (ed.), *Current Trends in Linguistics*, vol. 1, *Soviet and East European Linguistics*, pp. 345–373 (1963), good coverage of Soviet work since World War II. The best and most recent source on Paleosiberian languages is in Russian: П.Я. Скорик *et al.* (eds.), *Языки народов С.С.С.Р.*, vol. 5, *Монгольские, тунгусоманьчжурские и палеоазиатские языки* (1968).

(R.Au.)

Paleozoic Era, Lower

The Lower Paleozoic Era refers to the segment of Earth history from 395,000,000 to 570,000,000 years ago and includes the Cambrian, Ordovician, and Silurian periods. It is characterized by the evolution and marked preponderance of marine invertebrate faunas during this time interval, whereas terrestrial forms of life flourished in the Upper Paleozoic. This giant step from the seas to the land areas is the greatest biological revolution of the Paleozoic Era and is a reasonable basis for its division.

This article treats the rocks, life-forms, and environments of the Lower Paleozoic Era. The historical subdivision of Lower Paleozoic rock systems, with attendant nomenclature, is covered in the separate articles on the geological periods involved—*i.e.*, CAMBRIAN PERIOD; ORDOVICIAN PERIOD; and SILURIAN PERIOD. The other portion of this era is treated in PALEOZOIC ERA, UPPER. The interested reader should also consult STRATIGRAPHIC BOUNDARIES; GEOLOGICAL TIME SCALE; and, for an overview of all of geological time, EARTH, GEOLOGICAL HISTORY OF. The life forms of the Lower Paleozoic are given additional detail in the article FOSSIL RECORD.

LOWER PALEOZOIC ROCKS

World distribution. The trilobite *Asaphus boliviensis* and other fossils were reported from South America as early as 1842, and Cambrian fossils were described from eastern Asia and from South Australia in 1883 and 1884, respectively. Lower Paleozoic rocks are now known to be distributed extensively in all continents, although their extent is rather limited in the Southern Hemisphere.

In the Caledonian (Scotland), Appalachian (United States), Sayan-Altai (Soviet Union), Tasman (Australia), and other geosynclines (downward flexures of the Earth's crust), Lower Paleozoic sediments accumulated to great thicknesses. The seas extensively flooded the Canadian, Angara, and other cratonic areas (stable areas of the Earth's crust that generally form the central mass of a continent). Rocks of the ancient Precambrian basement are now extensively exposed in the Canadian and Baltic shields, but the thin Lower Paleozoic veneer largely mantles the basement of the central Siberian Platform, leaving only the southern border of the Angara Shield and the Anabar area in the north exposed. These large cratons and geosynclines already were differentiated before the deposition of the Sinian, Beltian, and other late Precambrian formations. From Korea and China to the Tarim and Fergana basins of Central Asia, cratonic and quasi-cratonic areas are sutured by various folded mountains. There the distribution of Lower Paleozoic formations and their thicknesses and interrelationships are highly complicated. The stratigraphy also is complex in central Europe and the Iberian Peninsula; Ordovician fossils are the oldest in the Alps. Little is known of the basement of the festoon islands of the western Pacific Ocean, but Middle Cambrian and Ordovician fossils have been discovered in New Zealand, and Silurian fossils occur in Japan and in West Irian, New Guinea.

Lower Paleozoic formations are tremendously thick in the geosynclines, attaining several thousands of metres or more in northeast Kazakhstan (Soviet Union) and elsewhere. The rocks are chiefly composed of terrigenous (land-derived) materials and various volcanic and pyroclastic sequences. Graywackes (sandstones containing fragments of other rocks and a clay-rich matrix) and greenstones (altered volcanics) are common members. Radiolarian chert, graptolitic shales (graptolites are extinct colonial organisms), and some limestone also occur. The characteristics of these deposits change horizontally as well as vertically, indicating the instability of the trough area. Conglomerates and arkose sandstones also

record the complicated geology of their hinterland source areas.

Compared with the geosynclinal sediment accumulation, the cratonic veneer is usually thin. It is composed of shallow marine sediments rich in various benthonic (bottom-dwelling) organisms. Fossiliferous carbonate rocks are common in Scandinavia, for example, and a reef facies is represented in the Lower Cambrian by the archaeocyathid (primitive marine invertebrates that resemble sponges but that may not be related to them) limestone. The coralline reefs become important sediment types in the Upper Ordovician and were well developed in the Niagaran of the Great Lakes and other Silurian formations. *Cryptozoon* (algal?) limestones are present in several Cambrian and Ordovician sections in North America. Limestone conglomerates are common in the Upper Cambrian Chaumitien Limestone of eastern Asia.

Sedimentary environments and ore deposits. In Lower Paleozoic sequences, conglomerate generally is rare, and shale is more common than sandstone. The St. Peter Sandstone, which is composed of water- and wind-worn quartz sand, is astonishingly persistent in the Mississippi Valley, showing how slowly and widely the Middle Ordovician sea flooded the almost level land. Some of the sand is pure enough to use in glass manufacture.

Oil shales, uranium, iron, and salt

The Middle and Upper Cambrian Alum Shale Group of southern Sweden includes oil shales containing lenses of uranium-bearing, bituminous nodules. Uranium deposits also are known from the Lower Cambrian of the Estonian S.S.R. and from the Silurian of Fergana, Central Asia.

Black carbonaceous shales of Ordovician age, containing extraordinary numbers of graptolites, are thought to represent a pelagic sediment—*i.e.*, one containing fossils of free-swimming or floating organisms—deposited in poorly ventilated basins in which no benthos could survive. The Middle Cambrian Burgess Shale of the Canadian Rockies, which yields a unique planktonic (floating) fauna, may have formed in a similar environment.

Oolitic (consisting of cemented small round grains) iron ores are common in the Ordovician formations in Bohemia (Czechoslovakia), Thuringia (East Germany), Bretagne (France), and the northern part of the Iberian Peninsula. The Wabana Series iron ore is found in the Lower Ordovician in Newfoundland; and Clinton Iron Ores, in the Middle Silurian of the Appalachian Mountains from New York to Alabama. Of interest to geochemists endeavouring to determine the history of seawater was the discovery of salt-crystal casts in the lowermost Cambrian (?) Spiral Creek Formation, eastern Greenland, below the *Olenellus*-bearing Bastin Formation. Evaporites, including salt and gypsum, were deposited throughout the Lower Paleozoic—in the Cambrian of Morocco and Iran; the Cambrian, Ordovician, and Silurian of central Siberia; the Ordovician of the Shansi Basin, northern China; and the Upper Silurian Salina Group of central New York.

LOWER PALEOZOIC LIFE

Three important steps in the history of the development of the biosphere occurred in the Lower Paleozoic. The Cambrian animals were exclusively marine, and all major invertebrate phyla were represented. The Ordovician animals also were aquatic; most classes of fossil invertebrates and many important orders in the Paleozoic fauna were included. Furthermore, bony armour plates of primitive jawless fishes have been discovered in Middle Ordovician rocks at three localities of western North America. The oldest fish tooth found is that of *Palaeodus* from the Lower Ordovician marine glauconite sand of the Estonian S.S.R. A third evolutionary step occurred during Silurian time. Corals and other reef builders developed rapidly in the Silurian, but the scorpions *Palaeophonus* and *Proscorpius* from the Upper Silurian of Sweden, if not themselves air breathers, are clearly ancestors of air-breathing scorpions; this reflects the dawn of animal life on land.

Overview of invertebrates and evolutionary trends. As far as the fossil record is concerned, life seemingly developed very suddenly during the transition between the Cryptozoic and Phanerozoic aeons (*i.e.*, at the Cambrian–Precambrian boundary, 570,000,000 years ago), although this interval may have been longer than a transition between any two eras. All of post-Precambrian time is presumably less than one-fifth the time span of the Cryptozoic. Precambrian fossils consist principally of ambiguous problematica or inorganic pseudo-fossils. The Ediacara coelenterate and annelid (worm) fauna is an exception because of its excellent preservation. It is so distinct from later faunas that its age is considered older than Cambrian.

The next oldest fossils are Lower Cambrian archaeocyathids and the small, straight-coned *Volborthella, Hyolithes,* and other primitive invertebrate shells. Trilobites (extinct arthropods whose external skeleton is divided into three longitudinal lobes) are not always associated but are well represented in the next younger faunas. Three Lower Cambrian faunal provinces (regions characterized by the occurrence of specific fossils or fossil assemblages) have been distinguished, each of which is based on the occurrences of trilobites: the Olenellidian fauna of the Arcto-American–Atlantic province; the Redlichian fauna of eastern and southern Asia and Australia; and the intermediate fauna of Siberia and the Mediterranean region, in which redlichid and olenellid types of trilobites are coexistent and protolenid types are common.

Trilobites and faunal realms

Trilobites were the dominant group in the Cambrian fauna; in witness to this fact, two-thirds of the named Cambrian genera are trilobites. Next in abundance were the brachiopods, shelled marine invertebrates in which the two valves, or shells, are of unequal size. About 10 to 15 percent of the fauna would include the archaeocyathids, the arthropods exclusive of trilobites, and other minor groups. Chitinous (chitin is a nitrogenous substance similar to mammalian fingernails and claws) and horny phosphatic shells are especially common among Cambrian animals. The Middle Cambrian Burgess fauna of the Canadian Rockies, containing coelenterate—*i.e.*, without hard parts, such as jellyfish—medusae (*Peytoia*), annelids (*Canadia, Ottoia*), the oncopod *Peripatus*-like *Aysheaia,* the arrowworm *Sagitta*-like *Amiskwia,* and other rarities, is undeniable evidence for the contention that the fossil fauna is only a part of past life and that pelagic animals are very poorly represented in the fossil record.

Graptolites, cephalopods, brachiopods, and trilobites were four important groups that subsequently profused, in the Ordovician fauna. The dendroid (branching) graptolites probably appeared in Middle Cambrian time, and they then flourished to become the most valuable index fossils for interprovincial correlations of the Ordovician record. The most primitive cephalopod (excluding *Salterella*) is the late Upper Cambrian *Plectronoceras* in China. The successive development of nautiloid groups can be seen in the Ordovician Tsinan Limestone of northern China and southern Manchuria. Post-Cambrian trilobite branches appeared suddenly in the Cambro-Ordovician transitional times when many Cambrian branches died out. The shell-bearing brachiopods flourished greatly during and after the Ordovician. Four rock series of the Silurian of the Oslo region, Norway, are based on brachiopod ranges.

Rise of bryozoans, echinoderms, and reef builders

Bryozoans (marine colonial animals) that appeared in the Upper Cambrian became important members of the Ordovician fauna. Among the mollusks, the earliest gastropods appeared in the Lower Cambrian, and pelecypods became common in the Ordovician. The ostracods (small bivalved crustaceans) and eurypterids (very large, extinct arthropods) also appeared at this time, and the echinoderms, marine invertebrates with five-fold symmetry, developed greatly in the Ordovician. Stromatopoods and tabulate corals became important reef builders during the latter part of the Ordovician and in the Silurian.

Among the Lower Paleozoic animals to die out and become extinct was the phylum Archaeocyatha; some brachiopods, cephalopods, and arthropods also disappeared. The ammonites (a large group of extinct mollusks), insects, amphibians, and higher vertebrates had yet to appear.

Table 1: Correlation of the Cambrian System Based on Trilobite Zones

Trilobite stage	Europe and North Africa	eastern Asia		Siberia Kazakhstan	North America	
Olenidian	*Acerocare* Zone *Peltura* Zone *Leptoplastus* Zone *Parabolina spinulosus* Zone *Olenus* Zone *Agnostus pistiformis* Zone	Chaumitian	Fenshanian	Shidertinian	Croixian	Trempealeauan

			Yulutsun			

*In North Africa.

The plant record. Within the plant kingdom, *Girvanella* occurs in the Lower Cambrian of China and elsewhere, and various kinds of algal remains have been described from the Cambrian of Siberia and Canada. Red and green algae were greatly developed in the Ordovician; brown algae became common in the Silurian.

Spores that presumably were derived from mosses or ferns have been reported from the Cambrian of the Baltic region and from the Urals. *Aldanophyton* has been discovered in the Cambrian of Siberia; and *Biophyton*, in the Ordovician of Bohemia. *Baragwanathia* and *Saxonia* from the Upper Silurian of Victoria, Australia, and Saxony, Germany, respectively, are considered to be lycopods. *Zosterophyllum*, a member of the psilopsids, appeared in the Silurian. The Lower Paleozoic plant record, however, is meagre in comparison with the extraordinarily developed Devonian land flora.

STRATIGRAPHIC CORRELATION

Trilobite zones and guide fossils

The Cambrian System. The Cambrian System is divided into zones chiefly on the basis of the trilobites that are contained in the strata (see Table 1). In Scandinavia, the Olenid Series is divided into eight zones in addition to 31 lesser units called subzones, and the *Paradoxides* Series is divided into three stages and nine zones. The Olenellid Series is best divided in the Anti-Atlas Mountains, Morocco, where eight zones and 18 horizons (stratigraphic layers of little thickness) of trilobites were recognized, in addition to an archaeocyathid limestone below them. This indicates the great accuracy of Cambrian time correlation, which is provided with about 60 key horizons in the European Mediterranean region. Assuming that the duration of the Cambrian Period was 75,000,000 years (it is actually nearer to 70,000,000 years in duration), its zone time is a little longer than 1,000,000 years (zone time is the duration of a period divided by the maximum number of zones or key horizons that exist in the corresponding rock system). This average provides some concept of the time scale relative to other periods (see STRATIGRAPHIC BOUNDARIES).

Some trilobite species or genera are distributed widely, but most are provincial. *Centropleura* is a late Paradoxidian genus known in northwestern Europe, Siberia and adjacent islands, Australia, and in Nevada and Vermont in North America. Thus its distribution is almost worldwide, although its occurrence is uncommon at these places: *Glyptagnostus reticulatus* is a better guide fossil for an early Upper Cambrian horizon because it is distributed widely in Europe, northern and eastern Asia, Australia, and western, southern, and eastern North America. This is the oldest global zone that is defined by the life range of a species.

In North America, the Lower Cambrian is divisible into four zones, the Middle Cambrian into nine zones, including four subzones, and the Upper Cambrian into 13 zones, including six subzones. Nearly all of the index fossils are trilobites, but the lowest zone is the *Obolella* brachiopod Zone in the Appalachian-type section. The Upper Cambrian, or Croixian, which typically is exposed in the upper Mississippi Valley, is divided into the Dresbachian, Franconian, and Trempealeauan stages.

In eastern Asia, the best display of the Mantoan Series is seen in Yunnan, South China, where ten zones, including the *Hyolithes* Zone at the base and the archaeocyathid zone at the top, are distinguished. In North and Northeast China, the Fuchouan and Chaumitian series are each divided into three stages, and 17 and 11 zones are distinguished in them, respectively. The Cambrian zone time is about 2,000,000 years for eastern Asia and 2,500,000 years for North America.

Much work remains to be done before adequate interprovincial correlation can be achieved, but the Chaumitian base may be a little higher and the Croixian base lower than that of the Olenidian Series. It still is questionable whether or not the top of the Trempealeauan is older than the base of the Tremadocian (Ordovician).

The Ordovician and Silurian systems. In the Ordovician and Silurian systems, graptolite and shelly facies are distinguished. In Great Britain, 15 graptolite zones are recognized in the Ordovician system. In Victoria, Australia, 18 zones are found, ranging from Tremadocian to Llanvirnian (see Table 2), whereas only eight zones are known in the equivalent formation in Great Britain. The Silurian system contains 21 zones in Great Britain, 22 zones in the Soviet Union, and 42 zones in Bohemia (see Table 3). The Ordovician zone time is about 2,500,000 years. The shortest zone time of the Lower Paleozoic Era is 850,000 years for the Silurian zone time of Bohemia, assuming the Silurian Period to be 35,000,000 years (the Silurian Period began 430,000,000 years ago and ended 395,000,000 years ago).

Graptolite zones and zone time

Dictyonema flabelliforme, *Glyptograptus teretiusculus*, *Nemagraptus gracilis*, and *Pristiograptus nilssoni* are, for instance, cosmopolitan species, but many others are regional or local. The *Didymograptus bifudus* Zone is known from Europe and North America, but the zone in the Marathon region of west Texas may be older than that of Great Britain.

The intercalation (alternation of layers) of graptolite shales in the sequence of shelly facies, or the reverse, as seen in New York state and central China, is of great value for the biostratigraphic correlation because it provides evidence of the time equivalence of fossils. The Cambrian and Tremadocian faunas of the Acado-Baltic province are sharply separated from the North American ones. The Tremadocian is related to the Arcto-North Atlantic faunas on one side and the Andine faunas on the other in Cambro-Ordovician time. The Durness Limestone of North Scotland and the Hecla Hoek Formation of Spitsbergen and Bjørnøya (Bear) Island, Norway,

yield various fossils of North American affinities. Trilobites and other fossils of Alaska and the Canadian Rockies are important links in correlating the Cordilleran with the Siberian and Korean–Chinese faunas.

The Tien Shan and Himalayan troughs were two important routes of migration. The Ordovician trilobites of eastern Asia show faunal connection with those of northern and southern Europe through the former and latter route, respectively. The eastern Asian fauna also was connected with the Andine fauna through both the Mediterranean and the Australian and New Zealand faunas.

LOWER PALEOZOIC ENVIRONMENTS

Distribution of land and sea. Epeirogenic movements (uplifts and downwarps of the Earth's crust over wide regions) took place at different times among the three northern megacratons (the shield areas of North America, Europe, and Asia), as did orogenic disturbances (more intensive vertical movements of the crust, associated with mountain building) in the various geosynclines. The Lower Cambrian sea generally was transgressive, and marine inundation was common during Middle Cambrian time. Laurentia, the entire northern landmass, was generally emergent until the Upper Cambrian transgression, at which time, however, the sea covered its southern half. In the Siberian Platform, on the other hand, the Cambrian sequence is complete except for the uppermost part, thus indicating that the area was probably above sea level. In the Baltic region, the Cambrian strata thin toward the east, and the basal Ordovician sandstone directly overlies the Lower Cambrian *Fucoid* and *Eophyton* sandstones in the Estonian S.S.R. The *Eophyton* sandstone is disconformably underlain by the blue mud (marine sediment) of Leningrad, which, on the contrary, becomes thinner toward the west from the Russian Platform.

Transgressive–regressive sequences in the Ordovician and Silurian

The Ordovician sequence is unbroken in the Baltic region, and, in the interior lowland of North America, the Canadian Series is widely underlain by the Croixian. The Middle Ordovician limestones lie above the basal St. Peter Sandstone. The Richmondian sea flooded the continent, and the Cordilleran sea became confluent with the Arctic sea. In the Siberian Platform, the Tremadocian Ustuisk Stage is transgressive, and the Arenigian Chunisk Stage is regressive. The Krivolusk Stage is transgressive again; a local unconformity exists at the base of the Mangazeisk in the southwest. The regressive Dolborsk Stage contains gypsum deposits. The sea retreated toward the Arctic at the end of the Caradocian, and the Silurian overlies the Ordovician transgressively.

The Lower Silurian in the interior lowland of North America overlies the Ordovician, and the Middle Silurian overlaps the Lower Silurian extensively. A large shallow sea with many coral reefs existed there. The salt-bearing Upper Silurian red and gray formations in central New York reveal a regressive facies that may represent an arid period of time. Like the Ordovician, the Silurian sediments of the Baltic region constitute a continuous sequence that terminates with the Downtonian sandstone facies at the top. In similar fashion, the Silurian marine sediments are well represented in the Siberian Platform and are thin and free from volcanic material. The Upper Ludlow, however, is lagoonal and saliferous.

Mountain building and volcanism. Generally speaking, the Cambrian was a quiet period, but, in the Tasman Geosyncline in eastern Australia and Tasmania, strong volcanism occasionally occurred during the Cambrian and later periods. The Tyennan–Jukesian orogeny took place in Tasmania in the Middle and Upper Cambrian; the Benambran movements in the Upper Ordovician and the Bowning movements near the end of the Silurian Period occurred in Victoria and New South Wales.

Crustal deformation in Asia

The Lower Paleozoic formations in the Sayan–Kazakhstan region are tremendously thick and are composed chiefly of terrigenous and volcanic materials. The Upper Cambrian and late Middle Cambrian formations are found in limited areas in the Sayan–Altai region. There, crustal movements were repeated from late Middle Cambrian to Ordovician time, the so-called Salair movements in the Kuznetsk Basin. Influenced by these deformations, the Ordovician sequence and facies vary greatly among the Kuznetsk Alatau, Chorie, and Salair mountains.

Geosynclinal sediments are traceable to the east into the Tien Shan, Nan Shan, and the Tsinling Shan. Near the end of the Silurian Period, there was a strong crustal deformation called the Kwangsi movement in South China and also in Nan Shan. Silurian volcanism is recorded in the Chichibu Geosyncline of Japan.

In Korea and North China, the Cambro-Ordovician Chosen Korean Group is underlain by the Sinian and overlain by the Permo-Carboniferous. The Silurian is absent (if Silurian-derived fossils in North Korea are excluded). The three Lower Paleozoic systems are, however, well represented in central and South China.

Events in Europe and North America

In Europe, the Paradoxidian of the Pribam Syncline in central Bohemia is underlain by a thick formation of sandstone and conglomerate; it is overlain by a volcanic and pyroclastic formation, and this, in turn, is overlain by the Tremadocian. The Lower Paleozoic systems are well developed in the Montagne Noire, southern France, where the Tremadocian is concordant with the Arenigian. In Sardinia, on the other hand, the Arenigian transgresses the folded Cambrian formation. The Arenigian lies on the older rocks in the Armorican Massif, northwestern France, and the Anglesey Island, Wales.

In the British Isles, the intrageosynclinal volcanism was violent during the Ordovician Period. The sea expanded in the Caradocian toward the south, and in the Ashgillian it expanded toward the north. The period closed with an extensive emergence of the lands. Then the Silurian transgression was renewed, but volcanism almost had ceased. Crustal movement was intensified toward the end of the period. In Norway, also, volcanism occurred repeatedly in the Caledonian Geosyncline in the Ordovician Period. There, five disturbances are distinguished: namely, pre-Arenigian Trondheim; post-Caradocian Ekne; post-Ashgillian Horg; Wenlockian; and Ardennian. As a result, the arcuate Caledonian range extending from Ireland to Spitsbergen, and probably farther to the north, was produced.

In the latter part of the Ordovician Period, the rising of Appalachia supplied sediments to form the Queenston Delta in New York and Pennsylvania. The Taconic disturbance culminated toward the end of the period in dislocations in the region between Quebec and Albany, New York. In the Lower Silurian Period, the northern Appalachian Mountains supplied terrigenous material to the western lowland, where the Shawangunk Conglomerate and Tuscarora Sandstone accumulated. In North America, the Late Paleozoic Era closed quietly, whereas the Caledonian disturbance was strong in northwestern Europe and some other geosynclinal zones.

Climate. Evaporites, such as the salt and gypsum in Lower Paleozoic rocks, indicate an age of relative aridity. The worldwide distribution of Lower Paleozoic limestones and dolomites, and particularly the Middle Silurian reef limestones, show that warm seas were widespread. Long before the development of hermatypic corals (warm-water types), archaeocyathid limestones were deposited in all continents but South America, including Antarctica, in the Lower Cambrian and probably during early Middle Cambrian. The optimum temperature for this extinct phylum is assumed to have been no less than 25° C (77° F). There is no record of a frigid climate in the Lower Paleozoic Era. The glaciations previously reported to be of Cambrian age actually were late Precambrian in age.

(T.K.)

Paleozoic Era, Upper

The Upper Paleozoic Era refers to the segment of Earth history lasting from 395,000,000 to 225,000,000 years ago. The Paleozoic Era was first proposed by Adam Sedgwick in 1838 for the rocks and life of the Cambrian through Silurian systems (395,000,000–570,000,000 years ago), the term meaning time of ancient life. Later, the Paleozoic Era was extended to include the Devonian, Carboniferous, and Permian systems as well, and these systems are informally called the Upper Paleozoic, as distinct from the Lower Paleozoic. The era ends before the Triassic Period of the Mesozoic Era. The Upper Paleozoic Era is distinguished from the lower division chiefly by its more advanced life forms; woody plants and vertebrates were prominent for the first time, trilobites and graptolites declined, and there was an upsurge of brachiopods and ammonites among marine organisms.

Upper Paleozoic rocks are a most important source of economic minerals. Much of the mining conducted by the Phoenicians and Romans in such places as Spain and Cornwall, England, derived copper, gold, and other mineral ores from Devonian volcanics. A similar source has provided copper, lead, and zinc since AD 900 in the Rhine region, and in nearby Thuringia the science of geology was considerably advanced with respect to mining the copper and salt deposits of Permian age. Both the Devonian and Permian were periods of widespread mineralization in most continents. Carboniferous coal has been important in the development of Western technology. Petroleum also is abundant in Upper Paleozoic rocks, especially in the U.S., the U.S.S.R., and Canada. The first well drilled deliberately for oil, in 1859 at Titusville, Pennsylvania, was in Devonian sands.

Knowledge of the Upper Paleozoic Era has increased enormously in the past decade or so, partly because of renewed interest in the theory of continental drift (*q.v.*). Evidently the Earth has been remarkably mobile throughout geological time. Such movement in the Upper Paleozoic caused periodic crises that affected climate and life forms and the distribution of lands and seas.

This article treats the Upper Paleozoic Era as a whole, tracing the development of the Earth and its diverse life forms and climatic regimes throughout this time interval. For additional detail on each of the time periods encompassed see DEVONIAN PERIOD; CARBONIFEROUS PERIOD, LOWER; CARBONIFEROUS PERIOD, UPPER; and PERMIAN PERIOD. See also FOSSIL RECORD; STRATIGRAPHIC BOUNDARIES.

UPPER PALEOZOIC ROCKS

Over the Precambrian shields, Upper Paleozoic rocks formed thin glacial and terrestrial deposits in peninsular India, Africa, and Antarctica, or thin shelf deposits on the Siberian Platform and parts of the Canadian Shield (see CONTINENTS, DEVELOPMENT OF). The thickest deposits, largely marine, occur in geosynclines. One of these major belts, the Cordilleran, passes along the west coast and Rocky Mountains of North America; the second, much larger belt, passes east–west, across southern Europe, through south Asia into the South Pacific islands of Indonesia, New Guinea, New Caledonia, and New Zealand (Figure 1). This second area is called the Tethyan Geosynclinal Complex, named after the Tethys or ancient Mediterranean Sea. Three major geosynclines also were present in South America from Venezuela to Patagonia; these were linked with North America and possibly with the Tethys as well. Other areas of thick marine deposition were the Uralian Geosyncline of the Soviet Union, the east Australian geosyncline, and some large geosynclines in Siberia and the American Arctic.

Shelf deposits, as a rule thin and laid down in very shallow waters, also were widespread over the central United States and Soviet Union. They lie above Lower Paleozoic deposits that rest in turn on Precambrian rocks. Thousands of feet of sediment also were deposited in basins located near the edge of continental shields, as in western Australia and western Canada.

Miogeosynclines and eugeosynclines

The greatest volume of Upper Paleozoic rock occurs as thick piles of volcanic lavas and sediment largely derived from the lavas. The piles accumulated under the sea in rapidly sinking troughs, termed eugeosynclines.

The lavas, rich in iron, magnesium, and calcium, and moderately poor in quartz, poured out from fissures under the sea or from narrow chains of volcanoes, which emerged from the sea as island arcs (*q.v.*). The accompanying sediments were rapidly deposited graywackes (*q.v.*) and mudstones eroded from the volcanoes and the narrow, locally upheaved parts of the geosyncline or its borders. Fossils are rare. Beds generally were deposited in deep water from great clouds of sediment carried in density currents (*q.v.*) originating on the continental slopes.

Sediments formed in miogeosynclines closer to the ancient shields also were thick but lacked large quantities of volcanic material. They are composed largely of detritus, carried from the shields, or of carbonates, derived from broken marine shells and algae. Such miogeosynclinal

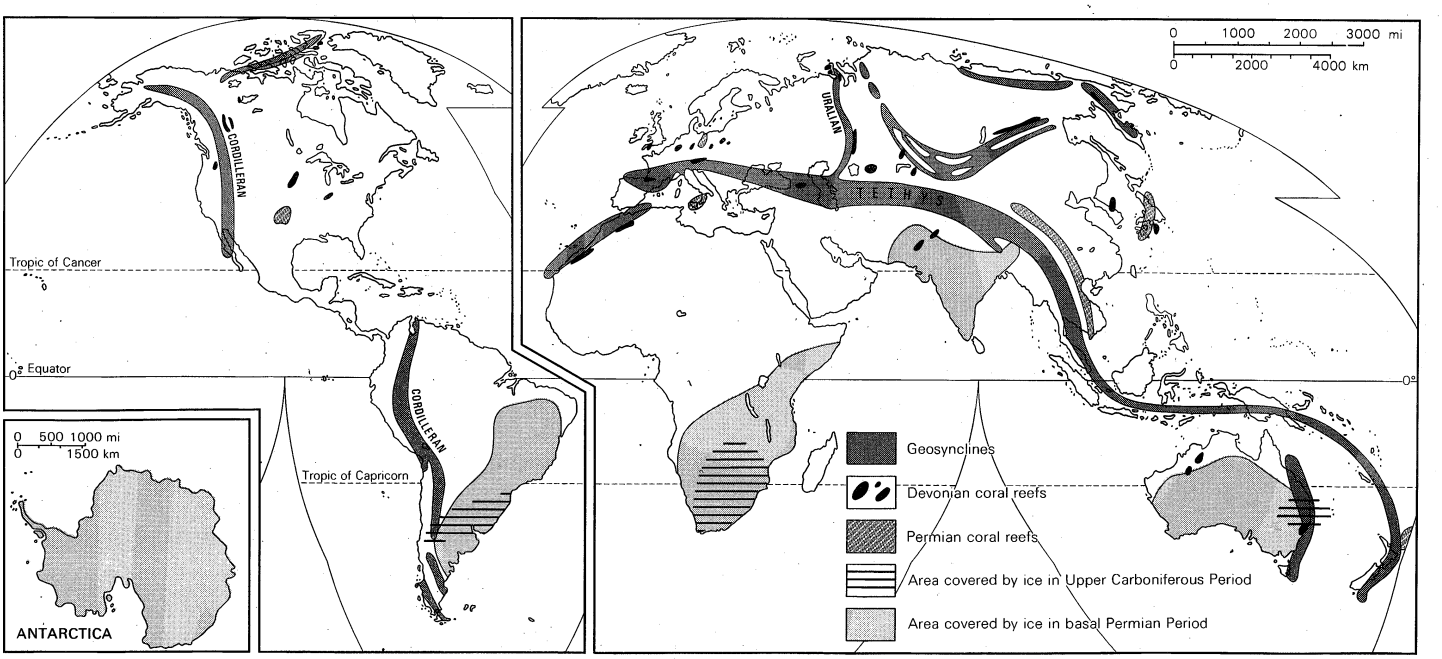

Figure 1: General paleogeography during the Upper Paleozoic Era, showing locations of geosynclines, coral reefs, and glacial deposits.

deposits are found along the eastern Rocky Mountains and through Europe north and south of the eugeosyncline.

Sediments accumulating on shelf regions, in basins, and on shields were mainly carbonates or lagoonal deposits. They are thin and extensive, often crammed with fossil shells. Whereas geosynclinal deposits for a single Upper Paleozoic period may total 3,000 to 18,200 metres (10,000 to 59,700 feet), shelf deposits that represent similar time intervals are only 300 to 1,800 metres (1,000 to 5,900 feet) thick. Frequently the shelves were emergent as low coastal plains or were submerged by only a few tens of feet as sea level changed or continents rose and fell.

The Upper Paleozoic is characterized by its diversity of sedimentary rock types, which fall into five categories (one formed on land, the other four, generally just above or below sea level): terrestrial desert deposits; marine salt deposits and coral reefs; coal measures; and glacial deposits. These special kinds of deposition are discussed below.

Deposition in arid regions

Pioneer geologists in Europe and eastern North America first distinguished the Upper Paleozoic by its red sandstones, which they divided into "Old Red Sandstone" and "New Red Sandstone." The sandstones commonly are coloured red by the oxidation of iron compounds. The sand grains are well rounded like those of present-day sand dunes. Associated beds consist of silt, with fish and plant remains. Cobbles and pebbles formed thick beds locally. Such rock groups may be matched today in mountainous deserts where depressions are occupied by lakes, and valley floors are covered by sand and crossed by ephemeral streams, loaded during floods with rubble from steep mountain sides. Five mountain basins were formed in Great Britain at the start of the Devonian by the Caledonian mountain-building episode, and somewhat similar elongated Devonian basins and uplands were formed in the eastern United States and Canada. The desert lands interfingered with normal marine sediments and river and tidal flat sediments in Ireland, Greenland, Norway, and Quebec.

Renewed uplift raised much of the sea floor above sea level, beginning in the Carboniferous of Europe and eastern North America and continuing into the Permian, in Antarctica, then India, then South America and Africa, and, finally, elsewhere in the world until only a few parts of the Tethys and Siberia remained submerged. Deserts covered most of this land area, apart from western Canada and northern Siberia.

Salt deposits and coral reefs

Before the final emergence of the sea floor by uplift, basins of seawater nearly were cut off from the sea. During the Devonian this occurred in the Michigan Basin and New Brunswick, and during the Permian the Zechstein (salt-stone) Sea of northern Europe formed, and the Delaware and Midland marine basins of Texas became severely constricted. Elsewhere, seas became so shallow that circulation became restricted, as in the Permian of the Russian Platform. Under warm conditions the water in these semienclosed areas became highly saline because of high rates of evaporation. Vast thicknesses of salt, such as sylvite, halite, and carnallite, were precipitated, yielding valuable resources of salt, sodium, and potassium. In Saskatchewan, Canada, there are 6,500,000,000 tons of potassium-rich salt of Devonian age. The complex histories of various basins and the geochemical relationships involved are detailed in the article EVAPORITES.

Coral reefs are deposits that are characteristic of shelf and miogeosynclinal deposits. They are formed by now extinct coral groups and marine plants. The coral islands, coral reefs, and atolls of Indonesia and the South Pacific are modern counterparts. Notable Late Paleozoic developments include the famous Devonian reefs of Alberta, Canada, which are rich in oil, and the Permian reefs of Texas and East Germany.

Some reefs grew to be tens to hundreds of miles long and hundreds of metres (thousands of feet) thick, showing that the growth of the reef kept pace with sea level, either because sea level rose, or the sea floor was slowly sinking. Many reefs, such as the Devonian examples of Germany and the Ural Mountains, grew on volcanic islands between the miogeosyncline and eugeosyncline. Others grew at the edge of the miogeosyncline or close to the Precambrian Shield, as in the Devonian of Alberta. The Permian reefs of Germany grew on folded Devonian rock around the edge of the Zechstein Sea.

Reefs, like desert deposits, have an interesting distribution in time and space (Figure 1). In the Devonian they occur as far north as Ellesmere Island and yet are absent from Africa south of the Sahara and from South America. They are especially abundant in the Middle Devonian, and very rare in the topmost Devonian Fammenian Stage. In the Lower Carboniferous they are restricted to England and a few other places where development is relatively feeble. They flourished again in the Lower Permian, especially Artinskian and lower Tatarian, before vanishing entirely.

Coal measures and glacial deposits

Special shelf deposits on areas close to sea level are coal measures, which form wherever vast amounts of vegetal matter have accumulated and have been buried and transformed by heat and pressure into coal (see COALS). Coal measures generally are rhythmic deposits called cyclothems (*q.v.*) and are made up of limestone and sandstone or shale as well as coal seams. Marine limestones intercalate the coal seams of Pennsylvania and Illinois showing that swampy forest regions, like those of Florida today, suddenly were invaded by the sea and were buried in shelly limestone. A withdrawal of the sea or infilling by sand and mud allowed the forest swamps to become re-established, and the rhythm was repeated many times. In Europe, the Carboniferous swamps often were buried by river-born sediment. Thus a very delicate oscillation of land and sea level was required to allow the forests to grow and then be buried.

Coals of the Upper Carboniferous are restricted to eastern North America, Europe, the U.S.S.R., and parts of China. In the Permian, vast coal deposits were formed in Siberia, India, Australia, Africa, and South America.

The most singular rocks of the Upper Paleozoic are glacial deposits (Figure 1). These rocks provide the best evidence for climatic change during the Upper Paleozoic. The earliest Upper Paleozoic glacial deposits are known from Brazil, in the western Maranhao Basin, of basal Devonian (Gedinnian, or Siegenian) age, with further deposits of possible Upper Devonian age. The deposits of tillite, consisting of boulders of diverse rock types scattered in a clay ground by ice (rock flour), are identical with tills formed by glaciers today. Finely layered shales, called varved deposits (*q.v.*), also are present; these are akin to varves formed in glacial lakes today. In addition, glacially striated pavements are found, where ice has ground over ancient rock and polished it smooth. In some outcrops are glacial bombs, which are boulders rafted by ice and suddenly released onto the underlying sediment on the sea floor or lake floor.

In the Upper Carboniferous such beds—in South Africa, east Australia, and South America—are more extensive than in the Devonian. The area covered by ice increased still further in the Lower Permian, when the rock record indicates that ice covered Africa up to the present Equator, the whole of Australia, east Antarctica, India–Pakistan into the Himalaya Chain (including Sikkim and Nepal), and South America east of the Andes. Younger glacial deposits, in the Middle and Upper Permian, are limited to eastern Australia, including Tasmania.

UPPER PALEOZOIC LIFE

The formation of extensive land masses with mountains and lakes at the outset of the Upper Paleozoic greatly increased the different kinds of dwelling places for life (Table 1). In response, plants and animals changed, in order to live out of water. A second only slightly less significant change was the development of cold regions, capped by ice, resulting in further diversification of life. Some forms adapted to cold conditions and others to warm; this had an important effect on the direction of evolution and the fossil record.

Plants. The simplest plants with woody tissue are of Upper Silurian age. They had erect shoots growing out rhizomes, with simple naked branching axes bearing terminal sporangia and no specialized leaves (*Cooksonia,*

Taeniocradia of the Rhyniophytina; see PSILOPSIDA). These plants persisted into the Devonian, and, with so much land and freshwater available, flourished and multiplied, especially by Siegenian times. One Early Devonian (Gedinnian) group had spikelike clusters of reniform sporangia (Zoosteophyllophytina), which evolved into the Lycophytina (*Protolepidodendron*) in the Siegenian (see LYCOPSIDA). The Trimerophytina (*Dawsonites*) arose in the Siegenian from the Rhyniophytina. Emsian times saw further ramification of groups, with the development of large leaves.

Carboniferous forests

Carboniferous plants flourished in extensive forests, and surviving relatives remain to this day, notably among the ferns. Other inhabitants of the forests included *Calamites* (Sphenopsida *q.v.*), related to scouring rushes, with whorls of slender simple leaves. Scale trees (Lycopsids) grew over 30.4 metres (100 feet) high, in a tall, slender trunk branching repeatedly near the top, forming a crown of stubby twigs with slender straplike leaves (*Lepidodendron*). Another kind, *Sigillaria,* had a thick high trunk with large bladelike leaves. *Cordaites* up to 36.5 metres (120 feet) tall, with leaves inches to 1.5–1.8 metres (5–6 feet) long and seeds in racemes, was a forerunner of conifers (*q.v.*).

In the Permian, the conifer group Voltziales (such as *Walchia*) gradually replaced *Cordaites,* and seed ferns (pteridosperms) became rare, dying out in the Jurassic. Scale trees perished by the end of the Permian Period. Primitive cycadeoids, which were related to the sago palm, became widespread, possibly arising in the Pennsylvanian. The onset of Permian glaciation encouraged the development of a specialized southern flora, typified by *Glossopteris* and *Gangamopteris,* with simple tongue-shaped leaves. The *Glossopteris* Antarctic flora penetrated as far as Siberia in the Middle Permian as well as into southern Asia but greatly declined at the end of the period.

Vertebrate life. Fish remains are rare before the Devonian, though known from Middle Ordovician. Sharks, known chiefly from teeth and fin scales, were common in Devonian seas. Some developed into the largest of Devonian animals, the Arthrodires, of which *Dinichthys* was over 6.08 metres (20 feet) long. Massive armour of bony plates over the head was hinged to the armour of the shoulder region of the body. This group died out by the end of the period. A significant development occurred in the Choanichthyes (also called Sarcopterygii, fleshy finned bony fishes), which are able to breathe air through openings in the roof of the mouth and thus survive in deserts when pools dry out. Of one branch, Dipnoi, five genera remain in deserts of the world. These bear weak fins and no true teeth. A second branch, the crossopterygian fishes (*q.v.*), had more highly organized limbs, giving greater mobility. An Upper Devonian example, *Eusthenopteron* from Escuminac, Gaspé Peninsula, Quebec, had sturdy fin bones, armour-plated head, and infolded teeth. This rhipidistid group of crossopterygian fishes gave rise to amphibians. The Late Devonian of Greenland has yielded skeletons 0.9 to 1.2 metres (three to four feet) long of crocodile-like amphibians called labyrinthodonts from the infolded enamel of their teeth. Nearly all Paleozoic amphibians belonged to this widespread extinct group. In the Carboniferous and Permian, the Amphibia developed considerable diversity, ranging from animals a few inches to ten feet long, and up to 226.5 to 271.8 kilograms (500 to 600 pounds) in weight, including such examples as *Eryops,* a stubby crocodile-like creature ten feet long, "with much belly and little leg, like Falstaff in his old age," according to T.H. Huxley.

Devonian amphibians

The renewal of desert conditions in the Permian gave further impetus to vertebrate evolution. The Amphibia were virtually at a dead end, because most of them were chained to the water for reproductive purposes. Even today, most of their young pass through a tadpole or swimming stage in water. They thus clung to river valleys and lake shores.

The key to future exploitation of the land lay with an offshoot that rapidly became more important and successful than the amphibia. This was the reptile, distinguished from the amphibian by its ability to lay eggs in desert conditions, from which the young emerged fully able to fend for themselves and independent of water. This greater degree of independence, achieved in the Late Carboniferous, saw a rapid expansion of the reptiles into various habitats. In the Permian some were agile like lizards (*Varanops*), some semiaquatic (*Limnoscelis*), others had thick legs and stubby tails. Some were carnivorous, others such as turtles were herbivorous, and others ate shellfish. The most bizarre kind, *Dimetrodon,* had a finback or sail of neural spines. One small group, the theriodonts of the order Therapsida, walked on two hind legs and had specialized teeth—incisors, canines, and molars. They were precursors to the mammals and some authorities consider that the mammals, or closely related forebears, also were present in Permian times.

Invertebrate life

Insects. One of the Late Paleozoic habitats awaiting invasion was the air. Vertebrate life had to await the following era before developing winged reptiles and birds. First to conquer the air were the insects, during Carboniferous times. From the coal measures of Upper Carboniferous age over 500 species are known, including giant dragonflies over two feet (.6 metres) across. Numerous other winged insects are found, together with spiders, scorpions, centipedes, and cockroaches, some as long as 7.62 to 30.48 centimetres (3 to 12 inches).

Marine invertebrate animals. Marine life was extremely varied by the close of the Lower Paleozoic and, unlike terrestrial animal and plant life, quite as diverse as today. It underwent moderate but not drastic change at the start of the Upper Paleozoic. The trilobites, most prolific animals in Early Paleozoic seas, continued their slow decline in numbers and perished in the Permian. The dominant Ordovician and Silurian fossils, called graptolites, persisted into the Devonian as a remnant. Ammonites, related to octopus, became prominent, arising in the Devonian and continuing through the Mesozoic Era, and brachiopods flourished, reaching a peak of diversity first in the Devonian, then again in the Permian. Other dwellers of the sea floor included bivalves, gastropods, and crinoids and corals, both compound corals, which built up sizable reefs, and solitary corals. Microscopic life was also abundant. One group of protozoans, the Foraminiferida (Foraminifera), developed the complex chambered, grain-shaped Fusulinacea, of great value to stratigraphers. Another, still mysterious in origin, formed millions of tiny fossils called coccoliths.

Some invertebrate life forms adapted to freshwater. A more significant development was the adjustment to cold marine waters such as those surrounding the southern ice cap of South America. By contrast, other life became adapted to tropical conditions. Animal life in warm tropical waters was greatly varied, in terms of numbers of orders and species and in morphology. Compared with life in cold waters, shells tended to be small, thin, and intricately ornamented and perhaps coloured as well, but colour is seldom preserved in fossils. These observations accord moderately well with present life, which is most diverse, numerous, and intricate at the Equator and least diverse at the poles.

One of the most exciting and ironic aspects of evolution in the Upper Paleozoic is that the high degree of specialization entailed in adaptation for warm or cold conditions did not pay off in the expected way. A sudden twist to Earth history almost ended in disaster for all life.

SEQUENCE OF FAUNAL CHANGES

The southern cold-water fauna developed first in the Devonian of South America, and by Emsian times some distinctive elements had entered Tasmania, New Zealand, and Antarctica. In the north, by contrast, coral reefs had begun to grow. The waters became much warmer in Eifelian times, to judge from the entry of northern species of brachiopods from North America into South America, the disappearance of the characteristic tillites, and the widespread development of coral reefs in Canada, western Australia, Siberia, the Urals, Europe, and North Africa (Figure 1). Near the close of the Devonian, coral reefs disappeared from most of these areas, and with them

Climatic changes

perished many brachiopods, trilobites, and other forms.

Two explanations of this drastic change have been suggested. Some authorities attribute it to a sudden exposure to ultraviolet light or increase in radioactivity due to mountain building or the impact of a huge meteor that crashed into the earth and raised enormous tidal waves that swept the seas. A less dramatic and perhaps more realistic suggestion is that profound refrigeration occurred, sufficient to kill off many of the warm-water-loving animals, especially coral reefs. Support for this is provided by the recognition of uppermost Devonian tillites in South Africa.

Coral reefs were slow to develop and seldom were prominent in the Carboniferous Period, but there is no strong evidence for refrigeration in the Lower Carboniferous, perhaps because the record is poor for this period in Africa and South America. In the Upper Carboniferous, glaciation covered east Australia, South Africa, and South America, leaving typical glacial rocks and strongly affecting marine life in the surrounding seas. The Northern Hemisphere also was affected: at least in the Yukon of Canada, where a sudden cold phase chilled the waters and changed the fossils in the Bashkirian and again in the late Moscovian.

The major surge of ice occurred in the basal Permian. Ice scraped rock bare and left glacial deposits over South America, Africa, Antarctica, and Australia and moved north in the Indian subcontinent. Simultaneously, cold-water life flourished in neighbouring seas and invaded the northerly waters of Siberia, Alaska, and Canada in force. Warm-water life was forced to retreat to equatorial waters and became threatened with complete extinction. Gradually conditions warmed, the ice melted, and warm-water life was saved to flourish again, eventually to enter a second great phase of reef building, second only to the Middle Devonian, especially in Asia, Texas, Canada, and Russia. These reefs were killed by a second Permian glacial episode, a second flourishing of cold-water life, and constriction of warm-water life. But this time the glacial phase was of lesser extent, ice covering only eastern Australia. A second prolonged warm period followed, but reefs were restricted to Asia, Texas, and Germany, because by then Russia and Arctic Canada had become land. A third short-lived cold phase in the Upper Permian formed tillites in Tasmania and New South Wales and encouraged a short-lived boost for cold-life forms. Then the crisis approached. There would be no further glaciation for at least 100,000,000 years. Life adapted to cold waters appeared to be doomed, and a great deal of life was doomed. The end of the Paleozoic Era was the greatest crisis in life history. There were few major groups that were not at least halved in variety, not to mention numbers. Among marine invertebrate life, Fusulinacea, half the Bryozoa, many ostracods, half of the insect life, corals (including reef builders), most of the elaborate brachiopods, most of the ammonites, all trilobites, many crinoid orders, and all blastoids perished completely. Life that changed but survived included Radiolaria; Foraminifera; sponges; half the Bryozoa; inarticulate, loop, and spire-bearing brachiopods; chitons; gastropods; bivalves; nautiloids; conodonts; and the echinoderm groups Ophiuroidea, Stelleroidea, and Holothuroidea, most of these being minor groups. Even within these groups a great number of species and genera perished.

Mass extinctions

Among the fish, many had perished in the Devonian, and some in the Carboniferous, with no outstanding death toll in the Permian, though half the bony fish of class Actinopterygii died. Many new groups appeared in the Triassic.

Land animals suffered more. Of the labyrinthodonts, order Anthracosauria, including the mainly tropical embolomeres, perished entirely, and the Rhachitomi (suborder including *Eryops*) were greatly reduced. Over half of the reptile orders died, according to A.S. Romer. Cotylosauria and subclass Synapsida were greatly reduced, and almost all Archosauria died. Norman D. Newell calculated that 75 percent of the amphibian families and over 80 percent of the reptile families had disappeared by the end of the Permian.

Some of the survivals of the era tell us little. Animals such as fish and reptiles were so mobile that they were able to flee from disaster areas and chance upon a refuge. More significant is what happened to more sedentary animals. The life that died was, on the whole, the tropical life, not the cold-water life. The compound corals, and many of the life forms that lived on them, died. The warmwater Fusulinacea and the elaborately decorated and evolved brachiopods all died. But they did not die because it became too cold. They were not exterminated by competition with cold-water life. There is no evidence for any glaciation except the minor affair in the Late Permian. There probably was a great increase in temperature in the uppermost Permian until conditions became too hot, especially in the tropics, for a great deal of life to exist; this is the simplest explanation that is compatible with the available evidence.

Warming effects

STRATIGRAPHIC CORRELATION OF UPPER PALEOZOIC UNITS

The correlation of Upper Paleozoic deposits, like those elsewhere in the geological record, depends on many variables and can be attempted by several methods.

The most important boundaries involved lie at the base and top of the Upper Paleozoic, and these have undergone change in recent years. The lower boundary has long been controversial because early workers never precisely defined it, and, as a result, their ideas changed from time to time. An international subcommission of geologists decided to fix the boundary at the base of the graptolite *Monograptus uniformis Zone*. This marks an arbitrary boundary, with the species, rather than genera, differing above and below.

The upper boundary also has been controversial. Pioneers again failed to fix a boundary, which lies somewhere in terrestrial beds without marine fossils. Marine successions that cross the boundary into the Triassic are extremely rare and are restricted to Armenia, Iran, and South China. Basal Triassic is well developed in Arctic Canada and Nevada, and uppermost Permian in New Zealand. In spite of the well-marked faunal change between the Permian and Triassic, a number of American, Australian, British, Japanese, and Soviet workers have inadvertently included Triassic rocks in their Permian systems thereby masking the differences. Chinese, New Zealand, and Canadian workers have brought out the faunal difference through worldwide studies, and their work apppears to be becoming more widely accepted by American and Soviet authorities.

Boundaries between the periods are arbitrary (Table 2). In many ways the uppermost Devonian Stage, the Famennian, has strong links with the basal stage, Tournaisian Stage of the Carboniferous, and the exact boundary, still unfixed, will be placed by consensus rather than on any strong faunal change. The same is true of the base of the Permian. The Upper Carboniferous or Pennsylvanian faunas closely resemble Lower Permian faunas, and the boundary between the two is now placed by investigators of ammonites at the base of the Asselian. Some workers on Fusulinacea prefer a higher base and include the Asselian in the Upper Carboniferous.

UPPER PALEOZOIC ENVIRONMENTS

The curious distribution of Upper Paleozoic rocks has been one of the prime sources of evidence in support of the theory of continental drift, which claims that continents have shifted their position relative to each other through time. Geologically there are at least three independent lines of evidence to suggest that the continents and oceans were differently disposed during the Upper Paleozoic Era (see PALEOGEOGRAPHY). Most striking is the occurrence of glacial deposits in the "southern continents" of Antarctica, Africa, Australia, South America, and the subcontinent of India. One would expect to find corresponding glaciation around the North Pole, but there is none.

The distribution of lands and seas

A second line of evidence lies in the similarity of Upper Paleozoic rocks along both shores of the Atlantic Ocean, both having had a similar history. In the past many have proposed that the two were linked by continents, or land

bridges, now foundered beneath the waves. But geophysical evidence shows that no such bridges existed. It is presently believed that the rocks lay close together in the Upper Paleozoic Era and since that time have been torn apart.

A third kind of evidence is based on the quality and diversity of marine and terrestrial Paleozoic life, which strongly suggests that the tropics then lay well north of their present position in Africa, Asia, and North America. Upper Paleozoic coral reefs are now concentrated at 30°–40° north of the Equator in Central Asia, Europe, and North America. It seems likely that the reefs formed near the Equator and then were moved north with the rest of the land. Marine and terrestrial animals also show a peak of diversity in the same regions, suggesting tropical conditions. Thus the distribution of fossil life, like glacial rocks, suggests a northward movement of both North America and Central Asia and Europe of some 35° latitude since the Permian.

Paleomagnetic evidence, which records the former position of the magnetic, and therefore probably the geographic poles, also suggests continental drift (Figure 2). There is particularly good agreement from all lines

From E. Irving, *Paleomagnetism and Its Application to Geological and Geophysical Problems* (1964); John Wiley & Sons, Inc., New York

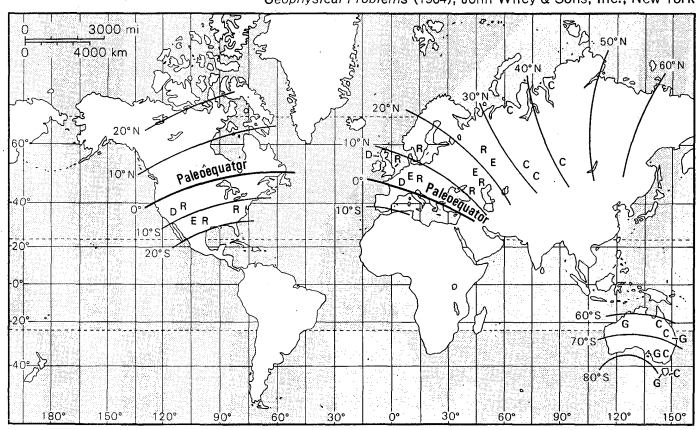

Figure 2: *Ancient latitudes of continents in Permian times.* C=coal deposits; D=desert sands; E=evaporites; G=glacial deposits; and R=red beds.

of evidence for Europe and Australia, two of the most closely studied regions. According to sedimentary, volcanic, paleontologic, and paleomagnetic evidence, Europe and North America lay in contact during Upper Paleozoic times, with the Equator passing through south Europe. According to similar evidence, Australia moved south in Upper Carboniferous times to lie close to the South Pole, placed close to Tasmania. Considerable paleomagnetic data supports the paleontologic and geological evidence that South Africa, India, and South America lay close by.

Igneous activity

Two kinds of volcanic and igneous activity may be distinguished in the Upper Paleozoic record. One accompanied the formation of geosynclines and is indicative of pulling apart of continents either at the edge of oceans (Tethys, Cordilleras) or within continents (Urals). Typically the volcanoes are basaltic in composition, like the lavas of Hawaii or Iceland, and these have poured out in great volume. They occur along the western and southern side of Carboniferous and Permian eugeosynclines, extending from New Zealand through the Himalayas into Europe, and along the geosynclines of British Columbia and the western United States. The extrusion of these lavas was accompanied by the intrusion at depth by chemically identical, more coarsely crystalline, rocks, such as gabbro. Other associated rock types are peridotite, dunite, and serpentinite, ultramafic rocks that probably formed as a heavy fraction from the basalt lavas, either during or before their extrusion. Examples include the ultramafics of the Urals (Devonian 360,000,000 to 380,000,000 years old), the Carboniferous or Permian "Great Serpentine Belt" of New South Wales, and the Kazanian Ultramafic Belt of New Zealand.

The second major kind of igneous and volcanic activity arose from the convergence rather than divergence of continents, in which one continent overrode another or so converged that piles of sediments in geosynclines were squeezed together and forced up into mountains and down deep into the earth. Under pressure and heat, such sediment and volcanics melted and then forced their way up to the surface as molten rock. During the mid-Devonian Acadian disturbance of eastern North America, intermediate to acid lavas and ash showers (rhyolites, ignimbrites—fire stones) were poured out in southern Quebec, Gaspé, New Brunswick, and Maine. The deep-seated roots of these volcanoes are exposed as granites in New England and Nova Scotia. Similar granites are exposed on the opposite side of the Atlantic Ocean in Cornwall and Brittany.

Orogeny

In Europe the Upper Paleozoic Era was ushered in by a drastic change in geography. Lower Paleozoic seas and lands were changed as geosynclines were raised into mountains called the Caledonides across Great Britain and Norway.

In eastern North America, on the other hand, the mountain building occurred a little later as the Acadian disturbance. A mountain range over 160.9 kilometres (100 miles) wide, from which great deltas grew westward in the Middle and Upper Devonian (Catskill Delta), formed from Newfoundland to Cape Hatteras or perhaps as far south as Florida.

Upper Mississippian disturbance was widespread in North America, forming mountains in the Appalachians and the Ouachita Mountains of Arkansas, Oklahoma, and Colorado. Red sandstones were deposited in the Yukon region of Canada. Grits (coarse sands) formed widely in Britain, and the Armorican and Hercynian mountains developed across northwest Europe with culmination of the upheaval at the end of the Carboniferous. Uplift also occurred in New Mexico, Texas (Marathon Uplift), the central interior of the United States, western Canada, eastern Australia, and the Himalayas. Sedimentation and volcanism were most continuous in the Arctic areas of Canada and Siberia and in the Urals, China, and New Zealand.

The Permian is particularly noted for its extensive land areas. During the Permian the seas steadily retreated from all continents, commencing with southern Africa and South America. The early Permian saw extensive submergence, apart from mountainous areas in Europe, followed by widespread deltaic conditions and the formation of coal swamps in the south. Emergence occurred in Australia, Antarctica, India, South Africa, South America, and even Siberia and China, and seas in the Urals, Arctic, and western Canada became considerably shallower. A second submergence of Australia occurred, followed later by similar events in the Urals. Finally, there was widespread emergence of North America, Australia, most of the Uralian area, Europe, and most of Siberia, leaving only parts of Texas, Mexico, the Cordilleran Geosyncline, eastern Siberia, and the Tethys submerged. Only parts of Tethys remained underwater in the last phase of the Permian, however, and even this area probably was briefly emergent.

Palermo

From its foundation by Phoenician traders in the 8th century BC, Palermo (ancient Panormus) has stood as one of the principal cities of Sicily. During the Middle Ages its subjection to successive conquerors and dynasties made it one of the most cosmopolitan cities of the Mediterranean world. The modern city, the capital of the autonomous region of Sicily in the Italian Republic, lies on the northwestern coast at the head of the Bay of Palermo, facing east. Behind the town is a fertile plain, the Conca d'Oro, backed by mountains.

The ancient city

History. The Phoenician city was established along a tongue of land between two former streams to the north and south of the present Via Vittorio Emanuele, and from the beginning Palermo linked its fortunes to its port. The Carthaginians inherited the Phoenician settlements in Sicily in the 5th century BC, and Palermo's thick walls and easy provisioning from the sea secured its independence from the Greeks in Sicily. Romans, however, conquered Palermo in 254 BC after a long siege in the First Punic War. The Roman emperor Augustus (ruled 27 BC–AD 14) established a Roman colony there, but under the empire the city underwent a gradual decay.

A Vandal chieftain, Gaiseric, took Palermo in AD 440 and made it the centre of his repeated raids throughout Sicily. In 476 the city, with the whole of the island, was ceded to Odoacer (Odovacer), the barbarian king of Italy. Palermo prospered mildly under the Ostrogoth kingdom of Theodoric, who had replaced Odoacer on the peninsula. The city was rejoined to the empire by Emperor Justinian's celebrated general Belisarius in 535 and under the Byzantines became the second city of the island, exceeded in political importance only by the capital, Syracuse.

The Arabs conquered Palermo in 831 and made it the capital of the emirate of Sicily. The city prospered under Muslim rule as an emporium of the rich trade with North Africa. Palermo was divided into five new districts, and its population was swelled by merchants from all over the Mediterranean—including many from the maritime cities of Italy. New agricultural techniques were introduced, and luxuriant gardens were planted in the Conca d'Oro.

Thus Palermo was already a flourishing metropolis when it fell to the Norman adventurers Roger I and Robert Guiscard in 1072. But the Norman era (1072–1194) is Palermo's real "golden age," particularly after the foundation of the Norman kingdom of Sicily in 1130 by Roger II. Greeks, Arabs, Jews, and Latins worked together with singular harmony and gave rise to a composite culture of remarkable vitality. The courts of the Norman kings attracted such diverse talents as the Arab poet and geographer Idrīsī, the Byzantine scholar Doxapater, and an Anglo-French man of letters, Peter of Blois. A distinctive Arab–Norman architecture is represented by the Cathedral, founded in 1185 by Gualterio Offamilio (Walter of the Mill) sent to Sicily by the English king Henry II as tutor to William II. From the same period date the Palazzo Reale (Royal Palace), the churches of San Giovanni degli Eremiti (1132) and the Martorana (1143), and several country palaces around the city such as the Cuba and the Zisa.

Palermo's "golden age"

Alinari

Norman rule in Sicily was replaced by that of the German Hohenstaufen dynasty with the crowning of the Holy Roman emperor Henry VI as king of Sicily on Christmas Day 1194. Henry's son, Emperor Frederick II (Frederick I of Sicily), shifted the focus of imperial politics to southern Italy and Sicily, and the cultural brilliance of his court at Palermo was renowned throughout western Europe. But Frederick's reign inaugurated a long period of economic decline. The population dwindled, mostly owing to Frederick's mass deportation of Arabs. Building was neglected, and commerce waned despite Frederick's attempts to force immigration from inland towns and to encourage settlement by Italian merchants. Palermo nevertheless supported the Hohenstaufen cause in Sicily until the last Hohenstaufen claimant to the Sicilian throne, Manfred, was crushed by the French Charles of Anjou in the Battle of Benevento in 1266.

Charles punished Palermo's pro-imperial stance by moving the capital of his new kingdom in Naples-Sicily to Naples. Further, he increased taxes and quartered French troops in the city. Popular resentment of Angevin oppression exploded in 1282 in the so-called Sicilian Vespers, in which the French garrison at Palermo was massacred, signalling the beginning of an uprising that within the year achieved the expulsion of the French from all Sicily.

The Sicilian Vespers

A parliament held in Palermo in 1282 invited Peter III of Aragon to the throne. Peter restored the city as the capital of Sicily, but the continuing war with the Angevins in Naples, combined with factional disputes among the Sicilian nobility, undermined royal authority and accelerated Palermo's economic decay. Throughout the 14th century, Palermo, under Aragonese rule, had to struggle hard to keep its predominance over the rival city of Messina.

After 1412 the crown of Sicily was united with that of Aragon (and later Spain), and, with the accession of Alfonso V of Aragon (I of Sicily) in 1416, Palermo took on a new aspect of prosperity. In the 16th and 17th centuries, Spanish viceroys such as Pignatelli, Colonna, Maqueda, and Toledo fostered the reconstruction of the city. Two large intersecting roads redefined the city, and modern squares, such as the Quattro Canti, and churches such as Santa Maria della Catena, Santa Maria di Porto Salvo, La Pietà, Santa Teresa, Santa Caterina, Casa Professa, San Giuseppe dei Teatini, San Domenico, L'Olivella and La Gancia bear witness to the prosperous era of the viceroyalty. But the splendid appearance was belied by repeated risings of the urban poor in the 16th and 17th centuries. The most famous of these was the revolt of 1647, led by the goldbeater Giuseppe d'Alessi and backed by the city's tanners, that threatened Spanish rule throughout Sicily.

In the wake of the War of the Spanish Succession (1701–14), Palermo passed for a short time under the rule of Victor Amadeus II of Savoy and, after 1718, of the Austrian Habsburgs. In the resettlement of Europe

after the Napoleonic Wars, Sicily-Naples was given to the Spanish Bourbons. Revolts against Bourbon rule erupted in Naples in 1820 and 1848; and in 1860 Garibaldi liberated the city. Attached to the newly reformed Kingdom of Italy, Palermo recovered its prosperity and soon expanded beyond its ancient walls.

The modern city. A few public buildings such as the post office were built under the Fascists, and the city suffered severe bombing damage in July 1943, when it was taken by Allied troops. In 1948 regional autonomy was granted to Sicily within the Italian Republic, and Palermo was restored as the leading city on the island. The population leaped from 150,000 to 600,000 and new industries developed in manufacturing, chemicals, and printing; but the problems of endemic poverty in the older parts of the city are still alive. The new port runs both merchant and passenger lines to Tunisia and Naples and handles a lively mercantile trade with the United States, Canada, and Germany. Citrus fruits, cereals, fresh fish, and chemicals are among Palermo's principal exports.

Palestrina

The most celebrated composer of the mid-16th century, Giovanni Pierluigi da Palestrina lived during the period of the Catholic Counter-Reformation and was a primary representative of the 16th-century conservative approach to church music. His music, noted for its transparent serenity, spiritual quality, and careful balancing of consonance and dissonance (the repose and tension of harmonies), is based on the contrapuntal style (*i.e.*, using counterpoint, or interwoven lines of melody) of the Franco-Flemish school of composition, which dominated Renaissance music. Palestrina's music was long taken as a standard of traditional Roman Catholic liturgical music, even by 18th- and 19th-century writers not truly acquainted with his musical traditions.

Life. Palestrina was born about 1525 in the town of Palestrina, near Rome, where his ancestors are thought to have lived for generations. His latinized signature, Joannes Petrus-Aloysius Praenestinus, was taken from Praeneste, the ancient Roman name for Palestrina.

As a child he went to Rome. In 1537 he was one of the choirboys at the basilica of Sta. Maria Maggiore, where he also studied music between 1537 and 1539. In 1544 Palestrina was engaged as organist and singer in the cathedral of his native town. His duties included playing the organ, helping with the choir, and teaching music. His pay was that of a canon and would have been received in money and kind. His prowess at the church there attracted the attention of the bishop, Giovanni Maria Ciocchi del Monte, who later became Pope Julius III.

In 1547 Palestrina married Lucrezia Gori. Three sons were born to them: Rodolfo, Angelo, and Iginio. Only the last outlived his father. In 1551 Palestrina returned to Rome, where he assumed the first of his papal appointments, as musical director of the Julian Chapel choir, and thus was responsible for the music in St. Peter's. Before he was 30 he published his first book of masses (1554), dedicated to Julius III, and the following year he was promoted to singer in the Pontifical Choir. About this time he became composer to the papal chapel. Palestrina repaid the pope's patronage by composing a mass in his honour. Yet he did not neglect the secular side of his art,

for his first book of madrigals (secular and spiritual partsongs) appeared in 1555, unfortunately at a time when the lenient regime of Julius III had given way to the sterner discipline of Paul IV. A decree of the new pope forbade married men to serve in the papal choir, and Palestrina, together with two of his colleagues, received a small pension by way of compensation for their dismissal.

For the next five years Palestrina directed the choir of St. John Lateran, but his efforts were continually thwarted by singers whose quality was almost as limited as their number, which was restricted because very little money was available for music. Nevertheless, he gained admission for his eldest son, Rodolfo, then about 13, as a chorister. Eventually he broke away from this uncongenial milieu. The chapter archives of St. John Lateran record that in July 1560 he and his son suddenly departed.

A year passed before Palestrina found employment. In March 1561 he accepted a new post at Sta. Maria Maggiore. This post was more congenial to him and he remained at it for about seven years. At the invitation of Cardinal Ippolito d'Este he then took charge of the music at the Villa d'Este in Tivoli, a popular summer resort near Rome. He was in the cardinal's service for four years, at which time he also worked as music master for a newly formed Seminarium Romanum (Roman Seminary), where his sons Rodolfo and Angelo became students.

Palestrina received an offer in 1568 to become musical director at the court of the emperor Maximilian II in Vienna. He refused the position because of the low salary and a disinclination to leave Rome. Palestrina's terms were also too high when he was invited to the court at Mantua in 1583. The composer, however, and the duke of Mantua, Guglielmo Gonzaga, an amateur musician of some pretensions, did become friends, and Palestrina was commissioned to write special compositions for the ducal chapel of Sta. Barbara.

Return to St. Peter's

With the death in 1571 of the composer Giovanni Animuccia, musical director at the Vatican since 1555, there was a chance for Palestrina to return to his old post as musical director of the Julian choir. The chapter, eager to have him back, increased the salary, and he forthwith returned to St. Peter's. When his growing fame as a composer prompted Sta. Maria Maggiore to rehire him, St. Peter's again raised his salary. In acknowledgment of his position as the most celebrated Roman musician, he was given in 1578 the title of master of music at the Vatican Basilica.

The series of epidemics that swept through central Italy in the late 1570s carried off his wife and his two elder sons, both of whom showed great musical promise. He

himself fell seriously ill. Grieving over his wife's death, he announced his intention of becoming a priest, to the delight of the pope, Gregory XIII. After having been made a canon, however, he renounced his vows in order to marry (1581) Virginia Dormoli, widow of a wealthy merchant. Although he spent considerable time administering her fortune, he retained his position at St. Peter's and continued to compose.

Although an attempt in 1585 to make Palestrina musical director of the Pontifical Choir proved abortive, he was considered by all the popes under whom he served as the official composer for the choir, and it is recorded that he marched at the head of the pontifical singers on the occasion of erecting the great Egyptian obelisk in the piazza of St. Peter's.

Pope Gregory XIII had commissioned Palestrina and Annibale Zoilo to restore the plainchant, or plainsong (a traditional liturgical chant sung in unison), then in use to a more authentic form. The task proved too great, and Palestrina's editorial work gave way to a flow of creative music. Much of it was published during the last 12 years of his life, including volumes of motets (choral compositions based on sacred texts), masses, and madrigals. He also helped to found an association of professional musicians called the Vertuosa Compagnia dei Musici.

Two years before Palestrina's death, the new pope, Clement VIII, increased his pension; and the same year, in a singular mark of respect and admiration, fellow composers paid their elderly senior the compliment of writing 16 settings of the Vesper Psalms to his praise. In return, Palestrina sent them a motet on the appropriate text: *Vos amici mei estis* "You are my friends, if you do what I teach, said the Lord." In January 1594 he was taken ill, and he died on February 2, in Rome.

Music. Palestrina's musical output, though vast, maintained a remarkably high standard in both sacred and secular works. His 105 masses embrace many different styles, and the number of voices used ranges from four to eight. The time-honoured technique of using a cantus firmus (pre-existent melody used in one voice part) as the tenor is found in such masses as *Ecce sacerdos magnus*; *L'Homme armé*; *Ut, re, mi, fa, sol, la*; *Ave Maria*; *Tu es Petrus*; and *Veni Creator Spiritus*. These titles refer to the source of the particular cantus firmus. Palestrina's mastery of contrapuntal ingenuity may be appreciated to the fullest extent in some of his canonic masses (in which one or more voice parts are derived from another voice part). His ability to ornament and decorate a solemn plainchant, making it an integral part of the texture and sometimes almost indistinguishable from the other, freely composed parts, is evident from some of his masses based on hymn melodies.

The masses

By far the greatest number of masses employ what has come to be known as the parody technique, by which a composer made use either of his own music or that of others as a starting point for the new composition. Many other masses derive from musical ideas by Palestrina's predecessors or contemporaries. Yet another type of mass is demonstrated by the nine works written for Mantua; in these the Gloria and Credo sections are so arranged that plainsong and polyphony alternate throughout. Finally, there is a small but important group of masses that are in free style, the musical material being entirely original. Perhaps the best-known example is the *Missa brevis* for four voices.

Palestrina's motets, of which more than 250 are extant, display almost as much variety of form and type as do his masses. Most of them are in some clearly defined form, occasionally reflecting the shape of the liturgical text, though comparatively few are based on plainsong. Many of them paraphrase the chant, however, with an artistry that is every bit as successful as that of the masses. On the same level as the canonic masses are such motets as *Cum ortus fuerit* and *Accepit Jesus calicem*, the latter apparently a favourite of the composer's—an assumption justified because he is depicted holding a copy of it in a portrait now in the Vatican.

His 29 motets based on texts from the Song of Solomon afford numerous examples of "madrigalisms": the use of suggestive musical phrases evoking picturesque features, apparent either to the ear or to the eye, sometimes to both. In the offertories, Palestrina completely abandons the old cantus firmus technique and writes music in free style, whereas in the hymns he paraphrases the traditional melody, usually in the highest voice. In the *Lamentations of Jeremiah* he brings effective contrast to bear on the sections with Hebrew and Latin text, the former being melismatic (floridly vocalized) in style and the latter simpler and more solemn. His Magnificats are mainly in four sets of eight, each set comprising a Magnificat on one of the eight "tones": *alternatim* structure is used here as in the Mantua masses.

Although Palestrina's madrigals are generally considered of less interest than his sacred music, they show as keen a sense for pictorial and pastoral elements as one finds in any of his contemporaries. Over and above this, he is to be remembered for his early exploitation of the narrative sonnet in madrigal form, notably in *Vestiva i colli*, which was frequently reprinted and imitated. His settings of Petrarch's poems also are of an exceptionally high order.

Palestrina's reputation

At the end of the 19th century the view that Palestrina represented the loftiest peak of Italian polyphony was in some ways detrimental to his reputation, for it cast his music into rigid preconceptions. Even more unfortunate was the insistence on "counterpoint in the style of Palestrina" in the examination requirements of academies and universities, for such requirements stultified a style that Palestrina had used with great flexibility. Generations of fledgling composers were taught to revere the music of Palestrina as a symbol of all that was pure in ecclesiastical counterpoint. Indeed, the greater part of his musical output, and in particular his masses (where his unerring sense of tonal architecture may be heard at its best), still remains worthy of admiration.

Palestrina, unlike Bach, did not have to be rediscovered in the 19th century, though the dissemination of his achievement was helped by the interest of the Romantic composers. There always was a Palestrinian tradition, mainly because his music supplied the need for a well-regulated formal system to be used for the embryonic composer in presenting himself to the unknown musical world. Strict counterpoint was associated with a technique acquired in this way. It became a standard type of musical discipline that, however, gradually moved farther and farther away from its progenitor. In his day, Palestrina was a senior figure who, utilizing the dominant musical style of his time, created works notable for their spiritual qualities and technical mastery.

MAJOR WORKS

MASSES: 105 masses, including *Ecce sacerdos magnus* (published 1554), *De Beata Virgine* (1567), *Papae Marcelli* (1567), *L'Homme armé* (1570), *Lauda Sion* (1582), *O magnum mysterium* (1582), *Aeterna Christi munera* (1590), *Jam Christus astra ascenderat* (1590), *Dum complerentur* (1599), *Tu es Petrus* (1601), *Veni Creator Spiritus* (1888).

MOTETS: More than 250, for 4, 5, 6, 7, 8, and 12 voices, including a set of 29 motets based on the Song of Solomon (1584); *Assumpta est Maria* (1572); three settings of *Alma Redemptoris Mater*; three settings of *Lauda Sion*.

MADRIGALS: Spiritual madrigals for three, four, and five voices; secular madrigals for various voices.

OTHER VOCAL MUSIC: including 68 Offertories, 13 complete sets, Lamentations, 12 Litanies, 20 Psalms, 35 Magnificats (mainly in four sets of eight, each set comprising a work on one of the eight "tones").

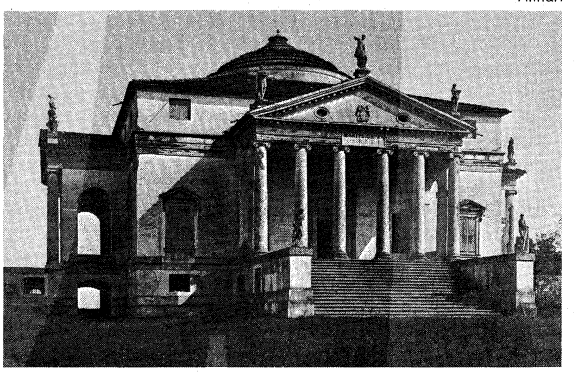
BIBLIOGRAPHY. HENRY COATES, *Palestrina* (1938), is the standard English-language study of the life and works of Palestrina and contains a complete list of works. JEROME ROCHE, *Palestrina* (1971), is a brief, up-to-date biography useful for new details about Palestrina's life. Information on more recent discoveries also appears in the excellent section on Palestrina in GUSTAVE REESE, *Music in the Renaissance*, rev. ed. (1959). KNUD JEPPESEN, *Der Palestrinastil und die Dissonanz* (1925; Eng. trans., *The Style of Palestrina and the Dissonance*, 2nd ed., 1946, reprinted 1970), is a specialized but thoroughgoing study of the technical aspects of the composer's contrapuntal style.

(D.W.S.)

Palladio, Andrea

The greatest architect of 16th-century northern Italy, Andrea Palladio is also one of the most influential figures in the whole development of Western architecture. The qualities that made him influential were numerous and varied. His palaces (*palazzi*) and villas were imitated for 400 years all over the Western world; he was the first architect to systematize the plan of a house and consistently to use the ancient Greco-Roman temple front as a portico, or roofed porch supported by columns (this was probably his most imitated architectural feature), and finally, in his *I quattro libri dell'architettura* (*Four Books on Architecture*), published in 1570, he produced a treatise on architecture that, in popularizing classical decorative details, was possibly the most influential architectural pattern book ever printed.

Alinari



Villa Rotonda, near Vicenza, Italy, by Andrea Palladio, 1550–51.

Palladio was born November 30, 1508, in Padua, in the Italian province of the Veneto, where, as a youth, he was known by his christened name of Andrea di Pietro della Gondola. He was apprenticed to a sculptor in Padua until, at the age of 16, he moved to nearby Vicenza and enrolled in the guild of the bricklayers and stonemasons. He was employed as a mason in workshops specializing in monuments and decorative sculpture in the style of the Mannerist architect Michele Sanmicheli of Verona. There were at the time no classical buildings of note in Vicenza, the Veneto having been badly disturbed by wars until the 1530s.

Early works in the Veneto. Between 1530 and 1538 Count Gian Giorgio Trissino, a Humanist poet and scholar, was rebuilding his villa at Cricoli outside Vicenza in the ancient Roman, or classical, style. Andrea, working there as a mason, was noticed by Trissino, who undertook to expand his practical experience with a Humanist education. The Villa Trissino was rebuilt to a plan reminiscent of designs of Baldassarre Peruzzi, an important High Renaissance architect. Planned to house a learned academy for Trissino's pupils, who lived a semi-monastic life studying mathematics, music, philosophy, and classical authors, the villa represented Trissino's interpretation of the ancient Roman architect and theorist Vitruvius (active 46–30 BC), whom Palladio was later to describe as his master and guide. The name Palladio was given to Andrea, after a Humanist habit, as an allusion to the mythological figure Pallas Athena and to a character in Trissino's poem "Italia liberata dai goti." It indicates the hopes Trissino had for his protégé.

Patronage of Trissino

At the Villa Trissino, Palladio met the young aristocracy of Vicenza, some of whom were to become his patrons. By 1541 he had stylistically assimilated the Mannerist works of Michele Sanmicheli and the High Renaissance buildings of Jacopo Sansovino, whose library of St. Mark's in Venice had been begun in 1536. He had probably been introduced in Padua to Alvise Cornaro, whose designs were the first to import the Roman Renaissance style to northern Italy. Palladio may also have met a prominent Mannerist architect and theoretician, Sebastiano Serlio, who was in Venice at that time and whose third and fourth books on architecture (*L'Architettura;* 1537 and 1540) were to be an inspiration to him.

In about 1540 Palladio designed his first villa, at Lonedo for Girolamo de' Godi, and his first palace, in Vicenza for Giovanni Civena. The Villa Godi has a plan clearly derived from the Villa Trissino but with similarities to traditional Venetian country houses. It contains all the elements of Palladio's future villa designs, including symmetrical flanking wings for stables and barns and a walled courtyard in front of the house. In elevation the Palazzo Civena is close to the High Renaissance palace type developed in the early 16th century in Rome. In plan it resembles Sanmicheli's Palazzo Canossa (*c.* 1535) in Verona. An innovative feature is the use of traditional arcaded pavement of northern Italy behind the main elevation, an idea that Palladio reinterpreted in imitation of an ancient Roman forum.

Visits to Rome and work in Vicenza. In 1541 and again in 1547 Palladio visited Rome with Trissino. These visits greatly affected his palace designs. On them, he saw the work of the greatest architects of the Roman High Renaissance style, Donato Bramante, Peruzzi, and Raphael, generally more remembered for his painting than for his architecture. He also measured ancient Roman antiquities, notably the baths. Palladio's principal ideas on palace design were formed between his first works of 1540 and his visit to Rome in 1554–56.

In 1546 Palladio prepared designs for the reconstruction of the 15th-century town hall in Vicenza, known since then as the Basilica, and in 1548 these plans were accepted, though much earlier designs, drawn in 1534 by the Mannerist architect and painter Giulio Romano and by several other distinguished architects, had been previously rejected. This was his first major public commission, and the work, which was not actually finished until 1617, involved recasing a vast hall with a two-story arcade of white stone to serve as a buttress to the old structure. Suited to both the Gothic style of the original structure and the dimensions of the classical orders, Palladio's arcade was of great proportional subtlety. The architectural motifs used were taken from Serlio and from Sansovino's library of St. Mark's in Venice. Up to 1556 Palladio produced three basic palace types. The first, in 1550, was the Palazzo Chiericati, in which he extended his Palazzo Civena forum idea of a block with its axis parallel to the pavement, which it envelops in a loggia, or roofed open gallery. The tripartite division of the colonnaded elevation, which gives the building a definite central focus, was an innovation. The second, in 1552, was seen in the Palazzo Iseppo Porto, Vicenza, in which he stated in its clearest form his reconstruction of a Roman house. The facade was closely based on the Roman Renaissance palace type, such as Bramante's House of Raphael (*c.* 1514), which Palladio had drawn in Rome. But it was planned in what Palladio believed to be the ancient Roman style. Two tetrastyle halls with four columns each were placed on opposite sides of a court surrounded by a giant colonnade of Corinthian columns. The third, in 1556, was in the Palazzo Antonini in Udine, which has a square plan with a central four-column tetrastyle hall and the service quarters asymmetrically to one side. The facade has six columns, which are attached to the wall rather than free-standing and which are centrally placed on each of the two floors, surmounted by a pediment or a low-pitched gable—a device normally used in his villas.

Three types of palaces

Palladio further developed the basic plan of his Palazzo Iseppo Porto in the Palazzo Thiene (*c.* 1545–50), Vicenza, the largest and most problematical of his palace designs, of which only the side and rear blocks were completed. Four wings, containing a combination of rectangular rooms and small octagons, similar to those of the Roman public baths, are symmetrically placed around a huge court. The elevations are of a grandeur unequalled in Palladio's other work. The design is the first in which Palladio was influenced deeply by the prevailing contemporary style of Mannerism and especially by Giulio Romano, who was in Vicenza when the project was begun.

During his stay in Rome, 1554 to 1556, Palladio in 1554 published *Le antichità di Roma* ("The Antiquities of Rome"), which for 200 years remained the standard guidebook to Rome. In 1556 he collaborated with the

classical scholar Daniele Barbaro in reconstructing Roman buildings for the plates of Vitruvius' influential architectural treatise (written after 26 BC) *De architectura* (*On Architecture*). The new edition was published in Venice in 1556.

Palladio's elevations have always a central emphasis that reflects the axial symmetry of the plan. This is developed in the Palazzo Valmarana, Vicenza, of 1565, along with an increasing use of stucco surface reliefs and giant orders, or columns, extending more than one story. The latter are both Mannerist elements, used particularly by Michelangelo. Giant orders were also used in the massive and unfinished Palazzo Porto-Breganze of *c.* 1570 and finally in the Loggia del Capitanio of 1571. The latter was built in emulation of many similar loggias, such as those of Florence and Venice. The lower floor was to be a raised platform open to the square and the upper a meeting hall. The original decoration was adapted to symbolize the contribution of Vicenza to the Venetian victory over the Turks at Lepanto in 1571, and a triumphal-arch motif was added to the side elevation. But the cost of the victory so impoverished the government that only three bays, or sections, were built of a possible five or seven intended.

Though Palladio absorbed contemporary Mannerist motifs, his plans and elevations always retained a repose and order not associated with Mannerist architecture, particularly that of Michelangelo and Giulio Romano. When the simplicity of his early designs was abandoned, it was largely to incorporate details warranted by the examination of buildings of the late Roman Empire, reflecting archaeological study common to his period.

Villas

Palladio's villas were less affected by his visits to Rome. For practical reasons these buildings were always of stuccoed brickwork with a minimum of carved-stone detail. His aim was to recreate the Roman villa as he had come to understand it from Latin descriptions in the writings of Pliny and Vitruvius. His villas were built for a capitalist gentry who, during the period of Palladio's maturity, gained in prosperity and found new economic outlets in agricultural improvement and land reclamation. He developed the prototype plan of Villa Trissino with many variations at Cricoli. The plan could change in scale and function to serve as a summer residence of an urban aristocrat or the estate headquarters of a gentleman farmer. Included in the former category are the least typical and most widely copied of Palladio's villa designs, the villa for Giulio Capra, called the Villa Rotonda, near Vicenza. This was a hilltop belvedere, or summer house, with a view, of completely symmetrical plan with hexastyle, or porticoes on each of four sides and central circular halls surmounted by domes. The Villa Trissino at Meledo, of the same type, was to have curved wings attached to the main portico. This was a device Palladio usually used when less consideration had to be given to farming and agricultural use of the land. Although the Villa Trissino was not built, it was a most influential design because it was illustrated in the *Quattro libri*.

Palladio adapted the classical temple front to the facades of his villas because it had the dignity suitable for an entrance. He reasoned that, since ancient temples such as the Pantheon in Rome had pedimented porticoes, houses, which preceded temples, would also have had them. Sometimes, as at the Villa Cornaro (*c.* 1560–65) at Piombino Dese and the Villa Pisani (*c.* 1553–55) at Montagnana, the portico is two-storied, with principal rooms on two floors. Normally (as at the Villa Foscari at Mira, called Malcontenta [1560]; the Villa Emo at Fanzolo [late 1550s]; and the Villa Badoer), the porch covers one major story and the attic, the entire structure being raised on a base that contains service areas and storage. In a third type the temple front covers the whole front of the house, as at the Villa Barbaro (*c.* 1555–59) at Maser, which Palladio designed for his friend the scholar Daniele Barbaro. This villa retains the contemporary fresco interiors painted by the Venetian master Paolo Veronese (*c.* 1528–88) and is one of the few interiors to survive from Palladio's day.

At the Villa Thiene (*c.* 1550) at Quinto, he started to build a grandiose house planned on the lines of his reconstruction of a Roman villa shown in the *Quattro libri*, but it was never finished. At the Villa Sarego (*c.* 1568–69) at Santa Sofia a similar inward-facing complex was also planned but not completed. This design differs from the normal villa in its two-story rusticated colonnade forming loggias to rooms arranged around three sides of a court. It is reminiscent of the court to the Pitti Palace in Florence, built in 1550 by the Mannerist architect and sculptor Bartolommeo Ammannati (1511–92). The rustication, or boldly hewn masonry, of Villa Sarego is probably derived from a style used on the Venice mint (begun in 1537) by Sansovino.

Palladio's villas were planned as total complexes but could be built in part to satisfy the owner's immediate requirements. He attached great importance to the courts that flanked or stood in front of the house, since they extended its axial symmetry and proportion.

I quattro libri

At the end of 20 years of intensive building, Palladio in 1570 published *I quattro libri dell'architettura*. This was a summary of his studies of classical architecture. He used many of his own designs to exemplify the principles of Roman design. The first book contains studies of materials, the classical orders, and decorative ornaments; the second, many of Palladio's designs for town and country houses, together with his classical reconstructions. His executed designs are often corrected, particularly in the case of early works like the Villa Godi. They are marked with dimensions according to a system of mathematical ratio. The ratios used are based upon the musical intervals in use in Palladio's day, and it was believed that numerical equivalents would result in a beautiful building, since it would be designed within a universal mathematical order. The third book contains designs for bridges, ancient town planning, and basilicas, or ancient Roman oblong halls for public assembly, later adopted as a prototype for the Christian church. The fourth book concerns the reconstruction of ancient Roman temples.

Venetian period. After 1570 Palladio's life was centred on the building of churches in Venice. In the Veneto, because of a war with the papacy, few churches had been built in the first half of the century, and there are no church designs in his early drawings. Palladio's first design was for the facade of S. Pietro di Castello (1558) in Venice—a design that does not survive. Around the 1560s he was working on monastic commissions in Venice for Sta. Maria della Carità and for the refectory and cloisters of S. Giorgio Maggiore. In the early 1560s he designed the facade for S. Francesco della Vigna, at Venice, which had been built according to Sansovino's designs of 1534 but was never finished. Palladio's facade became a design prototype for classical churches with a high nave, or central aisle, and lower aisles. He resolved this by intersecting classical temple fronts—one joining the side aisles and the other, grander front superimposed upon it and covering the higher elevation of the nave. This ingenious solution was refined and perfected in the facades of S. Giorgio Maggiore (1566, completed in 1610) and Il Redentore (1576, completed in 1592). The liturgical revival of the Counter-Reformation opposed the centrally planned church requiring separate functions for different parts of a Latin-cross church. Palladio's proposals for a circular church for Il Redentore, therefore, were rejected. In both churches the nave is a hall of gray stone columns, lit from windows at high level and covered with a plain stucco barrel vault. The interiors are a chaste white with no decoration. In Il Redentore the apse is lit from the dome above and from the choir, which stands behind a semicircular screen of columns.

At the end of his life, in 1579, Palladio designed a central-plan church as a chapel at Maser. It is a shallow Greek cross covered by a circular dome. Internally, the complex decoration of all surfaces relates it in style more closely to Palladio's late palace designs than to his churches. This was followed by a similar unexecuted project, S. Nicola di Tolentino (1579) in Venice. These demonstrate Palladio's ideal church plan and follow his reconstruction of the Pantheon in the *Quattro libri* and paralleling designs by Giacomo da Vignola (1507–73), the leading architect in Rome after Michelangelo.

With the death of Sansovino in 1570, Palladio became the leading architect of the Veneto region. Until then he had failed to gain official state patronage, and his designs for palaces in Venice, known from the *Quattro libri* and from drawings, had never found patrons. His later civic work in Venice consisted of advice on fortifications, designs for decorations used on state occasions, and interiors for the Doges' Palace. In 1572 his two sons died, and afterward he lived a secluded life, publishing only an illustrated edition of Julius Caesar's *Commentaries* as a memorial.

Palladio's last commission came in 1579–80—to build a theatre in Vicenza for the Accademia Olimpica for the performance of classical dramas. The design of the Teatro Olimpico was in the nature of an academic exercise, being based on the reconstruction of the ancient Roman theatre at Orange, in France. In August 1580 Palladio died, leaving a considerable number of unfinished buildings: the Basilica in Vicenza, the two Venetian churches, the Villa Rotonda, and the Teatro Olimpico. These were continued by his followers, notably Vincenzo Scamozzi (1552–1616) and O. Bertotti-Scamozzi (1719–90), but because of the changing taste of the period they were not strictly in accordance with Palladio's designs.

The influence of Palladio's buildings and publications reached its climax in the architecture of the 18th century, particularly in England, Ireland, the United States, and Italy, creating a style known as Palladianism, which in turn spread to all quarters of the world. His immediate influence on his contemporaries was largely confined to his pupil Vincenzo Scamozzi, who designed a number of villas in his master's style, notably the Villa Molin (*c.* 1597), near Padua.

MAJOR WORKS

VILLAS: Villa Godi, Lonedo (*c.* 1540–42); Villa Marcello, Bertesina (*c.* 1540–44); Villa Poiana, Poiana Maggiore (*c.* 1545–50); Villa Thiene, Quinto (*c.* 1550); Villa Pisani, Bagnolo (1540s–60s); Villa Rotondo, Vicenza (1550–51); Villa Pisani, Montagnana (*c.* 1553–55); Villa Badoer, Fratta Polesine (1554–63); Villa Chiericati, Vancimuglio (1554–57); Villa Emo, Franzolo (late 1550s); Villa Barbaro, Maser (*c.* 1555–59); Villa Cornaro, Piombino Dese (*c.* 1560–65); Villa Valmarana, Lisiera (*c.* 1565–66).

PALACES AND PUBLIC BUILDINGS: Palazzo Civena, Vicenza (1540–46); Palazzo Thiene, Vicenza (*c.* 1545–50); Basilica, Vicenza (design accepted 1548, finished 1617); Palazzo Chiericati, Vicenza (1550); Palazzo Valmarana, Vicenza (1565–66); Teatro Olimpico, Vicenza (1579–80).

CHURCHES: S. Giorgio Maggiore, Venice, refectory (1560–62), church (1566, completed 1610); S. Francesco della Vigna, Venice (*c.* 1565); Il Redentore, Venice (begun 1576); Tempietto, Maser (design 1579, begun 1580).

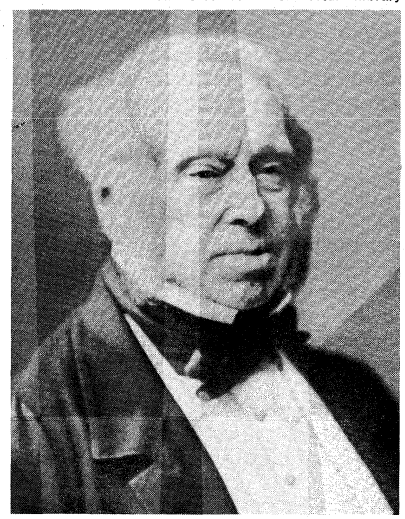
BIBLIOGRAPHY. ROBERTO PANE, *Andrea Palladio*, 2nd ed. (1961), although not translated into English, is useful for its lavish illustrations; the text is subjective. RUDOLPH WITTKOWER, *Architectural Principles in the Age of Humanism*, pt. 3–4, 3rd ed. (1962), provides the most illuminating analysis of Palladio's design ideas, particularly his use of mathematical proportions. The following works by the Italian scholar G.G. ZORZI, although not translated into English, provide an essential documentary archival foundation for the study of Palladio. Each contains a catalogue raisonné of the buildings and publishes all the original material (drawings) and documentary evidence: *I disegni delle antichità di A.P.* (1959); *Le opere pubbliche e i palazzi privati di A.P.* (1965); *Le chiese e i ponti di A.P.* (1967); *Le ville e i teatri di A.P.* (1969). JAMES S. ACKERMAN, *Palladio* (1966), is the most reliable recent historical-critical essay on Palladio's *oeuvre* as a whole. An introduction on the major influences on Palladio's career is followed by chapters on the different building types. The final chapter gives the author's definition of Palladio's principles, with full bibliography. The same author's *Palladio's Villas* (1967) is an expanded version of ch. 2 in *Palladio* above, with a catalog of the villas and documentary evidence.

(M.A.R.)

Palmerston, Lord

That "Palmerstonian" should become an adjective to describe any British foreign-policy chauvinist who is brusque in tone, propagandist and bullying in method, suggests the distinctiveness of the man who held the offices of foreign secretary in 1830–34, 1835–41, and 1846–51 and of prime minister in 1855–58 and 1859–65. In fact, Palmerston's policies were more traditional and orthodox, his methods more responsible and—when it mattered—usually more temperate than this caricature suggests; and in 1851 and 1858 he sacrificed his position by "truckling" to the French when it seemed to him that the public interest—not understood by the public—required it. But he did, uniquely, in the 1850s, represent Britain's confidence in its commercial ascendancy; in the fleet that maintained the "Pax Britannica" and protected British lives and property in many parts of the world; in the superiority and in the suitability for export of its liberal institutions; and in its right (though its military forces were meagre) to play a leading role in international relations. Becoming prime minister and (incidentally) leader of the Liberal Party in 1855, as a result of public pressure on Parliament, he remains the only British premier who twice increased his parliamentary majority by an appeal to the electorate.

Radio Times Hulton Picture Library



Palmerston, *c.* 1860.

Early life. The christening of Henry John Temple (born October 20, 1784, Broadlands, Hampshire) in the "House of Commons church" of St. Margaret, Westminster, was appropriate. His father, a cultured grand seigneur and dilettante politician, failed in his ambition to convert his Irish peerage into a United Kingdom peerage, which would have given him and condemned his son (known as Harry) to a seat in the House of Lords. Instead, with a break of less than a year (in 1835), Harry Temple was to sit in the Commons from 1807 until he died as prime minister on the eve of his 81st birthday (October 18, 1865, Brocket Hall, Hertford). After two years in Italy and Switzerland with his family, young Temple went to Harrow School in May 1795. Its classical curriculum was supplemented by French, Italian, and some German from a tutor brought home from Italy. In November 1800, Temple entered the University of Edinburgh, lodging with the Scottish philosopher Dugald Steward and imbibing the free-trade teaching of Adam Smith.

Succession to title and estates

In April 1802 Temple succeeded to his father's title and estates as 3rd Viscount Palmerston and to a burden of debt that conspired, along with a sense of public duty, to make him seek public office; the fact was, he could never afford to be out of office long. He soon began to extend and embellish the house and gardens of Broadlands in Hampshire and, from the mid-1820s, improved his Irish estates in County Sligo. Having survived a youth of ill health, he later displayed a rare stamina, cultivated by regular exercise. (His chronic liability of eyestrain, however, explains one of the exacting demands that made him unpopular with foreign office clerks and diplomats—a good bold hand. In his last 20 years he suffered severely from gout.) Entering St. John's College, Cambridge, in

October 1803, Palmerston was still an undergraduate when he contested the vacancy in the university parliamentary representation resulting from the death of William Pitt, the family political hero, in January 1806. He lost then and again in the general election of 1807, but he sat for the University of Cambridge from 1811 to 1831.

Political life, 1807–30. Only after being made—through the patronage of a guardian (Lord Malmesbury)—a junior lord at the admiralty in the Tory government of 1807 did Palmerston become a member of Parliament by a transaction with the patron of the pocket borough of Newport, Isle of Wight. Studious at Cambridge, though no recluse, the young junior minister was thought a bit of a prig. As he passed into middle age 20 years later, he was thought of politically as a dull dog; for, after refusing the chancellorship of the exchequer from the prime minister Spencer Perceval in 1809, he took the office of secretary at war, worth £2,480 a year, and found himself condemned to "tread water" for nearly 20 years. The office was humdrum, and its parliamentary duties were light. He rejected the post office in 1821 because it would have taken him to the House of Lords; and he resisted other offers, from the prime ministers Lord Liverpool and George Canning, because they would have taken him to Dublin, the Caribbean, or Calcutta. Palmerston would not forgo the delights of the London society centring around Almack's social club, the three principal hostesses of which—Lady Jersey, the Princess Lieven, and Lady Cowper (whom he married in 1839 after she was widowed)—were all probably his mistresses; he was known widely as "Lord Cupid." Because in 1827 the ultra-Tories, including the Duke of Wellington and Sir Robert Peel, refused to serve under Canning, Palmerston at last reached the Cabinet. But the offer of the exchequer by Canning was withdrawn, and it was as secretary at war that Palmerston sat in the cabinets of Canning, Viscount Goderich, and Wellington (who early in 1828 temporarily reunited the Tories).

Early career in Parliament

Known initially as a Pittite (but assumed at Cambridge in 1806 to be a supporter of the slave trade) and condemned by Radicals as a follower of Viscount Castlereagh, who was hostile to civil liberties, Palmerston acquiesced in the switch from unmoving resolution to "Liberal Toryism" over which Liverpool presided in 1821–23. But Palmerston was not an intimate of Canning and his follower, the financier and statesman William Huskisson, nor of Peel. Only after Canning's death, when Palmerston applauded "the great strides which public opinion has made in the last few years," could he be considered a Canningite. As such, he resigned, reluctantly, when Wellington drove Huskisson out of office in mid-1828; but he never closed the door to overtures from Wellington, though stipulating first that the Canningites as a body, and then that some Whigs as well, should come in. He had owed his return to the Cambridge seat in Parliament in 1826 to the Whigs—he was opposed by two ministerial colleagues hostile (as he was not) to Catholic Emancipation—and of the Whigs who sat with him in the cabinets of Canning and Goderich, he said that he liked them much better than the Tories and agreed with them much more. Palmerston, whose maiden speech in February 1808 had been a defense of a British attack on the Danish fleet to deny it to Napoleon, became in cabinet entranced with foreign affairs and adopted a position on events in Greece and Portugal in advance of the other Canningites. This he made public in the House on June 1, 1829, when he complained that Wellington and his foreign secretary, the Earl of Aberdeen, had made Britain the keystone of the arch of European absolutism. The circulation of his speech as a pamphlet indicates that Palmerston had now decided to play for high political stakes. By attacking and interrogating the Tory government from a Whiggish point of view all through 1830 and by rejoicing at the Paris revolution of that year, he qualified himself to become foreign secretary when Wellington's resistance to all parliamentary reform led to the creation of a Whig–Canningite coalition under Earl Grey.

Opposition to Wellington

Views on liberalism and conservatism. The Reform Bills of 1831 and 1832 were really more considerable than Palmerston liked, and he tried to modify them. Failing, he blamed "the stupid old Tory party" for making them necessary by refusing minor concessions, emphasized the "final" nature of the 1832 Act, and proclaimed his confidence that the landed interest would continue to prevail in politics as he thought it should. From 1849 to 1865 he came to personify the opposition of the landsmen and many of the middle classes to the enfranchisement of trade unionists and to resist fiscal and legislative assaults on landed property, opining (with regard to Ireland) that "tenant right was landlord's wrong." After one term (1832–35) as member for South Hampshire, he was defeated; and for the rest of his life he represented the Devon market town of Tiverton. There, at a time fixed for the convenience of the London press, he would expound opinions, platitudes, and prejudices, which caused it to be said that "he was not a common man, but a common man might have been cut out of him." A racehorse owner, he combined the conservatism of the countryman with a concern for the expansion of the manufacturer's foreign markets. His standard text was that reform in 1832 had prevented social revolution and that enlightened legislation thereafter (the new poor law of 1834, municipal reform in 1835, educational grants, corn-law repeal in 1846, factory acts, and other reforms, to some of which he contributed as home secretary and prime minister) was producing social peace. This made him proud of his country and more than ever inclined to exhort foreign autocrats and bureaucrats to behave like sensible Whigs and Canningites.

Attempts to export the British government system

Palmerston believed that something like the British system of responsible government would be good for all European states and that it would become the norm (as by the first decade of the 20th century it had). What he hinted at in speeches of 1829–30—that in office he would become an active verbal participant in Europe's ideological war—he confirmed in a speech of August 2, 1832, widely disseminated by German liberals. No English ministry was doing its duty, he declared, if inattentive to the interests of constitutional states, which were Britain's natural allies. Unlike Canning, he had persuaded himself that "the selfish interests and political influence of England were best promoted by the extension of liberty and civilisation," and even, against the evidence, that constitutional governments in Spain and Portugal, for instance, would be pro-British. Rebuked for "missionary diplomacy" not intended to lead to action but to inflame international relations, he retorted that ineffective protest was better than tacit acquiescence in wrong and that opinions were mightier than armies. He was charged with "disturbing the peace of Europe by giving encouragement to every revolutionary and anarchical set of men." For the Liberal and Radical following he gained by such allegations, repeated by the Tories at home and accepted as just by the Court, he was grateful. Yet his opinions on foreign and domestic matters were all of a piece. He did not want democratic or republican, least of all "Red," regimes abroad any more than at home. But he regarded the mission of Lord Minto to the Italian courts, on the eve of the revolutions of 1848, as mediatorial, not inflammatory; its object was to show the rulers of Europe that they should have their 1688 (English revolution against James II, led by William of Orange) and their 1832, lest worse befall them.

Views on nationalism. Palmerston was a British nationalist; he said that the country had no permanent allies, only permanent interests. The idea that because he applauded the cause of Liberalism in Europe, he wished to tear up the Treaty of Vienna in the interests of national self-determination, is nonsense. It was true that he was instrumental in securing confirmation of the independence of Greece and Belgium and the removal of Lombardy from the Austrians; but for Polish, Magyar, and Romanian patriotic causes he lifted not a finger, and he surprised the German liberal nationalists of Frankfort, in 1848, by a refusal of patronage, largely because German nationalism conflicted with the Vienna frontiers in Schleswig-Holstein.

Palmerston was a philhellene; but by the time he became

foreign secretary the only question was whether Greece should be a viable size, wholly independent of Turkey and under the surveillance of Britain, France, and Russia. By 1832 he had achieved this objective, only making the mistake of providing Greece with a king—the Bavarian Otho—who was not prepared to administer a constitution of London–Paris design; this mistake was remedied in 1863, when the Dane George I became king of Greece.

The Belgian revolt of 1830 was a *fait accompli*, and it had become a British interest to secure Dutch recognition of it without allowing the French to profit by intervening. In this matter, as chairman of the London Conference, Palmerston first showed his diplomatic proficiency. Twice the French marched—but with British goodwill only because the French were pledged to withdraw when they had dealt with the Dutch; "the French must go out of Belgium, or we have a general war . . . in a given number of days," wrote Palmerston on August 17, 1831. The outcome was an independent constitutional Belgium, with its neutrality guaranteed by the Five Powers in a famous "scrap of paper."

Palmerston's view of Austria

If he wanted Italian federation or unification—in 1848–49 as well as in 1859–61—it was from no addiction to the national principle in the abstract; and, if he wanted the Austrians out of Italy, it was not primarily because they were illiberal. His view was that Austria had been put into northern Italy in 1815 to provide, with the kingdom of Sardinia, a barrier against French aggression. Through mismanagement the Austrians had contrived to raise so much "national hatred" against themselves that their presence in Italy was an incitement to the French and a danger to the general peace, and it was weakening the Habsburg Empire as well. An able speech in Parliament on July 21, 1849, gave the coldest comfort to the Hungarians, against whose bid for independence Austria had to seek Russian aid. Palmerston said, wholly sincerely, that "the political independence and liberties of Europe are bound up . . . with the maintenance and integrity of Austria as a great European Power." Austria was, after all, Britain's natural ally in the Balkans, because of a lack of conflicting interests.

Palmerston's fears of France and Russia. Of the Great Powers, Palmerston felt that only Russia and France might directly threaten British interests, which he interpreted very widely and in which he certainly included all the routes to India and the Far East via the Mediterranean; from concern for India sprang Persian and Afghan wars as well as the Crimean War (see below). It was Palmerston's objective never to find France and Russia arrayed together against Britain and to practice, whenever direct confrontation could be avoided, the technique of "restraint by cooperation." The France of Louis-Philippe (ruled 1830–48) acted for most of the '30s as Britain's ally, and Palmerston's riposte to Metternich's coalition of the three emperors (of Austria, Prussia, and Russia) at Münchengrätz in 1833 was the Quadruple Alliance of Britain and France with the constitutional parties in Spain and Portugal, which were engaged in war with absolutist pretenders backed by Metternich. This alignment of 1834 was intended to "defeat the Holy Alliance in the arena which they themselves had chosen." But the French became irked at the restraining element in British cooperation and did not see why they should not be as predominant in Spain as the British were in Portugal. Relations, therefore, deteriorated even before there was an open breach in 1839–40 on the Eastern Question (regarding the Ottoman Empire). In 1833 Palmerston had been unable to act when Russia, by saving the Ottoman sultan from Muḥammad ʿAli Pasha, the ruler of Egypt, had gained predominance at Constantinople. At the end of the decade, Palmerston's fear that the tsar and Muḥammad would divide the Turkish Empire between them gave way to the fear that Muḥammad would aggrandize himself as the protégé of France. Palmerston's mobilization of the Powers to isolate France and confine Muḥammad to Egypt gave him (1840) a major diplomatic and parliamentary triumph, achieved amid the doubts and fears of Cabinet colleagues and the downright opposition of some.

Triumph over Muḥammad ʿAli Pasha

Relations with France were unnecessarily bad when Palmerston left office in 1841. His condemnation of Lord Aberdeen (Tory foreign secretary, 1841–46) for appeasing France and the United States also contributed to a feeling in the highest Whig circles that he ought not to return to the foreign office; and his refusal to take any other appointment was made the excuse for the prime minister Lord John Russell declining to form a government to repeal the Corn Laws in December 1845. In mid-1846, when Russell did form a government, Palmerston became foreign secretary again. He was worsted by the French in the Spanish Marriages affair (the son of Louis-Philippe of France married the sister of Isabella II of Spain) and also tangled with the French minister François P.G. Guizot and the princess Lieven over Switzerland and Italy, when the French showed signs of alliance with the illiberal Powers. After the revolution in 1848, as in 1830, Palmerston was concerned both with protecting the new French regime and deterring it from going to war (*e.g.*, in Italy). He and the tsar, both standing for the Treaty of Vienna and the balance of power, saluted one another from the twin rocks that stood amid the revolutionary tide.

The popular hero. In 1848–49 Palmerston was more intent upon preserving the general peace than upon patronizing Liberalism, but in 1849–51 he won Radical applause for his denunciations of the cruelty of counter-revolutionaries; for his release of British arms to Sicilian insurgents (for which he had to apologize to King Ferdinand II, 1849) and his later endorsement of William Ewart Gladstone's exposure of Ferdinand's treatment of political prisoners; by his evident approval of the hostile reception given to the Austrian general Julius, Freiherr von Haynau (known as Hyena), the villain of the counterrevolutionary repression in northern Italy and Hungary, when, against Palmerston's advice, he visited Britain in 1850; by his pressure on the Turks, first, not to yield up and, later, to release, Polish and Hungarian refugees; by his acceptance, when the defeated Hungarian patriot Lajos Kossuth visited Britain, of addresses describing the rulers of Austria and Russia in Kossuthian terms (1851).

This propagandist diplomacy infuriated Prince Albert, consort of Queen Victoria, whose moderating influence Palmerston sought to evade, and it embarrassed Cabinet colleagues who, like the Queen, were not kept fully informed. But Palmerston defeated Russell's intention of removing him from the foreign office by a famous dusk-to-dawn speech on July 8, 1850, in which, against the weight in the Commons, he defended the British bombardment of Athens, where the regime had proved less liberal than Palmerston had hoped, and the sabotaging of an agreement reached in London with France and Russia over British subjects' claims against Greece—including debts allegedly owed to an Iberian Jew, Don Pacifico. Exploiting with great skill every vein of British chauvinism, he "fearlessly challenge[d] the . . . House as representing . . . a commercial, a constitutional country," on the issue of whether a British subject in whatever land he might be could, like the Roman of old, "hold himself free from indignity when he could say 'Civis Romanus sum.' " His popularity as "the most English minister who ever governed England" was such, especially outside Parliament, that Russell did not dare dismiss him until December 1851, when Palmerston, to stand well with the ruler of France, approved the coup d'état by which President Bonaparte overthrew the constitution of the Second Republic.

Palmerston's defense of his policies

Palmerston at once brought about the fall of the Russell government and might have joined the minority Tory government if the prime minister Lord Derby had been willing to abandon his protectionist policies. He served as a reforming home secretary in a Peelite–Whig coalition under Aberdeen, which in 1854 took Britain into the Crimean War against Russia and allied with France in defense of Turkey. Often accused of what was later called "brinkmanship," Palmerston benefitted by the public opinion that if he had been in control, Russia would not have taken the risks that led to war with the West; and his resignation in December 1853, avowedly in opposition to

Russell's reform bill, was ascribed (especially by newspapers primed by Palmerston) to discontent with an infirm diplomacy. A switch to a more belligerent posture was regarded as the price of his immediate return.

Premierships. Under Aberdeen, Palmerston was a more loyal and reasonable colleague than was Russell. When Russell resigned as leader of the House of Commons because he would not oppose a motion for inquiry into the misconduct of the Crimean War—which was carried by the staggering majority of 305 to 148 (January 1855)—Palmerston succeeded him. With public opinion behind him, Palmerston became prime minister. He had to grant the inquiry into the war (and so lost the support of most of the Peelite ministers). His attempts to galvanize the war effort and remedy gross defects in many branches of the services were partly nullified by bad appointments at home and in the Crimea and by a characteristic refusal to bow to the anti-aristocratic campaign for administrative reforms. He was pressured by the French to make peace (1856) on terms he thought inadequate but which forced Russia to give up its control of the mouth of the Danube. He submitted to restraints by colleagues in quarrels with the United States, which he disliked as a democracy, as a competing imperialism, and as less than wholehearted in the suppression of the Atlantic slave trade, on which he himself was a passionate crusader. But when the Tory Opposition, with Peelites and Cobdenites (followers of the free-trade activist Richard Cobden), narrowly defeated him on the China War (the second in which the men in China had involved him), Palmerston confidently appealed to the electors against "an insolent barbarian" at Canton violating British persons and property. (Palmerston was not an imperialist in the late-19th-century sense, though he was responsible for adding Aden and Hong Kong [1841] and Lagos [1861] to the British Empire, but he never would admit the right of any part of the world to hold aloof from the impact of Western commerce and civilization.) The considerable majority achieved in the April 1857 election was a personal triumph, but it melted away when he did not make the lion's roar sufficiently loud in response to French attacks on Britain for harbouring refugees conspiring to murder Napoleon III; and Palmerston's government resigned after defeat in the House (February 1858).

First premiership

After the election of 1859 denied the Tories a majority, Palmerston resumed the premiership (June), in harness with Russell and the Peelite Gladstone, all being pro-Italian against Austria. This triumvirate ruled until Palmerston died, though there was often a prospect of Gladstone resigning in opposition to naval defense expenditure (on which Palmerston insisted), which cut across his passion for economy, and there were eventually differences of opinion on parliamentary reform and the Irish Church. Palmerston knew, however, that he would be able to rely on the Tories for support if Gladstone resigned and linked himself with the Radical John Bright. Although his determination that Britain "should count for something in the transactions of the world" was successfully challenged by Bismarck in the Schleswig-Holstein affair, 1863–64, Palmerston retained great prestige at home; and on the eve of his death he greatly enlarged the Liberal majority in an election on the cry "Leave it to Pam." It was rightly said, after his death, that "the exceptional sway of Lord Palmerston could not be reproduced by any other statesman, or any combination" and that "the reign of *moderate* Liberalism" was over. He had been a conservative statesman using radical tools and keeping up a show of liberalism in his foreign policy; after him the defense of the Conservative cause would revert to the Conservative Party.

Second premiership

BIBLIOGRAPHY. The official *Life*, 5 vol. (1870–76), was by LYTTON BULWER (vol. 1 and 2 and a skeleton of vol. 3) and EVELYN ASHLEY. Original sources were used by H.C.F. BELL in *Lord Palmerston*, 2 vol. (1936); and JASPER RIDLEY in *Lord Palmerston* (1970), neither of whom convey either the animation or the inner consistency of the man. Some are published in PHILIP GUEDALLA (ed.), *Gladstone and Palmerston* (1928); and BRIAN CONNELL (ed.), *Regina vs. Palmerston: The Correspondence Between Queen Victoria and Her Foreign and Prime Minister, 1837–1865* (1961). Guedalla's *Palmerston* (1926) is a piece of artistry, apt to mislead, unlike the less pretentious *Lord Palmerston* of W. BARING PEMBERTON (1954). WALTER BAGEHOT'S essay in *Biographical Studies* (1856); ANTHONY TROLLOPE, *Lord Palmerston* (1882); and the MARQUESS OF LORNE, *Palmerston* (1892), are still worth reading. Of works which are not avowed biographies, DONALD SOUTHGATE, *"The Most English Minister" . . . , the Policies and Politics of Palmerston* (1966), has as its subject Palmerston's effect upon British foreign policy, 1829–65; also expounded in BASIL KINGSLEY MARTIN, *The Triumph of Lord Palmerston* (1924). SIR CHARLES WEBSTER, *The Foreign Policy of Palmerston, 1830–1841*, 2 vol. (1951), has found no successor. A.J.P. TAYLOR'S first and best book, *The Italian Problem in European Diplomacy 1847–1849* (1934); and CHARLES SPROXTON, *Palmerston and the Hungarian Revolution* (1919), are perceptive; and GAVIN B. HENDERSON, *Crimean War Diplomacy, and Other Historical Essays* (1947), corrective. DEREK BEALES, *England and Italy, 1859–60* (1961); W.E. MOSSE, *The European Powers and the German Question, 1848–71* (1958); and E. PREVELAKIS, *British Policy Towards the Change of Dynasty in Greece, 1862–1863* (1953), are illuminating in their several fields.

(Do.S.)

Pamir Mountain Area

The Pamir mountain area belongs mainly to the Gorno-Badakhshan *avtonomnaya oblast* (autonomous region) of the Tadzhik Soviet Socialist Republic of the U.S.S.R. It is surrounded by the Central Asian mountain systems of the Hindu Kush, Kunlun, Gissar-Alai and Tien Shan.

The territory of the Pamirs is bounded on the north by the Trans Alai Range (Zaalaysky Khrebet); on the east by the Sarykol Range, which forms the border between China and the U.S.S.R.; on the south by Lake Zorkul, the Pamir River, and the source of the Pyandzh River bordering Afghanistan; and on the west by the north–south segment of the Pyandzh Valley. The eastern parts of the Peter I and Darvaz ranges on the northwest are included within the Pamirs, since their glaciers comprise a single system with the glaciers of the northwestern Pamirs. The derivation of the word Pamir has not been definitely established.

Relief. The Pamirs are a combination of east–west and north–south ranges, with the former predominating. The east–west Trans Alai Range, which forms the northern frame of the Pamirs, falls steeply to the intermontane Alai Valley. The high central part of the range, between the Tersagar Pass on the west and Kyzylart on the east, averages between 19,000 and 20,000 feet, reaching its highest point at Lenin Peak, 23,400 feet (7,134 metres). South from the Trans Alai extend three north–south ranges. Of these, the western, the Academy of Sciences Range, and the central, Zulumart, are relatively short; and the eastern, Sarykol Range, forms the eastern border of the Pamirs. The area east of the Sarykol Range is sometimes called the Chinese Pamirs.

Principal mountain ranges

The north–south Academy of Sciences Range enters into the northwestern Pamir system, where it rises into a huge barrier, reaching 24,584 feet (7,495 metres) in Communism Peak (the highest point in the U.S.S.R.). The eastern slope of the range is covered on the south face by the Fedchenko Glacier. The western slope intersects other ranges that lie still farther to the west: the Peter I Range, with Moscow Peak (22,300 feet); the Darvaz Range, with Arnavad Peak (20,000 feet); and the Vanchsky and Yazgulemsk ranges, with Revolution Peak (22,900 feet). The ranges are separated by deep ravines. To the east of the Yazgulemsk Range, in the central portion of the Pamirs, is the east–west Muzkol Range, reaching 20,400 feet in the Soviet Officers Peak. South of it stretches one of the largest ranges of the Pamirs, called Rushan on the west and Bazar-Dara or Northern Alichur on the east. Still farther south are the Southern Alichur Range and, to the west of the latter, the Shugnan Range. The extreme southwestern Pamirs are occupied by the Shakhdarin Range, composed of north–south (Ishkashim Range) and east–west elements, with the Mayakovsky Peak (20,000 feet) and Karl Marx Peak (22,100 feet). In the extreme southeast, to the south of Lake Zorkul, lies the east–west Vakhan Range.

It is customary to divide the Pamirs into a western area

Eastern and western Pamirs

and an eastern area, distinguished by their forms of relief. In the eastern Pamirs a medium-mountain relief predominates on a high raised foundation. While the heights above sea level average 20,000 feet or more, the relative heights of the peaks above their foundation do not in most cases exceed 3,300–5,900 feet. The ranges and massifs have mainly rounded contours, and the wide and flat-bottomed valleys and troughs between them, situated at heights of 12,100–13,800 feet, are occupied either by quietly running, meandering rivers or by dry channels. The valleys and slopes of the ranges are covered by layers of loose material.

In the western Pamirs the relief is high mountain and sharply disjointed, alternating between low ranges and alpine ridges capped by snows and glaciers; and there are deep, narrow ravines with high, rapid rivers. The valleys and depressions are filled with debris, so that almost the only suitable places for human settlement are the alluvial fans in the valleys of tributaries of the Pyandzh River. The transition from the eastern-Pamirs type of relief to the western-Pamirs type occurs gradually. The conventional boundary is a line joining the ridge of the Zulumart Range with Kara-Bulak Pass in the Muzkol Range; from Pshart Pass, it follows the ridge of the Northern Alichur Range to Lake Zortashkol, where it turns south to the valley of the Pamir River.

Geology and climate. Geologists divide the Pamirs into three zones according to the characteristics of their rock formations: the northern, central, and southern Pamirs. The southern zone consists of metamorphic rocks (gneiss, quartzite, marble, and others) to which a majority of researchers attribute a Precambrian age (more than 570,000,000 years ago). The zone on the whole represents a huge anticlinorium, or series of stratified arches. The central zone of the Pamirs contains limestone, sandstone, and shale rocks of the Jurassic, Triassic, and Permian periods (136,000,000 to 280,000,000 years ago) and also red-coloured terrestrial rocks of the Lower Cretaceous Period (136,000,000 years ago). There are some marine rocks of the Lower and Middle Paleozoic Era (345,000,000 to 570,000,000 years ago) and lava and tufaceous rocks of the Paleocene (54,000,000 to 65,000,000 years ago). The structure of the central Pamirs is that of a huge synclinorium (an inverted arch caused by fracturing); it is separated from the northern Pamirs by a deep fracture.

In the structure of the northern Pamirs, two subzones can be discerned: a Paleozoic zone, which stretches to the ridge of the Trans Alai Range, and a zone beyond, which is composed of more recent deposits. The Paleozoic subzone of the northern Pamirs is a huge anticlinorium with a complex internal structure. It is separated from the Trans Alai subzone by the Karakul fracture. The Trans Alai subzone is very complex. Its western part is a fan-shaped anticlinorium, in the centre of which emerge Jurassic deposits; radiating outward are more recent, dislocated rocks of the Lower Cretaceous Period. The eastern part has Cretaceous and Paleocene deposits in a system of conflicting folds. Because of the numerous overthrusts, or horizontal faults, in some places the layers overlap each other. On the north the Trans Alai subzone is bounded by the deep Gissaro-Trans Alai fracture, separating the Pamirs from the Gissaro-Alai system.

Severity of climate

The climate of the Pamirs is arid and continental. These features are more pronounced in the eastern part, where there are broad, closed basins in which cold air is retained and a barrier of high ranges intercepting moist air currents. There is a mixed circulation of air—western (cyclonic) and southern (monsoonal). In the valleys of the western Pamirs the amount of annual precipitation is four to ten inches, and in the eastern Pamirs two to five inches. In the high altitudes and on slopes of mountains, the amount of precipitation increases, reaching 32 to 40 inches on the Fedchenko Glacier. The thickness of the snow blanket in the western Pamirs reaches 20 to 28 inches, and in the eastern it reaches 1.5 to four inches. The average January temperature in the eastern Pamirs at heights around 11,500 feet is 0° F (−17.8° C). Winter here is long (October through April) and severe, and temperatures have been recorded at below −58° F (−50° C)—in Bulunkul in 1953, −64.9° F (−53.3° C). In the short summer, temperatures do not rise above 68° F (20° C). The climate of the valleys of the western Pamirs is milder. The average temperature in January at heights of about 6,900 feet is 18.7° F (−7.4° C), and in July it is 72.5° F (22.5° C), but temperatures vary greatly. The period of vegetation (with temperatures of 41° F [5° C]) is 223 days in Khorog and 140 days in Murgab.

The Pamirs have 1,085 glaciers, covering an area of 3,105 square miles. The largest centres of glaciation occur in the Academy of Sciences, Trans Alai, Rushan Northern Alichur, Yazgulems, Darvaz, Peter I, and Zulumart ranges. The largest valley glacier, Fedchenko (length 44.3 miles), starts in the Academy of Sciences Range; other glaciers in this range include the Grumm-Grzhemaylo (23 miles), Garmo (17 miles), Sagran (15 miles), and Geographic Society (13 miles). The main glaciers of the Trans Alai Range are the Sauk-Dara (16 miles), Korzhenevsky (around 13 miles), October (10.9 miles), and Lenin (5.9 miles). In the eastern Pamirs shallow bog glaciers and snow fields predominate.

The rivers belong mainly to the basin of the Amu Darya (the ancient Oxus), which forms the frontier between the U.S.S.R. and Afghanistan and flows into the Aral Sea. Its upstream extensions are the Pyandzh and the Pamir. The area also contributes to the basin of the Tarim, which flows eastward into China. Lakes include Karakul (a salt lake), Rangkul, Shorkul, Zorkul, Yashilkul, and Sarez.

Mountain flora

Plant and animal life. Vegetation in the Pamirs, especially in the eastern Pamirs, is poorly developed. Bare cliffs or a cover of surface rubble predominate. At high altitudes the vegetation changes with increasing altitude from mountain desert flora to mountain drought-resisting plants, then to mountain steppe vegetation, and finally to cold-resistant plants. Native forms predominate, but some forms from Central and Southwest Asia are found. The eastern Pamirs are a cold, high-mountain desert, with woody vegetation completely absent and with low-growing plants that are adapted to the severe conditions. On the dry mountain slopes there are low shrubs of winter fat, the only form of vegetable fuel in the area, and plant cover, such as the Pamir tansy, oxytropis, astragalus, local species of wormwood, the bulbous iris, and meadow grass. On the bottoms of the moist valleys, sedge and cobresia meadows are abundant.

The vegetation of the western Pamirs is richer, although on the mountain slopes and bottoms of valleys there is a prevalence of wormwood and haloxylon. At heights over 8,500 feet, spiny pillow-form plants (*e.g.*, acanthus, spiny astragalus) are widespread. At heights over 10,500 feet, yugan, kamol, fescue, and feather grass are found. At 12,500 to 14,100 feet are alpine cobresia meadows; above 14,500 feet vegetation is sparse. Along the rivers of the western Pamirs are dense growths of willow, sea buckthorn, birch, poplar, and hawthorn. A thinner wood–shrub vegetation reaches heights of 12,500 feet, including Juneberry, almond, birch, and juniper. On irrigated lands there are cultivated plantings of grape, apricot, apple, pear, walnut, and mulberry trees.

The fauna of the Pamirs are not numerous. In the eastern Pamirs are found the *arkhar* (a mountain sheep), the long-tailed marmot, and the large-eared Tibetan wolf. Birds include the Tibetan mountain turkey, the Tibetan raven, the horned lark, and the snow vulture. The western Pamirs have the mountain goat (*kiik*), brown bear, wolf, fox, snow panther, lynx, weasel, marten, *zayats-tolay* (a hare), dormouse, and flying mouse. Birds include the Indian oriole, bluebird, dark-breasted pheasant, stone partridge, and paradise flycatcher. The Pamirs have few fishes; only the carp and the Tibetan loach are known.

Population and industry. Some 98,000 people live in the Pamir area, and the average population density is four persons per square mile. More than 90 percent of the population are Tadzhiks living in the western Pamirs. Their languages belong to the Iranian group, and those who are religious are Shīʿite Muslims. The inhabitants of the eastern Pamirs are Kirgiz, who speak a Turkic language and are Sunnite Muslims.

Agriculture

Nearly all are peasants whose chief occupation is farming and livestock breeding (in 1969 there were 52 collective farms and one state farm). The small amount of arable land is planted with grain, beans, gourds, and potatoes, and there are orchards of apples, pears, apricots, and mulberry trees. Sheep and goats are the predominant livestock.

Industry in the Pamirs includes several small hydroelectric power stations and a few mines. In the eastern Pamirs, brown coal and common salt are mined. There is evidence of industrial deposits of gold, gems, jasper, lazulite, mica, asbestos, and talc. Thermal and mineral springs are common. There are auto routes across the Pamirs from Dushanbe in the west to Khorog in the south and from there to Osh in the east. Another route runs from Khorog south through the once impassable ravine of the Pyandzh–Pamir rivers. Buses go from Khorog to several regional centres. Many other routes are accessible only to pedestrians and pack animals.

Exploration

Modern exploration began with the Russian A.P. Fedchenko, who in 1871 succeeded in reaching the northern foot of the Pamirs from the Alai Valley. In 1877 the Russian geologist I.V. Mushketov visited the valley of the Muksu River and the vicinity of Lake Karakul. In 1877–78 the Russian zoogeographer N.A. Severtsov, penetrating into the depth of the mountain country, made a chart of its structure. In 1878 an expedition under the Russian naturalist V.F. Oshanin discovered the large valley glacier subsequently named A.P. Fedchenko. From 1884 through 1887, the Pamirs were explored by the zoologist G.Y. Grum-Grzhimaylo, who provided valuable data on glaciers of the northwestern and northeastern Pamirs.

Under the Soviets, explorations in the Pamirs have become systematic. In 1928 an expedition of the Academy of Sciences of the U.S.S.R. explored the region of the Fedchenko Glacier, making possible the first accurate topographical maps of the western Pamirs. In 1933 the first high-mountain glaciological observatory in the world was constructed on the Fedchenko glacier, at a height of about 14,800 feet. The Tadzhik–Pamir Expedition of 1932 resulted in important monographs on the geology, geomorphology, and hydrogeology of the Pamirs. Soviet alpinists have contributed much to the investigation of the Pamir region—a part of the world not easily accessible. (T.K.Z.)

BIBLIOGRAPHY. OLE OLUFSEN, *Through the Unknown Pamirs: The Second Danish Pamir Expedition, 1898–99* (1904); MALCOLM SLESSER, *Red Peak: A Personal Account of the British-Soviet Pamir Expedition 1962* (1964).

Panama

The Republic of Panama is a country in Central America, situated on the S-shaped Isthmus of Panama, which joins North and South America. Its area is 29,783 square miles (77,138 square kilometres), of which 29,208 square miles is on the mainland and 575 square miles is divided among the islands. The area given does not include the 558 square miles of the Canal Zone, a ten-mile-wide strip of land stretching across the Isthmus; through the zone runs the Panama Canal, connecting the Atlantic and Pacific oceans. Panama has granted to the United States jurisdictional rights over the zone, limited to the specific purposes of maintenance, operation, sanitation, and protection of the interoceanic waterway.

Location and boundaries

Panama extends for 384 miles from the Costa Rica frontier in the west to the Colombian border in the east. The shortest distance across the Isthmus is 31 miles, stretching from the mouth of the Río Nergalá (Necategua), which flows into the Golfo de San Blas on the northern (Caribbean) shore, to the mouth of the Río Bayano on the Pacific coast. Panama is bounded on the north by the Caribbean Sea, on the south by the Pacific Ocean, on the east by Colombia, and on the west by Costa Rica. Panama City, the capital, is located on the Pacific coast to the east of the Panama Canal. The state was ruled in the early 1970s by a provisional government junta.

Economically, Panama is a developing country: most of the population is engaged in agriculture and cattle raising. Although there is considerable international trade because of the country's strategic location, industry in the early 1970s was just beginning to develop. (For an associated feature, see PANAMA CANAL; for historical aspects, see CENTRAL AMERICAN STATES, HISTORY OF THE.)

THE LANDSCAPE

The natural environment. *Physiography.* The Panamanian landscape consists of three distinct areas: the lowlands, or hot lands, lying at altitudes below 2,300 feet, which are 87 percent of Panamanian territory; the lands of the temperate zone, situated at altitudes of between 2,300 and 4,900 feet, which comprise about 10 percent of the land; and the highlands, or cold lands, lying more than 4,900 feet above sea level and covering 3 percent of the whole.

The land surface may also be divided into two geological categories—the highlands and mountains of volcanic origin and the lowlands, plains, and hills of sedimentary origin.

The highlands include the Barú, or Chiriquí, volcano, 11,408 feet (3,478 metres) high; the central mountain range, a continuation of the Cordillera de Talamanca (Costa Rica), which stretches to the central part of the Isthmus at elevations of between about 3,300 and 10,000 feet; the northeastern mountain arc, including the Cordillera de San Blas; the southeastern mountain arc, including the summits of Chimán, Río Congo, Serranía del Sapo, and Pirre; and the southern volcanic chains, including the mountain systems of the Península de Azuero and the Macizo (massif) de Canajagua.

The lowlands include the plains of the provinces of Panamá and Chiriquí, the plains and hills of the central Isthmus of Panama; the eastern section, occupied by the Bayano, or Chepo, and the Chucunaque river basins; and the northern plains of the Caribbean region.

Panama's Pacific seaboard is 1,015 miles in length, and its Atlantic seaboard extends for 774 miles. On its continental shelf, wide in the Pacific and narrow in the Atlantic, are more than 1,600 islands. Its coasts have many bays, gulfs, peninsulas, headlands, and capes.

The principal archipelagoes off the Caribbean coast are those of Bocas del Toro and Mulatas (San Blas). Off the Pacific coast the principal islands are the Archipiélago de las Perlas (Pearl Islands), Taboga, Taboguilla, and—largest of all Panamanian islands—Coiba.

Rivers

Drainage and soils. Panama has approximately 500 rivers: 350 flow to the Pacific and 150 to the Caribbean sea. Most of the rivers have their sources in the highlands. They tend to erode their banks upstream, forming meanders in the middle parts of their courses and deltas and inlets at their mouths. Their volume of flow increases during the rainy season (May to December) and decreases during the dry season (from January to April). None of the rivers is navigable, except the Tuira (which is navigable for about 100 miles), and the Bayano (navigable by small boats for 35 miles). The most important rivers flowing to the Caribbean are the Sixaola, the Changuinola, the Río Indio, the La Miel, and the Chagres. (The Chagres Basin is the best known because of its use for the maintenance of the Panama Canal.) The most important rivers flowing to the Pacific are the Chiriquí Viejo, San Félix, San Pablo, Santa María, the Bayano, the Chucunaque, and the Tuira.

About half of the isthmian territory is formed of volcanic rock. There are also many clay and slate shales in the eastern and central provinces and some sedimentary rocks in the western provinces, in the central part of the Isthmus, the Canal Zone, and adjacent areas.

Soil types include soft, red clayey soils (situated in Chiriquí province in the southwest), which are easily eroded, containing some humus (decomposed plant and animal matter); hard clay soils, which are dry and unsuitable for cultivation; and savanna (grassy parkland) soils, which are good for pasture, even if they are dried out during the dry season. There are also alluvial soils (clay, silt, sand, and gravel deposited by rivers), limited to small areas

along the rivers, which are suitable for the cultivation of sugarcane, plantain (a starchy, banana-like fruit), and bananas; volcanic ash soils, which are fertile and contain great quantities of organic matter; and swampy soils.

Temperatures

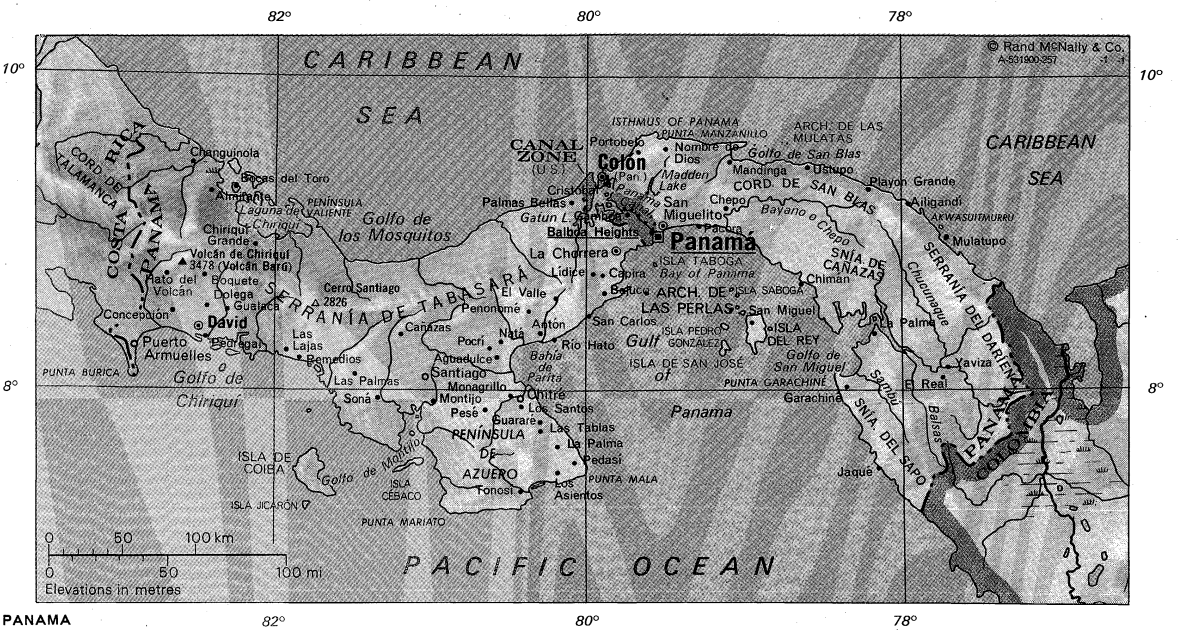
Climate. Panama has a tropical, rainy climate; except for the Caribbean coast and the high mountains, where rain falls at all seasons, there are two well-defined seasons —dry and rainy. The mean temperatures in the Caribbean region are 81° F (27° C) in the dry season and 84° F (29° C) in the rainy season; in the Pacific region the mean temperature is 81° F (27° C) in both seasons. The Caribbean region has the most rainfall, receiving between 59 and 138 inches (150 and 350 centimetres) a year. The more populated Pacific region receives between 59 and 79 inches a year.

Four climatic regions can be distinguished—the very wet tropical zone, the wet tropical zone, the arid tropical region, and the temperate wet zone. Wet tropical forests are found in the Caribbean lowlands, on the Pacific coast, and in the Bayano and Chucunaque depressions; the Canal Zone also experiences the same kind of climate. The arid tropical region is situated on the Pacific coast; it covers the savanna area and has a dry and a rainy season. The temperate wet zone occurs in the highlands of the central mountain range in the west and in the Alto (High) Darién region in the east.

Vegetation and animal life. The tropical rain forest of the lowlands occupies half the country. This vegetation, which includes a variety of species, is suitable for commercial forestry exploitation. The swamp woods, including plantations of mangrove trees, cativo (a large tree of the legume family), and orey (a tall hardwood tree), are abundant.

Tropical savannas are found mainly on the Pacific seaboard. Subtropical woods associated with heavier rainfall occur in the western provinces, in the Cerro Azul and Cerro Jefe regions, in the mountain ranges of San Blas, and in the sierras (mountains) of Alto Darién to the east.

Panamanian animal and plant life is abundant and var-



PANAMA

MAP INDEX

Cities and towns

Physical features and points of interest

ied. The animal life includes poisonous reptiles, crocodiles, armadillos, ocelots (spotted leopard-like cats), small tigers, monkeys, and birds with colourful plumage. Fish of many kinds are plentiful.

Regions of settlement. The jungle regions (lowlands with a rainy, tropical climate) comprise the Chagres Basin, the eastern part of the province of Panamá on the south central part of the Isthmus; the province of Darién in the east; and the Caribbean lowlands. The inhabitants are Negroes and Amerindians. Subsistence agriculture is common.

The savanna region, in the Pacific lowlands to the west of the Canal Zone, has a wet, hot climate. Natural vegetation is rich and varied. Occupied by rural mestizos (people of Spanish and Amerindian descent), the land is intensively cultivated. Rice, beans, sugarcane, plantains, ñame (a type of yam), and yuca (cassava) are grown, and cattle are raised.

The highlands comprise the central mountain range, the region around the Barú or Chiriqui volcano, and Alto Darién, a region of jungles and abundant rainfall. The Chagres, or Route, region covers the central Isthmus of Panama and is crossed by the Río Chagres. Through this zone, where the country is at its narrowest and lowest, runs the Panama Canal (*q.v.*).

The Chagres region also contains the Canal Zone; of its total area of 558 square miles, 163 square miles is occupied by the waters of the Gatun Lake. The zone covers five miles on each side of the canal and does not include the cities of Panama and Colón. The population of the Canal Zone varies periodically; in the early 1970s it was about 45,000, including military personnel and civilians.

The Canal Zone

The Canal Zone is administered for the United States Congress by the Canal Zone Government. The operation of the canal and related activities are in the hands of the Panama Canal Company. Both operate under the direction of the governor, who is directly responsible to the United States secretary of the army, and to the president of the United States; besides his administrative duties in the Canal Zone Government, the governor is the president of the board of directors of the Panama Canal Company. The seat of the government is in the town of Balboa Heights, near the Pacific, close to Panama City. Other towns in the zone are Ancon, on the slopes of Ancon Hill, Diablo Heights, Corozal, Pedro Miguel, Gamboa, Coco Solo, and Majagual–Gold Hill. There are army installations at Ft. Clayton and Ft. William D. Davis. The Canal Zone's ports are Cristobal, close to the city of Colón, and Balboa, on the Pacific. The United States Air Force Canal Zone base, Albrook Field, is also located in the zone on the northeastern outskirts of Balboa Heights.

The population of Panama is predominantly rural, but in the early 1970s the urban population was growing. At the time of the 1970 census, when Panama had a population of about 1,400,000, there were about 9,300 inhabited places, of which 14 were over 5,000. The Panamanian population is widely dispersed, with many people living in hamlets and isolated dwellings. These scattered Panamanians are engaged in subsistence agriculture and cattle raising.

Urban centres

The most important urban centres are Panama City and the city of Colón. Fifty-five percent of the total urban population is in Panama City, which had a total population of almost 350,000 inhabitants, while Colón has over 70,000 inhabitants. Panama City is situated on the Pacific coast overlooking Panama Bay. In addition to being the site of the government and the capital of the republic, it is the centre of industrial, commercial, political, and cultural activities.

THE PEOPLE

Ethnic and linguistic groups. In the 16th century, when the Spaniards first came to the Isthmus, it was occupied by Cuna, Guaymí, Chocó, and other American Indian groups. Out of a mingling of the Spaniards with the Indians, there resulted the mestizo. With the introduction of Africans, other mixed types appeared. During the 19th century, with the construction of the Panama–Colón railroad, new groups arrived—North Americans, French, and Chinese. During the construction of the canal, more North Americans came, as well as Negroes from the Caribbean islands, Spaniards, Italians, and Greeks.

The most numerous of the American Indian groups are the Guaymí, who live in the western provinces of Chiriquí, Bocas del Toro, and Veraguas. Their everyday language is called the *movere*, or the "language of the plains." Next in numbers are the Cuna, who live in the Archipiélago de las Mulatas and on the coast nearby as well as in other parts of the isthmus and along the shores of the Río Tuira and its tributaries; they speak the Cuna language. The Chocó (Chocoe) groups live mainly in the province of Darién. They engage in subsistence agriculture, fishing, and hunting. Their everyday language is the *emberá* dialect.

The Hispanic–Indian group (essentially mestizo) represents the largest population stock in Chiriquí province in the southwest and in the central provinces of Panamá and Colón. This group is mixed with elements of African ancestry in Panama City and Colón. The urban element in these two cities also experiences a strong North American influence from those living in the Canal Zone.

The descendants of the Negro slaves who arrived at the Isthmus during the period of Spanish colonization are distributed throughout Panama. The Antillean-form Negroes are a small minority whose ancestors originally came to Panama to work on the construction of the railroad and the canal.

North Americans have influenced both the economy and culture of Panama. They live in the Canal Zone and in Panama City. Other significant ethnic minorities are the Chinese, Hindus, and Jews, all of whom play an important role in commerce and industry and participate in the country's political and professional life.

Spanish is the official language. Roman Catholicism is the religion of 92 percent of the population. There is freedom of worship.

Demography. A striking attribute of Panamanian demography is the high rate of population increase. Numbers have increased from 336,000 in 1911 to 467,000 in 1930, 805,000 in 1950, and 1,400,000 in 1970.

Population growth

Panama, Area and Population

	area		population	
	sq mi	sq km	1960 census	1970 census
*Republic of Panama**				
Territory (*comarca*)

*Excluding the Canal Zone. †The Territory of San Blas is administratively part of the Province of Colón. ‡Total includes 575 sq mi (1,488 sq km) of offshore islands not accounted for in the areas of the provinces. §Figures do not add to total given because of rounding. ‖Of the two total area figures, the first is land area, the second is total, including non-tidal inland water.
Sources: Official government figures; Panama Canal Company.

The Panamanian population is very young (the average age is 19) with a high fertility rate. The rate of population growth is about 3.3 percent a year, largely the result of the high birth rate and a low mortality rate.

A second cause of growth has been immigration, which was substantial during World War II and then decreased. In addition, there is migratory movement within the country of rural people in search of land and of young people moving to the city in search of better conditions.

Eighty percent of the population is in the Pacific area, mainly in the southwest of the Isthmus. The greatest flow of population is from the villages to the cities of Panama and Colón.

Excluding the inhabitants of the Canal Zone, the population density is about 50 persons per square mile.

THE NATIONAL ECONOMY

In the early 1970s the production of goods and services was increasing at the rate of about 8 percent annually.

The majority of the economically active population is engaged in agriculture, forestry, cattle raising, fishing, commerce, and general services. Some mineral resources are exploited.

Resources and economic activity. *Mining.* Cement and salt are the leading mineral products, although gold and silver are also produced on a small scale. There are also commercially significant deposits of manganese, copper, iron, bauxite, and limestone. Plans had been made, in the early 1970s, to exploit copper in the Petaquilla area of Colón province. Oil has been found in several places. There are some outcrops of lead, zinc, rutile, and sulfur, but all are less important. Stones used in construction, such as slate, shale, basalt, andesites, and clays, are common, as are such semiprecious stones as quartz, jasper, and agate.

Forestry. The use of woods for industrial purposes is not completely developed. The Ministry of Agriculture and Cattle Raising, through a specialized organization, supervises the exploitation of the national forests. In the early 1970s, mahogany, oak, cedar, and other species were used to supply some 40 sawmills.

Energy. Electricity is provided by the Institute of Hydraulic Resources and Electrification (IRHE). The IRHE has built a hydroelectric plant at La Yeguada in the province of Veraguas, which in the early 1970s produced about 95 percent of Panama's hydroelectric output of 34,000 kilowatts; at that time several other irrigation or hydroelectric projects were also under study.

Agriculture. A seminomadic and subsistence type of agriculture coexists alongside large commercial enterprises using modern agricultural methods. Land tenure is characterized by the scarcity of rented land, only 6 percent of the total.

Principal crops

The most common agricultural products are rice, corn (maize), beans, sugarcane, plantain, and oranges. The growing conditions of the isthmus favour the cultivation of tropical fruit, although commercial production is limited. The industrial cultivation of coffee, cocoa, sugarcane, tobacco, and sesame was increasing in the early 1970s. Other products, such as potatoes, yuca, tomatoes, and other vegetables, are grown especially in the temperate zone, which includes Volcán, Cerro Punta, Boquete, and the Antón Valley.

Livestock raising (cattle, pigs, and poultry) is an important and long-established economic activity. The large cattle-raising farms are in the southwest of the Isthmus. The quality of meat produced has been greatly improved by better stock and better pasture. There are more than 1,300,000 head of cattle, mainly in Chiriquí, Veraguas, and Los Santos provinces. The production of pigs has increased very little in spite of a growing urban market and relatively high prices. The largest producers are the provinces of Chiriquí, Los Santos, and Veraguas. The largest centres for the production of chickens and eggs are Panamá, Chiriquí, and Veraguas.

Fisheries. Fishing has developed rapidly as a commercial venture. Shrimps are one of Panama's most important exports, with up to 7,600 tons of shrimp caught yearly. Lobster fishing has potential for development. The fishing centres are Bocas del Toro, Chiriquí, and the northeast of the Gulf of Panama on the Pacific coast.

Industries. The leading industries are engaged in cement manufacture (in the limestone areas near the Trans-Isthmian Highway), sardine processing, sugar refining, processing of general food products, banana and cocoa production, oil refining, and the production of gas and electricity. Other important industries include clothing and shoe manufacturing, breweries, distilleries, and the production of furniture, paper, hides, chemicals, and cigarettes.

There were almost 600 manufacturing concerns in Panama City in the early 1970s, with considerably fewer in Colón and David. The salt deposits in Aguadulce and Guararé are the basis of a significant industry. Tourism plays a major role in the country's economy, providing funds for industrial development.

Financial services. Financial services are provided by representative branches of some major Latin American, North American, and European banks. Some of these banks have branches in the provinces and provide loans for industrial, agricultural, and cattle-raising ventures.

Imports and exports. The main products purchased from abroad are manufactured goods, machinery, transportation equipment, food products, chemicals, and textiles. Most of the imports come from the United States, Venezuela, and Japan; some also come from South American countries. Exports are limited to food products, such as bananas, shrimps, coffee, cocoa, and petroleum products. The United States takes a large part of these exports; other notable buyers of Panamanian products are West Germany, The Netherlands, Canada, and the Panama Canal Zone itself.

Buying more from abroad than it exports, Panama achieves equilibrium in its commercial balance from "invisible revenues," resulting from the employment of Panamanians in the Panama Canal Zone and from the sale of goods and services to people from the Canal Zone.

The Zona Libre de Colón (Colón Free Zone), established at the northern end of the Canal Zone, has become increasingly important as a re-export centre. Its commerce is composed of chemical products, manufactured articles, machinery, and transportation equipment. Most of these products come from the United States, Japan, England, and West Germany and are sent to the countries of Central and South America, as well as to Panama itself.

Trade unions. The most important labour unions and associations are the Confederation of Workers of the Republic of Panama, the Isthmian Federation of Christian Workers, the Transportation Union, the Printers' Union, the Union of Hotel Workers, and the Commercial Employees Union. In the early 1970s the labour movement was tending toward the creation of a single workers' union. Employers are represented by the National Commission of Private Enterprises (CONEP), which also encourages the commercial development of the country's resources.

Management of the economy. The government is promoting Panama's growth. Among its programs are reforestation, development of commercial fishing, exploration and exploitation of mining deposits, improvement of agricultural techniques, improvement of transportation and communication systems, and electrification.

Developmental schemes

Transportation and communications. *Roads.* The main transportation routes extend from the capital to the central provinces (Coclé, Herrera, Los Santos, and Veraguas) and to the western section of the country (Veraguas and Chiriquí). The principal roads are the Trans Isthmian, or Boyd–Roosevelt, Highway, joining Panama with the city of Colón to the north; the road east to Chepo, which is to be extended to the Colombian border; and the National Highway, a paved road that runs from the capital to the Costa Rican boundary through the most inhabited and prosperous regions of the west. A branch goes south to Chitré, Las Tablas, and Pedasí and another one, north from David to Boquete.

Railroads. A transcontinental railroad, the Panama–Colón line, was inaugurated in 1855 and is 49 miles long. It is administered by the Panama Railroad, a North American company. The Chiriquí National Railroad runs between La Concepción and Puerto Armuelles on the Pacific, transporting agricultural products. In Bocas del Toro there is a railroad serving the banana-growing area.

Ports. The Panamanian coastline has many natural harbours with excellent conditions for sheltering vessels

but inadequate cargo facilities. The best ports are those at either end of the Panama Canal—Cristobal, near the city of Colón, and Balboa, near Panama City. Coastal shipping is important for Panamanian agriculturists and is the only means of transportation in certain regions.

Airports. There were about 140 domestic airports in the early 1970s and two international airlines. Tocumen, Panama's international airport, 16 miles from the capital, is served by several international airlines and is used by more than 400,000 passengers a year; by agreement it also serves as the commercial airport for the Canal Zone. There is also the Enrique Malek Airport in David, Chiriquí. The national airlines fly regularly from Paitilla (Marcos Gelabert) Airport in Panama City to San Blas, Darién, La Palma, Chitré, Bocas del Toro, Santiago, Puerto Armuelles, and Chiriquí.

Communications. The national government, with a few exceptions, operates and owns the communication system, maintaining a system of telephone, telegraph, and radio communication in the most populated regions. Two private companies—Tropical Radio and Intercomsa—operate an international communication system.

ADMINISTRATION AND SOCIAL CONDITIONS

The structure of government. *The constitutional framework.* After the coup d'etat by the National Guard in 1968, the legislative branch of government was suspended, and Panama was administered by a provisional government. Before that time, the 1946 constitution, the third in the country's history, was operative. It provided for an executive composed of the president and two vice-presidents to be elected for a four-year period by popular and direct vote. The Cabinet worked with the president and advised him. Legislative power under the 1946 constitution was in the hands of a National Assembly of 41 assemblymen, one for every 15,000 habitants, elected for a four-year period. A return to constitutional government was begun in August 1972 with the election of a 505-member assembly.

Justice. Judicial power is in the hands of a Supreme Court of nine members. They are appointed by the president with the approval of his Cabinet and of the Assembly. There are also two superior courts, municipal judges, a public attorney's office (under the control of the attorney general), an auxiliary district attorney, district attorneys, and other officials.

Local government. The country is divided into nine provinces and a territory (comarca), San Blas. The provinces are divided into municipal districts, which are subdivided into counties. The head of each province is the governor, appointed by the president.

The armed forces. There is no army or navy, but there are two coastguard patrol vessels. The National Guard, with a strength of about 5,000 men, is reponsible for national defense and security.

Services and social conditions. *Educational services.* Education is separated into four categories—pre-elementary, elementary, secondary, and university education. All children have the right to receive education from the state without discrimination as to race, sex, and economic or social standing. No private school system can teach in a foreign language without the consent of the Ministry of Education. Elementary education is compulsory and free from seven to 15 years. Illiteracy had greatly decreased by the early 1970s.

Universities

The institutions of higher education are the state-run University of Panama and the privately operated University of Santa Maria la Antigua in Panama City. The University of Panama, the official university of the republic, is an autonomous institution with enrollment of about 10,000 students.

Health and welfare. The state has built hospital and health centres and granted funds for their improvement. There are about two dozen hospitals and half a dozen hospital-clinics, 30 health centres, and a few mobile medical units. There are about 850 doctors, 150 dentists, and 1,000 nurses.

Social security provides a wide range of benefits; all employees must be registered. The social security administration maintains a hospital in Panama City for its beneficiaries and also supports medical centres and clinics in several places in the interior. The Saint Thomas Hospital, in Panama City, provides treatment for those unable to pay hospital expenses.

Housing. In the early 1970s there were about 290,000 dwelling units in the republic: one-family houses are common in rural areas, but rented multifamily dwellings are usual in urban areas. Condominium ownership was becoming popular in the 1970s.

Police services. Police services are operated by the National Guard, which works jointly with the National Department of Investigation (DENI) in dealing with thefts, homicides, assaults, and personal injury cases.

Wages and cost of living. About 90 percent of the working population is protected by a minimum wage law; the Price Control Office regulates prices. Salaries and wages are subject to great fluctuations. In the Canal Zone non-North Americans, numbering about 16,000, receive average monthly wages that are less than half those received by the 6,000 North American workers employed there. Most workers and professionals are union members. Collective labour contracts are usual. The Labour Code requires a monthly vacation for every 11 months of work.

Cultural life. The various regions are visited by musical or theatrical groups, poets, sculptors, and other artists.

Cultural institutions include the Panamanian Art Institute (Panarte), the Concert Association of Panama, the National Conservatory, the School of Plastic Art, the National School of Dance, and the University of Panama, which has its own ballet-concert musical and theatrical groups.

The Panamanian Tourist Bureau (IPAT) encourages the preservation of traditional holidays, folk music, and folk dances. Panamanian carnivals are famous for their beautiful costumes and joyous music. The Institute of Culture and Sports (INCUDE) promotes junior olympiads and other interprovincial events.

The republic has about 100 radio stations—about 60 in Panama, 13 in Chiriquí, and nine in Colón. There are two television stations; in addition the Canal Zone has its own television and radio station.

The main newspapers are *El Panamá América,* the *Panama-American, The Matutino, Crítica, La Hora, La Estrella de Panamá,* and *The Star and Herald.* In Colón the *Atlántico* and in David the *Ecos del Valle* are the principal papers.

Prospects for the future. Relations with the United States, which operates the Panama Canal, are governed by the provisions of the treaties concluded in 1903 and 1936. In the early 1970s, the outcome of talks between the Panamanian and United States governments on the future of the canal was awaited with interest. Like many other Latin American nations, Panama in the 1970s was passing through a period of economic, social, cultural, and political change. Efforts continued to be made to further expand tourism, which represented a vital element in the country's economy. Greater economic cooperation between Panama and Nicaragua was also anticipated.

(N.M.C.)

Panama Canal

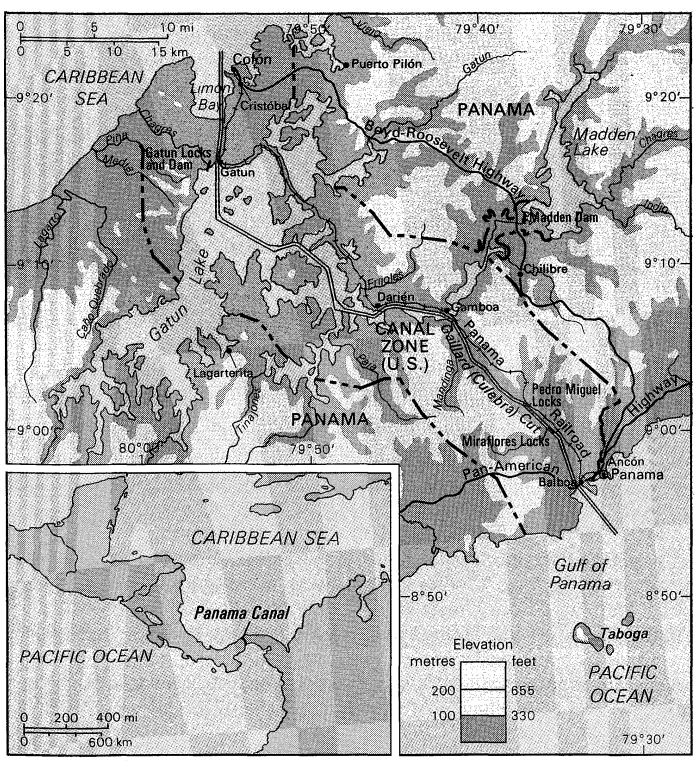
The Panama Canal is an interoceanic waterway connecting the Atlantic and Pacific oceans through the Isthmus of Panama. It is about 51 miles (82 kilometres) in length from deep water to deep water and is one of the two most strategic artificial waterways in the world, the other being the Suez Canal (*q.v.*). It is owned and operated by the United States. For a detailed discussion of canals, see the article CANALS AND INLAND WATERWAYS; for a discussion of the Panama Canal Zone, see the article PANAMA; for a consideration of historical aspects, see CENTRAL AMERICAN STATES, HISTORY OF.

The canal consists of short sea-level sections at each end, three pairs of locks that lift ships to 85 feet (26 metres) above sea level, a 32-mile elevated section that includes Gatun Lake, and a narrow eight-mile-long excavated channel, known as Gaillard Cut, running through the continental divide.

The dimensions of its lock chambers—1,000 feet in length, 110 feet in width, and 41 feet in depth—permit most commercial ships, as well as principal Navy ships, to pass through the canal. Some passenger liners, the largest sizes of cargo carriers and tankers, and the largest aircraft carriers cannot, however, be accommodated. Proposals for enlarging the locks or, alternatively, for building a sea-level waterway have been before the government since 1939.

Ships sailing between the east and west coasts of the United States, which would otherwise be obliged to round Cape Horn, shorten their voyage by about 8,000 nautical miles by using the canal. Savings of up to 3,500 miles are also made on voyages between one coast of North America and ports on the other side of South America. Ships sailing between Europe and East Asia, or Australia, save as much as 2,000 miles by using the canal. In terms of United States interests, the canal, which enables naval units to pass readily from one ocean to the other, is a link in the defense of North America.

The waterway. The Panama Canal lies nine degrees north of the Equator. It extends from north to south, running from the Atlantic terminus at Cristobal to Balboa on the Pacific Ocean. The waterway is set in the middle of a canal zone, which extends five miles on either side of the canal. The zone was granted to the United States in perpetuity by the Republic of Panama by the Hay-Bunau-Varilla Treaty of November 18, 1903, which also provided for the construction and operation of the canal. Waters from the Río Chagres and Gatun and Miraflores lakes are used to refill all the locks. The heavy rainfall of the tropics makes operation feasible despite the use of 52,000,000 gallons (196,560,000 litres) of water for the transit of each ship.



The Panama Canal.

The eight principal features of the canal are (1) a seven-mile dredged channel from the Atlantic terminus in Limon Bay to the Gatun Locks; (2) the Gatun Locks, which raise or lower ships 85 feet to or from Gatun Lake; (3) a 24-mile channel through Gatun Lake to Gamboa; (4) Gaillard Cut, an eight-mile, 500-foot-wide channel winding through the continental divide: (5) the Pedro Miguel Locks, constituting a 31-foot step down from Gaillard Cut; (6) a 750-foot-wide channel running for about a mile across Miraflores Lake; (7) the Miraflores Locks, constituting a 54-foot two-step drop down from the lake level; and (8) a sea-level dredged channel leading over eight miles to the Pacific terminus in Bay of Panama.

The canal locks operate by gravity flow of water from Gatun and Madden lakes. The locks themselves are of uniform length, width, and depth. Each set of locks is built in tandem, to permit simultaneous transit of vessels in either direction. To conserve water, two or more vessels are passed through together, in the same direction, when size permits. Each lock gate has two leaves, 65 feet wide by seven feet thick, set on hinges. The gates range in height from 47 to 82 feet; their movement is powered by motors recessed in the lock walls. They are operated from a control tower, located on the wall that separates each pair of locks, and from which the flooding or emptying of the lock chambers is also controlled. Due to the delicate nature of the lock mechanisms, only small craft are permitted to pass through the locks under their own power. Larger craft are towed through by locomotives. Ships are taken through the canal by a pilot, who boards each ship before it leaves the terminus. In time of war or emergency, armed guards also accompany each ship through the canal.

The canal locks

Navigation. Including waiting time, ships require about 15 hours to negotiate the canal. The average transit time through the canal, once a vessel has been authorized to proceed, however, is seven to eight hours from deep water to deep water. When Gaillard Cut is not being dredged, canal traffic is generally allowed to proceed in both directions.

Marine traffic is handled by a complex manual system that, with the increase in traffic in recent years, has become overburdened. Each ship is boarded by measurers to determine its carrying capacity for toll-collection purposes. Manifests, ship's papers, and other documents are inspected and recorded. Transits are scheduled and are monitored at points along the route. In 1970 an average of 41 oceangoing ships, with an average size of 7,800 tons each, passed through the canal each day. It has been calculated that by 1990 traffic will increase to 70 ships a day.

Tolls. The charter of the canal provides for the Panama Canal Company (an agency of the United States) to establish tolls for the use of the waterway at rates calculated to cover costs of maintenance and operation. Tolls are based upon the measured earning capacity of a ship. The rates have remained virtually unchanged since the canal was opened. The average charge for a ship in transit in 1970 was $6,850. Vessels owned, operated, or chartered by the government of Panama are exempted by treaty from payment of tolls. Changes in the rules for both the measurement and the collection of tolls may be made only after six months' notice, the holding of public hearings, and approval by the president of the United States.

Toll rates

Maintenance. Continual maintenance work on the canal and its associated facilities is needed to keep it in operation in a tropical climate. This includes the dredging of channels, the overhauling of locks, and the repairing of machinery. Especially in the early years of the canal's operation, landslides occurred in the hills adjoining Gail-

lard Cut. A close watch must be kept on soil conditions, since heavy rainfall and the removal of land still make earth slides probable. Preventive measures have frequently had to be taken to keep the channel open—most recently in 1968, when large cracks opened in the hills to the west of the cut.

History. As early as the 16th century the Spanish conceived the idea of constructing a canal across the isthmus. In 1846 the United States concluded a treaty with New Granada (now Colombia), which then exercised sovereignty over Panama, aimed primarily toward securing a canal route; the treaty provided that the United States should guarantee the "perfect neutrality" of the isthmus and its free and uninterrupted transit. In 1855 United States financial interests joined to build the Panama Railroad across the isthmus. In 1880 the French Panama Canal Company, under the leadership of Ferdinand de Lesseps, builder of the Suez Canal, undertook the first attempt to construct a canal. Ten years later, due to lack of planning, graft, and the ravages of yellow fever, malaria, and cholera, which decimated the work force, the company became bankrupt. It was reorganized in 1894 as the New Panama Canal Company but made little progress, due to lack of money. The U.S. Congress, by the Spooner Act of 1902, authorized and directed the President to acquire rights and to build an interoceanic canal. Following Panama's declaration of independence from Colombia in 1903, and the conclusion of the Hay-Bunau-Varilla Treaty between the United States and Panama in that year, canal-building rights passed into U.S. hands. Work began on the canal in 1904 but not until 1906 was it decided that, instead of being at sea level, the waterway would be of the high-level type, using locks. The canal was first opened to traffic on August 15, 1914.

Capital improvements. The first major capital improvement was the construction of Madden Dam and Power Project, which was completed in 1935. This not only stemmed and controlled the flow of water moving into Gatun Lake at the rate of 200,000,000,000 cubic feet (6,000,000,000 cubic metres) a year but also created a large reservoir in Madden Lake, as well as increasing the amount of electric power available.

In 1939 the United States Congress authorized the addition of a third set of locks removed from the existing facilities. Although excavation was begun the following year, work was suspended during World War II and has not been resumed. A highway built across the isthmus—much of it running outside the Canal Zone—has added a supplementary facility to the waterway and railroad. Following an agreement between the United States and Panama in 1955, the Thatcher Ferry Bridge was built, connecting Panama City and Balboa with the north side of the canal, and adding a fresh link to the Pan-American Highway system that connects the capitals and principal cities of South and Central America with the highways of the United States and Canada.

A major improvement to the canal itself, completed in 1970, was the widening of Gaillard Cut from 300 to 500 feet throughout, thus enabling ships to move through at faster speeds.

Canal traffic. Traffic through the Panama Canal is a barometer of world trade, rising in years of prosperity and declining in times of recession. From a low of 807 transits in 1916, traffic rose to a high point of 15,523 transits of all types in 1970. The cargo carried through the canal that year amounted to over 132,500,000 tons. The tolls collected for the fiscal year ending in 1970 totalled over $100,000,000.

Principal trade routes

The principal trade routes served by the Panama Canal, apart from the United States intercoastal trade route, run between the following points: Europe, and the west coast of North America; the United States east coast, and Hawaii and East Asian ports; the United States east coast, and the west coast of South America; the east and west coasts of South America; the West Indies and Asia; Europe and Asia; Europe, and the west coast of South America; Europe, and Australia.

Cargo movements in recent years have reversed the earlier pattern, when Pacific to Atlantic traffic was heavier. From 1968 to 1969, for example, traffic originating in Atlantic ports has been nearly double that from the Pacific. This is due in part to the military buildup in Southeast Asia; to heavy shipments of oil from the Caribbean and Gulf of Mexico ports to the Pacific; to shipments of grain to Asian ports; to the increased transport of ores and metals to Japan; to nitrate and phosphate shipments to the west coast of the United States; and to coal shipments to Japan. Coal and coke are the principal items shipped from the Atlantic to the Pacific, followed by petroleum and petroleum products. Grains, ores, metals, and nitrates rank next in tonnage of cargo.

Panama Canal, Commercial Ocean Traffic, 1971

country of registry	vessel transits (number)	total transits (percent)	cargo (long tons)	total cargo (percent)
Liberia	1,587	11.3	25,201,391	21.2
United Kingdom	1,558	11.1	14,288,579	12.0
Japan	1,462	10.4	13,541,685	11.4
United States	1,368	9.8	8,246,308	7.0
Norway	1,202	8.6	16,011,868	13.5
West Germany	1,069	7.6	4,918,407	4.1
Panama	948	6.8	3,699,065	3.1
Greece	629	4.5	7,735,546	6.5
The Netherlands	494	3.5	2,648,769	2.2
Sweden	479	3.4	3,366,568	2.8

Ships flying the United States flag previously held first place in number of transits among shipping from various countries using the canal route. They currently occupy third place, comprising 11.1 percent of the total. Ships flying the Liberian flag now hold first place, with 11.7 percent. British shipping is second, accounting for 11.6 percent. Norwegian shipping holds fourth place, followed by Japan and others. The large percentage of Liberian shipping results from the practice of ship owners of registering ships under "flags of convenience," to save costs, a practice which is particularly employed for registering large carriers of oil, ores, and grain. Seventy percent of the canal traffic is, however, destined for, from, or between parts of the United States, underscoring the importance of the canal to the United States economy.

Recent traffic statistics also reflect the rapid growth of the Japanese economy; over 45 percent of the cargo passing through the canal came from, or was destined for, Japan in the fiscal year ending in 1970. The canal cannot accommodate the ultralarge tankers and bulk carriers of 100,000 to 300,000 tons deadweight now being built until either larger locks or a sea-level waterway is built; with the greater numbers of large carriers operating on world trade routes and cargo passing through the canal increasing at a rate of 7 percent a year, larger facilities will be needed by the year 2000 if the canal is to remain economically competitive.

The Panama Canal Company. The Panama Canal Company, established by the U.S. Congress, is the corporate agency created to maintain and operate the canal, as well as to conduct business operations incident thereto, as well as those incident to the civil government of the Canal Zone. The company has a board of directors appointed by the U.S. secretary of the army, who is the sole stockholder, under authority delegated to him by the president of the United States.

The basic law requires that the company be self-sustaining. Its obligations include its own operating expenses; the net cost of civil government, interest, and depreciation on United States investment in the enterprise; and $430,000 of the $1,930,000 annuity paid to the Republic of Panama. (The remainder is provided by the U.S. Department of State and is thereby excluded in fixing tolls.)

The company also maintains ship facilities both at Cristobal at the Atlantic terminal, and at Balboa at the Pacific terminal of the canal. These accommodations include docks, warehouses, repair shops, bunkering facilities, and rail and road connections with Panama City and the city of Colón in the Republic of Panama.

The Canal Zone Government is responsible for civil

government in the Canal Zone and is administered by a governor who is directly responsible to the U.S. secretary of the army and to the U.S. president. He is appointed for a four-year term and is ex officio the president of the Panama Canal Company.

Over 15,000 persons were employed by the company and the government in 1970, of whom over 4,000 were U.S. citizens. In recent years an increasing number of Panamanian employees have been paid at U.S. wage rates.

The Panama Railroad

The Panama Railroad runs for 47 miles between Colón and Panama City. The original line, built to transport prospectors bound for the California goldfields across the isthmus, was completed in 1855. Its existence gave Panama a great advantage over Nicaragua when the choice of a canal site was made. The railway was used in the construction of the canal but had to be moved to higher ground on the east side of the canal before the waters began to rise. The railway carries goods and passengers across the isthmus, running close to the canal and crossing Gatun Lake by a man-made causeway.

The net value of the property, plant, and equipment at the Canal Zone was placed at $5,000,000,000 in 1969. The net investment of the United States in the canal enterprise is over $5,000,000,000. Capital expenditures average close to $17,000,000 a year. Direct operating expenses amount to $48,000,000; general and administrative expenses, $17,000,000. Tolls and toll credits produced an income of $100,900,000 in 1970.

International status of canal. Under the terms of the Hay-Bunau-Varilla Treaty of November 18, 1903, the United States received from the Republic of Panama the right to the use, occupation, and control of the Canal Zone "in perpetuity," for the "construction, maintenance, operation, sanitation, and protection" of the interoceanic canal. The treaty further granted to the U.S. "all the rights, power and authority" within the zone, which the U.S. would have "if it were the sovereign of the territory." Although Panama did not yield its ultimate sovereignty over the zone, it gave the U.S. the right to exercise sovereignty there "to the entire exclusion of the exercise by the Republic of Panama." Debates have been conducted how far this extends. It is apparently sufficient to give the U.S. a secure title to the canal, the power to defend it, and the right to decide how the canal and the Canal Zone shall be operated. For this grant the U.S. paid Panama $10,000,000 in cash in 1904, plus an annuity that was originally fixed at $250,000. Since 1955, the annuity has been $1,930,000.

A second component in the international status of the canal is the Hay-Pauncefote Treaty of November 18, 1901, by the terms of which the United Kingdom gave up its interest in an isthmian canal in return for agreement by the U.S. that a canal built by the U.S. would be "free and open" to the vessels of commerce and war of all nations, which observed the rules established for the Suez Canal by the Convention of Constantinople, 1888, by which the Suez Canal was made a corridor for all ships of all nations in peace and in war. This was subsequently interpreted as in no way forbidding the U.S. to take measures for ensuring the safety or defense of the Panama waterway. The Hay-Pauncefote Treaty also provided that there shall be "entire equality" in the treatment of ships of all nations with respect to "conditions and charges of traffic."

The fundamental act authorizing the U.S. government to acquire the rights for a canal route and to build a canal of "sufficient capacity and depth as shall afford convenient passage for vessels of the largest tonnage and greatest draft" then in use, "or such as may be reasonably anticipated," was the act of the U.S. Congress of June 28, 1902, known as the Spooner Act.

Need for a larger waterway

The future. The increasing size of bulk carriers, and of container ships, and the inability of the present canal to accommodate the largest aircraft carriers of the U.S. Navy have led to the consideration of the construction of a larger sized waterway. It remains to be decided whether the larger waterway should be constructed on the site of the existing canal or elsewhere, and whether it should be a lock or sea-level type of canal.

Among 29 conceivable routes across Central America, six are considered the most feasible. The first of these is a Nicaraguan route from San Juan del Norte (Greytown) on the Atlantic up the Río Indio to Lake Nicaragua (Spanish Lago de Nicaragua) and down to the Bay of Salinas (Spanish Bahía de Salinas). Although this is a shorter route, from the point of view of U.S. intercoastal trade, it would require cuts through high mountains and would pose difficult engineering problems. A second possibility is a sea-level route ten miles northwest of the present Canal Zone starting from the mouth of the Río Indio, crossing the continental divide near the town of La Chorrera, and exiting into the Bay of Panama near Taboga Island. Such a route would be about as long as the present canal and could be built up without disrupting traffic. A new United States–Panamanian treaty would be required for this. A third possibility is a sea-level canal within the present Canal Zone, replacing the existing canal either by using the existing route or else by employing a new cut through the divide; construction would seriously disrupt traffic. A fourth possibility is to make a deep-draft lock canal replacing the existing structures. The fifth possibility is a Sasardí-Mortí route in Panama, 100 miles east of the present canal, and the sixth is the so-called Atrato route in northern Colombia. Nuclear engineering is thought to be the only practicable means of construction for both these routes, and this is deemed to be politically unacceptable.

A United States Atlantic–Pacific Interoceanic Canal Study Commission in 1970 recommended building a sea-level canal through Panama just north of the present Canal Zone, retaining the existing canal as a supplementary facility. It believed this route to be the most feasible and to have the advantage of proximity to existing facilities, engineering skills, and a large labour force.

Ecologists have questioned whether a sea-level canal might not disturb the existing balance of nature by bringing organisms from the tropical Pacific into the Atlantic, but the commission did not think this a serious problem. Negotiations have been entered into with the Panamanian government to secure rights for building and operating a new canal. The alternative remains of constructing a sea-level canal in the present zone or of converting the existing canal into a deep-draft lock canal.

Pan Ku

A scholar-official of the Later, or Eastern, Han dynasty (AD 23–220), Pan Ku (in Pin-yin romanization, Ban Gu) was the second of China's three most famous historians, with Ssu-ma Ch'ien and Ssu-ma Kuang. Of the three, Pan Ku is the one whose organization has been most often followed by later historians.

His father's work

He was probably born in AD 32 at Ch'ang-an (modern Sian), the Former, or Western, Han capital, shortly before the interregnum that divided the dynasty into two different periods. His father, Pan Piao (AD 3–54), an intellectual and antiquarian, was given a court appointment by the Emperor during the early years of the restoration of the Han dynasty. Disliking court life, Pan Piao pleaded poor health and retired, thereafter devoting himself to the independent study of history. He collected material for the continuation of Ssu-ma Ch'ien's great history of China, the *Shih-chi*, which had begun with the earliest dynasties and stopped midway through the Former Han dynasty.

After his father's death, Pan Ku continued this historiographical undertaking. In the course of it, however, he was imprisoned for tampering with dynastic records. His twin brother, Pan Ch'ao, an outstanding general who extended China's western frontier to the Pamirs, interceded so successfully that Pan Ku was not only acquitted but was also appointed by the Emperor to the office of official historian.

"Han shu." With all obstacles now removed, he spent the next 16 years compiling and editing the vast *Han shu* (known in English as *The History of the Former Han Dynasty*), which became the prototype for the official histories of successive ruling houses in China, recording the administrations of their predecessors. Although modelled on the *Shih-chi*, the *Han shu* was not merely a supplement to that long-range work but was a new and comprehensive record of the Han Empire, from its beginning down to the regime of the reformer Wang Mang, who had proclaimed his own short-lived dynasty in AD 9. Pan Ku went back to the beginning of the Han, duplicating almost verbatim most of the documents Ssu-ma Ch'ien had used for that part of the Han period he had treated, excising redundancies or simplifying the prose that seemed to him awkward or obscure. And, since Pan Ku's own age enjoyed widening education, bureaucratic proliferation, improved writing materials and techniques, and standardized orthography, he had an even larger body of recent records from which to select. Dealing with a period of roughly 200 years, the *Han shu* is much longer than the *Shih-chi*, which purports to cover 3,000 years.

Plan of the *Han shu*

Both Ssu-ma Ch'ien and Pan Ku were court officials, and they inevitably used the official record of the lives of the emperors and their close relatives (and of the often more decisive activities of their civil and military administrators) to form their main chronological narrative. This constitutes Pan's part 1, the basic annals. He adopted Ssu-ma Ch'ien's methods for other parts: part 2, charts and diagrams of events, genealogies, persons, etc.; part 3, treatises on a wide range of topics, such as court ceremony, music, money and taxes, and navigation; and part 4, single or grouped biographies of memorable persons other than emperors. To these subjects he added new ones on natural phenomena, on geography, and on bibliography, a descriptive account of the books preserved in the Imperial library—invaluable to later scholars trying to judge textual authenticity and family lineages after many works had vanished. Pan Ku eliminated Ssu-ma Chi'en's fifth category of "hereditary houses," since China was no longer a collection of competing states.

Role in contemporary affairs. When the historian felt his task to be essentially completed, he apparently decided to participate more actively in the politics of his day. He had been at least on the periphery of intellectual controversy regarding the interpretation of the Confucian Classics—by no means a mere antiquarian pursuit but one fraught with political implications, as he remarked in one of his few personal observations in the *History*. Editorship of the *Pai-hu t'ung*, or "Symposium in the White Tiger Hall," which deals with this subject, is ascribed to him. In his middle 40s, however, he chose to undertake something more adventurous. Leaving the finishing touches on the *Han shu* to his sister Pan Chao, also an extraordinary scholar (not to be confused with his brother Pan Ch'ao), he joined the staff of the general Tou Hsien and accompanied him in successful campaigns against the northern Hsiung-nu tribes. The following victory inscription composed by Pan Ku was carved in stone 1,000 miles beyond the frontier:

> Our trained soldiery came hither on a campaign against barbarian hordes. We chastised Turkic insolence and restored our supremacy in this distant land. Across these vast plains they went back to their northern home, while our splendid troops set up this trophy that the achievements of our glorious Emperor should be heard of ten thousand generations hence.

The Emperor, however, who was 14 years old and Tou Hsien's nephew, became alarmed at the general's self-importance and, suspecting him of excessive ambitions, exiled him to his own lands. Pan Ku's fate was one common throughout Chinese history; his superior's fall implicated him, and he was incarcerated for interrogation. Falling ill in prison, he died there at the age of 60 (AD 92). His sister duly rounded out the vast *Han shu* manuscript and was officially sanctioned to instruct other scholars on its contents.

Death

Assessment. For centuries the Chinese have debated the relative merits of the history of the single, self-contained dynasty such as Pan Ku's, and the comparatively rare histories that span the rise and fall of successive hegemonies and systems, which are claimed to reflect more effectively the lessons of history. Obviously, the general historian must build on the work of those dealing with shorter periods, and the two kinds of enterprise cannot be compared qualitatively on the basis of scope. As a historian, Pan Ku must be evaluated on other grounds in relation to his predecessor and to the next great long-range narrator, Ssu-ma Kuang, who wrote more than 1,000 years later. Since both were more inclined to offer interpretations and personal comments, their commentaries appear to be more colourful and sometimes more interesting. Pan Ku, on the other hand, is admired for his thoroughness and his virtually complete objectivity.

Indeed, one might call Pan Ku a historiographer rather than a historian. He undertook simply to represent the Han dynasty and empire as factually as possible through an organized compendium of existing documents; hence the title *Han shu*—literally, "Han Documents."

Prose style

Pan Ku's prose style, to which he more or less adjusted the documents he incorporated, was simple, lucid, unecentric, and not especially vivid. It was terse but not lapidary; somewhat more carefully regulated than Ssu-ma Ch'ien's, it was still, probably, not altogether remote from the spoken Chinese of his own day and class. It was a model of what came to be known as the Han style, revived many centuries later in reaction to excessively elaborate prose.

When practicing the dominant literary form of his time, the *fu*, or rhymed prose, however, Pan Ku could be as extravagant, bizarre, and exhibitionistic as others displaying their talents in this fashionable genre. His two rhymed prose compositions on the merits of the successive Han capitals (the new one, of his present masters, of course, winning out) spawned many imitations, especially for their exhibition of unusual words. In a simpler vein he wrote some rather inconsequential verses modelled on the popular folk songs of his day. His name has been attached, spuriously, to a collection of anecdotes and hearsay about the reign of the Han emperor Wu Ti.

BIBLIOGRAPHY. Further information may be found in H.H. DUBS, *The History of the Former Han Dynasty*, 3 vol. (1938–55). Both CH'EN SHOU-YI, *Chinese Literature: A Historical Introduction* (1961); and BURTON WATSON, *Early Chinese Literature* (1962), discuss Pan Ku as historian and writer.

(G.W.Ba.)

Pantheism and Panentheism

Both "pantheism" and "panentheism" are terms of recent origin, coined to describe certain views of the relationship between God and the world that are different from that of traditional Theism (*q.v.*). As reflected in the prefix "pan-" (Greek *pas*, "all"), both of the terms stress the all-embracing inclusiveness of God, as compared with his separateness as emphasized in many versions of Theism. On

the other hand, pantheism and panentheism, since they stress the theme of immanence—*i.e.*, of the indwelling presence of God—are themselves versions of Theism conceived in its broadest meaning. Pantheism stresses the identity between God and the world; panentheism (Greek *en*, "in") holds that the world is included in God but that God is more than the world.

The adjective "pantheist" was introduced by the Irish Deist, John Toland, in a book, *Socinianism Truly Stated* (1705). The noun "pantheism" was first used in 1709 by one of Toland's opponents. The term "panentheism" appeared much later, in 1828, when it was used to characterize the view that the world is a finite creation within the infinite being of God.

Although the terms are recent, they have been applied retrospectively to alternative views of the divine being as found in the entire philosophical traditions of both East and West.

THE NATURE AND SIGNIFICANCE OF PANTHEISM AND PANENTHEISM

Pantheism and panentheism can be explored by means of a three-way comparison with traditional or Classical Theism viewed from eight different standpoints—*i.e.*, from those of immanence or transcendence; of monism, dualism, or pluralism; of time or eternity; of the world as sentient or insentient; of God as absolute or relative; of the world as real or illusory; of freedom or determinism; and of sacramentalism or secularism.

Immanence or transcendence. The poetic sense of the divine within and around mankind, which is widely expressed in religious life, is frequently treated in literature. It is present in the Platonic Romanticism of Wordsworth and Coleridge, as well as in Tennyson, Emerson, and Goethe. Expressions of the divine as intimate rather than as alien, as indwelling and near dwelling rather than remote, characterize pantheism and panentheism as contrasted with Classical Theism. Such immanence encourages man's sense of individual participation in the divine life without the necessity of mediation by any institution. On the other hand, it may also encourage a formless "enthusiasm," without the moderating influence of institutional forms. In addition, some theorists have seen an unseemliness about a point of view that allows the divine to be easily confronted and appropriated. Classical Theism has, in consequence, held to the transcendence of God, his existence over and beyond the universe. Recognizing, however, that if the separation between God and the world becomes too extreme, man risks the loss of communication with the divine, panentheism—unlike pantheism, which holds to the divine immanence—maintains that the divine can be both transcendent and immanent at the same time.

Distinctions viewed from the metaphysical standpoint

Monism, dualism, or pluralism. Philosophies are monistic if they show a strong sense of the unity of the world, dualistic if they stress its twoness, and pluralistic if they stress its manyness. Pantheism is typically monistic, finding in the world's unity a sense of the divine, sometimes related to the mystical intuition of personal union with God; Classical Theism is dualistic in conceiving God as separated from the world and mind from body; and panentheism is typically monistic in holding to the unity of God and the world, dualistic in urging the separateness of God's essence from the world, and pluralistic in taking seriously the multiplicity of the kinds of beings and events making up the world. One form of pantheism, present in the early stages of Greek philosophy, held that the divine is one of the elements in the world whose function is to animate the other elements that constitute the world. This point of view, called Hylozoistic (Greek *hylē*, "matter," and *zōē*, "life") pantheism, is not monistic, as are most other forms of pantheism, but pluralistic.

Time or eternity. Most, but not all, forms of pantheism understand the eternal God to be in intimate juxtaposition with the world, thus minimizing time or making it illusory. Classical Theism holds that eternity is in God and time is in the world but believes that, since God's eternity includes all of time, the temporal process now going on in the world has already been completed in God. Panentheism, on the other hand, espouses a temporal–eternal God who stands in juxtaposition with a temporal world; thus, in panentheism, the temporality of the world is not cancelled out, and time retains its reality.

The world as sentient or insentient. Every philosophy must take a stand somewhere on a spectrum running from a concept of things as unfeeling matter to one of things as psychic or sentient. Materialism holds to the former extreme, and Panpsychism to the latter. Panpsychism offers a vision of reality in which to exist is to be in some measure sentient and to sustain social relations with other entities. Dualism, holding that reality consists of two fundamentally different kinds of entity, stands again between two extremes. A few of the simpler forms of pantheism support Materialism. Panentheism and most forms of pantheism, on the other hand, tend toward Panpsychism. But there are differences of degree, and though Classical Theism tends toward dualism, even there the insentient often has a tinge of Panpsychism.

God as absolute or relative. God is absolute insofar as he is eternal, cause, activity, creator; he is relative insofar as he is temporal, effect, passive (having potentiality in his nature), and affected by the world. For pantheism and Classical Theism, God is absolute; and for many forms of pantheism, the world, since it is identical with God, is likewise absolute. For Classical Theism, since it envisages a separation between God and the world, God is absolute and the world relative. For pantheism, however, God is absolute and relative, cause and effect, actual and potential, active and passive. The panentheist holds that, inasmuch as they refer to different levels of the divine nature, both sets of claims can be attributed to God without inconsistency, that just as a man can have an absolute, unchanging purpose, which gains now one embodiment and now another, so God's absoluteness can be an abstract unchanging feature of a changing totality.

The world as real or illusory. Panentheism, Classical Theism, and many forms of pantheism hold the world to be part of the ultimate reality. But for Classical Theism the world has a lesser degree of reality than God; and for some forms of pantheism, for which Hegel coined the term Acosmism, the world is unreal, an illusion, and God alone is real.

Distinctions viewed from the human standpoint

Freedom or determinism. In those forms of pantheism that envisage the eternal God literally encompassing the world, man is an utterly fated part of a world that is necessarily just as it is, and freedom is thus an illusion. To be sure, Classical Theism holds to the freedom of man but insists that this freedom is compatible with a divine omniscience that includes his knowledge of the total future. Thus the question arises whether or not such freedom is illusory. Panentheism, by insisting that future reality is indeterminate or open and that man and God, together, are in the process of determining what the future shall be, probably supports the doctrine of man's freedom more completely than does any alternative point of view.

Sacramentalism or secularism. Insofar as God is the indwelling principle of the world and of man, as in pantheism, so far do these take on a sacramental character; and insofar as God is separated from the world as in 18th-century Deism (*q.v.*), so far does it become secular, neutral, or even fallen. In contrast, Classical Theism, though basically sacramental, places this quality in an enclave, the church.

DIVERSE VIEWS OF THE RELATION OF GOD TO THE WORLD

On the basis of the preceding characteristics, seven forms of pantheism can be distinguished in addition to Classical Theism and panentheism:

Hylozoistic pantheism. The divine is immanent in, and is typically regarded as the basic element of, the world, providing the motivating force for movement and change. The world remains a plurality of separate elements.

Immanentistic pantheism. God is a part of the world and immanent in it. Though only a part, however, his power extends throughout its totality.

Absolutistic monistic pantheism. God is absolute and identical with the world. The world, although real, is therefore changeless.

Relativistic monistic pantheism. The world is real and changing and is within God (*e.g.*, as the body of God). But God remains nonetheless absolute and is not affected by the world.

Acosmic pantheism. The absolute God makes up the total reality. The world is an appearance and ultimately unreal.

Identity of opposites pantheism. The opposites of ordinary discourse are identified in the supreme instance. God and his relation to the world are described in terms that are formally contradictory; thus reality is not subject to rational description. Whether being is stressed or the void, whether immanence is or transcendence, the result is the same: one must go beyond rational description to an intuitive grasp of the ultimate.

God as related to time and change

Classical Theism. God is absolute, eternal, first cause, pure actuality, an omniscient, omnipotent, and perfect being. Though related to the world as its cause, he is not affected by the world. He is essentially transcendent over the world; and the world exists relative to him as a temporal effect of his action—containing potentiality as well as actuality and characterized by change and finitude. Since all of time is part of God's eternal "Now," and since God's knowledge now includes the total future as though laid out before him like a landscape, it is not clear that, in this system, man can have freedom in any significant sense; for although foreknowledge does not of itself determine anything, it vouches for the existence of such determination. Nonetheless, human freedom is in fact asserted by Classical Theists.

Neoplatonic or emanationistic pantheism. God is absolute in all respects, remote from the world and transcendent over it. This view is like Classical Theism except that, rather than saying that God is the cause of the world, it holds that the world is an emanation of God, occurring by means of intermediaries. God's absoluteness is thus preserved while a bridge to the world is provided as well. In Plotinus (3rd century AD), the foremost Neoplatonist, the Nous (Greek, "mind"), a realm of ideas or Platonic forms, serves as the intermediary between God and the world, and the theme of immanence is sustained by positing a World-Soul that contains and animates the world.

Panentheism. In this alternative, both sets of categories, those of absoluteness and of relativity, of transcendence and of immanence, are held to apply equally to God, who is thus dipolar. He is the cause of the world and its effect; his essence is eternal, but he is involved in time. God's knowledge includes all that there is to know; since the future is genuinely open, however, and is not in any sense real as yet, he knows it only as a set of possibilities or probabilities. In this alternative man is held to have significant freedom, participating as a co-creator with God in the continuing creation of the world.

With only slight attention being accorded to Classical Theism (which is covered in another article), the incidence of the preceding eight forms of pantheism and panentheism in cultural history remains to be explored.

PANTHEISM AND PANENTHEISM IN NON-WESTERN CULTURES

The Vedas and *Upaniṣads*

Hindu doctrines. The gods of the Vedas, the ancient scriptures of India (*c.* 1200 BC), represented for the most part natural forces. Exceptions were the gods Prajāpati (Lord of Creatures) and Puruṣa (Supreme Being or Soul of the Universe), whose competition for influence provided, in its outcome, a possible explanation of how the Indian tradition came to be one of pantheism rather than of Classical Theism. By the tenth book of the Ṛgveda, Prajāpati had become a lordly, monotheistic figure, a creator deity transcending the world; and in the later period of the sacred writings of the *Brāhmaṇas* (*c.* 7th century BC), prose commentaries on the Vedas, he was moving into a central position. The rising influence of this Theism was later eclipsed by Puruṣa, who was also represented in Ṛgveda X. In a creation myth Puruṣa was sacrificed by the gods in order to supply (from his body) the pieces from which all the things of the world arise. From this standpoint the ground of all things lies in a Cosmic Self, and all of life participates in that of Puruṣa. The Vedic hymn to Puruṣa may be regarded as the starting point of Indian pantheism.

In the *Upaniṣads* (*c.* 600–300 BC), the most important of the ancient scriptures of India, the later writings contain philosophic speculations concerning the relation between the individual and the divine. In the earlier *Upaniṣads*, the absolute, impersonal, eternal properties of the divine had been stressed; in the later *Upaniṣads*, on the other hand, and in the *Bhagavadgītā*, the personal, loving, immanentistic properties became dominant. In both cases the divine was held to be identical with the inner self of each man. At times these opposites were implicitly held to be in fact identical—the view earlier called identity of opposites pantheism. At other times the two sets of qualities were related, one to the unmanifest absolute Brahman, or supreme reality (sustaining the universe), and the other to the manifest Brahman bearing qualities (and containing the universe). Thus Brahman can be regarded as exclusive of the world and inclusive, unchanging and yet the origin of all change. Sometimes the manifest Brahman was regarded as an emanation from the unmanifest Brahman; and then emanationistic pantheism—the Neoplatonic pantheism of the foregoing typology—was the result.

The views of Śaṅkara, Rāmānuja, and Radhakrishnan

Śaṅkara, an outstanding nondualistic Vedāntist and advocate of a spiritual view of life, began with the Neoplatonic alternative but added a qualification that turned his view into what was later called acosmic pantheism. Distinguishing first between Brahman as being the eternal Absolute and Brahman as a lower principle and declaring the lower Brahman to be a manifestation of the higher, he then made the judgment that all save the higher unqualitied Brahman is the product of ignorance or nescience and exists (apparently only in men's minds) as the phantoms of a dream. Since for Śaṅkara, the world and individuality thus disappear upon enlightenment into the unmanifest Brahman, and in reality only the Absolute without distinctions exists, Śaṅkara has provided an instance of acosmism.

On the other hand, Rāmānuja, a prominent southern Brahmin who held to a qualitied monism, argued strenuously against Śaṅkara's dismissal of the world and of individual selves as being mere products of nescience. In place of this acosmism he substituted the notion of world cycles. In the unmanifest state Brahman has as his body only the very subtle matter of darkness, and he decrees "May I again possess a world-body"; in the manifest state all of the things of the world, including individual selves, are part of his body. The doctrine of Rāmānuja approaches panentheism; he has certainly advanced beyond emanationistic pantheism. There are two aspects to the single Brahman, one absolutistic and the other relativistic. As in panentheism, the beings of the world have freedom. The only qualification is that, although it is Brahman's will to support the choices of finite beings, he has the power to prohibit any choice that displeases him. This power to prohibit indicates a preference for the absolute in Rāmānuja's thought, which is reflected in many ways: although God is the cause of the world, for example, and includes the world within his being, he is never affected by that world, and his motive in world creation is simply play. In sum, since the absolutistic categories were given the greater emphasis in his thought, Rāmānuja is representative of a relativistic monistic pantheism.

The presence in the Hindu tradition of both absolutistic and relativistic descriptions of the divine suggests that genuine panentheism might well emerge from the tradition; and, in fact, in the former president of India, S. Radhakrishnan, also a religious philosopher, that development did occur. Although Radhakrishnan had been influenced by Western philosophy, including that of A.N. Whitehead, later discussed as a modern panentheist, the sources of his thought lie in Hindu philosophy. He distinguishes between God as the being who contains the world and the Absolute, who is God in only one aspect. He finds

that the beings of the world are integral with God, who draws an increase of his being from the constituents of his nature.

Buddhist doctrines. Some 600 years after Buddha, a new and more speculative school of Buddhism arose to challenge the 18 or 20 schools of Hīnayāna (Sanskrit "Lesser Vehicle") Buddhism then in existence. One of the early representatives of this new school, which came to be known as Mahāyāna (Sanskrit "Greater Vehicle") Buddhism, was Aśvaghoṣa. Like Śaṅkara (whom he antedated by 700 years), Aśvaghoṣa not only distinguished between the pure Absolute (the Soul as "Suchness"; *i.e.*, in its essence) and the all-producing, all-conserving Mind, which is the manifestation of the Absolute (the Soul as "Birth and Death"; *i.e.*, as happenings), but he also held that the judgment concerning the manifest world of beings is a judgment of nonenlightenment; it is, he said, like the waves stirred by the wind—when the quiet of enlightenment comes the waves cease, and an illusion confronts a man as he begins to understand the world.

Whereas Aśvaghoṣa treated the world as illusory and essentially void, Nāgārjuna, the great propagator of Mahāyāna Buddhism who studied under one of Aśvaghoṣa's disciples, transferred *Śūnya* ("the Void") into the place of the Absolute. If Suchness, or ultimate reality, and the Void are identical, then the ultimate must lie beyond any possible description. Nāgārjuna approached the matter through dialectical negation: according to the school that he founded, the Ultimate Void is the Middle Path of an eightfold negation; all individual characteristics are negated and sublated, and the individual approaches the Void through a combination of dialectical negation and direct intuition. Beginning with the Middle Doctrine School, the doctrine of the Void spread to all schools of Mahāyāna Buddhism as well as to the Satyasiddhi (Sanskrit: "perfect attainment of truth") group in Hīnayāna Buddhism. Since the Void is also called the highest synthesis of all oppositions, the doctrine of the Void may be viewed as an instance of identity of opposites pantheism.

In the T'ien-t'ai school of Chinese Buddhism founded by Chih-i, as in earlier forms of Mahāyāna Buddhism, the elements of ordinary existence are regarded as having their basis in illusion and imagination. What really exists is the one Pure Mind, called True Thusness, which exists changelessly and without differentiation. Enlightenment consists of realizing one's unity with the Pure Mind. Thus, an additional Buddhist school, T'ien-t'ai, can be identified with acosmic pantheism.

Indeed, although a mingling of types is discernible in the Hindu and Buddhist strands of Oriental culture, acosmic pantheism would seem to be the alternative most deeply rooted and widespread in these traditions.

Ancient Near East doctrines. Just as the early gods of the Vedas represented natural forces, so the Canaanite deities known as Baal and the Hebrew God Yahweh both began as storm gods. Baal developed into a Lord of nature, presiding with his consort, Astarte, over the major fertility religion of the Near East. The immanentism of this nature religion might have sustained the development of pantheistic systems; but, whereas the pantheistic Puruṣa triumphed in India, the Theistic Yahweh triumphed in the Near East. And Yahweh evolved not into a Lord of nature but into a Lord of history presiding first over his chosen people and then over world history. The requirement that he be a judge of history implied that his natural "place" was outside and above the world; and he thus became a transcendent deity. Through much of the history of Israel, however, the people accepted elements from both of these traditions, producing their own highly syncretistic religion. It was this syncretism that provided the occasion that challenged certain men of prophetic consciousness to embark upon their purifying missions, beginning with Elijah and continuing throughout the Old Testament period. In this development, the absoluteness and remoteness of Yahweh came to be supplemented by qualities of love and concern, as in the prophets Hosea and Amos. In short, the categories of immanence came to supplement the categories of transcendence and, in the New Testament period, became overwhelmingly important. The transcendent Yahweh, on the other hand, had fitted more naturally into the categories of absoluteness. And, in the Christian West, it was the transcendent God who appeared in the doctrines of Classical Theism, while pantheism stood as a heterodox departure from the Christian scheme.

Baal, Yahweh

PANTHEISM AND PANENTHEISM IN ANCIENT AND MEDIEVAL PHILOSOPHY

Early Greek religion contained among its many deities some whose natures might have supported pantheism; and certainly the mystery religions of later times stressed types of mystical union that are typical of pantheistic systems. But in fact the pantheism of ancient Greece was related almost exclusively to philosophical speculation. For this reason it is more rationalistic, possessing a style quite different from the Pantheisms thus far examined.

Ancient Greco-Roman doctrines. The first philosophers of Greece, all of whom were 6th-century-BC Ionians, were hylozoistic, finding matter and life inseparable. The basic substances that they identified as the elements of reality—the water proposed by Thales, the boundless infinite suggested by Anaximander, and the air of Anaximenes—were presumed to have the motive force of living things and thus to be a kind of life, a position here called hylozoistic pantheism.

Pre-Socratic views

Impressed by the absolute unity of all things, the adherents of another philosophic position, that of Eleaticism (*q.v.*), so-named from its centre in Elea, a Greek colony in southern Italy, found it impossible to believe in multiplicity and change. The first step in this direction was taken by Xenophanes, a religious thinker and rhapsodist, who, on rational grounds, moved from the gods and goddesses of Homer and Hesiod to a unitary principle of the divine. He believed that God is the supreme power of the universe, ruling all things by the power of his mind. Unmoved, unmoving, and unitary, God perceives, governs, and apparently contains, or at least he "embraces," all things. So interpreted, Xenophanes provides an instance of monistic pantheism, inasmuch as, in this view, the Absolute God is united with a changing world, while the reality of neither is attenuated. This paradox may have encouraged Parmenides, possibly one of Xenophanes' disciples (according to Aristotle), to accept the changeless Absolute, eliminating change and motion from the world. Reality thus became for him a unitary, indivisible, everlasting, motionless whole. This position is basically that of absolutistic monistic pantheism in that it views the world as real but changeless. Insofar as the change and variety of the world are only apparent, Parmenides also approaches acosmic pantheism.

A third fundamental position is that of the Ephesian critic Heracleitus, among whose cryptic sayings were many that stressed the role of change as the basic reality. Heracleitus continued the hylozoistic tendencies of the Ionian philosophers. Fire, his basic element, is also the universal *logos*, or reason, controlling all things; and since fire not only has a life of its own but exercises control to the boundaries of the universe as well, the system is more complex than hylozoistic pantheism. In view of the circumstance that everything is either on the way from, or to, fire, this basic element is actually or incipiently everywhere. Since the divine works here from within the universe, indeed from within a single, but basic, aspect of it, the system is an instance of immanentistic pantheism.

The philosopher Anaxagoras, one of the great dignitaries at Athens in the golden age of Pericles, approached the problem somewhat in the manner of Heracleitus. *Nous* (or Mind) he held to be the principle of order for all things as well as the principle of their movement. It is the finest and purest of things and is diffused throughout the universe. This, like the preceding system, is an instance of immanentistic pantheism.

From the standpoint of the typology here employed, Plato may be regarded as the first Western philosopher to treat the problem of the absoluteness and the relativity in God with any degree of adequacy. In the *Timaeus* an absolute and eternal God was recognized, existing in

Plato's dualism

changeless perfection in relation to the world of forms, along with a World-Soul, which contained and animated the world and was as divine as a changing thing could be. Although the material can be variously interpreted, panentheists hold that Plato has adopted a dual principle of the divine, uniting both being and becoming, absoluteness and relativity, permanence and change in a single context. To be sure, he envisioned the categories of absoluteness as situated in one deity, and those of relativity in another; but the separation seems not to have pleased him, and in the tenth book of the *Laws*, by invoking the analogy of a circular motion, which combines change with the retention of a fixed centre, he explained how deity could exemplify both absoluteness and change. Plato thus may be viewed as a quasi-panentheist.

Aristotle, on the other hand, with his exclusivistic, transcendent God, exemplifying only the categories of absoluteness, anticipated the absolute God of Classical Theism, existing above and beyond the world.

Stoic pantheism, Neoplatonism

Stoicism, one of the foremost of the post-Aristotelian schools of thought, represents an immanentistic pantheism of the Heracleitean variety. First of all, the Stoics accepted the decision of Heracleitus that an indwelling fire is the principal element entering into all transformations and is also the principle of reason, the *logos*, ordering as well as animating all things, but that, second, there is a World-Soul, which is diffused throughout the world and penetrates it in every part. Rather than approximating Plato's spiritual World-Soul, the Stoic World-Soul is more like the *Nous* of Anaxagoras. The Stoics were Materialists, and their diffuse World-Soul is, thus, an extended form of subtle matter. That everything is determined by the universal reason is an unvarying theme in Stoicism; and this fact suggests that Stoic pantheism, despite its immanentism, stresses the categories of absoluteness rather than those of relativity in the relations holding between God and the world.

The life of reason brings man into harmony with God and with nature and helps him to understand his fate, which is his place in the universal system. Although the view is an amalgam of several types of pantheism, this particular mixture has retained its identity. It is therefore useful to call this position, or any similar combination of themes, by the name Stoic pantheism.

Plotinus, the creator of one of the most thoroughgoing philosophical systems of ancient times, may be taken to represent Neoplatonism, an influential modification of Plato's attempt to deal with absoluteness and relativity in the divine. Plotinus' system consists of the One—the absolute God who is the supreme power of the system—the intermediate *Nous*, and the World-Soul (with the world as its internal content). His World-Soul follows the Platonic model. The system really blends pantheism with Classical Theism, since the categories of absoluteness apply to the One, and the relativistic categories apply to the World-Soul. The doctrine of emanation, whereby the power of the One comes into the world, is a clear attempt to bridge the gap between absoluteness and relativity. For Plotinus, as for Classical Theism, there is immanent in man an image of the divine, which serves as well to relate man to God as does the divine spark in Stoic pantheism. Even Classical Theism may thus contain a touch of immanentistic pantheism. This view, or any similar combination of themes, is an instance of emanationistic or Neoplatonic pantheism.

Medieval doctrines. Though Scholasticism, with its doctrine of a separate and absolute God, was the crowning achievement of medieval thought, the period was, nonetheless, not without its pantheistic witness. Largely through Jewish and Christian mysticism, an essentially Neoplatonic Pantheism ran throughout the age.

The only important Latin philosopher for six centuries after St. Augustine was John Scotus Erigena. Inasmuch as, in his system, Christ's redemptive sacrifice helps to effect a Neoplatonic return of all beings to God, Erigena can be said to have turned Neoplatonism into a Christian drama of fall into sin and redemption from its power. When Erigena said that, even in the stage of separation from God, God in his superessentiality is identical with all things, he advanced beyond a strictly Neoplatonic pantheism to some stronger form of immanentistic or monistic pantheism.

In the two principal writings of the esoteric Jewish movement called the Kabbala, known for its theosophical interpretations of the Scriptures, a mystically oriented system of ten emanations is presented. A Spaniard, Avicebrón, a Jewish poet and philosopher, similarly presented a Neoplatonic scheme of emanations. And in Spain, Averroës, the most prominent Arabic philosopher, represented an Aristotelian tradition heavily overladen with Neoplatonism. For Averroës, the active intellect in man is really an impersonal divine reason, which alone lives on when man dies.

The German Meister Eckehart, probably the most significant of philosophical mystics, developed a markedly original theology. From his Stoic pantheism there arose his most controversial thesis—that there resides in every man a divine, uncreated spark of the Godhead, making possible both a union with God and a genuine knowledge of his nature. But Eckehart also distinguished between the unmanifest and barren Godhead and the three Persons who constitute a manifest and personal God. Thus, the system has similarities to both Stoic and Neoplatonic pantheism.

Cardinal Nicholas of Cusa, whose broad scholarship and scientific approach anticipated the coming Renaissance, continued the tradition into the 15th century. The "learned ignorance," in which a man separates himself from every affirmation, can have positive results, in Nicholas' view, because man is a microcosm within the macrocosm (or universe), and the God of the macrocosm is thus mirrored in all of his creatures. He also held that, in reference to God, contradictions are compatible —his "coincidence of opposites" doctrine, in which God is at once all extremes. Clearly, Nicholas wished to ascribe to God both the categories of transcendence and those of immanence without distinction. But in fact he displayed some preference for the categories of the absolute, insisting, for example, that the creatures of the world can add nothing to God since they are merely his partial appearances. Despite this bias toward absolutism, and even to acosmism, Nicholas can be appropriately viewed as espousing an identity of opposites pantheism.

PANTHEISM AND PANENTHEISM IN MODERN PHILOSOPHY

Renaissance and post-Renaissance doctrines. The humanism of the Renaissance included an enlarged interest in Platonism and in its historical carrier, Neoplatonism, as well as influences from Aristotle and from Kabbalistic sources. The view of man as a microcosm of the universe was widespread. Marsilio Ficino, one of the first leaders of the Florentine Academy, found the image and reflection of God in all men and anticipated the divinization of man and the entire cosmos. The humanist and syncretistic philosopher Pico della Mirandola, also a leading figure in the Academy, substituted for creation a Neoplatonic emanation from the divine.

The views of Ficino, Bruno, and Böhme

The most famous scholar of the Italian Renaissance was Giordano Bruno. Combining Copernican astronomy with Neoplatonism, Bruno thought of the universe as an infinite organism with monads as its ultimate constituents and world-systems as its parts. The universe, he held, is in a continual process of development and is infused with the divine life. Accepting Nicholas of Cusa's doctrine of the identity of opposites, he taught that contradictory ascriptions apply equally to God in particular and that claims concerning his immanence and transcendence are equally valid. More open to the categories of relativity than Nicholas, Bruno, however, exemplified a neatly balanced instance of identity of opposites pantheism.

The next great innovator of mystical religious thought was Jakob Böhme, who, in developing the concept of the divine life, took a decisive step beyond mere absoluteness. God goes through stages of self-development, he taught, and the world is merely the reflection of this process. Böhme anticipated Hegel in claiming that the divine self-development occurs by means of a continuing dialectic, or tension of opposites, and that it is the negative qualities

of the dialectic that men experience as the evil of the world. Even though Böhme, for the most part, stressed absoluteness and relativity equally, his view that the world is a mere reflection of the divine—apparently denying self-development on the part of creatures—tends toward acosmic pantheism.

Spinoza's rational pantheism

In the 17th century the foremost pantheist was a Jewish rationalist, Benedict Spinoza, whose training in the history of philosophy included both medieval Jewish philosophy and the Kabbala. He championed a rational rather than a mystical pantheism, so much so that all that remained of mysticism, in fact, was his concept of the intellectual love of God. The rationality of the system is suggested by Spinoza's argument that, since God is the infinite being, he must be identical with the world; for otherwise, God-and-world would be a greater totality than God alone. Also, since God is a necessary being and is identical with the world, the world must also be necessary in all its parts. It follows from this that human freedom is an impossible idea; and the sense that man has of such freedom is based on his ignorance of the causes that have determined him. Spinoza distinguished between God and the world in three ways: first, by stressing God's activity in the active sense of *natura naturans* ("the nature that [creates] nature"; *i.e.*, God) compared to the passive sense of *natura naturata* ("the nature that [is created as] nature"; *i.e.*, the world); second, he related God to eternity and the world to time; and third, he distinguished God as self-existing substance, the whole, from the world, which he conceived as the attributes and modes of that substance. In terms of the present classification, Spinoza represents a monistic pantheism tending toward absolutism.

Goethe, the incomparable German litterateur, claimed that he was a follower of Spinoza. In fact, however, his beliefs were rather different inasmuch as Goethe championed man's individuality; opposed mechanical necessity; and held a hylozoistic, or vitalistic, position in which nature was organic, a living unity. His personalistic pantheism mixes hylozoistic and Stoic types with a touch of relativism added to the mixture.

19th-century doctrines. During the 19th century, pantheism and panentheism were sustained by various kinds of Idealism that developed during the period. In these systems the categories of relativity gained in prominence; God was conceived as entering history and as being more intimately related to processes of change and development.

German Idealism. Although the philosophy of the German patriot J.G. Fichte, an immediate follower of Kant, began in the inner subjective experience of the individual, with the "I" positing the "not-I"—*i.e.*, feeling compelled to construct a perceived world over against itself—it turns out eventually that, at a more fundamental level, God, as the universal "I," posits the world at large. The world, or nature, is described in organic terms; God is considered not alone as the Universal Ego but also as the Moral World Order, or Ground of ethical principles; and since every man has a destiny as a part of this order, man is in this sense somehow one with God. In the moral world order, then, man has a partial identity with God; and in the physical order he has membership in the organic whole of nature. It is not clear, however, whether in Fichte's view God as Universal Ego includes all human egos, and the organic whole of nature. Should he do so, then Fichte would be a representative of dipolar Panentheism, since in his final doctrine the Universal Ego imitates an Absolute deity who is simply the divine end of all activity, serving equally as model and as goal. In this interpretation God is conceived both as absolute mobility and absolute fixity. It is not entirely clear whether the doctrine is to be understood as referring to two aspects of a single God, the panentheistic alternative, or to two separate gods, the alternative imbedded in Plato's quasi-panentheism. In either case, Fichte has enunciated most of the themes of panentheism and deserves consideration either as a representative or precursor of that school.

A second early follower of Kant was F.W.J. von Schelling, who, in contrast to Fichte, stressed the self-existence of the objective world. Schelling's thought developed through several stages. Of particular interest to the problem of God are the final three stages in which his philosophy passed through monistic and Neoplatonic pantheism followed by a final stage that was panentheistic.

In the first of these stages, he posits the Absolute as an absolute identity, which nonetheless includes, as in Spinoza, both nature and mind, reality and ideality. The natural series culminates in the living organism; and the spiritual series culminates in the work of art. The universe is, thus, both the most perfect organism and the most perfect work of art.

In his second, Neoplatonic, stage he conceived the Absolute as separated from the world, with a realm of Platonic ideas interposed between them. In this arrangement, the world was clearly an emanation or effect of the divine.

In the final stage of his thought, Schelling presented a theophany, or manifestation of deity, involving the separation of the world from God, and its return. In appearance this was quite like the views of Erigena or like the unmanifest and manifest Brahman of Indian thought. But, since the power of God continues to infuse the world and there can be no real separation, the entire theophany is clearly the development of the divine life. The Absolute is retained as the pure Godhead, a unity presiding over the world; and the world—having in measure its own spontaneity—is both his antithesis and part of his being, the contradiction accounting for progress. The positing within God of eternity and temporality, of being-in-itself and of self-giving, of yes and no, of participation in joy and in suffering, is the very duality of Panentheism.

It was a disciple of Schelling, Karl Christian Krause, who coined the term panentheism to refer to the particular kind of relation between God and the world that is organic in character.

Hegel's notion of Absolute Spirit

The third, and most illustrious, early post-Kantian Idealist was G.W.F. Hegel, who held that the Absolute Spirit fulfills itself, or realizes itself, in the history of the world. And in Hegel's deduction of the categories it is clear that man realizes himself through the attainment of unity with the Absolute in philosophy, art, and religion. It would appear, then, that God is in the world, or the world is in God, and that, since man is a part of history and thus a part of the divine realization in the world, he shares in the divine life; it would seem, too, that God is to be characterized by contingency as well as necessity, by potentiality as well as actuality, by change as well as permanence. In short, it would seem at first that the panentheistic dipolarity of terms would apply to the Hegelian Absolute. But this is not quite so; for Hegel's emphasis was on the deduction of the categories of logic, nature, and spirit, a deduction that provided the lineaments of Spirit-in-Itself (the categories of the intrinsic logic that the world, as Spirit, follows in its development), Spirit-for-Itself (nature as existing oblivious to its own context), and Spirit-in-and-for-Itself (conscious spiritual life, natural, and yet aware of its role in the developing world). This deduction, moving from the most abstract categories to the most concrete, is partly logical and partly temporal; it cannot be read either as a sheerly logical sequence or as a sheerly temporal sequence. As a logical sequence, it has the appearance of a Neoplatonic scheme turned on its head, since the Absolute Spirit that emerges from the deduction includes all of the steps of the preceding rich and multifarious deduction. As a temporal sequence, the system would seem to be a species of Stoic (*i.e.*, Heracleitean) pantheism, qualified by a clear Parmenidean motif (see above), which appears in its stress on an absoluteness that, from the eternal standpoint, cancels out time. This Parmenidean quality is to be found not only in Hegel but in most of the Idealists who were influenced by him. Time is real, on this view, and yet not quite real, having already eternally happened. And when Hegel spoke of the Absolute Spirit, this phrase held the internal tension of a near contradiction, for spirit, however absolute, must surely be relative to what is around it, sensitive to and dependent on other spirits. The fact that Hegel wished to give something like equal emphasis, however, both to absoluteness

and to relativity in the divine being or process suggests that his goal is identical with that of the panentheists, even though he is perhaps more fairly regarded as a Pantheist of an ambiguous type.

Monism and panpsychism. It is impossible for one to leave the 19th century without mention of the pioneering experimental psychologist Gustav Fechner (1801–87), founder of psychophysics, who developed an interest in philosophy. Fechner pursued the themes of panentheism beyond the positions of his predecessors. A panpsychist with an organic view of the world, he held that every entity is to some extent sentient and acts as a component in the life of some more inclusive entity in a hierarchy that reaches to the divine Being, whose constituents include all of reality. God is the soul of the world, which is, in turn, his body. Fechner contends that every man's volitions provide impulses within the divine experience, and that God gains and suffers from the experiences of men. Precisely because God is the supreme being, he is in process of development. He can never be surpassed by any other, but he surpasses himself continually through time. He, thus, argues that God can be viewed in two ways: either as the Absolute ruling over the world, or as the totality of the world; but both are aspects of the same Being. Fechner's affirmations comprise a complete statement of panentheism, including the dipolar deity with respect to whom the categories of absoluteness and relativity can be affirmed without contradiction.

Fechner's panentheism

Twentieth-century doctrines. The 20th century marks a decisive break with absolutism. In the first half of the century, panentheism gained in authority. The position of the Russian ex-Marxist Nikolay Berdyayev, a religious metaphysician, with his emphasis on divine and human freedom, is a manifesto of panentheism. Even more impressive was the work of the eminent British-American philosopher, Alfred North Whitehead. As in the case of Fechner, Whitehead came to philosophy from science and held an organismic view of the structure of the world. In Whitehead's view God has two natures: his primordial nature is abstract; his consequent nature is concrete and includes within itself the total history of the world. Whitehead was also a panpsychist and believed that feeling is present in some degree at every level of the world process. Whether or not he was, then, also a panentheist is in dispute. He held that the possible future and the total past are in God—in his primordial and consequent natures; but for Whitehead the present moment is relative, and contemporaries exclude each other. In the present moment of any entity, since it is the present of *that* entity, it is appropriate to say that God is in that entity, part of the data on which it acts; thus the Stoic spark of divinity has here a modern application. From the standpoint of God, on the other hand, all entities are part of God; they come from him and return to him in the passage of time, but they are not in God in the sense that their independence in the present moment is prejudiced.

The views of Whitehead and Hartshorne

It was left to Charles Hartshorne, one of Whitehead's followers, to provide the definitive analysis of panentheism. It is Hartshorne's suggestion that the organismic analogy, present in Whitehead as well as in many earlier thinkers, be taken seriously. For Hartshorne, God includes the world even as an organism includes its cells, thus including the present moment of each event. The total organism gains from its constituents, even though the cells function with an appropriate degree of autonomy within the larger organism.

CRITICISM AND EVALUATION OF PANTHEISM AND PANENTHEISM

Panentheism is then a middle way between the denial of individual freedom and creativity characterizing many of the varieties of pantheism and the remoteness of the divine characterizing Classical Theism. Its support for the ideal of human freedom provides grounds for a positive appreciation of temporal process, while removing some of the ethical paradoxes confronting deterministic views. It supports the sacramental value of reverence for life. At the same time the theme of participation with the divine leads naturally to self-fulfillment as the goal of life.

Many pantheistic and Theistic alternatives claim the same advantages, but their natural tendency toward absoluteness may make justification of these claims in some cases difficult and, in others, some argue, quite impossible. It is for this reason that a significant number of contemporary philosophers of religion have turned to panentheism as a corrective to the partiality of the other competing views.

BIBLIOGRAPHY. CHARLES HARTSHORNE and W.L. REESE, *Philosophers Speak of God* (1953), offers an extensive historical exploration of pantheism, panentheism, and Classical Theism. The fundamental basis of panentheism is discussed not only in the epilogue of the above volume, but in many other works by CHARLES HARTSHORNE, including *The Divine Relativity* (1948) and *The Logic of Perfection* (1962). For the relation of mysticism to pantheism, see W.T. STACE, *Mysticism and Philosophy* (1960). For information concerning any of the philosophers mentioned, reference may be made to their individual entries in *The Encyclopedia of Philosophy*, 8 vol., ed. by PAUL EDWARDS (1967); the *Enciclopedia filosofica*, 6 vol., 2nd ed., ed. by G.C. SANSONI (1967); or the *Diccionario de filosofía*, 2 vol., ed. by JOSE FERRATER MORA (1965).

Papacy

The papacy is the system of central government of the Roman Catholic Church, the largest of the three major branches of Christianity, presided over by the bishop of Rome, who is recognized by Roman Catholics as the pope and the successor of St. Peter, the "chief of the Apostles" of Jesus Christ.

This article is divided into the following sections:

NATURE AND SIGNIFICANCE

The word papacy (Latin *papatia*, derived from *papa*, pope; *i.e.* father) is of medieval origin. In its primary usage it denotes the office of the pope (of Rome), and, hence, the system of ecclesiastical and temporal government over which he directly presides. It is with the word in this latter sense that this article is concerned.

The papal office. The multiplicity and variety of papal titles themselves indicate the complexity of the papal office. In the *Annuario Pontificio*, the official Vatican directory, the pope is described as bishop of Rome, vicar of Jesus Christ, successor of the prince of the Apostles, supreme pontiff of the universal church, patriarch of the West, primate of Italy, archbishop and metropolitan of the Roman province, sovereign of the state of Vatican City, servant of the servants of God. In his more circumscribed capacities as bishop of Rome, metropolitan of the Roman province, primate of Italy, and patriarch of the West, the pope is the bearer of responsibilities and the wielder of powers that have their counterparts in the other episcopal, metropolitan, primatial, and patriarchal jurisdictions of the Roman Catholic Church. What differentiates his particular jurisdiction from these others and renders his office unique is the Roman Catholic teaching that the bishop of

Titles of the pope

Rome is at the same time successor to St. Peter, prince of the Apostles. As the bearer of the Petrine office, he is raised to a position of lonely eminence as chief bishop or primate of the universal church. The precise lineaments of this belief have undergone considerable development over the centuries, but as defined by the first Vatican Council in 1870 (and reaffirmed by the second in 1964) it involves these fundamental assertions: that Christ singled out St. Peter among the Apostles, conferring upon him not only a pre-eminence among them but also the leadership or primacy in that visible community or church which he established after his Resurrection; that Christ intended this primacy to be one not merely of honour but of true jurisdiction, and one exercised not merely by Peter himself but also by his successors down through the ages to the end of time; and that the bishops of Rome are to be recognized as these successors.

Papal primacy and functions

Because of the development of this belief, the popes have come over the course of time to wield supreme legislative, executive, and judicial powers (jurisdictional functions) in the church—issuing authoritative statements on matters of doctrine (the magisterial or teaching function), creating and suppressing church laws, establishing dioceses, appointing bishops, controlling missions, acting as a court of first instance as well as of appeal, and performing, either by deputy or in person, a host of other functions. Also, because of this belief, they had assumed already in the 5th century the title of supreme pontiff (*summus pontifex*) that had earlier been borne by the pagan Roman emperors as heads of the college of priests. During the Middle Ages the popes also began to monopolize the title of "vicar [*i.e.*, representative] of Christ," which, like the very name of "pope" for that matter, the early Latin Church had customarily accorded to bishops in general. The title of sovereign of the state of Vatican City refers to the pope's position as temporal ruler of the tiny sovereign state in Rome created in 1929 by Italy in accordance with the terms of the Lateran Treaty. The last title, "servant of the servants of God," an essentially pastoral designation, is the title that popes themselves have very often chosen to emphasize when called upon to issue solemn pronouncements of great importance for the whole church.

The instruments of papal government. In the day-to-day exercise of his primatial jurisdiction the pope relies on the assistance of the Roman Curia, a name first used of the body of papal assistants in the 11th century. The Curia had its origins in the local body of presbyters (priests), deacons (lower order of clergy), and notaries (lower clerics with secretarial duties) upon which, like other bishops in their own dioceses, the early bishops of Rome relied for help. By the 11th century, this body had, on the one hand, been narrowed down to include only the leading (or cardinal) presbyters and deacons of the Roman diocese, while, on the other hand, being broadened out to embrace the cardinal-bishops (the heads of the seven neighbouring, or "suburbicarian," dioceses). From this emerged the Sacred College of Cardinals, a corporate body possessed, from 1179 onward, of the exclusive right to elect the pope. This right it still possesses, as it does the right to govern the church in urgent matters during a vacancy in the papal office. Recent popes have extended the size of the Sacred College beyond the traditional limit of 70 and have attempted, with growing success, to broaden its national complexion and to make its membership more faithfully representative of the church's international character.

The Roman Curia

During the Middle Ages, the cardinals played an important role as a corporate body, not only during papal vacancies, as today, but also during the pope's lifetime. In the 12th century, the Roman councils that popes had hitherto convoked when urgent matters were at hand were replaced by the assembly of the cardinals, or consistory, which thus became the most important collegial (corporate) body advising the pope and participating in his judicial activity. Eventually it began to make oligarchic claims to a share in the powers of the Petrine office, and attempted with sporadic success, to bind the pope to act on important matters only with its consent. During the 16th century, however, with the final establishment of the Roman Congregations (administrative committees), each charged with the task of assisting the pope in a specific area of government, the significance of the consistory began to decline, and with it the importance of the cardinals as a corporate body. At the same time, there was an increase in the power and influence of the "curial" cardinals—those cardinals who did not administer local dioceses but served as the pope's representatives in important foreign affairs or resided permanently in Rome, holding responsibilities in the curial congregations, tribunals, and offices that proliferated in the course of the next three centuries.

By the early 20th century, the growth of the Roman Curia had produced a bewildering tangle of administrative and judicial bodies, in which neither temporal and ecclesiastical functions nor executive and judicial powers were clearly demarcated. The reforms of Pius V (reigned 1566–72) and Benedict XV (reigned 1914–22) clarified and streamlined the work of the Curia, introducing a measure of order into its maze of overlapping jurisdictions. But in the wake of the complaints about abuses of curial power that were voiced at the second Vatican Council (along with requests for an internationalization of curial staff and a modernization of curial functions and procedures), Paul VI pledged himself to act.

Modern reforms of the Curia

Though Paul VI made some changes in detail, his reforms leave intact the basic curial structure created by Pius V, with its tripartite division of the various curial bodies: the Roman Congregations composed of cardinals nominated by the pope (*e.g.*, the Congregation for the Doctrine of the Faith, which was the former Holy Office and direct descendant of the Roman Inquisition); the tribunals, three in number, which compose the judicial branch of the Curia and one of which, the Rota, handles matrimonial cases; a group of offices, councils, and secretariates, the most important of which is the Secretariat of State, presided over by the cardinal secretary of state, who now emerges as the pope's "prime minister." To promote a higher degree of coordination among the various jurisdictions, provision was made for regular meetings of department heads, summoned and presided over by the cardinal secretary of state. Similarly, to prevent bureaucratic empire-building, most curial appointments were to be made for an initial term of five years. Finally, in response to Vatican II's request, some diocesan bishops were to be present at the plenary sessions of the congregations, efforts were to be made to internationalize the curial staff, and there was to be some attempt to consult the laity. These reforms came into effect in January 1968.

HISTORY

The early bishops of Rome to Leo I. Historical evidence concerning the early Christian congregation at Rome is not extensive; that concerning its first bishops is extremely scanty. That St. Paul preached at Rome and was probably put to death there during Nero's reign (*c.* AD 67) is not contested. Somewhat less certain is the claim that St. Peter, too, visited Rome and was martyred there about the same time. Few scholars would endorse the claim that the excavations (1940s–60s) under St. Peter's Basilica have culminated in the discovery of Peter's tomb. Most would agree at the very least, however, that the excavations reveal that some Roman Christians of the early 3rd century believed that Peter's grave was on that site. This adds further weight to the already weighty tradition of Peter's presence at Rome—a tradition attested to by several important pieces of literary evidence from *c.* 96 onward, emanating from Africa and Asia Minor as well as from Rome itself, challenged by no rival tradition and contested by no contemporary witness.

St. Paul and St. Peter in Rome

Though none of the evidence indicates anything definite about the nature of Peter's position at Rome, many exegetes (interpreters employing critical techniques), both Roman Catholic and Protestant, agree that Christ singled out Peter among the Apostles and conferred upon him a certain pre-eminence. There is no necessary deduction, however, from Peter's primacy among the Apostles to the primacy of those early bishops of Rome who may have claimed to be his successors—the less so in the absence of any historical evidence permitting the assertion that

Peter exercised an office of episcopal nature at Rome. Not much light is shed on the question of the primacy by materials from the early post-apostolic era, either by the first lists of the bishops of Rome or by such important and much exploited pieces of evidence as I Clement, a letter sent by the church of Rome to the church of Corinth *c.* 96, or the letter that Ignatius of Antioch sent to the Romans *c.* 110. The interpretation of these and of similar data has been disputed. If read in historical context, what they actually state constitutes a less than persuasive witness to the primacy of the Roman bishops in the universal church. And what one reads into their silences depends very much upon one's theological presuppositions. Clement's letter is striking evidence, however, for the prominence of the Roman Church at the end of the 1st century, and, taken together, these early data indicate that in doctrinal matters, at least, the Roman Church was accorded a certain pre-eminence even among the handful of churches that claimed apostolic foundation and were therefore regarded as embodying the apostolic teaching in its full purity. They indicate, too, that this pre-eminence was intimately connected with the impressive apostolic credentials of the Roman Church and is not explicable solely by the fact that Rome was the imperial capital.

Early claims to primacy. By the 3rd century the Roman bishops were claiming for themselves a primacy of authority in the universal church comparable to that of Peter's primacy among the Apostles. This claim was asserted on doctrinal matters and did not go unopposed, a fact attested to by the vigorous resistance of St. Cyprian of Carthage to Pope Stephen I (reigned 254–257). Only in the 4th and 5th centuries was this claim transformed into the more sweeping claim to a primacy of jurisdiction. This was a response of the Roman bishops to the challenge posed by the then growing pre-eminence and mounting claims of the see of Constantinople (the seat of the patriarch of the capital of the Eastern Roman, or Byzantine, Empire). It also reflected their increasing tendency, as leading dignitaries of a civic church supported by the coercive force of the imperial administration, to understand their own primatial claim in juristic rather than biblical categories. Most actively responsible for this development were the popes Damasus I, Siricius, Innocent I, Boniface I, and, above all, Leo I (reigned 440–461). The gap between theory and practice, however, remained immense. Despite Leo's protests, the Council of Chalcedon in 451 decreed that the New Rome (Constantinople) was "to enjoy the same primacy" in the East as the Old Rome enjoyed in the West, revealing thereby the impact of the enhanced political status of Constantinople in the empire and also what was destined to be an enduring Eastern inability to understand the Petrine theory in the same terms as it was understood in the West. Although in his own day—in a Western patriarchate ravaged by barbarian invasion and the political and ecclesiastical disorganization that went with it—Leo's theoretical claims were generally conceded, it was to be centuries before they were effectively put into practice. In the meantime, it was the emperors residing in Constantinople who—summoning general councils (composed of bishops and theologians to decide doctrinal and ecclesiastical matters) as they had done since the time of Constantine (who convened the Council of Nicaea in 325)—could make the stronger claim to be the functioning supreme leaders of the Christian world, even in spiritual matters.

Opposition to the primacy of the bishop of Rome

Gregory the Great. The popes who succeeded Leo I, though they were able to play a significant, if tortuous, role in the great Christological controversies (concerning doctrines about the divine and human nature of Christ) of that period, were to a very considerable degree at the mercy of events. Threatened by the disintegration of the Western Empire, weakened as patriarchs of the West by the loss of the African, Spanish, and Italian provinces to rulers of heretical persuasion, their relationship with the emperors ruling from Constantinople continued to be one of subservience, except for Gelasius I (reigned 492–496). Gelasius, however, enjoyed the support of the Ostrogothic king Theodoric, and his pontificate predated that intensified imperial surveillance of papal activity that followed Justinian's reconquest of Italy (555). As it was, imperial influence survived even the Lombard invasion of Italy (568) and the actual demise of imperial protection.

In this respect, Gregory I, called the Great (reigned 590–604), whose fate it was to face a Lombard threat to Rome itself with no support from the emperor in Constantinople and to purchase Rome's freedom through tribute, in no way broke with his predecessors. Like them, he insisted that his own jurisdiction was universal; like them he sought to resist the growing pretensions of the patriarchs of Constantinople. Again, like his predecessors', and as befitted a former civil servant of Rome, his loyalty to the empire was almost instinctive. His writings reveal him to have been a man whose preoccupations were overwhelmingly pastoral, and it is altogether appropriate that he should have adopted the title of "servant of the servants of God." His supervision of the Italian and African churches, his efforts to convert the Lombards and Anglo-Saxons, to sponsor reform in the Frankish Church, and to re-establish links with the newly converted Visigoths in Spain were, by his own scale of values, the tasks truly congruent with his office. He took it upon himself to supervise the civil administration of Rome and to negotiate with the Lombards. This he did as the principal surviving civilian official at a time when the imperial government was clearly no longer effective and as the one who, by his reorganization of the vast landholdings of the Roman Church throughout Italy and Sicily, alone possessed the resources needed to feed the Romans, to pay the soldiers, and to buy off the invaders.

The claims and accomplishments of Gregory I

The early medieval papacy. To the inhabitants of the Roman world, Gregory I remained a leading dignitary in what was still an imperial church. To the barbarians of the West he personified the majesty of Rome, exercising over them influence rather than jurisdiction. Thus, despite his commitment of the papacy to a role of positive leadership in the Western regions (*e.g.*, Italy, Gaul, Spain, etc.) that escaped the Eastern Roman imperial orbit, it is perhaps more appropriate to regard Gregory I as a transitional figure than as "the first of the medieval popes." Only in the 8th century, after Islām had dealt shattering blows to the Eastern (Byzantine) Empire by conquering Byzantine-controlled areas, such as Egypt, Syria, the Holy Land, etc., and when the Lombards had renewed their drive to the south in Italy, did the popes finally turn to the West. The outcome of their connection with the Frankish monarchy was to be of the utmost importance. Though the Donation of Constantine (a document connected with later Pseudo-Isidorian decretals and forged in the mid-8th century presumably by pro-Roman clerics) furnished the popes with a persuasive though spurious title to the central Italian territory known later as the Papal States, it was the Frankish armies that forced the transfer of these nominally Byzantine territories from Lombard into papal hands. With the advent of Charlemagne, who exercised authority in matters ecclesiastical as well as civil with Byzantine impartiality, and who in 774 seized the Lombard crown for himself, it soon became clear that the papacy, in linking its fortunes with the Carolingians and committing itself to the exercise of temporal power in Italy, had not won the freedom of action that it had sought under Byzantine rule. But the period of Carolingian dominance was short.

Donation of Constantine

Ninth- and 10th-century developments affecting the papacy. By the latter half of the 9th century, dynastic dissension within and renewed invasion from without had so weakened the Carolingian monarchs that, for a few brief years, popes of the calibre of Nicholas I and John VIII were able not only to emphasize the primacy of honour due to the papacy but even to reaffirm with considerable force its claim to a primacy of jurisdiction, in spite of Byzantine opposition. By emphasizing the precedents that the papal coronation and anointing of emperors had repeatedly established during the earlier part of the century, the popes were also able to reinterpret that claim to involve the title to leadership of Christian society in matters temporal as well as spiritual.

In so extending their claims, these 9th-century popes were aided by factors not always of their own shaping.

Their claim to a primacy of jurisdiction drew marked theoretical support from the Frankish collection of canons later known as the Pseudo-Isidorian decretals (partially forged documents that upheld the freedom of the church from secular interference) and accepted as authentic during the Middle Ages. Again, their prestige was enhanced by the decline under Muslim rule of their ancient rivals in apostolic dignity—the patriarchates of Jerusalem, Alexandria, and Antioch. But their prestige was enhanced most by the ultimate effect of papal encouragement of evangelization and church reform in England, France, and Germany, and by the fact that to the newly converted peoples of the West the popes represented both the lost glamour of imperial Rome and the tradition of apostolic succession.

Decline of papal influence and prestige

Without this accumulated prestige and the precedents established by the 9th-century popes, the claim to primacy would have had difficulty in surviving the subsequent period of papal decadence. In the 870s the imperial government in Italy declined in influence, and the bishopric of Rome, along with other European bishoprics, was increasingly at the mercy of the local nobility, with only spasmodic interventions by the 10th-century German emperors who were powerless to effect any permanent deliverance. German "protection," however, had its own price. When the emperor Henry III descended into Italy in 1046, deposing three rival claimants to the papacy (Sylvester III, Gregory VI, and Benedict IX) and then appointing his own candidate, Clement II (and, later, several successors), the Roman Church was itself in grave danger of becoming an imperial proprietary church, similar to those multitudinous lower churches in Europe whose royal or aristocratic owners regarded them, in accordance with age-old custom, as their own private property to be disposed of at will. But with the advent in 1049 of Leo IX, the third of the popes appointed by Henry III, reform came to Rome.

The Hildebrandine papacy and the Investiture Conflict. Church reform, sponsored by two movements within monasticism in Burgundy and Lorraine and enjoying strong support from Henry III, had become very active and widespread. It was weakened, however, by the lack of unified guidance and control. Leo IX, a representative of the Lorraine movement, set out to provide the necessary guidance. He abandoned the preoccupation with local Italian politics that had characterized his immediate predecessors, and appeared in person at a whole series of synods in France and Germany to investigate, to judge, and to legislate.

Leo's reforming efforts were directed toward eliminating the corruptions of simony (the buying and selling of ecclesiastical office) and of clerical marriage (which, despite its canonical prohibition in the Latin Church, had become widespread). Both corruptions reflected the extent to which, during centuries of invasion and chaos, family and political interests had triumphed over the church's spiritual goals. At a deeper level they reflected the degree to which, in ecclesiastical and temporal realm alike, the crucial distinction that the Romans had made between the holding of office and the possession of property had become blurred. As a result, there had been a gradual extension of lay control (aristocratic, royal, or imperial) over the disposal of ecclesiastical benefices (properties), a control symbolized in the case of the higher churches by the ceremony of investiture in which the lay ruler conferred the ecclesiastical office upon his chosen nominee. Though enjoying the reforming collaboration of the emperor Henry III, Leo did not challenge this control. After many setbacks and disappointments, the more radical reformers were already beginning to doubt that the traditional objectives of moral reform could really be secured without the curtailment of lay interference. Only, however, when Henry III was gone, when a royal minority left the Roman Church without imperial protection, and when the Roman nobility seized the opportunity to try to regain control over the making of popes, did the papacy embrace a more radical approach, and only then because it was able to gain the support of new allies—hence the significance of Nicholas II's brief pontificate (1059–61). In 1059 he allied himself with the Normans of southern Italy, who thus became vassals of the papacy, pledged to support it militarily; and at a Roman synod he promulgated the historic decree placing the election of popes in the hands of the cardinal-bishops.

Reform of papal elections

The object of the decree was to destroy the power of the local aristocracy over the making of popes, but it encroached deeply upon an established imperial prerogative, nevertheless, and German opposition was immediate. Not until 1075, however, did that opposition erupt into an open battle, when the new German king, Henry IV, intent on restoring the religio-political status quo of Henry III's time but lacking his father's zeal for reform, finally clashed with Gregory VII.

Gregory VII (Hildebrand). From the early 1060s until his election in 1073, Gregory VII (Hildebrand) had been the leading radical among the reformers at Rome, and in 1075 he issued a blunt decree threatening with excommunication any prince who presumed to invest anyone with ecclesiastical office. In so doing, Gregory was not simply responding to Henry's lack of reforming zeal or to the pressure of events. Instead, it was his firm conviction that the papal primacy of jurisdiction in the universal church was no longer to be minimized. For Gregory this primacy involved an active exercise of jurisdiction in the local churches, which encroached markedly upon the cherished autonomy of the bishops. It also exalted the papacy to a position in the Christian commonwealth that involved some sort of superiority even over temporal rulers. The wholly unprecedented claim was expressed in the 12th clause of the document known as the *Dictatus Papae* ("Dictates of the Pope," 1075) and inserted in the papal register—"That he [the pope] may depose emperors."

The Investiture Conflict

On this remarkable claim Gregory acted twice during the course of the tragic conflict (Investiture Conflict) that broke out between emperor and pope late in 1075, and that outlasted both of the original protagonists. The conflict ended only in 1122 when Henry V agreed to the Concordat of Worms—a compromise settlement that failed to eliminate all vestiges of royal control over the higher churches and left lay control over the lower churches untouched.

The papacy at its height: the 12th and 13th centuries. Gregory VII has often been portrayed as an innovator who lacked both authentic ancestors and true successors. It must be affirmed, nonetheless, that the later history of the papacy, modern as well as medieval, was shaped by what he and his followers did, while the continuing disabilities characteristic of the medieval papacy owed much to what they left undone. Thus, the assimilation of the biblical notion of church office as grounded in love for others to the political notions of office as grounded in power and law—a development in process since the 4th century and earlier—reached a point of no return with Gregory. He functioned within a unified Christian society in which "state" and "church" were no longer conceived as distinct societal entities and was thus impelled by its very dynamic to assert a claim to jurisdictional supremacy even over the Christian emperor. For the next two centuries papal history was characterized by a deepening involvement, direct and indirect, in matters political. As a result, there were, under Alexander III (reigned 1159–81) and Innocent IV (reigned (1243–54), renewed clashes with the German emperors, and, under Innocent III (reigned 1198–1216), extensive and damaging papal interference in German internal affairs. What alarmed these popes was the fear that imperial policy, by encroaching upon papal territorial independence, also threatened the autonomy of papal action. But with Innocent IV, at least, such a fear was matched by his wish to vindicate, even in temporal matters, the papal claim to ultimate supremacy.

Though much of the drama of papal history in this period focuses upon these conflicts, the impact which the thoroughgoing politicization of church office had upon the nature and structure of ecclesiastical government and the pope's place in it was of more enduring significance. Here again Gregory's pontificate was something of a watershed. Any lingering belief that the pope's primacy

might be regarded primarily as one of honour was now dispelled, and any hesitation about implementing the jurisdictional primacy that had supplanted it now disappeared. The need for papal leadership was so widely accepted that throughout much of the 12th and 13th centuries the demand for it came from the local churches themselves. The outcome was an acceleration in the process that had led, by the late 13th century, to a papal exercise of judicial supremacy going far beyond the mere acceptance of appeals from lower courts: to an arrogation of the wide-ranging legislative powers manifest in the *Decretals* of Gregory IX (1234), the first officially promulgated collection of papal laws, and to the system of "papal provisions" (direct papal intervention in the disposal of benefices) that was finally to be completed by Benedict XII in 1335.

The papal monarchy. Papal leadership *in* the church was eventually replaced by papal monarchy *over* the church. Positively, this transformation was evident in the reforming legislation of the fourth Lateran Council (1215). The negative aspect was to become increasingly obvious as the 13th century wore on. It was no accident that what turned out to be the permanent schism between the Latin and Greek churches had occurred in 1054 at a time when Leo IX had embarked upon a more active exercise of the papal primacy. The more his successors succeeded in establishing the fullness of their jurisdictional power (*plenitudo potestatis*) within the Latin Church, the less chance there was of healing the schism. Nor did papal sponsorship of the Crusades, however great the prestige it had brought to Urban II at the time of the First Crusade, ultimately redound to the benefit of the religious life of the church. Least of all was the administrative centralization attendant upon the exercise of the *plenitudo potestatis* justified when it was finally measured against the price that had to be paid—notably the corruption spawned by the stringent financial measures (*e.g.*, sale of indulgences, benefices, etc.) needed to support the growing army of clerical bureaucrats at Rome. And on this point one of the things left undone by the Gregorian reformers proved to be crucial. Their failure to uproot the notion of the "proprietary church" explains both the willingness of later canonists to classify the laws governing the disposition of ecclesiastical benefices under the heading not of public but of private law (law pertaining to the protection of proprietary right), and also the tendency of medieval persons in general to regard ecclesiastical office less as a focus of duty than as a source of income or an object of proprietary right. When the 13th-century popes found that direct papal taxation did not yield funds sufficient to support their bureaucrats, they adopted the practice of "providing" them to benefices all over Europe, for the law itself encouraged them to think of such benefices as sources of much needed revenue. Thus arose the characteristic abuses of pluralism (holding more than one benefice) and nonresidence against which church reformers from the mid-13th century on railed in vain. The papacy had finally come to be regarded as an obstacle rather than a spur to reform.

Negative aspects of the 13th-century reforms

The crisis of the late Middle Ages: Boniface VIII to the Council of Trent. *The beginning of the Avignon papacy.* In 1303, despite its resounding claims and its complex governmental machinery, the prestige of the papacy had fallen so low that it was possible for mercenaries in French pay and under French leadership to harass with impunity and humiliate the pope himself, Boniface VIII, at Anagni, where he was arrested in his own family (Caetani) palace.

The aftermath of this "outrage of Anagni" was the "Babylonian Captivity"—the desertion of Rome by the popes and their long residence (1309–77) at Avignon, France. The Avignonese papacy was neither as morally corrupt nor as responsive to French pressure as generally believed. It was overwhelmingly French in complexion, and this, along with its intensification of centralization, did impose severe strains. Serious problems arose when to these strains were added the tensions engendered by the oligarchic ambitions of the cardinals, who became increasingly determined to transform their traditional involvement in the shaping of papal policy into a constitutional right.

The "Babylonian Captivity" at Avignon

The Great Schism and the rise of conciliarism. In 1378, only a year after Gregory XI had brought the papacy back to Rome, a disputed papal election initiated the Great Schism of the West (1378–1417) in which there were first two and then three rival claimants to the papal throne, and the subsequent emergence of the conciliar movement. Demanding reform "in head as well as in members," this fundamentally "constitutionalist" movement took its point of departure from the belief that the fullness of jurisdictional power pertained to the whole church and the general councils representing it, as well as to the pope himself. The assumptions basic to conciliarism were by no means novelties, and support was drawn from the commentaries of the medieval canon lawyers themselves. However, neither Urban VI nor Clement VII—the two claimants, Roman and Avignonese, who emerged from the disputed election—nor their respective successors proved capable of commanding the allegiance of the whole of Christendom or of displacing their rivals. It was their prolonged obduracy that finally, in 1409, rallied widespread support behind a conciliar solution. But even then the efforts of the Council of Pisa were unsuccessful and the notorious John XXIII emerged, not as sole pope, but as the representative of a third, or "Pisan," line of papal claimants. Only after the Council of Constance (1414–18) was the schism terminated. In its decree *Sacrosancta* (1415), it had affirmed the superiority of its authority even to that of the pope in matters pertaining to the faith, the ending of schism, and the reform of the church; the council also ended the schism of the church, deposed John XXIII and his Avignonese rival, accepted the resignation of the Roman claimant, and elected Martin V.

The decision of the fathers assembled at Constance to proceed to a papal election before enacting a full-scale program of reforming legislation turned out to be crucial. For despite the passage of the decree *Frequens* (1417), by the terms of which general councils were to assemble at frequent and regular intervals, despite the far-reaching claims and activities of the conciliarist party at the Council of Basel (1431–49), and despite the survival of conciliar theory as a viable theory of church government until well into the 18th century, the Conciliar movement (as such) diminished without effecting its full reform program and without engineering the constitutional revolution in church government that it had promoted.

The effect of nationalism on the papacy. From the early 14th century onward European royalty and nobility had extended their powers over the local churches. By the early 15th century the kings of France and England in particular had become adept at marshalling national anti-papal feeling in order to coerce the papacy to concede to them sizable shares of the taxes levied on their national churches and the benefices belonging thereto. The Avignonese popes and the popes of the schism had little choice but to yield to such diplomatic blackmail—even though, by so doing, they committed the church piecemeal to a revolution that would ultimately leave to their successors little more than a theoretically supreme authority. The substance of power over the national or territorial churches passed into the hands of kings, princes, and rulers of city-states, such as Venice. The concordats that Martin V concluded in 1418 with England and other countries were no substitutes for the reforming program espoused by the conciliarists. The infamous Concordat of 1516, which effectively delivered the French Church into the hands of the monarchy, marked the peak of this development. Its concomitant was the effective transformation of the 15th-century popes into sophisticated Renaissance princes, sometimes of dubious personal morality, always preoccupied with the restoration and preservation of their Italian principality and the consolidation in their own hands of despotic power over it, conducting their diplomatic relations as equals with the secular princes of Europe, and increasingly prone to the type of dynastic ambition current among those princes. That Adrian VI should have been the last of the non-Italian popes is symptomatic of this transformation; so, too, is the apparent inability of Leo X to comprehend the significance of Luther's chal-

The Renaissance papacy

lenge (*e.g.*, that even popes and councils can err) or the strength of the demand for church reform (*i.e.*, in head and members) made by many individuals and groups. Even when the magnitude of the Protestant threat and the pressing need for reformed and reforming papal leadership was finally recognized at Rome, the complexities of the European diplomatic situation in which the papacy was so deeply involved helped delay, until the greater part of northern Europe was lost to Catholicism as a result of the Protestant Reformation, the convocation of the urgently needed and long-awaited reforming general council.

The papacy in the modern world: Trent to the first Vatican Council. The convocation finally came during the pontificate of Paul III (reigned 1534–49), who had made reform a concern of the papacy itself. He gave his approval to the new Jesuit order that was destined to be so loyal to the papacy, appointed distinguished reformers to the College of Cardinals, established a reform commission, and embarked upon the reform of the Roman Curia itself.

Council of Trent

The opening of the Council of Trent in 1545 marked no weakening in the diplomatic and national pressures with which the late medieval papacy had increasingly been forced to accommodate itself. The council's long duration and the suspensions and reconvocations that punctuated its course reflect the incessant working of these pressures. Though the Tridentine (Council of Trent) popes were able by their diplomatic skill and their tenacity in the pursuit of reform to prevent accommodations with Protestant and quasi-Protestant demands and to preserve the uniformity of Catholic religious practice, their post-Tridentine successors were reduced progressively to political impotence because of increased autonomy in the local churches and increasing monarchical control of the national clergies.

The failure of the ecclesiastical sanctions that Paul V (reigned 1605–21) imposed on the Republic of Venice because of its violation of ecclesiastical rights pointed to the humiliations to be suffered by the papacy in the 18th century. Nationalism in the form of Gallicanism, Febronianism, and Josephism (French, German, and Holy Roman imperial doctrines, respectively, advocating the restriction of papal power) progressively isolated the pope, even in the Catholic world. Clement XIV's capitulation to Bourbon (French monarchical dynasty) pressure in 1773, when he decreed the suppression of the Jesuits, and the humiliation and imprisonment of Pius VI by the French revolutionaries and Pius VII by Napoleon Bonaparte appeared to threaten the very survival of the papal office.

Recovery of papal prestige. Following the Napoleonic Wars and the Congress of Vienna (1815), however, both the reaction to monarchism and the subsequent rise of constitutional regimes served, in different ways, to promote the recovery of the papacy. The reinstated monarchs of Catholic Europe did not share their predecessors' antipathy to the papacy. Instead, they viewed it as a valuable ally in the struggle to preserve the status quo. The later shift to constitutional regimes, weakening or severing, as it did, the bonds that had chained the clergy to the policies of their national governments, freed them to respond positively to a more vigorous and extensive exercise of papal authority.

19th-century developments

The restoration of the Papal States by the Congress of Vienna and the shape assumed by Catholicism in the wake of the Council of Trent helped to shape 19th- and 20th-century papal policy. The former disposed the 19th-century popes to align themselves with the politically conservative forces of Europe, even if this meant incurring the odium of the liberal and modernizing forces of the era. The latter disposed them to see the papacy as the hinge on which turned a complete and definitively articulated system of beliefs, clearly defined in opposition to the claims of Protestantism and increasingly and self-consciously at odds with most of the main, and quite a few of the tributary, currents of modern thought. During the early sessions, the fathers assembled at Trent had shown a willingness to understand reforms as a renewal that should go some way toward meeting legitimate Protestant demands, but during its later sessions and in the years after its closure, reform increasingly was conceived as the restoration of a purified (real or imagined) medieval norm. Thus, from the later 16th century onward the popes tended to interpret the piecemeal doctrinal and disciplinary decrees of Trent in a new and unintended way—as a closed and complete system and an "ultimate rule of faith and discipline." Ecclesiastical usages that predated Trent were progressively eliminated, so that even the slender links with Christian antiquity that Gratian's *Decretum* (*c.* 1140) had preserved in the body of the medieval canon law were now snapped.

In such a context, the popes of the modern era, despite their political weakness, have made much of their own spiritual authority and especially their teaching authority. With the growth of papal prestige after 1815, this trend remained the most persistent feature of papal history down to the mid-20th century. Pius IX identified the papacy with the Ultramontane position, which favoured an intensified centralization of ecclesiastical government in Rome and a vigorous exercise of papal authority in every aspect of religious life. But even before his pontificate, centralization was being strongly encouraged. Gregory XVI achieved—for the first time in history—complete papal control over Catholic missionary activity throughout the world. This, along with rapid advances in the technology of communication, promoted that aspect of papal domination that has characterized the Roman Catholic Church in the 20th century.

From the first Vatican Council to the second Vatican Council. After 1870, when the Papal States had been forcibly annexed to the new Kingdom of Italy and papal temporal power destroyed, the popes were free to exploit their growing spiritual authority within the church. They were also able to draw out the logical consequences of the definitions of papal primacy and infallibility promulgated by the first Vatican Council (1869–70), which was forced to a premature adjournment just before the entry of Italian troops into Rome.

Papal primacy and infallibility

While the definition of infallibility (ascribing inerrancy only to papal pronouncements made solemnly *ex cathedra* on matters pertaining to faith or morals) was a much more restricted one than many Ultramontanists (upholders of the doctrine of papal supremacy and power) had desired, it had the effect of surrounding with an aura of infallibility even papal pronouncements that laid no formal claim to it. Along with its companion definition of the papal primacy it took on an exaggerated importance—partly because it was promulgated in isolation from any general decree on the structure of the church at large and the role of the episcopate within it, and partly because of the very distinction of Pius IX's successors, notably Leo XIII. The years between Vatican I and Vatican II were marked by an increasingly energetic exercise of papal spiritual authority, both magisterial and jurisdictional. Never before had popes been so active in doctrinal and moral teaching, and the great encyclicals of Leo XIII and Pius XII, especially, became determinative in shaping the development of Catholic thinking on an imposing range of topics. At the same time, assisted by the promulgation in 1917 of the Code of Canon Law, by improvements in the technology of communication, and by the growth of the missionary churches and of native clergies deeply loyal to Rome, the process of administrative centralization was intensified to an unprecedented degree. Similarly, the rectification by the Lateran pacts of 1929 of the relationship between the Vatican and the Italian state enhanced the papacy's standing in the diplomatic world and restored to it a measure of temporal independence that was something more than symbolic. Rarely in its checkered history had the papacy seemed in a more secure position than it did in the 1950s.

But there was another side to all this. Leo XIII had done much to reverse the uncompromising hostility to modern thought symbolized so dramatically by Pius IX's *Syllabus of Errors* (1864), which condemned socialism, Bible societies, liberalism, modern scientific thought, and other 19th-century liberal views and movements. By the end of the century theologians were seeking to reshape Catholic teaching in such a way as to bring it into harmony with the dominant intellectual developments of the era—espe-

cially in philosophy, natural science, history, and biblical studies. Even Pius X's condemnation of Modernism in 1907 and the control over Catholic thought subsequently exerted by the Holy Office could not utterly destroy this process. Despite the ambivalence of Pius XII's attitude toward this rapprochement, it gained considerable momentum during his pontificate, and its unexpected strength was soon revealed when, in January 1959, to the consternation of his curial officials, the new pope, John XXIII, set in motion the machinery that led to the assembly of the second Vatican Council in October 1962.

Second Vatican Council

The contemporary papacy. The decrees of Vatican II —such as the great documents on the church, the sacred liturgy, ecumenism, and Religious liberty—attest to the degree to which its convocation liberated reforming energies and stimulated the forces of theological innovation already active in the church. Similarly, the doctrinal dissension and disciplinary turmoil increasingly characteristic of Catholic life in the late 1960s and early '70s also attest to the fact that the ending of the council in 1965 did not stifle those energies or curb those forces.

At the heart of the current controversy stands the papacy. The 1960s witnessed a broadening of the "progressive" theological vision. Paul VI's attitude to this vision apparently changed from an initial neutrality to an increasing conservatism. While the council was in session, he sought on several occasions to allay the fears of the conservative minority by such actions as withdrawing from conciliar discussion and reserving to himself the questions of clerical celibacy and family limitation; he also reiterated in a theological terminology redolent rather of Trent than of Vatican II the traditional Catholic teaching on the Eucharist (*Mysterium Fidei*, September 1965), which reaffirmed the doctrine of transubstantiation. After the end of the council his public pronouncements repeatedly reflected concern about the rapid spread of heterodox opinions among Catholics, about the increasing disrespect of some church members for ecclesiastical authority in general and papal authority in particular, and about threats to church unity. His reaffirmation of the traditional ban on the use of artificial methods of birth control (*Humanae Vitae*, July 1968) served only to exacerbate dissent and to intensify existing questioning about the fundamental status of papal authority and the mode of its current exercise.

These developments have obscured the great degree to which Paul VI continued the efforts of John XXIII both to promote the growth of Christian unity and to make of the papacy a moral and humanitarian force capable of appealing to the goodwill of all men, whatever their religion. They have also raised questions about the degree to which episcopal collegiality is manifesting itself in practice—despite the 1967, 1969, and 1970 meetings of the Synod of Bishops that Paul VI had himself established in 1965 in order to provide for it an institutional expression. Papal prestige had rarely stood higher than it did in 1963 at the time of John XXIII's death, but the papacy's fortunes have since undergone decline. From being a symbol of unity and hope, it has become, for some Catholics, a focus of dissension and apprehension.

THE THEORY OF PAPAL AUTHORITY

The title deeds: the Petrine theory. Basic to the claim of the Roman bishops to a position of primacy in the church is the Petrine theory, according to which Christ, during his lifetime, promised the primacy to Peter alone, and, after his Resurrection, actually conferred that role upon him. Thus John 1:42 and, especially, Matt. 16:18 f.: "And I tell you, you are Peter, and on this rock I will build my church, and the powers of death shall not prevail against it. I will give you the keys of the kingdom of heaven, and whatever you bind on earth shall be bound in heaven, and whatever you loose on earth shall be loosed in heaven." Also John 21:15 f.: "Feed my lambs . . . Tend my sheep." Vatican I, in defining the Petrine primacy, cited these three texts, interpreting them to signify that Christ himself directly established St. Peter as prince of the Apostles and visible head of the Church Militant, bestowing on him a primacy not merely of honour but of true jurisdiction. In defining also that the Petrine primacy was, by Christ's establishment, to pass in perpetuity to his successors and that the bishops of Rome were these successors, Vatican I cited no further scriptural texts. In defining further, however, that the Roman pontiffs, as successors in the Petrine primacy, possess the authority to issue infallible pronouncements in matters of faith or morals, the council cited both Matt. 16:18 f. and Christ's promise to Peter at the Last Supper: "But I have prayed for you that your faith may not fail; and when you have turned again, strengthen your brethren" (Luke 22:32).

Primacy of Peter

Historical conceptions of papal authority within the church. Of the Petrine texts, Matt. 16:18 f. is clearly central and has the distinction of being the first scriptural text invoked to support the primatial claims of the Roman bishops. Before the mid-3rd century, however, and even after that date, some Western, as well as Eastern, patristic exegetes (Early Church Fathers who in their interpretation of the Bible used critical techniques) understood that by the "rock" Christ meant to refer not to Peter but to Christ himself or to the faith that Peter professed. Nevertheless, in the late 4th and 5th centuries there was an increasing tendency on the part of the Roman bishops to justify scripturally and to formulate in theoretical terms the ill-defined pre-eminence in the universal church that had long been attached to the Roman Church and to its bishop. Thus, Damasus I, despite the existence of other churches of apostolic foundation, began to call the Roman church "*the* apostolic see." About the same time the categories of the Roman law were borrowed to explicate and formulate the prerogatives of the Roman bishop. The process of theoretical elaboration reached a culmination in the views of Leo I and Gelasius I, the former understanding himself not simply as Peter's successor but also as his representative, or vicar. He was Peter's "unworthy heir," possessing by analogy with the Roman law of inheritance the full powers Peter himself had wielded, which he interpreted as monarchical, since Peter had been endowed with the *principatus* over the church.

The vicar of Peter

Medieval views. On the purely theoretical level the distance between the claims advanced by Leo I and the position embodied in Vatican I's primacy decree is not great. Medieval popes, such as Gregory VII, Innocent III, and Innocent IV, clarified by their practice as well as by their theoretical statements the precise meaning of that fullness of power (*plenitudo potestatis*) over the church to which, according to some scholars, Leo I himself had laid claim. In this they were aided not only by the efforts of publicists such as the Italian theologian and philosopher Aegidius Romanus (died 1316), who magnified the pope's monarchical powers in unrestrained and secular terms, but also by the massive development during the late 11th, 12th, and 13th centuries of a highly romanized canon law. Gratian's *Decretum* (*c.* 1140), the unofficial collection of canons that became *the* fundamental textbook for the medieval student of canon law, laid great emphasis on the primacy of the Roman see, accepting as genuine certain canons that were the work of 6th- and 9th-century forgers—such as two principles that the 1917 Code of Canon Law restates: "that there cannot be an ecumenical council which is not convoked by the Roman Pontiff" and that "the First See is under the judgment of nobody."

The prevalence of such ideas and the absence of a formidable challenge to papal primatial claims during the High Middle Ages explains the lack of any conciliar definition of the Roman primacy at the great "papal" general councils of that period. Hence it took the (abortive) attempt at reunion with the Orthodox Church at the Council of Florence in 1439 to evoke the first solemn conciliar definition of the Roman primacy. This definition was included in the decree of union with the Greeks (*Laetentur Coeli*), and it went as follows:

The first conciliar definition of Roman primacy

> . . . We define that the Holy Apostolic See and the Roman Pontiff hold the primacy over the whole world, that the Roman Pontiff himself is the successor of Peter, prince of the Apostles, that he is the true vicar of Christ, head of the whole

church, father and teacher of all Christians, and [we define] that to him in [the person] of Peter was given by our Lord Jesus Christ the full power of nourishing, ruling and governing the universal church; as it is also contained in the acts of the ecumenical councils and in the holy canons.

Early modern and modern views. This decree was the basis for the solemn definition that Vatican I promulgated in 1870 as part of its dogmatic constitution (*Pastor Aeternus*). Having asserted as a matter of faith the primacy of Peter and the succession of the popes in that primacy, and having quoted in full the Florentine definition, the constitution clarified what is to be understood by "the full power of nourishing, ruling, and governing" the church, which, according to that definition, inhered in the pope's primacy. Unlike Florence, *Pastor Aeternus* specified this to include the pope's judicial supremacy, insisting that there is "no higher authority," not even an ecumenical council, to which appeal can be made from a papal judgment.

This definition marked the culmination of a development reaching back at least to the 4th and 5th centuries. But the doctrinal development that culminated in Vatican I's definition of papal infallibility cannot lay claim to a comparable antiquity. There has always been much discussion about the meaning of the prerogative of infallibility and what it implies about the status of individual doctrinal pronouncements of the church's teaching authority. The notion that the church (conceived as the community of the the faithful) is by virtue of Christ's own promise infallible—in the sense that it cannot totally deviate from the truth—is clearly scriptural in foundation and was not questioned even by the Protestant Reformers. Similarly, the notion that a pre-eminent authority attached to the doctrinal pronouncements of the Roman Church and its bishops was of great antiquity, long predating the extension of papal jurisdictional claims by the 4th- and 5th-century popes. But the combination of these two notions—*i.e.*, the identification of the supreme teaching authority of the universal church with that of the pope, and the claim that the infallibility promised to the church itself was possessed also by the pope acting as its head to guarantee the inerrancy even of his individual doctrinal pronouncements—is essentially a modern theological development and one characteristic primarily of the Roman or Ultramontane (pro-papal) theological school. This school rose to prominence in the 16th and 17th centuries; one of its most distinguished representatives was Cardinal Robert Bellarmine (died 1621). Though it drew from earlier materials—notably from the Pseudo-Isidorian decretals and from the writings of such medieval theologians as St. Thomas Aquinas (died 1274), Aegidius Romanus (died 1316), and Augustinus Triumphus (died 1328)—the Ultramontane school derived much of its initial strength from the papalist reaction that followed in the wake of the conciliar movement, and it was shaped very much in opposition to the claims that the conciliarists and their Gallican successors made on behalf of the general council. This is evident in the solemn definition of the doctrine promulgated by Vatican I, with its insistence that the *ex cathedra* definitions of the pope (those made from "the chair," or papal throne), "are irreformable of themselves and not by virtue of the consent of the Church." The conciliar debates indicate that this sentence was intended to exclude the Gallican notion that a papal definition could not claim infallibility unless, subsequently or concomitantly, it received episcopal assent. Despite the maximalist (extremist) tendencies both of subsequent Catholic apologists and of their Protestant critics, the sentence apparently was not intended to restrict the church's infallible teaching authority to the pope alone or to suggest that the pope was free to define doctrine without making every effort to take into account the mind of the church.

Ultramontanism

Nevertheless, after 1870, when the memory of the heated conciliar debates had faded away, maximalist interpretations became prominent. In particular, there was a marked tendency to stress the absolute and unlimited nature of papal jurisdictional power and to end in favour of the papacy the hitherto unresolved question of the source of episcopal jurisdiction. In response to this development, Vatican II, in its dogmatic constitution, *De Ecctesia* (1964), while endorsing Vatican I's teaching on papal primacy and infallibility, also focussed on the nature of episcopal authority. It insisted that bishops "are not to be regarded as vicars of the Roman Pontiff, for they exercise an authority which is proper to them," since, "by divine institution . . . [they] . . . have succeeded to the place of the apostles as shepherds of the Church" and are themselves, in fact, "the vicars and ambassadors of Christ." Also, "Just as, by the Lord's will, St. Peter and the other apostles constituted one apostolic college, so in a similar way the Roman Pontiff as the successor of Peter and the bishops as the successors of the apostles are joined together." This college, "together with its head, the Roman Pontiff, and never without this head" is "the subject of supreme and full power over the universal Church," a supreme authority that it can exercise in more than one fashion but "in a solemn way through an ecumenical council." The supreme authority in the church can be exercised not only personally by the pope himself but also in a collegial fashion by the *whole* episcopate, which of necessity includes the bishop of Rome as its head.

Episcopal collegiality

In so emphasizing the doctrine of episcopal collegiality, Vatican II was responding to the findings of modern New Testament and patristic scholarship concerning the nature of the primitive and ancient church, and it insisted that it was restoring an ecclesiological emphasis of great antiquity. Recent medieval scholarship indicates that this emphasis persisted into the Middle Ages and survived, in the writings of canonists and theologians, side by side with the more prominent concern with the papal primacy. The great Conciliarists active at the Council of Constance made an unsuccessful attempt to effect a stable balance between these two emphases, and even in the modern period, despite the growing prominence of Ultramontane views and their eventual triumph at Vatican I, the collegial concern was never fully displaced. It was not lost sight of by the Gallican theologians of the 16th, 17th, and 18th centuries who, however much their subservience to the exigencies of royal policy may have damaged their credibility, apparently are now recovering in Catholic eyes, at least, a certain measure of esteem.

Eastern Orthodox views and critiques. The recovery of this ecclesiological emphasis has an importance outside Roman Catholic theology. It has never ceased to dominate in the churches of Eastern Orthodoxy, with their stress on episcopal equality, their respect for the autonomy of the national or regional churches, and their insistence that the supreme teaching authority in the universal church resides (if anywhere) in the collegial decisions of the bishops assembled together in an ecumenical council. Up to the 11th century, Byzantine churchmen and theologians certainly accorded some sort of primacy to the church of Rome and its bishop. But with the growth of papal claims to a universal jurisdictional power, with the growing conviction that the Roman Church had fallen into heresy, and above all with the disastrous crusading onslaught on Byzantium in 1204, the attitude of Orthodox churchmen to Rome underwent an understandable shift. Though Byzantine theologians rarely questioned the fact of Peter's primacy among the Apostles, they concluded that their own fundamentally collegial ecclesiology necessitated the rejection of the primatial claims advanced on behalf of those who claimed to be uniquely his successors. The very attempt by the bishops of a single local church to claim a monopoly on the Petrine succession was regarded as something of a deviation, in that all bishops, insofar as they professed the faith of Peter, were to be understood as his successors.

Rejection of Roman primatial claims

In the modern period, then, the Eastern Orthodox churches have been unanimously adamant in their rejection of the papal claims to primacy and infallibility. Orthodox theologians are often careful to insist that what they are rejecting is not the notion of primacy itself but rather that actual primacy of jurisdiction as it was conceived in the Latin Middle Ages and as it has been exercised by Rome in the modern period—with its apparent corollary that all power in the church is to be regarded as proceeding outward from the primatial office and its concomitant tendency to stifle independent life in the

local churches. The original primacy of honour, which these theologians argue, was one accorded to the Roman bishops by emperors and ecumenical councils, they clearly regard as a different matter altogether. Given this fact, and also the common ground shared in ecclesiological matters by the Roman Catholic and Orthodox churches, Vatican II's affirmation of episcopal collegiality may soften the edges of the Orthodox rejection of the papal primacy.

Protestant views and critiques. The impact of that doctrine on Protestant thinking is more difficult to predict. Historically, the Protestant rejection of papal claims has been much less qualified than that of the Orthodox. Thus, in the modern theologian Karl Barth's view, Vatican I's definition of papal infallibility completed the process by which the Roman Catholic Church abandoned the Christian belief in the unique character of divine revelation, identified itself instead with that revelation, and made the pope's teaching "the infallible revelation for the present age." Philipp Melanchthon, the Lutheran author of the Augsburg confession of 1530, may have been willing to admit that a truly evangelical pope had a certain superiority over other bishops; however, even if one de-emphasizes Luther's denunciations of the pope as the Antichrist, the rejection by the major Reformers and their successors of the Petrine theory and of papal primacy by divine institution is absolute. Peter, they argued, exercised no primacy. The powers communicated to him were the powers communicated to all the Apostles. By the "rock" Christ meant himself; upon him the church is founded, and in Matt. 16:17 f. Peter stands only as the type or figure of the Christian faithful who believe in Christ as the sole "rock."

Unlike such medieval predecessors as the Waldensians (Italian reform group founded in the 12th century) or the political philospher Marsilius of Padua (died *c.* 1342), who had likewise attacked the Petrine theory, the Reformers did not base their attack upon the historical argument that Peter had never visited Rome. This argument was embraced by many a liberal Protestant theologian of the 19th century, but in the 20th it has lost most of its appeal.

Modern Protestant reinterpretation of Roman primatial claims

In the mid-20th century some Protestant theologians shifted toward the Roman Catholic understanding of the status and meaning of Matt. 16:17 f. According to Oscar Cullmann (the French Protestant biblical critic and theologian), any sound exegesis of the relevant scriptural texts points to the conclusion that Peter enjoyed a pre-eminence among the disciples even during Christ's lifetime; that the "rock" in Matthew refers not to Christ or to the faith of Peter but to his person; that Christ promised him, therefore, the leadership of the church; and that after the Resurrection Peter actually exercised that leadership. Though Cullmann argued that Peter did so only for a short time, being replaced in the leadership by James, other Protestant scholars have disagreed and have claimed for Peter a more enduring role. All, however, continue with Cullmann to distinguish sharply between conditions in the apostolic and post-apostolic church, to deny on exegetical grounds that the "primacy," or leadership, promised to Peter was intended to be passed on to any post-apostolic successors, and to insist on historical grounds that no such succession in the primacy actually occurred in the primitive church. Nevertheless, because of the degree of convergence already occurring between the Roman Catholic and Protestant exegesis of the Petrine texts, because of the re-examination of the Catholic tradition begun by Vatican II, and because of the growing Protestant sense of the need for some striking symbol of unity in the worldwide Christian community, some Protestant ecumenists in the last third of the 20th century have shown a degree of openness to the papal office that would have been unimaginable only 50 or 60 years before.

Historical conceptions of the relationship of the papacy to the world. Theories concerning the relationship of the papacy to the world at large have both reflected the established political conceptions of the day and been in tension with them. The pope has been conceived successively as a leading dignitary in an imperial church headed in effect by the emperor, as a majestic potentate possessed of a supreme and direct authority even in temporal matters, and as a primarily spiritual figure who had in temporal matters no more than an indirect power of intervention. With the post-Reformation fragmentation of Christendom, the growth of secularism, and the emergence of the unified modern state claiming within its own borders jurisdictional omnicompetence, even such attenuated claims to an indirect power became increasingly anachronistic. In the 20th century, in his relations with the world at large, the pope, while affected by the conventions regulating the relationships of heads of state with one another, possesses primarily a moral authority deriving from the dignity and prestige of his office. The strength of that authority, however, depends upon his moral standing as a person, upon the persuasive force of his cause, and upon the degree of enthusiasm it can arouse within the church.

Contemporary teaching on papal authority. After the mid-20th century, some voices were raised in Roman Catholic circles questioning both the doctrine of papal infallibility and the exercise of the papal primacy—at least as it is envisaged in the teaching of Vatican I and of the Code of Canon Law. The church's official teaching on the papal office remains that of Vatican I, solemnly reaffirmed at Vatican II. Nevertheless, the latter council's juxtaposition of the doctrine of episcopal collegiality with the existing teaching on papal primacy and infallibility created something of a dilemma in Catholic ecclesiology. Though the text of *De Ecclesia* had insisted that the doctrine of episcopal collegiality in no way impugned the pope's primacy, a minority of the council fathers remained unconvinced and were commonly said to have been won over by the explanatory note that the Theological Commission by papal authority appended to the decree as an "authentic norm of interpretation." The note is framed in much more juristic terms than is the decree itself, and, in discussing the possession by the College of Bishops of "supreme and full power over the whole Church" it insists that "there is no distinction between the Roman Pontiff and the bishops taken collectively," that "necessarily and always, the College carries with it the idea of its head" so that the bishops acting independently of the pope cannot be considered to constitute a college. At the same time, the note insists that "since the Supreme Pontiff is the head of the College, he alone can perform certain acts which in no wise belong to the bishops, for example, convoking and directing the College, approving the norms of action etc.," norms that "must always be observed."

Recent questioning of the doctrines of papal infallibility and primacy

Already in 1964 there were some who regarded this note with considerable misgiving, feeling that it withdrew from the bishops, in practical and legal terms, that supreme authority in which they had been said, on theological grounds, to be sharers. Subsequent events did little to dispel such misgivings. Despite the unquestionable vitality shown at its 1967 and 1969 meetings, the Synod of Bishops was not really allowed to function as a decision-making rather than a merely advisory body, and it was no more consulted than were the bishops as a whole when, in 1968, the pope promulgated *Humanae Vitae* (the encyclical on birth control)—considered by some observers to be the most divisive papal initiative of recent times, and one that amounted to a *de facto* negation of collegiality.

Humanae Vitae

Because of the dissent over *Humanae Vitae* and the tension engendered by the rigour of the pope's stand on the much-debated problem of clerical celibacy, attention probably will focus increasingly on the old and difficult question of the limits of papal power. Because of this, considerable importance attaches to the current revival of interest in the late medieval conciliar movement and to the assertion made by some Roman Catholic scholars (if hotly disputed by others) that a continuing dogmatic validity must be accorded to the decree *Sacrosancta*, promulgated in 1415 by the Council of Constance. This decree declared that the general council possessed an authority superior to that of the pope in matters pertaining to the faith, the ending of the schism, and the reform of the church. Those who assert this view do not always wish by so doing to cast any doubt on the dogmatic validity of

Vatican I's teaching on papal primacy and infallibility, but the efforts thus far made to demonstrate the compatibility of the respective teachings of the two councils (*i.e.*, Constance and Vatican I) remain somewhat less than persuasive.

Conclusion. Those who take a gloomy view of the papacy's future because of the current discontent may be reassured somewhat by the enduring vitality the institution has shown in the past and by its astonishing powers of recovery. But the history of past triumphs is no more an adequate guide to future developments than is that of past disasters; and there are some novel components in the current decline in papal fortunes that make predictions about its future unusually difficult. Among these may be singled out the recovery by Roman Catholic biblical scholars and theologians of a fundamentally scriptural and nonpolitical conception of the ecclesiastical office as one of service rather than of dominion, and the growing insistence with which the struggle for Christian unity has impressed itself on the consciences of Catholic and non-Catholic alike. These two developments converge to portray in a critical manner papal primacy as it has traditionally been conceived and continues currently to be exercised, and to underline the important ecumenical role that primacy might be able to fill if its traditional conception were transformed. The emphasis on the "primacy of dominion," which had its origins in the 4th and 5th centuries, was elaborated in the later medieval and modern periods, and has continued to be characteristic of the 20th-century papacy, may yet be transformed in the years immediately ahead.

BIBLIOGRAPHY. For bibliographical information on papal history, see O. CHADWICK, *The History of the Church: A Select Bibliography* (1962). For listings of theological works concerning the Petrine question and the papal office, see E. DUBLANCHY, "Infaillibilité du Pape," *Dictionnaire de théologie catholique*, vol. 7, pp. 1638–1717 (1922); G. GLEZ, "Primauté du Pape," and M. JUGIE, "Primauté dans les églises séparées d'Orient," *ibid.*, vol. 13, pp. 247–391 (1936); and for the more important recent works, H. KUNG, *Structures of the Church* (Eng. trans., 1964).

Historical: Of the general histories, J. HALLER, *Das Papsttum: Idee und Wirklichkeit*, 2nd ed., 5 vol. (1951–53), is something of a classic. Useful largely for reference are the following detailed accounts: H.K. MANN, *The Lives of the Popes in the Middle Ages*, 18 vol. (1902–32), which goes to 1304 and is continued for the period up to 1800 by L. VON PASTOR, *The History of the Popes from the Close of the Middle Ages*, 40 vol. (Eng. trans., 1891–1953). J. SCHMIDLIN, *Papstgeschichte der neuesten Zeit*, 4 vol. (1933–39), discusses the history to 1939. The standard collection of documents is C. MIRBT, *Quellen zur Geschichte des Papsttums*, 4th ed. (1924). There is much on the papacy in general church histories. The most complete of recent scholarly accounts is A. FLICHE and V. MARTIN (eds.), *Histoire de l'Église depuis les origines jusqu'à nos jours*, 24 vol. (1934 *et seq.*). The most valuable account currently appearing in English is H. JEDIN and J. DOLAN (eds.), *Handbook of Church History*, 6 vol. (Eng. trans., 1965 *et seq.*). An excellent brief introduction to papal history up to the Reformation, including a good bibliography, is G. BARRACLOUGH, *The Medieval Papacy* (1968). For the recent shift in Roman Catholic discussion of the early evidence concerning the Roman primacy, see J.F. MCCUE, "The Roman Primacy in the Second Century and the Problem of the Development of Dogma," *Theological Studies*, 25:161–191 (1964); and for the development of medieval papal claims, W. ULLMANN, *The Growth of Papal Government in the Middle Ages*, 2nd ed. (1962). For the subsequent crisis of papal authority, see F. OAKLEY, *Council Over Pope? Towards a Provisional Ecclesiology* (1969), which contains a brief history of conciliar theory and discusses much of the recent literature on the significance of the Council of Constance. E.C. BUTLER, *The Vatican Council, 1869–70*, new ed. (1962), is a satisfactory history of the first Vatican Council; reference should also be made to R. AUBERT, "L'Ecclésiologie au concile de Vatican," in B. BOTTE *et al.*, *Le Concile et les conciles: contribution à l'histoire de la vie conciliaire de l'Église* (1960). The essays gathered together in this last volume constitute a good guide to recent studies in the history of the relationship of pope to general council. W.M. ABBOTT (ed.), *The Documents of Vatican II* (1966), is an introduction to the achievement of that council.

Theological: O. CULLMANN, *Peter: Disciple, Apostle, Martyr* (Eng. trans., 1953); and O. KARRER, *Peter and the Church: An Examination of Cullmann's Thesis* (Eng. trans., 1963), are influential statements of modern Protestant and Roman Catholic thinking on the Petrine question. K. RAHNER and J. RATZINGER, *The Episcopate and the Primacy* (Eng. trans., 1962), is a fundamental analysis of the pope-bishop relationship; H. KUNG, *Infallible? An Inquiry* (Eng. trans., 1971), *The Church* (Eng. trans., 1967), and *Structures of the Church* (Eng. trans., 1964), are basic to any understanding of contemporary "liberal" Roman Catholic thinking on the papacy. For Eastern Orthodox views on the papal primacy, see F. DVORNIK, *Byzantium and the Roman Primacy* (Eng. trans., 1966); and N. AFANASSIEF *et al.*, *La Primauté de Pierre dans l'Église Orthodoxe* (1960).

(F.C.O.)

Papaverales

Papaverales, an order of flowering plants in the class Dicotyledoneae, consists of three families: Papaveraceae, Fumariaceae, and Hypecoaceae. The order as a whole contains about 44 genera and 625 species.

GENERAL FEATURES

Most plants making up the order Papaverales are herbaceous (nonwoody), though there are some shrub and small tree species and a few with a climbing growth habit. The order occurs primarily in the temperate regions of the world, extending only sparingly into the tropics. Many different species are utilized as showy garden plants, and the genus *Papaver* (poppy) is the source of edible poppy seed, poppy-seed oil, and opium. The latter is a narcotic long derived from the dried juice that exudes from the cut, unripe capsules of the opium poppy (*Papaver somniferum*). A number of substances, including morphine, codeine, heroin, and other derivatives of opium, obtained from the opium poppy are in wide medical use for the relief of pain, and many are involved in drug addiction problems.

Source of drugs

The family Papaveraceae is one of the important drug-producing families of the plant kingdom, and alkaloids are abundant in many species of the order. Some alkaloids, such as protopine, are widespread within the group but are little known outside of it. Morphine is found only in the opium poppy.

Plants of the order Papaverales do not occupy as many different types of habitats as do many orders of angiosperms (flowering plants), but at the same time they are not restricted to a narrow range of ecological situations. Although there are genera with a marked preference for woodlands and forests, and some groups can be found occupying nearly every kind of terrestrial habitat, the most favoured sites are open and well drained. Habitats range from Arctic and Alpine settings to deserts, moist woods, and stream banks. There are, however, no strictly aquatic members. A number of species are found in deserts, semideserts, and arid areas. The California poppy (*Eschscholzia*), for example, is very abundant in open valley and desert lands of southwestern North America.

Many Papaverales species are weeds and are found in fields and waste places. The great abundance of poppies in the grainfields of Europe and elsewhere is well-known; the weedy tendencies of the prickly poppies (*Argemone*) in the arid areas of the southwestern United States and in Mexico are no less marked. These plants occupy cultivated areas and spread deeply into overgrazed rangelands as well. Celandine, or swallow wort (*Chelidonium majus*), usually occurring in damp or shady places along roadsides, rock walls, and in wastelands, is a ubiquitous weed in Europe, Asia, and eastern North America.

Split distribution pattern

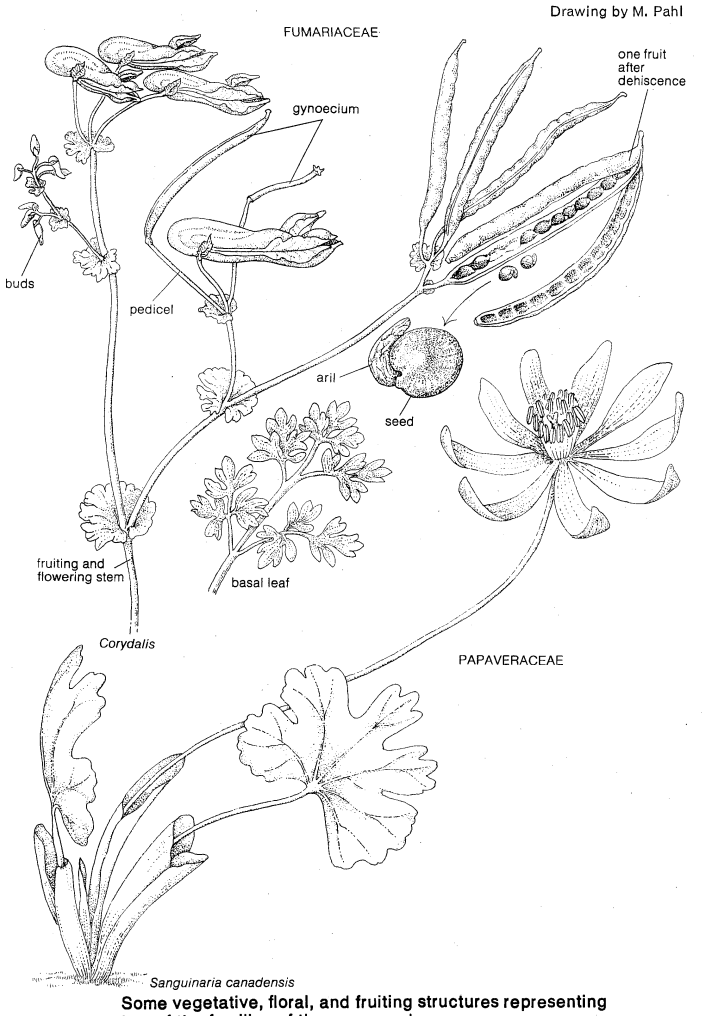
Genera of both the Papaveraceae and Fumariaceae families display the disjunct eastern Asia–eastern North America distribution pattern that was used as a geographical test of evolutionary theory by Charles Darwin and by Asa Gray. The genus *Stylophorum* of the Papaveraceae family, for example, has species found only in eastern North America and Eastern Asia, and the single species of *Adlumia* of the Fumariaceae is found in Korea and the eastern United States with a tremendous gap between.

There is a natural and practical, although not absolute, division of the order Papaverales into those plants in which the sap is watery and those in which it is milky or coloured. In plants belonging to the families Fumariaceae

and Hypecoaceae the sap is watery and acrid, and there is an abbreviated calyx (green leaflike sepals of the flower). These two characteristics serve to distinguish the two families from the Papaveraceae, in the majority of species of which the sap is milky or coloured and the calyx is well developed, fully enclosing the bud until the flower opens.

A fleshy aril (an appendage on the seed) is present, often forming a crest on the seeds of a number of species in what appears to be an adaptation to dispersal by ants. Seeds are carried away from the producing plant by the ants, and the aril is utilized as a source of food, but this does not disturb normal germination.

The widely known poppy flower is the most common flower type within the order. Even dwarf Arctic poppies and the giant matillia poppy, which is woody at the base and otherwise quite different from the common poppy, are quickly identified as poppies by the average person. At a divergent extreme are the flowers of bleeding heart (*Dicentra spectabilis*) and Dutchman's-breeches (*D. cucullaria*), which are laterally compressed and appear to be irregular in shape. Flowers of all members of the order are perfect (*i.e.*, have both pistil and stamens, the female and male flower parts) and hypogynous (the sepals, petals, and stamens attach at the base of the ovary) and have a compound ovary with parietal placentation (*i.e.*, the ovules attach to the ovary wall). An exception to the compound ovary is found in the genus *Platystemon*, in which six to 25 carpels are weakly united when young, but become free in fruit.



Some vegetative, floral, and fruiting structures representing two of the families of the poppy order.

NATURAL HISTORY

Though the breeding system of many species has not been investigated, some species of *Fumaria* and *Corydalis* are known to produce cleistogamous (closed when mature) flowers and to produce fruit without fully opening. Self-pollination is known to occur in the order, but the prevalent mode as a whole is cross-pollination, and insects are the primary carriers of pollen between plants. The open, many stamened flowers of the poppy type are inviting to many kinds of bees and similar insects; the more closed and spurred flowers of many Fumariaceae species provide for a narrower range of insect visitors. No flower type is known to be so insect-specific that only a single species is its pollinator. Even though some flowers are somewhat tubular because of the weak fusion of their petals and are more or less closed by the overlap and fusion of the inner petals, they are dependent on insects for the transfer of pollen from plant to plant to ensure a seed set. Frustrated short-tongued bees sometimes bite through the base of the corolla (flower petals) and gain direct access to the source of nectar without pollinating the flowers, however.

Pollination

There are usually several to many seeds in each fruit, but some genera have single-seeded fruits, and in a few groups the fruits break into single-seeded joints. The seeds are shed from the fruits by the opening of valves, through pores, or by the breaking of the fruit into one-seeded joints. In a few species the valves open explosively, throwing the seeds some distance from the plant. In some, the fruits are one-seeded and indehiscent (do not open along definite seams). Seed dispersal is mostly unspecialized, and seeds are spread around by water, by moving soil, or by the movements of the mature plant after it is uprooted or broken off. Ant dissemination of the arillate seeds is common in certain members of the group.

Evidently, most plants of the order are little eaten by animals, and none is known to have edible vegetative parts. The juices are either acrid and bitter or milky and often narcotic, which apparently is the basis for avoidance of the plants by both animals and man. Poppy seeds, however, are widely used to sprinkle on pastries and other foods or are ground for flour. The narcotic principle is not present in the seeds of even the opium poppy.

FORM AND FUNCTION

Taproots, rhizomes (rootlike stem structures), bulblets, and tubers make up the range of underground structures found in the order Papaverales. The stems are mostly herbaceous but may be woody and are erect or sometimes climbing. Although some leaves are entire (*i.e.*, smooth edged), they are mostly divided into pinnate (*i.e.*, the veins originate along a midrib, as in a feather) or palmately (*i.e.*, the veins radiate from a common point where the leafstalk attaches) arranged lobes or are more highly dissected. A common pattern is a group of petioled leaves arranged in a rosette at the stem base, without stem leaves or with stem leaves reduced from base to apex. The fern-shaped leaves of *Pteridophyllum* are unusual.

The inflorescences (arrangements of flowers) are diverse in form, ranging from a single scapose (stemmed) flower to a cymose or racemose (*i.e.*, clustered along a central axis on short lateral stalks, the cymose type maturing from the terminal blossoms downward, the racemose type maturing from the base upward) inflorescence in a terminal or lateral position. The flowers are of a hypogynous type or, rarely, perigynous (*i.e.*, the sepals and petals arise from a cuplike structure partially enclosing the ovary) and are fully bisexual. They are radially or bilaterally symmetrical and are complete (*i.e.*, they have all four basic flower parts, sepals, petals, stamens, and pistil), even though the two sepals present in the family Fumariaceae are much reduced and often drop early in development. In the family Papaveraceae the two to three sepals tightly enclose the buds until the flower opens, when they are shed. The sepals are usually free except in the genus *Eschscholzia*. The petals are similar to each other, in two whorls, and their number is twice as many as the sepals. In the family Fumariaceae the petals differ from each other, the four petals forming two pairs, the outer pair being somewhat saccate, or spurred, at the base.

The androecium (male complement) is made up of six stamens in two groups in the Fumariaceae family, but

Male flower parts

there are many stamens arranged in concentric whorls in the various species of Papaveraceae. *Pteridophyllum* is a special case with free petals and four stamens. Stamen development takes place centripetally (*i.e.*, from the flower margin toward the centre) which contrasts with the centrifugally developed stamens of the order Capparales, an order once held to be closely related to the Papaverales.

The styles (the upper part of the pistil), if present, may be either deciduous or persistent and sometimes become beaklike on the ultimate fruit. In many genera the style is virtually absent, and the stigmatic areas (pollen-receiving regions) are located directly upon the ovary. There is an unusually wide range of stigma types among various groups of the order Papaverales. The entire, or bilobed, type is common, but greatly expanded, recurved, crested or lance-shaped stigmas are present in *Glaucium*, among other genera, and elaborate stigmatic ridges and crests occur in a number of genera including *Cathcartia, Meconopsis, Argemone,* and *Papaver*. The basic gynoecial (female) structure is constructed of two or more fused carpels. In the family Fumariaceae, there are consistently two carpels, and the ultimate fruit produced is unilocular (*i.e.*, has only one chamber). On the other hand, the gynoecium of the family Papaveraceae, while having two or more carpels and usually being unilocular, in some taxa becomes multilocular in fruit. The fruit is two to many valved (*i.e.*, it has openings through which seeds are released).

Seeds of the order are most commonly kidney shaped, obovoid, or spherical and are frequently pitted. In a number of genera, crestlike arils are present on the seed, but true seed wings are absent. The seeds are plump to somewhat flattened and contain an endosperm (nutrient tissue for the developing embryo) that is usually oily, in addition to the small, straight to somewhat curved embryo.

Plants of the order Papaverales are widely recognized for their medicinal and poisonous properties, and more than 200 alkaloids are known in the order. Most of these are found elsewhere among the higher plants, sometimes commonly so, but in some instances only in one or a few families. At least eight alkaloids are distinctive and are known only from this order of plants.

EVOLUTION

Recorded fossils placed definitely in the order Papaverales are few and contribute little of significance to an understanding of the probable origin of the group. Based on evidence from present-day species, it is now agreed by the most recent authorities that the order is more nearly related to the order Ranunculales than to Capparales, as had been thought by earlier investigators. Within the Papaverales, the family Papaveraceae has more archaic features than the family Fumariaceae, and the Hypecoaceae family has been suggested as forming a connecting link between them.

CLASSIFICATION

Distinguishing taxonomic features. The family Hypecoaceae, with but one genus, *Hypecoum*, is distinguished by free petals and four free stamens, except that these features are also shared by the controversial monotypic (one species) genus, *Pteridophyllum*. The latter has been the basis for the family Pteridophyllaceae, but it is sometimes placed in the family Papaveraceae and at other times in the Fumariaceae. The genera *Hypecoum* and *Pteridophyllum* are distinctive, and a recent treatment gives subfamily rank to each in the family Fumariaceae.

Distinction between the two main families

The families Papaveraceae and Fumariaceae differ substantially in many characters, but the surest distinguishing features are the many regularly inserted stamens, large bud-enclosing sepals, and regular flowers of the Papaveraceae, as contrasted with the six stamens in two groups, small, scalelike sepals, the bilaterally symmetrical to irregular flowers of the Fumariaceae. Although some authorities recognize the Hypecoaceae as a family distinct from Fumariaceae and only questioningly include *Pteridophyllum* in Papaveraceae, others give subfamily rank to both *Hypecoum* and *Pteridophyllum* in the family Fumariaceae. Another possibility sometimes suggested is to place both of these genera in the family Hypecoaceae.

Alkaloid distribution supports the association of the families Papaveraceae and Fumariaceae together in the same order. Protopine, for example, is found in all members of both families so far investigated but is almost unknown elsewhere, having been reported from only one species, *Nandina domestica*, of the family Nandinaceae (order Ranunculales). The subordinate taxa (subfamilies, genera, species, etc.) of Papaveraceae mostly have their own combination of alkaloids, and different combinations appear to characterize different sections of the family. On the other hand, members of the family Fumariaceae possess a combination of isoquinoline derivatives different from anything found in Papaveraceae.

Annotated classification.

ORDER PAPAVERALES

Mostly fleshy herbs, some shrubs or small trees; sap milky (white to yellow or reddish-orange) or colourless and watery; leaves without stipules, basal or alternate, rarely opposite, flowers regular or bilaterally symmetrical; calyx falling off very early; petals 4–12, often falling early; ovary superior, of fused carpels; fruit a capsule or of 1–seeded indehiscent joints; seeds with small embryos and a fleshy, usually oily endosperm. Three families, 44 genera, and about 625 species, distributed mainly in temperate regions.

Family Papaveraceae

Herbaceous annuals or perennials, rarely shrubs or small trees; sap milky, white to yellow or reddish-orange, rarely colourless and watery; leaves alternate (rarely whorled) without stipules, entire to pinnately or palmately lobed; flowers regular, bisexual, usually solitary; sepals 2, 3, or 4, petals twice the number of sepals; stamens mostly numerous; gynoecium of 2 to several carpels; seeds usually numerous. Twenty-five genera and about 200 species.

Subfamily *Chelidonioideae*

Trichomes (plant hairs) multicellular, uniseriate (of a single row of cells); perianth (petals and sepals) 3-merous (present in groups of 3 or multiples thereof); pollen tricolpate (with 3 germination furrows) or polyporate; gynoecium 2-valved; seeds arillate. Ten genera, mostly of Asia.

Subfamily *Papaveroideae*

Trichomes multicellular, multiseriate; perianth 2- to 3-merous; pollen tricolpate; gynoecium 3-valved, but in *Papaver* with added pseudomedian traces (vascular tissue) and false partitions; seeds without an aril. Seven genera, distributed in the northern hemisphere.

Subfamily *Eschscholzioideae*

Trichomes unicellular or the plants glabrous (smooth); perianth 2-merous; pollen polycolpate; gynoecium 2-valved; seeds usually without arils. Three genera of western North America.

Subfamily *Platystemonoideae*

Trichomes multiseriate; perianth 3-merous; pollen tricolpate; gynoecium of 3 to several carpels, carpels splitting at maturity; seeds without arils. Three genera of western North America.

Family Hypecoaceae

Herbs with watery sap and mostly pinnately or palmately divided leaves; flowers small, regular; petals 4 in 2 whorls, inner petals often lobed; stamens 4; gynoecium superior; fruit articulated into many 1-seeded joints, usually tapered above into a beak. The single genus *Hypecoum*, with about 15 species, occurs from Europe and the Mediterranean area to China.

Family Fumariaceae

Herbaceous annuals, biennials or perennials, commonly glaucous (smooth, no plant hairs); sap colourless and watery; leaves in basal rosettes or along the stem or both, ternate (3-lobed) to pinnately lobed or dissected; flowers bilaterally symmetrical to somewhat irregular (rarely regular), erect to nodding, bisexual, mostly cymose or racemose; sepals 2, often bractlike (*i.e.*, small and simple in the manner of bracts, small, green appendages attached just below flowers); petals 4 in 2 series, outer often saccate or spurred; stamens 6 in two groups (4 and ungrouped in *Pteridophyllum*); gynoecium 2-carpeled; fruit 2-valved; seeds 1 to many, often lustrous or arillate or both. Nineteen genera and about 425 species.

Subfamily *Pteridophylloideae*

Herbaceous perennial; leaves basal, pinnately lobed and fernlike; inflorescence without bracts, racemose; flowers regular, petals 4, free; nonsaccate; stamens 4. A single species (*Pteridophyllum racemosum*), restricted to Japan.

Subfamily *Fumarioideae*

Inflorescences with bracts; flowers bilaterally symmetrical to irregular; outer petals saccate to spurred, inner petals joined apically; stamens 6, diadelphous (fused by their filaments into two bundles). About 18 genera and 424 species, with the greatest concentration in the Northern Hemisphere and centred in Asia.

Critical appraisal. Many of the Asiatic species of the Papaverales order have been little studied from modern points of view, and this is one of taxonomic needs in the group. Further research on *Hypecoum* and *Pteridophyllum* would help to better place these genera with respect to each other and with respect to the principal families Papaveraceae and Fumariaceae.

The great divergence of taxonomic treatments of certain genera is baffling and calls for a sound evaluation. For example, the recognition by one authority of 123 species of *Eschscholzia* (California poppy) mostly from California is not compatible with the treatment by another, in which only eight species are given for the state. A third has recently suggested that *Eschscholzia* consists of about 14 species. A similar disparity of treatments exists for the genus *Platystemon*, and this should be carefully resolved.

BIBLIOGRAPHY. W.R. ERNST, "The Genera of Papaveraceae and Fumariaceae in the Southeastern United States," *J. Arnold Arbor.*, 43:315–343 (1962), although ostensibly limited geographically, this paper offers an important review of the taxonomy of the Papaverales as a whole; a broad bibliographical coverage is included. J. HUTCHINSON, "The Genera of Fumariaceae and Their Distribution," *Kew Bull.*, 1921:97–115 (1921), is an abbreviated taxonomic treatment of the family with keys to genera and species and includes geographical information. M.A. RYBERG, "A Morphological Study of the *Fumariaceae* and the Taxonomic Significance of the Characters Examined," *Acta Horti Bergiani*, 19:122–248 (1960), includes a general discussion of the geography of the family and a critique of the taxonomy on a worldwide basis.

(R.C.R.)

Paper and Paper Production

Paper is the basic material used for written communication and the dissemination of information. In addition, paper and paperboard provide materials for hundreds of other uses, such as wrapping, packaging, towelling, insulating, and photography.

Paper has been defined as a matted or felted sheet formed on a wire screen from water suspension. The word paper is derived from the name of the reedy plant papyrus, which grows abundantly along the Nile River in Egypt. In ancient times, the fibrous layers within the stem of this plant were removed, placed side by side, and crossed at right angles with another set of layers similarly arranged. The sheet so formed was dampened and pressed. Upon drying, the glue-like sap of the plant, acting as an adhesive, cemented the layers together. Complete defibring, an indispensable element in modern papermaking, did not occur in the preparation of papyrus sheets. Papyrus was the most widely used writing material in ancient times, and many papyrus records still survive.

Manufacture of papyrus

This article is divided into the following sections:

I. The papermaking process

HISTORICAL DEVELOPMENT

Beginnings of papermaking. Papermaking can be traced to about AD 105, when Ts'ai Lun, an official attached to the Imperial court of China, created a sheet of paper using mulberry and other bast fibres along with fish nets, old rags, and hemp waste. In its slow travel westward, the art of papermaking reached Samarkand, in Central Asia, in 751; and in 793 the first paper was made in Baghdad during the time of Harun-ar-Raschid, with the golden age of Islāmic culture that brought papermaking to the frontiers of Europe.

By the 14th century a number of paper mills existed in Europe, particularly in Spain, Italy, France, and Germany. The invention of printing in the 1450s brought a vastly increased demand for paper. Through the 18th century the papermaking process remained essentially unchanged, with linen and cotton rags furnishing the basic raw materials. Paper mills were more and more plagued by shortages; in the 18th century they even advertised and solicited publicly for rags. It was evident that a process for utilizing a more abundant material was needed.

Improvements in materials and processes. *Wood pulp.* In 1800 a book was published that launched development of practical methods for manufacturing paper from wood pulp and other vegetable pulps. Several major pulping processes were gradually developed that relieved the paper industry of dependency upon cotton and linen rags and made modern large-scale production possible. These developments followed two distinct pathways. In one, fibres and fibre fragments were separated from the wood structure by mechanical means; and in the other, the wood was exposed to chemical solutions that dissolved and removed lignin and other wood components, leaving cellulose fibre behind. Made by mechanical methods, groundwood pulp contains all the components of wood and thus is not suitable for papers in which high whiteness and permanence are required. Chemical wood pulps such as soda and sulfite pulp (described below) are used when high brightness, strength, and permanence are required. Groundwood pulp was first made in Germany in 1840, but the process did not come into extensive use until about 1870. Soda pulp was first manufactured from wood in 1852 in England, and in 1867 a patent was issued in the United States for the sulfite pulping process.

Mechanical and chemical pulping

Vat sizing. A sheet of paper composed only of cellulosic fibres ("waterleaf") is water absorbent. Hence, water-based inks and other aqueous liquids will penetrate and spread in it. Impregnation of the paper with various substances that retard such wetting and penetration is called sizing.

Before 1800, paper sheets were sized by impregnation with animal glue or vegetable gums, an expensive and tedious process. In 1800 Moritz Friedrich Illig in Germany discovered that paper could be sized in vats with rosin and alum. Though Illig published his discovery in 1807, the method did not come into wide use for about 25 years.

Chlorine bleaching. Discovery of the element chlorine in 1774 led to its use for bleaching paper stock. Lack of chemical knowledge at the time, however, resulted in production of inferior paper by the method, discrediting it for some years. Chlorine bleaching is a common papermaking technique today.

Introduction of machinery. Prior to the invention of the paper machine, paper was made one sheet at a time by dipping a frame or mold with a screened bottom into a vat of stock. Lifting the mold allowed the water to drain, leaving the sheet on the screen. The sheet was then pressed and dried (see Figure 1). The size of a single sheet was limited to the size of frame and mold that a man could lift from a vat of stock.

In 1798, Nicolas-Louis Robert in France constructed a moving screen belt that would receive a continuous flow of stock and deliver an unbroken sheet of wet paper to a pair of squeeze rolls. The French government recognized Robert's work by the granting of a patent.

The paper machine did not become a practical reality, however, until two engineers in England, both familiar with Robert's ideas, built an improved version for their employers, Henry and Sealy Fourdrinier, in 1807. The Fourdrinier brothers obtained a patent also. Two years later a cylinder paper machine (described below) was devised by John Dickinson, an English papermaker.

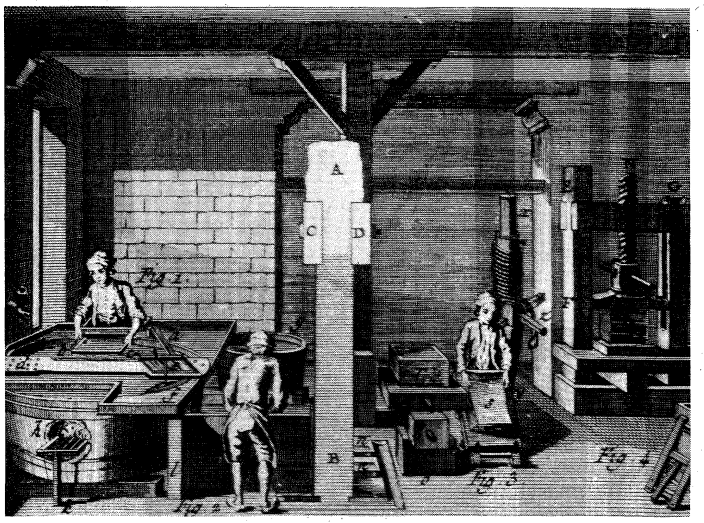


Figure 1: *Making paper by hand in an 18th-century paper mill.* The workman in "Fig. 1," the vatman, is dipping the mold into the vat of stock. The workman in "Fig. 2" is "couching" or pressing the wet sheet while it is still on the mold. The workman in "Fig. 3" is separating the sheets from the molds, making a stack to be pressed by the device in "Fig. 4." Woodcut from the *Encyclopédie*, edited by Denis Diderot and Jean Le Rond d' Alembert, 1751–72.

From these crude beginnings, modern papermaking machines evolved. By 1875 paper coated by machinery was being made for use in the printing of halftones by the new photoengraving process, and in 1884 Carl F. Dahl invented sulfate (kraft) pulp in Danzig, Germany.

Although the paper machine symbolizes the mechanization of the paper industry, every step of production, from the felling of trees to the shipment of the finished product, has also seen a dramatic increase in mechanization, thus reducing hand labour. As papermaking operations require the repeated movement of large amounts of material, the design and mechanization of materials-handling equipment has been and continues to be an important aspect of industry development.

Basic operations in papermaking

Though modern inventions and engineering have transformed an ancient craft into a highly technical industry, the basic operations in papermaking remain the same to this day. The steps in the process are as follows: (1) a suspension of cellulosic fibre is prepared by beating it in water so that the fibres are thoroughly separated and saturated with water; (2) the paper stock is filtered on a woven screen to form a matted sheet of fibre; (3) the wet sheet is pressed and compacted to squeeze out a large proportion of water; (4) the remaining water is removed by evaporation; and (5) depending upon use requirements, the dry paper sheet is further compressed, coated, or impregnated.

The differences among various grades and types of paper are determined by: (1) the type of fibre or pulp; (2) the degree of beating or refining of the stock; (3) the addition of various materials to the stock; (4) formation conditions of the sheet, including basis weight, or substance per unit area; and (5) the physical or chemical treatment applied to the paper after its formation.

FIBRE SOURCES

Properties of cellulose fibres

The cell walls of all plants contain fibres of cellulose, an organic material known to chemists as a linear polysaccharide. It constitutes about one-third of the structural material of annual plants and about one-half that of perennial plants. Cellulose fibres have high strength and durability. They are readily wetted by water, exhibiting considerable swelling when saturated, and are hygroscopic —*i.e.*, they absorb appreciable amounts of water when exposed to the atmosphere. Even in the wet state, natural cellulose fibres show no loss in strength. It is the combination of these qualities with strength and flexibility that makes cellulose of unique value for paper manufacture.

Most plant materials also contain nonfibrous elements or cells, and these also are found in pulp and paper. The nonfibrous cells are less desirable for papermaking than fibres but, mixed with fibre, are of value in filling in the sheet. It is probably true that paper of a sort can be produced from any natural plant. The requirements of paper quality and economic considerations, however, limit the sources of supply.

Wood. Pulped forest tree trunks (boles) are by far the predominant source of papermaking fibre. The bole of a tree consists essentially of fibres with a minimum of nonfibrous elements, such as pith and parenchyma cells.

Softwood and hardwood fibres

Forests of the world contain a great number of species, which may be divided into two groups: coniferous trees, usually called softwoods, and deciduous trees, or hardwoods. Softwood cellulose fibres measure from about two to four millimetres (.08 to .16 inch) in length, and hardwood fibres range from about 0.5 to 1.5 millimetres (0.02 to 0.06 inch). The greater length of softwood fibres contributes strength to paper; the shorter hardwood fibres fill in the sheet and give it opacity and a smooth surface.

When the sulfite process (see below) was the chief method of pulping in the early days of the pulp industry, spruce and fir were the preferred species. Since that time, advances in technology, particularly the introduction of the kraft process (described below), have permitted the use of practically all species of wood, greatly expanding the potential supply.

Because of the enormous and rapidly growing consumption of wood for pulp, concern regarding the depletion of forest resources has been expressed, even though yearly growth often exceeds the annual harvest. In 1962, for example, though new growth exceeded the harvest by a considerable margin, much of it was inferior in quality and less accessible than the harvested trees. Moreover, wood is now being harvested at a more rapid pace. Approximately 40 percent of the harvest is going into pulp, and that figure is expected to increase. There is also a rising public demand for withdrawal of forest land from timber production for recreational use and to prevent disturbance to the ecology of certain areas. On the other hand, application of new techniques in fertilization and genetics have brought about enormous increases in the productivity of forest lands in some areas. Universal adoption of these new methods could help to assure a future supply of wood.

Two significant trends in pulpwood utilization deserve mention. Until recently, lumbering and other wood-using industries were operated quite independently of the pulp industry. Since World War II, however, the waste from the wood-using industries, such as sawdust, has increasingly been used for pulp. In addition, more abundant and less desirable hardwoods have been used as a source of pulp. The woodyard of a pulp mill formerly stored pulpwood in the form of roundwood logs, but recently there has been a trend toward storing in the form of chips.

Rags. Cotton and linen fibres, derived from textile and garment mill cuttings; cotton linters (the short fibres recovered from the processing of cottonseed after the separation of the staple fibre); flax fibres; and clean sorted rags are still used for those grades of paper in which maximum strength, durability, and permanence are required, as well as fine formation, colour, texture, and feel. These properties are attributed to the greater fineness, length, and purity of rag fibre as compared with most wood pulp. Rag papers are used extensively for bank note and security certificates; life insurance policies and legal documents, for which permanence is of prime importance; technical papers, such as tracing paper, vellums, and reproduction papers; high-grade bond letterheads, which must be impressive in appearance and texture; lightweight specialties such as cigarette, carbon, and Bible papers; and high-grade stationery, in which beauty, softness, and fine texture are desired.

Properties of rag paper

Rags are received at the paper mill in bales weighing from 400 to 1,200 pounds (200 to 500 kilograms). After mechanical threshing, the rags are sorted by hand to remove such foreign materials as rubber, metal, and paper and to eliminate those rags containing synthetic fibres

and coatings that are difficult to remove. Following sorting, the rags are cut up, then dusted to remove small particles of foreign materials, and passed over magnetic rolls to remove iron.

The cut and cleaned rags are cooked (to remove natural waxes, fillers, oils, and grease) in large cylindrical or spherical boilers of about five-ton (4,500-kilogram) capacity. About three parts of cooking liquor, a dilute alkaline solution of lime and soda ash or caustic soda combined with wetting agents or detergents, are used with each part of rags. Steam is admitted to the boiler under pressure, and the contents are cooked for three to ten hours.

Once cooked, the rags are washed, then mechanically beaten. The beating shortens the fibre, increases the swelling action of water to produce a softened and plastic fibre, and fibrillates or frays the fibre to increase its surface area. All of these actions contribute to better formation of the paper sheet, closer contact between fibres, and the formation of interfibre bonding that gives the paper strength and coherence.

Wastepaper and paperboard. Table 1 shows the consumption of wastepaper stock in selected countries during the year 1969, both in tons and as a percentage of all paper produced in each country.

Table 1: Consumption of Wastepaper Stock in Selected Countries, 1969

	wastepaper stock used (000 tons)	percentage of paper produced
United States	10,446	19.5
Japan	4,646	26.8
West Germany	2,543	44.6
United Kingdom	2,039	37.1
France	1,464	33.3
Netherlands, The	545	31.0
Sweden	255	5.7
Finland	145	3.2

Source: *Pulp and Paper*, June 25, 1970.

By using greater quantities of wastepaper stock, the need for virgin fibre is reduced, and the problem of solid waste disposal is minimized. The expansion of this source is a highly complex problem, however, because of the difficulties in gathering wastepaper from scattered sources, sorting mixed papers, and recovering the fibre from many types of coated and treated papers.

Wastepaper may be classified into four main categories: high-grades, old corrugated boxes, printed news, and mixed paper. High-grade and corrugated stocks originate mainly in mercantile and industrial establishments. White paper wastes accumulate in envelope and printing plants, while tabulating cards are supplied by large offices. Much magazine stock comes from newsstand returns, but some comes from homes. Corrugated waste is supplied by manufacturing plants and retail stores. Printed news is derived from newsstand returns and home collections. Mixed paper comes from waste baskets of office buildings and similar sources. In recent years there has been considerable interest in wastepaper recycling in the interest of ecology.

Converters of paper and paperboard have also increasingly turned to new materials combined with paper and paperboard to give their products special characteristics. Although these new materials have broadened the market for paper, their presence has posed new problems in reusing paper stock. The most common new ingredients are asphalt, synthetic adhesives, metal foils, plastic and cellulose-derivative films and coatings, and some printing inks.

Some objectionable materials can be sorted from wastepaper, and packers generally try to remove them completely. If the producer of wastepaper knows the materials he is using, he can usually segregate trouble-causing substances at the source. Much depends on good cooperation and communication among the papermaker, dealer, packer, and producers so that all may understand what is and what is not acceptable.

There are two distinct types of paper recovery systems: (1) recovery based upon de-inking and intended for printing-grade or other white papers, accounting for about 5 to 6 percent of the total; and (2) recovery without de-inking, intended for boxboards and coarse papers, accounting for the remainder.

Paper recovery systems

Recovery with de-inking. In the de-inking recovery process, the bales of wastepaper are opened, inspected, and fed into a pulper, a cylindrical tank with capacity ranging from one to several tons of stock and provided with agitator blades that circulate and agitate the stock. Hot water and various chemicals help the agitator separate and disperse the fibres.

The amount and type of chemicals used vary considerably from mill to mill. Caustic soda is by far the most generally used, but it is often supplemented with soda ash, silicate of soda, phosphates, and surfactants (wetting agents). The temperature range is from 150° to 190° F (65° to 90° C).

The pulpers are aided in the collection and separation of large pieces of trash by special devices. After the stock leaves the pulper, it is screened to remove finer trash particles and washed to remove the dispersed ink and chemicals. In some instances the stock is bleached with hypochlorite to improve its whiteness.

Recovery without de-inking. In pulping paper stock where de-inking is not necessary, the equipment is similar to that already described. Hot water is also used in the pulper, but the chemicals for dissolving and dispersing the ink are not needed. The stock is screened and washed to remove trash and dirt.

The use of paper stock in the paper mill presents difficulties because of the presence of foreign materials. Miscellaneous trash has always required operators to be watchful, and its presence depends on the source of the waste and the care with which the paper is prepared for market.

Natural fibres other than wood. Since cellulose fibre is a major constituent of the stems of plants, a vast number of plants represent potential sources of paper; many of these have been pulped experimentally. A rather substantial number of plant sources have been used commercially, at least on a small scale and at various times and places. Indeed, the use of cereal straws for paper predates the use of wood pulp and is widely practiced today throughout the world, although on a relatively small scale of production. Because many parts of the world are deficient in forests, the development of the paper industry in these areas appears to depend to a considerable degree upon the use of annual plants and agricultural fibres.

Agricultural fibres

Nonwoody plant stems differ from wood in containing less total cellulose, less lignin, and more of other materials. This means that pulps of high cellulose content (high purity) are produced in relatively low yield, whereas pulps of high yield contain high proportions of other materials. Papers made from these pulps without admixture of other fibre tend to be dense and stiff, with low tear resistance and low opacity.

The morphology (form and structure) of the cells of annual plants also differs considerably from wood. Whereas the nonfibrous (parenchyma) cells of coniferous wood comprise a minor proportion of the wood substance, in annual plants this cell type is a major constituent. As hardwoods also often contain considerable amounts of nonfibrous cells, there is a closer resemblance between hardwood pulps and pulps from annual plants.

The preferred pulping reagents for nonwood plants are the alkalis: caustic soda, lime and soda ash, and kraft liquor (caustic soda and sodium sulfide). A characteristic of the pulping of annual plants, compared with wood, is the milder treatment necessary to produce pulp. Straw, for example, may be pulped with milk of lime in a spherical digester at a steam pressure of 25 pounds per square inch (about two kilograms per square centimetre) and a cooking time of eight to ten hours. The amount of lime used is about 10 percent of the amount of dry fibre.

Pulping reagents

Cereal straws. In the United States straw pulp was formerly used extensively for corrugating medium (*i.e.*, sheet fluted to form the inner ply of corrugated board). Since then, the use of straw pulp for corrugating medium

has been replaced by semichemical hardwood pulp. Straw pulp is still made in several European and Asiatic countries on a small scale.

Bagasse. The residue from the crushing of sugarcane, called bagasse, contains about 65 percent fibre, 25 percent pith cells, and 10 percent water solubles. An essential element in the conversion of bagasse to a satisfactory paper is the mechanical removal of a substantial proportion of the pith prior to the pulping operation. Pulping may be carried out either with soda or with kraft cooking liquor and by batch or continuous systems. Bagasse fibre averages 1.5 to two millimetres (0.06 to 0.08 inch) in length and is relatively fine.

The use of bagasse is substantial in several Latin-American countries and in the Middle East. The utilization of bagasse for paper in all the sugar-producing countries that are deficient in forest resources is a practical step.

Esparto. A desert plant of the Mediterranean area, especially in southern Spain and northern Africa, esparto grass has a higher cellulose content than most nonwood plants, with greater uniformity of fibre size and shape. The use of esparto for papermaking was developed in Great Britain in 1856. Consumption rose steadily until the mid-1950s, but since has steadily declined.

Esparto held its own against the competition with wood pulp for some time because of its favourable papermaking properties. The stock forms well on a paper machine because of free drainage and uniform fibre length, compared with rag or wood pulp. Esparto printing papers possess good resilience in contact with the printing plate, have good opacity and smoothness, and are relatively lint-free. Another important characteristic of papers made from esparto is dimensional stability with changes in moisture content.

Bamboo. Botanically, bamboo is classified as a grass, even though it attains a considerable size and the stems or culms resemble wood in hardness and density. It was demonstrated many years ago that satisfactory pulp could be made from bamboo.

Because of the abundance of bamboo in Southeast Asia, where increased production of paper is greatly needed, much interest has been displayed in bamboo pulp development. The growing cycle of bamboo is favourable, for the culms can be harvested without destroying the root system. Under ideal conditions of soil fertility and moisture, an established stand of bamboo probably would produce more fibre per acre (or hectare) per year than any other plant. Wild bamboo, however, is difficult to harvest and transport economically; so far, the interest in it has not been translated into any large-scale production. Pulp mills make use of bamboo in India, Thailand, and the Philippines. Considerable quantities of bamboo pulp are said to be made in China, but details are lacking.

Flax, hemp, jute, kenaf. These plants are characterized by a high proportion of long, flexible bast fibres that are readily separated and purified from the other materials in the plant. Consequently, such fibres have long been used for textiles and rope-making. Most of this fibre reaching the paper industry in the past has been secondary or waste fibre. It has been highly prized because of the strength and durability it imparts to such products as tags, abrasive paper (sandpaper), cover stock, and other heavy-duty paper. It is also used for duplicating and manifold paper, in which extremely light weight must be combined with exceptional strength. Flax is grown expressly for high-grade cigarette paper. Experimental quantities of kenaf have been grown and made into various grades of paper.

Synthetic fibres. The development and use of a great variety of man-made fibres have created a revolution in the textile industry in recent decades. It has been predicted that similar widespread use of synthetic fibres may eventually occur in the paper industry. Active interest has been evident in recent years, both on the part of fibre producers and of paper manufacturers. Many specialty paper products are currently being made from synthetic fibres.

The advantages of synthetic or man-made fibres in papermaking can be summarized as follows:

Whereas natural cellulose fibres vary considerably in size and shape, synthetic fibres can be made uniform and of selected length and diameter. Long fibres, for example, are necessary in producing strong, durable papers. There are limitations, however, to the length of synthetic fibres that may be formed from suspension in water because of their tendency to tangle and to rope together. Even so, papers have been made experimentally with fibres several times longer than those typical of wood pulp; these papers have improved strength and softness properties. Advantages of synthetic fibres

Natural cellulose fibres have limited resistance to chemical attack and exposure to heat. Because synthetic fibre papers can be made resistant to strong acids, they are useful for chemical filtration. Paper can even be made from glass fibre, and such paper has great resistance to both heat and chemicals.

The natural cellulose fibres of ordinary paper are hygroscopic; *i.e.*, they absorb water from the air and reach an equilibrium depending upon the relative humidity. The moisture content of paper, therefore, changes with atmospheric conditions. These changes cause swelling and shrinkage of fibers, accounting for the puckering and curling of papers. Synthetic fibres not subject to these changes can be used to produce dimensionally stable papers.

The cheapest man-made fibre, rayon, costs from three to six times as much as an equivalent amount of wood pulp, whereas most of the true synthetics, such as the polyamides (nylon), polyesters (Dacron, Dynel), acrylics (Orlon, Creslan, Acrilan), and glass, cost from ten to 20 times as much. This difference in cost does not preclude the use of existing synthetics, but it limits their use to special items in which the extra qualities will justify the additional cost. The cost factor is increased by the absence in most synthetic fibres of the bonding property of natural cellulose fibres. When beaten in water, natural fibres swell and cement together as they dry. Paper made from synthetics must be bonded by the addition of an adhesive, requiring an additional manufacturing step. Cost of wood pulp and synthetic fibres

There is a distinct similarity between synthetic fibre "papers" and the class of sheet materials known as nonwovens. As a step in the manufacture of yarn, staple fibres are carded (*i.e.*, separated and combed) to form a uniform, lightweight, and fragile web. Subsequently, this web is gathered together to form a strand or sliver, which is drawn and spun into yarn. If several of these flat webs, however, are laminated together and bonded with adhesive, a nonwoven fabric that has properties resembling both paper and cloth results. In this area it is difficult to draw a clear distinction between what is paper and what is cloth. Processes are now available to form sheet material both by the dry forming method and by the water forming or paper system. When textile-type fibres are formed into webs by either of these processes, the resulting products have properties that enable them to compete in some fields traditionally served by textiles.

PROCESSES FOR PREPARING PULP

Mechanical or groundwood pulp is made by subjecting wood to an abrading action, either by pressing the wood against a revolving grinding stone or by passing chips through a mill. The wood fibres are separated and, to a considerable degree, fragmented.

Chemical wood pulp is made by cooking wood chips with chemical solutions in digesters operated at elevated temperature and pressure. The chemicals used are: (1) sulfite salts with an excess of sulfur dioxide, and (2) caustic soda and sodium sulfide (the kraft process). The lignin of the wood is made soluble, and the fibres separate as whole fibres. Further purification can be accomplished by bleaching. Chemical wood pulp that is purified both by bleaching and by alkaline extraction is called alpha or dissolving pulp. It is used for specialty papers, for rayon and cellulose film production, and for cellulose derivatives, such as nitrate and acetate.

Semichemical pulp is made by treating wood chips with sulfite or alkali in amounts and under conditions that soften the lignin but dissolve only part of it. The softened chips are then defibred.

Mechanical or groundwood pulp. Pulpwood may arrive at the mill as bolts four feet (1.2 metres) in length or as full-length logs. The logs are sawn to shorter length, and the bolts are tumbled in large revolving drums to remove the bark. The debarked wood is next sent to grinders, where its moisture content is important for ease of grinding and quality of pulp. Moisture content should be at least 30 percent and preferably 45 to 50 percent. Wood of low moisture content is presoaked in a pond or sprayed with water.

Importance of moisture content

Early grinders employed round slabs of natural sandstone 27 inches (69 centimetres) wide and 54 inches (137 centimetres) in diameter, often directly connected to water wheels, to produce five or six tons (4,500–5,400 kilograms) of pulp per day. The wood was hand-loaded into the grinders.

Today's much larger pulp grinders are usually powered by electric motors and automatically loaded. In a recently built mill, each grinder is gear connected to a 10,000 horsepower motor; the pulpstone, at 360 revolutions per minute, can handle wood 60 to 64 inches (1.5–1.6 metres) long. Hydraulic cylinders produce a pressure of 200 pounds per square inch against the stone face. Pulp production from each stone is 130 to 150 tons (120,000–135,000 kilograms) every 24 hours.

The first artificial grinding stone was produced in 1924; since that time, artificial stones have replaced natural sandstone. Silicon carbide and aluminum oxide are the abrasives used in the manufacture of pulpstones. The abrasive material is broken down into a mixture of sizes that is screened to give fractions of uniform grain size. The abrasive grains are mixed with binder and fired at high temperature (2,300° C or 4,200° F) in the form of segments that are assembled to form the abrasive surface of the pulpstone.

The pulp stock flows from the grinder pit to a series of rifflers and screens, which separate the heavy foreign material and pieces of unfibred wood (shives), knots, bark, and the like.

Most groundwood pulp flows directly to an adjacent paper mill for use as stock. When shipped, it is formed into a sheet on a cylindrical vacuum filter. The sheets are pressed in a hydraulic press to a moisture content of about 50 percent, and the pressed sheets are formed into bales.

An important test to control the quality of groundwood pulp is freeness: the readiness with which water drains from and through a wet pad of pulp. Groundwood pulps are much less "free" than chemical wood pulps.

Freeness characteristic

In groundwood pulp, the fibres are fragmented, and there is considerable debris (fines). Also, groundwood contains all the chemical constituents of wood, including lignin, hemicellulose, resin, and various colouring materials. This means that papers containing groundwood are subject to discoloration (yellowing) upon exposure to light and heat and after aging. The yellowing of newspaper and much book paper is an example of this. Because groundwood fibres are relatively short and have only a moderate ability to bond to each other, papers containing them do not have high strength. On the other hand, papers containing groundwood have good opacity; they are bulky and have good printing qualities.

Groundwood pulp does not have a high whiteness, being limited in this quality by the colour of the wood from which it is made. Though often bleached with peroxide or hydrosulfite to improve whiteness, it does not equal pure cellulose.

Chemical wood pulp. The effect of sulfurous acid (H_2SO_3) in softening and defibring wood was observed by B.C. Tilghman, a U.S. chemist, as early as 1857. Several years later he renewed his experiments and, in 1867, was granted a patent for making paper pulp from vegetable material. He used high temperature and pressure and observed that the presence of a base such as calcium was important in preventing burned or discoloured batches of pulp. His work, however, did not result in commercial use of the process.

The sulfite process. During the 1870s the sulfite process for pulping wood was the subject of experimental work in Sweden, England, Germany, and Austria. Within a few years the process was in commercial operation both in Europe and in North America. For many decades, the sulfite process was the leading process for the pulping of wood. Since 1940, however, the kraft process has taken a predominant position, and sulfite mills are no longer being constructed.

Sulfite cooking liquor, as it is pumped to the digester at the start of a "cook," consists of free sulfur dioxide dissolved in water at a concentration of 4 to 8 percent, together with from 2 to 3 percent in the form of bisulfite. Sulfite digestion is normally carried out as a batch process in a pressure vessel, a steel shell with an acid-resistant lining of ceramic tile set in acid-proof cement or stainless steel. A common digester measures 16 feet (five metres) in diameter and 50 feet (15 metres) in height, with a domed top and a conical bottom. It has a capacity of 12 to 15 tons (11,000–13,500 kilograms) of pulp per batch. Digesters of up to 35 tons (32,000 kilograms) capacity have been constructed. Pulp mills normally have a series of digesters arranged in a digester building.

Sulfite digestion

After the blow valve is closed at the bottom, the wood chips are allowed to flow into the top opening and are distributed to fill the digester completely. Hot acid from the accumulator is pumped into the digester unit, completely filling it and replacing the air. Steam provides the heat.

At the end of the cook, the contents of the digester are blown to a blowpit by rapid opening of the bottom valve. The violence of the blow defibres the cooked chips.

From 1 to 6 percent of the digester charge is undesirable material such as knots, uncooked chips, dirt, bark, fibre bundles, and shives. The screen room separates the unwanted particles from accepted fibre, normally on the basis of particle size; there is an increasing use of the centrifugal principle, which separates particles on the basis of density.

The sulfite cooking liquor does not "cook out" or disintegrate bark and other foreign material to the same degree as kraft liquor (described below), and hence more care must be used in selecting and cleaning wood chips for sulfite.

In the conventional sulfite cook using softwood, the typical yield is 44 to 46 percent, based on wood and with a lignin content of 2 to 5 percent. At that point, a relatively light-coloured pulp with good strength properties is obtained, suitable for use in the unbleached state, especially in mixture with groundwood for a variety of printing papers. For pulps in which high brightness (whiteness) is desired, the residual lignin is removed by bleaching.

The soda process. In 1851 paper pulp was experimentally produced from wood by cooking it with caustic soda at elevated temperature and pressure. Though this soda process attained commercial importance, soda pulp was of relatively low strength; and use of the process was limited to manufacturing filler pulps from hardwood, which were then mixed with a stronger fibre for printing papers. Because this process consumed relatively large quantities of soda, papermakers devised methods for recovering soda from the spent cooking liquor; recovery has remained an integral part of alkaline pulping ever since.

The kraft process. In 1884 a German chemist, Carl F. Dahl, employed sodium sulfate in place of soda ash in a soda pulping recovery system. This substitution produced a cooking liquor that contained sodium sulfide along with caustic soda. Pulp so produced was stronger than soda pulp and was called "kraft" pulp, so named from the German and Swedish word for "strong." The process has also been termed the sulfate process because of the use of sodium sulfate (salt cake) in the chemical makeup. Sulfate, however, is not an active ingredient of the cooking liquor.

Many soda mills were converted to kraft because of the greater strength of the pulp. Kraft pulp, however, was dark in colour and difficult to bleach; for many years the growth of the process was slow because of its limitation to papers in which colour and brightness were unimportant. In the 1930s, bleached kraft became commercially important with the discovery of new bleaching tech-

niques. The availability of pulp of high whiteness and the expanding demand for unbleached kraft in packaging resulted in rapid growth of the process, making kraft the predominant wood-pulping method.

Paper produced by the kraft process is particularly strong and durable. Acceptable pulp can be produced in the kraft process from many species of wood not suitable for sulfite. The various pines, for example, especially southern yellow pine, contain large amounts of wood resin or pitch. Chemically altered and dissolved in the kraft process, this material is removed from the pulp and becomes a valuable by-product. The wood pitch is not removed to the same degree in the sulfite process, and hence high-resin woods, such as pine, are not suitable.

The kraft cooking operation

In the cooking operation, wood chips are prepared and fed to the digesting equipment by methods previously described. The cooking vessels are still widely used as batch digesters. In the past 25 years, however, continuous digesters have been developed and are being widely adopted by the kraft industry. These huge cylindrical towers, over 200 feet (60 metres) in height, have a number of zones or compartments. Wood chips and cooking liquor are fed into the top and injected into successive zones of high pressure and temperature, where impregnation and cooking takes place as the chips progress downward. Additional zones wash the spent liquor from the chips. Continuous digesters are capable of producing 600 tons (or about 540,000 kilograms) of pulp per day.

In batch cooking, after the digester is charged with chips, a mixture of "black liquor," the spent liquor from a previous cook, and "white liquor," a solution of sodium hydroxide and sodium sulfide from the chemical recovery plant, is pumped in. The digester is heated either by direct injection of steam or by the circulation of the cooking liquor through a heat exchanger.

Figure 2 shows a flow diagram of a kraft pulping operation. After completion of the cook, the spent cooking liquor is washed from the pulp; the latter is then screened and sent to the bleach plant or directly to the paper mill if it is to be used unbleached. Some of the spent liquor (black liquor) is used for an admixture with white liquor to charge new cooks; the remainder is sent to the recovery plant to reconstitute cooking chemicals.

All the sodium used for digestion is contained in the spent liquor, mostly in the form of sodium salts and sodium organic derivatives. The amount of sodium present is such that its re-use is economically necessary.

Semichemical pulp. For semichemical pulping wood preparation and chipping are essentially the same as that for other wood-pulping processes. The chips are steeped and impregnated with inorganic chemical solutions similar to those used for full chemical pulping, but in smaller amounts and with less severe conditions. Probably the most common is the solution of sodium sulfite in the neutral range, between acidity and alkalinity. Other agents used in some cases are acid sulfite, caustic soda, and kraft cooking liquor.

After the impregnation operation, the chips are fed into one or more disk refiners (described below) in series. The attrition action of refiners reduces the softened chips to pulp. The yield of semichemical pulp based on wood is 66 to 90 percent. The higher fibre yield pulps are usually termed chemimechanical pulps.

The semichemical pulps have chemical and strength properties intermediate between softwood, groundwood, and full chemical pulps. These are used in a fairly wide range of papers and boards. The major tonnage of semichemical pulps goes into the light board, termed corrugating medium, which is fluted to serve as the interior layer of corrugated boxboard in heavy-duty containers. Stiffness and adequate strength are the important properties. Semichemical pulp is used extensively in a variety of low-cost printing papers.

Bleaching and washing. The use of calcium and sodium hypochlorites to bleach paper stock dates from the beginning of the 19th century. In the early days of sulfite pulp manufacture, a single-stage treatment of pulp at low consistency, using calcium hypochlorite (chlorinated lime), satisfied most requirements.

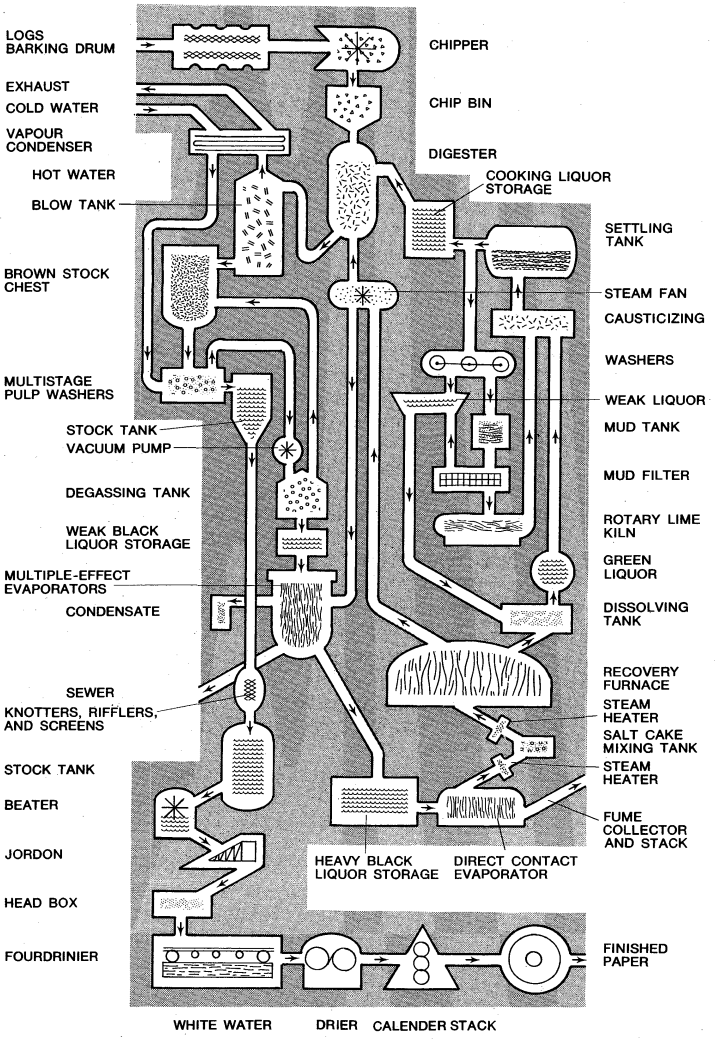

Figure 2: Stages in the kraft pulping process.
Drawing by D. Meighan

This simple bleaching treatment, however, is not practical for kraft that is difficult to bleach, nor can it retain maximum pulp strength. Accordingly, multistage bleaching systems have evolved in which various sequences of chemical treatment are employed, depending upon the type of unbleached pulp and special requirements.

During the normal first stage in a modern bleach plant, the unbleached pulp is chlorinated. Three to 4 percent of gaseous chlorine is rapidly mixed with pulp at a temperature of 70° to 80° F (21° to 27° C); the mixture is quite acid due to the acidity of the chlorine. Chlorine is absorbed largely by reaction with the non-carbohydrate components of pulp, with no brightening effect and with only slight dissolution of lignin.

Alkaline extraction

In the following stage an alkaline extraction with dilute caustic soda dissolves chlorinated compounds, which are then washed out.

In its simplest sequence the final stage consists of a treatment with a very alkaline hypochlorite to neutralize the solution, followed by a final wash.

In recent years the compound chlorine dioxide (ClO_2) has become available for on-site preparation; it is too unstable to be shipped for wood pulp bleaching. By the use of small amounts of ClO_2 in later bleaching stages, it is possible to achieve high degrees of purification and brightness without the degradation of cellulose.

The brightness of paper and other materials is determined by special reflection meters containing photoelectric cells that measure the amount of light of selected wavelength reflected by the surface. Freshly prepared pure magnesium oxide is considered to be 100 on the brightness scale. On this scale unbleached sulfite and groundwood cover the range from about 50 to about 62;

peroxide bleached groundwood, 66 to 72; single-stage hypochlorite sulfite, 80 to 85; multistage bleached pulp, 85 to 88; and multistage with chlorine dioxide, 90 to 94.

MANUFACTURE OF PAPER AND PAPERBOARD

Preparation of stock. Mechanical squeezing and pounding of cellulose fibre permits water to penetrate its structure, causing swelling of the fibre and making it flexible. Mechanical action, furthermore, separates and frays the fibrils, submicroscopic units in the fibre structure. Beating reduces the rate of drainage from and through a mat of fibres, producing dense paper of high tensile strength, low porosity, stiffness, and rattle.

The Hollander beater. An important milestone in papermaking development, the Hollander beater consists of an oval tank containing a heavy roll that revolves against a bedplate. The roll is capable of being set very accurately with respect to the bedplate, for the progressive adjustment of the roll position is the key to good beating. A beater may hold from 300 to 3,000 pounds (135 to 1,350 kilograms) of stock, a common size being about 24 feet (7 metres) long, 12 feet (4 metres) wide, and about 3.5 feet (1 metre) deep. A centre partition provides a continuous channel.

Pulp is put into the beater, and water is added to facilitate circulation of the mass between the roll and the bedplate. As the beating proceeds, the revolving roll is gradually lowered until it is riding full weight on the fibres between it and the bedplate. This action splits and mashes the fibres, creating hairlike fibrils and causing them to absorb water and become slimy. The beaten fibres will then drain more slowly on the paper machine wire and bond together more readily as more water is removed and the wet web pressed. Much of the beating action results from the rubbing of fibre on fibre. Long fibres will be cut to some extent.

Sizing, fillers, and dyes

The beater is also well-adapted for the addition and mixing of other materials, such as sizing, fillers, and dyes. By mounting a perforated cylinder that can rotate partially immersed in the beater stock, water can be continuously removed from the beater, and the stock can be washed.

Though many design modifications have been made in the Hollander beater over the years, the machine is still widely used in smaller mills making specialty paper products. For large production modern mills have replaced the beater by various types of continuous refiners.

Conical refiner. In mills that receive baled pulp and use refiners, the pulp is defibred in pulpers. While there are a number of variations in basic design, a pulper consists essentially of a large, open vessel, with one or more bladed, rotating elements that circulate a pulp–water mixture and defibre or separate fibres. The blades transform the pulp or wastepaper into a smooth mixture. Unlike beaters and refiners, pulpers do not reduce freeness and cause fibrillation in the fibres. A typical pulper has a capacity of 2,000 pounds (900 kilograms) of fibre in 6 percent solution and requires 150 horsepower to drive it.

The original continuous refiner is the Jordan, named after its 19th-century inventor. Like the beater, the Jordan has blades or bars, mounted on a rotating element, that work in conjunction with stationary blades to treat the fibres. The axially oriented blades are mounted on a conically shaped rotor that is surrounded by a stationary bladed element (stator).

Disk refiner. Like other refiners, the disk refiner consists of a rotating bladed element that moves in conjunction with a stationary bladed element. The disk refiner's plane of action, however, is perpendicular to the axis of rotation, simplifying manufacture of the treating elements and replacement. Since the disk refiner provides a large number of working edges to act upon the fibre, the load per fibre is reduced and fibre brushing, rather than fibre cutting, may be emphasized.

Sizing. Sizing has been described above as the treatment given paper to prevent aqueous solutions, such as ink, from soaking into it. A typical sizing solution consists of a rosin soap dispersion mixed with the stock in an amount of 1 to 5 percent of fibre. Since there is no affinity between rosin soap and fibre, it is necessary to use a coupling agent, normally alum (aluminum sulfate). The acidity of alum precipitates the rosin dispersion, and the positively charged aluminum ions and aluminum hydroxide flocs (masses of finely suspended particles) attach the size firmly to the negatively charged fibre surface.

Filling or loading. Paper intended for writing or printing usually contains white pigments or fillers to increase brightness, opacity, and surface smoothness, and to improve ink receptivity. Clay (aluminum silicate), often referred to as kaolin or china clay, is commonly used, but only in a few places in the world (Cornwall, in England, and Georgia, in the United States) are the deposits readily accessible and sufficiently pure to be used for pigment. Another pigment is titanium dioxide (TiO_2), prepared from the minerals rutile and anatase. Titanium dioxide is the most expensive of the common pigments and is often used in admixture with others.

Kaolin pigment

Calcium carbonate, also used as a filler, is prepared by precipitation by the reaction of milk of lime with either carbon dioxide (CO_2) or soda ash (calcium carbonate, Na_2CO_3). Calcium carbonate as a paper filler is used mainly to impart improved brightness, opacity, and ink receptivity to printing and magazine stocks. Specialty uses include the filling of cigarette paper, to which it contributes good burning properties. Because of its reactivity with acid, calcium carbonate cannot be used in systems containing alum.

Other fillers are zinc oxide, zinc sulfide, hydrated silica, calcium sulfate, hydrated alumina, talc, barium sulfate, and asbestos. Much of the filler consumed is used in paper coatings (see below).

Since most fillers have no affinity for fibres, it is necessary to add an agent such as alum to help hold the filler in the formed sheet. The amount of filler used may vary from 1 to 10 percent of the fibre.

Colouring. The most common way to impart colour to paper is to add soluble dyes or coloured pigment to the paper stock. Many so-called direct dyes with a natural affinity for cellulose fibre are highly absorbed, even from dilute water solution. The so-called basic dyes have a high affinity for groundwood and unbleached pulps.

Interfibre bonding agents. Various agents are added to paper stock to enhance or to modify the bonding and coherence between fibres. To increase the dry strength of paper, the materials most commonly used are starch, polyacrylamide resins, and natural gums such as locust bean gum and guar gum. The most common type of starch currently used is the modified type known as cationic starch. When dispersed in water, this starch assumes a positive surface charge. Because fibre normally assumes a negative surface charge, there is an affinity between the cationic starch and the fibre.

Cationic starch

The natural cellulose interfibre bonding that develops as a sheet of paper dries is considered to be due to interatomic forces of attraction known to physical chemists as hydrogen bonding or van der Waals forces (see CHEMICAL BONDING). Because these attractive forces are neutralized or dissolved in water, wet paper has practically no strength. Though this property is convenient for the recovery of wastepaper, some papers require wet strength for their intended use. Wet strength is gained by adding certain organic resins to the paper stock that, because of their chemical nature, are absorbed by the fibre. After formation and drying of the sheet, the resins change to an insoluble form, creating water-resistant bonds between fibres.

Formation of paper sheet by machines. In a paper machine, interrelated mechanisms operating in unison receive paper stock from the beater, form it into a sheet of the desired weight by filtration, press and consolidate the sheet with removal of excess water, dry the remaining water by evaporation, and wind the travelling sheet into reels of paper. Paper machines may vary in width from about five to over 25 feet (1.5–eight metres), in operating speed from a few hundred feet to over 3,000 feet (900 metres) per minute, and in production of paper from a few tons per day to over 300 tons (270,000 kilograms)

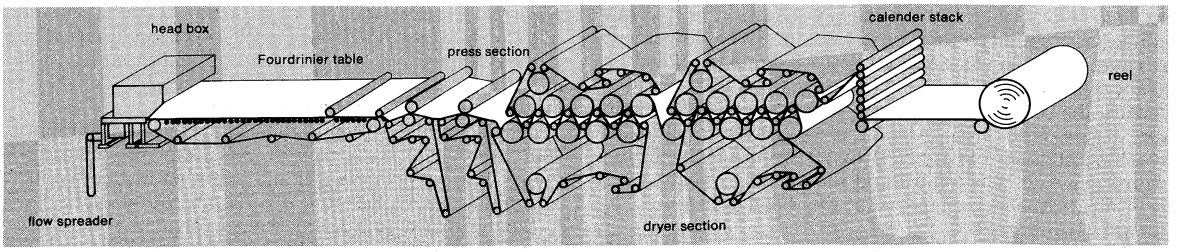

Figure 3: Elements of a Fourdrinier-type paper machine.

per day. The paper weight (basis weight) may vary from light tissue, about ten grams per square metre (0.03 ounce per square foot), to boards of over 500 grams per square metre (1.6 ounces per square foot).

Cylinder and Fourdrinier machines

Traditionally, paper machines have been divided into two main types: cylinder machines and Fourdrinier machines. The former consists of one or more screen-covered cylinders, each rotating in a vat of dilute paper stock. Filtration occurs by flow action from the vat into the cylinder, with the filtrate being continuously removed. In the Fourdrinier machine, a horizontal wire-screen belt filters the stock. In recent years a number of paper machines have been designed that depart greatly from traditional design. These machines are collectively referred to as "formers." Some of these formers retain the travelling screen belt but form the sheet largely on a suction roll. Others eliminate the screen belt and use a suction cylinder roll only. Still others use two screen belts with the stock sandwiched between, with drainage on both sides.

Figure 3 shows a typical modern Fourdrinier machine. The various functional parts are the headbox; stock distribution system; Fourdrinier table, where sheet formation and drainage of water occur; press section, which receives the wet sheet from the wire, presses it between woolen felts, and delivers the partially dried sheet to the dryer section; dryer section, which receives the sheet from the presses and carries it through a series of rotating, steam-heated cylinders to remove the remaining moisture; size press, which permits dampening the sheet surface with a solution of starch, glue, or other material to improve the paper surface; calendar stock, for compressing and smoothing the sheet; and the reel.

The headbox. The function of the headbox is to distribute a continuous flow of wet stock at constant velocities, both across the width of the machine and lengthwise of the sheet, as stock is deposited on the screen. Equal quantities of properly dispersed stock should be supplied to all areas of the sheet-forming surface. The early headbox, more commonly called a flowbox or breastbox, consisted of a rectangular wooden vat that extended across the full width of the machine behind the Fourdrinier breast roll. The box was provided with baffles to mix and distribute the stock. A flat metal plate extending across the machine (knife slice) improved dispersion of the fibre suspension, providing distribution of flow across the machine, and also metered the flow to produce a sheet of uniform weight. To accommodate increased speed in modern headboxes, the knife slice is designed to develop a jet of liquid stock on the moving wire. Modern headboxes are enclosed, with pressure maintained by pumping.

Forming Section. The Fourdrinier table section of a paper machine is a large framework that supports the table rolls, breast roll, couch roll, suction boxes, wire rolls, and other Fourdrinier parts. The wire mesh upon which the sheet of fibre is formed is a continuous rotating belt that forms a loop around the Fourdrinier frame. The wire, not a permanent part of the machine, is delicate and requires periodic replacement. It is a finely woven metal or synthetic fibre cloth that allows drainage of the water but retains most of the fibres. The strands of the Fourdrinier wire are usually made of specially annealed bronze or brass, finely drawn and woven into a web commonly in the range of 55 to 85 mesh (strands per inch). Even finer wires are used for such grades as cigarette paper, coarser wires for heavy paperboard and pulp sheets. Various types of weave are used to obtain maximum wire life and to reduce wire marking on the wet sheet.

The table rolls, in addition to supporting the wire, function as water-removal devices. The rapidly rotating roll in contact with the underside of the wire produces a suction or pumping action that increases the drainage of water through the wire.

The dandy roll is a light, open-structured unit covered with wire cloth and placed on the wire between suction boxes, resting lightly upon the wire and the surface of the sheet. Its function is to flatten the top surface of the sheet and improve the finish. When the dandy roll leaves a mesh or crosshatch pattern, the paper is said to be "woven." When parallel, translucent lines are produced, it is said to be "laid." When names, insignia, or designs are formed, the paper is said to be "watermarked." Paper watermarks have served to identify the makers of fine papers since the early days of the art. A watermark is actually a thin part of the sheet and is visible because of greater transmission of light in its area compared with other areas of the sheet. Because light transmission can be varied by degrees, it is possible to produce watermarks in the form of portraits or pictures.

Watermarks in paper

The final roll over which the formed sheet passes, before removal from the Fourdrinier wire, is the "couch roll." Prior to the transferring operation, the couch roll must remove water from and consolidate the sheet to strengthen it. In modern machines the couch roll is almost always a suction roll.

The press section. The press section increases the solids content of the sheet of paper by removing some of the free water contained in the sheet after it is formed. It then carries the paper from the forming unit to the dryer section without disrupting or disturbing sheet structure and reduces the bulk or thickness of the paper.

The first two functions are always desirable and necessary. Pressing always results in compaction, and this may or may not be desirable depending upon the grades being made.

Paper machine felts

Felts for the press section act as conveyor belts to assist the sheet through the presses, as porous media to provide space and channels for water removal, as textured cushions or shock absorbers for pressing the moist sheet without crushing or significant marking, and as power transfer belts to drive nondriven rolls or parts.

Woven felts of wool, often with up to 50 percent synthetic fibres, are made by a modified woolen textile system. Selected grades of wool are scoured, blended, carded, and spun into yarn. The yarn is woven into flat goods, leaving a fringe at each end. The ends are brought together and joined to produce an endless, substantially seamless belt.

Paper machine felts have a limited life ranging from about a week to several months. Their strength and water-removal ability is gradually lost through wear, chemical and bacterial degradation, and by becoming clogged with foreign material.

Press rolls must be strong, rigid, and well-balanced to span the wide, modern machines and run at high speed without distortion and vibration. Solid press rolls consist of a steel or cast iron core, covered with rubber of various hardnesses depending upon the particular service required. Suction press rolls consist of a bronze or stainless steel shell two inches (five centimetres) or more in thickness and usually covered with one inch of rubber.

The dryer. Paper leaving the press section of the machine has a solids content or dryness of 32 to 40 percent. Because of the relatively high cost of removing water by evaporation, compared with removing it by mechanical means, the sheet must be as dry as possible when it enters the dryers. The dryer section of a conventional paper machine consists of from 40 to 70 steam-heated drying cylinders. After passing around the cylinders, the sheet is held in intimate contact with the heated surfaces by means of dryer felts.

Until recently, relatively heavy, rather impermeable cloths composed of wool, cotton, asbestos, or combinations of these materials covered the dryer portion of the paper machine. Such cloths are termed dryer felts, though felting or fulling process is rarely used in their manufacture. Recently, relatively lightweight, highly permeable cloths called dryer fabric have come into use.

For conventional dryer felts, cotton is still the most commonly used fibre, although it is seldom used alone. The main difference between the conventional dryer felt and the open-mesh dryer fabric is air or vapour permeability. High permeability is desirable because it allows the escape of the water vapour from the sheet.

Vapour permeability

For every ton of paper dried on the paper machine, approximately two tons (1,800 kilograms) of water are evaporated into the atmosphere. About 50 to 60 tons (45,000 to 54,000 kilograms) of air are required to remove the water vapour, with about 6,000 pounds (2,700 kilograms) of steam required by the dryers.

Finishing and converting. The rolls of paper produced by the paper machine must still undergo a number of operations before the paper becomes useful to the consumer. These various operations are referred to as converting or finishing and often make use of intricate and fast-moving machinery.

There are two distinct types of paper conversion. One is referred to as wet converting, in which paper in roll form is coated, impregnated, and laminated with various applied materials to improve properties for special purposes. The second is referred to as dry converting, in which paper in roll form is converted into such items as bags, envelopes, boxes, small rolls, and packs of sheets. A few of the more important converting operations are described here.

Coating. Paper has been coated to improve its surface for better reproduction of printed images for over 100 years. The introduction of half-tone and colour printing has created a strong demand for coated paper. Coatings are applied to paper to achieve uniformity of surface for printing inks, lacquers, and the like; to obtain printed images without blemishes visible to the eye; to enhance opacity, smoothness, and gloss of paper or paperboard; and to achieve economy in the weight and composition of base paper stock by the upgrading effect of coating.

The chief components of the water dispersion used for coating paper are pigment, which may be clay, titanium dioxide, calcium carbonate, satin white, or combinations of these; dispersants to give uniformity to the mixture or the "slip"; and an adhesive binder to give coherence to the finished coating. The latter may be a natural material such as starch or a synthetic material such as latex.

Equipment installed between dryer sections on the paper machine can apply the coating (on-machine coating), or it can be done by a separate machine, using rolls of paper as feed stock (off-machine coating).

Extrusion coating

The extrusion coating process, a relatively new development in the application of functional coating, has gained major importance in the past 20 years. The process is used to apply polyethylene plastic coatings to all grades of paper and paperboard. Polyethylene resin has ideal properties for use with packaging paper, being waterproof; resistant to grease, water vapour, and gases; highly stable; flexible in heat sealing; and free from odour and toxicity.

In the extrusion-coating machine, the polyethylene resin is melted in a thermoplastic extruder that consists of a drive screw within an electrically heated cylinder. The cylinder melts and compacts the resin granules and extrudes the melt in a continuous flow under high pressure. The resin is discharged through a film-forming slot die. The die has electric heaters with precision temperature controls to give uniform temperature and viscosity to the plastic melt. The slot opening can be precisely adjusted to control film uniformity and thickness.

The hot extruded film is then stretched and combined with paper between a pair of rolls, one of which is a rubber-covered pressure roll and the other a water-cooled, chromium-plated steel roll. The combination takes place so rapidly that a permanent bond is created between the plastic film and the paper before they are cooled by the steel roll.

Corrugating. The most widely used package for commodities and manufactured products is the corrugated shipping container. A corrugated box consists of two structural elements: the facings (linerboard), and the fluting structure (corrugating medium).

Linerboard facings are of two general types: the Fourdrinier kraft liner is made of pine kraft pulp, usually unbleached, in an integrated mill as a continuous process from the tree to the paper web, and the cylinder liner is made from reprocessed fibres, generally from used containers, providing a content of about two-thirds kraft.

The operation begins by unwinding the single-face liner and corrugating medium from holders, threading the medium into the fluting rolls, applying adhesive to the tips, and bringing the medium in contact with the liner to form a single-face web. Next, the single-face web passes another glue roll that applies adhesive to the exposed flute tips of the medium. The second face liner is brought in contact with the single-face web, and the combined board travels through a hot plate section between belts to set the bond, to a cooling section, and then to a slitter–scorer.

THE WORLD PAPER INDUSTRY

The paper industry tends to be concentrated in those countries that are industrially advanced and have abundant supplies of fibrous raw material, especially wood. There is a large-scale international trade in wood pulp, pulpwood, and paper flowing from those countries with large forest resources to those countries with less or that are as yet undeveloped. The world production of paper and paperboard in the early 1970s was about 140,000,000 tons with the leading countries as shown in Table 2.

Table 2: World Production of Paper, Paperboard, and Pulp, 1970
(in 000 tons)

	paper and paperboard	pulp
U.S.	47,599	38,298
Japan	12,973	8,801
Canada	11,655	16,117
U.S.S.R.	6,704	6,714
West Germany	5,516	1,803
U.K.	4,979	—
Sweden	4,359	8,148

China	3,750	2,700
Italy	3,451	891
Norway	1,421	2,205

Source: *Pulp and Paper*, June 30, 1971.

The world production of pulp in 1969 was estimated to be 114,112,000 tons. The difference between the tonnage of paper and that of pulp is accounted for by the utilization of wastepaper and the use of various nonfibrous additive materials in paper manufacture. The production of pulp is widespread, occurring in practically all countries that have appreciable paper production. The abundance of suitable wood species in North America and the Scandinavian countries has established these areas as the chief pulp-producing regions. The leading pulp-producing countries are also listed in Table 2.

II. Paper properties and uses

Used in a wide variety of forms, paper and paperboard are characterized by a wide range of properties. In the

thousands of paper varieties available, some properties differ only slightly and others grossly. The identification and expression of these differences depend upon the application of standard test methods, generally specified by industry and engineering associations in the papermaking countries of the world.

SUBSTANCE AND QUANTITY MEASUREMENT

Weight or substance per unit area, called basis weight, is a fundamental property of paper and paperboard products. From the first uses of paper in the printing trades, it has been measured in reams, originally 480 sheets (20 quires) but now more commonly 500 sheets (long reams). The term ream weight commonly signifies the weight of a lot or batch of paper. Since the printing trades use a variety of sheet sizes, there can be numerous ream weights for paper having the same basis weight.

Measurement in reams

Table 3 gives basis weight ranges for some common papers.

Table 3: Basis Weight Ranges for Common Papers

paper grade	basis weight*
Carbonizing tissue†	5¾–25
Facial tissue	9–10
Manifold tissue‡	10–20
Tea-bag tissue	8–12
Blotting paper	114–266
Bond	25–60
Book, uncoated	27–91
Book, coated two sides	45–109
Bristol, postcard	135
Envelopes	16–40
Greaseproof (glassine)	20–50
Newsprint	30–35
Multiwall bag stock	40–70
Kraft wrapping, most common	25–80
Cover stock, file folders	66–216

*Basis weight in pounds per 480 sheet ream, cut to 24 by 36 inches. †Paper to be impregnated with wax and pigment to make carbon paper. ‡Employed for making several carbon copies.

To determine basis weight, the sample is brought to equilibrium under standard conditions (75° F or 24° C; 50 percent relative humidity). The paper specimens must consist of at least ten sheets with a total area of not less than 100 square inches (about 600 square centimetres). Since the properties of paper change with moisture content, all tests are conducted under standard conditions.

The caliper (thickness) of paper or paperboard in thousandths of an inch is measured by placing a single sheet under a steady pressure of seven to nine pounds per square inch between two circular and parallel plane surfaces, the smaller of which has an area of 0.25 square inch (1.6 square centimetres).

The density or specific gravity of paper is calculated from the basis weight and caliper and may vary over wide limits. Glassine, for example, may be 1.4 grams per cubic centimetre and creped wadding, used for packaging breakables, only 0.1 gram per cubic centimetre. Most common papers are in the range of 0.5 to 0.7 gram per cubic centimetre.

STRENGTH AND DURABILITY

The strength of paper is determined by the following factors in combination: (1) the strength of the individual fibres of the stock; (2) the average length of the fibre; (3) the interfibre bonding ability of the fibre, which is enhanced by the beating and refining action; and (4) the structure and formation of the sheet.

Resistance to rupture when subjected to various stresses is an important property in practically all grades of paper. Most papers require a certain minimum strength to withstand the treatment received by the product in use; but even where use requirements are not severe, the paper must be strong enough to permit efficient handling in manufacture. Tensile strength is the greatest longitudinal stress a piece of paper can bear without tearing apart. The stress is expressed as the force per unit width of a test specimen.

Since the weight of the paper and the width of the test specimen affect the force of rupture, a conventional method of comparing inherent paper strength is the breaking length; that is, the length of a paper strip in metres that would be just self-supporting. This value varies from about 500 metres (1,600 feet) for extremely soft, weak tissue to about 8,000 metres (26,000 feet) for strong kraft bag paper, and to about 14,000 metres (46,000 feet) for sheets of paper made under ideal laboratory conditions.

Breaking length

Because some paper products such as towels, sanitary tissues, and filter paper are subjected to wetting by water in their normal use, wet tensile testing has become important. This test is essentially the same as that for dry tensile strength, except that the specimen is wetted. Paper that has not been specifically treated to produce wet strength possesses from about 4 to about 8 percent of its dry strength when completely wetted. By treating paper as described above, wet strength can be raised to about 40 percent of the dry strength.

Bursting strength. One of the oldest and most widely used strength tests for paper and paperboard is the bursting test, or Mullen test. It is defined as the hydrostatic pressure (caused by liquids at rest) necessary to cause rupture in a circular area of a given diameter. Paperboard has a requirement of several hundred pounds per square inch. Other strength tests for which standard methods exist are tearing strength and folding endurance.

Stiffness and softness. The resistance of paper to a bending force is evident in the various operations of its manufacture and in its many uses. The range in this property extends from very soft, flexible tissues to rigid boards. Thicker and heavier sheets tend to be stiff, whereas soft, flexible sheets are light and thin. Even at the same weight there is a considerable difference in stiffness, chiefly due to the compactness and the amount of bonding of the sheet.

Liquid penetration. Because paper is composed of a randomly felted layer of fibre, the structure has a varying degree of porosity. Thus, the ability of fluids, both liquid and gaseous, to penetrate the structure is a property both highly significant to the use of paper and capable of being widely varied by the conditions of manufacture.

Sizing paper with vegetable materials and rosin-like substances has already been described. When paper began to be used for wrapping, consumers demanded sizing treatments that could protect the contents of the package from the effects of fluid transfer through the paper wrapping. In some instances complete impermeability was required. In another direction the use of paper as an absorbent medium for wiping up liquids, for filtering, and for saturating has created a demand for maximum wettability and permeability toward water and other fluids.

In certain types of packaging, paper must resist grease and oil penetration. The resistance of paper to the penetration of water can be increased by treatment of fibre with materials that lack affinity for water, with little effect upon sheet porosity, but the penetration of oil materials is little affected by such treatment. Oil and grease resistance is attained, in fact, by reduction in porosity. So-called greaseproof paper is made by beating an easily hydrated pulp to extremely low freeness, which results in a dense sheet with very little void space.

Absorbent papers such as towelling, sanitary tissue, and blotting and filter paper are normally made from lightly beaten stock. Since cellulose is naturally hydrophilic (*i.e.*, has a strong affinity for water), absorbent papers have a minimum of foreign materials associated with the fibre. Of particular importance are the wood rosins that may be present in pulp and produce a self-sizing effect, especially upon aging.

Absorbent papers

OPTICAL PROPERTIES

The most important optical properties of paper are brightness, colour, opacity, and gloss.

The term brightness has come to mean the degree to which white or near-white papers and paperboard reflect

the light of the blue end of the spectrum (*i.e.*, their reflectance). This reflectance is measured by an instrument that illuminates paper at an average angle of incidence of 45° and a wavelength of 457μ (microns). Brightness measured in this way is found to correlate closely with subjective estimates of the relative whiteness of paper.

Opacity is one of the most desired properties of printing and writing papers. Satisfactory performance of such papers requires that there be little or no "show-through" of images from one side of the sheet to the other. Satisfactory opacity in printing papers requires that white mineral pigments be incorporated with the paper stock or applied as a coating.

The terms gloss, glare, finish, and smoothness are used in describing the surface characteristics of paper. The broad term finish refers to the general surface characteristics of the sheet. Smoothness refers to the absence of surface irregularities under either visual or use conditions. Gloss refers to surface lustre and connotes a generally pleasing aspect. Glare is used for a more intense reflection and a more unpleasant effect. Calendering and coating are important paper-treating methods that affect gloss. Gloss of paper is determined by measuring percent reflectance at a low angle of incidence, 15 degrees (75 degrees from the perpendicular).

PAPER GRADES

Bond paper. Bond is characterized by a degree of stiffness, durability for repeated handling and filing, resistance to the penetration and spreading of ink, bright colour, and cleanliness. There are two groups of bond papers: rag content pulp and chemical wood pulp. Rag content bond may vary from 25 to 100 percent cotton fibre content. The principal uses of bond paper are for letterhead stationery, advertising pieces, announcements, leases, deeds, writs, judgments and other legal documents, currency, certificates, and insurance policies.

Types of bond papers

Book paper. Most book papers are made of various combinations of chemical wood pulp; and for lower priced grades, groundwood, semichemical, and de-inked wastepaper are also used. In addition to pulp, the "furnish" from which book papers are made contains various amounts of sizing, fillers, and dyes.

Uncoated book paper comes in four finishes: (1) antique or eggshell, (2) machine finish, MF, (3) English finish, EF, and (4) supercalendered. Antique has the roughest surface. High bulking pulps, such as soda pulp, are used and only slightly beaten in stock preparation. The sheet is lightly calendered (pressed between rollers) to provide a degree of surface smoothness while preserving the antique or eggshell appearance. Machine finish has a medium-smooth surface obtained for this finish from a calender stock at the dry end of the machine. Machine finish book is a relatively inexpensive general utility paper. It is principally used for books, catalogs, circulars, and other matter using line etchings. Machine finish book may be used for halftones up to a 100-line screen. English finish is a step higher in the book paper scale; this finish is distinguished from machine finish by a higher degree of stack beating, by greater pressure between the rollers of a machine calender, and by calendering at a greater moisture content of the sheet. Supercalendered book is the smoothest surface that can be obtained without coating. The finish is obtained by a special calendering operation after the paper leaves the paper machine. The supercalender presses the paper between successive sets of iron and compressed fibre rolls that make a smooth, compact printing surface. It is used for books, brochures, and magazines where halftone printing in the range of a 100–120 line screen is required.

Coated book papers are produced to create surfaces suitable for the printing of fine-screen halftones. Coated book paper must be uniformly smooth, receptive to printing inks, have high brightness and gloss, and be capable of folding without cracking.

Bible paper, as the name implies, was developed for lightweight, thin, strong, opaque sheets for such books as bibles, dictionaries, and encyclopaedias, which require minimum bulk. Bible papers are pigmented (loaded) with such pigments as titanium dioxide and barium sulfate and contain long fibres and artificial bonding agents to maintain strength.

Bristol. The general term bristol refers to a group of stiff, heavy papers with thicknesses ranging from 0.006 inch (0.15 millimetre) upward. These grades are made from various combinations of chemical wood pulp. The stock is beaten to a medium degree and usually well sized to prevent penetration of moisture. Increasingly important in recent years has been the use of bristols for the punch cards used in tabulating and sorting machines.

Groundwood and newsprint papers. These are printing and converting grades containing varying amounts of groundwood pulp, together with small percentages of chemical wood pulp for strength and durability.

For many years newsprint was virtually the only use for groundwood pulp, but more recently, due to improvements in the pulping process and to the introduction of a bleaching process for this pulp, a class of printing papers of broad utility has been developed. Magazines, paperbound books, catalogs, directories, and general commercial printing consume large quantities of these papers.

Groundwood papers are noted for an even, uniform formation and a high degree of opacity. These papers tend to be bulky and are receptive to printing ink. They do not have high whiteness and tend to turn yellow when exposed to light and after long aging.

Kraft wrapping. Kraft wrapping, a heavy stock used for paper bags, is used in greater volume than all other wrapping papers combined. It is composed of wood pulp in unbleached condition made from softwoods, usually pine. It is distinguished by outstanding tensile and tearing strength. Kraft wrapping is sized to retard wetting when exposed to water. For wrapping of wet materials, the paper may be given wet strength by treatment with special resins. Multiwall sacks of kraft paper are used for shipment of bulk materials.

Paperboards. The term paperboard is a general term descriptive of products 0.012 inch (0.30 millimetre) or more in thickness, made of fibrous materials on paper machines. Paperboard is commonly made from wood pulp, straw, wastepaper, or a combination of these materials.

There are three main types of paperboard: (1) boxboards, used for such products as food board, food trays, plates, and paper boxes; (2) container boards, for the manufacture of corrugated and solid fibre shipping containers; and (3) paperboard specialties, including such items as binders board, electrical pressboard, and building boards.

Types of paperboard

Sanitary papers. The group of papers known collectively as the sanitary grades include toilet tissue, towelling, facial tissue, and napkins. These grades are made from various proportions of sulfite and bleached kraft pulps with relatively little refining of the stock to preserve a soft, bulky, absorbent sheet. This sheet is further softened by machine creping, in which the wet sheet is pressed upon a smooth drying roll and subsequently removed by running against a flat stationary metal blade (doctor blade). The sheet is piled up upon itself, thus producing a creped effect. Facial tissue is dry-creped; that is, drying is complete on the drying roll before the creping doctor blade. Other papers are creped while still partially wet. Towelling is generally of heavier weight than the tissues and is usually creped while still wet. Napkins are of somewhat heavier weight than tissues. The plastic nature of paper fibres when slightly moist permits the reproduction of surface patterns by embossing to a remarkable degree. Paper napkins are an example of this art.

Because of the soft, bulky texture of sanitary papers, they are relatively weak. Since they are often exposed to wetting in use, they are often treated with resins to increase wet strength.

BIBLIOGRAPHY. AMERICAN PAPER AND PULP ASSOCIATION, *The Dictionary of Paper*, 3rd ed. (1965), is a compilation of terms and definitions relating to paper and paper manufacture. K.W. BRITT (ed.), *Handbook of Pulp and Paper Technology*, 2nd ed. rev. (1970), contains 61 articles grouped in 9 sections describing the most important features of pulp

and paper manufacturing technology. A multivolume textbook that has gone through several editions is J.N. STEPHENSON (ed.), *Pulp and Paper Manufacture*, 4 vol. (1950–55). Each volume covers a particular area of the industry: pulp manufacture, stock preparation, paper manufacture, and finishing and converting. JAMES P. CASEY, *Pulp and Paper: Chemistry and Chemical Technology*, 2nd ed. rev., 3 vol. (1960–61), emphasizes the chemistry of papermaking and is noteworthy as a review of published literature with extensive references. A two-volume work intended as a textbook for students and prepared under the auspices of the Joint Textbook Committee of the Technical Association of the Pulp and Paper Industry is *Pulp and Paper Science and Technology*, ed. by C. EARL LIBBY (1962). S.A. RYDHOLM, *Pulping Processes* (1965), places primary emphasis on the chemical reactions of pulping and is a standard reference work in the field, of interest primarily to specialists in pulping. DARD HUNTER, *Papermaking: The History and Technique of an Ancient Craft*, 2nd ed. rev. (1957), is a classic account of handmade paper over the centuries since its invention in China early in the Christian era.

(K.W.Br.)

Papuan Languages

The Papuan languages are those languages spoken in an area centred around New Guinea and extending from the islands of Alor, Halmahera, and Timor in the west to the Santa Cruz Archipelago in the east. The group includes approximately 700 languages, used by about 2,400,000 speakers. The term Papuan was originally employed merely to distinguish these languages from the Austronesian (Malayo-Polynesian) and Australian languages, and, until recently, most Papuan languages were believed to be unrelated to each other. Intensive research by teams of linguists in the New Guinea area since the late 1950s, however, has resulted in a revolutionary change in the Papuan linguistic picture, and it is now known that about 350, and perhaps even as many as 450, of the approximately 650 identified Papuan languages are related. These are spoken by more than 1,600,000 speakers, who occupy almost three-quarters of the New Guinea mainland. Belonging to 76 to 105 language families (depending on the classification used), these languages together form the Central New Guinea macrophylum. A macrophylum is a group of languages related less closely than those of a language family or stock.

Unrelated Papuan groups and languages. Of the known Papuan languages that cannot yet be linked with the macrophylum, about 130 belong to large groups, and 26 to small individual groups. Approximately 50 languages, called isolates, seem to be unrelated either to each other or to the established groups. Further research may well show that additional Papuan languages belong to the macrophylum, especially after hitherto linguistically unknown areas in New Guinea have been studied.

Enga, the numerically largest language

Each of the individual Papuan languages is, for the most part, spoken by only a few hundred to a few thousand people, though the numerically largest one, Enga, in the Western Highlands District of Australian New Guinea, has over 130,000 speakers, and several other languages are each spoken by tens of thousands. Even if related, the languages generally show considerable diversity, especially in vocabulary. A few basic grammatical characteristics are, however, shared by many languages. In numerous instances it is difficult to determine the border line between the languages and dialects, despite the presence of marked differences between two forms of speech.

Recent extensive research into the Papuan languages has resulted in the preliminary classification of most of them. Numerous new languages have been discovered, though large areas, mainly in West Irian, remain unknown. Despite the concentration of research on discovery and classification, a number of grammatical and lexical studies have been prepared, and folklore has been collected. The Summer Institute of Linguistics, an association of Protestant missionaries specializing in studying primitive languages and involved in literacy training and Bible translation, has carried out an extensive native language literacy program in New Guinea with a measure of success.

Linguistic characteristics. Most Papuan languages show extreme grammatical complexity. Their verbs vary to reflect a wide range of numbers and other features of the subject as well as of the direct and indirect objects and the beneficiary. For example, in Kiwai, a language of the Central and South New Guinea phylum, the verb *ai-ni-mi-bi-du-mo-iauri-ama-ri-go* means "they three will certainly see us two." Similarly, in the Monumbo language of the Torricelli phylum *mbepe*$_1$*-nge*$_2$ *tsi*$_3$*-p*$_4$*-ing*$_5$*-em*$_6$ can be translated as "you gave him a taro." Literally, the parts of this utterance are: taro$_1$–singular$_2$, 2nd person singular subject (you)$_3$–give, past form$_4$–masculine class 3rd person singular indirect object (to him)$_5$–plant class singular direct object$_6$. Verbs also indicate tense, aspect, mood, and the direction and circumstances in which the action they designate is performed; *e.g.*, in Gadsup, of the East New Guinea Highlands phylum, *kùmù-à-nk-ədəd-òn-ték-əp-ón-ì-nó-ké*, "had he indeed wanted to go down for him?", has several prefixes and suffixes indicating emphasis, tense, direction, and the question status. (The accent marks indicate tones; the ə is a sound pronounced like *a* in "sofa." The dashes separate the various components of the utterances, but do not normally appear in nonlinguistic texts).

Verb forms for one or more actions

There are, basically, two major types of verb forms in many Papuan languages. One, which can be referred to as the normal type, is found in sentences in which only one action is referred to; the other, which may be referred to as the special verb form, occurs in sentences in which more than one action is mentioned. In the latter type of sentence, which may have one or more special verb forms, the normal verb form also appears with the last verb in the sentence.

Numerous Papuan languages have gender and noun class systems, some with up to ten or more classes. Bewilderingly complex variations of adjectives, numerals, demonstratives, and subject and object markers often result, since these words have special forms for each of the various classes of nouns. An example is the sentence *ame akwum kuvambakwum sumupar amenakwum salikəmba*, "I saw my two big women," from Angoram of one of the small Sepik phyla. If "women," *akwum*, is replaced by "arrows," "gardens," or "frogs," etc., the entire sentence, rather than a single word, is changed: when "arrows" is substituted, the phrase becomes *ame pwanggli kəpanggli klupar amenakanggli salikənggliya;* and when "gardens" is used, it changes to *ame konggəmbər kəvambər pələpar amenkəmbər salikəmbəra.*

Many languages are tonal, with changes of pitch in words and syllables that affect the meaning of the words. The interaction of Papuan tonal systems with patterns of stress and syllable length can be extremely intricate.

Classification and distribution. Interrelated language families are grouped in phyla, groups of languages more distantly related than those of a family or stock but more certainly or closely related than those of a macrophylum. Apart from the isolates, or unrelated languages, the number of known Papuan phyla is 21. Of these, 8 are small and consist of only 2 to 6 languages each. Of the remaining 13, 6 constitute the central New Guinea macrophylum, and 3 more can tentatively be included in it.

Central New Guinea macrophylum

The central New Guinea macrophylum comprises: (1) the East New Guinea Highlands phylum, found predominantly in the Highlands and Chimbu Districts of Australian New Guinea; (2) the Finisterre-Huon phylum in the Morobe and Madang Districts, Australian New Guinea; (3) the Central and South New Guinea phylum, located mainly in the Gulf and Western Districts of Papua in the Australian sector of New Guinea and in southern and northeastern West Irian; (4) the West New Guinea Highlands phylum of the highlands area of West Irian; (5) the South-East New Guinea phylum, in the Central, Northern, Morobe, and Milne Bay Districts of the Australian sector of New Guinea; (6) the Madang phylum in the Madang District of Australian New Guinea.

Tentative member phyla of the Central New Guinea macrophylum are: (1) the Adelbert Range phylum in the Madang District of Australian New Guinea; (2) the Middle Sepik-Upper Sepik-Sepik Hill phylum, which could also be classified as constituting three separate phyla; (3) the

Anga stock (stocks are intermediate between phyla and families) spoken in the Eastern Highlands, Morobe, and Gulf Districts of the Australian sector of New Guinea.

Large Papuan phyla that are not members of the Central New Guinea macrophylum are the Ramu phylum in the Madang and East Sepik Districts of Australian New Guinea; the Torricelli phylum in the same districts; the West Papuan phylum on the Doberai (Vogelkop) Peninsula of West Irian, and in northern Halmahera, eastern Timor, and Alor; and the Bougainville phylum on the island of Bougainville. Small isolated phyla are located mainly in the West Sepik and Gulf Districts of the Australian sector of New Guinea and in the Santa Cruz Archipelago. The highest concentration of known isolates is also in these districts and in the East Sepik District, the New Britain-New Ireland area, and the British Solomon Islands.

Some Papuan languages are difficult to classify because of strong Austronesian influence upon them. Most Papuan languages are of only regional importance, but a few have achieved some cultural significance outside their immediate area because of their use as missionary languages.

BIBLIOGRAPHY. Most earlier general studies have become obsolete. Comprehensive recent bibliographical and factual information may be found in D.C. LAYCOCK and C.L. VOORHOEVE, "History of Research in Papuan Languages," in *Current Trends in Linguistics*, vol. 8, *Linguistics in Oceania* (1971); and in S.A. WURM, "Papuan Linguistic Situation," *ibid.*, updated in *Papuan Languages of Oceania* (1972). Individual language descriptions are given in H. MCKAUGHAN (ed.), *Languages of the Eastern Family* (1971). Extensive descriptive and comparative materials on Papuan languages appear in the serial publications *Pacific Linguistics*.

(S.A.W.)

Pará

Pará is a state (*estado*) of northern Brazil through which the Lower Amazon River flows to the sea. It is bounded on the north by Guyana, Surinam, and the Territory of Amapá, on the northeast by the Atlantic Ocean, on the east by the states of Maranhão and Goiás, on the south by Mato Grosso, and on the west by Amazonas. Although it is the third-largest state in Brazil and lushly tropical, it supports but a small and scattered population. Its area is 481,872 square miles (1,248,042 square kilometres). Its population (1970) was 2,197,072. The capital and chief city is Belém.

History. The Amazon region was never very attractive to the Portuguese settlers of Brazil. Belém was founded in 1615, chiefly to keep other European nations from settling there. Spanish Jesuit missions were the first settlements upstream, as at Santarém in 1661; they were finally expelled by the Portuguese in 1710. Pará was made a captaincy in 1652, reunited with Maranhão in 1654, and re-established in 1772. It did not acknowledge the Brazilian Empire established in 1822 but yielded to force in 1823. It became a state when the new republic was founded in 1889. In the 1870s a colony of people from the southern United States, together with slaves they brought with them, settled near Santarém and tried to plant cotton and sugarcane. The colony was not successful. Between 1850 and 1910 there was a period of feverish activity as workers went out into the forests to tap the rubber trees. Rubber in large quantities was shipped out through Belém, and the city grew rapidly in size and importance. Production dropped rapidly after 1910, however. Even the Ford Motor Company plantations on the Rio Tapajóz, although technically successful, failed to produce enough rubber for the needs of the Ford industries.

The natural environment. The dominant physical feature of Pará is the outlet of the Amazon Basin, which crosses the state for about 500 miles (800 kilometres) from west to east in entering the Atlantic Ocean. The lower valley is comparatively narrow, the territory on both sides rising to the level of the ancient plateau that once covered this part of the continent. On the north is the Guiana Highlands, and on the south the country rises in forested terraces and is broken by escarpments caused by the erosion of the northern slope of the great central plateau of Brazil.

Climate

The state is crossed by the Equator, and the climate is equatorial: contrary to popular impression, the temperatures are never so high as in the central and southern Mississippi River Valley of the United States. A temperature of 100° F (37.8° C) has never been recorded. The average is 78° F (26° C), with a range between the coldest and warmest months of between 2° and 3° F (1.4° C). Rainfall and humidity are high. The year is divided into a very rainy season from January to June and a season of less rain for the rest of the year. Average annual rainfall is more than 59 inches (1,500 millimetres). Wherever there is exposure to the easterly trade winds the humidity is compensated for, and the climate is quite comfortable.

An enormous amount of water pours into the ocean through the State of Pará. The Amazon itself winds about on its floodplain, leaving a maze of abandoned channels in the form of oxbow lakes and an intricate crescentic pattern of levees and swamps, much like the Lower Mississippi in North America. At Óbidos the floodplain is scarcely a mile in width, but it opens out again downstream. The margins of the floodplain are marked by valley bluffs—steep slopes that rise abruptly about 150 to 200 feet above the river. The floodplain—which is somewhat less than 10 percent of the total area of Pará—is inundated each year during high-water stages, but the country above the valley bluffs is never flooded. The chief towns are located on the bluffs at places where the main channel of the river swings against the margin of the floodplain. The Amazon receives the water of several great tributaries. From west to east on the southern side are the Tapajóz, the Xingu, and the Tocantins. No large tributaries reach the Amazon on the northern side within Pará. At the mouth of the Amazon is the Ilha de Marajó (Island of Marajó). It is 150 miles (241 kilometres) long by 100 miles (161 kilometres) wide, with an area of 18,519 square miles (42,964 square kilometres). The northwestern part of the island is a part of the floodplain; but in the east and south the island is made up of higher ground. The Tocantins provides most of the water in the Rio Pará, southern side of the Ilha de Marajó, while the main stream of the Amazon passes to the north. The Rio Pará and the Amazon are connected by a network of side channels. Lying across the mouth of the main stream, north of the Ilha de Marajó, are two smaller islands that, like eastern Marajó, stand above the floods. They extend in a southeast to northwest direction: the Ilha Caviana is 48 miles (77 kilometres) long, and the Ilha Mexiana is 34 miles long.

Soils

The soils of much of Pará are not fertile. The alluvial material on the floodplain could yield abundant crops, especially rice, but the settlers along the Amazon have never made much use of it. Beyond the valley bluffs, where the land is never flooded and where mud and silt are never deposited, the soil has for a long time been exposed to the action of percolating rainwater. Water sinking into the soil carries the finer soil particles down far beyond the reach of shallow-rooted crops; it also dissolves and carries away the more easily soluble of the minerals. The result is a sandy, red-coloured soil made up largely of iron and aluminum compounds in which crops do poorly. Trees, with deeper roots, grow luxuriantly in the moist climate.

As for plant and animal life, except for a few patches of savanna, most of the state is covered with dense, tropical rain forest, or *selva*, with thousands of species of broadleaf evergreen trees. It is the soil under the *selva*, where little light reaches the ground, that is deeply leached and that, when the forest is cleared, quickly loses its capacity to produce crops. The native Indians used a small clearing only for a year or so before shifting to a new clearing. There are no large game animals such as are found in the tropical regions of Asia and Africa. The largest land animal of the *selva* is the tapir; there are many smaller animals, including several species of cat, and the area is rich in both kinds and number of birds, insects, and reptiles. The rivers abound with fish

and river turtles, and much of the Indians' food supply came from the Amazon itself—from fish, turtles, and turtle eggs.

The contemporary state. *Population.* The population of Pará was 2,197,072 in 1970, as compared with 1,550,935 in 1960 and 1,123,273 in 1950. Population density is about five persons per square mile, but at that is higher than that of the other states (Acre and Amazonas) and territories (Rondônia, Roraima, and Amapá) that make up the northern region of Brazil. As in the rest of the nation, the population is young.

Urban and rural settlements

The population is concentrated in the few cities and towns, which in turn are concentrated along the rivers. The largest is Belém, the capital, with 565,097 people, on the Rio Pará; others include Santarém, on the Tapajóz; Óbidos, on the Amazon; and Bragança, on the small river Caeté, near the coast. Aside from these, of which only Santarém has a population of more than 20,000, there are a few small settlements and trading posts on the principal rivers and tributaries, a few plantations, and small, scattered, tribal groups of Indians. Some are so remote and isolated that well into the second half of the 20th century they had still had no contact with modern civilization.

Ethnically the population is composed of people of European, Indian, and mixed European and Indian ancestry; and, since the 1930s, Japanese, who have settled in northern Pará.

Administration and social conditions. The state government and administration is centred in Belém, the capital. As has been the case with most of the other states of Brazil, it has had to rely heavily on the federal government for financial and other assistance. The federal government has assumed special interest and responsibility in the economic development of the Amazon Basin.

One indication of social conditions in an area is the average life-span of the inhabitants. In Pará it is 38 years. Health, education, and welfare programs in the cities are limited; outside the cities they are nonexistent.

Educational institutions

Belém is the leading educational centre of northern Brazil. Academic training is available in medicine, dentistry, pharmacy, law, engineering, and the fine arts. There is also a normal school to train teachers, an institute for research on tropical diseases, and an institute specializing in tropical agriculture.

Economy. In colonial times Pará (*i.e.*, Belém and its environs) prospered from the production of sugar and, later, of rice, cotton, and coffee, until other places in Brazil began to produce them more economically. For a while in the late 19th and early 20th centuries the economy was based on rubber. Since then it has been based primarily on the collection and export of other forest products, chiefly Brazil nuts, medicinal herbs, organic oils and insecticides, and fibres. Since World War II some plantation products have been introduced with considerable success by Japanese colonists, jute in increasing quantities along the Amazon River and black pepper just to the south of Belém and near Santarém in the north.

Transportation and communications. Transportation within the state and externally is almost entirely by water or air. The main port for Amazon River craft as well as for international and coastal shipping is Belém, and the Belém Airport is the principal air facility in northern Brazil. The only railway in the state runs from Belém to Bragança, a distance of 145 miles (233 kilometres).

The construction of the Belém do Pará–Brasília Highway, and the Transamazônica road running west from Belém to the Peruvian border, both built during the 1970s, are leading to a new tide of pioneer settlement and resource development in the hitherto most isolated parts of the Amazon Basin.

Cultural life. Cultural life is centred in Belém, to which most of the rest of the population has little access. Cultural institutions there include the Museu Paraense Emílio Goeldi, the Teatro da Paz, a classical theatre, and the Biblioteca e Arquivo Públivo do Pará (Public Library and Archives of Pará).

Future prospects. Two oil strikes in the Lower Amazon Valley have led to hopes that commercially important deposits of petroleum may be found. The Belém–Brasília Highway will provide a link with the centre of the country. Like the first Europeans to set eyes on that lush valley, in the 16th century, many 20th-century men instinctively feel that any place that is able to produce tropical growth in such rich profusion must be capable of producing wealth for man. Someday perhaps it will.

(P.E.J.)

Paracanthopterygii

The fishes that constitute the superorder Paracanthopterygii are a predatory, primarily marine group and modern one of about six major branches of the Teleostei, or bony fishes, the dominant living aquatic vertebrates. Some 1,160 living species of paracanthopterygian fishes have been described; they range in length from a few centimetres to about two metres (more than six feet).

In general body form there is considerable diversity, but ichthyologists have classed them as a discrete group, largely on the basis of a distinctive jaw musculature, on the structure of the caudal (*i.e.*, at the tail end) vertebrae, and the placement of the pelvic fins (they are usually in the midbody region or further toward the head).

The Paracanthopterygii comprises six orders: Batrachoidiformes, or toadfishes, about 45 species; Gadiformes, or codfishes, about 800 species; Gobiesociformes, or clingfishes, about 100 species; Lophiiformes, or anglerfishes, about 210 species; Percopsiformes, or trout-perches, about eight species; and Polymixiiformes, or beardfishes, three species. Most of the orders are primarily marine, with worldwide distribution; the percopsiforms, however, occur only in freshwaters of North America. Batrachoidiforms and gobiesociforms occur mainly in tropical and temperate shallow water along continental coasts and to a limited extent in freshwater. Gadiforms are represented by both shallow-water and deep-sea types. The most widely known gadiforms are the commercially important species and the only economically important paracanthopterygians: the true cods (*Gadus*); hakes (*Merluccius, Urophycis*); haddocks (*Melanogrammus*); pollocks (*Pollachius*); and whitings (*Merlangius*). All are abundant in waters of the continental shelf of the North Atlantic, where they have been commercially fished for centuries. Lophiiforms live on tropical reefs as well as in the ocean depths. Polymixiiforms occur at moderate depths in most warm seas, generally near continents.

Size range

The largest of the Paracanthopterygii are the codfishes, which grow to about two metres in length and attain weights that may exceed 90 kilograms (about 200 pounds). Certain goosefishes (Lophiiformes) reach a length of about two metres and a body weight of 35 kilograms (about 75 pounds); other lophiiforms are as small as 2.5 centimetres (about one inch) long. Batrachoidiforms grow to about 30 centimetres (one foot) in length, gobiesociforms to about eight centimetres (three inches). The largest percopsiforms are about 15 centimetres (six inches) long. Polymixiiforms reach no more than 30 centimetres in length.

NATURAL HISTORY

Life cycle and reproduction. Eggs of the oyster toadfish (*Opsanus tau*) of the western Atlantic—one of the most carefully studied batrachiforms—are laid in dark recesses of all sorts, including sunken tin cans and shoes. The male guards the eggs and young for about three weeks, after which the young fishes begin life on their own; some have been found living in living oysters. Luminous organs known as photophores, numbering several hundred and set in long horizontal rows, are believed to be sexual attractants in the midshipman (*Porichthys*)—so named because the organs resemble rows of bright buttons on a naval uniform. The northern midshipman (*P. notatus*), a common species on the eastern Pacific coast, spawns in shallow water, attaching its eggs to a rocky surface. The male guards the eggs. Like other batrachoidiforms, the midshipman lives and grows on the ocean bottom.

Most species of codfishes (which comprise some 70 species of Gadiformes) migrate over long distances. They gather in late winter and early spring to spawn, each species going to a particular area. The periodic movements are closely related to seasonal variations in water temperature. Fecundity of some codfish species is prodigious. The European ling (*Molva molva*) may deposit as many as 60,000,000 eggs each season. The eggs and larvae of most species are found in the plankton (*i.e.*, the aquatic organisms, collectively, suspended in the sea). Weeks or months elapse before the eggs hatch. Young codfishes are commonly found in very shallow water, but they move into deeper water as they become older. The eggs of grenadiers (family Macrouridae), a bottom-feeding group of cods, are believed to be laid near the bottom; the buoyant eggs rise part way to the surface. The larvae are known mainly from below 100 fathoms (about 180 metres, or 600 feet); older larvae occur at greater depths. In the Mediterranean pearlfish (*Carapus acus*), a member of another codlike group (family Carapidae), clumps of eggs, released by the female in late summer, appear at the surface and hatch into a specialized larva, the vexillifer, which lives amid the plankton. After attaining a length of about seven to eight centimetres (about three inches), it transforms to another larval stage, the tenuis, descends to the bottom, and becomes a parasite in a sea cucumber (*Holothuria tubulosa* or *Stichopus regalis*). The tenuis, apparently dependent upon its host for survival, undergoes a further transformation to the juvenile stage; in the process, its length decreases from 20 to 10 centimetres (eight to four inches). The Mediterranean pearlfish is believed to pass most of its life in the host. Very little is known of the general biology of reproductive habits of the brotulas and cusk eels (family Ophidiidae), also of the cod group. They are both oviparous (egg-laying) and viviparous (live-bearing). The males of some viviparous species produce spermatophores (sperm cases). The European eelpout (*Zoarces viviparus*) of the cod family Zoarcidae bears living young about five centimetres in length and numbering as many as 400. Fertilization is internal, and embryonic development occurs in the ovary of the female. Other eelpouts are believed to be live-bearing, but the ocean pout (*Macrozoarces americanus*) of the western Atlantic lays eggs that are guarded by one or both parents. The lophiiforms are primarily bottom fishes as adults, but many produce floating rafts of eggs. The eggs of the deep-sea anglerfishes (suborder Ceratioidei) are unknown; but it is believed that they float to the surface; the larvae occur in surface waters, gradually descending to deeper waters as they grow older. The females of the deep-sea anglers are from three to 13 times as large as the males. Females have an illicium, or "fishing pole," which is a modified spine of the dorsal, or back, fin that has moved forward onto the top of the head. At the tip of the illicium is a fleshy enlargement, the esca, used to lure prey within range of capture. (The illicium and esca are generally present also in male anglerfish other than in the Ceratioidei.) Commonly the esca is luminous; the female also has other light-producing organs. In 1922 a specimen of the anglerfish *Ceratias holboelli* was discovered; small specimens attached to its abdomen were thought to be its young. A few years later similar finds led to the discovery that the smaller fish were really mature males living parasitically on the female. Further investigation showed that the males, soon after their transformation from the larval state, bite onto an older, larger female, after which the female and male tissues unite; the separate circulatory systems join; and the male becomes a permanent appendage of the female.

Little is known of the reproductive habits of the gobiesociforms, percopsiforms, or polymixiiforms. Gobiesoci-

Parasitic habit of pearlfish

Parasitism of male anglerfish

forms are known to lay eggs in shallow water, attaching them to rocks or plants; and percopsiforms are known to spawn in the spring of the year in shallow water.

Ecology and behaviour. All batrachoidiforms are bottom dwellers. True toadfishes (Batrachoidinae, about 25 species) occur in shallow or moderate depths along continental coasts; some ascend rivers. The oyster toadfish lives under rocks or amid debris, awaiting prey of almost any type, which is taken with a sudden snap. Venomous toadfishes (Thalassophryninae, about nine species) are restricted to the coasts and rivers of Central and South America. Because of their sluggish habits, these fishes are sometimes stepped on by man and can inflict painful wounds. Midshipmen (Porichthyinae, about 12 species), which are restricted to tropical and temperate coasts of the Americas, are unusual in being shallow-water fishes with photophores, a feature generally found in deepwater forms. Most midshipmen occur in depths of less than 50 fathoms (one fathom = six feet), and all are found in water shallower than 200 fathoms.

Gadiform fishes of the family Gadidae (about 70 species) are all marine species, except for the burbot (*Lota lota*); some, however, ascend rivers with the tides. Bottom dwellers, they occur on the continental shelves from shallow water to about 200 fathoms and, although distributed throughout the oceans, are most numerous in the eastern North Atlantic. Deep-sea cods (Moridae, about 70 species) are cold-water bottom fishes, living at greater depths along the continental slopes. Grenadiers (Macrouridae, about 300 species), typically bottom fishes, live along the continental slopes at depths of 100 to 1,000 fathoms. Few species are cosmopolitan in distribution, but the group as a whole is widely distributed in tropical and temperate latitudes. A few species of gadiforms (Muraenolepididae, four species) are confined to Antarctic seas, and, like the cods, they are bottom fishes, living at moderate depths. The pearlfishes (Carapidae, about 27 species) are marine, mainly tropical, shallow-water, eel-like fishes adapted to living inside the body of various invertebrates. They have been collected from a variety of hosts, including tunicates, oysters, and sea cucumbers. Brotulas and cusk eels (Ophidiidae, about 250 species) are mainly bottom dwellers. Some are shallow-water species with nocturnal habits, but the group as a whole is the dominant teleostean family at depths greater than 2,000 fathoms. Some have been taken at depths of about 4,000 fathoms, the greatest depth at which any form of fish life is known.

Eelpouts

Eelpouts (Zoarcidae, about 80 species) are bottom fishes, commonly occurring from shallow water to depths of 1,000 fathoms. Species are most abundant in the higher latitudes of both hemispheres, especially in the north. Eelpouts are common in shallow water of Arctic and Antarctic seas, and they constitute a significant part of the polar faunas.

Gobiesociforms (about 100 species) are mostly marine fishes, typically inhabiting the intertidal zone. Some species (*Diademichthys*) hide among the spines of sea urchins. In tropical America, four species (*Gobiesox*) are known from swift-flowing freshwater streams.

Of the lophiiforms, the ceratioids, or deep-sea anglerfishes, are the only abyssal (deep-sea) forms. They occur primarily at depths of 1,000 to 3,000 fathoms. Unlike other lophiiforms, they are midwater fishes, are uniformly black, and have no pelvic fins. They are apparently feeble swimmers, depending primarily on their light organs to attract prey. Some (*Melanocetus, Linophryne*) are known to swallow fishes several times their own length, accommodating them in a highly distensible stomach. Crustaceans and other invertebrates are also eaten. Many lophiiforms—so-called frogfishes (Antennariidae, about 60 species)—are shallow-water forms, commonly inhabiting coral reefs. Frogfishes typically have highly varied colour patterns, and some species are able to change colours. In habit they are sedentary but can use their fins to walk on the bottom and to climb over obstacles. The tropical sargassum fish (*Histrio histrio*), so called because it lives amid floating brown algae of the genus *Sargassum*, clings with prehensile (*i.e.*, adapted for seizing, or wrapping around) pectoral fins as it searches for prey, which is sucked into the mouth by the powerful jaws and expandable cheeks.

The lophiiform group known as goosefishes (Lophiidae, about 12 species) seldom occur in shallow water, preferring instead the moderate depths (10 to 500 fathoms) along the continental slopes of tropical and temperate regions. The batfishes (Ogcocephalidae, about 60 species), are mainly deepwater lophiiforms, but some (*Ogcocephalus, Halieutichthys*) are regularly found in water only a few feet deep. Like frogfishes, they walk on the bottom, using their pectoral fins. Batfishes are awkward swimmers and, when disturbed, tend to bury themselves in the bottom rather than swim away.

Fishes without eyes

Percopsiforms (about eight species) live under conditions of dim light. Cave fishes, with eyes reduced to nonfunctional rudiments, have elaborate systems of sense organs in the skin of the head, body, and tail; they live in total darkness. Because of the secretive habits of percopsiforms, little is known about species other than the trout-perch (*Percopsis omiscomaycus*), which is widely distributed in central North America and is abundant in some of the Great Lakes, where it occurs in clear water to a depth of about 35 fathoms. Polymixiiforms, numbering only three marine species, are generally found at depths of 150 to 350 fathoms.

FORM AND FUNCTION

Batrachoidiforms generally have two dorsal fins; a small anterior fin, usually with two spines; and a long posterior fin. In venomous species, the hollow fin spines form an efficient apparatus for the injection of venom. A similar spine is found on each cheek (operculum).

Among the gadiforms, the dorsal and anal fins of some deep-sea cods are distinctively arranged as three dorsals and two anals. This arrangement also occurs in some codfishes (Gadidae). The macrourids are characterized by a long, tapering tail. A tubular light organ containing luminescent bacteria is sometimes present along the ventral midline of both sexes. All but a few species have a well-developed swim bladder; in the males of some species and in some codfishes, the swim bladder is equipped with drumming muscles, indicating that sound can be produced. In the bregmacerotids and muraenolepidids there are two dorsal fins, with the anterior fin represented by a single ray. Brotulas may have the pelvic fins either present or absent, but cusk eels have them anterior in position, under the lower jaw. They are kept in continuous probing motion, as the fish swims just off the bottom, and aid in detecting food. Zoarcids (eelpouts) are elongated, eel-like fishes, with pelvic fins rudimentary or absent.

Suction disk for attachment to bottom

Gobiesociforms, with a depressed head, wide mouth, and tapering body, resemble toadfishes, but they are distinctive in having a prominent sucking disk on the ventral surface. The paired pelvic fins, thoracic in position, form part of the disk, various fleshy pads and folds forming the remainder. The disk allows clingfishes to hold fast to rocky bottoms amid the often turbulent wave action of their shallow-water environment.

Some lophiiforms are unique among teleostean fishes in having only two gills. The ogcocephalids are somewhat flattened anglers, in this respect resembling lophiids rather than the balloon-like antennariids; they are distinctive in having the illicium, when not in use, concealed in a tube (illicial cavity) between the eyes and over the mouth. Like most anglerfishes they lack typical scales but are distinctively equipped with bony tubercles (projections) and spines imbedded in the skin.

The polymixiiforms are singular in having a pair of fleshy barbels, or "whiskers," under the jaw. Each barbel is supported by three small bones.

EVOLUTION AND PALEONTOLOGY

Fossil batrachoidiforms include only material from lower Pliocene marine deposits (about 5,000,000–7,000,000 years old) of North Africa. These fossils are similar to a living species, *Batrachoides didactylus.*

Fossil gadiforms are relatively numerous and are known primarily from Tertiary marine deposits (about 2,500,000–65,000,000 years old) of the Northern Hemi-

sphere. A Paleocene fossil (54,000,000–65,000,000 years old) has been identified as a codlike fish; some Eocene fossils (38,000,000–54,000,000 years old) have been identified for the families Bregmacerotidae and Gadidae; and Oligocene-Miocene fossils (7,000,000–38,000,000 years old) for the families Bregmacerotidae, Gadidae, Macrouridae, and Ophidiidae. In addition, many fossil ear stones (otoliths) and scales, beginning with specimens from the Cretaceous (65,000,000–136,000,000 years ago), are similar to the Gadiformes. Fossil gobiesociforms are unknown. Fossil lophiiforms include two species from Eocene marine deposits of Europe and one species from Pliocene marine deposits of North Africa; one Eocene species has been identified as a goosefish (Lophiidae), the other as a frogfish (Antennariidae).

Fossil percopsiforms include three genera from Tertiary freshwater deposits of North America and one (*Sphenocephalus*) from Cretaceous marine deposits of Europe. Of the North American genera, two (*Amphiplaga, Erismatopterus* from the middle Eocene) have been identified as trout-perches (Percopsidae), and one (*Tricophanes*, Oligocene–Miocene) as a pirate perch (Aphredoderidae). The relationships of *Sphenocephalus* are obscure. Fossil polymixiiforms include a diversified group of about six genera known primarily from Cretaceous marine deposits of Europe and the Middle East; a few others are known from the Tertiary.

CLASSIFICATION

Annotated classification.

SUPERORDER PARACANTHOPTERYGII

Most with a distinctive type of jaw musculature (involving levator maxillae superioris muscle and associated structures); pelvic fins usually placed anteriorly, thoracic (midbody) or even further forward; primarily marine; worldwide distribution; about 1,600 living species.

Order Polymixiiformes (beardfishes)

Middle Cretaceous to Recent. Barbels supported by rays; spines on the dorsal and anal fins; pelvic fins subthoracic. Deepwater marine fishes; three species. Adult length about 30 cm.

Order Percopsiformes (trout-perches, pirate perches, and cave fishes)

Eocene to Recent. Mouth gape and buccal dentition reduced; median fin spines reduced or lost; head with spine ornamentation. About 8 living species, all freshwater; North America; length 8–15 cm.

Order Gadiformes (cods, cusk eels, pearlfishes, eelpouts and grenadiers)

Paleocene to Recent. Early gadiforms were similar in structure to early percopsiforms, but almost all remained marine and subsequently specialized into a variety of environments. Reduced caudal skeleton; elongate body; altered head and jaw structure. Very reduced fin spines; marine, worldwide. About 800 species. Length 7 to about 200 cm.

Order Batrachoidiformes (toadfishes)

Miocene to Recent. Bottom fishes with short, small, spinous dorsal fins; long soft-rayed dorsal fins; flat heads; about 45 species; marine, occasionally freshwater, shore fishes of tropics. Length to about 30 cm.

Order Lophiiformes (goosefishes, anglerfishes, frogfishes, and batfishes)

Eocene to Recent. Spinous dorsal fin modified as a movable lure. Some deep-sea forms with light organs and males parasitic on females. Marine, widespread; in shallow-water and deep-sea habitats. About 210 species. Length to about 200 cm.

Order Gobiesociformes (clingfishes)

Recent; flattened, depressed fishes with a ventral sucker formed of the pelvic fins and surrounding tissue; no spiny dorsal fin; about 100 species; marine and occasionally freshwater in tropics and along many temperate seacoasts.

Critical appraisal. The interrelationships of the groups listed here as paracanthopterygians are not yet well established, and the classification given here is provisional. There is considerable agreement that trout-perches (Percopsiformes) and cods (suborder Gadoidei) are closely related, and this agreement may be considered the basis of the group Paracanthopterygii. What other fishes should be included in the Paracanthopterygii is a question receiving continued study. Some ichthyologists have held that clingfishes (Gobiesociformes) are related to dragonets (Callionymidae); that eelpouts (Zoarcidae) are related to blennies (Bathymasteridae, Blenniidae, etc.); that brotulas, cusk eels, and pearlfishes (suborder Ophidioidei) are related to the river blackfish of Australia (the perchlike *Gadopsis*); that beardfishes (Polymixiiformes) are related to squirrelfishes and their relatives (Beryciformes); and that toadfishes (Batrachoidiformes) and anglers (Lophiiformes) also have their relationships within the great mass of perchlike fishes (Acanthopterygii). In addition, killifishes (Cyprinodontidae) and related live-bearers (Poeciliidae) are believed by some writers to be related to trout-perches (Percopsiformes) and by others to silversides, flying fishes, and their relatives (Atheriniformes). Thus, future study may result in the transfer of some groups from the Paracanthopterygii to the Acanthopterygii and vice versa.

(G.J.N.)

Paracelsus

Known as Paracelsus the Great to his devoted followers and as the Medical Luther to his many enemies, Philippus Aureolus Theophrastus Bombast von Hohenheim was one of the most extraordinary and outrageous men of the Renaissance. He also had the characteristics of a natural extrasensory perceptionist and was perhaps best described in his own time as a "magician." As a physician, surgeon, and chemist, he stimulated the development of pharmaceutical chemistry by his discovery and use of

new medical remedies. These, however, were only by-products of his central teaching, which often upset his contemporaries and remains controversial today. His basic dictum, "Magick is a Great Hidden Wisdom—Reason is a Great Open Folly," best expresses his teaching, and his declaration, "Resolute Imagination can accomplish all things," reflects his magical presuppositions. He was always forthright, frequently vitriolic, scurrilous, scathing, and caustic.

Paracelsus, engraving by an unknown artist, c. 1600.
By courtesy of the Musee National Suisse, Zurich, Switz.

Paracelsus was born near the village of Einsiedeln (now in Switzerland), on November 10 (some say November 14), 1493, the only son of a somewhat impoverished German doctor and chemist. Theophrastus, as he was first called, was a small boy when his mother died; his father then moved to Villach in southern Austria. There the boy attended the Bergschule, founded by the wealthy Fugger family of merchant bankers of Augsburg, where his father taught chemical theory and practice. Youngsters were trained at the Bergschule as overseers and analysts for mining operations in gold, tin, and mercury, as well as iron, alum, and copper-sulfate ores. The young Paracelsus learned from miners' talk of metals that "grow" in the earth, watched the seething transformations in the smelting vats, and perhaps wondered if he would one day discover how to transmute lead into gold, as the alchemists sought. Thus Paracelsus early gained insight into metallurgy and chemistry that, doubtless, laid the foundations of his later remarkable discoveries in the field of chemotherapy.

In 1507, at the age of 14, he joined the many vagrant youths who swarmed across Europe in the late Middle Ages, seeking famous teachers at one university after another. During the next five years Paracelsus is said to have attended the Universities of Basel, Tübingen, Vienna, Wittenberg, Leipzig, Heidelberg, and Cologne but was disappointed with them all. He wrote later that he wondered how "the high colleges managed to produce so many high asses," a typical Paracelsian jibe.

Rejection of traditional education and medicine

His attitude upset the schoolmen. "The universities do not teach all things," he wrote, "so a doctor must seek out old wives, gipsies, sorcerers, wandering tribes, old robbers, and such outlaws and take lessons from them. A doctor must be a traveller, . . . Knowledge is experience." Paracelsus held that the rough-and-ready language of the innkeeper, barber, and teamster had more real dignity and common sense than the dry-as-dust scholasticism of Aristotle, Galen, and Avicenna, the recognized Greek and Arab medical authorities of his day.

Paracelsus is said to have graduated from the University of Vienna with the baccalaureate in medicine in 1510, when he was 17. He was, however, delighted to find the medicine of Galen and the medieval Arab teachers criticized in the University of Ferrara, where, he always insisted, he received his doctoral degree in 1516 (university records are missing for that year). At Ferrara he was free to express his rejection of the prevailing view that the stars and planets controlled all the parts of the human body. Against this astrological determinism, he declared:

> Man is a star. Even as he imagines himself to be, such he is. He is what he imagines. . . . Man is a sun and a moon and a heaven filled with stars. . . . Imagination is Creative Power. Medicine uses imagination strongly fixed. Phantasy is not imagination, but the frontier of folly. . . . *Because Man does not imagine perfectly at all times, arts and sciences are uncertain, though, in fact, they are certain and, by means of imagination, can give true results. Imagination takes precedence over all.*

He is thought to have begun using the name "para-Celsus" (above or beyond Celsus) at about that time, for he regarded himself as even greater than Celsus, the renowned 1st-century Roman physician.

Clearly a man of this type could never settle for long in any seat of learning, and so, soon after taking his degree, he set out upon many years of wandering through almost every country in Europe, including England, Ireland, and Scotland. He then took part in the "Netherlandish wars" as an army surgeon, at that time a lowly occupation. Later he went to Russia, was held captive by the Tatars, escaped into Lithuania, went south into Hungary, and again served as an army surgeon in Italy in 1521.

Ultimately his wanderings brought him to Egypt, Arabia, the Holy Land, and, finally, Constantinople. Everywhere he sought out the most learned exponents of practical alchemy, not only to discover the most effective means of medical treatment but also—and even more important—to discover "the latent forces of Nature," and how to use them. He wrote:

> He who is born in imagination discovers the latent forces of Nature. . . . Besides the stars that are established, there is yet another—*Imagination*—that begets a new star and a new heaven.

After about ten years of wandering, he returned home in 1524 to Villach to find that his fame for many miraculous cures had preceded him. When it became known that the Great Paracelsus, then aged 33, had been appointed town physician and lecturer in medicine at the University of Basel, students from all parts of Europe began to flock into the city. Pinning a program of his forthcoming lectures to the notice board of the university on June 5, 1527, he invited not only students but anyone and everyone. The authorities were scandalized and incensed by his open invitation. Ten years earlier Luther had nailed his Theses on Indulgences to the doors of the Wittenberg Schlosskirche. Later, Paracelsus wrote:

Height of his career

> Why do you call me a Medical Luther? . . . I leave it to Luther to defend what he says, and I will be responsible for what I say. That which you wish to Luther, you wish also to me: you wish us both in the fire.

Three weeks later, on June 24, 1527, surrounded by a crowd of cheering students, he burned the books of Avicenna, the Arab "Prince of Physicians," and those of the Greek physician Galen, in front of the university. No doubt his enemies recalled how Luther, just six and a half years before at the Elster Gate of Wittenberg on December 10, 1520, had burned a papal bull that threatened excommunication. Paracelsus seemingly remained a Catholic to his death, although it has been said that his books were placed on the *Index Expurgatorius*. Like Luther, he also lectured and wrote in German rather than Latin, for he loved the common tongue.

Despite his bombastic blunders—the adjective indeed derives from his surname Bombast—he reached the peak of his tempestuous career at Basel. His name and fame spread throughout the known world, and his lecture hall was crowded to overflowing. He stressed the healing power of nature and raged against those methods of treating wounds, such as padding with moss or dried dung, that prevented natural draining. The wounds must drain, he insisted, for "If you prevent infection, Nature will heal the wound all by herself." He attacked venomously many other medical malpractices of his time and jeered mercilessly at worthless pills, salves, infusions, balsams, electuaries, fumigants, and drenches, much to the delight of his student-disciples.

Paracelsus' triumph at Basel lasted less than a year, however, for he had made too many enemies. By the spring of 1528, he was at loggerheads with doctors, apothecaries, and magistrates. Finally, and suddenly, he had to flee for his life in the dead of night. Alone and penniless he wandered toward Colmar in Upper Alsace, about 50 miles north of Basel. He stayed at various places with friends. Such leisurely travel for the next eight years allowed him to revise old manuscripts and to write new treatises. With the publication of *Die grosse Wundartzney* ("Great Surgery Book") in 1536 he made an astounding comeback; this book restored, and even extended, the almost fabulous reputation he had earned at Basel in his heyday. He became wealthy and was sought by royalty.

In May 1538, at the zenith of this second period of notoriety, he returned to Villach again to see his old father, only to find that he had died four years previously. On September 24, 1541, Paracelsus himself died in mysterious circumstances at the age of 48 at the White Horse Inn, Salzburg, where he had taken up an appointment under the prince-archbishop, Duke Ernst of Bavaria.

Assessment

His medical achievements were outstanding. In 1530 he angered the city council of Nuremberg by writing the best clinical description of syphilis up to that time, maintaining that it could be successfully treated by carefully measured doses of mercury compounds taken internally, thus foreshadowing the Salvarsan treatment of 1909. He stated that the "miners' disease" (silicosis) resulted from inhaling metal vapours and was not a punishment for sin administered by mountain spirits. He was the first to declare that, if given in small doses, "what makes a man ill also cures him," an anticipation of the modern practice of homeopathy. Paracelsus is said to have cured many persons in the plague-stricken town of Stertzing in the summer of 1534 by administering orally a pill made of bread containing a minute amount of the patient's excreta he had removed on a needle point. He was the first to connect goitre with minerals, especially lead, in drinking water. He prepared and used new chemical remedies, including those containing mercury, sulfur, iron, and copper sulfate, thus uniting medicine with chemistry, as the first *London Pharmacopoeia*, in 1618, indicates. Paracelsus, in fact, contributed substantially to the rise of modern medicine, including psychiatric treatment. Carl Gustaf Jung, the psychiatrist, wrote of him that "We see in Paracelsus not only a pioneer in the domains of chemical medicine, but also in those of an empirical psychological healing science." (J.G.H.)

BIBLIOGRAPHY. *The Hermetic and Alchemical Writings of Aureolus Philippus Theophrastus Bombast of Hohenheim, Called Paracelsus the Great*, trans. by A.E. WAITE, 2 vol. (1894), contains a useful biographical preface and full text of the 28 principal works of Paracelsus—now long out of print. FRANZ HARTMANN, *The Life of Philippus Theophrastus Bombast of Hohenheim, Known by the Name of Paracelsus, and the Substance of His Teachings* (1887), is a useful biographical outline, with good translations of extracts from the main works. See also A. STODDART, *The Life of Paracelsus, Theophrastus von Hohenheim* (1911), a clear biographical outline, with a popular summary of his writings; BASILIO DE TELEPNEF, *Paracelsus: A Genius Amidst a Troubled World* (1945), a concise biographical essay and an outline of his teaching, notes, and a map of his travels, based upon research to 1945; JOHN G. HARGRAVE, *The Life and Soul of Paracelsus* (1951), an attempt to correct certain misconceptions regarding the outlook and teaching of this extraordinary genius; HENRY M. PACHTER, *Paracelsus: Magic into Science* (1951); WALTER PAGEL, *Paracelsus* (1958), an analysis of antecedents of Paracelsus, his thought and influence; and ALLEN G. DEBUS, *The English Paracelsians* (1965), a study of the influence of Paracelsus on English thought in the years after his death.

Paraguay

Paraguay is an independent republic of South America, located in the south central part of the continent. A landlocked country, it is dwarfed by the larger bordering countries of Bolivia to the northwest and north; Brazil to the east; and Argentina to the southeast, south, and west. It has an area of 157,048 square miles (406,752 square kilometres) and a population of about 2,400,000. The national capital of Asunción is located at the confluence of the Paraguay and Pilcomayo rivers. Rivers play a vital role in the nation's economic life, providing the country with access to the distant Atlantic Ocean. Indeed, the name of the country is said to derive from the word *Paraguay* which, in the Guaraní Indian language, could be defined as a place with a great river.

The many wars in which Paraguay has been engaged in the past have gained for its people a high reputation for courage. Yet the ravages of war have left their mark upon national life—Paraguay's population is now small, its economy is underdeveloped, and its politics centralized. The tensions that exist between the European and Indian populations in other Latin-American countries do not, however, exist in Paraguay. Its people are largely persons of mixed Spanish and Indian ancestry and are generally bilingual in both Spanish and Guaraní. National problems are, therefore, often more economic than social in nature. The economy is based upon agriculture and forestry and is in need of diversification and industrial development. (For history, see PARAGUAY, HISTORY OF. For related physical features, see GRAN CHACO; PARAGUAY RIVER; PARANA RIVER.)

THE LANDSCAPE

Natural features. *Relief.* The Paraguay River, which runs through the country from north to south, divides it into two distinct geographical regions—the Región Oriental (Eastern Region) and the Chaco Boreal (Northern Chaco).

Región Oriental and the Chaco Boreal

The Eastern Region, comprising about a third of the country, is an extension of the Brazilian Plateau and lies at a height of between 1,000 and 2,000 feet above sea level. The Cordillera de Amambay (Amambay Mountains) runs approximately north to south along part of the frontier with Brazil. From the northeast, the Montañas de Aracanguy extend roughly southward in the direction of Encarnación, diminishing to hills in their southern range. To the east of these mountains runs the Alto Paraná (Upper Paraná) River Valley. (The Paraná forms both the eastern and southern borders of the country.) To the west lies the broad valley of the Paraguay River. The western part of the Oriental is the most favourable to human settlement. It contains the Ypoá and Ypacaraí lakes in the south.

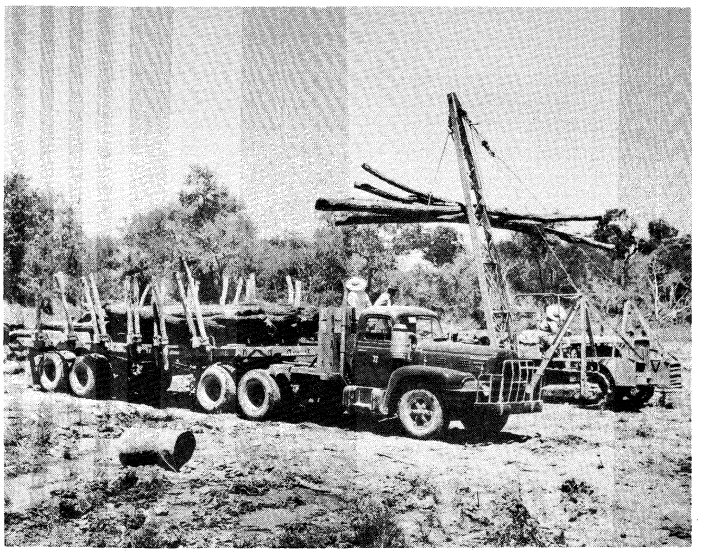
The Chaco Boreal, which covers 95,000 square miles—about two-thirds of the country—forms part of the Gran Chaco (*q.v.*), a flat and largely featureless tropical region that also extends into Bolivia and Argentina.

Drainage. Four-fifths of the country's perimeter is traced by the Paraguay, Apa, Alto Paraná, and Pilcomayo rivers. Multiple tributaries cross the eastern and central regions. The mountain ranges of Amambay and Mbaracayú form the watershed between the Paraguay and the Alto Paraná rivers that join to form the Paraná at the country's southernmost corner. Important eastern tributaries of the Paraguay River include the Jejuy, the Apa, the Tebicuary, and the Aquidabán. The only important tributary flowing from the west is the Pilcomayo, which joins the Paraguay at Asunción. It forms the southern border of the Chaco Boreal and is the main river of the area. The other rivers of the Chaco are slow and sluggish; they often drain into marshes or disappear completely in dry areas.

The river system

The largest lake in Paraguay, Ypoá is located 40 miles south of Asunción. Its waters are dispersed through various channels into the Río Tebicuary and the marshlands of the Ñeembucú. A smaller lake, Ypacaraí, is situated in a valley of the Cordillera de Los Altos, 18 miles east of the capital. It gives rise to the Río Salado, which flows into the Paraguay River.

Soils. The eastern third of the country is composed of crystalline rocks that are largely covered by red sandstones, lavas, and other volcanic rocks. In the Alto Paraná Basin there is a layer of *terra rossa*, or red ochre. The iron-bearing soils of the region contain red and yellow ochres and black clays. The forested areas are enriched by humus. The Paraguay River Basin is covered with a



Workmen loading quebracho logs obtained from the eastern Chaco Boreal region, Paraguay.
By courtesy of the Organization of American States

layer of fertile alluvial soil, interrupted by outcroppings of the underlying crystalline formations. The soils of the Chaco are composed of alluvial mud, clay, and sand brought down from the Andes.

Climate. The climate does not resemble that of other tropical countries. There is little difference between the seasons, and the days of extreme temperatures are few. During the summer months between October and March, the temperature extremes range between 77° and 104° F (25° and 40° C) whereas in the winter months from April to September the range is between 50° and 68° F (10° and 20° C). Annual average rainfall decreases gradually from east to west, from about 50 inches in the Apa River region to about 32 inches in the Chaco. In the west, the low rainfall combines with a high evaporation rate and the porosity of the soil to produce periodic droughts that are often followed by floods that are caused by the periodic rise in the waters of the main rivers.

The tropical forests

Vegetation and animal life. The far eastern region is densely forested with such tropical hardwoods as the urunday, cedar, curupay (family Mimosaceae), and lapacho (family Bignoniaceae), which are used for building materials. There is also a small supply of softwoods. Between the low eastern hills and the Paraguay River, well-watered and often marshy land is covered with tall grasses; forests grow on the uplands and along the river valleys. The river valleys of the Chaco are marshy and sporadically forested. There are scattered stands of the quebracho, or axbreaker, a tree with red wood that yields a valuable tanning extract. To the west, the land is dotted with scrub thorn trees, dwarf shrubs, and giant cacti. There are also stands of the tall caranday palm; and the *palo santo*, or "holy wood," that contains a valuable oil; as well as pineapples, which are native to Paraguay; *guaimipiré*; and sugarcane.

Medicinal plants—including the paratodo tree that yields quinine—are found in profusion. Yerba maté, or the Paraguayan tea plant, is a form of holly that grows wild in the northeast and is cultivated in the southwest.

The name Chaco means hunting ground, and the area teems with wildlife. The jaguar, locally known as *tigre*, lives among herds of wild boar, water hog, and deer. The armadillo and anteater are common, as is the otter and the coypu—a South American aquatic rodent. The varied birdlife includes ibis, herons, toucans, muscovy ducks, doves, partridges, parakeets, and parrots. Insect life is extensive and includes the deadly tarantula spider.

The animal life of the east is similar to that of Brazil and Argentina. There are various monkeys, tapirs, peccaries, deer lions, and jaguars, as well as foxes, weasels, and otters. The more than 400 species of birds include eagles, falcons, partridge, pigeons, and herons. The waters abound with crocodiles, caymans, and a large variety of fish.

Settlement patterns. *Rural settlement.* Almost the entire rural population lives within the 50-mile-wide corridor between the Paraguay River and the eastern hills. There are six principal areas of settlement within the region. These are the northern zone in the triangle between the Paraguay, Apa, and Ypané rivers; the Cordillera region associated with the Salado, Pirayú, and Caañabé rivers; the Guaireña region watered by the Caaguazú, Ybytimí, and Tebicuary rivers; the Misiones zone through which flow the Ypoá and Alto Paraná rivers; the Ñeembucú region traversed by the Paraguay, Paraná, and Tebicuary rivers; and the area around Encarnación.

Settlement in the Chaco is sparse. Indigenous tribes devote themselves to hunting and fishing, and there are several agricultural religious colonies.

Urban settlement. The largest urban concentration is found in the national capital, Asunción, and its major suburb, Lambaré. The five departmental capitals—Concepción, Villarrica, Coronel Oviedo, Ñeembucú (Pilar), and Encarnación—each have populations of about 20,000. Caacupé, east of Asunción, has over 7,500 residents, but most of the other cities are small and serve as administrative or marketing centres.

THE PEOPLE

Population groups. *Ethnic composition.* Paraguay has the most homogeneous population in South America. About 75 percent of its inhabitants are native Paraguayans who are mainly of Guaraní descent, but who have at least one Spanish ancestor.

The immigrant population is small and generally assimilated. Immigrants came largely from western Europe, but Japan, Korea, and Australia are also represented. Assimilation has been resisted by the colonies of Mennonites (a Christian sect noted for its simple life-style and for its rejection of public and military service) and of Hutterites (a Christian sect that stresses communal living and communal ownership of property). These sects have been granted a special legal status exempting them from military service and awarding them their own legal jurisdiction.

The religious colonies

There are only about 65,000 Indians living in the country. Small Indian tribes such as the Tapietés and the Ñanaguás inhabit the Chaco, as do the Matacos, Lenguas, Sanapanás, Chamacocos, Moros, Chulupies, and Macás.

Language groups. Spanish and Guaraní are the official languages of the country. Spanish is the medium of instruction, business, and government, whereas Guaraní is

mainly the language of the home. Most of the population is bilingual.

Religious groups. Roman Catholicism is the official religion, and its adherents constitute the majority of Paraguayans. There is tolerance for other Christian sects, as well as for other religions that are practiced by about 5 percent of the population.

Demography. In 1962 the population numbered about 1,800,000, and by 1970 it was estimated to have grown to 2,400,000. Most of the population is rural, and there are more women than men. Although life expectancy at birth is about 60 years of age, the population is young, and over 70 percent is under 30 years old. Infant mortality is high, with about one child out of every eight dying before it is one year old.

Population distribution

The mean density of population is 15.3 persons per square mile. Distribution is uneven, and the highest density occurs at Asunción. The Chaco Boreal has only about 1.3 persons per square mile.

The rate of emigration has been high since the 1940s. It has been estimated that between 1940 and 1970 about 400,000 Paraguayans have fled to Argentina and Brazil in search of more political freedom or better economic opportunities. Immigration has remained sparse and restricted and is far from compensating for the loss of population.

THE ECONOMY

Although there is a favourable balance of trade, with exports exceeding imports, the gross national product is small and average per capita income is low. The country has few developed mineral resources, and its economy is dependent upon agricultural and forestry products.

Distribution of resources. *Minerals.* Most mineral deposits are found east of the Paraguay River. Manganese is located near Emboscada, malachite (a green ore of copper) and azurite (a blue ore of copper) are found near Caapucú, feldspar and mica near Concepción, and talc and *pirofilita* (hard, iron-bearing flagstone) near Caapucú and San Miguel. Ochre is found in the Cordillera region, and gypsum and limestone near the Paraguay River. Other minerals include marble, iron, and salt.

Biological resources. Biological resources include hardwood forests and stands of quebracho trees. There are over 6,000,000 head of cattle, as well as horses, sheep, pigs, and goats. Fish are plentiful in the rivers and marshes and include shad, mackerel, and flounder.

Power resources. There are three main sources of hydroelectric power—the tributaries of the Paraguay River, the tributaries of the Alto Paraná River, and the Alto Paraná River itself. The tributaries of the Paraguay are largely located in the north of the eastern region. They flow down from a height of about 165 feet above the middle watermark of the Paraná and are broken by waterfalls and rapids. The Acaray and the Monday rivers, tributaries of the Alto Paraná, have a total power potential of 400,000 kilowatts, and the power station operation on the Acaray generates 90,000 kilowatts.

The hydroelectric potential

In the Alto Paraná, the Guairá Falls on the Brazilian border and the Apipé Rapids on the border with Argentina have a potential of 10,000,000 and 2,000,000 kilowatts, respectively, but are located far from the main centre of power consumption at Asunción.

Sources of national income. *Agriculture, forestry, and fishing.* Agriculture represents the most common economic activity and employs over half of the working population on 2 percent of the land. Most of the farmers are squatters on land held by absentee landlords, and they supplement their income by working on ranches or trade. Cassava and maize (corn) are the most common crops; and rice, tapioca, sugarcane, and wheat are also widely grown. Tobacco and cotton, tung oil, peanuts, and other oil seeds are grown for export. Yerba maté, coffee, and a variety of fruits are raised mainly for domestic use.

Cattle raising is a traditional activity that contributes to both domestic consumption and to the export trade. The cattle are raised in the southern district of Misiones, in the central region near Concepción, and in the eastern and northeastern Chaco. Almost all cattle are raised for slaughter; the dairy industry is little developed.

Forestry products

Forestry accounts for about one-fourth of the value of exports, and large quantities of wood are used for the generation of electricity in thermal power stations. Forestry is extensive, but further development is hampered by inadequate transportation facilities and the lack of sufficient machinery.

Fishing is carried out on the country's rivers and marshes on an individual basis. There is no organized fishing industry.

Mining and quarrying. Despite the varied mineral deposits already described, mining and quarrying are the least developed economic activities. They are hampered by the remote location of most ore deposits. Much of the existing activity is directed toward the production of clay

domestic utensils and jewelry, construction materials such as limestone and cement, and lime.

Manufacturing. Paraguay is one of the most industrially undeveloped countries of South America. Most manufacturing is located at Asunción, although some processing plants are located near sources of raw materials. Most manufacturing consists of the production of such extractive products as canned meat, tannin extract, vegetable oils, petitgrain oil (derived from the bitter-orange tree), ginned cotton, and tea. There are, however, growing textile and consumer-goods industries; and shoes, sugar, cigarettes, soap, cement, furniture, plywood, and matches are also produced.

Energy. Most electricity is produced in the wood- and oil-burning thermoelectric plants at Asunción. The hydroelectric plant on the Acaray River is also important, and in the late 1960s a total of over 200,000,000 kilowatt-hours of electricity were produced.

Financial services. The two main banking establishments are the Central Bank, which handles all monetary and foreign exchange functions, and the National Development Bank, which grants credits to large and small agricultural and industrial enterprises and conducts normal banking functions. There are also branches of other Latin-American, European, and United States banks. Foreign exchange reserves are limited, but loans are obtained from international development banks and associations.

Foreign trade. The principal exports—processed meat, forest products, vegetable oils, and tobacco—are chiefly marketed in Argentina, the United States, the United Kingdom, western Europe, and Uruguay. The main sources of imports—the United States, Argentina, West Germany, and the United Kingdom—provide Paraguay with heavy machinery, motors, transportation equipment, foodstuffs, fuel and lubricants, and iron and iron products. Paraguay is a member of the Latin American Free Trade Association (LAFTA). An elaborate system of subsidies, surcharges, and multiple exchange rates ensures a favourable balance of trade. Many goods, however, escape customs control along the country's river boundaries.

The government's role in the economy

Management of the economy. Although private initiative is encouraged, the government plays an important role in the planning of economic activities. It defines economic and social policy and participates directly in business life. The government holds a monopoly on the production of alcohol and has nationalized most of the transportation and the telecommunications services.

Taxation. Most of Paraguay's revenue is derived from import duties and from income, inheritance, and real estate taxes. Profits derived from commerce, industry, finance, pastoral farming, and real estate are taxable, but those from arable farming, the professions, and manual labour are exempt. There is little indirect taxation.

Trade unions. There are two large trade unions. The Confederation of Paraguayan Workers and the Syndicalist Movement of Paraguay are centred in Asunción. Strikes are illegal, and labour disputes are resolved by intervention of the National Council of Economic Coordination.

Economic policies and problems. Economic policy is directed toward the maintenance of a favourable balance of trade while improving agricultural and industrial production. Foreign loans are often floated, and the public debt continues to increase. Domestic inflation is serious, and the value of services has increased more rapidly than the production of goods. The country is attempting to reduce its dependence upon Argentina and Brazil, although it receives preferential treatment from LAFTA as an underdeveloped country.

Transportation. *Roads.* Economic expansion has been hampered by the lack of an adequate system of roads; the government, however, has sponsored highway construction since the early 1960s. Paraguay's link in the Pan-American Highway runs east from Asunción to Puerto Stroessner on the Alto Paraná River, where it is connected by bridge to the town of Foz de Iguacu, Brazil, and the highway to the Atlantic Ocean port of Paranagua, Brazil. The Chaco is served by a highway that runs northwestward from Asunción through Filadelfia and Palmar Ustares to the northeastern Bolivian border. Another road runs north from the national capital through Concepción to the Bolivian border at Pedro Juan Caballero.

Railways. Most of the railway system is composed of government-owned routes. The Paraguayan Central Railway operates between Asunción and Encarnación on the Alto Paraná in the southeast and connects with a train ferry to Posadas, Argentina. The Northern Railway runs a line between Concepción and Horqueta, 33 miles to the north. The Chaco is served by privately owned industrial railways.

Water transport. The chief mode of transportation is by water. The Alto Paraná is the artery for trade with Brazil and Argentina, and the Paraguay is the commercial highway for the port of Asunción. International traffic includes Paraguayan, Argentinian, Dutch, and British shipping companies.

The national merchant marine was founded in 1945 and began operations three years later. It owns cargo vessels, oil tankers, refrigerated ships, and passenger ships.

Air services. Air transport is provided by the government-owned national airline, the air force-operated military air transport, and two private companies. Because of its strategic location, Asunción is an important international junction, and ten foreign airlines use its airport. There are six domestic airports at Asunción, Pilar, Concepción, Encarnación, Coronel Oviedo, and Mariscal Estigarribia, as well as several private airstrips.

ADMINISTRATION AND SOCIAL CONDITIONS

The presidency

Structure of the government. *Constitutional framework.* The president is elected by direct vote for a five-year term. He must be a Catholic, be a Paraguayan by birth, and be over 40 years of age. The president is accorded wide powers; these include the appointment of ministers and other administrators, the conduct of foreign affairs, the declaration of a state of siege, the dissolution of the legislature, the periodic enactment of decrees, and the mobilization of troops.

The Council of State is an advisory body composed of nine members, all of which are appointed by the president. Four of its members are representatives for agriculture, manufacturing, commerce, and labour. The council's functions include the approval of measures initiated by the president.

The legislature is composed of a 60-member Chamber of Deputies and a 30-member Chamber of Senators. The legislators are chosen by popular vote for a term of five years. They are empowered to initiate legislation and may override a presidential veto or reject a budget by a vote of two-thirds majority in each house.

Local government. The country is divided into two provinces—the Occidental, to the west of the Paraguay River, and the Oriental region, to the east. Occidental Province is divided into three large departments, whereas the heavily populated Oriental Province is divided into 13 departments. The capital, Asunción, together with the suburb of Lambare, is administered separately. Each department is further divided into *partidos*, or rural districts, that are controlled by the central government. *Partidos* are composed of a number of still smaller units called *compañías* that often correspond to areas inhabited by kin groups. The *compañías* often have Guaraní names.

The political process. *Elections.* Voting is compulsory for all men and women who are 18 years of age and older. Resident aliens are also allowed to vote in municipal elections. Elections for the executive and legislative branches of the central government are, as mentioned, held every five years. If the president dissolves the legislature, elections must be held within two months.

Political parties. Paraguay is constitutionally a multiparty state. Parties are legally free to organize, but they are closely regulated by the executive branch of the government. Parties can be prohibited if they attempt to commit a crime against the regime in power, and they are not allowed to align themselves with, or accept aid from, foreign nations.

The political process is, in effect, controlled by the party of the chief executive. Other parties are recognized, however, in the composition of the legislature. The party that wins a simple majority is awarded two-thirds of the seats of both houses, and the rest of the seats are proportionately distributed among the minority parties. While giving nominal recognition to the legal existence of other organizations, this process ensures executive control of the political life of the country.

The Supreme Court

Justice. The Supreme Court is composed of five members who are chosen by the president and confirmed by the Council of State. Judges of the lower courts and magistrates are appointed by the Supreme Court. The judiciary is supervised by the Ministry of Justice, and judges can be tried by the legislature. Judges are not allowed to hold any other position except that of a teacher. Magistrates, who are often political functionaries, are granted legal immunity.

The armed forces. More than one-third of the total national budget is spent upon the police and the armed forces. Military service is compulsory for all male citizens. The armed forces are composed of an army, national and territorial guards, an air force, and river-patrol gunboats.

Government services. *Education.* Elementary education is free and compulsory for children between the ages of seven and 14. School facilities are inadequate; about 22 percent of the population is illiterate and only about 75 percent of school-age children attend classes. Almost all children speak Guaraní at home, and the schools provide their first contact with the Spanish language, which is the medium of instruction. Instruction includes reading and writing, mathematics, and science; in addition, agriculture, home economics, and health are emphasized.

Secondary education is provided by government-run *colegios* (high schools), and privately owned lycees. Primary schoolteachers are given six years of training. The Normal School at Asunción prepares students for further training as secondary schoolteachers at the National University. The secondary level provides training in business and the professions, and there are technical and vocational schools, as well as a bilingual secretarial school for women.

The two universities—the National University and the Catholic University—are located in Asunción. The larger National University is financed by the state and attendance is free. The International Higher Institute of Public Relations confers a Master of Public Relations degree that is recognized by the National University. There are also schools of agriculture and veterinary medicine, as well as bacteriological and radiology institutes.

Health and welfare services. The Social Welfare Institute serves all wage earners. Benefits include treatment of both occupational and nonoccupational diseases and accidents, maternity care, disability compensation, and life insurance covering accidental death. Railway and bank employees receive benefits through retirement and pension funds. There are state agencies for the planning and implementation of land reform and for technical, economic, and social assistance to small farmers.

Most medical facilities and physicians are located in Asunción. There are a few provincial hospitals, but most care is available in health centres. Voluntary organizations combat leprosy; inter-American cooperative services combat tuberculosis and malaria.

Housing. Except for the larger cities, housing conditions are inadequate. The most common home is an adobe hut roofed with reeds and floored with packed earth. In the cities, Spanish architecture predominates. Water supply and sewage systems are most inadequate in urban areas and nonexistent in the countryside. The cities are faced with a chronic housing shortage, due to the influx of people from the countryside and the expanding population. Crowded housing conditions are also related to the unequal distribution of land; large estates are depopulated while small plots are overcrowded. To encourage building, the Inter-American Development Bank grants 30-year mortgage credits.

The police. Police chiefs, or *comisarios*, are appointed by the president. The police in Asunción are responsible for the maintenance of dossiers on the country's citizens, for the prevention and investigation of crime, and for the maintenance of the prisons. People arrested while committing a crime can be detained for 24 hours before being placed under judicial jurisdiction.

Social conditions. *Wages and the costs of living.* Minimum wages were introduced by the Ministry of Labour in 1961. The average annual per capita income is equivalent to about $200 U.S., but this figure is deceptive because most subsistence farmers do not participate in the cash economy. Chronic inflation has resulted in a continually rising cost of living and in a decreasing value of the minimum wage.

Health conditions. Intestinal and lung diseases are the major causes of death. Inadequate shelter during the winter months is the chief factor in the prevalence of influenza, pneumonia, and tuberculosis. There is an incidence of malaria and leprosy, and, as mentioned, infant mortality is high.

Economic and social divisions. The main divisions of Paraguayan society follow economic lines. The chief groupings are the rich and the poor, the learned and the unlearned, the owners and the labourers.

CULTURAL LIFE AND INSTITUTIONS

Guaraní and Spanish traditions

The main characteristic of Paraguayan culture is its fusion of both the Guaraní and Spanish traditions. Folklore, the arts, and literature reflect this dual origin. Guaraní musicians adopted the Spanish harp and guitar, and Latin-Americanized versions of European dances are popular. Sculpture and wood carving were adapted for the embellishment of Catholic churches and missions. Paraguayan artists were receptive to the European Impressionist movement. The country's outstanding handicraft is the production of ñandutí lace, which is thought to represent a combination of 16th-century needlepoint lacemaking techniques from Europe with Guaraní traditional patterns and designs.

Cultural institutions. Almost all cultural institutions are located in Asunción. There are three learned academies concerned with Paraguayan and Guaraní history and culture, as well as various societies and research institutes. The fine arts are represented by the Normal School of Music, the Conservatory of Music, the National Academy of Fine Arts, and the Asunción Symphony Orchestra. There are museums concerned with ethnography, natural history, and military history, as well as collections of the work of Paraguayan artists and private collections of national memorabilia.

Library services are also centred upon the national capital. The largest are the National Library, the National Museum, and the National Archives; other government institutions include the Public Library of the Ministry of Defense, and the Library of the Ministry of Foreign Affairs. The American Library is attached to the Godoi Museum. Scientific materials are collected by the Library of the Museum of Natural History and Ethnography and the Library of the Paraguayan Scientific Society.

The press and broadcasting. Although Paraguay's political life is subject to control, censorship of the public media is not excessive, and moderate criticism of the government is allowed. All newspapers are published in Spanish and are issued on a daily or weekly basis. *ABC*, founded in 1967, and *La Tribuna*, founded in 1925, have the largest circulations in the country. *La Tarde* and *Comunidad* carry Catholic news items. *El Páis* is the official government organ; *Patria* supports the Colorado Party; and *El Radical, El Liberal*, and *El Enano* are all liberal newspapers.

Radio Nacional is the government radio station. Its programs are supplemented by those broadcast from the eight privately owned commercial radio stations. Television service is available only in Asunción.

Future prospects. The future of Paraguayan political life depends on the maintenance of the principles of free enterprise, on the liberty of all to work without being

obligated to belong to a certain political party, and on free elections. Economic advance is dependent upon greater and more equitable use of hydroelectric power, the suppression of smuggling, better use of foreign loans, and the attraction of emigrants back to Paraguay.

(J.P.P.)

Paraguay, History of

The first Europeans known to have visited what is now Paraguay were Alejo García, in 1525, and Sebastian Cabot, in 1528. The area was colonized for Spain by Domingo Martínez de Irala, under whose orders Juan de Salazar founded Asunción in 1537. During the 17th and 18th centuries the country was chiefly noted for its *reducciones*, unique autonomous communities of Christian Indians run by Jesuit missionaries. After 1776 it was part of the viceroyalty of Río de la Plata, centred at Buenos Aires.

The establishment of the nation. Paraguay's struggle for independence was not so much a fight against far-off Spain as against nearby Buenos Aires, which, considering itself heir to the Spanish viceroyalty, sought to extend its rule over Paraguay when it declared its own autonomy in 1810. The junta of Buenos Aires sent an army to Paraguay under the command of their spokesman, Manuel Belgrano; the Paraguayans resisted Belgrano, defeating him at Paraguarí and Tacuarí. On May 14–15, 1811, a Paraguayan revolution led by Capt. Pedro Juan Caballero repudiated Spanish rule. One month later a governing junta was established, presided over by Fulgencio Yegros, hero of the recent campaigns; its principal member, however, was José Gaspar Rodríguez Francia. The new government proposed to Buenos Aires that the two provinces form a confederation, but the plan was not accepted. Instead, on October 12, 1811, a military alliance was arranged, based on Paraguayan independence. Difficulties emerged very soon, with Buenos Aires' unsuccessful attempt to recruit Paraguayan troops for the war against Spain. Asunción requested, also without success, arms to meet a Portuguese threat in the north. The alliance was torn asunder. The leader of the Banda Oriental (now Uruguay), José Gervasio Artigas, tried to involve Paraguay in his struggle against Buenos Aires, unfurling the banner of federation. Paraguay proclaimed its neutrality in the civil wars of the Plata, but Buenos Aires applied economic pressures to reduce Paraguay to submission. A delegation was sent to Asunción to stress the necessity and the advantages of annexation. Outraged, the Congress proclaimed a republic on October 12, 1813, rejecting any accord with Buenos Aires. The regime was headed at first by two consuls, in imitation of ancient Rome. José Gaspar Rodríguez Francia, one of the consuls, was an admirer of classical antiquity. The other consul was Fulgencio Yegros, whose prestige quickly waned.

The Francia dictatorship

The consulate was soon replaced (1814) by a dictatorship under Francia, a strange, misanthropic figure, an antimilitarist in a warrior nation and a follower of Voltaire and Rousseau. In the absence of a constitution and with no defined limits on his powers, Francia (officially designated "El Supremo Dictador") affirmed his will as the only law until he died. When Congress ceased to meet, he concentrated all power in himself, prohibiting any political activity and ruthlessly suppressing his opposition. The discovery of a conspiracy in 1820 brought on a reign of terror. Yegros and other leaders of the revolution were executed or committed suicide. Paraguay became cloistered in an impenetrable isolation, cut off from contact with the outside world. Foreign commerce was forbidden; no one could leave or enter the country. The French botanist Aimé Bonpland spent ten years in captivity for crossing the border. Bolívar, at the zenith of his prestige, proposed that Argentina invade Paraguay in order to free Bonpland, "a mission which would command the world's attention." Francia declared that "he wanted neither peace nor war with anyone," defending his regime as the only way to save Paraguay from the anarchy in which South America was floundering. He did in fact impose the most absolute law and order, but the people lived, however tranquilly, in a vacuum, ignorant of everything that happened elsewhere. Paraguay was "the China of America" until the dictator died a natural death on September 20, 1840, leaving no provisions for a successor.

There were tendencies to anarchy as one government rapidly succeeded another until Carlos Antonio López, a philosophy professor, came to the fore. He had remained prudently away in the countryside all during the dictatorship. López briefly re-established the consulate, sharing power with Mariano Roque Alonso, an obscure military man. In 1842 Paraguay belatedly issued a formal declaration of its independence, but the dictator of Argentina, Juan Manuel de Rosas, refused to recognize this act. López, chosen as president of the republic in accord with a constitution adopted in 1844, obtained the support of Brazil against Buenos Aires; in 1845 and 1849 he declared war on Argentina, without occasioning major repercussions. Finally, on July 17, 1852, after the fall of Rosas, the new Argentine chief of state, Gen. Justo José Urquiza, recognized Paraguayan independence. The great powers followed suit.

Paraguay's conflicts with its neighbours. Once Paraguay became active in international affairs, the country began a period of great progress, aided by hundreds of European and North American technicians. The state, nevertheless, maintained strict economic controls and continued to be the principal entrepreneur. Blast furnaces, railroads, a river merchant fleet, shipyards, arsenals, and a powerful army made Paraguay one of the foremost nations of South America, more and more in conflict with its neighbours. In 1855 boundary and navigational disputes prompted Brazil to send an unsuccessful ful naval expedition against Paraguay. The complaints of an American-backed industrial company, the only one allowed by López, and the bombardment of the gunboat USS "Water Witch" in 1855 caused the U.S. to dispatch a punitive squadron. Through the good offices of President Urquiza, the dispute was resolved by arbitration favourable to Paraguay. There were other grave conflicts with France and England, caused by López' firm opposition to European influence. Because of an unresolved boundary dispute, relations with Argentina were also poor. When Carlos Antonio López died, on September 10, 1862, he gave this last advice to his son and successor, Gen. Francisco Solano López:

> There are many disputes which you must settle; do not try to resolve them with the sword but rather with the pen, especially in the case of Brazil.

Francisco Solano López soon found himself involved in a disagreement with Argentina and Brazil, which viewed the growing power of Paraguay with uneasiness. A Uru-

guayan faction, citing a threat against their country by Argentina and Brazil, asked Paraguay's aid. López, convinced that the balance of power in the region was in danger and believing that Paraguay owed its independence to that balance, demanded clarifications, which Argentina and Brazil denied him. On August 30, 1864, López lodged an unheeded protest over a Brazilian invasion of Uruguay. On November 12, he ordered the capture of the Brazilian ship "Marqués de Olinda," and hostilities were begun. In a lightning campaign Paraguay seized the principal strongholds of Brazil's Matto Grosso region. López asked permission to cross Argentine territory for the purpose of attacking Brazilian forces in Uruguay. When the request was denied, the Paraguayan Congress declared war on Argentina on March 18, 1865. In less than a month the Paraguayans had occupied the Argentine province of Corrientes and were advancing toward Uruguay. On May 1, 1865, Uruguay (where anti-Paraguayan forces had triumphed) signed a secret alliance with Argentina and Brazil by which the three powers agreed to cooperate against López. They arranged in advance for the partition of Paraguay when he had been deposed.

The Paraguayan War

Defeated at Uruguaiana, Brazil, Paraguayan forces retreated to their own territory, to the region around Humaitá, near the confluence of the Paraná and Paraguay rivers. For two years bloody battles were fought in that sector; finally the Paraguayans had to abandon Humaitá, and López dug in around Villeta. In December 21–27, 1868, a gigantic battle took place at Lomas Valentinas, ending in the virtual extermination of the Paraguayan army. López retreated to the mountains, where he formed a new army. The final campaign, in Amambay, was the most dramatic of all. Paraguayans died not only from their wounds or from hunger but even at the hands of López himself, whom the defeat had driven desperate. He even ordered that his own mother be beaten. Only 400 starving soldiers arrived with López at Cerro Corá, his last encampment. There, on March 1, 1870, shouting "I die with my native land," he was killed in combat. Paraguay had been razed to the ground, with 1,000,000 dead. Most of the survivors were women.

Under a liberal constitution, ratified November 25, 1870, Paraguay undertook a difficult reconstruction. Although the domination of the victorious nations was complete, they nearly went to war with each other over the interpretation of the severe provisions of their secret pact. In 1872 Brazil imposed its version of the boundaries of the conquered nation, helping Paraguay contain the territorial ambitions of Argentina. Buenos Aires finally agreed to submit its border dispute with Paraguay to arbitration. Pres. Rutherford Hayes of the United States ruled in favour of Paraguay in 1877. When the former allies returned home, Paraguay was left to its own fortunes and entered a period of great political instability: in 80 years only six presidents served a full term. The two political parties that even today polarize the views of Paraguayans were founded almost simultaneously in 1887—first the opposition Partido Liberal (Liberal Party) and then the Partido Colorado, which had assumed power. In 1904, when a revolution removed the Colorados from office, the Liberales took control of the government. Efforts to reconstruct the nation became hampered by a dispute with Bolivia over possession of the Gran Chaco region in western Paraguay. Colorado administration made repeated concessions (1879, 1887, and 1894), in the hope of attracting Bolivian commerce. To contain Bolivian incursions into the Chaco, the Eligio Ayala government (1924–28) armed the nation and entered the disputed territory. A clash occurred on June 15, 1932, when Ft. Carlos Antonio López, or Pitiantuta, was captured by the Bolivians. For the next three years, Paraguay and Bolivia fought bitterly in the inhospitable Chaco. While Eusebio Ayala held civil power in Paraguay, the military commander, Gen. José Félix Estigarribia, demonstrated an intelligent strategy and by a string of victories pushed the Bolivians back almost to the edge of the disputed territory. Through the mediation of Argentina, Brazil, Chile, Peru, Uruguay, and the United States, a cease-fire was concluded June 12, 1935. A peace conference convened at Buenos Aires, signing the final treaty on July 21, 1938. The Paraguay–Bolivia boundary was submitted to the arbitration of the presidents of the six mediating nations, who handed down their decision the following October 10. Paraguay retained three-fourths of the Gran Chaco, including its frontier along the Paraguay River.

The Chaco War

Recent history. On February 17, 1936, a military coup jailed Ayala and Estigarribia, removed the Liberales from power, and abrogated the constitution of 1870. The new government was short-lived; in 1939 Estigarribia was elected president with the support of the Liberales. On September 7, 1940, a few days after dictating a new constitution along authoritarian lines, he was killed in an airplane crash. His successor was Gen. Higinio Morínigo, who relentlessly persecuted the Partido Liberal. He sided with the Allies of World War II. With the support of the Colorados he crushed a revolt in 1947, but the following year he was deposed by those same Colorados, who used that means to return to power. Six presidents succeeded each other for short terms until 1954, when Gen. Alfredo Stroessner took over the government, supported by the army and the Colorado Party.

Close cooperation by the United States allowed Stroessner to undertake important public works. The currency was stabilized; the geographic isolation of the country was broken down by modern highways stretching to the Atlantic and the Río de la Plata, and by a network of airlines. Stroessner's dictatorship was modified in 1967, when a new constitution reinstated Congress and granted some civil liberties. Still, opposition continued to be severely suppressed. The church clashed repeatedly with the government. In the early 1970s there was no guerrilla action or terrorism in Paraguay, but the standard of living was one of the lowest in Latin America, and, in spite of heavy foreign aid, progress in the struggle against underdevelopment was slight.

General works include CECILIO BAEZ, *Resumen de la historia del Paraguay desde la época de la conquista hasta el año 1880* (1910); EFRAIM CARDOZO, *Paraguay independente* (1949) and *Breve historia del Paraguay* (1965); and HARRIS GAYLORD WARREN, *Paraguay: An Informal History* (1949), with an excellent annotated bibliography.

Well-documented studies of the independence movement are BLAS GARAY, *La revolución de la independencia del Paraguay* (1897); FULGENCIO R. MORENO, *Estudio sobre la independencia del Paraguay* (1911), an economic interpretation. These have been superseded by JULIO CESAR CHAVES, *Historia de las relaciones entre Buenos-Ayres y el Paraguay, 1810–1813* (1938). On the Francia dictatorship, JULIO CESAR CHAVES, *El supremo dictador, biografía de José Gaspar de Francia*, 2nd ed. (1946), is a masterly work. On the López period, JUAN FRANCISCO PEREZ ACOSTA, *Carlos Antonio López, obrero máximo, labor administrativa y constructiva* (1948), is well documented; and JUSTO PASTOR BENITEZ, *Carlos Antonio López: estructuración del Estado Paraguayo* (1949), provides a sociological interpretation. On the War of the Triple Alliance, see PELHAM HORTON BOX, *The Origins of the Paraguayan War*, 2 vol. (1929, reprinted 1967); and with new documentation, HAMON J. CARCANO, *Guerra del Paraguay: acción y reacción de la Triple Alianza*, 2 vol. (1941); EFRAIM CARDOZO, *Vísperas de la guerra del Paraguay* (1954), *El imperio del Brasil y el Río de la Plata* (1961), and Cardozo's journalistic diary *Hace cien años* (1964–70), a day-by-day account of the war. For the period between the two wars, see ANTONIO ZINNY, *Historia de los gobernantes del Paraguay, 1535–1887* (1887); and GOMES FREIRE ESTEVES, *Historia contemporanea del Paraquay* (1921).

On the Chaco War, the memoirs of MARSHAL ESTIGARRIBIA, *The Epic of the Chaco* (1950); and DAVID H. ZOOK, JR., *The Conduct of the Chaco War* (1960), are basic.

(E.C.)

Paraguay River

The fifth largest river in South America, the Paraguay River (Portuguese Rio Paraguai) is the principal tributary of the Paraná River and an important artery of the Río de la Plata system, which serves the interior of South America; it is 1,584 miles (2,550 kilometres) long. The source and upper course of the Paraguay River are in Brazil, where it demarcates part of the frontier with Para-

guay before entering Paraguay itself, which it traverses from north to south; it then forms the frontier between Paraguay and Argentina for the last 150 miles of its course before entering into the Paraná River, which flows into Argentina.

The "river of cockades"

The name Paraguay is taken from the Guaraní language and could be translated "river of *paraguas* (coloured, plumed birds)" or "river of cockades," an allusion to the plumed headdresses once worn by the riverine peoples.

Inaccessible to oceangoing ships, the river is used only for local traffic; steamers from Buenos Aires, capital of Argentina, ply upstream as far as Asunción, capital of Paraguay. Often flowing through country rife with malaria and other tropical diseases and subject for much of its length to seasonal flooding, the Paraguay River constitutes more of an obstacle than an aid to the development of its basin. Surveys of its upper course, however, are being conducted by the Brazilian government in conjunction with the United Nations to assess the area's economic potential. (For details on associated physical features, see GRAN CHACO; PARANA RIVER; and PLATA, RIO DE LA.)

The natural environment. *Physiography.* The Paraguay rises in Brazil, in the central plateaus of Mato Grosso, at an altitude of 980 feet above sea level. Where it becomes navigable, about 150 miles downstream, near Cáceres in Brazil, after its confluence with the Sepotuba, it is 275 feet wide and 20 feet deep. Another 20 miles downstream, where the Jauru joins it at an altitude of 400 feet above sea level, the Paraguay enters the alluvial Mato Grosso *pantanal* (floodplain); it crosses the plain's western edge over a sandy bed, flowing around the many islands in its course. During its passage through the *pantanal*, it receives such important tributaries as the Cuiabá, the Taquari, and the Miranda.

About 470 miles downstream, it flows north to south to form the boundary between Brazil and Paraguay before being joined by a tributary, the Río Apa, which flows in from the east and demarcates part of the Brazilian–Paraguayan frontier. The river then enters Paraguay, having travelled about 950 miles from its source. After flowing for more than 200 miles across Paraguay, it is joined by the Río Pilcomayo at the Argentinian border, near Asunción. It then flows south-southwest along the Argentinian–Paraguayan frontier for about 140 miles, until it is joined on its west bank by the Bermejo. Continuing along the border for another 40 miles, it then empties into the Paraná River at a short distance from the Argentinian city of Corrientes.

Hydrography. Throughout its hydrographic basin, which covers more than 380,000 square miles, altitudes rarely exceed 650 feet above sea level. Rainfall varies from 40 to 80 inches annually. Over a long distance, the gradient of the river varies from about three-quarters of an inch to an inch per mile. The various streams of the basin have low banks or natural levees, built up when silt is deposited along the slower flowing portions of the river channel during flood stage. When the river recedes, its banks thus remain elevated above the level of the neighbouring plains. During floods a continuous water table, often as much as 15 miles wide, underlies the inundated plains, and about 38,600 square miles of surface area are flooded.

The Paraguay River has varying rates of flow between its source and its mouth. Above Corumbá, in Brazil, it has a typically tropical regime—at its highest in February and at its lowest from July to August. Below Corumbá, the high point occurs in July and the low point from December to January.

Variations in the rate of flow

At Corumbá, the mean discharge rate during the driest period exceeds 30,000 cusecs (cubic feet per second); the mean annual rate, 68,000 cusecs; and the mean discharge of floodwaters, 100,000 cusecs. At Puerto Sastre, at the confluence of the Apa, the average discharge of floodwaters reaches more than 225,000 cusecs, with the maximum occurring from June through August and the minimum in January. The variation in rate of flow is not attributable to the regimes of the river's tributaries but is explained primarily by the overflowing of water onto the *pantanal* in summer and by the gentle gradient of the riverbed. The upper Paraguay (down to Concepción, Paraguay) consequently floods from December to March, while the middle Paraguay (from Concepción to Asunción) floods between May and June as a result of the delay in flow of waters from the upper stream. Along the lower Paraguay (from Asunción to the Paraná River), tributaries with tropical regimes carry their greatest volume of water from December to March, causing floods in February; whereas the contributions of the Andean tributaries, the Bermejo and the Pilcomayo, produce floods between February and June. The flood area exceeds 30,000 square miles.

From its confluence with the Apa for the 630 miles to its mouth, the Paraguay, while still navigable, runs on a shallow, broad bed, with an average width of about 2,000 feet. Its right (Argentinian) bank gradually lowers, whereas its left (Paraguayan) bank becomes elevated, forming cliffs. Along this stretch, floods develop principally on the western bank, spreading over the Argentinian plain for distances of from three to six miles. These lands form part of the Gran Chaco (*q.v.*). Downstream from the complex of low hills south of Assunção known as Lomas Valentinas, the floods spill out over both banks, inundating areas between six and nine miles wide. At this point, the riverbed has an average width of about 2,300 feet.

Climate. The predominant climate of the Paraguay Basin is of the hot and humid savanna type, characterized by dry winters from April to September and heavy rains in summer from October to March. More than 80 percent of the annual precipitation occurs in the summer months, with little or no rainfall in June and July. Annual mean temperatures are above 64° F (18° C), the absolute maximum temperature being from 104° to 107° F (40° to 42° C) and the absolute minimum temperature being about 34° F (1° C). October is frequently the warmest month, except in the south, where the warmest month is January and where the contrast between rainy summers and dry winters is more pronounced. The extreme southern portion of the basin has a humid, moderately warm climate in which the heaviest rains occur during the summer and the winters are not completely dry.

The *pantanal* complex

Vegetation and animal life. Some of the *pantanal*'s vegetation, called the "*pantanal* complex," is typical of the Mato Grosso plateau regions, while some other is typical of lowlands. Plants that thrive in water and in moist soils as well as those that flourish at moderate temperatures or are adapted to dry regions are found within the complex. As on the banks of the Niger in West Africa, both forest and grassland types occur. The water plants, found on the permanently flooded lands, are typified by the water hyacinth and by the "Victoria regia" water lily. Moisture-loving species, such as the trumpetwood and the guama, flourish over most of the floodplain.

On the savanna, after the floods, various grasses such as paspalum and knotroot bristle grass reappear. Vegetation of a more evolved type, which thrives at moderate temperatures, occupies the unflooded highland. It is represented by nut-bearing palms and by various types of laurels. In the forests of the region, the carandá, or copernicia palm (a tropical palm that yields wax), the paratudo, the muriti palm (a large fan palm), and various types of quebracho trees (South American hardwoods that are a source of tannin) predominate. In the Gran Chaco region along the west bank of the river, and in other sections where drought is more pronounced, plants adapted to dry conditions occur. In the lowlands of eastern Paraguay, forest cover and savanna grasslands alternate.

Among the fish of the Paraguay River, some of which supplement the diet of the riverine population, are the dorado (a fish resembling salmon), the piranha (a fish resembling the bluegill that travels in large schools and devours any meat that falls in the water), and the pacu (which resembles bass).

The development of the river. *Early history.* Before the arrival of the Spaniards in the 16th century, the region was inhabited primarily by the Paiaguá (a part

The original inhabitants

of the Guaycure tribe) and by the Guaraní. A subgroup of the Guaraní, the Xaraiés, lent their name to the original designation of the *pantanal*—the Lagoon of the Xaraiés. The Paiaguá and the Guató of the *pantanal* engaged in foraging, hunting, and fishing. Others, such as the Tereno and the Guiana (Arawak), practiced a rudimentary type of agriculture, building hillocks above flood level. The southern Guaraní cultivated maize and cassava (manioc). The inhabitants of the Gran Chaco—the Paiaguá, Mataco, Mascoy, and Zamuco—were nomadic fishers and hunters.

In what is now Paraguay, the Spaniards and Portuguese interbred freely with the indigenous Amerindians. Consequently, the present riverine population of the country is largely mestizo, or mixed, and Guaraní as well as Spanish is the common language. In Brazil, however, miscegenation was less general, so that some groups of indigenous peoples remain, forming isolated nuclei. Others, like the Bororo, the Tereno, the Cadiueu, and the Bacairi, constitute minorities who have adopted Christianity and Brazilian culture and who live on the fringe of the region.

Among the first Europeans to enter the region were the Spanish Jesuits who mapped the river in the 17th century. In the 19th century, the first hydrographic survey of the river was made, followed in the 20th century by a more detailed hydrographic survey.

Navigation. The Paraguay is navigable from its mouth as far upstream as Cáceres, a total distance of about 1,400 miles. Several of its Brazilian tributaries are navigable, such as the Jaurú, the Sepotuba, the São Lourenço, and the Taquari. Ships with a draft of more than six feet, however, cannot go upstream beyond Corumbá. The major ports of the river are Corumbá, Cuiabá, and Pôrto Esperança in Brazil and Asunción in Paraguay.

At Pôrto Esperança, the Northwest Brazil Railway, from São Paulo on the Atlantic coast, crosses the river over the President Dutra Bridge (6,500 feet long) and runs north to Corumbá, where it links with the Brazil–Bolivia Railway at nearby Puerto Suárez, Bolivia.

Economic resources. The Brazilian section of the Paraguay Basin is sparsely peopled, with a population that becomes slightly more numerous toward the Río Apa in the south. Livestock raising for local consumption is the principal economic activity. Subsistence agriculture is carried on by traditional nonmechanized methods; attempts to establish settlers in the region have failed. A vegetable-extract industry is based on maté (Paraguayan tea), while condensed tannin, used in leather making, is extracted from the bark of the quebracho tree. Manganese deposits also are exploited. Transport and communications are poorly developed.

Prospects. Largely because of flooding, the Paraguayan section of the basin is similarly economically underdeveloped—even in the vicinity of Asunción and Concepción, where there are larger population concentrations. Since 1967 the Brazilian government and the United Nations Special Fund have been conducting jointly a hydrological study of the upper Paraguay with a view to developing the region. Another United Nations Survey, in which the Argentinian and Paraguayan governments are participating, is investigating navigational problems and the potential for river transport between Asunción, the Paraguayan capital, and Corrientes in Argentina.

(W.F.O.)

Paraíba

Paraíba, a primarily agricultural state of northeastern Brazil, is bounded by the states of Rio Grande do Norte on the north, Ceará on the west, and Pernambuco on the south and by the Atlantic Ocean on the east. Its area is 21,765 square miles (56,372 square kilometres), and its population early in the 1970s was over 2,400,000. Its chief river, the Paraíba, rises on the Pernambuco border and flows toward the sea past the state capital, João Pessoa, 11 miles from the port of Cabedelo. The only other large city is Campina Grande, a cotton-shipping centre farther inland.

Paraíba (or, as it is known in its older variants, Parahyba and Parahyba do Norte) is a name of Tupí Indian origin formed from the words *para* and *hiba,* meaning "arm of the river." The name of the capital was itself formerly Paraíba, but it was changed to honour the memory of a former governor, João Pessoa, a reformist and vice presidential candidate whose assassination in 1930 helped spark the revolution that brought Getúlio Vargas to national power in Brazil.

Historical background

Northeastern Brazil was the first part of the country to become wealthy when, in the 16th century, the Portuguese established the world's first large-scale sugarcane plantations there with African slave labour. Founded on August 5, 1585, as the captaincy of Itamaracá (a captaincy being a kind of fiefdom granted by the Portuguese crown), Paraíba shared in the sugarcane riches of the period; and, because sugar required large investments, cheap labour, and machinery, economic and political power fell into the hands of a few wealthy families. In the 18th century, cotton, Paraíba's chief product today, began to be produced and became a significant export.

Physical features and economy

Physiographically, Paraíba in the east has a narrow coastland of sandy beaches and dunes, off which deep-sea fishermen, or raftsmen (*jangadeiros*), ride the surf on tree-trunk rafts. There is no coastal plain; from this seaboard the land rises abruptly to coastal mesas (*taboleiros*), which, together with a few inland river valleys, provide the principal wealth of the state—from cotton, sugar, and sisal, together with tobacco, corn (maize), cacao, oiticica oil, and hides. These coastal areas, enjoying dependable rainfall, were once covered by dense tropical forests but from the early period of plantations were cleared away for crops and pastures. To the west, behind the zone of coastal mesas, a hilly upland known as the Bordorema Plateau occupies most of the central part of the state. Copper, tin, and a variety of rare minerals are mined on the plateau, though their economic importance is less than that of agriculture. The plateau is a semi-arid region once covered by deciduous, thorny scrub woodland called *caatinga.* In the *caatinga* there are only small islands of abundant rains and forests on the tops of the higher mountains. Generally, though, the area is dry not so much because of a lack of measurable rain as because of the unevenness of the rainfall and the poor drainage. Rain falls in summer and autumn and evaporates quickly or, partly because of man's excessive clearing of the land, runs off the impermeable ground, leaving sandy gullies and pebble-strewn stretches of dry earth. Life in the *caatinga* country thus depends on irrigation; even though the federal government has built a number of reservoirs, however, the nature of the hilly land permits irrigated crops to be raised only around the margins of the lakes behind the dams. Finally, Paraíba's farthest western section consists of broad plains—peneplains, or semi-arid flatlands, developed by erosion, with only a few tablelands called *chapadas* remaining from an earlier era.

In the 1960s Paraíba began to industrialize; two industrial parks in João Pessoa and Campina Grande housed some 30 industries, including clothing, agricultural machinery, cellulose, plastics, soaps, synthetic fibres, stoves, and rubber shoes. Two highways crosscut the state to connect it with the rest of Brazil; in the early 1970s power lines brought electrical energy from Pernambuco and distributed it among all the towns of Paraíba.

A university, the Universidade Federal da Paraíba, located in João Pessoa, with a faculty also in Campina Grande, was founded in 1955. (C.de P.L.)

Parallax, Astronomical

Parallax is the difference in direction of an object as seen by an observer from two different positions. In astronomy, the measurement of parallax is used directly to find the distance of a celestial body from the Earth (geocentric parallax) and from the Sun (heliocentric parallax). The two positions of the observer and the position of the object form a triangle; if the base line between the two observing points is known and the direction of the object as seen from each has been measured, the apex angle (the parallax) and the distance of the object from the observer

can be found simply. In the determination of celestial distance by parallax measurement, the base line is taken as long as possible in order to obtain the greatest precision. For the Sun and Moon, the base line is the distance between two widely separated points on the Earth; for all bodies outside the solar system, it is the axis of the Earth's orbit. The largest stellar parallax is 0.76″, for Alpha Centauri; the smallest that can be directly measured is about 25 times smaller, but indirect methods discussed below permit calculation of the parallax, inversely proportional to the distance, for more and more distant objects but also with more and more uncertainty.

LUNAR AND SOLAR PARALLAX

Definitions of lunar and solar parallaxes

The parallax of the Sun or Moon is defined as the difference in direction as seen from the observer and from the Earth's centre. In Figure 1, let O be the observer on the surface of the Earth, E the centre of the Earth, and M the position of the Moon; then the angle OME is the parallax. This varies with the altitude of the Moon. If the Moon is directly overhead, the parallax is zero, and parallax is greatest when the body is on the horizon. At an angular distance z from the zenith, Z, we find from the triangle OME that $\sin p = a/r \sin z$. When $z = 90°$, $\sin p = a/r$ and this value is called the horizontal parallax or, briefly, the parallax. For all bodies except the Moon, p is so small that it does not differ appreciably from $\sin p$, and it is usually expressed in angular measure. The definitions of lunar and solar parallax must be further refined because of the spheroidal figure of the Earth. The numerical values generally given are those of the equatorial horizontal parallax. The solar parallax is usually derived from measurements of the positions of other bodies of the solar system.

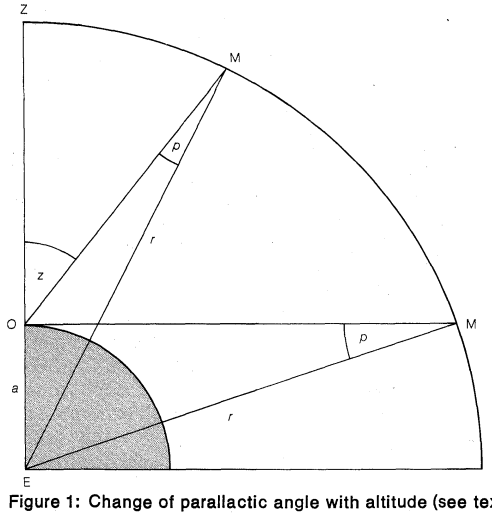

Figure 1: Change of parallactic angle with altitude (see text).

Lunar parallax. The first parallax determination was for the Moon, by far the nearest celestial body. Hipparchus (150 BC) determined the Moon's parallax to be 58′ for a distance of approximately 59 times the Earth's equatorial radius as compared with the modern value of 57′02.6″; that is, a mean value of 60.2 times. Lunar parallax is directly determined from observations (see Figure 2) made at two places, such as G, Greenwich, England, and C, the Cape of Good Hope, that are nearly on the same meridian. Angles z_1 and z_2 are observed, and other data are obtained from the latitudes of the observatories and the known size and shape of the Earth. In practice, stars near the Moon are observed also to eliminate uncertainties of refraction and instrumental errors. In this way Thomas Henderson obtained a value of 57′01.8″ for the Moon's equatorial horizontal parallax in 1837. From a series of observations of a small lunar crater (1905–10), the value 57′02.5″ was found.

Lunar landings in 1969 have brought at least the possibility of direct measurement of the Earth's equatorial angular diameter as seen from the Moon. This is slightly more than 2°, about twice the lunar horizontal equatorial parallax.

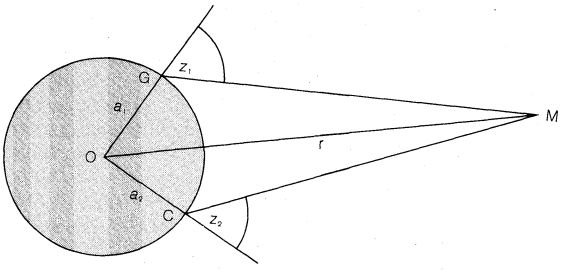

Figure 2: Measurement of parallax by observations from a northern and a southern observatory.

Another method rests on a comparison of the force of gravity at the Earth's surface with its value at the Moon. If M and m are the masses of the Earth and Moon, r the mean distance, P the sidereal period of revolution of the Moon about the Earth and k the constant of gravitation $k(M + m) = 4\pi^2 r^3/p^2$ where $\pi = 3.14$. Also, g, the value of gravity at the Earth's surface, determined accurately from pendulum observations, is equal to kM/a^2. Hence

$$\left(\frac{a}{r}\right)^3 = 4\pi^2 \frac{M}{M+m} \cdot \frac{a}{gP^2} \qquad (1)$$

As the quantities on the right-hand side are known with great accuracy, a/r is accurately determined as 57′2.7″.

Observations of lunar occultations, eclipses of stars by the Moon, also can be used to determine the lunar parallax. Observing the occultation of the same star from two or more stations may be compared to the Henderson method described above, because the same point on the Moon is observed from two or more geographic locations. In 1950 the lunar parallax was thus obtained from observing four occultations at nine stations in the United States, tying the lunar distance to the U.S. geodetic network. A value of 57′02.602″ for the parallax was obtained.

Radar measures of the distance from the Earth to the Moon have provided a recent value of the lunar parallax. Radar ranges have the advantage of being a direct distance measure, although the ranges are affected by variations in the surface topography of the Moon and require assumptions about the lunar radius and the centre of mass. The first systematic measurements were made at the U.S. Naval Research Laboratory by B.S. Yaplee, who obtained a value of 57′02.540″.

Adopted value of the lunar parallax

The International Astronomical Union, on the basis of existing observations, in 1964 adopted a value of 57′02.608″ for the lunar parallax corresponding to a mean distance of 384,400 kilometres.

Laser beams directed at retro-reflectors placed on the Moon by Apollo 11 astronauts in 1969 have led to lunar ranging with 15 centimetres precision and promise accuracies approaching 2 centimetres in the point to point measurement of the distance.

Solar parallax. *Trigonometrical methods.* In accordance with the law of gravitation, the relative distances of the planets from the Sun are known; and the distance of the Sun from the Earth can be taken as the unit of length. The measurement of the distance or parallax of any planet will determine the value of this unit. The smaller the distance of the planet from the Earth, the larger will be the parallactic displacements to be measured with a corresponding increase in accuracy of the determined parallax. The most favourable conditions are therefore provided by the observation, near the time of opposition, of planets approaching close to the Earth. The determination can be based either on simultaneous or nearly simultaneous observations from two different places on the Earth's surface, or on observations made after sunset and before sunrise at the same place, when the displacement of the place of observation produced by the rotation of the Earth provides the base line for the measurements.

The first reasonably accurate determination of the Sun's parallax was made in 1672 from observations of Mars at Cayenne, French Guiana, and Paris, from which a value of 9.5″ was obtained.

In 1877 Sir David Gill made an expedition to Ascension Island and observed the opposition of Mars, using a heliometer to measure the distance of the planet from neighbouring stars, making observations after sunset and before sunrise. A value of 8.78″ was deduced.

In 1898 the minor planet Eros was discovered; it has an orbit so elliptical that at its nearest approach Eros comes within about 24,000,000 km of the Earth. The opposition of 1900–01 (when the least distance was less than 50,000,000 km) was extensively observed and gave a value for the solar parallax of 8.804″. A more favourable opposition occurred in 1930–31 when the least distance was only 26,000,000 km. From photographic observations in both hemispheres, Sir Harold Spencer Jones derived a solar parallax of 8.790″ ± 0.001″. This parallax corresponds to a distance of 149,670,000 km.

Methods depending on velocity of light. The value of the velocity of light has been determined with very high precision and may be utilized in several different ways. A direct method is the converse of the procedure of Ole Rømer in the discovery of the velocity of light; *i.e.*, to use the light equation, or time taken by the light to reach us at the varying distances of Jupiter, but great accuracy is hardly obtainable in this way. A second method is by means of the constant of aberration, which gives the ratio of the velocity of the Earth in its orbit to the velocity of light. As aberration produces an annual term of amplitude 20.496″ in the positions of all stars, its amount has been determined in numerous ways. Observations made at Greenwich in the years 1911 to 1936 gave the value 20.489″ ± 0.003″ leading to the value 8.797″ ± 0.013″ for solar parallax. This method is not free from the suspicion of systematic error.

The velocities of stars toward or away from the Earth are determined from spectroscopic observations. By choosing times when the orbital motion of the Earth is carrying it toward or from a star, the velocity of the Earth in its orbit may be obtained. In this way the solar parallax was found from observations at the Cape of Good Hope to be 8.802″ ± 0.004″.

In a similar way, and with higher precision than by the method just mentioned, the solar parallax has been determined from radio wavelength velocity measurements of the 21-cm neutral hydrogen features of the four brightest radio sources in space. In this manner S.H. Knowles, at the U.S. Naval Research Laboratory, obtained in 1967 a solar parallax of 8.7940″ ± 0.0006″.

Radar measures of the distance from the Earth to Venus have provided the best determination of the solar parallax. By measuring the flight time of a radar pulse to Venus, the distance between the two planets can be obtained, allowing the determination of the unit distance between the Earth and the Sun.

Value of the astronomical unit

The present value for the radar astronomical unit is 149,598,000 km ± 200 km, corresponding to a solar parallax of 8.79414″ ± 0.00004″. The principal limitations of the method are its dependence on knowledge of the planetary orbits, the uncertainty in the value of the velocity of light, and the possibility of electromagnetic effects in the Earth-Venus plasma delaying the radar pulse.

Gravitational methods. In lunar theory there is a term of period one month known as the parallactic inequality. The coefficient of the term contains the ratio of the parallaxes of the Sun and Moon as a factor. The large size of this coefficient makes it of value. From the discussion of occultations of stars from 1672 to 1908, Spencer Jones found the value 125.023″ ± 0.033″ for this term giving for the solar parallax 8.796″ ± 0.004″.

The ratio of the combined mass of the Earth and the Moon to that of the Sun may be determined from the disturbing action of the Earth and Moon on the elliptic motion of the planets. The ratio of the Moon's mass to that of the Earth is 1/81.30, and thus the ratio of the Earth's mass to that of the Sun is found. In a manner similar to that described above for the Moon's parallax, the solar parallax is then derived.

From an exhaustive discussion of the perturbations of the minor planet Eros from 1926 to 1945, which included the favourable opposition in 1930–31, Eugene Rabe in 1945 made a determination of the solar parallax as 8.7984″ ± 0.0004″. In 1967, G. Zeck, using the same data as Rabe but including revised values of the coefficients of the reciprocal mass of the Earth–Moon system, obtained a value of 8.7944″ ± 0.0003″ in excellent agreement with the radar results.

At the General Assembly of the International Astronomical Union in 1964 the value 8.79405″ (8.794″) for the solar parallax was adopted, corresponding to an astronomical unit of 149,600,000 km.

STELLAR PARALLAX

The stars are too distant for any difference of position to be perceptible from two places on the Earth's surface; but as the Earth revolves at 149,600,000 km from the sun, stars are seen from widely different viewpoints during the year. The effect on their positions is called annual parallax, defined as the difference in position of a star as seen from the Earth and Sun. Its amount and direction vary with the time of year, and its maximum is a/r, where a is the radius of the Earth's orbit and r the distance of the star (Figure 3). The quantity is very small and never

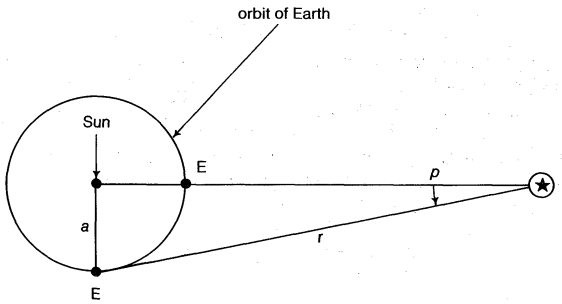

Figure 3: Stellar parallax.

reaches 1/206,265 in radians, or 1″ in sexagesimal measure. Many unsuccessful attempts to measure the parallax of a star were made after the acceptance of the Copernican system, including one by James Bradley, which led to the discovery of aberration (see LIGHT, ABERRATION OF), and one by Sir William Herschel, which led to the discovery of binary stars. The first successful results were announced by F.G.W. Struve in 1837 for Alpha Lyrae, by F.W. Bessel in 1838 for 61 Cygni, and by T. Henderson in 1839 for Alpha Centauri.

First parallax determinations

Direct measurement. Early measurements of stellar parallaxes were made visually with instruments of small size having apertures between 10 to 15 centimetres and focal lengths of the order of 1.5 to 3 metres. The observations were laborious and imprecise, and by the 20th century, parallaxes had been determined for only 72 stars.

The introduction of the photographic method by F. Schlesinger in 1903, using the large Yerkes Observatory refractor, considerably improved the accuracy of stellar parallaxes. In practice a few photographs are taken when the star is on the meridian shortly after sunset at one period (epoch) of the year and shortly before sunrise six months later. Since the star's positions also change because of its motion across the sky (proper motion), a minimum of three such sets of observations is necessary for obtaining the parallax. From approximately 25 photographs taken over five epochs, the parallax of a star usually is determined with an accuracy of about ± 0.010″ (probable error), even though the diameter of the photographic disk of the star is rarely less than 2.0″. The concerted effort of observatories in the Northern and Southern hemispheres resulted in the determination of parallaxes of about 6,000 stars by 1950. These include most of the stars brighter than magnitude 6.0 (roughly the limit of visibility with the naked eye) and many fainter stars whose comparative nearness is suggested by their relatively large annual motion in the plane of the sky (proper motion).

The results have been compiled in a Yale University publication, *General Catalogue of Trigonometric Stellar Parallaxes,* published in 1952.

The unit in which stellar distances are expressed by as-

tronomers, the parsec, is the distance of a star whose parallax is 1″. This is equal to 206,265 times the Earth's distance from the sun, or approximately 30,000,000,000,000 km. When p is measured in seconds of arc and the distance d in parsecs, the simple relation $d = 1/p$ holds. One parsec is equal to 3.26 light years.

The star with the largest known parallax, 0.76″, is Alpha Centauri. Fifty-eight separate stars are known within a distance of five parsecs from the Sun. These stars include the bright stars Alpha Centauri, Sirius, Procyon, and Altair, but the majority are faint telescopic objects.

Indirect measurement. For stars beyond a distance of 30 parsecs (parallactic angle .03″) the trigonometric method is in general not sufficiently accurate, and other methods must be used to determine their distances.

The parallax can be derived from the apparent magnitude of the star if there are any means of knowing the absolute magnitude of the star; *i.e.*, the magnitude the star would have at the standard distance of ten parsecs. For many stars a reasonable estimate can be made from their spectral types (see STAR) or their proper motions. The formula connecting the absolute magnitude, M, and the apparent magnitude, m, with parallax, p, is

$$M = m + 5 + 5 \log p \qquad (2)$$

expressing the condition that the light received from a star varies inversely as the square of the distance.

Some groups of stars, such as the Hyades cluster in Taurus and the Ursa Major cluster, have proper motions converging toward a definite point on the celestial sphere and are called moving clusters. The apparent convergence is due to the effect of perspective on parallel motions. Once the direction toward the convergent point is known, and the proper and radial motion of a member star is known, the parallax can be determined from the geometry.

Mean parallaxes. The solar system is moving through space with a velocity of 19.5 kilometres per second, carrying it four times the Earth's distance from the Sun in one year. This produces a general drift in the angular movement of the stars away from the apex or point in the sky to which the movement is directed. Were the stars at rest, this would give a ready means of determining their individual distances. As the stars are all moving, the method gives the average distance of a group of stars examined, on the assumption that their peculiar motions are eliminated. In this way the average, or mean, parallaxes of stars of successive apparent magnitudes, of different galactic latitudes, and of different spectral types are obtained. Thus the mean parallax of fifth magnitude stars (*i.e.*, of stars just visible to the naked eye) is 0.018″, and of the tenth magnitude stars (*i.e.*, of stars each giving about 1/100 of the light of a star of the fifth magnitude) is 0.0027″.

As spectroscopic observations have given the mean, peculiar velocities of stars of different types, the average proper motions perpendicular to the direction of the solar motion may also be used as a criterion of parallax. There is great diversity in the parallaxes of individual stars included in these mean values, but the means are useful for statistical studies.

Spectroscopic parallaxes. The spectra of nearly all stars can be grouped into a small number of classes, which form a continuous sequence depending on the effective (surface) temperatures of the stars. The Henry Draper (HD) classification, which is of this kind, uses the letters O–B–A–F–G–K–M to denote classes with temperatures descending from about 30,000° K for class O to about 2,500° K for class M. The HD system has been generally adopted, usually in combination with a decimal subdivision for refined work.

Empirical studies show that the spectra of the stars also include important clues to their true luminosities. A. Maury noticed that stars of the same spectral class often had marked differences in line sharpness; E. Hertzsprung found that the sharp-lined stars were intrinsically brighter than the broader-lined objects. In 1914 W.S. Adams and A. Kohlschütter established the spectroscopic differences between giant and dwarf stars of the same spectral type and laid the foundation for the determination of spectroscopic parallaxes. These differences, depending upon the intrinsic brightness of the star, allow an estimate of its absolute magnitude, and the parallax can then be deduced by means of the equation (2) given above. This method has been applied to most of the brighter stars in the Northern Hemisphere, using stars of known parallax as standards.

MK classification system

A two-dimensional classification system of stellar spectra, which has been universally adopted, has greatly improved the accuracy of spectroscopic parallaxes. The system, developed by W.W. Morgan, P.C. Keenan and E. Kellman and called the MK-system, assigns a precise system of Draper classes and five luminosity classes, using the Roman numerals I to V. The system divides the majority of stars into supergiants, bright giants, subgiants, and main sequence (dwarf) stars, depending upon their intrinsic brightness, as determined from the spectral lines most sensitive to this property. The luminosity classes are then calibrated in terms of absolute magnitude.

Photometric parallaxes. The colours of the stars can also be used as indicators of their absolute magnitude, as first shown by E. Hertzsprung in 1905 and 1907. A measure of the colour of a star is the difference in brightness, measured in magnitudes, in two selected wavelength bands of its spectrum. Initially the difference between the visual and the photographic magnitude of a star was defined as the colour of its light, and called its colour index. A comparison between the colour index and the spectral classification of a star has made it possible to develop a quantitative method of measuring a star's absolute magnitude. Several photometric systems have been developed. The most widely used system is the two-dimensional quantitative classification method developed by J.M. Johnson and W.W. Morgan, based upon photoelectric measurements in three wavelength bands in the ultraviolet, blue, and yellow (or visual) regions of the spectrum, hence called the *UBV* system. The system of the two colour indices *U-B* and *B-V* is calibrated in terms of spectral class and luminosity class on the MK-system, based upon a set of standard stars.

The relationship between the two indices in the *UBV* system and the absolute magnitudes for the main-sequence stars is of particular interest.

By means of this relationship, and the inverse square law, it is possible to determine the distances to galactic clusters from photoelectric observations of main-sequence stars in these clusters.

Dynamical parallaxes. If the relative orbit of a visual binary system is known, the following relation connects the combined mass, M, of the two stars expressed in the Sun's mass as unit; the orbital period, P, expressed in years, the semi-major axis of the relative orbit; a, expressed in seconds of arc; and the parallax p: $p = a/\sqrt[3]{MP^2}$. Both a and P are known, but not M; it will be noted that an error in the value of M gives rise to a much smaller error in p. Thus, for instance, increasing M by a factor of 8 only halves the value of p. The value of p obtained by assuming the combined mass to be equal to the mass of the Sun is called the hypothetical parallax.

In many visual pairs the complete orbit has not been observed. If s denotes the apparent distance in seconds of arc and ω the relative motion in seconds of arc per year, a hypothetical parallax can be derived from the formula $p = 0.418\sqrt[3]{s\,\omega^2}$.

By use of the relationship between mass and luminosity of a star, it is possible, knowing the spectral type of the star, to derive a correcting factor that will give a more accurate value of the parallax. Parallaxes so determined are called dynamical parallaxes. Details are given in *The Masses of the Stars* by H.N. Russell and Charlotte E. Moore (1940), which lists the dynamical parallaxes of 166 binaries with determined orbits and those of 2,363 pairs showing relative motion.

PARALLAXES OF DISTANT OBJECTS

Globular clusters. Globular clusters are star systems containing 100,000 to 1,000,000 stars and distinguishable by their spherical appearance. Their estimated number of 125 forms a spherical system centred on the Galaxy. The

globular clusters contain the so-called RR Lyrae-type variable stars that are easily recognizable and are known to have mean absolute magnitudes of 0.5. Also, it has been found from the nearer systems that the 25 brightest stars in a globular cluster have a mean absolute magnitude of − 0.8. These absolute magnitudes, compared with the observed apparent magnitudes, lead to the determination of the cluster distance or the parallax from the formula $M = m + 5 + 5 \log p$ above. Two other less reliable criteria are the assumptions that all globular clusters have the same absolute diameters and the same total integrated absolute magnitude; in both cases the distance scales are determined from the nearer globular clusters. Except for a few very distant ones, the globular clusters all lie within a distance of about 70,000 light years of the galactic centre.

Pulsars. The most recently discovered type of astronomical object is the pulsar, a rapidly pulsing cosmic radio source with a period of the order of a second. The pulsar with the shortest period so far discovered, 0.033 second, has been identified optically with a 17th-magnitude star near the centre of the Crab Nebula.

The pulsars discovered so far all appear to be too distant for direct parallax measurement. The Crab Nebula pulsar is assumed to be at the distance of the nebula itself, about 6,500 light years. Distances to some pulsars have been estimated from observations of the galactic neutral-hydrogen 21-centimetre line in absorption.

Galaxies. Galaxies are star systems similar to our own Galaxy and contain many millions of stars.

The determination of their distances depends upon a stepwise procedure, with errors increasing with the distances. For the nearest resolved galaxies (the Local Group), the distances can be determined from observations of the apparent magnitudes of the Cepheid variables, whose absolute magnitudes are related to their period of variation, as determined from distance calibration in our Galaxy. With the 200-inch Hale telescope it is possible to resolve such distance indicators in galaxies as the bright red and blue supergiant stars, novae, and supernovae up to a distance of 60,000,000 light years. Beyond that limit, the red shifts in the spectrum lines of the galaxies (see UNIVERSE, STRUCTURE AND PROPERTIES OF; UNIVERSE, ORIGIN AND EVOLUTION OF) appear to be related to their distances according to the expansion law of Edwin P. Hubble:

$$c\,\Delta\lambda/\lambda = H\,D \qquad (3)$$

where c is the velocity of light, $\Delta\lambda/\lambda$ the observed fractional wavelength shift, D the present distance, and H the Hubble constant, presently estimated to be of the order of 30 kilometres per second per million light years, but perhaps as low as 15 in the same units. The largest red shift observed for a galaxy is of the order of half that of the velocity of light leading to a distance of 5,000,000,000 light years.

Another important method to determine the distances to distant galaxies is based upon observations of the brightest member galaxy in a cluster of galaxies. These are giant elliptical galaxies with a constant order of brightness and can therefore be used as distance indicators.

Quasi-stellar sources. These objects, also called quasars or QSO's and discovered in 1963 as strong cosmic radio sources, were later identified as starlike objects with large red shifts.

The observed, proportional red shifts, $\Delta\lambda/\lambda$ (see equation 3), range from 0.06 to 2.35. The latter figure indicates a recession of 84 percent of the velocity of light if the exact formula for a Doppler shift, from relativity theory (see RELATIVITY), is applied. Red shifts of this magnitude, if interpreted cosmologically, lead to distances so vast and luminosities for these correspondingly so enormous that other possible causes for the red shift have been investigated, including gravitational or unknown physical effects.

The most recent studies, however, of similarities between Seyfert galaxies and QSO's have made it increasingly probable that the QSO red shifts are cosmological. The QSO's are possibly the youngest objects of an evolutionary sequence of galaxies (see QUASI-STELLAR SOURCES).

BIBLIOGRAPHY. An account of determining parallaxes has been treated historically by A. PANNEKOEK, *A History of Astronomy* (1961); updated results on the lunar parallax have been discussed by I. FISCHER in "The Distance of the Moon," *Bull. Geod.*, 71:37–63 (1964). For an evaluation of the accuracy of stellar parallaxes see K.A. STRAND (ed.), in *Basic Astronomical Data*, vol. 3 of *Stars and Stellar Systems*, ed. by G.P. KUIPER and B.M. MIDDLEHURST (1963). For information on the modern techniques in determining stellar parallaxes see P. VAN DE KAMP, *Principles of Astrometry* (1967); and K.A. STRAND, "The 61-inch Astrometric Reflector, Basic Design and Accuracy," in *Vistas in Astronomy*, vol. 8, ch. 2, pp. 9–15 (1966). Statistical parallaxes have also been described by P. van de Kamp, and by D. MIHALAS and P.M. ROUTLY, *Galactic Astronomy* (1967). Spectroscopic and photometric parallaxes have been covered in several chapters of *Basic Astronomical Data*. The distances of quasi-stellar sources are discussed by M. SCHMIDT in "Quasistellar Objects," *A. Rev. Astro. Astrophys.*, 7:527–552 (1969).

(K.A.S.)

Paraná

Paraná is one of the 22 states of the Federative Republic of Brazil. It is situated in the southern part of the country and is bounded to the east by the Atlantic Ocean, to the south by the state (*estado*) of Santa Catarina, to the southwest by Argentina, on the west by Paraguay, on the northwest by the state of Mato Grosso, and on the north and northeast by São Paulo state. Its area is 77,048 square miles (199,554 square kilometres), and in the 1970 census its population was reported to be 6,998,000. The capital of Paraná, named for the Paraná River (Rio Paraná), which forms its west and northwestern border, is Curitiba. Paraná plays an important role in the Brazilian economy because it is the country's principal coffee-producing state. (For associated physical features, see the articles IGUACU FALLS and PARANA RIVER.)

History. After a century of gradual penetration by bands of Spanish explorers from São Paulo and by Jesuit missionaries, the territory of the present state was occupied, to a large extent, by the forces of a Portuguese emissary, Gabriel de Lara, in the 1640s. Gold was discovered at several locations in the 17th century, and attracted settlers. Eventually recognized as belonging to Portugal's sphere of influence, not to Spain's, the territory was attached at first to the captaincy of São Paulo and subsequently to the province of the same name. Paraná became a separate province of the Brazilian Empire in 1853 and later a state of the Brazilian Republic in 1891.

The natural environment. *Physiography.* Paraná is divided into five zones, each running approximately northeast to southwest. Proceeding westward there is the coastal region, backed by the high mountain ranges of the Serra do Mar to the west; a series of three successive plateaus, each lower than the one before; and the Paraná River borderland. Less than 3 percent of the state's area is under 600 feet above sea level; it forms part of the Serra dos Orgãos. Pico Paraná, 6,305 feet (1,922 metres) high, is the highest point in the state.

The coastal region is fringed with dunes and mangrove swamps. Numerous streams, such as the Nhundiaquara and the Cubatão, flow down from the mountainous hinterland to the ocean. The Serro do Mar ranges consist of Precambrian rocks (from 570,000,000 to 4,000,000,000 years old), which in the east overlook the sea's deeper inroads into the coastline and in the west reach their greatest heights in the peaks of Capivarí Grande (5,499 feet, or 1,676 metres, high), Serra da Graciosa (6,193 feet, or 1,888 metres), Marumbí (4,999 feet, or 1,524 metres), and Prata (4,835 feet or 1,474 metres). The Serro do Mar forms a watershed between the coastal region and the first of the three plateaus.

The plateaus

The first plateau, which lies at a height of between 2,700 and 3,000 feet above sea level, is formed mainly of crystalline rock. To the north of Río Ribeira de Iguape collects its headwaters and forms the state border for a short distance before flowing west into the state of São Paulo. Curitiba is located in the south, at about 3,000 feet above sea level.

On the western side of the first plateau, a cuesta (an

escarpment with a steep slope on one side and a gentle slope on the other), rising to heights of from 3,500 to 3,800 feet, marks the beginning of the second plateau, which gradually falls to an average altitude of 2,200 to 2,500 feet.

A basaltic scarp with a maximum altitude of 3,800 feet rises at the western border of the second plateau, forming the eastern edge of the third plateau, which slopes westward and downward till it reaches the fringes of the Paraná River at altitudes of between 640 and 960 feet. This plateau is characterized by fertile red-coloured earth. Rivers subdivide it into four highland massifs (mountain masses)—the Araiporanga massif in the northeast, the Serra da Apucarana massif extending from the east to the northwest, the Campo Mourão massif in the west, and the Guarapuava massif in the south.

Three major rivers cross the second and third plateaus. Two of them are immediate tributaries of the Paraná. The first of these, the Río Iguaçu, which rises on the first plateau, is the great river of the southern quarter of the state and is about 820 miles long. The second is the Rio Ivaí, which rises in the Serra da Boa Esperança (a scarp of the third plateau) and flows northwestward and westward. The third great river is the Río Tibagi, which rises in the southeast of the second plateau and flows northward for 340 miles to join the Río Paranapanema tributary of the Paraná. The Paranapanema, itself, flows westward along the Paraná–São Paulo boundary for a considerable distance.

The Rio Paraná borderland

The Paraná River borderland, with its low altitudes and steep gullies, is dominated by rain forest; some tracts of wilderness occur to the south of Guaíra. On the Paraná, just below the confluence of the Río Piquiri (a river of the third plateau), a break in the level of the adjacent highlands is marked by the Guaíra Falls, or Salto das Sete Quedas, 375 feet or 114 metres high. The falls have a hydroelectric potential of 13,500,000 horsepower at the average rate of flow. The cataracts of the Río Iguaçu, which occur just before its junction with the Paraná, include the Santa Mariá Falls, which is 264 feet (or 80 metres) high and has a potential of 1,485,000 horsepower at an average rate of flow.

Climate. Paraná state, the northern region of which crosses the Tropic of Capricorn, has a climate influenced by the equatorial continental air mass in the summer and by the tropical Atlantic and Polar Antarctic air masses in the winter. Moderate heat prevails. Winters are dry in the northwest, while other parts receive adequate precipitation throughout the year; summers are hot in the lower altitudes and cooler—below 72° F (22° C)—at the higher levels. On the coast the annual mean temperature is 70° F (21° C) at Paranaguá. The rainfall reaches 81 inches annually, with the largest amounts falling in January and February. In the northwest, Londrina has a mean annual temperature of 71° F (22° C), and Umuarama one of 69° F (21° C). Heat and heavy rains occur there in the summer. On the eastern edge of the second plateau, however, mean annual temperatures are lower than 69° F (21° C), with an annual rainfall of 55 inches. More temperate conditions, with greater differentiation between the seasons, are found at Curitiba, where the average temperature is 61° F (16° C), as well as in the south, where at Guarapuava the temperature averages 64° F (18° C), with a rainfall of about 67 inches a year. The climate of the south has encouraged European immigration.

Vegetation. Dense tropical rain forest extends along certain tracts of the Atlantic coast and over the uplands into the Paraná River borderland. Notable species are *Ilex paraguariensis*, or Paraguay tea, the leaves of which are used for maté, a popular South American drink; the imbuia tree, the wood of which is highly esteemed for furniture making; and the Paraná pine, which covers much of the high ground. Some areas consist of treeless savanna—those around Curitiba, Campos Gerais, and Guarapuava, for example. There are also localized bushlands, which are found around Campo Mourão along the Río das Cinzas tributary of the Río Paranapanema in the northeast, and elsewhere.

Population. The population of the state, large areas of which were practically uninhabited as late as 1850, is largely of Portuguese-Brazilian descent. After the Portuguese, waves of other immigrants began to arrive as labourers and businessmen; these included Poles, Ukrainians, Italians, Germans, and Arabs. Some towns, such as Mallet, Prudentópolis, and Vera Guarani, represent comparatively early settlements; Carambeí (Castro), which was developed by Dutch dairy farmers, and Assaí, where Japanese labourers established themselves, were settled later.

The common language is Portuguese, and the principal religion is Roman Catholicism.

The principal towns

Of the state's 288 municipalities, about 20 have more than 50,000 inhabitants. Those with more than 100,000 include the capital, Curitiba (608,000 in 1970); Londrina and Maringá in the coffee-growing north; Ponta Grossa, the important railroad junction; Guarapuava; and Umuarama.

Administration and social conditions. The governor of the state is elected for a five-year term. The Legislative Assembly, elected for four years, seats 37 deputies. The state is represented by three senators and 25 deputies in the federal government. Public health is the responsibility of the state, which maintains a health centre in each town. The state has a separate welfare department, which deals with social assistance and is also responsible for slum clearance.

The state is responsible for primary and secondary education. Among the institutions of higher learning are the Universidade Federal do Paraná (Federal University of Paraná) and the Catholic university, both located in Curitiba.

Economy. *Agriculture and mining.* Paraná is one of the richer states of Brazil. Intensively developed plantations made Paraná Brazil's chief producer of coffee (1,645,000 tons in 1969), the most important centres for this crop being Umuarama, Rondon, and Londrina. Woodcutting for various industries produced 543,400,000 cubic feet of timber in 1967. Other important crops are maté (34,000 tons in 1967); cotton (471,000 tons), with Assaí as the major centre of production; and peanuts, with Umuarama as the major centre. There is also a notable output of ramie (a strong lustrous fibre capable of being spun or woven).

Agricultural products

Maize (almost 3,000,000 tons in 1969) is grown for the most part around Ivaiporã, Rondon, and Toledo; rice, manioc, potatoes, beans, oats, rye, barley, and wheat are cultivated quite widely, as are garlic, onions, and tomatoes; and there is a continually increasing output of soybeans. Sugarcane (2,220,000 tons in 1969) is grown mainly around Porecatu. Fruit production includes oranges, bananas, grapes, and pineapples.

Paraná's livestock herds have been much enlarged and improved with help from official agencies: in 1969 cattle numbered more than 4,000,000, pigs more than 8,000,000, sheep and horses less than 1,000,000. Dutch and East Indian (zebu) breeds of cattle have become acclimatized, notably around Guarapuava and Rondon. Yields in 1968 amounted to 129,400,000 gallons of milk, 2,200,000 tons of butter, and 550 tons of wool, mainly from the north and from the east.

In addition to a regular output of dolomite (a type of limestone or marble), lead, iron, talc, and lime, Paraná in 1969 produced 457,000 tons of coal from Venceslau Brás and 341,000 tons of cement from Rio Branco do Sul.

Transport. The main railroad in Brazil from São Paulo to the south traverses the eastern half of Paraná state; an important branch line from Ponta Grossa serves Curitiba and the Atlantic ports; other branch lines serve some of the major centres of the north and south. Highways link the state with São Paulo to the north and Santa Catarina to the south, and also link Curitiba with the hinterland. Since the rivers are generally navigable only for limited distances, the communications of the hinterland depend mainly on motor highways. Paranagua and Antonina are the chief seaports, and Curitiba and Londrina the chief airports.

Cultural life. Several towns have public libraries, that at Curitiba being the most important. The principal towns also have theatres and cinemas. The theatre at Guaíra, the best known in the state, is widely known in South America; its architecture is in the modern style.

Paraná River

The Paraná River, or Río Paraná (Paraná means "Father of Waters" in the Guaraní language) together with its tributaries forms the larger of the two river systems that drain into the Río de la Plata Estuary on the east coast of South America. Its basin of 1,081,000 square miles (2,800,000 square kilometres) includes the greater part of southeastern Brazil, Paraguay, eastern Bolivia, and northern Argentina. The third greatest river of the New World (after the Amazon and the Mississippi), and an important commercial waterway, the Paraná is 2,485 miles (3,998 kilometres) long. It extends from the confluence of the Grande and Paranaíba rivers in southern Brazil, and runs generally southwestward for most of its course, before turning southeastward to drain into the Río de la Plata. (For associated physical features, see IGUACU FALLS; PARAGUAY RIVER; and PLATA, RIO DE LA.)

The natural environment. *Physiography.* The Paraná begins in Brazil, at the confluence of the Grande and Paranaíba rivers, in latitude 20° S. The Grande rises in the Serra da Mantiqueira, part of the mountainous hinterland of Rio de Janeiro, and flows westward for approximately 800 miles; but its numerous waterfalls (such as the Cachoeira do Marimbondo [Marimbondo Falls], with a height of 72 feet) makes it of little use for navigation. The Paranaíba, which also has numerous waterfalls, is formed by many affluents, the northernmost headstream being the São Bartolomeu, which rises in the Serra dos Pirineus near Brasília.

The Alto Paraná and its tributaries

From its origin in the Grande–Paranaíba confluence to its junction, 1,740 miles downstream, with the Paraguay, the river is known as the Alto (Upper) Paraná. This upper course of the river receives many tributaries, some from the right, some from the left. The three most important of these tributaries, namely the Tietê, the Paranapanema, and the Iguaçu, all belong to the left bank, having their sources near the Atlantic coast of Brazil (the first two in São Paulo state, the last-named in Paraná state).

The Alto Paraná flows at first in a southwesterly direction down a deep cleavage in the ancient Brazilian massif (mountainous mass), the configuration of which determine its course. Just before it begins to run along the frontier between Brazil to the east and Paraguay to the west, the river has to cut through the Serra de Maracaju (or Cordillera de Mbaracayú), which has the effect of a dam; as the river approaches this natural barrier, it expands its bed into a lake two and a half miles wide and four and a half miles long. Pôrto Guaíra in Brazil stands on the southern shore of this lake. The river's passage through the mountains is marked by the Salto das Sete Quedas (Guaíra Falls), which have eight times the water volume of the Niagara River of North America. Below these falls the river flows through a narrow canyon, 196 feet wide and 328 feet deep, for a distance of two miles; farther south, however, its bed becomes wider again and the bordering heights lower, so that at Pôrto Mendes, on the left (Brazilian) bank 37 miles downstream from the falls, the canyon is 492 feet wide and only 295 feet deep.

The Río Iguaçu ("Great Water" in the Guaraní language) joins the Alto Paraná at the point where Brazil, Paraguay, and Argentina converge, 82 miles downstream from Pôrto Mendes. Rising in the Serra do Mar near the Brazilian city of Curitiba (for which reason it is sometimes called the Rio Grande de Curitiba), the Iguaçu has a course of 820 miles from east to west, during which some 70 waterfalls reduce its bed's altitude above sea level by a total of about 2,650 feet. While the Ñacunday Falls are 131 feet high, the spectacular Iguaçu Falls, on the frontier between Brazil and Argentina, 14 miles upstream from the Iguaçu–Alto Paraná confluence, have a height of 269 feet. One of the currents into which the river is divided descends from this height at a single drop, but most of the others make two successive drops of 98 feet each. The cataracts have a mean water volume of 59,400 cubic feet per second. The crescent-shaped edge over which the water pours is more than one and a half miles wide; thereafter, the river passes for several miles through the Garganta del Diablo, or Devil's Gorge—a canyon only 164 feet wide between heights varying from 65 to 328 feet. At its junction with the Alto Paraná, however, the Iguaçu is 820 feet wide and 40 feet deep.

From the Iguaçu confluence to its junction with the Paraguay River, the Alto Paraná continues as the frontier between Paraguay and Argentina. So long as it is flanked on the left (Argentinian) bank by the steep edge of the Sierra de Misiones, the river proceeds in a generally southwesterly direction, but twists repeatedly to and fro over a rocky bed studded with outcrops of melaphyre (a dark-coloured rock of porphyritic texture). At Posadas in Argentina, however, where it is about one and a half miles wide, it turns abruptly westward and begins a more amply meandering course, embracing islands of quite considerable size and punctuated so frequently by rapids and by outcrops of basalt that navigation is difficult. At the Apipé Rapids the river is only about four to six feet deep.

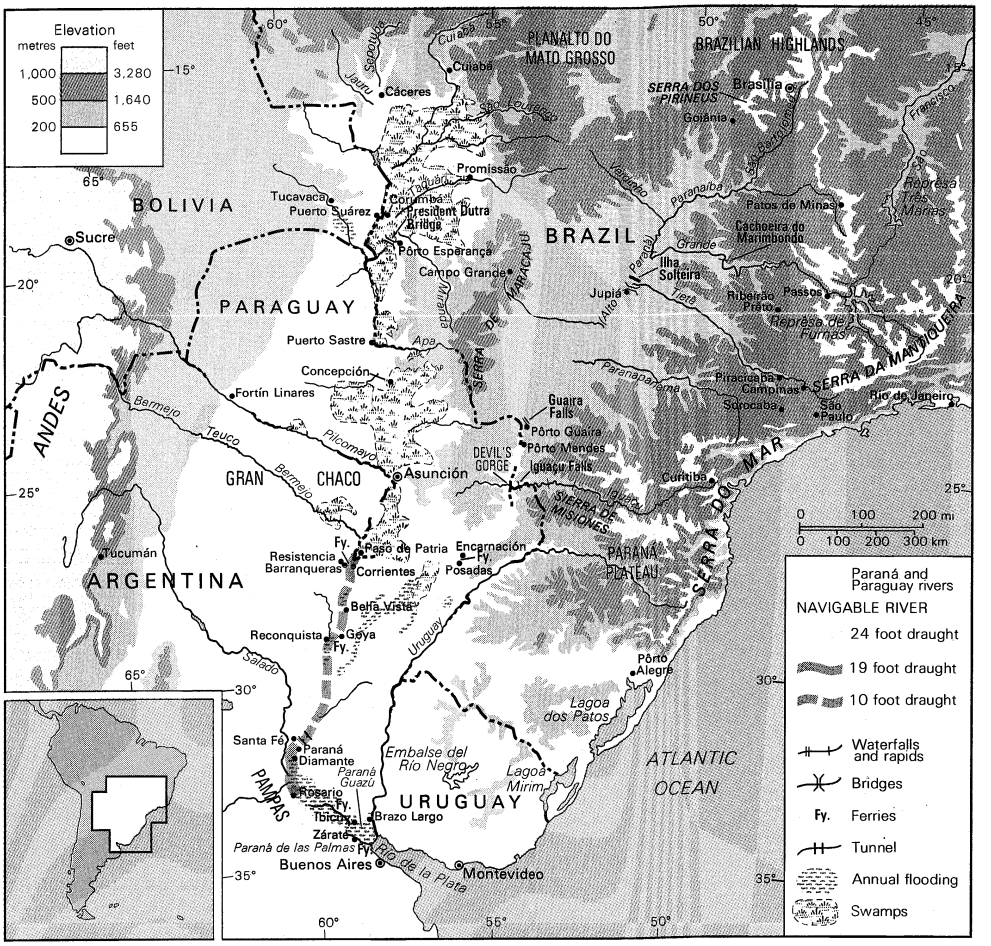
At Paso de Patria, on the right (Paraguayan) bank, at a place appropriately named Confluencia, the Paraná receives its greatest tributary, the Paraguay River, that joins it on the right bank. Thenceforth it flows on through only Argentinian territory.

The lower Paraná

The combined stream of the Paraná turns southward as it passes Corrientes. It now becomes a typical "plains-type" river, banked by its own alluvial deposits and having an extensive floodplain on its righthand side for the next stretch of its course, with tracts up to 24 miles wide liable to inundation. Its permanent bed, about two and a half miles wide at Corrientes, narrows to about 8,000 feet at Bella Vista, to about 7,000 feet at Santa Fé, and to about 6,000 feet at Rosario and is strewn throughout with chains of islands. Santa Fé, on the right bank opposite the port of Paraná, stands where the Paraná River receives its last considerable tributary, the Salado. Between Santa Fé and Rosario, however, the right bank begins to rise as the river skirts the edge of the undulating pampa (grassy plain), which flanks it all the way down to the delta, and reaches altitudes ranging from about 30 to 65 feet. The left bank, meanwhile, is always higher than the right but has to sustain the erosive action of the water, which becomes more and more turbid as great masses of earth are constantly falling into it; in the delta the main branch of the river runs along a break in the terrain, with its left bank consisting of a cliff about 75 feet high.

The delta

The delta of the Paraná has its apex as far north as Diamante, upstream from Rosario, where branches of the river begin to turn southeastward. About 11 miles wide at its upper end, the delta is 40 miles wide at its lower, where the separated branches flow into the Río de la Plata, about 200 miles from Diamante. With an area of 5,500 square miles in 1970, the delta—from calculations based on the maps made in 1818, 1912, and 1945—appears to be advancing at the rate of 230 feet per annum, the yearly volume of alluvial deposit being estimated at 165,000,000 tons. Within the delta the river divides again and again into distributary branches, the most important being the two last great channels, the Paraná Guazú and the Paraná de las Palmas. The islands of the delta, alluvial in origin, are low-lying and of varying size. Their shores and the outer fringes of the river have protective embankments covered with trees, but may nevertheless be submerged in times of flooding, when they present the appearance of flooded forests.



The Paraná and Paraguay river basins.

Hydrology. The velocity of the current of the Paraná changes frequently during the River's long course. For the Alto Paraná, the rate becomes slower wherever the bed widens (especially when a real lake is formed, as before the Guaíra Falls) and very much faster wherever the bed narrows (as in the canyon downstream from Guaíra). Farther downstream it slackens on its way to Posadas, but accelerates thereafter over a series of rapids and races. Downstream from Corrientes it becomes slower again, stabilizing its flow at a mean rate of two and a half miles per hour on the way to the Río de la Plata.

The volume of flow

The volume of the Paraná is, for practical purposes, correlated to the amount it receives from the Paraguay, which supplies about 25 percent of the total. Where it flows into the Río de la Plata, the river's overall mean volume is 610,740 cubic feet per second. While the highest recorded volume is 2,295,000 cubic feet per second (1905) and the lowest 86,400 (1945), averages are 1,587,600 for the seasonal high-water period and 218,700 for the low-water period.

High periods occur normally in the summer (November–February); low periods in August and September. An important factor is that the Alto Paraná and the Paraguay reach their maximum flow at different times. Whereas the mountainous basin of the Alto Paraná is drained so rapidly that water begins to rise at Corrientes in November, reaching its maximum height there in February, the swamps of the upper basin of the Paraguay retain precipitation so much longer that the Paraguay's high water does not reach Corrientes till May, reaching its maximum in June. Thus, levels on the lower Paraná begin to sink in March, then rise again from May, and sink again from July to September. Whenever both the Alto Paraná and the Paraguay reach their highest levels at the same time, the lower Paraná has to carry an exceptionally heavy volume of water—as it did in 1905, when the whole delta and much of the valley experienced heavy flooding.

Climate. The basin of the Upper Paraná has a hot and humid climate all the year round. The winters are dry, and the summers (lasting from November to April) are rainy, with precipitation averaging 60 inches a year but decreasing toward the west. Rainfall takes the form of drenching downpours often accompanied by hailstorms; the rainwater is drained away rapidly into the mainstream. The middle and lower basins have a subtropical climate of temperate humidity, with less plentiful rainfall (except in the Misiones Region) but without seasonal differences, the mean annual precipitation being 39 inches in the delta as opposed to 66 in Misiones. The climate along the Lower Paraná is very humid indeed and sometimes quite stifling in summer; the moist vapours become still thicker in the delta when the river brings down the torrential waters of the tropical basin.

Vegetation. The Brazilian section of the Alto Paraná forms the boundary between two natural zones: that of the forest to the east, that of the savanna (grassy parkland) to the west. Wood and maté tea leaves from the forest are shipped on the river, and the treeless savannah, with grasses and bushes, is good for cattle raising. On Argentina's section of the river, forest extends from the Misiones region to the vicinity of Corrientes; some forest trees, outside the zone of the forest proper, still occur in areas of woodland all the way downstream to the delta.

Animal life. The Paraná has a rich and varied animal life. Among its many edible fish, the pejerrey (a marine fish, silver in colour, with two darker bands on each side), the dorado (a brilliantly coloured river fish with a golden appearance), the surubi (a fish with a long rounded body, flattened at the nose), the pati (a large scaleless fish, which frequents deep and muddy waters), and the pacu (a large river fish with a flat body, almost as high as it is long) are worth mentioning; every year sportsmen visit the stretch of the river upstream from Corrientes to angle for dorado. Reptiles include the iguana lizard, two species of cayman (a crocodilian),

Species of fish

the water boa, the rattlesnake, the cross viper, and the yararáa (the most prevalent South American representative of the viper family). Frogs and toads are plentiful, as also are freshwater crabs. There are innumerable species of insects and spiders, and the islands are plagued by mosquitos. Herons, cormorants, storks, and game birds are also seen.

The human imprint. The peoples who live up and down the Paraná, be they fishermen, farmers, herdsmen, boatmen, pilots, shipwrights, or raftmakers, all share certain customs and interests in common arising from their environment, from their racial identity, and from the cultural underdevelopment of the region. Originally, almost the whole length of the river region was populated by Guaraní Indians. The Spaniards, for whom the river was the only practicable way of penetrating the interior of the country, mingled freely with the Guaraní. The cultural, physical, and linguistic characteristics of the present population reflect this mingling.

On the Alto Paraná most of the people are poor fishermen living in huts on the fringe of the forest, and depending on the river both for their food and for their transport: apart from their fishing, they profit from services rendered to passing river traffic.

On the lower Paraná the economy is more diversified, but still primitive. Apart from fishing and providing services, the islanders raise livestock; some crops, such as maize, manioc, tobacco, and fruit, are grown. Settlement of the adjacent country was begun from the banks of the river and the economy remains dependent on the river in the absence of a system of roads.

The most distinctive features of human life and activity on the Paraná can best be observed in the delta, where water transport is the sole means of movement for people and for goods alike. Such local fruit growing as there is contributes little to ecological development, as the fruit trees are not suited to the climate and are frequently damaged by floods; it would seem more rational to proceed with the afforestation of the islands liable to flooding with pine and other softwood species.

History of the mapping of the river. The Paraná, as has been said, was the principal thoroughfare used by the Spaniards for their conquest of the interior of this part of South America; Santa Fé and Corrientes in Argentina and Asunción in Paraguay (up the Paraguay River) were among the earlier settlements founded. The mapping of the river, however, preceded the European exploration of it: thanks to information obtained from Indians, Sebastián del Cano was able to include relatively accurate markings of the Paraná, Paraguay, and Uruguay rivers in the map of the estuary of the Río de la Plata that he drew in 1523—three years before Sebastian Cabot's expedition began sailing up the Paraná in 1526. Further cartographic work by agents of the Spanish crown was considerably supplemented by that of Jesuit missionaries, who first covered the whole basin of the Paraná in a series of 98 maps. In the second half of the 18th century, commissioners demarcating the frontiers between Spanish and Portuguese possessions produced a fresh quantity of maps. Of later cartographers, Félix de Azara (a Spanish naturalist and geographer sent to study the frontier question) and Martin de Moussy (a French doctor and naturalist, commissioned to undertake geographical work for the Argentinian government) are the most important.

Navigation. The Paraná is Argentina's and Paraguay's most important waterway. If one allows for changes in the water level, it is navigable from the Río de la Plata to Pôrto Mendes and, then, after a short interruption, from Pôrto Guaíra to Jupiá, just below the Salto do Urubupungá (Urubupungá Falls) in Brazil—that is to say, for a distance of 1,677 miles all the year round.

Thanks to regular dredging, seagoing vessels can go upstream for 250 miles from the Río de la Plata in any season of the year. Vessels with a draught of 24 feet can use the port of Rosario, those with a draught of 19 feet can reach the ports of Santa Fé and of Paraná, 100 miles upstream. Draughts, however, must not exceed 10 feet between Paraná and Corrientes or 4 feet between Corrientes and Pôrto Mendes, and navigation on the latter stretch is further hindered by rapids such as those of Apipé. Corrientes has consequently become a major port for transshipment. Between Pôrto Mendes and the Salto das Sete Quedas, navigation is interrupted, but transport over the 37 miles from Pôrto Mendes to Pôrto Guaíra is provided by a Brazilian railroad. From Pôrto Guaíra as has been said, the river is navigable again up to Jupiá.

River traffic

There are also regular boat services on the Lower Paraná and the Paraguay linking Buenos Aires on the Río de la Plata with Asunción in Paraguay. The Paraná carries 90 percent of Paraguayan exports and 30 percent of Argentinian exports.

Principal crossings. As the Paraná is a wide river, for much of its course, with a network of channels round its islands, it is difficult to establish permanent crossing points. The international railroad from Buenos Aires to Asunción crosses the river twice by means of ferries—between Zárate and Ibicuy in the delta and between Posadas and Encarnación on the southern frontier of Paraguay. Work is in progress for a Zárate–to–Brazo Largo road and rail link to replace the delta ferry by bridging the Paraná de las Palmas and the Paraná Guazú, and a tunnel one-and-a-half miles long under the river between Paraná and Santa Fé was built in 1969. An old-fashioned crossing by means of balsa rafts between Goya and Reconquista, upstream from the tunnel, is not of much importance; the busier crossing by the same means between Corrientes and Barranqueras is being replaced by a long bank-to-bank bridge 5,465 feet long. In Brazil the São Paulo–Corumbá railroad crosses the Alto Paraná at Jupiá, where the river is narrow.

Economic resources and prospects. The Paraná Basin is economically underexploited.

Whereas in Brazil the Alto Paraná and its affluents account for 50 percent of the river's hydroelectric potential, only those tributary rivers that rise near the comparatively populous zones of the Atlantic littoral are at present harnessed for power.

Hydroelectrical schemes

An agreement between Brazil and Paraguay for the building of one of the world's greatest dams at the Salto das Sete Quedas, due to start in 1973, was to bring some progress to a thinly populated and barely developed region. There is also a dam at Jupiá (with a capacity of 1,200,000 kilowatts [kW]), and another under construction at Ilha Solteira is to have a capacity of 3,200,000 kW. Meanwhile, Brazil makes use of the Paraná as a waterway for the transport of agricultural and forest products and for trade with neighbouring countries.

For Paraguay, pending exploitation of the river's hydroelectric potential, the Paraná is of major importance as a channel of access to the Atlantic. Paraguay's freedom of navigation on the thoroughfare is assured by its treaties with Argentina.

For Argentina, the Paraná supplies water both to the rice fields of the lands between the Paraná and the Uruguay River and to a number of cities and industrial towns; the river also provides a route for the transport not only of the river basin's produce—cereals, fruit, wood, tobacco, cotton, vegetable oils, and meat—but also of its imports—petroleum, coal, iron, and manufactured goods. The downstream traffic, however, is noticeably greater than the upstream. Argentina might also derive hydroelectric power from the Apipé Rapids and from the cataracts of the Iguaçu.

If the water power of the Paraná is to be exploited without any one country's profiting from it to the disadvantage of any other, multilateral agreements between the interested states must be concluded. The five states with river systems draining into the Río de la Plata—Argentina, Bolivia, Brazil, Paraguay, and Uruguay—in 1967 declared their readiness "to co-operate in the study and integrated development" of practical means, both by national and by international undertakings, of bringing progress to the region of which the Paraná River constitutes the major axis.

Parapsychological Phenomena, Theories of

Parapsychological phenomena of two types have been described. They may be cognitive, as in the case of clairvoyance, telepathy, or precognition and prophecy; here one person is believed to have acquired knowledge of facts, of other people's thoughts, or of future events, without the use of the ordinary sensory channels—hence the term extrasensory perception (ESP), often used to designate these phenomena. Alternatively, parapsychological phenomena may be physical in character: the fall of dice or the dealing of cards is thought to be influenced by a person's "willing" them to fall in a certain way; or objects are moved, often in a violent fashion, by "poltergeists"; the term psychokinesis (PK effect) is often used in this connection. The general term psi has become established to denote all kinds of parapsychological phenomena. Scientific interest in the subject is of relatively recent origin, but belief in the reality of such phenomena has been widespread since the earliest recorded times. Before the rise of modern science the causation of all complex physical phenomena was very poorly understood, and hence appeals to nonmaterial agencies (ghosts, devils, angels, sorcerers and witches, warlocks, demons, mythological beings) took the place of a causal, scientific explanation. Even so, there were widespread debates about the reality of phenomena that obviously transcended the bounds of everyday happenings, such as veridical prophecies, as by the oracle of Delphi, or the revival of the dead. The field was an obvious one for charlatans to enter, and even outstanding scientists believed in the possibility of astrological prediction—Johannes Kepler, for instance, earned his living by casting horoscopes.

Even now, the very existence of parapsychological phenomena is still very much in dispute, although societies for the study of psychic phenomena, made up of eminent scientists and laymen, have been in existence for almost a century and although the subject has been studied by many academic departments in British, continental, and American universities, often by scientists of outstanding ability. The discussion has sometimes assumed emotional overtones, unsuitable to scientific discipline, and outspoken but contradictory opinions are still frequently voiced. Believers and nonbelievers in psi may base their belief or disbelief on what they consider to be the scientific evidence, on their personal experiences, or on some larger system of attitudes and values into which ESP does or does not fit. When such extreme and contradictory views are widely held, it is almost certain that the evidence is not conclusive either way and that confident conclusions are unlikely to be supported by a survey of all the known facts.

Types of ESP

Extrasensory perception. While it is possible to differentiate various types of ESP, this differentiation is difficult to maintain experimentally because in any actual investigation the types tend to blend into each other. The terms used in this connection are as follows: (1) clairvoyance, defined as the perception of objects and events by paranormal means; (2) telepathy, defined as the perception of the thoughts and mental states (*e.g.*, emotions) of another person by paranormal means; (3) precognition, defined as the perception of some future event, which may be an act, a thought, or an emotion. Evidence regarding any of these three alleged types of phenomena may be by reference either to naturally occurring phenomena or to especially arranged experiments. The earlier investigations were almost exclusively of naturally occurring phenomena; it is only in the last half century that methods of experimental investigation have been elaborated.

Naturally occurring phenomena are quite diverse; they include prophetic dreams, other types of prophecy, thought reading, and allied events, which are frequently reported by normal and relatively disinterested people who are themselves surprised by the events that they recount. An unusual example is the case shown on British television of a middle-aged woman, Mrs. Rosemary Brown, who had had, as a girl, some slight musical tuition but had since then not practiced on the piano or shown any interest in music; upon the death of her husband she suddenly claimed that famous musicians like Beethoven, Brahms, and Schubert had appeared to her and were dictating musical scores to her, which she took down. When these were shown to outstanding experts they agreed that had these scores been found in some derelict attic they would have been regarded as genuine; each was not simply reasonable pastiche but genuinely expressive of what was known of the composer's emotion and personality. Apparently even highly trained musical experts could not easily (if at all) have produced work of this calibre; how a simple working-class woman with very little musical training could have done so is baffling, particularly as she was never taught composition. On the other hand, the idea of the ghosts of these Germanic musicians queuing up to dictate their recent compositions to this woman in English is not appealing. The facts are undisputed; no obvious explanation is forthcoming. As such, the story is typical of many others.

Much work has been devoted to professional mediums, persons (usually female) who make a profession of parapsychological experiences; Mrs. Leonore Piper, an American, Mrs. G.O. Leonard, British, and many others provided material for numerous books and articles. Most mediums claim to be controlled by someone in the spirit realm who speaks and sometimes acts through them; these controls enable them to perform acts of clairvoyance, telepathy, and precognition and to put people in touch with departed relatives and friends. Many mediums have been exposed as frauds; whether this makes it likely that those not so exposed were simply lucky or whether they were genuine as opposed to the fakes is still the topic of controversy. It seems unlikely that the study of naturally occurring phenomena, whether involving normal people or mediums, can throw much light on the scientific problem itself. Odd events happen all the time and every day; unless the probability of a particular event's happening can be calculated with some accuracy, it is not possible to adduce it as meaningful evidence in favour of the occurrence of ESP. Many people have reported dreaming that a particular horse won the Derby, only to find that in fact this horse did win. This does not prove that these dreams were veridical; it is equally important to know how many people dreamed about other horses winning the Derby that did not in fact win. Suppose that there are 20 runners; if 100 people report dreaming the correct winner but 1,900 dream the incorrect winner, then clearly there is nothing to be explained. Unfortunately the people who dream about the wrong horse seldom come forward so that this control figure is not known. Without such knowledge nothing can be said about the reported accurate dreams; they may be precognitive, but the evidence is completely inconclusive. The same argument may be applied to most of the claims made for ESP under naturally occurring conditions. The verdict must be that it is not proved.

Formal testing of ESP

The experimental arrangement of conditions such that proof for or against ESP can be obtained is difficult; best known in such investigations is the work of the American Joseph Banks Rhine and his many collaborators and students. Much of this was done with the so-called Zener cards; these bear one of five symbols (cross, star, circle, wave, rectangle), and 25 of them make up a pack. The experimenter may shuffle a pack and put it on the table, hidden from the subject, who then has to try to guess the order of the cards (clairvoyance), or the experimenter may look at each card in turn and ask the subject to guess at which card he is looking (telepathy, or possibly a mixture of telepathy and clairvoyance). There are many ways of varying this procedure, and millions upon millions of guesses or calls have been made in many different countries and by many different people. The advantage of this procedure is twofold: (1) a perfectly foolproof experimental design can be formulated that excludes completely the possibility of sensory knowledge of the cards and which is repeatable by other experimenters; and (2) the probability of any particular score (number of correct matchings of cards and calls) can be calculated and evaluated according to standard statistical formulae. When this is done

there emerge a number of studies where the probability of achieving the reported success in guessing correctly by chance is so small that it may be ruled out for all practical purposes. Such studies are typically of two kinds: (1) it is possible to find isolated individuals who score so highly that coincidence is ruled out; and (2) when groups of individuals are tested no one does *much* better than chance, but there is on balance a slight excess over chance that is statistically unlikely to happen. The most likely value in calling through a pack is five; this represents complete chance. If a talented person scores consistently around 15, he only has to run through three or four packs to make chance an unlikely explanation of his performance. If 100 people are tested and each person averages 5.5 correct calls, this means little for each person, but the excess adds up to a most unlikely total. Some of the most exceptionally high-scoring individuals have been discovered by the British mathematician S.G. Soal, but these are few and far between, and most work is done on large groups of subjects. Occasionally subjects persistently "recognize" not the card presented but that next to be presented; this may be evidence of precognition. Sometimes believers in ESP score positively, disbelievers negatively; when the scores are averaged they do not depart from chance, but, when they are separated according to the prior belief or disbelief of the subject in the existence of ESP, then scores significantly higher (for believers) and lower (for disbelievers) than chance are found. Many other detailed findings are reported in the experimental literature.

Criticism of ESP tests

Critics have argued about the experimental designs and about the statistical treatment. It seems clear that early experiments suffered from poor controls experimentally and that statistical analyses were subject to valid criticisms. This is not true of more recent work, and it would be difficult to fault either experimental design or statistical treatment of studies done in the last 20 years; the former has been investigated by the American Psychological Society, the latter by the American Statistical Society, and neither society made any adverse criticisms. Hence critics now tend either to throw doubt on the applicability of statistics to these phenomena or to claim that there was cheating on the part of the subject or the experimenter or both. No coherent and acceptable argument, in fact, has been put forward to show that statistical methods are not applicable to ESP work, although the possibility that negative conclusions will not be published and that positive ones will must make one doubtful about the exact values reported. But the reported values add up to such a large probability that every inhabitant of the earth would have to guess cards continually and unsuccessfully for many centuries in order to render the reported results insignificant. The question of cheating is not capable of rational discussion; no case of an academic ESP research worker actually cheating has in fact been reported, and the probability that this will happen on a large scale seems slight. Nevertheless, the possibility cannot be completely ruled out that there is a massive conspiracy on the part of a hundred or more respected psychologists and other research workers to defraud the public into believing in the reality of ESP phenomena that in reality do not exist, a conspiracy which in many cases would also have to involve their subjects. Why these people should expose themselves to the danger of being found out when their only reward for their work is that of being vilified is not made clear. If the hypothesis of widespread fraud is rejected, then the evidence for ESP is stronger than that for many tenuously supported psychological phenomena.

Psychokinesis. Here, too, there is need to distinguish between naturally occurring phenomena and experimentally arranged sessions. One of the best known of the former is the story of how D.D. Home, surrounded by witnesses, floated out of a third-story window and in at another—over 100 years ago. The event took place in Ashley House, London, in 1868, and was attested by Lord Adare, Lord Lindsay, and Captain Charles Wynne; possibly because of the high social standing of the witnesses this became the most famous of many such "proofs" of the existence of parapsychological faculties. Certainly many scientists and public men accepted it as such; yet when the original accounts are consulted little remains of the mystery. Home went to room A, leaving his companions in room B; he was then seen outside the window of room B and finally arrived in room C, which was on the other side of room B to room A. It would have been easy for him to have made arrangements beforehand to enable him to appear outside the window of the room containing his friends, either by way of a plank or by swinging from a rope attached to the roof and hanging over the parapet. Every stage magician nowadays does more difficult tricks before larger audiences and under conditions of much brighter illumination. Reports of this kind are inherently unreliable, and the uncontrolled conditions under which they are gathered make them impossible to evaluate properly. Most psychologists realize the weakness of their unaided senses in giving veridical reports of happenings, particularly when these occur quickly, unexpectedly, under conditions of poor illumination, or when powerful emotions are involved; all these factors are at work in the majority of reported psychokinetic phenomena and make reports on them, even by trained scientists, unreliable and useless. Investigators who cannot explain every trick performed by stage magicians should consider themselves barred from investigating alleged psi phenomena.

Poltergeists and children

Poltergeists constitute a particular class of agencies supposed to produce PK phenomena. What is reported to be happening is that furniture is moved, things are thrown, windows are broken and other, sometimes massive, rearrangements of physical objects take place. Loud noises may be made, but there is seldom any physical injury done to people. It is usually found that when poltergeists plague a house a young child is living in that house; whether poltergeists are attracted by children or whether children produce the phenomena is an open question. Efforts have been made to photograph such happenings and to record them by other means, but such efforts have not led to any notable results. It is still necessary to rely on personal reports, and for reasons already stated such reports are not on the whole acceptable as scientific evidence. Some serious students of the subject report themselves convinced that no natural explanation is possible of the phenomena they have observed, but this belief is not widely shared. What is curious is the similarity of the events in places separated by thousands of miles and by hundreds of years; the question remains of course whether this similarity is between different groups of poltergeists or between different children. No other PK effects are so extensive, involving such large expenditure of physical energy, as are the alleged efforts of the poltergeists, and it often seems quite beyond the capacity of children to produce such effects; some critics have suspected the help of more adult members of the family or even efforts made by outsiders having their own reasons for frightening the inhabitants.

Intermediate between accounts of poltergeist phenomena and serious experimental work on PK come studies like those done recently on Ted Serios, a poorly educated, hard drinking, ex-bellhop from Chicago who claimed to be able to produce "thoughtographs"—*i.e.*, images on film under conditions when the physical objects whose pictures appeared on the film were not present and where all physical interference with the film by Serios had been prevented. Serios was brought to scientific notice by a psychoanalyst who later accompanied him around the country and argued forcibly that this phenomenon (fitful though it was—successful pictures were only rarely produced, even in lengthy sessions) provided the breakthrough so often demanded of parapsychologists. Scientists were asked to investigate Serios; they tended to complain that they were not allowed to arrange conditions in such a way that trickery was excluded. Two expert photographers, who also had experience of amateur conjuring, investigated Serios and showed that his performance could be imitated under conditions similar to those under which he worked, without the help of occult forces; when they tried to search Serios in order to find evidence that he was using certain physical agents, they were prevented from doing so by the psychoanalyst, whom they also found ignorant of simple

laws of photography and "naïve" in many ways. It is clear from their account that such studies of Serios as have been reported are far from being scientifically impregnable and leave ample leeway for natural ways of producing the phenomena; as is often the case with mediums, here too the excuse for not allowing certain precautions to be taken is that the medium (or Serios in this case) would not like it and would be upset and thus would not be able to function properly. Even stage magicians do not have to invoke such excuses. When conditions were indeed more rigorous, as when the two photographers investigated Serios, no thoughtographs were produced.

Experimental investigation of PK effects

PK effects have been investigated experimentally by means of dice thrown at random, either by people or by mechanical means; the subject of the experiment "wills" the dice to come up high or low or with a particular face upwards, and as the probability of that happening is known, it is possible to calculate the departure from chance, very much as in the card guessing experiments. The results of much work in this field have been similar to those for ESP, but perhaps somewhat less impressive; positive results have been reported sufficiently often to make a strong case for the existence of PK, but the case is still not strong enough to convince all those who consider the evidence in favour of ESP sufficient. There is nothing wrong with the method, and, indeed, several ingenious variants on it have been used; it is simply that far fewer experiments have been done with it and that no really high-scoring subjects have yet appeared. Reliance therefore has to be placed on large numbers of marginally above-chance scoring subjects and the detailed statistical evaluation of their answers. Many gamblers, of course, are convinced of the reality of PK, as is shown in their obvious attempts to influence the fall of the dice by "willing"; this, of course, does not constitute evidence.

Theories of psi. Two difficulties with ESP and PK effects are that they (1) contradict orthodox scientific theories, notably those relating to space and time barriers, and (2) have not given rise to meaningful theories of their own. There are, indeed, so-called theories of psi, but these are mostly ad hoc and in any case do not serve the main function of a scientific theory, which is to guide research in a rigorous fashion. At best, these theories are philosophical attempts to integrate putative phenomena with some highly speculative version of "reality"; usually these theories are idealistic and opposed to materialistic views, and frequently theorists have simply used psi phenomena as a stick with which to beat materialists. Such theories as exist may be grouped as follows: (1) Physical theories. These suggest the existence of some as yet undiscovered form of energy that has produced the phenomena in question; such a form of energy would have to differ from all others by not obeying the inverse-square law, as simple physical distance does not seem to affect psi much. (According to the inverse-square law, one quantity varies inversely as the square of another; for example, light decreases by the square of its distance from its source.) (2) Field theories. These suggestions, not in essence very different from the physical theories, deal with fields of force in the language of Maxwell; essentially they fall into the same class and are subject to the same difficulties. (3) The collective unconscious. According to this theory, all minds participate in some mysterious, common, unconscious source of knowledge; and the unconscious portions of one mind may interact with those of another. Such an explanation raises more problems than it answers. The so-called theory of a subliminal self is perhaps little more than another variant of the collective unconscious type of theory; it encounters the same difficulties. (4) Projection hypothesis. This theory endows the mind with some powers that can act independently of the physical world but which can interact with it. Such a hypothesis simply asserts the facts and does little to explain them. Many other theories, similar in kind to those mentioned, could be cited, but none of them has gained wide acceptance, and none of them has been found useful by research workers. In short, the how and why of psi, assuming even that psi does in fact exist, are unknown.

One of the reasons for this state of affairs may be that research workers have been obsessed by the need to prove the existence of psi and have neglected the need to investigate the effects of altering conditions. How much and precisely in what way is psi influenced by distance, by changes in the physical properties of the cards or dice used, by electric screening, by drugs administered to subjects, by learning, by state of mind, by rewards and punishments for correct or incorrect guessing? Extroverts seem to do better than introverts. Are there other personality traits that predispose subjects to do well or poorly? Until a certain amount of knowledge is available on these points (and some efforts are now being made to study these factors) theorizing is perhaps premature. Simple repetition of experiments is unlikely to convert unbelievers and has thus a limited usefulness; what is needed are parametric experiments of the kind suggested above.

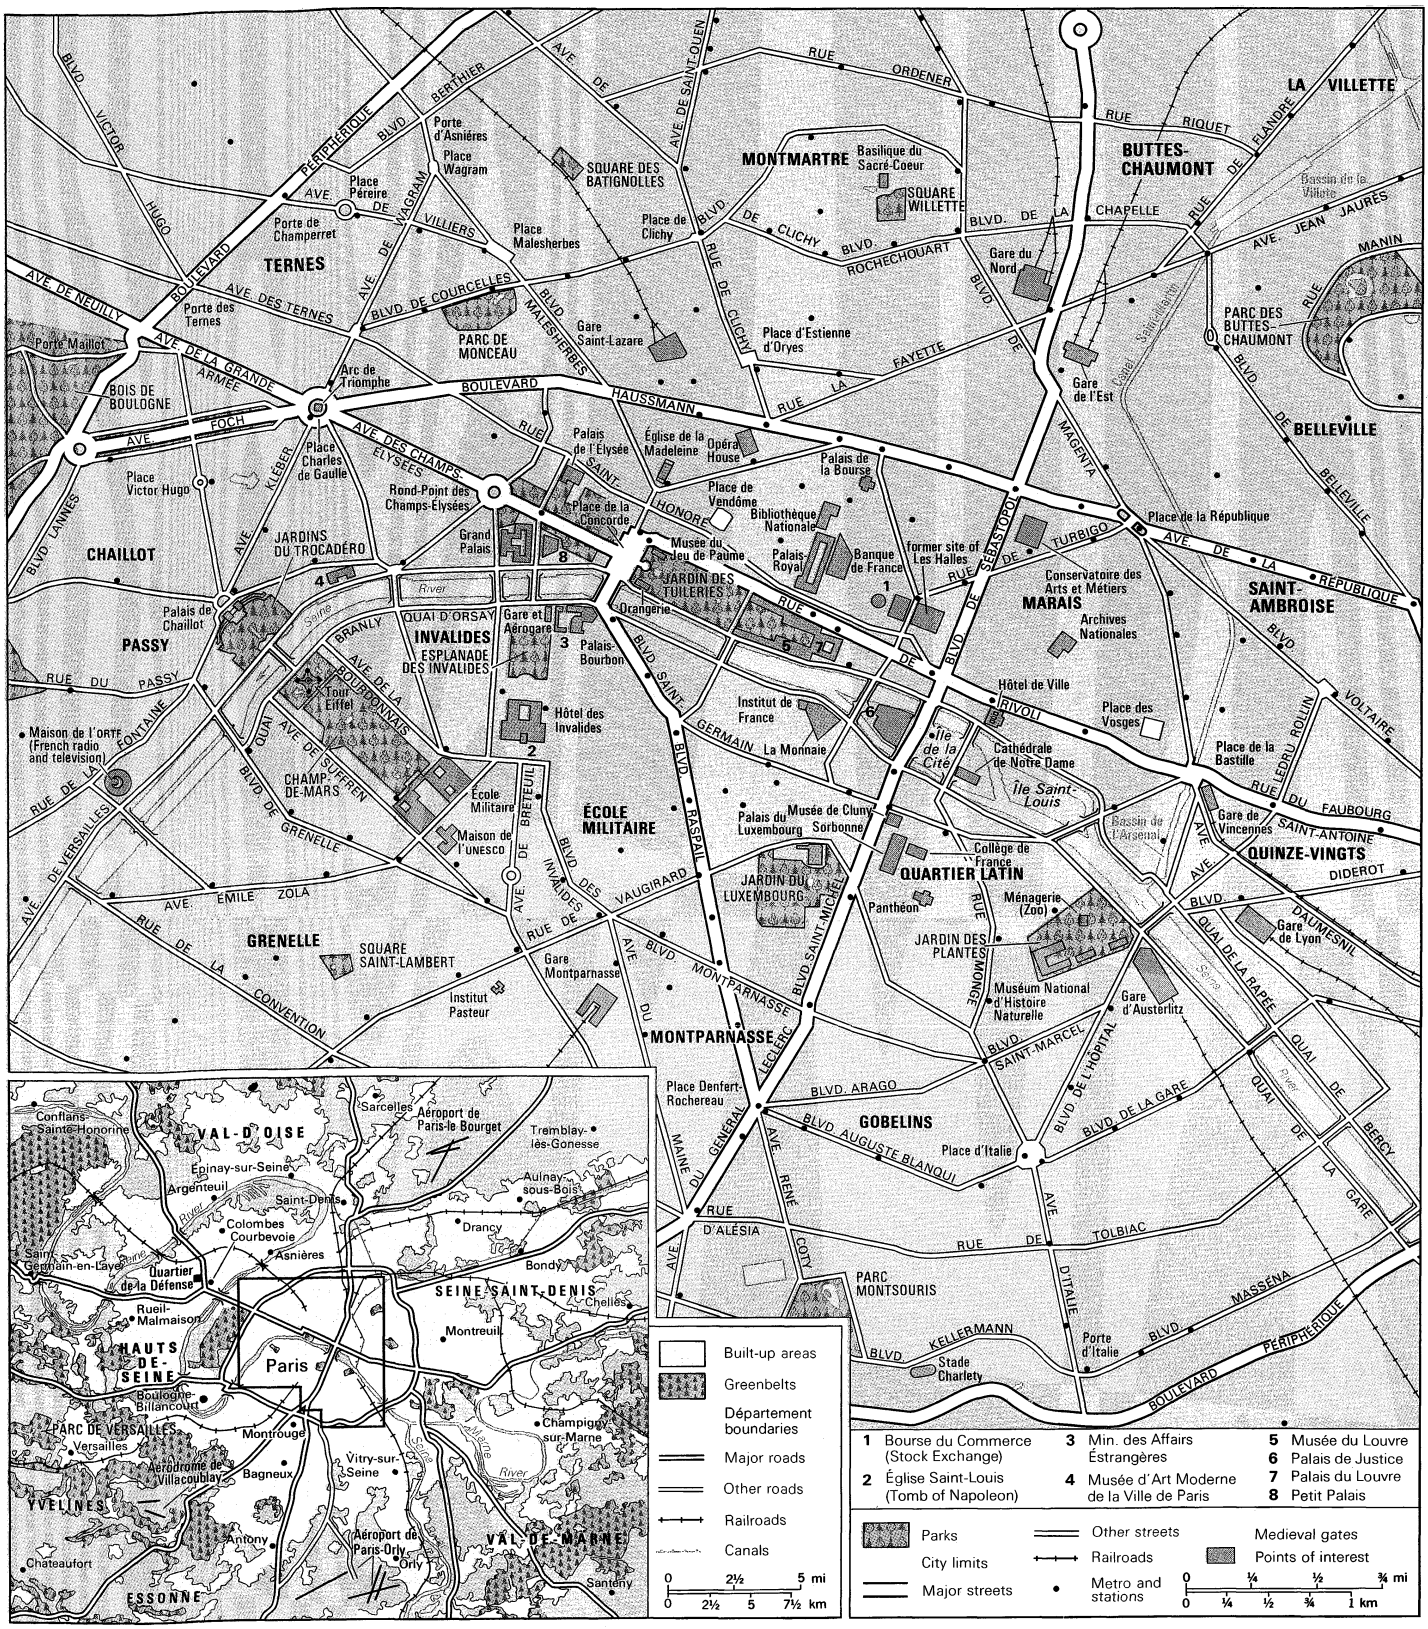
Can it be said that the existence of psi has been proved? No simple answer can be given because different people require different standards of proof. In the sense that there is much experimental evidence, collected under sound and well-controlled conditions and properly analyzed statistically, which supports such a view, the answer must be that ESP certainly, and PK probably, does exist. If to prove the existence of psi it is necessary to have replicable phenomena that can be demonstrated with certainty and that behave according to certain well-known laws, the answer must be in the negative. This position is not unusual in science, particularly in the initial phases of research; stellar parallax was searched for but not definitively discovered for over 200 years, although it formed an essential part of Copernicus' heliocentric theory. Neutrinos, having no charge and hardly any mass, were difficult to find and pin down; antimatter has a similar shadowy existence. The best summing-up might be that very intriguing demonstrations have been given that suggest the existence of something outside the purview of orthodox physics and psychology but that no one has yet succeeded in bringing this something under adequate experimental control. Until this is done and until the ways in which this something responds to changed experimental conditions are known, and until it is possible to formulate quantitative theories that are not simply question begging, it would be unwise to claim any more. Certainly it is premature to look for proof of immortality or survival of the soul in experiments with dice and playing cards; neither is it reasonable to claim that these findings undermine modern science. The relevance of these phenomena to either cannot reasonably be discussed until a better understanding of their nature has been achieved—assuming always that they exist at all and are not the product of imagination, cheating, and chance. The probability that these factors are responsible for all that has been discovered is small, but it cannot be completely excluded.

BIBLIOGRAPHY. A popular account and discussion of the field is given in H.J. EYSENCK, *Sense and Nonsense in Psychology* (1957). A thorough review of the experimental literature, written from a point of view favourable to parapsychology, is K.R. RAO, *Experimental Parapsychology* (1966). It is complemented by C.E.M. HANSEL, *ESP: A Scientific Evaluation* (1966), a highly critical review. J. EISENBUD writes on *The World of Ted Serios: Thoughtographic Studies of an Extraordinary Mind* (1967); D.B. EISENDRATH, JR., and C. REYNOLDS give a critical account of their study, "Spend an Amazing Weekend with the Amazing Ted Serios," *Popular Photography* (Oct. 1967). A theory of parapsychology and descriptions of some famous mediums are presented in C. MCGREERY, *Science, Philosophy and ESP* (1967). Two works by parapsychologists discussing their own experiments are J.B. RHINE and J.G. PRATT, *Parapsychology: Frontier Science of the Mind* (1957); and S.G. SOAL and F. BATEMAN, *Modern Experiments in Telepathy* (1954). A philosophical approach is taken by C.D. BROAD in *Lectures on Psychical Research* (1962).

(H.J.E.)

Paris

Founded on the island where a natural north–south highway crosses the Seine River, some 233 miles (375 kilometres) upstream from the river mouth on the English Channel, Paris, the largest city proper of continental Europe and the capital of France, is over 2,000 years old.



The city of Paris and (inset) its metropolitan area.

THE CHARACTER OF THE CITY

For hundreds and hundreds of years, by a process never successfully explained, Paris has radiated an enchantment irresistible to millions around the world, including hosts of people who would live and die without ever seeing the place. In the early 1970s, however, this magical Paris exists almost exclusively in the hearts of the believers.

"Gay Paree"—that honeycomb of breathtaking women and women-taking men, capital of the arts, of savoir-faire (literally, "knowing-how-to-do") and savoir-vivre ("knowing-how-to-live")—survives only in scattered, scanty fragments. It has shrunk to the dimensions of the same small international set who made it gay in the 16th century, together with an excursion version for the tourist. The naughtiness of French bedroom farces, French cabaret nudity, and French yellow-backed novels has long

The Parisian image

since been rendered innocuous by the "permissive society" of other rich Western nations. The celebrated *cocottes* have become anonymous call girls, the famous *maisons de tolérance* were closed down in 1948, and there remains nothing unique about commercial vice in Paris. Even the practice of amateur dalliance has altered: the traditional *cinq-à-sept* (literally "five-to-seven"; *i.e.*, those hours, intervening between office and home, used for mistress-visiting) has, it appears, been abandoned.

Once capital of the arts, Paris has become provincial. During the 19th century and halfway through the 20th, Paris was the great garden of creative talents. Painters and sculptors, writers, musicians, and dancers came from around the world, hoping to blossom in the incredibly propitious intellectual climate. By the 1970s, however, nothing was left but nostalgia.

Savoir-faire has become largely managerial-technological in orientation and is the specialty of other cities in other countries. Savoir-vivre, too, in Paris, as in every other major city, has been outstripped by the savoir-faire.

The city has always been quick to anger. In spite of the French *mission civilisatrice*, no year in Paris has passed without some manifestation of mass violence. In this, contemporary Paris remains unchanged.

As Parisians themselves took note in the late 1960s, when they launched a campaign in favour of courtesy, their traditional noninterference in the lives of others had degenerated into indifference. By the 1970s the satisfaction of a legitimate demand in Paris often required either bluster or wheedling, so that a perfectly banal transaction seemed to become a conspiracy or a contest.

The delivery boy seems to have ceased his whistling, and the house painter to have stopped his habitual singing. In the past, even though life was often brutal for the masses, the small people of Paris seemed as much under its spell as anyone else. The city seemed to bewitch even those whom it devoured, and songs celebrating the joys of Paris bubbled up from the most wretched of corners.

Despite this devotion, Parisians began leaving Paris after 1921, the year that the population attained the total of 2,906,500. By 1971 the number of inhabitants (2,550,000) was lower than it had been in 1895. As more dwellings disappeared to make room for offices, the remaining population was squeezed into smaller areas of the city. The very poorest—mostly immigrant labourers—could not cram themselves in at all: between 25,000 and 35,000 existed in miserable circumstances in the more than 150 shanty towns (*bidonvilles*) huddled outside the city limits. With more people leaving Paris, the notably morose fringe suburbs began to spread like a fungus onto the rolling richness of the Île de France.

A crisis of expansion

To save the surrounding spaces from speculator-induced blight and to save Paris itself from the epidemic ills of great cities in mid-20th century, the government went into action as early as 1958. Parisians and suburbanites were cynical. Previous government efforts in the suburbs had been catastrophic, resulting in barren collections of housing units intended to receive a maximum number of population units. In the city itself the last improvement of first magnitude had been made in 1898, when—after a nasty 26-year fight—tunnelling began for the métro (*chemin de fer métropolitain*, designated the *Nécropolitain* by its opponents).

Table 1: Paris, General Data

Geography					
Altitude			85–128 feet (26–128 m)

1872	1,851	1936	2,830	1968	2,591
			(Région Parisienne)	1968	9,251

THE REGION

This time, given the personal intervention of Pres. Charles de Gaulle and his successor, the action was carried through. The area in question was huge—2 percent of the entire national territory—comprising 4,600 square miles (12,000 square kilometres) and including 1,305 communes with a total (1971) population of 9,690,000. It was decided to develop the area as a region, rather than to extend the city limits to include the suburbs, thus forming overnight a grotesque city a dozen times its present size. The next move was to give the new region coherence, authority, and autonomy, enabling it to operate as an entity and to insure its survival against the hostility of often powerful interests. To accomplish this, new political units were devised, equipped with new administrative machinery, and provided with ample legal and financial powers.

By 1968 two of the three *départements* comprising the region had been divided into seven new units: Seine became Ville-de-Paris, Hauts-de-Seine, Seine-Saint-Denis, and Val-de-Marne; Seine-et-Oise was carved into Essone, Yvelines, and Val-d'Oise. Seine-et-Marne was left intact. There were now eight prefects, instead of a mere three, to administer the territory, and as a common financial tool they had the district of the Paris region, which was created as an autonomous public body in 1961. Deriving its considerable treasury from a special regional tax (the only such in France), it invests directly in local development projects through its administrative council of mayors and departmental councilmen.

Studies were undertaken to establish what the city and region contained, how it was being used or abused, and what solutions were possible to problems thus identified and defined. An early result was the discovery that previous estimates of future population were grievously short and that the region would probably have 14,000,000 to 16,000,000 inhabitants by the year 2000.

A master plan for the region was made public in 1965 and that for the city of Paris in 1968. The regional plan bore an epigraph from Seneca, "It is not because things are difficult that we do not dare: it is because we do not dare that they are difficult." The most daring proposal was for the establishment of five new cities on two axes of urbanization extending both north and south of Paris.

These are: to the southeast, Évry (with 300,000 inhabitants) and Melun-Sénart (400,000); to the east, Vallée de la Marne (500,000 inhabitants in four settlements separated by parkland); to the west-northwest, Cergy-Pointoise (100,000 inhabitants); and, finally, to the south-southwest, Trappes (with six major settlements and a total of 350,000 inhabitants). The architecture is bold, the siting combats monotony, and the planners start with the essentials of good small-town life, attempting to find the modern equivalents of the parish pump, the village green, and the old swimming hole. The regional plan makes sweeping provisions for green spaces, and the development of recreational, educational, and hospital facilities, while highway construction and public transport are also an integral part of the scheme.

The power of the *préfet*

In 1966, the Cabinet named a *préfet de la région parisienne*, who commanded powers greater than the 100 other prefects of France. To give him financial leverage, he also was named delegate general of the district. The eight departmental prefects take orders from him in matters relating to planning and development, and he has authority over the public transit system, the Port of Paris, the Public Housing Office, and other public bodies and teams of experts dealing with plans for expansion. Since ministers can initiate or quash projects, or withhold funds, he also was given a seat on the interministerial committees. By 1968 the new Paris began to emerge.

THE CITY PROPER

By the early 1970s the heart-shaped city, comprising the 20 *arrondissements* (wards) threaded by the Seine, had already lost its cherished skyline. Clutches of 30-story towers (and one of 56 stories) look down upon scores of 16-story apartment houses. The clover-leaf, the elevated highway, the underpass have arrived on the outskirts.

A progress report from one of the planning bodies expresses the hope that the inhabitant may "recognize the Paris he does not know through the Paris that he loves." The Paris that he loves was in large measure created from 1835 to 1870 by Baron Georges Haussmann, the iron-fisted *préfet de la Seine* under Napoleon III. There were cries of alarm from the more traditionally minded when he slashed the boulevards through the tangles of slums (at the same time beginning the modern sewer and water systems), gutted the Île de la Cité, the heart of Paris, rebuilt the ancient market of Les Halles and constructed the Opera House (Opéra), as well as adding four new Seine bridges and rebuilding three old ones. The modern architecture that bordered his new streets was for the most part pretentious and lugubrious, but Paris remained lovable for all that. Tomorrow's Paris—the master plan carries to the year 2000—will have harder work being seductive. The planners' announced aim is to make a Paris "more human" than the one given into their hands.

According to them, the old Paris is dying of "asphyxiation." They envisage not only a cure for the malady but also a restoration of some ease and elegance to Paris life.

The principal visible agent of suffocation is traffic, human and vehicular. Under its pressures rush hours last longer and start earlier in the slowing flow of 2,000,000 commuters. Of the travellers, 900,000 come in from the suburbs—334,000 by railway and about 271,000 by automobile—and the rest come by subway and bus from the immediately adjacent communities. In 1970 a report by the prefect of the region said that street traffic was approaching the "limit of the absurd."

The traffic crisis

The daily migration is further complicated by the fact that most of the city's employment opportunities lie west of the Cathedral of Notre-Dame, while the greater part of the population lives east of that central point. Four of the nine stations of the suburban railways are also west of the centre. Humanity thus sloshes back and forth across the city at peak hours like slurry in a basin. A frequent plaint scrawled on the métro walls is: "Métro-Boulot-Dodo" (*boulot* is slang for "work"; *dodo* is baby talk, like "beddy bye"); a free translation might chronicle the unhappy commuter's day as "Subway line, salt mine, beddy mine."

To reduce this daily abrasion, the authorities are promoting the establishment of new "poles of attraction" in the west of Paris, in the shape of skyscraper commercial complexes sited around the railway stations. New westward office construction is slowed through restriction of building permits and increased taxation. Outlying parking garages (*parkings de dissuasion*) have been constructed in the hope that drivers will leave their cars at the city gates. The first (east–west) leg of the regional subway system called the Réseau Express Régional (RER), a high-speed subway in its own deep-level tunnel, was put into service from the suburbs in 1970. More métro lines —and they are all being modernized—have been extended into abutting municipalities.

The last of the much-romanticized open-platform buses made their final run in 1970. While London was experimenting with small single-deck red buses, manned only by the driver, Paris was experimenting with big green double-deckers, which require the services of conductors as well. The number of miles of traffic lanes for the exclusive use of buses and taxis was tripled in 1971 to get the average speed above seven miles (ten kilometres) per hour.

All projects to run express highways through the city have been vetoed by the Paris municipal council. An expressway (built 1961–72) encircles the city, following the line of the old ramparts. Other highways will mesh the Paris region in a spider-web design centred on the capital.

For in-town parking, many leafy Paris squares have been dug up, scooped out, and re-covered, often with disastrous defoliatory results, although public outcry at the start of the 1970s forced the city to abandon plans to eviscerate some favourite neighbourhood squares. The giant new buildings, however, are equipped for underground parking.

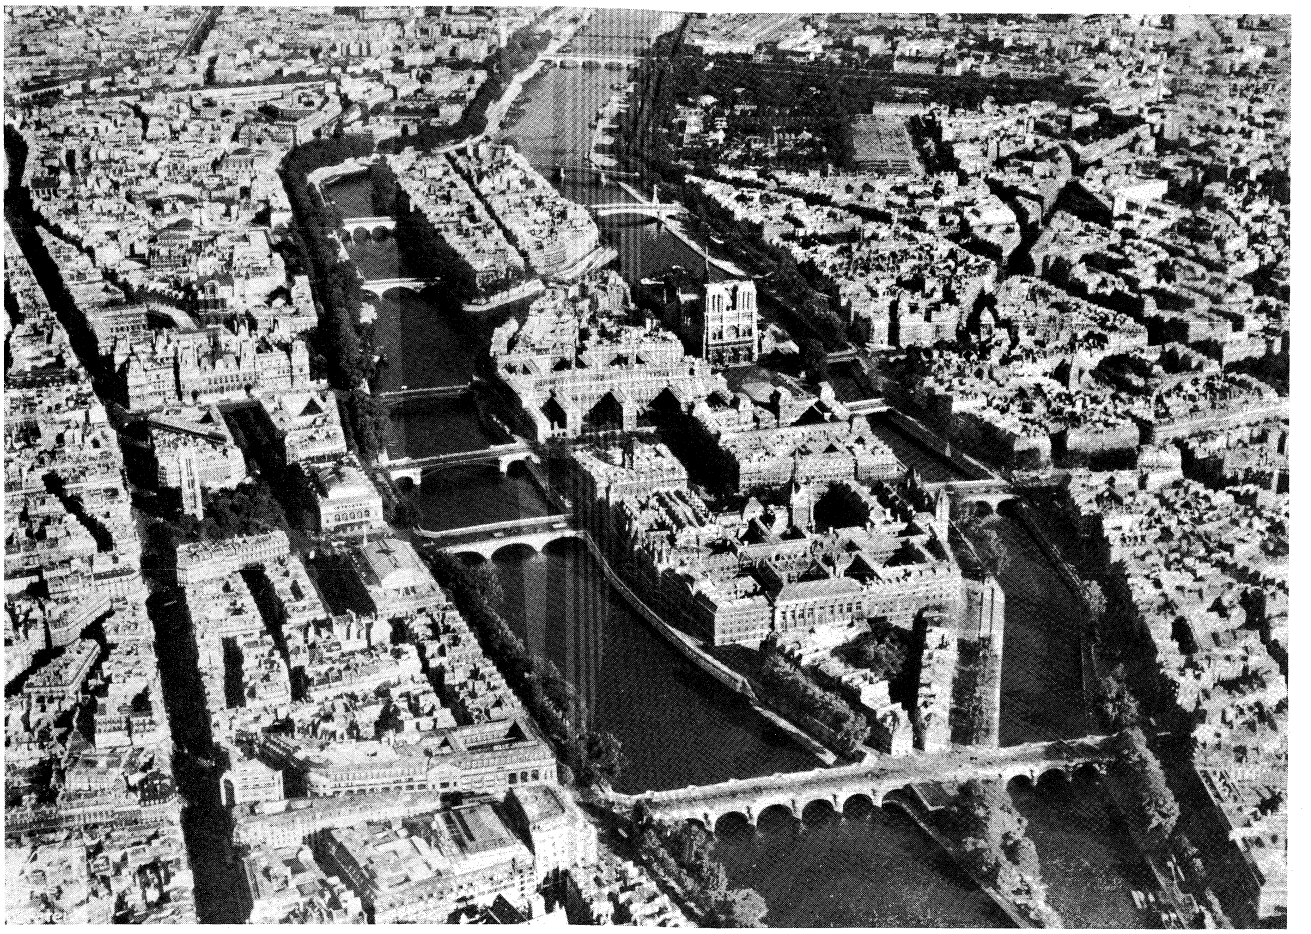
The plan for the year 2000 provides for more of everything the city needs: hospitals, schools, housing, day nurseries, additional centres of sport and leisure, and more green space. (For related information see FRANCE; FRANCE, HISTORY OF; and SEINE RIVER.)

THE HEART OF THE CITY

Paris and its river. Paris is small; no corner is farther than six miles from the square in front of Notre-Dame Cathedral. The city has a total area of 41 square miles (105 square kilometres), if the two big parks at either extremity are included, and 34 square miles without them. The city occupies a bowl hollowed out by the Seine in its prehistoric vigour, and the surrounding heights have been respected as the limits of the city. The river arches through the centre of town, visiting 10 of the 20 *arrondissements*. Entering the city at the southeast corner, it arcs northward and bends out of Paris at the southwest corner. As a result, what starts out as the stream's east bank becomes its north bank and ends as the west bank, and the Parisians therefore adopted the simple, unchanging designation of Right and Left Bank (when facing downstream). These terms are not much used in conversation, as specific places are usually indicated by *arrondissement* (*e.g.*, *quinzième*) or by *quartier* (*e.g.*, *Observatoire*).

The river bank

At water level, some 30 feet below street level, the river is bordered—at least on those portions not transformed into expressways—by cobbled quays graced with trees and shrubs. From street level another line of trees leans toward the water. Between the two levels, the retaining walls, usually made of massive stone blocks, are decorated with the great iron rings of a past age's commerce and sometimes pierced by mysterious openings (water gates for old palaces or inspection ports for subways, sewers,



Île de la Cité and Île Saint-Louis, on the Seine River at the heart of Paris.
By courtesy of the French Government Tourist Office

and underpasses). Here and there the wall is shawled in ivy.

The old buildings, the riverboats, the changes of colour reflected by the water, the gardens, and the 32 bridges (many of them handsome) compose one of the world's grandest, yet most endearing cityscapes. Along the river are two of the great set pieces of urban spectacle in the contemporary world. The first sweeps down from the Palais de Chaillot on the Right Bank, crosses the river to the Eiffel Tower, and continues through the gardens of the Champ-de-Mars to the 18th-century École Militaire; the other begins at the Seine and marches up a broad esplanade to the golden dome of the Invalides.

The Palais de Chaillot dates from the International Exposition of 1937 and is a period piece of between wars, timid-modern style. It replaces a structure of tepid Moorish sympathies left over from the 1878 International Exposition. Earlier in the 19th century, after demolition of the Convent of the Visitation, the top of this 230-foot (65-metre) hill had been levelled for the construction of a palace (never built) for the King of Rome, son of the emperor Napoleon.

The Palais is made of two separate pavilions, each of which sprouts a curved wing. The Musée de l'Homme (Museum of Man), the Musée de la Marine, and the Musée des Monuments Français (Museum of French Monuments) are located there. Under the terrace which separates the two sections are two theatres, the variable-formation (1,500 to 3,000 seats) National Popular Theatre (TNP) and a small hall that serves as one of the two cinemas of the National Film Library (Cinémathèque Française).

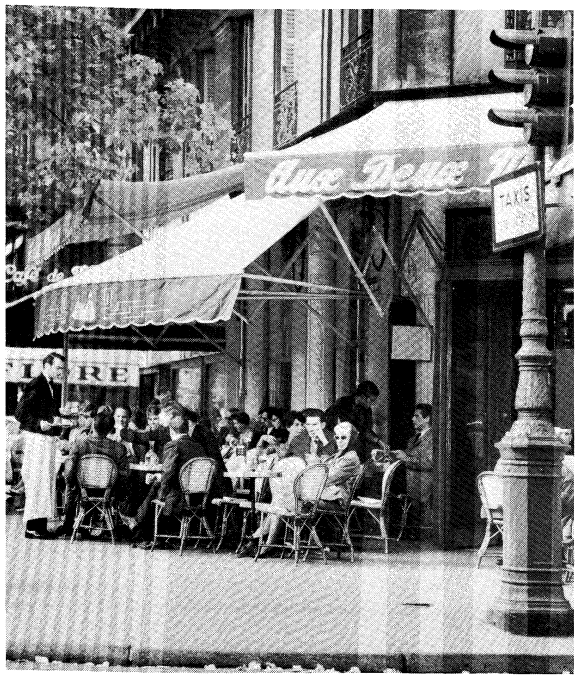
The statue-guarded terrace gives a splendid view across Paris and makes an enduring travel-poster setting for photographs of visitors and fashion models. The hill descending to the river has been made into a terraced park, the centre of which is adance with mighty fountains, cascades, and pools. The Paris aquarium is in a grotto to the left.

One of the enchantments of the view—and some others in Paris—is that it has all the qualities of a *trompe-l'oeil* (literally, "deceive the eye") painting into which, extraordinarily, one can walk. From the bottom of the hill the five-arched Pont d'Iéna springs across the river. It was built for Napoleon I in 1814, although the imperial "N's" with which it is decorated were in fact put there by Napoleon III. After the bridge comes the unclad metal truss tower of Gustave Eiffel. It was built for the International Exposition of 1889, against the strident opposition of national figures who believed it to be unsafe or ugly, or both. When the exposition concession expired in 1909, demolition of the 984-foot (300-metre) tower was averted by demonstration of its value as an antenna for the newly developed radio. Additions made for television transmission have added 56 feet (20.75 metres) to the height. From the topmost of the three platforms the view extends for 50 miles—when air pollution is low and the sun is near the horizon.

The Eiffel Tower

From the two-acre base of the tower the Champ-de-Mars stretches inland to the École Militaire (built 1769–72 and still used by the École Supérieure de Guerre [War College]), where the 15-year-old cadet Napoleon Bonaparte was enrolled in 1784. Originally the school's parade ground, the field was the scene of two vast revolutionary rallies, that of the Federation (1790) and that of the Supreme Being (1794). From 1798 there were annual national expositions of crafts and manufactures, followed by world's fairs between 1855 and 1900. The International Exposition of 1937 spread around it, for between 1908 and 1928 the field had been made into a formal park.

Behind the École Militaire, which was designed by Gabriel, architect of the Place de la Concorde, stands the Y-shaped headquarters of the United Nations Educa-



(Left) Aux Deux Magots, a famous Paris sidewalk cafe. (Right) The fountain and obelisk in the Place de la Concorde.
(Left) Roger-Viollet, (right) Josef Muench

tional, Scientific, and Cultural Organization. The building, erected in 1958, was designed by an international trio of architects and decorated by artists of member nations.

The Invalides. Just one street away to the northeast is the Hôtel des Invalides, founded by Louis XIV to shelter 7,000 aged or crippled former soldiers. The enormous range of buildings was completed in five years, (1671–76). The gold-plated dome (six kilograms of gold leaf were involved) that rises above the hospital buildings belongs to the Church of Saint-Louis (1675–1706), designed by Jules Hardouin-Mansart. The architect employed a style known in France as "Jesuit," since it derives from the Jesuits' first church in Rome, built in 1568. The churches of the Académie Française (French Academy), the Val-de-Grâce Hospital, the Sorbonne, as well as three others in Paris, all of the 17th century, followed this style. By a freer use of the classical elements, the French made it something recognizably Parisian.

Napoleon's tomb

In the chapels of Saint-Louis are the tombs of Napoleon's brothers Joseph and Jérôme, of his son (whose body was returned from Vienna in 1940 by Adolf Hitler), and of the marshals of France. Immediately beneath the cupola is a red porphyry sarcophagus that covers the six coffins enclosing the body of Napoleon I, which was returned from Saint-Helena in 1840 through the efforts of King Louis-Philippe. Napoleon's uniforms, personal arms, and death bed are displayed in the rich Musée de l'Armée (Army Museum) at the front of the Invalides. Fewer than 100 pensioners now live at the hospital, which is used as a paraplegic centre.

The grassy, tree-lined Esplanade des Invalides (810 feet wide) slopes gently for 1,470 feet to the Quai d'Orsay and the Pont Alexandre III. The first stone for the bridge was laid in 1897 by Alexander's son, Tsar Nicholas II. A steel span with upper works of stone, it embodies the "Gay Nineties" (*la Belle Époque*), solid, sumptuous, and luxuriant, with its pomposity mocked by its own gaiety. Finished in time for the International Exposition of 1900, it leads to two faded souvenirs of that year's fair, the Grand Palais and the Petit Palais. Both are still used for seasonal painting salons and major visiting art exhibits, and the Grand Palais also shelters overflow classes from the Sorbonne and a science museum.

For millions around the world the name "Paris" connotes an image of a mile-long stretch of the Seine between the Pont du Carrousel and the Pont Sully. The city's most celebrated bridge, its most famous museum, its most admired Gothic churches are all found here in the ancient heart of the capital. Here, too, are the quayside bookstalls, the bird and flower markets, and the sempiternal anglers of the Seine.

The Louvre. The Vikings camped on this spot on the Right Bank in their unsuccessful siege of Paris in 885, and in 1220 King Philippe-Auguste selected it to plant a square crusader's castle before the new city wall, as key to the western defenses. Through subsequent centuries and the attentions of 11 monarchs, the château-fort was made into one of the world's biggest palaces, completed in 1852. The last of the Gothic portions disappeared only in 1673. From the original square, two galleries extend westward for 1,640 feet, one along the river, the other along the rue de Rivoli. Only 19 years after the huge oblong was finally completed, its western face, the Tuileries Palace (begun 1563), was destroyed by the insurrectionists of the Commune, in 1871.

The Cour Carée

Two of the facades of the original palace square, the Cour Carée, have considerable architectural importance and were strong influences on the development of French styles. Pierre Lescot began his inner courtyard facade in 1546, adapting the Renaissance rhythms and orders he had observed in Italy, and adding purely French decoration to the classical motifs. Claude Perrault, also distinguished as an anatomist and court physician, created a masterpiece for the outer east face of the palace in 1673. It, too, employs classic elements—coupled columns and a pediment—but they are handled with a grace and originality that makes it perfect for the late reign of the Sun King.

For so many centuries the seat of French power, the Louvre of the early 1970s still contains some national administrative offices in the rue de Rivoli gallery, where a separate museum—the Musée des Arts Décoratifs—is also housed. The gallery is an awkward 19th-century counterfeit of the riverside arm (Galerie du Bord de l'Eau) built in the last half of the 16th century. The Louvre, known formally as the Musée du Louvre, occupies the older gallery, the palace around the Cour Carée, and, at the far end of the Tuileries Garden, the galleries of the Orangerie and the Musée du Jeu de Paume. Among the treasures of the museum—one of the world's greatest—are the Victory of Samothrace, the Venus de Milo, and the Mona Lisa. The enormous collections contain works from 7 BC to the mid-19th century, with a

huge cultural and geographic spread. The École du Louvre, in addition to its regular university-level curricula, offers free public evening classes in art history.

Crossing from the Louvre to the Institut, the Pont des Arts is one of the most charming of all the Parisian bridges. It was the first (1803) to be made of iron, and has always been reserved for pedestrians: it provides an intimate view of riverside Paris and of the Seine itself.

Institut de France. Since 1806, these Left Bank buildings have been the home of the five French academies. Originally, a defense work for the Left Bank terminus of the 1220 city wall stood here. Named the Tour de Nesle, it was for centuries celebrated in romantico-erotic song and story. Louis Le Vau, architect to the king, designed the new buildings in 1663 to house the Collège des Quatre-Nations, paid for by a legacy from Cardinal Mazarin who had brought the four entities in question—Piedmont, Alsace, Artois, and Roussillon—under the French crown. Again, Italian notions were subtly gallicized: from a domed church, twin wings arch out to twin pavilions, more suavely and less heavily than in the Italian models. The five contemporary academies are: the Académie Française, founded by Richelieu in 1635, which edits the official French dictionary (the two-volume 8th revised edition was published in 1932 and 1935), awards literary prizes, and has a membership of "40 Immortals"; the Académie des Inscriptions et Belles-Lettres, founded 1663 by Colbert; the Académie des Sciences, founded 1666, also by Colbert; the Académie des Beaux Arts, two sections formed at different times by Mazarin and Colbert and joined in 1795; and, finally, the Académie des Sciences Morales et Politiques, created by the Convention in 1795 to ponder questions of philosophy, economics, politics, law, and history. After he became one of the Immortals, François Mauriac was asked what they did at their meetings, and he said, "We watch ourselves grow old."

The Académie Française

Almost next door is La Monnaie (the Mint), a sober late-18th-century building where visitors may watch coins being struck and visit a museum of coins and medals.

Pont Neuf ("New Bridge"). This is the oldest (1578–1604) of the Paris bridges, the sturdiness of which has become literally axiomatic: Parisians still say, "Solid as the Pont Neuf." It crosses the broadest part of the river and is supported in the middle by the tip of the Île de la Cité, to which it extends five arches from the Left Bank and seven from the Right. The parapet corbels are decorated with more than 250 different grotesque masks, and the parapet curves out toward the water at each bridge pier, forming half-moon bays along what was the first sidewalk in Paris; it was in these that the street vendors and medicine men set up shop. For 200 years this bridge was the main street and the perpetual fair of Paris. Although the structure undergoes regular repair, in the main today's Pont Neuf is the original bridge.

At the island crossing the bridge touches the spot where Jacques de Molay, Grand Master of the Knights Templars, was executed March 11, 1314, after Philip the Fair (Philippe le Bel), King of France, and Pope Clement V agreed to suppress the financially and politically powerful order. Downstream and just below the bridge is the prow of the island, fashioned into a triangular gravel-pathed park bordered by flowering bushes, with rustic benches under the ancient trees. It bears the nickname of Henry IV, being titled Square du Vert-Galant (Square of the Green Gallant). It is surrounded by a wide cobbled quay much used for sunbathing and lovemaking.

Where the steps come onto the bridge from the park there is a bronze equestrian "statue of Henry IV," who insisted on completion of the Pont Neuf. It is an 1818 reproduction of the 1614 original, the first statue to stand on a public way in Paris. Opposite the statue is the narrow entrance to the Place Dauphine (1607), named for Henry's heir. The *place* was formerly a triangle of uniform red-brick houses pointed in white stone, but the row of houses along its base was ripped out in 1871 to facilitate the exposure of the new rear elevation of the Palais de Justice.

Île de la Cité. This ship-shaped island is ten streets long and five wide, with eight bridges to the riverbanks and a ninth to the scow-shaped Île Saint-Louis, which lies abaft to starboard. The first recorded name (*c.* 3rd century BC) for the settlement of rivermen on the island was Lutèce, which meant midwater-dwelling. When the Romans arrived, the Parissi tribesmen were already sufficiently organized and wealthy to have their own superior gold coinage. Caesar's *Commentaries* record that in 52 BC the inhabitants burned their town rather than surrender it to the Romans.

There is some evidence that the Roman governors' palace was on the site of the present Palais de Justice, although their new town spread up the hill on the Left Bank, the present Latin Quarter (Quartier Latin). By the end of the 5th century the Salian Franks, under Clovis, had conquered Paris, which they made the capital of Gaul. It remained the capital until the end of Chilperic's reign in 584, but succeeding Merovingians carried the crown elsewhere and the town's political importance diminished. Charlemagne's line, the Carolingians, left the city in the charge of the counts of Paris who eventually took the town and the kingdom for their own. Their power was intermittent until the election of Hugues I, Capet to the throne in 987, when the palace in Paris again became the seat of power.

Foundation of the city

The palace was rebuilt on the same site by St. Louis (Louis IX) in the 13th century, and enlarged 100 years later by Philip the Fair, who added the grim, gray-turreted Conciergerie, with its impressive Gothic chambers. The Great Hall (Grand Salle) was known throughout Europe for its Gothic beauty, but today, after the fires of 1618 and 1871 (most of the rest of the palace was devastated by flames in 1776), there is almost nothing left of the original room, which, under the kings, was the meeting place of the Parlement (the high court of justice). It serves now as a waiting room for the courts, in one of which, the adjoining first Civil Chamber, the Revolutionary Tribunal sat from 1793, condemning 2,600 persons to the guillotine. After sentencing, the victims were taken back down the stone stairs to the dungeons of the Conciergerie to await the tumbrils. The Conciergerie still stands and is open to visitors; the Gothic Salle des Gens d'Armes, restored in 1970 along with the royal kitchens, can be hired for "receptions of quality."

After the counsellors of the Dauphin Charles (later Charles V) were slain before his throne in 1358, the 20-year old regent turned the palace over to the Parlement and went to live in his new Right Bank residence, the Hôtel Saint-Paul. No monarch ever again lived in the palace on the Île de la Cité.

Tucked away in the palace courtyards is one of the great monuments of France, the 13th-century Sainte-Chapelle. Built between 1243 and 1248, it is a masterpiece of Classic (known in French as *rayonnant*, radiant) Gothic. With great daring, the architect (possibly Pierre de Montreuil) poised his vaulted ceilings on a trellis of slender columns, the walls between being made of stained glass. This jewel box was designed to hold the Crown of Thorns, bought from the Venetians, who had it in pawn from Baldwin, the Latin king of Byzantium. Other holy relics, such as nails and pieces of wood from the True Cross, were added to the chapel's miraculous collection, the remnants of which are now in the treasury of Notre-Dame.

Under King Louis-Philippe (1830–48), the "sanitization" of the island was begun and continued for his successor, Napoleon III, by Baron Haussmann. It was a mass clearing of antique structures, widening of streets and squares and the erection of ponderous new government offices, including parts of the Palais de Justice. That portion which borders the Quai des Orfèvres is headquarters of the Paris municipal detective force, the Police Judiciaire, which keeps a small museum on the fourth floor.

Across the Boulevard du Palais is the Préfecture de Police, another 19th-century construction. Paris is the only French city to have its own police prefect, and his authority in the capital is broad, covering a multiplicity

Police agencies

of duties that in other cities usually devolve on other officials. In addition to dealing with crime, traffic, and public order, the Paris police register all vehicles; license drivers; issue passports, identity cards, and aliens' residence permits; and conduct political surveillance. Civil defense and many aspects of public health are part of police duties, together with some responsibility for fire fighting, although Paris firemen are, in fact, an army unit. The Garde Républicaine are detached for service to the prefect, but this mounted squadron of spurred, helmeted, plumed, breastplated sabre-flourishers are really *gendarmes,* members of the national rural police run by the Ministry of Defense.

There are several other police agencies in Paris, including several shadowy investigatory and counter-espionage agencies as well as the famed national detective force, the Sûreté Nationale, and the Compagnies Républicaines de Sécurité (CRS), whose duties range from teaching youngsters to swim to dispersing demonstrations. The Sûreté and CRS are responsible to the Minister of Interior, who also appoints the *préfet de police,* the *préfet de la Ville-de-Paris,* and the 20 mayors in the town halls of the *arrondissements.* Some ministers take a strong personal role in the policing of Paris, but at times the prefect of police himself has been an important figure in the city's ever-turbulent life.

It was the police who hoisted the tricolour above the Préfecture in August 1944 to begin the insurrection that led to the liberation of Paris. They held out against the Germans for three days until the arrival of French and American forces.

On the far side of the Préfecture is the Place du Parvis-Notre-Dame, an open space enlarged six times by Haussmann, who also moved the Hôtel-Dieu, the first hospital in Paris, from the riverside to the inland side of the square. Its present buildings date from 1868.

Notre-Dame de Paris. At the east end of the square is the Cathedral of Notre-Dame, sited on a spot Parisians have always reserved to the practice of religious rites. The boatmen of the *cité* erected their altar to Jupiter there (it is now in Cluny Museum), and, once Christianity was safely established, a church was built on the temple site. The first bishop of Paris, St. Denis (Dionysius), became its patron saint. The red in the colours of Paris represents, in popular legend, the blood of this martyr who, after decapitation, picked up his head and walked.

When Maurice de Sully became bishop in 1159 he decided to replace the decrepit Cathedral of Saint-Étienne (St. Stephen's Cathedral) and the 6th-century Notre-Dame with a new church in the newest style, Gothic. The style was conceived in France, and a new structural development, the flying buttress, which added to the external beauty and permitted interior columns to soar to new heights, was introduced in the building of Notre-Dame. Construction began in 1163 and terminated in 1345.

After being damaged by the celebrated crowds of the French Revolution, the church was sold at auction to a building-materials merchant: fortunately, Napoleon came to power in time to annul the sale and ordered the edifice redecorated for his imperial coronation in 1804.

Restoration of Notre-Dame

Before abdicating in 1848, Louis-Philippe, a king whose architectural services to Paris have gone largely unrecognized, initiated restoration of the dangerously neglected church. The architect Eugène Viollet-le-Duc worked from 1845 to 1864 to restore the monument.

Like all cathedrals in France, Notre-Dame is the property of the state, although its operation as a religious institution is left entirely to the church.

A few 16th- and 17th-century buildings still remain north of the cathedral. They are remains of the cloister of the cathedral chapter, whose school was famous long before the new cathedral was built. Early in the 12th century, one of its theology professors, Abélard, upholder of the conceptualist thesis, left the cloister with his disciples, crossed to the Left Bank and set up an independent school in the open air near the present Place Maubert. After a prolonged struggle with the Notre-Dame authorities in matters of doctrine and academic freedom, the followers of Abélard (died 1124) won the right, from king and pope, to form and govern their own community in 1200. This was the start of the University of Paris. Abélard is best remembered for the romantic tragedy he acted out with Héloïse, niece of the vengeful Fulbert (Canon of Notre-Dame).

City walls. After the Roman town on the Left Bank was sacked by barbarians, some time between 250 and 275, the fire-blackened stones were freighted across to the Île de la Cité, where a defensive wall was constructed. Neglected in times of peace, it was rebuilt several times over the course of the centuries. The bridge to the Left Bank (Petit Pont, first of the Paris bridges) was guarded by a fortified gate, the Petit Châtelet, and that to the Right Bank (Pont au Change) by the Grand Châtelet, a fort, prison, torture chamber, and morgue, finally demolished in 1801.

In the years 1180 to 1225, Philippe-Auguste (Philip II Augustus) built a new wall that protected the settlements on both banks. In 1367–70 the Right Bank *enceinte* (enclosure) was greatly enlarged by Charles V, with the massive Bastille protecting the eastern approaches as the Louvre protected the west. By the late 14th century Paris was undoubtedly the largest town in France, with a population between 150,000 and 200,000. Louis XIV had the Charles V extensions transformed into the primitive form of the tree-planted Grands Boulevards in 1670, embellished at the Porte Saint-Denis and the Porte Sainte-Antoine with triumphal arches still standing. The word *boulevard* was a military engineering term for the platform of a defensive wall. As the city grew, so did its population, which is estimated to have reached half a million by the end of the 17th century.

Another century passed before a new wall was begun, enabling the *fermiers généraux* (farmer-generals) to collect customs duties on goods entering Paris (they gave the royal treasury a flat annual sum in anticipation of customs revenues and pocketed the difference, which made them all extraordinarily wealthy men). The tollhouses are still standing at Place Denfert-Rochereau. The pre-Revolutionary population of the city was probably around 600,000, although the first official census in 1801—taken after many citizens had fled during the Revolutionary turmoil—showed a figure of 548,000.

The last wall

The last wall, built by Adolphe Thiers for Louis-Philippe, was a genuine military installation with outlying forts. By the time it was finished it enclosed more than a dozen hamlets outside Paris: Vaugirard, Grenelle, Auteuil, Passy, Les Batignolles, Montmartre, La Chapelle, La Villette, Belleville, Charonne, Gobelins and Observatoire. Post-Revolutionary rebuilding and post-Napoleonic economic recovery, with expansion of employment due to the Industrial Revolution, drew more and more people to Paris, and—as railways developed—with ever-increasing facility. In 1851 the city population had reached 1,053,000. Between 1852 and 1870 Haussmann razed the walls of the *fermiers généraux* and built the *boulevards extérieures*. Parisians numbered 1,852,000 in 1872, and 2,447,000 20 years later. The 1845 walls were finally knocked down and made into boulevards yet more exterior in 1925. By that year the population, after reaching a peak in 1921, had already begun the decline which has continued ever since.

Île Saint-Louis. In 1627, Louis XIII accorded a 60-year lease on two mudbanks behind the Île de la Cité to a contractor, Christophe Marie, and two financiers. It was 37 years before Marie was able to unite the islets, dike the circumference, lay out a central avenue with 10 lateral streets, and rent space to some householders. The Church of Saint-Louis-en-l'Île was begun the same year, 1664, but one of the finest houses, by Le Vau (who designed the Academy buildings), was completed in 1640. Another, the Hôtel de Lauzun, a few yards upstream on the Quai d'Anjou, was completed in 1657 and is used by the municipality to receive illustrious visitors. A great number of the houses on the island are originals. The Pont Marie to the Right Bank, completed as part of the contract, is—though modified for modern traffic—the original span. In 1740 it was the first of the bridges to lose the houses and shops along its back.

The Île Saint-Louis is one part of the mythical Paris that still exists in reality. Tranquil and lovely, it has matchless views of Notre-Dame, maintains its intimacy with the Seine, and constitutes a genuine neighbourhood with a disproportionate number of writers, artists, actors, and musicians among the residents.

The Bastille. The road off the upper end of the Île Saint-Louis leads to the Place de la Bastille on the Right Bank. From the river to the *place* runs a canal, the Bassin de l'Arsenal, which brought water to the moat around the Bastille. Under the Place de la Bastille the waterway continues underground for almost a mile, then emerges to form the Canal Saint-Martin, which, with its bridges and locks, and its barges sailing slowly down the centre of city streets, makes one of the least known and most picturesque sections of Paris. In 1972 traffic engineers were threatening to drain the water and make the canal into a highway.

The capture of the Bastille on July 14, 1789 (since annually celebrated), was a symbolic blow at tyranny rather than an act of liberation for tyranny's victims. The prison, virtually unused for years and scheduled for demolition by the monarchy, held on that July 14 but four counterfeiters, two madmen, and a young aristocrat who had displeased his father.

Napoleon had the *place* laid out in 1803. It was to be one of the stations on a triumphal way from the Place de la Nation (which lies to the east) to the Arch of Triumph at the Étoile. The neighbourhood between Bastille and Nation, the rue du Faubourg Saint-Antoine, has been one of skilled craftsmen since the mid-15th century, when the self-governing royal abbey gave space within its wide domains to those cabinetmakers who refused to abide by the restrictions of Paris guilds as to styles and types of wood to be used. The Faubourg was always among the first to revolt when revolution was in the air and was noted for the speed with which it raised barricades of impressive height. In the 1970s the Faubourg's character was changing because the small workshop, like the small grocery shop, was being squeezed to death by economic pressures.

The Marais. To the west of the Bastille lies a triangle of terrain which has its base along the river up to City Hall (Hôtel de Ville) and its apex just short of the Place de la République to the north. It keeps its name—*le marais* ("marsh")—from the Middle Ages, and because it became the market garden of Paris, it gave its name to all market gardens in France (*culture maraîchère*). Extension of the city walls along the Right Bank led to diking of the shore and drainage of the soil. In 1107 the Knights Templars established their Paris Temple, a vast fortified enclosure, at the top of the triangle. In 1360, Charles V moved into his new royal residence in the lower right-hand corner, where the rue de Lions marks the former location of the menageries.

Charles VII preferred to live just behind the Bastille, in the Hôtel des Tournelles, which Henry II had had enlarged and beautified by Philibert Delorme in 1550. Great nobles, such as the dukes of Guise and Lorraine, followed the King and had palaces built in the vicinity. When Henry II was killed in a joust on the rue Saint-Antoine in 1559, his widow, Catherine de Médicis, had the Tournelles razed. On the site, in 1607, construction began on the first residential square to be designed in Paris (others had arisen accidentally at wide crossroads). Henry IV had it built "to fill in the blanks" within the city's walls and reserved a house for himself among those he commanded "builded of a same cimettry for the decoration of the towne." They are three stories high, red brick with white-stone quoins (solid-corner angles) and window surrounds, the ground floors forming arcades over the sidewalks, still standing in full state and grace. Completed in 1612, the square was named la Place Royale, known to the thronging public simply as La Place. Another wave of building by the rich, anxious to be close to a royal project, endowed the Marais with 200 more private palaces. In 1800 the name was changed to Place des Vosges, which it is still called.

The first residential square

In 1792 the Knights Hospitallers of St. John of Jerusalem were turned out of the Temple that had been given to them in 1313 when the Templar order was dissolved. On August 13, 1792, the Royal family was incarcerated in the keep, the King was taken off to his death January 21, 1793, and the Queen removed to the Conciergerie August 2 (execution October 16). Two years later the death of the Dauphin—from maltreatment and malnutrition—was announced, but there are those who still believe that the 10-year-old child buried at the Church of Sainte-Marguerite, on the rue Saint-Bernard, was a substitute for the heir to the throne.

The Temple keep, a possible rallying point for royalists, was levelled in 1808, and in 1857 Haussmann installed on the site the *mairie* (town hall) of the third *arrondissement* and the Square du Temple.

After the 17th-century building boom the Marais remained virtually untouched, and three-quarters of the buildings there date from before 1870. Toward the end of the 19th century, while some of the oldest and most imposing of the palaces were being knocked down by private entrepreneurs, other private owners managed to restore a few mansions, and the nation and the municipality also restored a handful of fine buildings. The district became a dumping ground for Jewish refugees from eastern Europe, and to profit from the poverty-stricken newcomers scores of fine houses were subdivided into tiny apartments, with workshops on the lower floors and in courtyard sheds. In 1970 there were still 7,000 shops and workshops in the district, with 40,000 employees, although one of the prime industries, textiles and clothing, was rapidly diminishing. Through centuries of neglect the Marais became one of the worst slums in Paris: in the early 1970s there was no running water in 30 percent of the dwellings, 10 percent had no electric light, and 60 percent were without toilets. Cleaving to the pattern of bygone ages, buildings cover more than 85 percent of the area, compared with a city-wide average of 55 percent land occupation. Despite a population decline of 19 percent between 1962 and 1968, it remains the most densely inhabited part of Paris, some streets attaining a density of 5,800 inhabitants per acre (2,000 per hectare), the Paris average being 240 per acre.

Degeneration of the Marais into a slum

In 1969 the Municipal Council approved the creation

of a plan for the restoration of the locality. Not a "museum" plan, it is an urban renewal scheme for ending slum conditions while preserving the workaday life and animation and restoring the undeniable beauty of the quarter.

Among the restored ancient buildings open to the public are: the Museum of the History of Paris (Musée Carnavalet) 1545, enlarged by François Mansart 1645; the Museum of the History of France (National Archives, Hôtel de Soubise) parts from 1375 and 1553, main portions 1704–15; the Museum of Nature and the Hunt (Fondation Somer, Hôtel Guénégaud) by François Mansart 1648–51; and the Caisse Nationale des Monuments Historiques (Hôtel de Sully) by Androuet du Cerceau (Jean I). There are currently at least a dozen more.

Closer to the Hôtel de Ville is the Gothic Hôtel de Sens, built at the end of the 15th century for the bishops of Sens then also bishops of Paris. Restored after 40 years' work, it served by the 1970s as a city library of specialized collections. Nearby, behind facades of a much later date, two half-timbered medieval houses have been uncovered. Here and there through the Marais portions of the 13th-century city wall, including one of the watch towers, are still to be seen.

Hôtel de Ville. Three city halls have stood on this site, the last two grander, "improved versions" of their predecessor. The present building (1874–82) replaces the Renaissance structure in use from the 16th century until it was burned by the insurrectionary Communards in 1871. The first was the Maison aux Piliers (House with Pillars) used by the municipality from 1357 to 1533.

In the building are the official apartments of the *préfet de la Ville-de-Paris*, representing the national authority which has ruled the capital—with few brief and usually bloody exceptions—since the first kings appointed the counts of Paris as administrators of the city.

The three Paris-based prefects and diverse departments of the national government hold almost all the administrative and financial power. The municipal council serves the voters by airing public problems in debate and by obstructing or rejecting proposals they deem inimical to the city. Frenchmen at times complain that they are "the most governed people in the world"; Parisians, deprived of municipal self-rule, complain that they are the most governed of Frenchmen.

The municipal framework

The beginnings of the municipality were promising. In 1141 the crown sold the principal port (by the site of the Hôtel de Ville) to the river merchants guild, la Marchandise de l'Eau, whose ship-blazoned arms eventually were adopted as those of Paris. In 1171 Louis VII gave La Marchandise a charter confirming their "ancient right" to a monopoly of river trade. In 1190, when Philippe-Auguste went off crusading for a year, he entrusted the administration of the city, not to his Provost, but to the guild. In 1220, the crown ceded one of its own precious rights to the townsmen: the right to collect duty on incoming goods. The merchants were also made responsible for maintaining fair weights and measures. St. Louis recognized the Parloir aux Bourgeois as the municipal body with the Prévôt des Marchands heading an elected council of *échevins* (municipal magistrates).

The Provost of the Merchants in 1356 was Étienne Marcel, who wanted a Paris as rich and free as the independent cities of the Low Countries. It was he who gave the Maison aux Piliers to the municipal government, and it was he who slew the Dauphin's counsellors in the Palace throne room and took over the city. He showed great executive skill and equally great political stupidity. He allied himself with the revolting peasants (the Jacquerie), with the invading English, and with Charles the Bad, ambitious King of Navarre. While going to open the city gates to the Navarese in 1358, Marcel was slain by the citizens.

In 1382 a tax riot grew into a revolt called the "Maillotin uprising" because the rioters armed themselves with *maillets*, mauls. They were ruthlessly put down and the municipal function was suspended for the next 79 years. It was not until 1533, when Francis I ordered the teetering Maison aux Piliers replaced by a new building, that a monarch manifested an encouraging interest in municipal government.

The massacre of thousands of Protestants, on St. Bartholemew's Eve, 1572; the Day of the Barricades, May 12, 1588, when the Catholic League drove Henry III out of Paris; and the Fronde, 1648–53, all involved the Paris masses, but were palace revolutions rather than popular uprisings. When the people rose in their own cause, the focus of their action was inevitably the Hôtel de Ville, as was indeed the case in 1789, 1830, 1848, 1871, and 1944.

In July 1789, for example, after killing the Provost, the revolutionary mob took the Hôtel de Ville as it had already taken the Invalides and the Bastille. Three days later Louis XVI appeared on the balcony, wearing the tricolour cockade (royal white added to municipal red and blue), and was cheered by the crowd. Four years later the building was taken as headquarters for the fanatically extremist Commune, which directed mob action to control the Convention. On 9 Thermidor, year II (July 27, 1794), the Convention's guards entered the Hôtel de Ville and seized Robespierre and his Communards; all were executed soon after.

The Hôtel de Ville as a revolutionary centre

In August 1830, Louis-Philippe appeared on the balcony accompanied, as had been Louis XVI, by the Marquis de La Fayette, and he, too, was acclaimed by the revolutionary crowd. The name of the square was changed in that year to Place de l'Hôtel de Ville. As the Place de Grève (strand, or bank) it had been the principal port of Paris for centuries (the refusal of boatmen to put out gave the French worker the phrase for going on strike *faire la grève*). From 1310 to 1832 it was Paris' principal place of execution.

In 1871, after Napoleon III's defeat at Sedan, a new republic was declared from the Hôtel de Ville steps, but when the national government, in its turn, capitulated, Parisians refused to accept defeat and in March formed the Commune of Paris. In May, troops of the government entered the town and fought sharp engagements with the Communards, who set fire to the Hôtel de Ville, the Tuileries Palace, the Palais de Justice, the Préfecture de Police, the Arsenal, and other government buildings. The Communards executed 67 hostages, including the archbishop of Paris, and then went on to die after combat among the tombs of Père-Lachaise Cemetery.

In a bloodbath unparalleled in the history of France, the government subsequently rounded up and executed 20,000 Parisians, shipping thousands of others to penal colonies.

Finally, in 1944, in the bloody turmoil of World War II the National Council of Resistance made the Hôtel de Ville its headquarters during the Liberation combat. General Charles de Gaulle appeared on the balcony and was acclaimed by the crowd.

Les Halles. On the rue de Rivoli westward from the Hôtel de Ville is the Tour Saint-Jacques, the bell tower of a 1550 flamboyant Gothic church, the body of which was removed under the Directoire. A few streets further northwest toward the Louvre is the *quartier* of Les Halles, from 1183 to 1969 the central market of Paris. An incredible monument to human appetites, Les Halles burst with an infinity of colours, sounds, and odours. Its almost permanent traffic jam girdled some of the happiest *bistros*, some of the busiest streetwalkers, and some of the biggest fortunes in Paris. It was traditional for merrymakers to come down during the night to have onion soup, snails, or pig's feet and to depart at dawn with armloads of blossoms bought at the wholesale flower market. When the markets moved out to a new location, the picturesque, bawling, brawling district became a silent, empty, waiting stage.

The markets of Les Halles

To remake a unified space in the antique heart of Paris in any way that Paris wished was an opportunity that might not come again for another 100 years. After three years of public hearings and unpublic disputes, a general plan was agreed to by the municipality and Cabinet. Not one of the ten market pavilions—eight originals designed in 1866 by Victor Baltard, and two 1936 imitations—will remain here for posterity, even though the iron-and-glass "umbrellas" were admired by leading 20th-century arch-

itects and by simple Paris sentimentalists. While the meat market still waited for its new quarters in the scandal-stained La Villette slaughterhouses, the pavilions remained standing, the emptied ones used for exhibitions, concerts, and the like. The Church of Saint-Eustache (1532–1637) remains, as does the circular Halle au Blé (Grain Exchange) 1811–13, burned by the Commune and restored in the 1880s as the Bourse de Commerce (Commercial Exchange). Many of the old houses—a few are very old, with the majority somewhat elderly—will be renovated or restored to keep some of the Vieux Paris flavour. The central 25 acres (ten hectares) and an adjacent 12-acre (five-hectare) plot are being transformed. Around the edges will appear new structures, most of them low-built: the new Ministry of Education, an International Centre of Commerce with exhibition halls, a museum of contemporary art, a public library, an auction sale room, and several apartment houses and hotels. The empty space they border is simply a concrete skin over a huge underground installation. Its surface, something like a dried lake bed, will be varied by terraces of different levels, small gardens, some thin stands of trees, and light wells. Beneath, on several levels, a subterranean city will emerge. At the bottom will be the tracks of the east–west express subway (RER) and the extended north–south suburban Sceaux railway line; above that, the rail stations and waiting rooms; above that, on several floors around a central garden, the "Forum" through which 80,000 commuters a day will stream, containing movie theatres, sports installations, eating places, bars, and shops. Just under the surface will be the regular métro with its usual Les Halles station, a small cab and bus station, and some subterranean roads. There will be underground parking.

To the west of Les Halles is the Banque de France, which also has an important underground installation (the French national gold reserve), and, to the north of the bank, the Stock Exchange (Bourse). The bank is in close proximity to most of the banking and insurance headquarters offices in Paris. The city is the location of only 27 percent of all such headquarters in France, but those in Paris count 95 percent of all those with more than 1,000 employees, lending fuel to the provincial objection that "everything is run from Paris." What is not run from the city by the central government has a good chance of being run from there by some giant corporation. The last available statistics show that over 62 percent of all French corporate tax was paid by Paris-based companies. The region produced close to a third of the national product in services (exclusive of civil service) and the same amount of industrial product.

The city's financial section

MODERN DEVELOPMENTS

Rue de Rivoli. The Louvre and the Tuileries Garden take up the south side of this street, and on the other side runs an arcade more than a mile long. Napoleon I opened up the street from the Place de la Concorde, Charles X continued it, as did Louis-Philippe, and Napoleon III carried it on down into the Marais.

Opposite the middle of the Louvre, the Place du Palais-Royal leads to the palace of Cardinal de Richelieu, built in 1624 and willed to the royal family. Louis XIV lived there as a child, and during the minority of Louis XV the kingdom was ruled from there by the debauched but gifted regent. Late in the 18th century Louis-Philippe d'Orléans, who became Philippe-Egalité after the Revolution, undertook extensive building around the palace garden. It was a commercial operation, and the prince hoped to pay his debts from the property rents. ("Well cousin," said Louis XVI, "so you're going to keep shop; we'll never get to see you except on Sunday.") Around the garden he built a beautiful oblong of colonnaded galleries, and at each end of the gallery farthest from his residence, a theatre. The larger playhouse has been the home of the Comédie-Française, the state theatre company, since Napoleon's reign. The princely apartments now shelter high state bodies such as the Conseil d'État.

The prince's financial success was modest, but the social impact was sensational. From the 1780s to 1837 the Palais-Royal was the local synonym for excitement. It was the centre of Parisian political and amorous intrigue and the site of the most celebrated gambling dens and popular cafes. Today the garden and its galleries are still beautiful but are wistfully deliquescent, a Pompeii where even the tourists are rare.

Just behind the garden is the Bibliothèque Nationale, the national library of deposit, with the expected enormous collections of books and prints, some 6,000,000 of each.

When Haussmann greatly enlarged the Place du Palais-Royal in 1852, he did not molest the palace when he pushed through the Avenue de l'Opéra. At the top of the new street, where the Grands Boulevards crossed an enormous new *place*, the new Opera House was built, pulling pleasure seekers further away from the Palais garden. The Opéra (1825–98), the neo-Baroque masterwork of Charles Garnier, is a splendiferous monument to the Second Empire. By acreage it is the largest theatre in the world, but so much space is devoted to such embellishments as the Grand Staircase that in seating capacity it is not the largest theatre in Paris. Just behind the Opera House the large department stores indulge in the same kind of uninhibited monumentality, the sort of thing they now avoid in their branches at suburban shopping centres springing up around the country.

The Opéra

On the rue de Rivoli the next *place* is the Place des Pyramides. The gilded equestrian statue of Joan of Arc stands not far from where she was wounded (at the Saint-Honoré Gate) in her unsuccessful attack on British-held Paris, September 8, 1429.

Farther along toward the Place de la Concorde the rue de Castiglione leads to the Place de Vendôme, an elegant octagonal *place*, little changed from the 1698 designs of Jules Hardouin-Mansart. In the centre, the Trajanesque Vendôme Column, 44 metres high and spiralled in the bronze of 1,200 captured cannon, bears the effigy of Napoleon, who had it erected in 1810. It was pulled down during the Commune and put back up by the Third Republic. The *place* and the gas-lit rue de la Paix have lost none of their discreet distinction, nor have their shops. The rue de Rivoli shops, once equally chic, have in many cases acquired a disguised but unmistakably vulgar accent. The street's hotels maintain their traditional high quality. The German commander of Gross Paris, Dietrich von Choltitz, who disobeyed Hitler's order to burn the city, was captured in his headquarters at the Meurice Hotel August 25, 1944.

La Voie Triomphale. From the Arc de Triomphe du Carrousel in the courtyard between the open arms of the Louvre, there extends one of the most remarkable perspectives extant in any modern city. It is called—though not in everyday speech—the Triumphal Way. From the middle of the Carrousel Arch, the line of sight runs the length of the Tuileries Garden, lines up on the obelisk in the Place de la Concorde, and goes up the Champs-Élysées to the centre of the Arch of Triumph.

The Louvre's modest triumphal arch stands in the open space where costumed nobles performed in an equestrian display—*un carrousel*—to celebrate the Dauphin's birth in 1662. The design of the arch, an affable imitation of

that of the Arch of Septimius Severus (Rome), was confected in 1808 by Percier and Fontaine, who also perpetrated a great deal of the Empire style's sphinx-fraught furniture and decoration. Napoleon, a record of whose victories is incised on the arch's flanks, decorated the summit with the famed four bronze horses from St. Mark's in conquered Venice. The Venetians had taken them from conquered Constantinople, which had acquired them in Rome, which, in turn, had looted them from, it is believed, the Temple of the Sun in Corinth. After Napoleon's defeat, France was forced to return them—to Venice.

The Tuileries Garden

The Tuileries Garden, which fronted the Tuileries Palace (looted and burned in 1871 during the Commune), has not altered much since André Le Nôtre laid it out in 1664. Le Nôtre, who was born and who died right in the garden, in the gardener's cottage, carried the line of his central *allée* beyond the garden and out into the country by tracing a path straight along the wooded hill west of the palace. On this hilltop, 170 years later, the Arch of Triumph was erected.

At the western edge of the garden, Napoleon III erected a hothouse—the Orangerie—and a court for real (or royal or court) tennis—the Jeu de Paume. The former is used for temporary art shows, the latter houses the Louvre collection of paintings by the Impressionists and their forerunners. Among the artists represented are: Cézanne, Degas, Gauguin, Manet, Monet, Renoir, Rousseau (*le douanier*), Toulouse-Lautrec, van Gogh. From the terraces on which these museums stand there are splendid views of the olympian traffic jams of the Place de la Concorde.

The formal exit gate from the Tuileries is flanked by two winged horses (17th century), and the entrance to the Champs-Élysées across the square is similarly garnished (horses, earthbound, 18th century), both pairs having been removed in turn from the water trough at Chateau de Marly.

The Place de la Concorde was designed as a moat-skirted octagon in 1755 by Jacques Ange Gabriel. He had won competition set by the *échevins* of Paris for a king-flattering "Place Louis XV." The river end was left open, and on the inland side, two matching buildings were planned. The ground floor was arcaded and the facade was nimbly adapted from the Louvre colonnade, all with a refinement typical of the era. Although Gabriel built eight giant pedestals around the periphery of his *place*, they remained untenanted until Louis-Philippe gave them statues representing provincial capitals going clockwise from the Navy Ministry (Ministère de la Marine): Lille, Strasbourg, Lyons, Marseilles, Bordeaux, Nantes, Brest, and Rouen. Louis-Philippe also had the Luxor Obelisk, a gift from Egypt, installed in the centre and flanked by two fountains. Later, the surrounding moat was filled in, and the Place de la Concorde took on its present geography.

Louis XVI was decapitated near the statue of Brest, January 21, 1793. The guillotine was brought back to the *place* four months later and erected near the gates of the Tuileries, and the executions went on for nearly three years, with a total of 1,343 deaths on this spot. An approximately equal number of persons perished in other parts of town.

La Madeleine

Between the twin buildings the broad rue Royale mounts to the Church of La Madeleine, a stern oblong, fenced with columns 20 metres high, ostensibly a Greek temple but closer to the Roman notion of Greek. From 1764 to 1806 three false starts were made on building a church on this site. Napoleon ordered Vignon to build a temple to the glory of the Grande Armée but then vanished from the scene, and La Madeleine was not consecrated until 1842.

The Place de la Madeleine is the western terminus of the Grands Boulevards, which imitate the arch of the river from there north and east to the Place de la République and the Bastille. The glittering chic of the Grands Boulevards, which flavoured Paris life from 1750 to the 1880s, is gone with the *boulevardiers*, gone with Café Tortoni, the Café Riche, the Maison Dorée. The state-run Opéra-Comique persists just off the boulevard des Italiens, the wax museum is still there on the boulevard Montmartre, and, a few doors away, Offenbach's theatre, the Théâtre des Variétés, still operates. The Théâtre de la Renaissance, where Coquelin created Cyrano de Bergerac in 1897, still functions on the boulevard Saint-Martin, as does the Théâtre de l'Ambigu, where Frédéric Lemaître, idol of boulevard melodrama, thrilled all Paris in the mid-19th century. Some of the movie palaces of the 1930s are still serving along the boulevards as well.

West off the rue Royale runs the rue du Faubourg Saint-Honoré, which, in addition to the British Embassy and the Élysée Palace (residence of the French president), has on its shop windows some of the most prestigious names in Paris retail trade and has as its window shoppers some of the most richly dressed and—at times—most beautiful women in the world.

Along the first 2,500 feet (800 metres) of the Champs-Élysées, between Concorde and the Rond-Point des Champs-Élysées, little has changed since the childhood of Marcel Proust. The 230-foot-wide avenue is bordered with chestnut trees, behind which on both sides are gardens, usually full of children, often with their nannies. Rides on donkeyback and in goat-drawn carts are still offered. Punch still punches Judy. The discreet pavilions in the gardens are tearooms, restaurants, and theatres. Along the paths it is still possible to get one's shoes dusty on the way to the office.

The Champs-Élysées today

From the Rond Point up to the Arch of Triumph just about everything has changed, and continues to change, along the Champs-Élysées. Under the Second Empire this was a street of luxurious town houses, of which but two were left in the early 1970s. Then came the cafés, night-clubs, luxury shops, and the cinemas, but the street retained its feeling of luxury and the tree-shaded sidewalks (wide as a normal street) offered promenades that were the pride of Paris. Since the 1950s, however, more buildings designed as corporate headquarters have evicted shops, tearooms, and hairdressers alike. Automobiles park on the sidewalks and in many places one rank of the double file of trees has been felled. Pedestrians seem to mill rather than stroll. In the 1970s this street, once one of the most justly famous in the world, was becoming another in the international series of "downtown prestige addresses" from which all that bestowed the prestige has been extirpated.

At the top of the Champs-Élysées is a circle 450 feet in diameter from which 12 imposing avenues radiate to form a star (*étoile*). From 1753 to 1970, it was called Place de l'Étoile, then was re-named Place Charles de Gaulle. In the centre of the circle is the Arch of Triumph, commissioned by Napoleon in 1806. After Napoleon's fall it stood unfinished until Louis-Philippe saw to its completion in 1832–36. At 50 metres, it is twice as high as the Arch of Constantine, which inspired it, and, at 45 metres, a little more than twice as wide. Jean Chalgrin was the architect and François Rude sculpted the frieze and the spirited group, "La Marseillaise" (real title, "The Departure of 1792"). On Armistice Day in 1920, the Unknown Soldier was buried under the centre of the arch, and each evening the flame of remembrance is rekindled by a different patriotic group.

La Défense

The westward thrust of the city was dramatically demonstrated in the 1970s when the biggest concentration of tall buildings in the nation arose over two miles beyond the Arch, on the far side of the rich little suburban wedge of Neuilly. The site, called Quartier de la Défense, was formerly just a place in the road where the depressed suburban municipalities of Puteaux, Courbevoie, and Nanterre listlessly touched. Now, 30 office towers, 30 stories tall, heated and air conditioned from a central plant, are the hub of a complex, balanced city plan. The "ground level" between buildings is a raised platform reserved to pedestrians, with roads and parking below. There will be shops, restaurants, cafés, a shopping centre, hotels, and apartment houses. Before the project was begun, the state had already constructed at La Défense its Centre National des Industries et des Techniques, an exhibition hall with 90,000 square metres of floor space. Nanterre became the site of a campus of the

University of Paris in the 1960s, and in the 1970s specialized schools of university level were installed in the new centre: a National School of Architecture, the National School of Decorative Arts, the National Conservatory of Music, and the Institute of Advanced Cinematographic Studies. The three municipalities benefit directly by acquiring low-built public housing in park settings, a large park, day child-care centres, and new schools.

New business quarters. As a counterbalance to the westward march of office buildings and as part of the effort to limit the obliteration of residential quarters around the business centre, five "poles of attraction" were instituted in other parts of Paris in the late 1960s and early 1970s. Two of these are directly on the waterfront at each end of Paris, Front de Seine in the southwest corner, and Austerlitz-Bercy-Lyon in the southeast corner.

The Front de Seine covers 70 acres (29 hectares) on the Left Bank, between the Eiffel Tower and the southern city limits. A neighbourhood of factories and substandard housing is replaced by a spread of 16 towers of 32 stories and four buildings 15 stories high. One-quarter of the space is used for offices, the rest for apartments, some of which are low-cost housing.

The project at the opposite end of the river straddles the Seine, putting office buildings around the Gare d'Austerlitz (Left Bank) and the Gare de Lyon (Right Bank). Bercy, which lies directly on the river (Right Bank) between the two stations, was until this development one of the secret cities of Paris. Fenced and guarded, its chalets lined cobbled lanes named for the great vineyard districts of France. The great oaks, it was said, flourished because their roots were soaked in wine. This was the village of vintages, where merchants stored and sold their stocks of liquid treasure. Now the dealers, abandoning folklore for modern conveniences, have retreated into a modern block on the city line at the river. The rest of their domain is occupied by a 20-acre (eight-hectare) park, around which are 14 buildings, which range from 16 to 40 stories in height. Half the 6,000 apartments are low-rent public housing, and the rest of the tower space is for offices. Schools and shops complete the project.

Bercy

At the Place d'Italie, 5,000 feet south of the Gare d'Austerlitz, there is developing what the planners call "an urban strong point" midway between the city centre and Orly airport. The project was begun in 1969 and should be terminated in 1989. On 215 acres (87 hectares) there will finally be 14,000 new apartments, 200,000 square metres of office space, and 150,000 square metres of retail shops.

The run-down areas around the Gare de l'Est and the Gare du Nord (the East and North railway stations), high on the Right Bank, are also being developed as another commercial complex.

The project that literally overshadows the others is Maine-Montparnasse, where the centre piece of the composition is a 56-story (200-metre-high) office tower. Planned for completion in 1973, it was designed as the tallest in Europe. It stands on the site of the old (1850) Montparnasse railway station. A more compact station has been built one street away on the avenue du Maine, where the rails are hidden on three sides by three buildings 15 to 18 stories high, which include 30 floors of offices and 1,000 apartments. The units are joined by a raised platform that serves as "ground level" above the street. Excluding employees of the retail shops, there is room for 21,000 jobholders in the project.

The effect on the surrounding neighbourhood of Montparnasse is prodigious. Always fairly seedy, it was nevertheless dear to many as the playground, classroom, and workshop of the 1920–35 "lost generation." The population of painters and writers declined after World War II, but it has been further reduced by the effects of real-estate euphoria provoked by the big tower. Some favourite old *beehives of Bohemia* have been replaced by new speculative buildings, and the remaining studios have property values now as absurdly high as most artistic ambitions.

Montparnasse

Factories and workshops disappear from Paris at an even faster rate than the vanishing artist's *atelier*. Permits for expansion or even rebuilding such premises are rare, taxes are purposely inhibitory, and concessions and premiums for relocating in the new regional industrial zones are attractive. During debate on the city plan, some municipal councilmen expressed apprehension that eventually there would be no more "blue collar" workers in Paris, a state of affairs that would change Paris far more profoundly than any number of skyscrapers.

The ministry quarter. The government, both local and national, is a gargantuan occupier of Paris office space and at an accelerating pace: in 1970 there were four times as many public agents per inhabitant as there were ten years earlier. One civil servant out of every six in France works in Paris. The seventh *arrondissement*, a delta-shaped district the base of which runs along the river from the Eiffel Tower past the Esplanade des Invalides to the Pont du Carrousel, is known as the *quartier des ministères*. Ten of the 15 ministries are located there along with the prefecture of the Paris Region and the National Assembly.

Most of the territory of the seventh *arrondissement* is government property. This is the old *Faubourg Saint-Germain*, an impeccable address since the early 18th century. As such, it was subject to heavy expropriation during the Revolution, and ministries are lodged mostly in splendid old mansions and convents. Properly imposing, these are never large enough and always difficult to adapt to modern administration. When it proves impractical to spread into adjacent buildings or to construct quite dreadful annexes in the garden, branches are installed wherever space can be found—in this case a total of 115 different locations. The Ministry of Finance has 25 different buildings; Social Affairs has 25; and the Prime Minister, who lives and works in the Hôtel de Matignon (1722) on the rue de Varenne, also uses 18 other scattered buildings.

Probably the best known of all ministries is the low-built, ornate Ministry of Foreign Affairs on the Quai d'Orsay between the Esplanade des Invalides and the National Assembly. The address "Quai d'Orsay" has become a synonym for the ministry.

The Quai d'Orsay

The National Assembly is housed in the 1722–28 Palais-Bourbon, seized during the Revolution. Succeeding regimes have tacked bits and pieces onto the old palace, including the Greek peristyle facing the river as ordered in 1807 by Napoleon.

The Pont de la Concorde, just below the gates of the Palais-Bourbon, was built 1787–91, partly with stones from the demolished Bastille.

Quartier Latin. At the Pont de la Concorde the Boulevard Saint-Germain begins, curving two miles (three and one-fourth kilometres) eastward to find the river again at the Pont de Sully. A little less than halfway along the boulevard is the pre-Gothic Church of Saint-Germain-des-Prés. Belonging to a Benedictine abbey founded in the 8th century, it was sacked four times by the Vikings, and rebuilt between 990 and 1201, parts of the present church dating from that time.

The area has long been a meeting place for artists. Racine died there in 1699; Delacroix had his studio in the still-winsome little Place Fürstenberg; publishing houses moved in during the 19th century; and the principal cafés have been meeting places for artists, writers, and publishers since. From 1945 to 1955 it was the hub of the "Existentialist" movement, which stemmed from Jean-Paul Sartre's adaptation of Kierkegaardian philosophy but which is more generally remembered as the excuse for a revived Bohemia and a renewed expatriate flood into Paris. The first *discothèque*—an institution which gained international currency in the 1960s—was founded here. In the 1970s it was still a very lively centre for literature, food, and talk.

Straight north from the Saint-Germain-des-Prés crossroads is the École des Beaux-Arts on the Quai Malaquais, the state school of painting and sculpture. For many generations the students' annual *Bal des Quatz'Arts*, usually concluding with a nude dawn dip in the Concorde fountains, was one of the memorable wild youthful moments of the Paris calendar. In recent years it has gained

as little attention as the works of art produced during the academic year.

Two streets south of the crossroads is the Church of Saint-Sulpice (1646–1780), the work of six successive architects who, in 134 years, scarcely had a good day among them. The street alongside the church is sprinkled with shops specializing in devotional statuary, much of it on the aesthetic level of seaside souvenirs and known in France as "Saint Sulpicerie."

Eastward to the boulevard Saint-Michel, the area toward the river from boulevard Saint-Germain is a tangle of narrow, animated streets, "typically Parisian" in a noisy, happy way that now, alas, typifies so little of Paris.

East of the boulevard Saint-Michel is the university precinct, self-governing under the kings, where, in class and out, students and teachers spoke Latin until 1789. On the corner of the boulevards Saint-Germain and Saint-Michel are the remains of one of the three baths of the Roman city. These are in the grounds of the Cluny Museum, a Gothic mansion built 1485–1500, which now houses a collection of 20,000 objects and works of art of the Middle Ages, including the renowned six-panel unicorn tapestry "La Dame à la Licorne."

The wide, straight boulevard Saint-Michel (no longer the Boul Mich in the student lexicon) is the main street of the student quarter. The university buildings are curiously little visible to the casual visitor who sees a mile of bookshops, cafés, cafeterias, and cheap movie houses.

La Sorbonne

The university was built up of colleges, each founded and supported by a donor, often a prelate or a religious order. Robert de Sorbon, chaplain to St. Louis, established a college in 1235 that eventually became the centre of administration for the university to which it gave its name, La Sorbonne. The liberal arts faculty off the Place Sorbonne, which is the administrative seat for the whole University of Paris, is housed in large, anonymous 1900 buildings tucked away behind small streets. Some faculties, schools, and institutes have been moved out of Paris, some to the new towns, and others are dispersed at some distance. The Science faculty has done both, with new buildings (1968) in the town of Orsay and also on the site of the old Halle aux Vins, still in the fifth *arrondissement* but down on the river next to the Jardin des Plantes, a 1626 botanical station to which are attached the Museum of Natural History and a small, charming, old fashioned *ménagerie*.

This decentralization, plus the creation of new "campuses" (the concept has been so completely forgotten in France that the American word is used) in the provinces as well as in the Île de France, should eventually end classroom overcrowding and the student housing shortage in Paris. Application of reforms promulgated in the 1960s should provide curricula as modern as the new buildings.

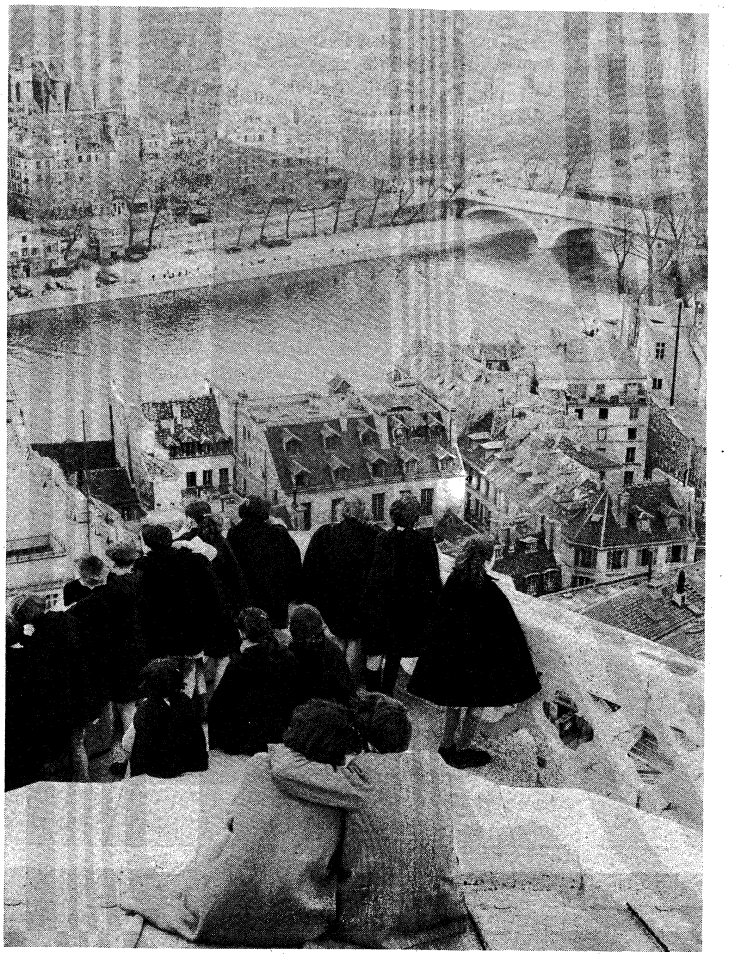
The oldest Sorbonne building is the chapel (1635–42), the gift of Cardinal de Richelieu, who is buried there. Designed by Lemercier, it was another of the new domed "Jesuit" churches of the period.

The independent Collège de France was set up a few steps from the University by Francis I in 1529 to offer a more liberal, modern curriculum than the narrow theology and limited Latin of the Sorbonne. Bestowing no degrees, it has always had a superb faculty of famous specialists, especially in philosophy, literature, and the sciences.

At the top of the hill rising from the river the boulevard skirts the Luxembourg Garden, the remains of the park of Marie de' Medici's Palace (1616–21), which now houses the French Senate. The chestnut-planted garden, with its pond for toy sailboats, its marionette theatre, and its ridiculous statuary, has a curious power of persuading many visitors that they are 19th-century persons of quality.

The Panthéon

Across the boulevard at the end of the rue Soufflot stands the Panthéon, 1755–92, by Jacques-Germain Soufflot. The colonnaded facade, the great dome, the barrel-vaulted interior make for power and dignity. Cured of an illness, Louis XV built the church as a votive offering to Ste. Geneviève, in replacement of the moldering 5th-century abbey named for her. When the church was finished, the Revolutionary authorities decreed it to be the Panthéon, final resting place for heroes of the Revolution. Napoleon restored it to the church, which lost it to the next revolution, and so on until the 1885 burial of Victor Hugo, after which it remained the Panthéon, but with the cross still atop the dome. Voltaire, Jean-Jacques Rousseau, La Fayette, Hugo, Zola, Felix Éboué and the 1943 Resistance leader Jean Moulin are among those buried under the inscription, "Aux grands hommes, la Patrie reconnaissante" ("To great men, [from] the grateful Motherland").



The Seine River and its embankments.
Henri Cartier-Bresson—Magnum

Behind the Panthéon is a steep street named La Montagne Saint-Geneviève. It was the Caesars' paved road to Italy. The hill leads down to the lively market square of Place Maubert and a tangle of ancient, picturesque, riverside streets. The best known of these is the medieval rue de la Huchette, from which the Street of the Fishing Cat (rue du Chat-qui-Pêche)—a blank, sweaty-walled airshaft—leads to the Quai Saint-Michel. Two Gothic churches, modest Saint-Severin (1489–94) and humble Saint-Julien-le-Pauvre (1165–1220), nest in this urban bramble patch. Saint-Julien-le-Pauvre was cut in half when collapsing portions were removed in 1651. The Sorbonne's annual assembly met in the church for 250 years, until 1524, when the meetings were forbidden because of student rowdiness. The square in front of the church offers one of the finest views of Notre-Dame de Paris.

The Buttes. The river valley of Paris is almost entirely circled by high ground. Upon the heights of Passy, on the Right Bank between the southern and western city limits and the Arch of Triumph, perch the *beaux quartiers* of the 16th *arrondissement*. The population contains a preponderance of persons with above-average incomes and, in many cases, of above-average pretensions.

The old-shoe amiability of Montparnasse (14th and a little of the 15th *arrondissement*) has been tainted by an injection of modishness provoked by the presence of the skyscraper and its attendant structures.

The Butte-Montmartre (18th *arrondissement*) and the Buttes-Chaumont (19th *arrondissement*), which rise along the northern rim of the city, are still unaffectedly "popular" in the sense of "populi." The oblong 18th *arrondissement* may perhaps be characterized as an urban pudding full of ill-assorted lumps. The range runs from the beautiful to the quaint, through the tawdry to the sordid. It has many seductive village corners and even more brutal city traps. It has broad avenues, but it also has winding lanes, some of which transform themselves into five-flight stairways. From the early 19th century until the 1920s' migration to Montparnasse, it was the great art colony of Paris. Some sections are mercilessly gewgawed for the tourist trade and others are unselfconsciously picturesque. It is the home of hundreds of thousands of hardworking, ordinary folk and one of the main centres of crime and prostitution. Montmartre itself is strewn with cheap little nightclubs, which often prove to be menacingly expensive.

Montmartre

The most noted landmark of Montmartre, one of the most indelibly Parisian, was inserted into the landscape only in 1919: the Basilica of the Sacré Coeur (Sacred Heart), more fully, of the National Vow to the Sacred Heart, paid for by national subscription after the French defeat by the Prussians in 1870. The work began in 1876 but was delayed by the death of the architect, Paul Abadie, who took inspiration from the 12th-century five-domed Romanesque Church of Saint-Front in Perigueux, itself inspired either by Venetian or Byzantine churches. Alongside the monumental terraced stairway of the garden-planted Square Willette below the church entrance runs the only funicular railway in Paris.

On the Buttes-Chaumont, just to the west of Montmartre, are the gasworks, the canal, the abbatoirs, and one of the most engaging parks in Paris. Called the Parc des Buttes-Chaumont, it was yet another Haussmann enterprise (1864–67). A bare hill, half hollowed out by abandoned tunnel quarries, stinking with the dumped refuse of generations, and the lair of army—especially Foreign Legion—deserters turned thug, it was turned into a romantic landscape with a lake, a waterfall, a grotto (false stalactites), winding woodland paths, and picturesque bridges. It is the largest park within the walls of Paris, 60 acres (25 hectares), and the only one to stay open as late as midnight.

This portion of the 19th *arrondissement* is known as Belleville, and just below on the slope toward the river is Ménilmontant, in the 20th *arrondissement*. Together, these two sections produce the Brooklynites or Cockneys of Paris, who have their own nasal, buzz-saw manner of speech and a hardheaded, warm-hearted approach to life. Part of their domain is Père-Lachaise Cemetery, site of the wall—le Mur des Fédérés—against which the last of the Communard fighters were shot, and to which pilgrimages are still made. Chopin, Marshal Ney, Baron Haussmann, Alfred de Musset, Balzac, Delacroix, Bizet, Rossini, Sarah Bernhardt, Isadora Duncan and Colette are among the noted persons buried here.

Green spaces. Paris appears to have much more green, open space than it really has. This optical-psychological illusion is fostered by the garden effect of the Seine's open waters and its tree-lined banks (2,300 of its own trees, in addition to nine major parks and gardens along its route) and by the parklike effect of 87,000 trees (mostly plane trees, only 10 percent chestnuts) planted along the streets. One earnest civil servant, wishing to demonstrate that the illusion was no illusion but a reality, showed in 1970 that—counting everything, including cemeteries and large private gardens—there is one tree for every 6.6 inhabitants of Paris, far above international minimum standards.

The city's abundance of trees

Every plan for improving Paris has called for more parks and playing fields, and every plan has fallen short of its goals.

The large parks and gardens of the central city were on the outskirts when first created by royalty, and the city grew around and beyond them. The hero of the green-space movement remains Napoleon III. During the years of his exile in England he had been impressed by London parks and resolved to give Paris the same joys. Two ancient royal military preserves at the approaches to Paris were made into "English" parks: the Bois de Boulogne, 2,380 acres (962 hectares) on the west, and the Bois de Vincennes, 2,460 acres (995 hectares) to the east. Also under the Second Empire, 173 acres (70 hectares) were given to promenades and to 24 garden-planted city squares, and the number of trees planted along the streets was almost doubled.

In the century from 1870 to 1970 a total of 252 acres (102 hectares) was gained for the population. From 1953 to 1967 successive plans provided for the addition of two dozen new squares to the "green patrimony" of the citizens, but financial and administrative difficulties proved too great for more than token progress. Administrative complexities are suggested by a short list of the institutional organisms responsible for greenery: public squares by the City Parks Department; street trees by the City Streets Department; riverbank trees by the Navigation Service; Tuileries and Palais Royal by the Cultural Affairs Ministry; Luxembourg by the Senate; and Jardin des Plantes by the Ministry of National Education.

Just outside the city three enormous recreational facilities have been established, with facilities for most sports, stadia, green fields, and woodlands. One of these, at Issy-les-Moulineaux, immediately beyond the city limits, was borrowed by the army in 1890 and returned to the city in 1970.

The number of public swimming pools in Paris intramurals was increased from 39 to 54 in the years 1962 to 1972.

SOME PARISIAN FACTS AND FIGURES

Cultural facilities. There are 60 theatres and 200 motion picture theatres, 15 concert halls, and 65 museums in Paris. The city operates 75 neighbourhood lending libraries and two specialized collections. The libraries of the Arsenal, Saint-Geneviève, and Bibliothèque Nationale are research libraries requiring special readers' cards.

Consumption. Paris consumes one-quarter of all the commercially prepared foodstuffs in France. More than 400,000 metric tons of meat and a thousand million litres of wine are sold in the capital every year. Every day the inhabitants and industries use 4,000,000 cubic metres of water. Treatment stations cleanse 1,200,000 cubic metres of water and 3,000,000 cubic metres of effluent each day. Each inhabitant throws away one kilogram of household refuse per day.

Paris underground. From Roman times to the end of the 19th century, Paris was tunnelled for the extraction of gypsum, limestone, and brick clay. Notre-Dame, Saint-Germain-des-Prés and Saint-Severin are among the churches built of local stone. The galleries, which extend under seven *arrondissements*, were filled in many years ago, save for the catacombs of Place Denfert-Rochereau and 90 miles (150 kilometres) of inspection galleries.

The 1,200 miles (2,000 kilometres) of sewer tunnels serve as host for drinking-water ducts 987 miles (1,588 kilometres), industrial and street-hydrant ducts 1,048 miles (1,686 kilometres) and also for the telephone, *télex*, telegraph circuits, the system of fire and police alarms, and the traffic signals. Also hung in the sewer conduits are the pipes of a system—unique in the world—for furnishing compressed air to homes and workrooms. Installed by an Austrian, Victor Popp, in 1881, the system was designed to furnish motive power for clocks and elevators. The compressed air still finds many applications, and three stations service 600 miles (1,000 kilometres) of tubes.

Electricity 6,000 miles (10,000 kilometres) of cable and gas 1,400 miles (2,300 kilometres) of pipe are both laid under the sidewalk. Some 89 miles (144 kilometres) of separate tubing deliver compressed gas to 2,000 street lamps and 1,800 homes.

Steam for central heating, furnished to 2,200 subscrib-

ers, has been circulated under the city streets since 1928. The steam comes from two rubbish incinerators, an electrical generating plant, and two steam generators. The subway uses 105 miles (169 kilometres) of tunnels.

BIBLIOGRAPHY

General description: P. COHEN-PORTHEIM, *The Spirit of Paris* (1937), provides a short and agreeable introduction that is supplemented rather than superseded by J. RUSSELL, *Paris* (1960). For a rather fuller treatment the English reader may consult: A.H. BRODRICK (ed.), *Paris* (1950) and *Greater Paris and the Île-de-France* (1952); G.R. MARTINEAU (ed.), *Paris: Its Environs* (1954); H.P. CLUNN, *The Face of Paris*, new ed. (1958); B. EHRLICH, *Paris on the Seine* (1962); or V. CRONIN, *The Companion Guide to Paris* (1963). There are also two very well-illustrated volumes with English versions of text by distinguished French writers: ANDRE GEORGE, *Paris* (1952; Eng. trans., new ed., 1957); and MARCEL BRION, *Paris* (1962; Eng. trans., *Paris in Color*, 1964). Famous writers whose personal presentations of Paris must be read in the original French include: LEON-PAUL FARGUE, *Le Piéton de Paris* (1939); JEAN COCTEAU, *Paris tel qu'on l'aime* (1950); HENRY DE MONTHERLANT, *Le Fichier parisien*, augmented edition, especially interesting on the life of the city (1955); PAUL MORAND, *Paris*, sumptuously illustrated with photographs (1970); and GEORGES SIMENON, *Le Paris de Simenon*, with sketches by FREDERICK FRANCK (1970).

History: Good general histories available in English are H. BIDOU, *Paris* (1937; Eng. trans., 1939); and R. LAFFONT (ed.), *Illustrated History of Paris and the Parisians* (1958). Major works in French include: M. POETE, *Une vie de cité: Paris de sa naissance à nos jours*, 3 vol. and album (1924–31); L. DUBECH and P. D'ESPEZEL, *Histoire de Paris*, 2 vol. (1931); and PHILIPPE LEFRANCOIS, *Paris à travers les siècles*, 10 vol. with photographs (1948–56). For the history of the town's growth, see particularly R. HERON DE VILLEFOSSE, *Construction de Paris* (1939); or the handier surveys by M. RAVAL, *Histoire de Paris*, 6th ed. (1953); and by P. LAVEDAN, *Histoire de Paris*, new ed. (1960). Studies of special periods range from P.M. DUVAL, *Paris antique: des origines au troisième siècle* (1961), to B. CHAMPIGNEULLE, *Paris de Napoléon à nos jours* (1969); and there is also a remarkably documented forecast of future development by P. MERLIN, *Vivre à Paris 1980* (1971).

Antiquities: The monumental work of F. DE ROCHEGUDE and M. DUMOLIN, *Guide pratique à travers le vieux Paris* (1923, rev. 1925), has been adapted by J.P. CLEBERT under the title *Les Rues de Paris*, 4 pts. (1958), which may be supplemented by G. PILLEMENT, *Paris inconnu: itinéraires archéologiques* (1965), and *Les Environs de Paris inconnus . . .*, 2 vol. (1961). Also by Pillement is a comprehensive series of works on the old houses or palaces: *Les Hôtels de Paris*, 2 vol. (1945); *Les Hôtels du Faubourg Saint-Germain* (1950); *Les Hôtels de l'Ile Saint-Louis, de la cité, de l'université, et du Luxembourg* (1951); *Les Hôtels d'Auteuil au Palais-Royal* (1952); *Les Hôtels des boulevards à Charonne* (1953); and *Les Hôtels du Marais*, 3rd ed. (1955). For the churches, see A. BOINET, *Les Églises parisiennes*, 3 vol. (1958–64). Of sentimental interest are L.P. FARGUE *et al.*, *Dans les rues de Paris au temps des fiacres* (1950); R. HERON DE VILLEFOSSE, *Histoire et géographie galantes de Paris* (1957); J. GALLOTTI, *Le Paris des poètes et des romanciers* (1964); and G. PILLEMENT, *Paris disparu* (1966) and *Les Environs de Paris disparus* (1968), with copious engravings and photographs.

Economy: R. MINGUET, *Géographie industrielle de Paris* (1957) and *Paris au travail* (1959).

(B.E.)

Parkman, Francis

Francis Parkman, often called America's greatest historian, is best known for his seven-volume history of the Anglo-French struggle for North America, in which he displayed a rare talent for dramatic exposition combined with the strict historical accuracy of the scholar. He was born in Boston on September 16, 1823, the son of Francis Parkman, a leading Unitarian minister of Boston. As a boy, he met many of his father's literary friends and read widely in the family library. He spent many summers at his grandparents' farm in nearby Medford, while during the rest of the year he was drilled in Greek, Latin, and mathematics at the Chauncy Place School, in Boston, in preparation for Harvard.

Early years

At college Parkman, a talented linguist, read almost as many books in foreign languages as in English, including the original texts of great historians of antiquity and Italian writers such as Niccolò Machiavelli. He also devoured the major works of French literature and history. The romantic themes of many of the works of Chateaubriand and of Jules Michelet, the historian, attracted him, as had the novels of Sir Walter Scott. In serious archival studies he was encouraged by his Harvard teacher, the renowned historian Jared Sparks. Sparks, a man drawn to adventure and exploration, who wrote about the French explorer Robert Cavalier, sieur de La Salle, in North America, and at one time planned a safari to Timbuktu, exerted an enormous influence on an impressionable undergraduate such as Parkman.

Though teachers and books helped to shape Parkman's thinking in his formative years, he gathered data, as indicated by his letters and journals, through direct observation. During his college years he exhausted friends who struggled to keep pace with him on woodland expeditions through New England and southeastern Canada. Yet he did not neglect to participate in whiskey punch and Indian war cries that sometimes followed dormitory suppers. Pretty girls and horses, he concluded, were "the 'first-ratest' things in nature." After a breakdown in health during his last year in college, he made a grand tour of Europe in 1844. His particular interest in the Roman Catholic Church prompted him to observe it at close range, even to the extent of living for a short time in a monastery in Rome. In the following year, he toured historic sites in the northwest of America and, to please his father, completed requirements for a law degree at Harvard. In the summer of 1846 he embarked on a journey to the Great Plains in which he travelled a portion of the Oregon Trail to Ft. Laramie.

Beginnings of literary career

Parkman's literary career had its real beginning after he returned from the West. Despite temporary illness and partial loss of sight, he managed to write a series of Oregon Trail recollections for the *Knickerbocker Magazine*. Published in 1849 as *The California and Oregon Trail*, the book's title was misleading because Parkman had ventured nowhere near California. He keenly regretted the "publisher's trick" of the mention of California as a stimulus to better sales. The book, in later editions called *The Oregon Trail; Sketches of Prairie and Rocky-Mountain Life*, became one of the best selling personal narratives of the 19th century.

The Oregon Trail served notice that a new writer, at home on the frontier as well as in staid, provincial Boston, had appeared. *History of the Conspiracy of Pontiac*, completed just before his marriage to Catherine Scollay Bigelow in 1851, was his first historical work, a comprehensive survey of Anglo-French history and Indian affairs in North America, culminating in the great Ottawa chief's "conspiracy" and Indian war of 1763. In the "dark years" of illness following the death of his young son (1857) and his wife (1858), Parkman entered a period of depression and semi-infirmity. His complaints of heart trouble, insomnia, painful headaches, semiblindness, wa-

ter on the knee, and finally arthritis and rheumatism, which fill his correspondence, were probably the result of what modern physicians have diagnosed as an underlying neurosis. By personalizing his illness and calling it the "enemy," Parkman seems to have forced himself to play the role of a man of action at the cost of great tension. His struggle against the "enemy" enabled him to maintain his self-respect and appears to be at least partly responsible for the powerful drive and creative force behind his writings.

History of France and England in North America

By the time the U.S. Civil War ended, Parkman had at least partly overcome his personal "enemy" of illness to complete his *Pioneers of France in the New World,* a vivid account of French penetration of the North American wilderness that created a setting for his later volumes. In the 27 years following the Civil War, Parkman (who had to content himself with writing militant, patriotic letters to the press during the conflict) completed his elaborate series by writing six more historical works in addition to the *Pioneers. The Jesuits in North America in the Seventeenth Century* (1867) is a powerful narrative of the tragedy of the Jesuit missionaries whose missions among the Hurons were destroyed by persistent Iroquois attacks, and his *La Salle and the Discovery of the Great West,* first published in 1869 as *The Discovery of the Great West* but later revised after French documents were made available, is in many respects one of the best one-volume biographies in the English language. La Salle, a hardy, gallant figure who overcame almost every obstacle in his path, was a heroic figure almost made for Parkman's pen. *Count Frontenac and New France Under Louis XIV* (1877) tells the story of New France, the early French settlement in Canada, under its most formidable governor, a man of vanity, courage, and audacity. Yet it was in *Montcalm and Wolfe* (1884)—a true biography of the French general Marquis de Montcalm and the English general James Wolfe, both of whom died at the Battle of Quebec in 1759—that Parkman not only reached his highest achievement in character portrayal but also showed how great biography can be used to penetrate the spirit of an age. By contrast, Parkman's *The Old Régime in Canada,* published in 1874, provides a sweeping panorama of New France in her infancy and youth, a pioneer work in social history that holds the interest of the reader no less than his narrative volumes. Parkman's literary artistry is perhaps best studied in his *Half-Century of Conflict,* completed shortly before his death which occurred in Jamaica Plain, Massachusetts, on November 8, 1893. This final link in his history *England and France in North America* is a fascinating but complex account of events leading up to the French and Indian War.

Assessment

Parkman's weaknesses as a writer have often been exposed. There is little question that he tended to stress dramatic qualities of his narrative and thus to give individuals an importance in events that they may not have deserved. His unbrotherly depiction of Indians as conspirators and ferocious savages, criticized by many of his contemporaries, obscured the fact that the Indians under Pontiac were fighting for self-determination. Parkman's belief that leadership should be in the hands of the cultured and capable was projected into his work to explain, for example, that La Salle accomplished as much as he did because he was "a man of thought, trained amid arts and letters." And there are passages that show that Parkman, in some cases, was a spokesman for Anglo-America who saw in French Canada a source of spiritual and political despotism that would attack society like mildew and stifle its growth. Yet because he showed that authoritarianism has its evils, he was not necessarily an exponent of democratic Anglo-Saxonism. Rather, he portrayed the Anglo-French and Indian wars as part of a struggle between contesting civilizations, in which the interior wilderness acted as a modifying force on rival colonial cultures. Perhaps Parkman's greatest achievement was his skill in recognizing the dramatic potentials in the raw materials of history, so that he could create a narrative both historically accurate and, as he said, "consistent with just historic proportion." When he wrote that his aim was "to get at the truth," he explained the lifelong search for factual data that underlies his entire work. Not all of his interpretations have been accepted unquestioningly, but Parkman's genius with the pen was such that his main figures—Frontenac, Montcalm, Wolfe, La Salle, and Pontiac—are not so much remembered today because of what they did but because Parkman made them the heroes of his history of Anglo-French rivalry in North America.

BIBLIOGRAPHY. WILBUR R. JACOBS (ed.), *Letters of Francis Parkman,* 2 vol. (1960), includes a short biography with an analysis of Parkman's illness. LOUIS CASAMAJOR, a physician, probes the psychological implications of Parkman's neurosis in "The Illness of Francis Parkman," *Am. J. Psychiat.,* 107: 749–752 (1951). MASON WADE, *Francis Parkman: Heroic Historian* (1942), is an excellent one-volume biography; and SAMUEL ELIOT MORISON (ed.), *The Parkman Reader* (1955), contains representative selections from Parkman's historical writings. Parkman's literary techniques and skills as a writer are explored by WILBUR R. JACOBS, "Some of Parkman's Literary Devices," *New England Quarterly,* 31:244–252 (1958); DAVID LEVIN, *History As a Romantic Art: Bancroft, Prescott, Motley, and Parkman* (1959); and HOWARD DOUGHTY, *Francis Parkman* (1962). The criticism of Parkman's work as a historian of the Indian is well exemplified by FRANCIS P. JENNINGS, "A Vanishing Indian: Francis Parkman Versus His Sources," *Pennsylvania Magazine of History and Biography,* 87:306–323 (1963); and ROBERT SHULMAN, "Parkman's Indians and American Violence," *Massachusetts Review,* 12:221–239 (1971). Further criticism and appraisal of Parkman's significance as a historian is in DAVID E. GRIFFIN, "'The Man for the Hour,': A Defense of Francis Parkman's Frontenac," *New England Quarterly,* 43:605–620 (1970); and in WILBUR R. JACOBS, "A Message to Fort William Henry," *Huntington Library Quarterly,* 16:371–380 (1953).

Parnell, Charles Stewart

An Irish nationalist and the leader of the struggle for Irish Home Rule in the late 19th century, Charles Stewart Parnell, by his radical tactics and "new departure," upset the land settlement that had been imposed by the British on the Irish for three centuries. He took the question of self-government for Ireland out of its academic domain and made it a practical political issue, converting one of the two great British parties to its cause. British authority in Ireland, after Parnell, never again rested on so solid a foundation. Both Sinn Féin republicans and Irish literary revivalists saw him as a hero and a precursor.

Parnell, painting by Sydney Prior Hall, 1892. In the National Gallery of Ireland.

Parnell was born at Avondale, County Wicklow, on June 27, 1846. His mother was a daughter of Commo. Charles Stewart of the United States Navy, a hero of the War of 1812 whose parents had emigrated from Belfast before the American Revolution. The anti-British tradi-

tions and atmosphere of Parnell's home were significantly different from those of the majority of the Anglo-Irish Protestant landowning class to which he belonged. They did not, however, prevent his parents from giving him an education normal for his class. He went to three English boarding schools, where he seems to have been unhappy, and to Cambridge, where in 1869, after an undistinguished career, he was suspended for a relatively minor breach of discipline and decided not to return.

The Home Rule League and the Land League. The Ireland to which Parnell returned was in ferment (see BRITAIN AND IRELAND, HISTORY OF). The government's oppressive measures against the revolutionary Irish Republican Brotherhood (the Fenians) aroused intense national feelings among even the moderate Irish. In 1870 a new political group, the Home Rule League, was set up to press for Irish autonomy in local government; in 1874 it returned 56 candidates to Parliament, where they formed a party under the nominal leadership of Isaac Butt. Though socially conservative and deferential to the opinions of the Roman Catholic hierarchy, all appealed in some degree to the national sentiments of the electorate. Parnell, an eminently suitable Home Rule candidate, was elected to Parliament for Meath in April 1875. Within two years he distinguished himself by his indifference to the opinion of the House of Commons and his sensitivity to Irish nationalist opinion. He embraced the policy of obstructing English legislation to draw attention to Ireland's needs, and his handsome presence and commanding personality gave him a powerful appeal. In September 1877 the Home Rule Confederation of Great Britain elected Parnell its president; he had become, at the age of 31, the most conspicuous figure in Irish politics.

Policy of obstructionism

In 1878 an agricultural crisis in Ireland seemed to threaten a repetition of the terrible famine and mass evictions of tenant farmers of the 1840s. To resist eviction and make Irish landlordism unworkable, the Irish Land League was founded in 1879 by a Fenian, Michael Davitt. Many moderates condemned the league, but Parnell identified himself with it and became its first president, thus becoming the centre of the great "new departure" national movement in which revolutionary devotion was combined with agrarian agitation and was supported by the obstructionist tactics of the "active section" in Parliament. Soon after the general election of 1880, Parnell was elected chairman of the Home Rule group in the new Parliament. After the rejection by the House of Lords of a moderate measure for Irish land reform, Parnell organized a massive land agitation, for which he then won the support of the clergy and of "moderate" opinion. It was combined with parliamentary obstruction on so large a scale that ultimately 36 Irish members were suspended. At this time Parnell rejected a policy of secession from Parliament, put forward by the Land League.

The passage in 1881 of Gladstone's Land Act, which conceded the principle that fair rents could be judicially determined, presented Parnell with a serious test of statesmanship. Its passage was unquestionably a great achievement for the Land League, but the most active Land Leaguers were not content and a split in the movement seemed likely. This Parnell avoided by pursuing a policy moderate in substance—testing the act by bringing selected cases before the land commission—but making speeches couched in violent language. As a result, probably in accordance with his wish, he was, on October 13, 1881, lodged in Kilmainham jail, Dublin. This assured his continued popularity and absolved him of responsibility for subsequent events.

Imprisonment in Kilmainham

Parnell's arrest was followed by the suppression of the Land League and a winter of sporadic local terror. It became clear to the government that only Parnell could restore order. In the spring of 1882 Parnell began negotiations for his release, conducted in the main through Capt. William O'Shea, a "moderate" Home Rule member, whose wife had been Parnell's mistress since 1880. A settlement was reached, the so-called Kilmainham Treaty, whereby tenants were to obtain substantial concessions and Parnell was to use all his influence to decrease further agitation.

The murders by nationalists in Phoenix Park, Dublin, of the chief secretary and the permanent undersecretary, which occurred within a few days of Parnell's release (May 2, 1882), caused a general revulsion against terrorism, and Parnell had little difficulty in bringing the nationalist movement again under firm discipline, subordinating the Irish National League (the successor to the Land League) to the Home Rule Party in Parliament.

Parliamentary manoeuvres. The Kilmainham Treaty ended the revolutionary phase of the "new departure." The results of by-elections showed that Parnell's leadership was unquestioned, except in eastern Ulster, and, after the Reform Bill of 1884 extended the franchise to agrarian workers, it became apparent that Parnell was likely in the next Parliament to lead a party of between 80 and 90 members. With this potential strength Parnell became a force to be reckoned with. He contemptuously refused overtures made for his support by the radical wing of the Liberal Party led by Joseph Chamberlain and Charles Wentworth Dilke.

Alliance with Tories

The Tory advances to him led very quickly to a combination in which Tories and Irish voted together to defeat the Liberal government (June 1885), and in the election campaign that followed (November–December 1885), Parnell, having failed to get a satisfactory Home Rule statement from Gladstone, issued the "vote-Tory manifesto." Although the Irish could put the Liberals out, they could not keep the Tories in. In these circumstances, the Tories immediately broke with them and announced the intention of reintroducing coercion in Ireland. Parnellites and Liberals voted together to bring down the government, and Gladstone took office in February 1886. For his continuation in office he depended on Irish support.

There followed the curious and ominous episode of the Galway election. Parnell, under pressure from the O'Sheas and Joseph Chamberlain, put forward Captain O'Shea as Home Rule candidate, although he had refused to take the pledge "to sit and vote with the party." The evidence suggests that Chamberlain was attempting to undermine Parnell's authority and split his party. If so, he failed. A mutiny of a small faction was quelled and O'Shea was elected.

Although Gladstone's Home Rule proposals—involving a wide measure of autonomy—fell short of nationalist aspirations, Parnell accepted them as a basis of settlement and enlisted public opinion in their support. The introduction of the bill, though it was later rejected by the Commons on the second reading (June 1886), was regarded as his personal triumph. When the Conservative Lord Salisbury succeeded Gladstone as prime minister, Parnell withdrew to some extent from active political life. This was partly due to ill health but also to political reasons. With the Irish party firmly allied to the opposition, there was now no room for parliamentary obstruction. Parnell would neither challenge Gladstone's leadership nor appear as his henchman. He also held aloof in Ireland from the ingenious rent-withholding combination known as the plan of campaign, devised by William O'Brien.

The Times forgery

Despite his relative inactivity Parnell was kept before the public through the efforts of his enemies. On April 18, 1887, *The Times* published a facsimile of a letter purporting to be written by Parnell condoning the Phoenix Park murders of May 1882. Parnell immediately denounced it as a forgery. Nearly two years later the forger, a journalist named Richard Pigott, collapsed under cross-examination before an investigating commission. Parnell, after Pigott's suicide in Madrid soon afterward, was transformed in the eyes of the English liberals from a dubious ally into a hero and martyr. This brief period was the peak of Parnell's career.

Parnell's fall. On December 24, 1889, Captain O'Shea filed a petition for divorce, naming Parnell as co-respondent. Although Parnell's liaison had been known to some members of the Irish party, nationalist Ireland in general took it that the proceedings represented another attempt to wreck Home Rule. This was given colour by the fact that O'Shea was a follower of Joseph Chamberlain. The theory that there were political motives behind the di-

vorce proceedings is not necessarily false. The suit being undefended, the court returned a verdict against Parnell and Mrs. O'Shea on November 17, 1890.

The initial reaction of the Irish public was to uphold Parnell. In Britain, however, Nonconformist opinion was so hostile that the Irish parliamentary party found itself in an agonizing dilemma. Parnell was determined to hold the leadership and defy Gladstone. If the party upheld Parnell they would be destroying the Liberal alliance, and with it the hopes of Home Rule in their generation. If they rejected Parnell, they would be turning against him at the bidding of an Englishman. After a long and emotional debate, the majority rejected his leadership; a sizable minority remained with him.

There followed a series of bitter electoral campaigns. The Catholic hierarchy, although slow to pronounce, now declared Parnell morally unfit for leadership. His marriage to Mrs. O'Shea in June 1891 exacerbated Catholic opposition. He himself displayed feverish energy and increasing recklessness, directing his appeal more and more to the revolutionary elements. This appeal left a deep impression on the young but was rejected by the majority of the nation. When his principal ally, the nationalist *Freeman's Journal*, fell to his enemies shortly after his marriage, his cause was clearly lost. He died at his wife's home in Brighton on October 6, 1891, and was buried in Glasnevin Cemetery, Dublin. The city, Parnellite to the end, gave him a magnificent funeral.

BIBLIOGRAPHY. R.B. O'BRIEN, *The Life of Charles Stewart Parnell, 1846–1891*, 2nd ed., 2 vol. (1899), has not been superseded, although several lives of Parnell have been published since. CONOR CRUISE O'BRIEN, *Parnell and His Party, 1880–90* (1957, corrected impression 1964), is a study of Parnell's political leadership and of the political machine that he controlled. F.S.L. LYONS, *The Fall of Parnell, 1890–91* (1960), is an excellent detailed study of the divorce crisis and its sequel; and the same author's *Parnell* (1963), a very useful short study.

(C.C.O'B.)

Particles, Subatomic

Subatomic particles, often called elementary particles, are the fundamental units of matter and energy.

The growth of knowledge in the present century has profoundly altered the accepted view of the nature and properties of subatomic particles. As of the early 1970s, the existence of more than 200 such particles has been firmly established, and a number of laws governing the relations among them had been stated. No complete theory as yet exists, but experimental and theoretical research is being carried out on a large scale at the major universities of the world and at laboratories organized especially for this purpose such as the CERN (European Organization for Nuclear Research) laboratory at Geneva, the National Accelerator Laboratory near Chicago, and the Serpukhov laboratory near Moscow. (For a more detailed account of the research tools used in this work, see ACCELERATORS, PARTICLE; RADIATION DETECTION AND CHARACTERIZATION.)

This article is divided into seven parts. The first section embraces the concepts and theories of subatomic particles developed in historic sequence before 1960. During this period relatively few particles were known, but there were complicated developments, both conceptual and experimental, that make this section more difficult to understand than those that follow it. The second section, *Four basic forces and four classes of particles*, which may be read independently, describes the hundreds of new particles discovered since 1960. The next section, *Conservation laws and quantum numbers*, treats the principles of basic symmetry, by which the new multiplets of particles are organized. The fourth section, *Spectroscopy of the hadrons; the quark model*, develops a table of particles. The fifth section, *Experiments*, returns to a historical description, starting in 1960. The section on *Relations between the interactions* is concerned with the concepts of currents and the algebra of currents. The final section, *Undiscovered particles*, deals with theories that assume the existence of certain undiscovered particles.

HISTORY UP TO 1960

Atomic structure and nuclear forces. This section reviews developments of particle physics up to the early 1960s. The reader who does not need this detailed history, but is more interested in the hundreds of new particles discovered in the 1960s and the new concepts such as the quark model, by which the new periodic table of particles is organized, can omit this section.

The idea that matter is composed of elementary building blocks goes back at least as far as Democritus (500 BC). Until the discovery of the electron and the structure of the atom (see the articles ELECTRON; ATOMIC STRUCTURE), atoms could be and sometimes were regarded as elementary particles in this sense, and, indeed, the 100 or so different atoms are still spoken of as chemical "elements." After the discovery of the "electron" (e) in 1897 and of atomic nuclei in 1911, however, it was clear that an atom had to be regarded as a composite system consisting of a cloud of electrons surrounding a tiny heavy central core, the atomic nucleus. The electron cloud was found to obey quantization rules in that it can exist only in discrete, or definite, energy states (also called energy levels). The state of lowest energy, the ground state, is stable, whereas those of higher energy, the excited states, can make transitions to lower states with the emission of light quanta ("photons," symbol γ) the energy of which makes up the difference in energy between the initial and the final states involved in the transition. This concept was not at first supported by a systematic quantitative theory, though the behaviour of the electron clouds could be semiquantitatively described by a combination of the classical theory of electricity and magnetism with the quantization rules of Niels Bohr, a Danish physicist. A far-reaching improvement in the theoretical situation resulted from the discovery in 1926 of the true quantum mechanics (see MECHANICS, QUANTUM). Once the quantum mechanics of the electromagnetic field had been worked out in 1927 by P.A.M. Dirac, an English physicist, a quantitative theory of photon emission and absorption that agreed with experiment became possible.

Early notions of elementary particles

In summary, in the theory of atoms of the late 1920s, electrons, nuclei, and photons were all understood as elementary particles, and the electrons and nuclei were understood as bound together to form atoms by the electromagnetic forces between them.

That the treatment of the atomic nucleus in this theory of atoms is only schematic was recognized from its inception. Experiments on nuclei had shown that, like atoms, nuclei can exist in excited states. Thus an extension to atomic nuclei of the point of view that had been successful in the theory of atoms led to a picture in which the constituent protons (the nuclei of hydrogen atoms) and other (then unknown) particles are also governed by the laws of quantum mechanics and are bound together by (then unknown) forces. Within a few years experimental discoveries confirmed this general atomic picture, and it was reduced to a concrete quantitative theory. In 1932, James Chadwick, an English physicist, discovered the neutron (n), a particle slightly heavier than the proton and of zero electric charge, and evidence grew that the constituents of all atomic nuclei are "nucleons," nucleon being a generic term meaning either proton or neutron. The nucleons are bound together, according to the laws of quantum mechanics, by a nuclear force acting strongly only when the particles are separated by extremely small distances (less than a few times 10^{-13} centimetre). Nuclear force refers to those forces other than electrical that act between nucleons (see NUCLEUS, ATOMIC).

Nuclear forces

Quantum mechanics also made possible a quantitative description of the phenomenon of beta (β-) radioactivity, in which a nucleus, through the emission of both a negative electron and a neutral particle of small mass (usually taken to be zero), undergoes a transition to a lower energy state, thus becoming a nucleus with one more proton and one less neutron. This neutral particle, later named the neutrino, is difficult to detect because its interaction with matter is so weak. The first experiment in which a neutrino beam produced an observable effect was reported in 1956.

The three phenomena mentioned above illustrate a classification of interactions that is basic for an understanding of the remainder of this article: strong, electromagnetic, and weak interactions. Nuclear forces are strong interactions, stronger than electromagnetic. The difference in strength implies that nuclear binding energies are much larger than atomic energies. On the other hand, weak interactions, such as those responsible for beta radioactivity, are much weaker than electromagnetic.

At first sight, this theory of atomic nuclei would seem to be a natural extension of the older view that matter is composed of an elementary building block, the atom: a list of elementary particles should include electrons, protons, neutrons, and neutrinos. The theory of atomic nuclei, however, contained some radically new ideas about transformations of elementary particles. The neutron can transform into a proton and emit an electron and a neutrino. This transmutation contrasts with the behaviour of the electrons in atomic theory; in the atom, electrons retain their identity while interacting with photons. To develop the full consequences of such predictions, it is necessary to make an apparent digression to describe developments in the relativistic theory of electrons.

Negative energy states and quantum field theory. The first quantum-mechanical theories of the electron, those used in the theory of atoms in the mid-1920s, were nonrelativistic and did not take into account the effects of the finite propagation velocity of light. In 1927 Dirac introduced a relativistic theory of the electron that was successful in accounting for the spin of the electron and for the fine structure of the energy levels of hydrogen (*i.e.*, some energy states have a substructure). Unfortunately, the theory also predicted the existence of states the properties of which did not make sense, the so-called negative energy states. All attempts to amputate these negative energy states from the theory proved unsatisfactory.

Negative energy states

In 1930 Dirac made a bold proposal to put the negative energy states to good use to explain the existence of the proton. He noted that, according to the so-called Pauli exclusion principle (see MECHANICS, QUANTUM), two electrons in an atom cannot occupy the same state. He then made the hypothesis that *in vacuo* all the negative energy states predicted by his theory are occupied by electrons but that the resulting charge distribution is unobservable. Thus a positive-energy negatively charged electron (e^-) moving in the vacuum cannot jump into a negative energy state with the emission of a photon because there is no negative energy state that is not occupied. Furthermore, the removal of an electron from a negative-energy state would result in an observable "hole," which, Dirac showed, would behave like a normal positive-energy particle of opposite charge (e^+). His initial proposal to interpret the proton as this hole, however, turned out to be unsatisfactory for two reasons. First, it was found that a hole in the sea of negative-energy electrons would have to have the same mass as an ordinary electron, in disagreement with the observation that protons are 1,836 times heavier then electrons. Second, the hydrogen atom formed of an electron and a hole would annihilate itself in a small fraction of a second leaving nothing but photons. In 1931 Dirac concluded that, if holes existed, they would describe a new positive particle.

About a year later the positive electron was discovered by Carl D. Anderson, a U.S. physicist, who named it the positron. (There is a standard ambiguous usage of the word electron. Sometimes it stands for the negatively charged, e^-, and sometimes it is used as a generic term for the positive or negative particles, $e^\pm$. The symbols e^+ and e^- should be used when any significant ambiguity arises. A similar ambiguity, in the case of neutrinos, is resolved by distinguishing between them as neutrinos and antineutrinos.) Dirac's prediction, one of the most spectacular achievements of theoretical physics, was comparable to the prediction by Hideki Yukawa, a Japanese physicist, of the existence of another elementary particle, the meson (see below *Yukawa mesons and strong interactions*).

It was later shown that Dirac's hole theory is essentially equivalent to a theory in which electrons and positrons appear symmetrically with positive energies only, so that there is no unobservable sea of negative-energy electron states. The natural language for such a description is that of the quantum theory of fields. Dirac's relativistic theory of the electron was reinterpreted as a theory of two interacting fields, the electron–positron field and the electromagnetic, or photon, field.

The notion of the particle has quite different statuses in the relativistic quantum theory of fields and the nonrelativistic theory of particles. A leading idea of quantum field theory is that all particles of the theory appear as quanta of some field. For example, photons are particles associated with the electromagnetic field, whereas electrons and positrons are quanta of the Dirac field. This appears to be a perfectly innocent requirement, and indeed it is, until the additional requirement is made that the theory be consistent with the special theory of relativity. Then, remarkably, it is found that, if the particles are to interact with one another at all, it must also be possible for them to be created and annihilated. Thus, if electrons and photons are to be described by a relativistic field theory and interact at all, the creation and annihilation of electron–positron pairs must be possible. The fact that particle creation and annihilation necessarily takes place in such a theory makes the definition of an elementary particle essentially more complicated. Even if in a given physical situation no actual particle creation is possible without violation of the laws of conservation of energy and momentum (*i.e.*, neither energy nor momentum—mass times velocity—can be destroyed), nevertheless the interaction responsible for pair creation and annihilation has indirect effects, the so-called virtual creation and annihilation processes. In such a theory, for example, a single electron moving through the vacuum polarizes it (*i.e.*, the electron may be thought of as surrounded by a cloud of virtual photons and electron–positron pairs). Under such circumstances there are at least two possible ways (and actually many more) to define an electron: with its cloud (the dressed electron) or without (the bare electron). The situation is even more complicated in the theory of beta radioactivity put forth by Enrico Fermi, an Italian physicist, in which a proton has to be considered as existing virtually as a neutron plus a positron plus a neutrino, as well as having a cloud of photons, e^+e^- pairs, and nucleon–antinucleon pairs surrounding it. Such a notion of an elementary building block is remote from the pictures of particles as little billiard balls that had motivated the work only a few years earlier, and it was not the end of the evolution of the idea of elementary particles.

Annihilation of particles

Yukawa mesons and strong interactions. In 1934 Yukawa proposed a theory of nuclear forces that turned out to be of great significance. Yukawa's ideas were based on an instructive analogy with the theory of electrical forces, which will next be explained. Coulomb's law of electrostatics states that the force that two charges, e_1 and e_2, exert on one another when they are separated by a distance r is given as the product of the two charges divided by the distance of separation squared, e_1e_2/r^2. There is an equally accurate but somewhat less familiar description of this force (shown schematically in Table 3) that attributes it to the exchange of virtual photons between the two charges. The factors e_1e_2 in Coulomb's law then comes about because the ability of the first charge to emit and absorb photons is proportional to e_1 and that of the second charge is proportional to e_2. The dependence of the force (F) on the separation turns out to be the simple geometrical factor, $1/r^2$. Yukawa pointed out that, if two nuclear particles, instead of emitting and absorbing massless photons, emitted and absorbed certain particles of finite mass, $m \neq 0$ (later called mesons), then (see again Table 3) the only essential change in the results is the replacement of quantities e_1 and e_2 by two other numbers, g_1 and g_2, which are measures of the ability of the particles to emit and absorb mesons, and the appearance of an exponential factor, $\exp[-r/(\hbar/mc)]$, in Yukawa's force law, in which the symbol $\hbar$ is Planck's constant divided by two times pi ($\hbar = h/2\pi = 1.06 \times 10^{-34}$ joule-second) and c is the speed of pho-

tons in vacuo (3×10^8 metres per second—*i.e.*, the velocity of light). This new factor is important because it means that the force between two particles falls off much faster with increasing separation than it would according to the Coulomb's law. Stated briefly, the force that could arise from the exchange of virtual mesons of mass m has a range that is approximately inversely proportional to that mass—*i.e.*, a length called the Compton wavelength of the meson. For a mass of the order of magnitude of a few hundred electron masses, the quantity $\hbar/mc$ is of the order of magnitude of 10^{-13} centimetre, the range observed for nuclear forces. The strength of the forces is determined by the parameter, or quantity, g ($g_{NN\pi}$ in Table 3) for a nucleon, called the meson–nucleon coupling constant (see below *Four basic forces and four classes of particles*).

Problem of the "divergencies"

Two decades of experimental and theoretical effort were necessary before it became clear that Yukawa was essentially correct. The situation was much complicated by the fact that, during the 1930s and '40s, it was widely believed that quantum electrodynamics is a defective theory. The prime pieces of evidence for this belief were the "divergencies"—*i.e.*, the infinitely large or ambiguous answers to some simple physical questions that follow from the equations of the theory. These difficulties were almost universally attributed to the physical assumption underlying the theory, viz., that electrons are point particles. It was well-known that difficulties of a similar type occur in the classical theory of electrons and are overcome by attributing a spatial extension to the electron. In the classical theory that predates the era of quantum physics, this spatial extension led to modifications not only of the divergent quantities of the theory but also of the quantities for which the point electron theory predicts finite answers. Similar effects were expected in quantum theory. Thus, for example, a breakdown in the theory was expected in the description of processes in which an electron, colliding with a nucleus, loses energy by the emission of photons. When, between 1933 and 1936, preliminary evidence appeared in cosmic rays for particles with anomalously high penetrating power, it was tempting to explain them as electrons the energy of which was sufficiently high that the predictions of quantum electrodynamics break down. This explanation was short-lived because more detailed experiments showed there were two groups of particles, one of which lost energy by radiation precisely according to the predictions of quantum electrodynamics as worked out in 1934 by Hans Bethe and Walter Heitler, whereas particles of the other group were far more penetrating. By 1937, the conclusion was inescapable; the discovery of a new particle was announced, first called a mesotron, known later as a meson, and now called the muon (μ) the mass of which is 207 times that of the electron. The laws of electrodynamics had not broken down in the anticipated way at all, and Yukawa's predicted meson had appeared—or so it seemed.

The two-meson hypothesis

It was ten years later, in 1947, that Italian physicists Marcello Conversi, Ettore Pancini, and Oreste Piccioni found that those same cosmic-ray mesons were captured in solid materials at a rate 10^{12} times slower than Yukawa's theory predicted. Numerous suggestions of varying plausibility were made to save the theory. The one that proved to be correct (1947) was a two-meson hypothesis: the mesons observed at sea level are not Yukawa mesons but weakly interacting decay products (muons; μ) of the true Yukawa particles, themselves produced copiously in nucleon–nucleon collisions high in the atmosphere. Shortly thereafter, C.M.G. Lattes and co-workers at the University of California, Berkeley, turned a plausible explanation into an important discovery by publishing pictures of the real positive Yukawa particles produced in a cyclotron, later called pions (π^+) that decay into one positive particle, later called a muon (μ^+) and one neutral particle, later called a μ-neutrino (ν_μ). The decay proceeds according to the following schematic representation: $\pi^+ \rightarrow \mu^+ + \nu_\mu$. Cloud-chamber experiments later showed that the muon in turn decays into a positron (positive electron) and two light neutral particles by a reaction that can be written as $\mu^+ \rightarrow e^+ + \nu_e + \bar{\nu}_\mu$, in which the symbol $\bar{\nu}_\mu$ represents a μ-antineutrino and ν_e a neutrino. The discovery of pions, π^+, and muons, μ^+, was followed shortly by systematic studies of their negative counterparts, the negative pion, π^-, and the negative muon, μ^-, by means of the nuclear disruptions or "stars" that they cause when absorbed in photographic emulsions.

Ignorant of the fact that the experimental meson was not the Yukawa meson, theoretical physicists systematically developed a theory of mesons in the period from 1934 to World War II. The mesons introduced by Yukawa were positively or negatively charged. Charged and neutral mesons of spin zero and one were subsequently considered. One of the most significant developments of the period (1938) was the creation by the English physicist, Nicholas Kemmer, of the charge-symmetrical theory, in which the interaction of nucleons with charged mesons is so related to their interaction with neutral mesons that the resulting nuclear forces are the same between proton and proton, proton and neutron, and neutron and neutron. What was emerging was a basic symmetry, which, in a terminology to be explained below, is isospin, or $SU(2)$, symmetry (see below *Spectroscopy of the hadrons; the quark model*). Applied to pions the charge-symmetrical theory led to the prediction of a neutral pion (π^0), which was found in 1950 by the detection of photons resulting from the decay of the neutral pion into two gamma ray photons, $\pi^0 \rightarrow \gamma + \gamma$.

Isospin

If the state of elementary-particle theory had been assessed, say in 1950, a long list of fundamental building blocks, would have been encountered: photon (γ), negative electron (e^-), positron (e^+), proton (p), neutron (n), negative pion (π^-), neutral pion (π^0), positive pion (π^+), negative muon (μ^-), positive muon (μ^+), neutrino (ν), and antineutrino ($\bar{\nu}$). They are shown in Table 1.

Table 1: Stable and Metastable Particles

symbol	J^P	helicity	mass (MeV)	mean life (sec)	typical decays (or name)
Quanta					
γ	1^-	± 1	0	stable	photon
g	2^+	± 2	0	stable	graviton
Leptons					
ν_e, ν_μ	$\frac{1}{2}$	$-\frac{1}{2}$	0	stable	neutrino
e^-	$\frac{1}{2}$	$\pm\frac{1}{2}$	0.5	stable	electron
μ^-	$\frac{1}{2}$	$\pm\frac{1}{2}$	106	2×10^{-6}	$\rightarrow e^-\bar{\nu}_e\nu_\mu$
Mesons (B = O)		Y^*, I^*			
$\pi^\pm$	0^-	0, 1	140	3×10^{-8}	$\rightarrow \mu^\pm\nu_\mu$
π^0	0^-	0, 1	135	1×10^{-16}	$\rightarrow \gamma\gamma$
$K^\pm$	0^-	$\pm 1, \frac{1}{2}$	494	1×10^{-8}	$\rightarrow \mu^\pm\nu_\mu$
K^0	0^-	$\pm 1, \frac{1}{2}$	498	1×10^{-10} 5×10^{-8}	$K_S \rightarrow 2\pi$ $K_L \rightarrow 3\pi$
η	0^-	0, 0	549	3×10^{-19}	$\rightarrow 3\pi$
Baryons (B = 1)					
p	$\frac{1}{2}^+$	$+1, \frac{1}{2}$	938	stable	
n	$\frac{1}{2}^+$	$+1, \frac{1}{2}$	940	1×10^{3}	$\rightarrow pe^-\bar{\nu}_e$
Λ	$\frac{1}{2}^+$	0, 0	1,116	3×10^{-10}	$\rightarrow p\pi^-$
Σ^+	$\frac{1}{2}^+$	0, 1	1,189	$.8 \times 10^{-10}$	$\rightarrow p\pi^0$
Σ^0	$\frac{1}{2}^+$	0, 1	1,193	$\sim 10^{-19}$	$\rightarrow \Lambda\gamma$
Σ^-	$\frac{1}{2}^+$	0, 1	1,197	1×10^{-10}	$\rightarrow n\pi^-$
Ξ^0	$\frac{1}{2}^+$	$-1, \frac{1}{2}$	1,315	3×10^{-10}	$\rightarrow \Lambda\pi^0$
Ξ^-	$\frac{1}{2}^+$	$-1, \frac{1}{2}$	1,321	2×10^{-10}	$\rightarrow \Lambda\pi^-$
Ω^-	$\frac{3}{2}^+$	$-2, 0$	1,672	1×10^{-10}	$\rightarrow \Lambda K^-$

* Y = hypercharge, I = isotopic spin.

There are only five stable particles; the rest are metastable, *i.e.*, immune to strong decay. About 25-meson resonances and 50-baryon resonances are omitted. The particles listed in Table 1 are plotted in Figure 1. Furthermore, there was clear experimental evidence that this list was not complete. In 1947, two clear pictures made with a cloud chamber (a device that shows particle tracks in a gas) showed the decays of two new particles, one neutral and one charged, which came to be known as V particles because of the characteristic appearance of their

decays in a cloud chamber. What emerged after some years of painstaking study was the addition to the list of elementary particles (see Table 1) of four "strange" *K*-mesons with masses between those of the pion and the proton—two neutral (K^0 and $\overline{K}^0$) and two charged ($K^{\pm}$)—and six "strange" baryons with masses greater than that of the proton, called Lambda neutral (Λ^0), Sigma minus, neutral, and plus (Σ^-, Σ^0, Σ^+), and Xi zero and Xi minus (Ξ^0, Ξ^-). (For an explanation of "strangeness," see below *Strangeness, or hypercharge.*) To regard all these particles as fundamental building blocks was to invite comparison with the Ptolemaic theory of the solar system (with its many epicycles).

Elementary and "strange" particles

Meanwhile, theoretical developments cast a new light on the conceptual foundations of the theory.

Theoretical development. As was pointed out above in connection with the discovery of mesons, "divergences" can appear in the answers given by electrodynamics to very simple questions. In the late 1940s great progress in overcoming these difficulties was made by the theoretical physicists Shin'ichiro Tomonaga in Japan, Julian Schwinger, Richard P. Feynman, and Freeman J. Dyson of the United States, and others. Their contribution was twofold. First, they reworked the formalism of electrodynamics, using methods that made calculation and insight much easier. Second, they showed that the divergences appearing in physical quantities are all direct or indirect consequences of two fundamental divergences, those in the corrections to the mass and to the charge of the electron arising from its interaction with photons. If the corrected mass and charge are set equal to the observed mass and charge of the electron (a process called mass and charge renormalization), all answers to the physical questions become finite.

Actually, much of this advance in theory was stimulated by two fundamental experimental discoveries explained below: the anomalous gyromagnetic ratio of the electron and the Lamb shift. In experiments carried out in 1947 in the United States, physicists Polykarp Kusch and Henry M. Foley showed that the value of the spin magnetic moment (a quantity associated with the torque experienced by a rotating charged body in a magnetic field) of the electron is not $e\hbar/2mc$ (e is the charge on the electron, m is its mass, c is the velocity of light, and $\hbar$ is Planck's constant divided by 2π), as had been predicted by Dirac's 1927 theory of the electron but, rather, this quantity multiplied by a factor, 1 plus a small constant, or $(e\hbar/2mc)\ (1 + \varepsilon)$, in which ε is small but nonzero. (The quantity $2[1 + \varepsilon]$ is called the gyromagnetic ratio.) Later measurements by others gave a value of the constant ε equal to $0.001\ 159\ 622 \pm 0.000000027$. At about the same time Willis Eugene Lamb, Jr., a United States physicist, measuring the position of the energy levels of hydrogen, found a shift from those predicted by Dirac's 1927 theory. From the 1930s the hole theory had predicted corrections to Dirac's original values for both quantities, but the corrections were, unfortunately, divergent. The existence of these experiments was an enormous incentive to make some sense out of the predictions of the theory. After this had been done in a more or less ad hoc way for these particular experiments, it was extended to the general theory described above. The detailed comparison with experiment gives excellent agreement. For example, theory gives an equation for the quantity ε as equal to $(\alpha/2\pi) - 0.328\ \alpha^2/\pi^2$, in which α, the fine structure constant, is equal to $1/137.03602 \pm .00021$. Substitution in this equation gives the value ε equal to 0.001 159 641, as compared with the experimental value above.

The Lamb shift

The renormalization process was extended to meson theory in 1951, when it was shown that renormalization of nucleon mass, meson mass, meson–nucleon coupling constant g, and a meson-scattering constant is sufficient to yield finite answers for all physical quantities. It turned out, however, that these results were of little practical value because the entire method was based on expansions of the quantities involved as a sum of terms proportional to powers of the quantity $g^2/\hbar c$ (a so-called perturbative expansion); for the large values of this quantity $g^2/\hbar c$ necessary to describe mesons, it is doubtful whether the sum is a useful expression. The situation is different in quantum electrodynamics in which the fine-structure constant $e^2/\hbar c$ is small and the first few terms of the expansion are a good approximation.

The remarks of the preceding paragraph are indications of a general problem. The success of renormalization theory represented great progress in quantum field theory but did not go far enough. The infinities could not be eliminated from the theory without resort to perturbative expansions. The response to this problem was twofold: the development of a general theory of quantized fields and dispersion theory. Since the latter became immediately an important practical tool, it will be described first in the following discussion.

Dispersion theory

The quantitative description of the collisions of subatomic particles is in terms of their scattering and production "amplitudes." These are complex-valued functions (such a function contains a real term and an imaginary term—*i.e.*, one containing the factor $\sqrt{-1}$) of the parameters describing the collisions (energy of particles, angle through which they are scattered, and so on). The square of the absolute value of the function gives the probability of the collision. Dispersion theory makes two kinds of assertions about such amplitudes. First, it makes the qualitative assertion that they are analytic functions (see ANALYSIS, COMPLEX). This is a strong restriction on the kind of behaviour the function can have. Second, it makes quantitative assertions—*e.g.*, that the real part of the function is equal to a certain integral transform (a mathematical operation) of the imaginary part. Such an equation is usually called a dispersion relation because the first examples in physics occurred in the optics of dispersive media. In that case, the function in question is the complex refractive index of the medium regarded as a function of the frequency of light; and the dispersion relation connects the real part of the refractive index with the imaginary part, which is essentially the absorption coefficient of the medium. In 1927, Hendrik Anthony Kramers, a physicist in The Netherlands, showed that this relation is a consequence of the principle that signals cannot be propagated faster than the speed of light. In 1946 a similar relation was suggested for the amplitudes describing collisions of the particles; but it was not until 1954 that physicists were successful in linking dispersion relations directly to quantum field theory. Within a few years, dispersion relations for a larger number of collision processes were found. Although in its modern form it was sired by quantum field theory, dispersion theory soon developed a technique and an outlook independent of its starting point. From the middle 1950s on, much of the quantitative description of particle reactions was worked out in the language of dispersion theory.

Most dispersion relations contain quantities (the analytic continuation of amplitudes) that are not directly observable. There are dispersion relations, however, that contain only observable quantities. Since they are in good agreement with experiment, these provide a valuable support for the ideas of dispersion theory.

Although the general theory of quantized fields eventually provided a derivation of dispersion relations starting from first principles, its initial objectives were conceptual; it sought to locate those general properties of a field theory indispensable for a reasonable description of particles, and then to see what consequences followed. A clear cut example of this kind was the proof in 1957 of the so-called *CPT* theorem. The theorem says that under very general assumptions, the equations that describe the laws of nature possess a certain symmetry; *i.e.*, they remain unchanged in form under a certain transformation denoted *CPT*. (The letters indicate that the transformation behaves like an inversion of space–time coordinates, *PT*, followed by an interchange of particle and antiparticle, *C*; *C* is sometimes called charge conjugation, whence the letter *C*; *P* recalls the parity operation, which replaces the space coordinate x by $-x$; *T* stands for time inversion, which replaces the time coordinate t by $-t$.) As a consequence of *CPT* symmetry, for example, the masses of particle and antiparticle have

The *CPT* theorem

Table 2: The Four Basic Forces

force	acts on:	"quanta" exchanged	range	strength (*see* Table 3, col. 3)	examples: stable systems	examples: reaction induced by force

Weak interaction	all particles except γ and g	proposed weak boson, W	$<10^{-14}$ cm	unknown	none	radioactivity: *e.g.*, uranium→lead
Electromagnetism	particles with electric charge†	photon, γ	long, *i.e.*, $F \propto 1/r^2$	1/137	atoms, rocks	chemical reactions
Strong interaction	hadrons: mesons (π, K, . . .) baryons (N, Λ, . . .)	the hadrons themselves	10^{-13} cm	10	hadrons, nuclei	πp scattering, nuclear reactions

*Because all particles have energy or rest mass. †Here electric charge includes magnetic properties and (if they exist) magnetic monopoles.

to be exactly equal, and so do their total lifetimes against decay if they are unstable. The theorem holds even when space inversion, P, or particle–antiparticle transformation, C, do not separately define symmetries of the system. That is fortunate because one of the great discoveries (the parity revolution) of the 1950s was that neither parity P nor charge C is a symmetry in weak interactions such as those that cause decay of the neutron and muon (United States physicists Tsung-Dao Lee, Chen Ning Yang, Chien-Shiung Wu, and others). See CONSERVATION LAWS AND SYMMETRY.

Dawn of a new age. Rather than continuing the above history of particle physics up to the present, a description of events since the parity revolution of 1956 will be incorporated in the systematic account of present knowledge, found below. To complete this section, however, a few general remarks are in order. In the decade of the '60s, there was a continuation of the steady progress that had marked earlier decades, but in another respect it was a new age. The new age came about because of the discovery of literally hundreds of new particles, the resonances. It became clear once and for all that not every such particle should be regarded as an elementary building block. It was and is much more natural to regard the particles as different states of excitation of matter and to seek to classify them by methods analogous to those of the spectroscopy of atoms and atomic nuclei. Much of the theoretical work of the 1960s can be regarded as an effort to provide such a classification.

FOUR BASIC FORCES AND FOUR CLASSES OF PARTICLES

Four basic forces. The particles observed in nature are acted on by, and at the same time give rise to, various forces. There are four basic forces, differing greatly in strength. Listed in order from the weakest to the strongest, they are gravitation, weak interaction, electromagnetic interaction, and strong interaction. Some of the salient features of each are listed in Table 2.

Force of gravity. The force of gravity is unique among forces because, as Sir Isaac Newton said, it is universal; all objects that have mass or energy attract each other with a gravitational force. Two particles of masses m_1 and m_2 separated by a distance r attract one another with a force proportional to the product of the masses divided by the distance squared, or in equation form, $F = Gm_1m_2/r^2$, in which $G = 6.67 \times 10^{-8}$ centimetre^3-gram^{-1}-second^{-2} is the Newtonian constant of gravitation. This is called a long-range force (or sometimes infinite-range force) to contrast its $1/r^2$ dependence with the much more rapidly decreasing $1/r^2 \exp[-(r/a)]$ dependence of strong interactions, which are said to have range a. Although, compared with all other forces, the force of gravity is extraordinarily weak and therefore normally negligible, there are circumstances in which it dominates. For example, the motion of the planets in the solar system is essentially determined by their gravitational attraction because they are so far outside the range of strong forces and they are approximately neutral electrically, so that electric forces are unimportant.

The Newtonian constant of gravitation

Weak interaction. The weak interaction is more conspicuous for the transmutations it produces (the slow decays of particles) than for the force to which it gives rise. In fact, the force has never been detected directly. At short distances ($\sim 10^{-13}$ centimetre) it is swamped by the much larger strong interaction, at atomic distances ($\sim 10^{-8}$ centimetre) it is unappreciable compared with Coulomb forces, and (at still larger distances where Coulomb forces are shielded) the weak interaction is still smaller than the intermolecular forces arising from the electrical polarizability (charge separation) of molecules, forces that are difficult to treat theoretically and measure experimentally.

Electromagnetic interaction. The electromagnetic interaction gives rise to the forces between electrical charges and currents. The simplest example is that already described above, Coulomb's law for the force between charges e_1 and e_2, in which the force is equal to the product of the charges divided by the square of the separation distance (r); *i.e.*, $F = e_1e_2/r^2$; for two charges of the same sign the force is repulsive and for unlike charges the force is attractive. All charges occurring in nature are integer multiples of the basic unit e, the magnitude of the charge on the electron. Neutral (charge zero) particles have no Coulomb force between them, but they may have magnetic interactions arising from electrical currents they contain. The electromagnetic interaction is responsible for the binding of electrons around atomic nuclei—*i.e.*, for atomic structure. Its laws thus provide a theoretical foundation for chemistry and biology.

Strong interaction. The strong interaction is responsible for the nuclear force that binds neutrons and protons together to form atomic nuclei, for nuclear scattering and reactions, and for creation and annihilation processes occurring in the collisions of high-energy particles. As was stated above, in connection with Yukawa's contribution to an understanding of strong interactions, a typical contribution to the force between two nucleons is $g^2/r^2 \exp(-r/[\hbar/mc])$, in which g is a meson-nucleon coupling constant and $\hbar/mc$ is the Compton wavelength of that meson.

Comparing the forces

A standard elementary way to compare the gravitational, electromagnetic, and strong forces is to compare Gm_em_p/r^2, e^2/r^2, and $g^2_{NN\pi}/r^2 \exp[-r/\hbar/m_\pi c]$ for values of r sufficiently small that the exponential factor in the last expression is approximately one, or unity. Here m_e is the electron mass and m_p is the proton mass; $g_{NN\pi}$ is the coupling constant for the nucleon–pion interaction as shown in row four of Table 3. This is equivalent to comparing the three dimensionless coefficients shown in Table 3:

$$\frac{Gm_em_p}{\hbar c} = 3 \times 10^{-42} \qquad \frac{e^2}{\hbar c} = \frac{1}{137} \qquad \frac{g^2_{NN\pi}}{\hbar c} \approx 10.$$

For the weak force the comparison is more involved. If it arises from the exchange of a virtual "intermediate" (so far undiscovered!) W-meson as indicated in row two of Table 3, and, if the coupling constant (the analogue of e for electric forces and $g_{NN\pi}$ for strong forces) is g_W, then the analogue of the above three dimensionless numbers is $g_W{}^2/\hbar c$. What experimentation has determined so far, however, is the so-called Fermi constant G_F given by the expression $G_F = g_W{}^2 (\hbar/m_Wc)^2 \sqrt{2} = 1.42 \times 10^{-49}$ erg-centimetre^3, in which m_W is the mass of the hypothetical W-meson. In the absence of knowledge of this mass, one cannot determine the desired number $g_W{}^2/\hbar c$, from Fer-

Table 3: Strength and Range of the Four Basic Forces

force and Feynman diagram explaining the force via exchange of virtual quanta	force law	dimensionless force coefficient	typical reaction and mean life
Gravity 	$F = Gm_p m_e \frac{1}{r^2}$	$\frac{Gm_p m_e}{\hbar c} = 3 \times 10^{-42}$	—
Weak 	$F = g^2_W \frac{e^{-r/\lambda_W}}{r^2}$	unmeasurable*	$\Lambda \rightarrow p\pi^-$ 2.5×10^{-10} sec
Electromagnetic 	$F = e^2 \frac{1}{r^2}$	$\frac{e^2}{\hbar c} = \frac{1}{137}$	$\Sigma^0 \rightarrow \Lambda\gamma$ 10^{-19} sec
Strong 	$F = g^2_{NN\pi} \frac{e^{-r/\lambda_\pi}}{r_2}$	$\frac{g^2_{NN\pi}}{\hbar c} \approx 10$	$\pi p \rightarrow \Lambda K$ $\sim 10^{-23}$ sec

*The weak force is unmeasurable outside a range $\lambda_W = \frac{\hbar}{m_W c} < 10^{-14}$ centimetre. From neutron decay, $n \rightarrow pe^-\bar{\nu}$ (explained by same diagram, but with ν *out*going), one measures instead $\sqrt{2}\, g_W^2 \left(\frac{\hbar}{m_W c}\right)^2 \equiv G_F = 10^{-5} \frac{\hbar^3}{m_p^2 c}$.

mi's constant. The standard way of comparing weak forces to other forces is to compute the dimensionless quantity $G_F/\hbar c(m_p c/\hbar)^2 = 1.02 \times 10^{-5}$. This is indeed much smaller than the fine-structure constant $e^2/\hbar c$ and much larger than the gravitational constant $Gm_e m_p/\hbar c$, both shown above (for further discussion of the intermediate meson, see below *Undiscovered particles*).

Four classes of particles. The classification of interactions by strength is associated with a classification of particles by the forces that influence them. Particles that are directly acted upon by the strong interactions are called hadrons or strongly interacting particles; those that are acted on by the three weaker interactions, the nonhadrons, are called the leptons, the graviton, and the photon. Most particles react to several forces (see Table 4). The strongest force they experience usually controls

Table 4: Relation of Forces to Particles

particle	forces that the particle experiences			
	gravity	weak interaction	electromagnetism	strong interaction
Graviton g	X			
Photon γ	X		X	
Lepton ν	X	X		
Leptons μ^-, e^-	X	X	X	
Hadrons	X	X	X	X

their behaviour, but weaker forces may govern their decay. Furthermore, even electrically neutral hadrons respond to electromagnetic forces because the hadrons interact so very strongly that pure, untarnished hadrons are not found in nature, rather each hadron is partially a mixture of other hadrons. Thus, the neutral neutron behaves part of the time as if it were a mixture of a proton (of positive electric charge) and a π^- meson.

Hadrons. Hadrons, the strongly interacting particles, are numerous (see below *Spectroscopy of the hadrons*). Here, only the classification according to baryon number will be introduced. The baryon number, B, is an integer, positive, negative, or zero, assigned to each hadron. The particles of baryon number 0, ± 1, have special names: those of baryon number 0 are mesons, those of baryon number 1 are baryons, and those of baryon number −1, antibaryons. Particles of baryon number 1 and larger include ordinary atoms. For example, hydrogen has baryon number 1, deuterium baryon number 2, helium baryon number 4, etc. For such atoms the baryon number coincides with the mass number used in chemistry and nuclear physics—*i.e.*, the baryon number is the number of nucleons in the nucleus. Anti-atoms (composed of antinuclei with positron clouds surrounding them) then have negative baryon numbers.

The baryon number

The nonhadronic particles, those not subject to strong interactions, deserve special remarks:

Gravitons. The long-range gravitational interaction between two masses may be thought of as arising from the exchange of particles (see the top sketch of Table 3). The exchanged particles are called gravitons; they are massless and have spin 2 in units of $\hbar$. Individual gravitons are undetectable (see below *Undiscovered particles*).

Photon. The photon plays the same role for electromagnetism as the graviton does for gravitation; its exchange is responsible for electromagnetic forces. The photon is massless and has spin 1 in units of $\hbar$.

Leptons. The only other massless particles besides the graviton and photon are the neutrinos, ν_e and ν_μ, both of which have spin ½ in units of $\hbar$ and negative helicity; *i.e.*, their spin is pointed opposite to their velocity; the antineutrinos, $\bar{\nu}_e$ and $\bar{\nu}_\mu$, are also of spin ½ but have positive helicity. All known massless particles are electrically neutral and move with speed c.

The remaining leptons are the negative electrons, e^-, and muon, μ^-, and the antiparticles, e^+ and μ^+, respectively. All have spin ½, and, as will be shown in the section that follows, there are two conservation laws linking the leptons.

CONSERVATION LAWS AND QUANTUM NUMBERS

Particles are classified by their quantum numbers. It is the purpose of this section to list the 11 most important quantum numbers (see Table 5) and to describe how they arise from conservation laws (see CONSERVATION LAWS AND SYMMETRY).

Some conservation laws are exact; some are approximate. The typical form of an exact conservation law is an assertion that some quantity does not change, whatever interactions are taking place (*e.g.*, in classical mechanics, mass and energy in any closed system do not change). For an approximate conservation law the corresponding assertion is that the quantity is conserved in, say, strong

Table 5: Conservation Laws

conservation law	quantum numbers and observed values*	holds for				example		
		strong	electro-magnetic	weak	gravity†	p	π^0	e
1. Four-momentum	mass, not quantized: unit of mass is MeV	X	X	X	†	938	139	0.51
2. Angular momentum	$J = 0, \frac{1}{2}, 1, \frac{3}{2}, 2, \ldots$ [$\hbar$]	X	X	X	†	$\frac{1}{2}$	0	$\frac{1}{2}$
3. *CPT*	none	X	X	X	†			
4. Charge	$Q = 0, \pm 1, 2, \ldots$ [e]	X	X	X	†	+1	0	−1
5. Baryon number	$B = 0, \pm 1$	X	X	X	†	+1	0	0
6. Lepton number	$l_e = \pm 1, l_\mu = \pm 1$	X	X	X	†	0	0	$l_e = 1$
7. Charge conjugation	$C = \pm 1$	X	X		†	−1	+1	−1
8. Parity	$P = \pm 1$	X	X		†	+1	−1	+1
9. Time inversion	no quantum number							
10. Isospin symmetry	$I = 0, \frac{1}{2}, 1, \frac{3}{2}$	X			†	$\frac{1}{2}$	1	‡
11. $SU(3)$ symmetry	$Y = -2, -1, 0, +1$	X§			†	1	0	‡

*The list of the observed values is restricted to "elementary" particles; nuclei and antinuclei are excluded. †The gravitational force introduces no new explicit violations of conservation laws; it reflects the symmetries and absences thereof occurring in the other three interactions. ‡Inapplicable. §Approximately.

interactions but not in weak and electromagnetic. Of particular importance are the additive conserved quantities. Such a quantity takes a definite value for each particle, and its value for a system of particles is the sum of the values for the individual particles.

Meaning of quantum number. The phrase quantum number requires explanation. It originated in the Bohr theory of the atom, in which certain quantities must take only integral values, whereas according to classical mechanics, they could have any values. Most of the quantum numbers that are dealt with in this article take integral or half-odd integral values. For exceptional cases such as mass, energy, or momentum, which can take a continuum of values, it is customary to use the same terminology; they are also referred to as quantum numbers.

The list of exact conservation laws starts with those associated with space-time symmetries.

Energy and linear momentum. In the absence of outside forces, the energy, E, and the linear momentum, p (mass times velocity; vectors—quantities having magnitude and direction—are designated in this article by italicized boldface characters), of a system are conserved. This conservation law can be shown to follow from the invariance of the dynamical laws describing the evolution of the system under translation (motion) in time and space, respectively. Two observers in relative motion with a fixed velocity with respect to one another will attribute different energy and different momentum to a given system, but the connection between these descriptions is given by the special theory of relativity. In particular, that theory says that the rest mass, m, of the system is the same for all observers; *i.e.*, the rest mass is an invariant. For brevity, the adjective "rest" is usually omitted, and, for convenience, mass is measured in units of energy (ergs, joules, but, most frequently, electron volts). When a system is at rest with respect to an observer, momentum p is zero, and its energy is equal to its mass times the velocity of light squared ($E = mc^2$).

If a subatomic particle is completely stable (as are the electron and the proton, for example), then it has a precisely determined mass. Particles that decay last only a finite length of time and therefore (by a fundamental law, the so-called uncertainty relation) cannot have a definite energy and mass. Instead, they are characterized by an "average mass" and a mass breadth Δm related to their mean life at rest, τ, by the equation $\Delta mc^2 = \hbar/\tau$. Here c is the velocity of light and $\hbar$ is Planck's constant divided by 2π. The quantity mean life is introduced because an unstable particle does not always survive for the same time. The mean life is an average time of survival.

Angular momentum, spin, and helicity. In the absence of outside torques (twists), the angular momentum, J, of a system is conserved. The law of conservation of angular momentum is a consequence of the invariance under rotations of the dynamical law of evolution of the system. Associated with the angular momentum, J, is a quantum number, J, the total angular momentum in units of $\hbar$, taking only integer and half-odd integer values: $J = 0, 1/2, 1, 3/2, \ldots$.

Particles themselves have an intrinsic angular momentum, called spin, but massless particles (γ, ν, and graviton) differ from particles with nonzero rest mass in the way that their spin behaves and even in the way that it is defined. To be specific, when an observer moves with the same speed as a massive particle, the particle appears to be at rest; then its spin is defined as its angular momentum, J, as viewed by that observer. Its component J_z along the direction of motion z is called its helicity. This component ranges in integer steps from $+J$ to $-J$; *i.e.*, it can take on the $2J + 1$ different helicity values J, $J - 1$, $J - 2$, . . . $- J$. Examples are given, as heavy dots, in Figure 1. Many massive particles of low spin

Helicity

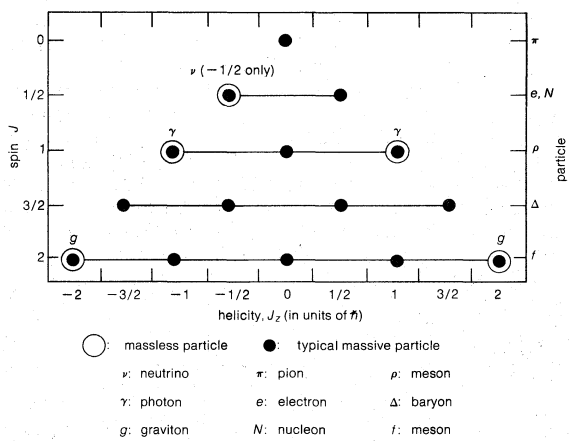

Figure 1: Allowed helicities for massless and typical massive particles (see text).

have been found; 0, ½, 1, 3/2, 2, 5/2, 3, for example, and it is likely many of the resonances the spins of which have not been measured have much higher spins than these. Massless particles are different. They move with the speed of light, and no observer can move fast enough to catch up with them. The helicity for a massless particle is defined directly as the component of the angular momentum (in units of $\hbar$) along the direction determined by the momentum. The possible values of the helicity for a massless particle are 0, ± ½, ± 1, . . . just as for a massive particle. If one of these values occurs, however, *no other need be possible.* This statement has to be qualified in a theory invariant under P the operation of space inversion. Then if s is a possible helicity, so is $-s$. In any case, the magnitude, $|s|$, of the helicity is called the spin. This situation is illustrated with open dots in Figure 1. The photon has spin 1 and helicities ± 1. The graviton has spin 2 and helicities ± 2. The neutrinos ν_e and ν_μ have spin ½ and negative helicity, whereas their antiparticles $\bar{\nu}_e$ and $\bar{\nu}_\mu$ also have spin ½ but positive helicity.

CPT symmetry and statistics. Two examples of conservation laws that do not fit precisely into the previous mold are those associated with *CPT* symmetry and with statistics. As already remarked (see above *History up to 1960*), *CPT* symmetry is a symmetry operation that exists and is compatible with any dynamical law having certain general properties. The only quantum number associated with *CPT* is $(CPT)^2$, which takes the values ± 1. It is $+1$ for states of integer angular momentum and -1 for states of half-odd integer angular momentum. The phrase "statistics of particles" refers to the symmetry properties of states involving several indistinguishable particles. In quantum mechanics every particle and every system composed of particles has a wave function that describes its state. Two laws of transformation of wave functions under interchange of particles occur for the particles observed in nature: the law of Fermi–Dirac statistics in which the wave function is antisymmetric (*i.e.*, changes sign under interchange of any pair of particles) and the law of Bose–Einstein in which it is symmetric (*i.e.*, is unchanged by the interchange of any pair of particles). The latter law is named after the Indian physicist Satyendra Nath Bose and Einstein. According to the Pauli exclusion principle, electrons satisfy Fermi–Dirac statistics. Any admissible dynamical law of evolution must have the property that it preserves the symmetry or antisymmetry of states of identical particles, *i.e.*, preserves their statistics.

It is a notable experimental fact that particles satisfying Fermi–Dirac statistics always have half-odd integer spin, whereas those satisfying Bose–Einstein statistics have integer spin. One of the most important general theorems of quantum field theory asserts that this law of the connection of spin with statistics is a consequence of general assumptions of quantum field theory. The customary terminology for particles, fermions for half-odd integer spin particles, and bosons for integer spin particles, takes the law of the connection of spin with statistics for granted. Since the possibility of a violation of this law seems remote, for the rest of this article it will be assumed valid. Thus, no quantum number describing the statistics of a particle need be listed in the Tables.

The connection of spin and statistics

The remaining exact laws of conservation seem to be connected not with space-time symmetries but rather with some internal characteristics of particles.

Electric charge. The electric charge, Q, is not only conserved; it is quantized. Every system has a charge that is a whole multiple of charge, ne, in which n is an integer (positive, negative, or zero). The charge Q is an additive quantum number, and so the electric charge of a system of particles is the sum of the charges on the individual particles. All the long-lived subatomic particles have charges 0 or $\pm e$, but, as will be shown, there are excited states of baryons that are doubly charged. The fact that most subatomic particles have charges 0 or $\pm e$ is, thus, happenstance.

Baryon number. The baryon number, B, is a conserved quantity similar to the charge in being quantized (taking integer values) and in being additive. As already remarked above, the number B is $+1$ for baryons, -1 for antibaryons, and 0 for mesons, leptons, photons, and gravitons. Baryon number B is called atomic mass number A in the areas of chemistry and nuclear physics. Conservation of baryon number is responsible for the stability of the proton, reactions such as the decay of a proton into a positron plus photon ($p \rightarrow e^+ + \gamma$) being forbidden according to the theory. Only in collisions of matter and antimatter can baryons annihilate, this energy going into the production of mesons; *e.g.*, $p + \bar{p} \rightarrow \pi^+ + \pi^-$.

CPT symmetry an aid in classification

The validity of *CPT* symmetry permits simplification of the classification of particles because it shows that antiparticles have characteristics deducible from those for particles. They must have the same mass, the same spin, opposite charge, opposite baryon number, opposite magnetic moment, and the same lifetime. Consequently in the tables that follow, the antiparticles of the baryons will not be separately listed.

It should be remarked that, although *CPT* symmetry is a generally accepted symmetry, experimental physicists are constantly searching for tests of its validity as well as that of other conservation laws. Such tests serve to strengthen support for the basic principles underlying present ideas about particles.

Lepton, electron, and muon numbers. The lepton number is an additive quantum number, l, assigned as follows:

$l = +1$ for ν_e, e^-, ν_μ, μ^-, (*i.e.*, all leptons);
$l = -1$ for ν_e, e^+, ν_μ, μ^+, (*i.e.*, all antileptons);
$l = \ \ 0$ for all other particles.

The electron number is an additive quantum number, l_e, assigned as follows:

$l_e = +1$ for ν_e, e^-;
$l_e = -1$ for ν_e, e^+;
$l_e = \ \ 0$ for all other particles.

The muon number, l_μ, is an additive quantum number, l_μ, assigned as follows:

$l_\mu = +1$ for ν_μ, μ^-;
$l_\mu = -1$ for ν_μ, μ^+;
$l_\mu = \ \ 0$ for all other particles.

Clearly, the lepton number for any particle is equal to the sum of the corresponding electron and muon numbers ($l = l_e + l_\mu$); so only two of the three quantum numbers are independent.

Conservation of muon number *or* electron number explains the absence of the decays $\mu^+ \rightarrow e^+ + \gamma$ or $\mu^+ \rightarrow e^+ + e^- + e^+$. Similarly, their conservation explains why the neutrinos ν_μ produced in π^+ decays ($\pi^+ \rightarrow \mu^+ + \nu_\mu$) are observed to interact with nucleons only via the interaction $\nu_\mu + n \rightarrow p + \mu^-$, but not $\nu_\mu + n \rightarrow p + e^-$.

The remaining conservation laws are approximate, being valid only for some subset of the four kinds of interactions.

Particle–antiparticle conjugation, C. This operation is often called charge conjugation, recalling its discovery in the theory of electrons in which it interchanges the positron and the negative electron, e^+ and e^-. That is to say, charge conjugation is a mathematical operator that transforms a state describing a particle into a state describing its antiparticle. In general, it interchanges particles and antiparticles without affecting space–time coordinates. The strong and electromagnetic interactions are invariant under charge conjugation, but the weak interaction is not. This implies that, to the extent that weak interactions may be neglected, the probability of a reaction remains the same if all particles are replaced by their corresponding antiparticles. Thus, e^+e^+ scattering (the deflections of one beam of positrons by another) has the same probability as e^-e^- scattering. Under charge conjugation, baryons go into antibaryons and leptons into antileptons, but mesons and photons go into mesons and photons. For example, charge conjugation interchanges π^+ and π^- mesons. Neutral particles may be their own antiparticles (as in the case of π^0 and γ) or not (as in the case of K^0 and $\bar{K}^0$). When a neutral particle is its own antiparticle, operation on it by charge conjugation amounts to multiplication by a plus or minus sign called the charge conjugation, or C, quantum number. For example, C, operating on a gamma-ray state changes its sign and a γ is said to be "odd" under C; a π^0 is "even" under C.

Space and time inversion, P and T. The operation of space inversion, P, acts on space–time coordinates by leaving t alone, $t \rightarrow t$, and transforming x into its negative, $x \rightarrow -x$. There is an associated quantum number, the parity, which is equal to $+1$ for a wave function that is unchanged under P inversion, and equal to -1 for a wave function that is multiplied by -1. States with these transformation laws are said to be of even and odd parity respectively. Strong and electromagnetic interactions are invariant under space inversion, but the weak interaction is not. The parity revolution of 1956 resulted from the realization that, in neutron decay and muon decay, the neutrinos and antineutrinos appearing experimentally have definite helicity, in violation of the law of conservation of parity. The parity, symbolized as P, is a multiplicative quantum number; the parity of a composite sys-

Parity violation

tem is determined by multiplying the intrinsic parities of the particles with the parity of any orbital angular momenta the system may have.

The result of the parity revolution, that neither space inversion, *P*, nor charge conjugation, C, is an exact symmetry of the weak interaction, led to a quantitative theory in which, nevertheless, the combined operation, symbolized as *CP*, is an exact symmetry. (This phenomenon can be thought of as being analogous to the conservation of baryon number $n = n(B) - n(\bar{B})$. In spite of the fact that the number of baryons $n(B)$ can change with time and so can the number of antibaryons $n(\bar{B})$, their difference is conserved.) A few years after the parity revolution, however, it was found that the long-lived decay mode, K_L^0, of the K^0 meson can decay into $\pi^+ + \pi^-$. This process violates *CP* symmetry, and hence the weak interaction has none of the operations *P*, *C*, or *CP* as an exact symmetry. The only discrete symmetry that appears to be exact is the combination of *CP* with time reversal *T*—that is, *CPT*.

Isospin (I) and hyperchange (Y). In Table 5 there are two more quantum numbers, *I* and *Y*, but they are defined only for hadrons and so are explained in the section below.

SPECTROSCOPY OF THE HADRONS; THE QUARK MODEL

Classes of hadrons. It is notable that there is only a superficial difference between the "old" metastable hadrons of Table 1 and more recently discovered unstable "resonances."

In terms of stability there exist three classes of hadrons:

Unstable "resonances." An example of an unstable resonance is the omega (ω) meson. It has a mass of 784 million electron volts (MeV) and decays into three pions (3π, each of mass 140 MeV) with a surplus energy of nearly 400 MeV. If the ω meson were not a resonance, it would fall apart immediately in $\frac{1}{3} \times 10^{-23}$ second (this is the time needed for a pion, moving with nearly the speed of light to move 10^{-13} centimetre and thus escape beyond the range of nuclear forces). But the omega meson *is* a resonance, the name given to long-lived states, and it actually holds together for a surprisingly long time: 10^{-22} second.

Metastable hadrons. Metastable hadrons eventually decay via weaker interactions. If the omega meson weighed less than three pions it would be unable to decay by the strong interaction and thus would be called a "metastable" hadron. The ω meson would eventually decay via electromagnetism into a pion and a photon (in 10^{-21} second) or by weak interaction into two leptons (in 10^{-10} second).

Stable hadrons. There is only one absolutely stable hadron, the proton. The examples above should show that stability is really an accidental property (depending on the availability of final states), although, of course, it is certainly important to the experimenter who has to deal with the particle. In what follows below, metastable and resonant hadrons will seldom be distinguished from each other.

Charge multiplets and isospin. Figure 2 shows the known stable and unstable particles and as many resonances as fit into the picture. As may be noted, hadrons occur in "charge multiplets" of one to four particles, each with the same mass. In fact, it turns out that hadrons share all properties except the electric charge, which seems to have no role in the strong interaction (it is as though it had been sprayed on superficially). Thus the neutron and the proton—the members of the $N(939)$ "nucleon" doublet (see below)—share practically the same mass and nuclear interactions and the same spin and parity. This explains why it is possible to give a family name (N, π, . . .) to a multiplet and to indicate the charge of one of its members with a separate superscript; *e.g.*, (π^+, π^0, π^-).

Although the nuclear force barely distinguishes between differently charged members of a multiplet, it is much concerned with the total size of the family; *i.e.*, the total "multiplicity" (*M*) is a most significant quantum number. To give an example, there are some reactions for

Total "multiplicity"

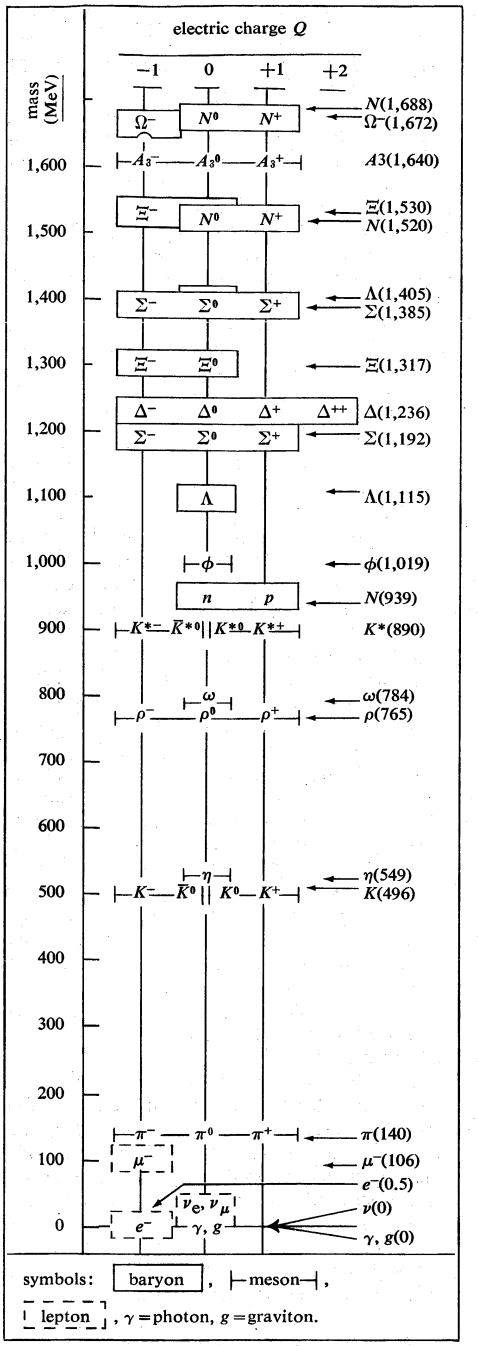

Figure 2: Metastable particles and some resonances with mass up to 1,700 MeV. The horizontal lines and bars link members of the same charge multiplet. Among the hadrons (mesons and baryons), no distinction is made between metastable states and resonances. Details of all the metastable particles are given in Table 1.

which hadrons with multiplicity equal to zero ($M = 0$) are forbidden to participate, while there are also others for which a multiplicity equal to one or greater than one ($M \geqq 1$) is forbidden, etc.

Often, for convenience, multiplicity is translated into a closely related vector quantity, *I*, according to the relation $M = 2I + 1$.

Experimentally it is found that the quantity *I* is conserved in the strong interaction. The multiplets of hadrons suggest the multiplets of states arising from the existence of angular momentum and the formalism of isospin is based precisely on this analogy. One introduces an isospin vector operator, *I*, analogous to the angular momentum operator, *J*, but acting on some internal coordi-

nates of the hadron rather than on its space coordinates. In this hidden internal coordinate system, electric charge increases along a particular axis conventionally labelled the z-axis, and is equal to the sum of two terms: $Q = \langle Q \rangle + I_z$, in which the second term, I_z, can take on $2I + 1$ different values, and the first term, the average charge $\langle Q \rangle$ (later called $Y/2$), is discussed in the following section on hypercharge Y.

Strangeness, or hypercharge. The baryon multiplets plotted in Figure 2 are not all centred symmetrically about the charge = 0 axis. The last quantum number Y, the hypercharge, is a measure of their displacement. To define this quantum number precisely, the centre of each multiplet is defined by its average charge $\langle Q \rangle$. This is literally the value of charge Q at which each of the multiplets drawn in Figure 2 can be balanced. Thus, for the box in Figure 2 containing n and p, (the nucleon doublet) $\langle Q \rangle$ is $+ \frac{1}{2}$, and, for the pion triplet, $\langle Q \rangle$ is zero. To avoid dealing with half-integral values, the hypercharge Y is defined as twice the average charge, $2\langle Q \rangle$. The strong interaction conserves hypercharge. This completes the list of conservation laws (see Table 5).

The hypercharge can be related to an older measure of the displacement called strangeness, S, which is twice the displacement of some multiplet measured not from $Q = 0$ but from the most familiar multiplet (π for mesons, N for baryons). For mesons, in which the reference pion has $Y = 0$, Y and S are the same; but, for the baryons, in which the reference nucleon has $Y = 1$, strangeness S is $(Y - 1)$. As mentioned above, the first strange particles were discovered in 1947. They were called "strange" because they did not decay by the strong interaction, and at the time that seemed strange. Accordingly, physicists Murray Gell-Mann and Abraham Pais, in the United States, and Kazuhiko Nishijima, in Japan, introduced a law of conservation of strangeness (now called conservation of Y). Thus, the K^+ meson would "normally" be expected to decay strongly in 10^{-23} second into π^+ and π^0, but the meson has $S = Y = 1$, and the pions have $S = Y = 0$; and so the reaction is forbidden to the strong interaction. The weak interaction finally leads to this and other decays, but it takes 10^{-10} second, or 10^{13} times "too long."

Conservation of strangeness

Multiplets and super-multiplets. The symbol (N, π, . . .) was used above to describe a multiplet, and an explanation of this nomenclature is in order: when a resonance is first discovered, the most apparent quantum numbers are B (baryon number), Y (hypercharge), and I (isospin) and the superficial one Q (charge); hence a symbol is invented that represents the (B,Y,I) for the particle, and the superscript Q is appended (*e.g.*, N^+ for proton), and this is followed by another symbol (m, J^P), representing (mass, angular momentum parity), so that the full specification for the proton is, technically speaking, $N^+(939, \frac{1}{2}^+)$. Sometimes an asterisk is used to show that a multiplet is an "excited state" of a multiplet of lower mass. Thus, there is the $K(496)$ meson and the next one found, $K^*(890)$, is often called simply the K^*.

In January 1961, Gell-Mann and physicist Yuval Ne'eman of Israel independently proposed an "eightfold way" [$SU(3)$ invariance] to explain the jumble of hadron' multiplets. This explanation starts with the eight stable baryons that were known at the end of 1960. In Figure 3A each of these eight stable baryons has been plotted as a black dot. The horizontal-scale is almost the same as that of Figure 2: charge Q still increases to the right, but the displacement of the multiplets has been corrected by plotting charge *minus* average charge, $Q - \langle Q \rangle$. Thus, the top entry is the N doublet, with the neutron (n) at the left and proton (p) at the right. To describe each particle there remain six quantum numbers and the mass. Many physicists had tried plotting many different combinations, but the most satisfying is to collect hadrons with the same J and P as is done here, and choose hypercharge Y for the vertical axis; a striking hexagonal snowflake configuration then emerges, with six corner dots and two more at the centre. Thus the first complete supermultiplet, an octet, those baryons with $J^P = \frac{1}{2}^+$, has been plotted. Unfortunately this plot has no way to display mass.

Ne'eman's "eightfold way"

If the same process is tried with the seven stable mesons that were known at the beginning of 1961, another hexagon emerges—the one shown in Figure 3B; these mesons all have zero angular momentum and negative parity ($J^P = 0^-$). In 1961 only one more meson doublet, the K^*, was known, but its J^P were unknown, and so no more octets could be assembled.

Returning to the baryons, by 1961 two unstable baryon multiplets had been discovered. One of them, the Δ (1,236, $3/2^+$), had been known since the '50s. It is a quartet, appearing as Δ^-, Δ^0, Δ^+, and Δ^{++}; so it is clear that it cannot fit into a hexagon, which seats at most three abreast. It has $Y = 1$ and is plotted at the top of Figure 3D. Another baryon doublet had just been discovered and named Y_1^* (1,385). It is now called $\Sigma(1,385)$, and, since it has $Y = 0$, it is plotted below the multiplet $\Delta(1,236)$. This was the last clue necessary for the formulation of the eightfold way.

The quark model. Figure 3 strongly suggests that hadron multiplets occur in groups (called supermultiplets) sharing the same J^P. These regular patterns in turn suggest that hadrons must be composed of even more primitive elements fitted together in an orderly way. They were named "quarks" by Gell-Mann and are drawn in Figure 3 as a triangular array of three asterisks (perhaps question marks would have been better). Despite many attempts to find them, they have not shown up, but they are essential for organizing knowledge; hence particle physicists all speak of the "quark model" of hadrons.

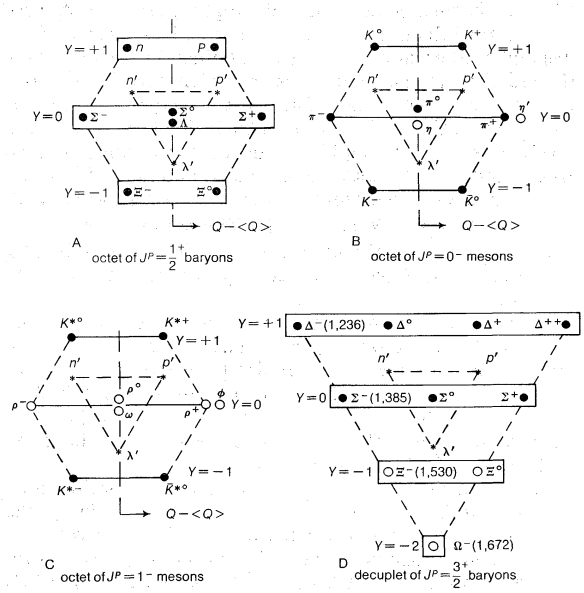

Figure 3: Supermultiplets of hadrons—octets and decuplets. The horizontal lines link members of the same charge multiplets in a fashion similar to that of Figure 2; solid dots represent particles that were known when the eightfold way was formulated in 1961; open dots are particles predicted and later discovered; asterisks labelled n', p', and λ' are the possible set of primitive particles called quarks; Q stands for electrical charge; $\langle Q \rangle$ indicates average charge of the multiplet taken as a whole.

The quark model is thus oversimplified.

To clarify the Periodic Table of the chemical elements, atoms are explained as being composed of more primitive units called nuclei and electrons, and, just as the electrons group into shells of 2, 8, 18, 32, . . . , similarly the quark model can be used to explain the supermultiplets of hadrons: 1's, 8's, and 10's. Historically the eightfold way had a more mathematical formulation, involving group theory, and the emphasis on the physical role of the quark (by Gell-Mann and another United States physicist, George Zweig) came later. The nonmathematical presentation used here is thus oversimplified.

Three quarks (q) are postulated, (but because all particles have antiparticles, the existence of three antiquarks [$\bar{q}$] is implied). The quarks are assigned baryon number

B = ⅓ ($\bar{q}$ then has $B = -⅓$). Mesons can then be considered as $q\bar{q}$ pairs bound together by the strong interaction, and baryons as bound states of three quarks (qqq). Returning to mesons, since there are three quarks (called n', p', and λ'—see Figure 4) and three antiquarks,

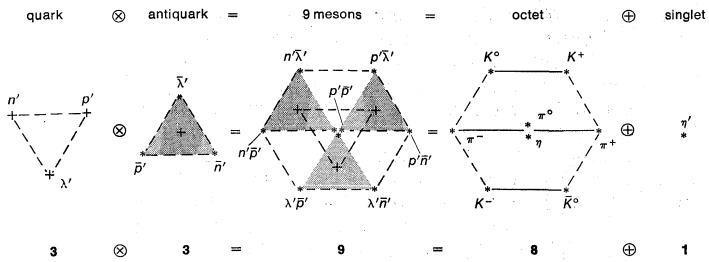

Figure 4: Combining quarks. Three hypothetical quarks and three antiquarks combine to form nine mesons, which group into an octet plus a singlet. Two such real octets + singlets are shown in Figure 3B and 3C.

then $q\bar{q}$ might be expected to combine into $\mathbf{3} \otimes \bar{\mathbf{3}} = \mathbf{9}$ different mesons ($n'\bar{n}'$, $n'\bar{p}$, $n'\bar{\lambda}'$, $p'\bar{n}$, . . . $\lambda'\bar{n}'$ . . . $\lambda'\bar{\lambda}'$). But the hexagons contain only eight particles! A way out of this dilemma came from a 19th-century Norwegian mathematician, Marius Sophus Lie, who investigated the symmetrical ways in which groups of basic objects might combine. One of the ways—the special Lie group called $SU(3)$—breaks $\mathbf{3} \otimes \mathbf{3}$ up into an **8** (hexagons) and a singlet. Some of these singlets have since been found—they are called η' and ϕ' in Figure 3.

The Lie group $SU(3)$

Mathematicians summarize the discussion above with equation $\mathbf{3} \otimes \bar{\mathbf{3}} = \mathbf{9} = \mathbf{8} \oplus \mathbf{1}$. (The symbols ⊕ and ⊗ come from group theory.) Figure 4 shows graphically how the **3** and $\bar{\mathbf{3}}$ triangles actually combine to generate a hexagon.

It was stated above that *baryons* are postulated to be formed of three quarks (qqq). The computation of the equation $\mathbf{3} \otimes \mathbf{3} \otimes \mathbf{3} = \mathbf{27}$ remains to be explained; group theory "algebra" of $SU(3)$ gives the answer as $\mathbf{3} \otimes \mathbf{3} \otimes \mathbf{3} = \mathbf{27} = \mathbf{1} \oplus \mathbf{8} \oplus \mathbf{8} \oplus \mathbf{10}$. Furthermore, $SU(3)$ predicts correctly that the **8** will again look like the hexagon and the **10** will look like the triangle of Figure 3D.

While theorists were making predictions, experimenters working with hydrogen bubble chambers (notably the Berkeley, California group of Luis W. Alvarez) were discovering new particles. The stable meson octet was completed with the discovery of the eta (η) particle in 1961. In the same year the rho (ρ) and omega (ω) mesons were discovered and found to have $J^P = 1^-$; and in 1962 the spin of the K^* was found to be 1^- also; this completed the 1^- octet. The first baryon "decuplet" was not completed until 1964, when the Ω^- was rediscovered. (A single probable Ω^- had been observed in 1954, but its discovery had attracted little attention.) The twin discoveries of η and Ω were triumphant vindications of $SU(3)$.

The 1973 particle data tables (see bibliography) list approximately 25 meson multiplets (in contrast to seven in Figure 2) and 50 baryon multiplets (ten are in Figure 2), and many of these have already been fitted into supermultiplets. By now, quarks, as concepts, are well established. Not so the real, free quarks. Physicists are always looking for them, but so far none has been established, despite perennial rumours of their discovery (see below *Undiscovered particles*).

In the presentation of the quark model here, geometrical arrays have been emphasized; but actually this is but a small part of the predictive power of the model, which relates the masses of all those multiplets within a supermultiplet and also their decay rates into various other hadrons, and even their electromagnetic decays.

Without entering into the technical details of the quark model or the eightfold way, the main features of these theories may be sketched. There are two essential ideas involved, the first of which is that the fundamental strong interaction consists of a dominant part that is very symmetrical and a weaker part that is less symmetrical. If the dominant part alone were present, all members of the same supermultiplet would have the same mass. For example, the members of the octet consisting of $N(939)$, $\Lambda(1{,}115)$, $\Sigma(1{,}192)$, and $\Xi(1{,}317)$ in Figure 2 would coincide in mass. The weaker part of the strong interaction is less symmetrical, and its lack of symmetry results in the splitting of the supermultiplet into the observed mass spectrum. (The quark model and eightfold way have this idea in common with half a dozen previous theories that failed to account for the facts.) The second essential idea is that the symmetry of the interaction is expressed in a specific way; there is a family of transformations that leave the dominant part of the strong interaction invariant and form a group called $SU(3)$. (See TOPOLOGICAL GROUPS AND DIFFERENTIAL TOPOLOGY and CONSERVATION LAWS AND SYMMETRY.) The $SU(3)$ group consists of all 3×3 unitary matrices of determinant 1. The weaker part of the strong interaction has a specific transformation law under $SU(3)$, which determines how the supermultiplets split into multiplets.

The dominant and weak parts of strong interaction

EXPERIMENTS

The article so far has dealt mainly with history, classification schemes, and theoretical explanations. But on a world-wide basis, several hundred million dollars are spent each year on active, experimental programs. This section, therefore, is devoted to some pictures of interacting subatomic particles and a plot of their cross section versus energy.

Formation of neutron and proton resonances. In some 1952 experiments, pions from the University of Chicago cyclotron were directed at protons (in liquid hydrogen), and the "scattering cross section" was measured for different energies of the pion beam. Scattering refers to the change of direction when two particles collide; scattering cross section is the probability that scattering will occur. When the probability is large, the two particles act as if they were big, with a large cross section.

Scattering experiments

The "effective" mass of the pion–proton system is calculated for each setting of the pion beam. (The effective mass is the sum of the rest masses plus the kinetic energies of all the particles in a system, as viewed from the system's centre of mass.) When the effective mass is plotted along the x-coordinate of a graph and the scattering cross section is plotted along y, it is found that the cross section peaks sharply when the system has an effective mass of about 1,236 million electron volts (see Figure 5).

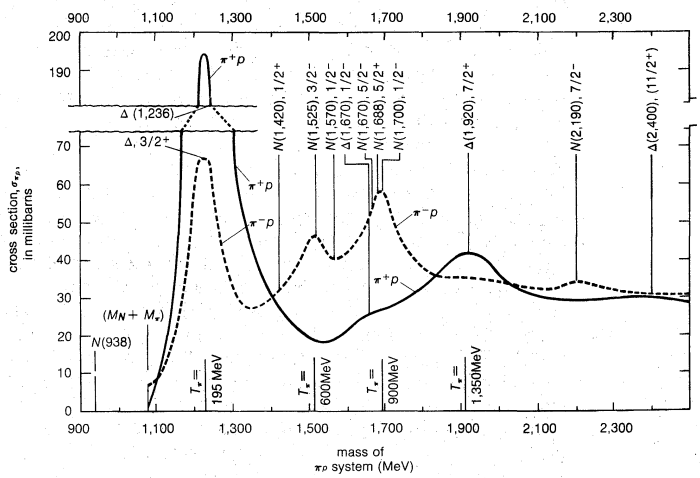

Figure 5: Total cross section for π^+ and π^- mesons incident on protons. Bumps in cross section represent formation of resonances.

Figure 5 shows cross-section plots for both π^+p (solid curve) and π^-p (dashed). Both cross sections show the peak at 1,236 MeV, although it is threefold higher for π^+ than for π^-. Such a peak is the signature of a resonance. This one is called $\Delta(1{,}236)$; it is a charge quartet (see Figure 2), meaning that it can be formed in four charge states: Δ^{++}, Δ^+, Δ^0, Δ^-. By shooting both π^+ and π^- beams into hydrogen, two of these states can be formed: $\pi^+p \rightarrow \Delta^{++} \rightarrow \pi^+p$ and $\pi^-p \rightarrow \Delta^0 \rightarrow \pi^-p$. Figure 5 shows

many resonances at higher mass that are not as prominent as the $\Delta(1,236)$ and that cannot be detected merely by hunting bumps in the cross-section plots. It is then necessary to analyze the angular distribution of the scattered pions, and it may even be necessary to "polarize" the protons (*i.e.*, align their spins with their direction of motion) in the target hydrogen and to look for resulting asymmetries in the angular distributions.

Production of the $\Sigma(1,385)$ resonance. Next to be examined is how the experimentally more remote resonance $\Sigma(1,385)$ is studied. This resonance has two decay modes: $\Sigma(1,385) \rightarrow \Lambda\pi$ and $\Sigma\pi$. The direct approach would be to study a bump in the $\Lambda\pi$ scattering curve at mass 1,385 MeV, but a Λ decays via the weak interaction in 10^{-10} second, and a π decays in 10^{-8} second; so a Λ beam on a π target is impractical.

The best that can be done is to study a reaction such as $K^-p \rightarrow \Lambda\pi^+\pi^-$, in which $\Lambda\pi$ "diparticles" are produced over a large region of $\Lambda\pi$ mass, and see whether or not some masses in particular are produced copiously. Figures 6 and 7 show several steps in a hydrogen-bubble-chamber experiment that yields $\Sigma(1,385)$.

Principle of a bubble chamber

Figure 6 shows a hydrogen chamber exposed to a beam of K-mesons. A bubble chamber consists principally of a volume of superheated, but not yet boiling, liquid hydrogen. Any charged particle, passing through the liquid,

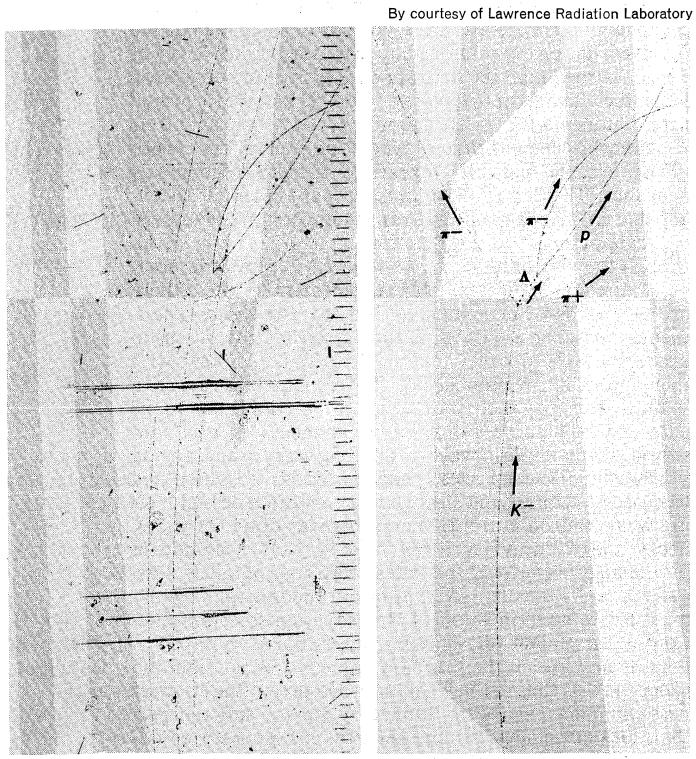

Figure 6: (Left) Photograph of a K^- meson interacting in a hydrogen bubble chamber. The interaction at the centre is shown and labelled at right.

agitates the molecules and heats the liquid. Boiling starts at these hot spots, and the path is recorded as a string of tiny bubbles that can be photographed. The chamber is in a magnetic field that bends the charged particles. The curvature of the tracks then tells the speed of the particle (see RADIATION DETECTION AND CHARACTERIZATION).

Three K^- mesons enter the bottom of Figure 6 (left) and travel through the chamber. Two pass through uneventfully, while one hits a proton to produce the reaction $K^-p \rightarrow \Lambda\pi^+\pi^-$. In its brief life of $\sim 10^{-10}$ second, the neutral Λ flies about one centimetre, then decays into two charged particles, $\Lambda \rightarrow p\pi^-$. Thus the Λ is seen as a gap of one centimetre, ending in a V formed by the p and π^-. For clarity, Figure 6 (right) repeats the tracks of interest, separated from the rest and labelled. An automatic film reader then measures the lengths and positions of labelled tracks to an accuracy of a few thousandths of a centimetre, and their coordinates are transmitted to a computer. If the tracks have been measured using two (or three) stereoscopic (*i.e.*, photographed from different viewpoints) pictures, the computer can then reconstruct their position, direction, curvature, and velocity.

Once the momentum of the Λ and of each of the π's has been computed, the computer can easily compute the effective mass $M_{\Lambda\pi^+}$ of the $\Lambda\pi^+$ diparticle and the effective mass $M_{\Lambda\pi^-}$ of the other. Further, it can make a "scatter plot" of one mass versus the other. This is shown in Figure 7B, in which each of the 5,640 dots represents an entire $\Lambda\pi^+\pi^-$ event like the one just described. For technical reasons it is more convenient to plot not the mass M but its square, M^2. For this particular choice of coordinates, it turns out that, if Λ and π did not attract one another to form resonances, the dots would be uniformly scattered over the allowed region. Instead, an almost black vertical band is seen, representing a considerable excess of events, at a value of $M^2_{\Lambda\pi^+} = (1{,}385\ \text{MeV})^2$, equal to $1.9\ (\text{BeV})^2$. This shows that there is a $\Lambda\pi^+$ resonance called $\Sigma^+(1{,}385)$. It can be shown that, if there is such a $\Lambda\pi^+$ resonance, then invariance of the strong interaction to transformations in isospin space requires that there should exist another resonance in the minus charge state, $\Lambda\pi^-$ of the same mass; in other words, the scatter plot of charge should show both the Σ^+ and Σ^- members of the $\Sigma(1,385)$ triplet. Although $\Sigma^-(1,385)$ is produced less intensely, a horizontal excess of events is indeed seen near the bottom of the allowed region, near $M^2_{\Lambda\pi^-} = 1.9\ (\text{GeV})^2$. It is conventional to display the projections of the dots onto the horizontal and vertical axes as histograms (bar graphs). The $\Lambda\pi^+$ and $\Lambda\pi^-$ enhancements can then be seen as sharp bumps, even sharper than the $N\pi$ bumps that are seen in Figure 5.

The "scatter plot"

In looking along the $-45°$ line of the scatter plot (parallel to the long straight "skin" of the allowed region), yet another enhancement will be seen, the projection of which is shown as the third histogram in Figure 7B. This turns out to be the signature of a $\pi^+\pi^-$ resonance known as the ρ meson.

Figure 7B, with 5,640 events, was published in 1967, and Figure 7A, earlier, in 1960. Comparison of these figures shows the rapid increase in technical capability in the intervening seven years. Figure 7A is taken from a paper that announced the discovery of the $\Sigma(1,385)$ as the first strange particle resonance. It displays 141 events that were measured and plotted with relatively little automation. This number of events was sufficient to show the existence of a bump (resonance) at 1,385 million electron volts but was insufficient to permit determination of the spin or parity of the resonance or even to hint at the production of the ρ meson in the same reaction.

Discovery of first strange particle resonance

RELATIONS BETWEEN THE INTERACTIONS

Currents. In the section above *History up to 1960*, it has been pointed out that the proposal of Lee and Yang about the violation of the law of conservation of parity in K-meson decays led to the discovery of its violation in muon decay ($\mu^- \rightarrow e^- + \nu_e + \nu_\mu$) and nuclear beta decay ($n \rightarrow p + e^- + \nu_e$). Further experiments have led to a much deeper understanding of the weak interactions and their relations to strong and electromagnetic interactions. The starting point was the discovery in the late 1940s that meson decay, nuclear beta decay, and meson capture ($\mu^- + p \rightarrow n + \nu_\mu$) can be described by Fermi interactions with nearly the same basic rate constant (the Fermi constant, G_F, of Table 3). The near equality of these three Fermi constants led to speculations about the possibility of a universal Fermi interaction among spin ½ particles. The question of the detailed structure of the interaction was not settled at that time. Ten years later (1956–58), after a series of definitive experiments, it became possible to single out a specific type of Fermi interaction. In particular, it was shown that the massless particle appearing in the reaction $e^- + p \rightarrow n + \nu_e$, which by convention is called an e-neutrino (ν_e), has negative helicity (as shown in Figure 1). The e-antineutrino (ν_e) turns out to have positive helicity.

Universal Fermi interaction

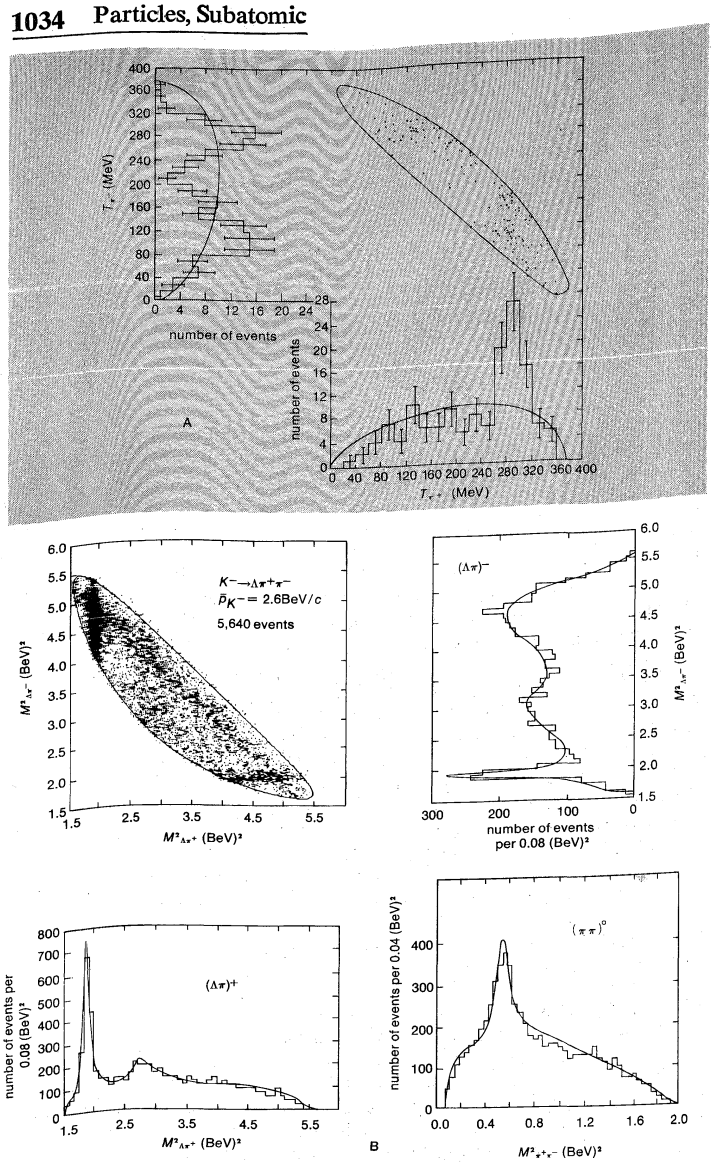

Figure 7: (A) Discovery, in 1960, of Σ(1,385), based on 141 events. This same reaction is pictured in (B) with 5,640 events.

An important notion that played a considerable role in this clarification of the structure of the weak interactions is that of a conserved current. Current conservation is really a shorthand for conservation of charge. The reason for a dual notation of conserved current and conservation of charge is that for charges in motion the expression for the conservation law of electric charge in a small region involves both the density of charge and the density of current. It has become conventional to lump these quantities together and call them current (or charge-current). The notion of conserved current was first used to explain how it is that the strong interactions (which affect the n and p in the reaction $n \to p + e^- + \bar{\nu}_e$ but none of the particles in the decay $\mu^- \to e^- + \bar{\nu}_e + \nu_\mu$) do not make the rate of the two reactions different. The explanation given can be understood by analogy with the case of the electric charges of particles. That the charges of all elementary particles are integer multiples of the same basic charge (even though some of the particles are strongly and some only weakly interacting) is a consequence of the conservation law of electric charge. Similarly, if the e^- and $\bar{\nu}_e$ produced in the decay of the neutron are coupled to a conserved current, the near equality of the rates is at least in part accounted for.

In the detailed application of this idea to the weak interactions, it is necessary to introduce in addition to the electromagnetic current, a so-called weak current of the hadrons and a weak current of the leptons. These currents then interact, for example, via the exchange of a W-meson, an intermediate boson of the weak interactions. (This exchange is indicated in Table 3, in which the weak current of the nucleons is indicated at the left and that of the leptons at the right.)

The *CVC* hypothesis

Now it turns out that the weak hadron current splits into two parts, one of which, the so-called vector current, is conserved like the electromagnetic current. (This is the so-called conserved vector current, or *CVC*, hypothesis.) The other part of the current is called the axial vector current. There are certain nuclei whose beta radioactivity involves only the vector part of the weak hadron current. According to the *CVC* hypothesis, the rate of these decays can be compared directly with the rate of muon decay, since there are no corrections to either rate attributable to the strong interactions. The comparisons of the late 1950s gave fairly good agreement under the assumption of the equality of the Fermi constants. On the other hand, for reactions involving the axial part of the current, corrections to the rate of nuclear beta decay are expected arising from the strong interactions, and, in the early 1960s, no one knew how to calculate them. Empirically the corrections seemed to be of the order of magnitude of 20 percent.

The work described in the two preceding paragraphs left completely open the question whether or not the neutrino involved in negative muon (μ^-) capture or the decay of the π^- is the same as that appearing in neutron decay. With the advent in the early '60s of the great proton accelerators at the CERN laboratory in Geneva and in Brookhaven, New York, a whole new class of experiments became possible: experiments with high-energy neutrinos. This led to the important experimental discovery that neutrinos resulting from pion decay ($\pi^- \to \mu^- + \bar{\nu}_\mu$) cannot produce the reaction $\bar{\nu}_\mu + p \to n + e^+$, although they do produce $\bar{\nu}_\mu + p \to n + \mu^+$. As the notation already indicates, this experiment shows there are two kinds of neutrinos, ν_e and ν_μ. The same experiments were consistent with the idea that the neutrino appearing in K decay ($K^- \to \mu^- + \bar{\nu}_\mu$) is identical with that appearing in pion decay. To explain this fact in a natural way, the theory of weak interactions has to be extended to decays in which strangeness is not conserved. The simplest way to do this was to add to the previously discussed weak hadron current (which led to processes conserving strangeness) a strangeness-changing weak hadron current. When this was done for the K decay and Λ decay ($\Lambda^0 \to p + e^- + \bar{\nu}_e$), a significant discrepancy appeared; the rates were anomalously low.

The Cabbibo angle

Algebra of currents. An important theoretical development led to a clarification of this situation, the introduction by the Italian physicist Nicola Cabbibo in 1963, of what is now called the Cabbibo angle, θ_c. What Cabbibo proposed was that in the weak hadron current the strangeness-changing part be multipled by sin θ_c, and the part that does not change strangeness, by cos θ_c. As a consequence, the rate of neutron decay is reduced relative to the rate of muon decay by a factor $\cos^2\theta_c$, while the rate of Λ^0 decay is reduced by a factor sin $^2\theta_c$. A value $\theta_c = 13°$ eliminated all major discrepancies involving the vector part of the weak hadron currents.

There remained the problem of computing the corrections arising from the strong interactions to the decays involving the axial vector part of the weak hadron current. To solve it one needs relations between strong and weak interactions. Here, it was the idea of current algebra that led to decisive progress. According to Gell-Mann, the same hadron currents that appear in the weak interactions are basic dynamical variables of the strong-interaction theory and appear directly in the quantities describing the symmetry of the strong interactions. In the idealized case in which $SU(3)$ is an exact symmetry, there are several strictly conserved hadron currents, and the corresponding charges define quantum numbers. Even if, as is indicated by the mass splitting between the multiplets in Figure 2, $SU(3)$ symmetry is only approximate, certain relations among the hadron currents still persist. It is

these that are known as current algebra. These relations enable one to express the strong corrections to those weak decay rates that involve the axial part of the weak hadron current in terms of the scattering of pions on nucleons (a strong interaction effect). Experimental values of the latter are in good agreement with experiments on the weak interactions. Current algebra provides one of the few quantitative links among the strong, weak, and electromagnetic interactions. Many authors took up its methods, and, by the late 1960s, it had become a valuable tool in many branches of particle physics.

With the arrival of the Cabbibo theory, the structure of the weak interactions was largely fixed and in good agreement with experiment. There were only a few indications that essential mysteries remained. One is the phenomenon of CP violation in K^0 decays described above. The other, the very existence of the intermediate W-meson, will be discussed in the next section.

UNDISCOVERED PARTICLES

The particles known as quarks appeared above as a convenient mathematical tool in the description of hadrons. The question naturally arises whether, in fact, free quarks occur in nature. Such quarks, if discovered, would be fundamental building blocks for the particles so far seen; the particle physics of today would become the chemistry of quarks. It would be necessary to go to even higher energies and shorter distances to find out whether or not the quarks themselves are in turn complex objects. That this possibility is taken seriously is indicated by the fact that, as each new accelerator comes into operation, a search is made to see if it is producing quarks.

Whether quarks are naturally occurring

A position somewhat similar to that of the quarks is occupied by the undiscovered W-meson drawn in Table 3, and often called the intermediate (or weak) boson. So far no free W-mesons have been seen, and the principal argument for their existence is that they would complete the analogy between the weak and electromagnetic interactions, with the W-mesons playing a role for the weak interactions analogous to that of the photon for the electromagnetic interactions. Because, in the low-energy experiments to date, it is the ratio $G_F = \sqrt{2}g_W^2 (\hbar^2/m_W c)^2$ that is determined, it is not yet known whether or not the W-meson is really weakly coupled (then $g_W^2/\hbar c$ is much less than one, and m_W is not far from the proton mass) or much more strongly coupled (then m_W would be much larger than the proton mass). A favourite speculation is $e^2/\hbar c = g^2/\hbar c$; then $m_W c^2$ would be about 40 GeV (40 giga-electron volts, *i.e.*, 40,000,000,000 eV). The feasibility of detecting intermediate mesons is strongly dependent on their mass. As of 1971, experiments showed that the mass is necessarily greater than 4 GeV, and new experiments promised to raise this limit considerably.

Magnetic monopoles

The next undiscovered particle, the magnetic monopole, has quite a different place in particle physics. A quantum theory of a particle carrying magnetic instead of electric charge was first constructed by Dirac in 1931. The existence of such a particle in nature is so intriguing a possibility that much experimental effort has gone into its detection, all without success. The Dirac magnetic monopole is a theoretical possibility seemingly uncalled for by any known experimental facts.

From a theoretical point of view, magnetic monopoles are also intriguing. It was pointed out by Dirac that, if a particle of electric charge, e, and a second particle of magnetic charge, e', are present, the product, ee', is quantized so that $ee'/2\hbar c$ is a nonzero integer. The reason for this is that the charges generate an electromagnetic field that carries a nonvanishing angular momentum, ee'/c, and that has therefore the magnitude ½, 1, 3/2, . . . in units of $\hbar$. This fact that $e'e/\hbar c$ is at least ½ implies that the fundamental magnetic charge e' is at least 137/2 times larger than e, the smallest unit of electric charge. This can be seen by invoking the fine-structure constant $e^2/\hbar c = 1/137$ and writing

$$\frac{e'e}{\hbar c} = \frac{e'e^2}{ehc} = \frac{e'}{e} \cdot \frac{1}{137} \geq \frac{1}{2}.$$

consequently the monopole is so strongly coupled to the electromagnetic field that no existing theory can treat it reliably.

Although the dynamical theory invoking concepts of force and motion of magnetic monopoles is shaky, various alternative kinematical possiblities for their description have been explored. For example, Schwinger's "dion" is a hypothetical particle capable of four states of respective electric and magnetic charge (e, e'), $(-e, e')$, $(e, -e')$, and $(-e, -e')$. Dions are used to build up observed particles by a process somewhat analogous to the construction of hadrons from quarks.

The above list of undiscovered particles does not include the graviton, and that for a peculiar reason. Although any reasonable theory of gravitation predicts gravitons, individual gravitons are extraordinarily difficult to detect. Thus it is natural to adopt the attitude of physicists toward neutrinos that prevailed in the early 1950s. Although neutrinos had not been directly detected, the indirect arguments for their existence were so compelling that there were few who doubted it. Similarly, it seems very likely that gravitons exist.

Gravitons

In the late '60s, Joseph Weber, a physicist in the United States, performed experiments to detect gravitational waves—not individual gravitons but coherent bundles of many gravitations. These experiments are controversial, but if they have been interpreted correctly, they constitute a check on the existence of the graviton. What is remarkable about the experiments is that they indicate that the universe contains an enormous amount of energy in gravitational waves. Thus the experiments are more significant for their cosmological implications than for their impact on particle physics.

A similar remark applies to the question of the presence of antimatter in the universe. (As remarked above, antimatter consists of atoms in which the atomic nuclei are composed of antinucleons instead of nucleons and the surrounding cloud consists of positrons instead of electrons.) Particle physicists are already convinced that for every particle there must exist, in principle, an antiparticle. But it will be of great significance for cosmology when and if antimatter is found to occur naturally in some regions of the universe. (A clue would be the discovery of nuclei of antimatter in some of the cosmic rays that arrive at the Earth from distant galaxies.)

Anti-universes

These statements about what particle physics has to learn from cosmology may be too pessimistic. Perhaps the study of the extreme conditions prevailing in very dense stars will lead to some unexpected insights into the role of gravitation in particle physics. Perhaps it is more likely that progress will come from trying to understand what happens to gravitational forces at short distances; this would enable one to establish a fundamental connection between the fourth basic force and the other three. All that is really clear in the early 1970s is that the physics of subatomic particles is still far from being a closed subject.

BIBLIOGRAPHY. There are many texts and journals devoted to particle physics, but most of them assume a knowledge of quantum mechanics. Non-quantum-mechanical treatments may be found in *Scientific American* magazine, specifically M. GELL-MANN and E.P. ROSENBAUM, "Elementary Particles," 197:72–88 (1957); and G.F. CHEW, M. GELL-MANN, and A.H. ROSENFELD, "Strongly Interacting particles," 210:74–93 (1964). For a historical review, see the Nobel Prize Lecture of LUIS W. ALVAREZ, "Recent Developments in Particle Physics," reprinted in *Science*, 165:1071–91 (1969). Other journals that give nontechnical articles are *Physics Today* and the CERN *Courier*, the latter issued in Geneva, Switzerland, by the European Organization for Nuclear Research. There is an annual "Review of Particle Properties," alternating each April between *Reviews of Modern Physics* and *Physics Letters*, which contains all the latest tables of data and references. Some books for the layman are: A.H. ROSENFELD and J.G. GOLDHABER, "Elementary Guide to Elementary (?) Particles," in A.B. BRONWELL (ed.), *Science and Technology in the World of the Future* (1970); R.K. ADAIR and E.C. FOWLER, *Strange Particles* (1963); K.W. FORD, *The World of Elementary Particles* (1963); R.D. HILL, *Tracking Down Particles* (1963); and C.N. YANG, *Elementary Particles* (1962).

(A.H.Ro./A.S.Wi.)

Parturition, Human

Parturition, or labour, is the process of bringing forth a child from the uterus, or womb. The prior development of the child in the womb is described in the article EMBRYOLOGY, HUMAN: *The acquisition of external form;* the changes that take place in the mother during the development of the child in the uterus, in the article PREGNANCY.

At the termination of pregnancy in the human female, the irregular, intermittent contractions of the uterus that began in the early months of pregnancy become more regular and increase in frequency and intensity. This assumption of a rhythmic character by the uterine contractions marks the beginning of the process by which the maternal organism separates and expels the mature products of conception.

Labour is divided into three stages: the first stage, dilatation, having to do with the opening up of the neck of the womb, begins with the onset of labour and ends when the cervix, or neck of the womb, is dilated sufficiently (*i.e.*, nine to ten centimetres, or about four inches, in diameter) to permit the passage of the child's head; the second stage, expulsion—the passage of the child through the maternal birth canal—begins when the cervix is sufficiently dilated to permit the passage of the child's head and terminates with the expulsion of the child; the third, or placental, stage, related to the separation and extrusion of the placenta (afterbirth), begins with the birth of the child and ends when the placenta is expelled and bleeding from the vessels in the uterus is arrested.

THE STAGES OF LABOUR

First stage: dilatation. Early in labour the uterine contractions come on at intervals of 20 to 30 minutes and last about 40 seconds. They are then accompanied by slight pain, which usually is felt in the small of the back. The term labour pains is often used as a synonym for uterine contractions.

As labour progresses these uterine contractions become more intense and also progressively increase in frequency until, at the end of the first stage, when dilatation is complete, they recur about every three minutes and are quite severe. With each contraction a twofold effect is produced to facilitate the opening up of the cervix. Because the uterus, or womb, is a muscular sac containing a bag of waters (the sac containing the amniotic fluid) that more or less surrounds the child, contraction of the musculature of its walls should diminish its cavity and compress its contents. Because its contents are quite incompressible, however, they are forced in the direction of least resistance, which is in the direction of the internal os, or upper opening of the neck of the womb, and are driven, like a wedge, farther and farther into this opening. In addition to forcing the uterine contents in the direction of the cervix, shortening of the muscle fibres that are attached to the neck of the womb tends to pull these tissues upward and away from the opening and, thus, add to its enlargement. By this combined action each contraction of the uterus not only forces the bag of waters and fetus downward against the dilating neck of the womb but also pulls the resisting walls of the latter upward over the advancing bag of waters, presenting (farthest advanced) part of the child.

Duration of first stage

In spite of this seemingly efficacious mechanism, the duration of the first stage of labour is rather prolonged, especially in women who are in labour for the first time. In them the average time required for the completion of the stage of dilatation is between 13 and 14 hours, while, in women who have previously given birth to children, the average is eight to nine hours. Not only does a previous labour tend to shorten this stage but this tendency often increases with succeeding pregnancies, with the result that a woman who has given birth to three or four children may have a first stage of one hour or less in her next labour.

The first stage of labour is often somewhat prolonged, also, in women who become pregnant for the first time after they have passed the age of 35, because the cervix dilates less readily. A similar delay is to be anticipated in cases where the cervix is extensively scarred as a result of previous labours, amputation, deep cauterization, or any other operation on the cervix. Even a woman who has borne several children and whose cervix, accordingly, should dilate readily may have a prolonged first stage if the uterine contractions are weak and infrequent or if the child lies in a faulty position and, as a direct consequence, cannot be forced into the mother's pelvis.

On the other hand the early rupturing of the bag of waters often increases the strength and frequency of the labour pains and thereby shortens the stage of dilatation; occasionally, premature loss of the waters leads to molding of the uterus about the child and thereby delays dilatation by preventing the child's normal descent into the pelvis. Just as an abnormal position of the child and molding of the uterus may prevent the normal descent of the child, an abnormally large child or an abnormally small pelvis may interfere with the descent of the child and prolong the first stage of labour.

Second stage: expulsion. About the time that the cervix becomes fully dilated, the bag of waters breaks, and the force of the involuntary uterine contractions is augmented by voluntary bearing-down efforts of the mother. With each labour pain she takes a deep breath and then contracts her abdominal muscles. The increased intra-abdominal pressure thus produced may equal or exceed the force of the uterine contractions. When properly used, accordingly, these bearing down efforts may double the effectiveness of the labour pains. As the child descends into and passes through the birth passages, the sensation of pain is often increased. This condition is especially true in the terminal phase of the stage of expulsion, when the child's head distends and dilates the maternal soft parts as it is being born.

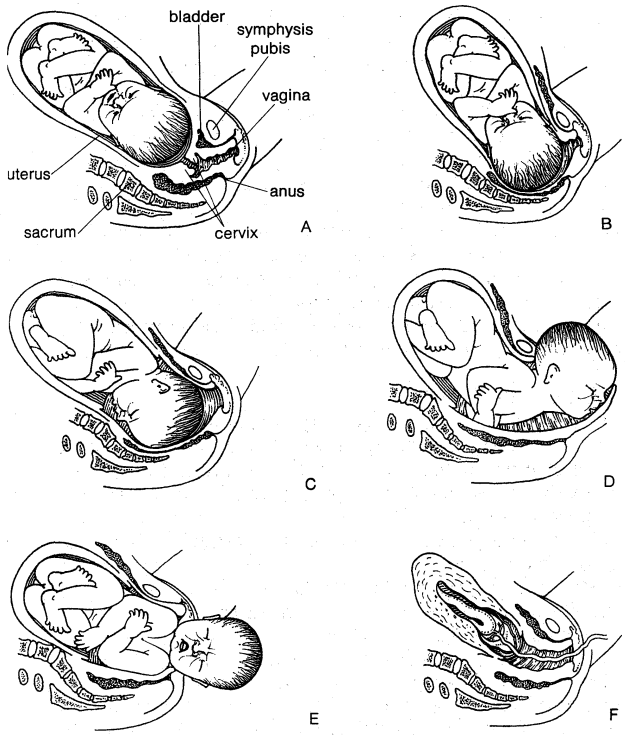
Transverse position of the head. The manner in which the child passes through the birth canal in the second stage of labour depends upon the position in which it is lying and the type of the mother's pelvis. The sequence of events described in the following numbered paragraphs is that which frequently occurs when the mother's pelvis is of the usual type and the child is lying with the top of its head lowermost and transversely placed and the back of its head (occiput) directed toward the left side of the mother (A in the Figure). The top of the head, accordingly, is leading and its long axis lies transversely.

Flexion and internal rotation of head

1. The force derived from the uterine contractions and the bearing-down efforts exerts pressure on the child's buttocks and is transmitted along the vertebral column to drive the head into and through the pelvis. Because of the eccentric attachment of the spine to the base of the skull, the back of the head is made to advance more rapidly than the brow with the result that the head becomes flexed (*i.e.*, the neck is bent) until the chin comes to lie against the breastbone (B in the Figure). As a consequence of this flexion mechanism, the top of the head (occiput) becomes the leading pole and the ovoid head circumference that entered the birth canal is succeeded by a smaller, almost circular circumference, the long diameter of which is about two centimetres (three-fourths inch) shorter than that of the earlier circumference.

2. As the head descends more deeply into the birth canal, it meets the resistance of the bony pelvis and of the slinglike pelvic floor, or diaphragm, which slopes downward, forward, and inward. When the back of the head, the leading part of the child, is forced against this sloping wall on the left side, it naturally is shunted forward and to the right as it advances, just as a ferryboat is shunted into its wharf by meeting the sloping resistance of its ways (C in the Figure). This internal rotation of the head brings its longest diameter into relation with the longest diameter of the pelvic outlet and thus greatly assists in the adaptation of the advancing head to the configuration of the cavity through which it is to pass.

3. Further descent of the head directly downward in the direction in which it has been travelling is opposed by the lower portion of the mother's bony pelvis, behind, and



Sequential changes in the position of the child during labour. (A) Onset of labour. (B) Flexion. (C) Internal rotation of the head. (D) Extension. (E) External rotation of the head. (F) Uterus immediately after birth; cord has been cut and placenta is separating from uterine wall.
Drawing by Ramon Goas after Alfred C. Beck

the resisting soft parts that are interposed between it and the opening of the vagina (C in the Figure). Less resistance, on the other hand, is offered by the soft and dilatable walls of the lower birth canal, which is directed forward and upward. The back of the child's head accordingly advances along the lower birth canal, distending its walls and dilating its cavity while the head progresses. Soon the back of the child's neck becomes impinged against the bones of the pelvis, in front, and the chin is forced farther and farther away from the breastbone. Thus, as extension (bending of the head backward) takes the place of flexion, the occiput, brow, eye sockets, nose, mouth, and chin pass successively through the external opening of the lower birth canal and are born (D in the Figure).

Extension of head and then resumption of original position

4. The neck, which was twisted during internal rotation of the head, untwists as soon as the head is born. Almost immediately after its birth, therefore, the occiput is turned toward the left and backward.

As the child's lower shoulder advances, it meets the sloping resistance of the pelvic floor on the right side and is shunted forward and to the left toward the middle of the pelvis in front. This position brings the long diameter of the shoulder circumference into relation with the anteroposterior, or long diameter, of the pelvic cavity. Because of this internal rotation of the shoulders, the occiput undergoes further external rotation backward and to the left so that the child's face comes to look directly at the inner aspect of the mother's right thigh (E in the Figure).

Birth of the shoulders. Soon after the shoulders rotate, the one in front appears in the vulvovaginal orifice and remains in this position while the other shoulder is swept forward by a lateral bending of the trunk through the same upward and forward curve that was followed by the head as it was being born. After this shoulder is delivered, the shoulder in front and the rest of the child's body are expelled almost immediately and without any special mechanism.

An average of about one hour and 45 minutes is required for the completion of the second stage of labour in women who give birth for the first time. In subsequent labours the average duration of the stage of expulsion is somewhat shorter.

Posterior position of the occiput. The child may lie so that the back of its head is directed backward and toward either the right or left side. The leading pole is then in the right or left posterior quadrant of the mother's pelvis, and the condition is referred to as a posterior position of the occiput. In such cases the back of the child's head usually rotates to the front of the pelvis and labour proceeds as in transverse positions. Because of the longer rotation required, labour may be somewhat more prolonged than in transverse positions.

Face presentation. When the child's head becomes bent back (extended) so that it enters and passes through the pelvis face first, the condition is known as a face presentation. The chin is then the leading pole and follows the same course that is followed by the back of the head in occipital presentations. If the chin lies to the front as it enters the pelvis, labour often is easy and of short duration. Should it be directed backward, on the other hand, considerable difficulty may be encountered, and the head may have to be flexed or rotated artificially.

Breech presentation. Passage of the lower extremities or the buttocks through the pelvis first, called breech presentation, is encountered about once in every 30 labours. Because the head in such cases is the last part of the child to be delivered and because this part of the delivery is the most difficult, the umbilical cord (navel string) may be compressed while the aftercoming head is being born, with the result that the child may be asphyxiated. Asphyxia or injurie , to the child that result from the attendant's effort to hasten the delivery in order to prevent the child's asphyxiation are responsible for the loss of three times as many breech babies as head-on babies.

The infant mortality rate in countries with well-developed systems of medical care varies from 2 percent to 10 percent according to the size of the child and skill of the attendant. Because very small, premature infants are particularly susceptible to the dangers of breech delivery, the mortality among them is very high when they are born breech first.

Transverse presentation or cross birth. In this relatively rare situation the long axis of the child tends to lie across, or transverse to, the long axis of the mother. Unless the child is very small or has been dead for some time and has become greatly softened, delivery through the natural passages is impossible in such cases. For this reason the child must be turned by the attendant or delivered by the surgical procedure called cesarean section (through the mother's abdominal wall) if it is alive.

Slight risks of pregnancy

That the above-mentioned complications are infrequent and can be cared for easily is shown by the excellent statistics of many maternity services, in which the maternal death rate is less than one per 1,000 and would be still lower if the deaths caused by complicating systemic diseases were excluded. The infant mortality rate is also usually low, ranging between 1.5 percent and 3 percent. It likewise would be much lower if the premature and poorly developed infants were excluded. In other words, the risk to a healthy mother who carries her child to maturity is less than one per 1,000, and the risk to her mature child is about 0.5 percent.

Third stage: placental stage. With the expulsion of the child, the cavity of the uterus is greatly diminished (F in the Figure). As a consequence the site of placental attachment becomes markedly reduced in size, with the result that the placenta (afterbirth) is separated in many places from the membrane lining the uterus. Within a few minutes subsequent uterine contractions complete the separation and force the afterbirth into the vagina, from which it is expelled by a bearing-down effort. The third stage of labour, accordingly, is of short duration, seldom lasting longer than 15 minutes. Occasionally, however, the separation may be delayed and accompanied by bleeding, in which case artificial removal of the placenta is necessary. The attendant always remains with the mother until the possibility of hemorrhage has been eliminated by firm retraction of the uterus.

(A.C.Bk.)

RELIEF OF PAIN IN LABOUR

Not much was done to relieve the suffering of childbirth before chloroform was first widely used in the 1850s for this purpose. Because of its toxicity, even this drug was employed sparingly and ultimately came into disuse. Early in the 20th century, a combination of the drugs morphine and scopolamine was given, according to the "twilight sleep" technique, to lessen the pain that accompanies the stage of cervical dilatation. While this technique was found to be less safe than had been hoped, it gave a new and strong impetus to the search for a satisfactory method of pain relief, with the result that the old methods were improved and many new ones were suggested. No completely satisfactory method was found, and, at the beginning of the 1970s, it still remained impossible to secure total relief from pain in all women without adding to the maternal and fetal risk. On the other hand, the judicious employment of one or more of the drugs described briefly in the following paragraphs eliminates much of the pain of childbirth with safety (see also ANESTHETIC).

Twilight sleep

Morphine and scopolamine. By the use of injections of morphine and scopolamine, a condition of seminarcosis, twilight sleep, is induced. When the method is successful, the mother awakens after her child is born and has no recollection of having felt any pain during her labour. Such a result is attributable either to the actual relief of pain or to her inability to remember such pain as did occur because of the scopolamine-induced loss of memory. If given too soon, these drugs may stop the labour completely. If given too late, their effect on the child's respiratory centre may cause its death from asphyxia. This lack of safety has led to more or less abandonment of the twilight sleep routine.

Barbiturates. The barbiturate drugs, usually combined with scopolamine, are frequently employed for the relief of pain during labour. As in the case of twilight sleep, their successful use is followed by a loss of memory, and the mother either has no pain or forgets it completely. To obtain a satisfactory result, unpleasant side effects sometimes are encountered. The commonest of these is excitement of varying degrees. Restraint, accordingly, may be necessary, and the constant presence of a nurse or other attendant is required. The patient's restlessness or inability to use her bearing-down efforts properly often makes it necessary to deliver the child with instruments and with the mother under anesthesia. Although some infants delivered in this way do not breathe so readily as do those born to mothers who have had no medication for the relief of pain, the effect of the barbiturates on the child is much less marked than that produced by the twilight sleep routine.

Meperidine. The drug meperidine, combined with scopolamine, has been employed to relieve pain and to induce forgetfulness (amnesia) during labour. Evidence accumulated after the mid-20th century seemed to indicate that this combination would ultimately prove to be the safest and best method of pain relief during the first stage of labour. The dilatation of the cervix apparently is hastened by use of meperidine. If the combination of meperidine and scopolamine is supplemented by local anesthesia during the stage of expulsion, the greater part of the pain of childbirth may be eliminated without risk to mother or child.

Nitrous oxide. Nitrous oxide, or laughing gas, is one of the most popular of the analgesic (pain-relieving) agents. It is given during the latter part of the first and throughout the second stage of labour and is administered only for the duration of the uterine contractions. While the child is being delivered, the addition of ether is usually necessary. Unless adequate amounts of oxygen are added to the nitrous oxide mixture that the mother breathes, the child may suffer from lack of oxygen or die from asphyxia.

Chloroform, ether, ethylene, and cyclopropane. Chloroform, ether, ethylene, and cyclopropane are often given while the child is being delivered. Chloroform is rarely used because of its toxicity. Ether is much safer than chloroform but is not pleasant to take and is irritating to the respiratory passages. Ethylene is not widely used in obstetrics, because it is disagreeable to take and is highly explosive. For cyclopropane, an excellent gaseous anesthetic agent well suited to the needs of obstetric practice but highly explosive, a special apparatus is required for administration, and adequate measures must be employed to prevent the occurrence of static sparks. Trichloroethylene, a volatile anesthetic agent, is suitable for self-administration during the latter part of labour. The patient inhales it through a special inhaler that she places over her nose and mouth at the onset of each uterine contraction. Loss of consciousness occurs before the contraction ends; the inhaler thus drops away from her nose and the administration of the gas is discontinued. Trichloroethylene anesthesia is used extensively in Great Britain.

Self-administration of trichloroethylene

OPERATIVE OBSTETRICS

Most women deliver a baby spontaneously. Complications, however, that were present before labour or that develop during labour may threaten the life of the mother or of the baby and may require intervention by the attending physician.

When a complication develops, the obstetrician's choice of treatment depends upon the problem. He may use the obstetrical forceps, an instrument that is so constructed that it can be applied to the fetal head for the purpose of extracting the fetus by traction or of rotating the fetal head in order to correct an unsatisfactory or undeliverable position. Forceps delivery is indicated when the mother's expulsive forces are unable to effect a spontaneous delivery because of ineffective uterine contractions, abnormalities in the mechanism of labour, or lesser degrees of disproportion between the size of the baby's head and the mother's pelvis. Labour is terminated by forceps when the mother or the fetus is in distress that can be relieved by prompt delivery. It is often used for delivery of the aftercoming head. Forceps delivery may save the mother from the stress of the second stage of labour in some cases of heart disease, tuberculosis, and other debilitating diseases. Infection occurring during delivery, certain cases of placenta praevia, and premature separation of the placenta may be indications for forceps delivery. (Placenta previa, described in the article PREGNANCY, is development of the placenta so that it covers the internal opening of the cervix and must precede the infant during delivery.) Conditions must be suitable, of course, for forceps delivery before the instrument is employed.

Manual rotation may be used instead of the forceps when the fetal head is in an abnormal position that makes delivery difficult or impossible. In carrying out the procedure, the obstetrician inserts his hand into the birth canal and turns the fetal head to a more favourable position.

Bleeding from the uterus during or after the third stage of labour may be controlled by manual removal of the placenta and packing of the uterus. In the former method the operator inserts his hand into the uterine cavity and separates the adherent placenta from the uterine wall. Modern obstetricians rarely pack the uterus with gauze to control bleeding, because it fails to stop bleeding, and it carries with it an increased risk of infection.

Cesarean section

When conditions are such that the delivery of a child through the vagina would be a hazard to the mother or to the fetus, it may be necessary or preferable to resort to cesarean section, a procedure in which the fetus is delivered through a surgical opening in the uterus made after the uterus has been exposed through an opening in the abdominal wall.

Cesarean section is so much better for the mother and the fetus when there is bleeding from a placenta previa or prematurely separated placenta that it is the preferred method of delivery in many cases of uterine hemorrhage during the later months of pregnancy and labour. Difficult or prolonged labour is a frequent indication for abdominal delivery. Uterine inertia, once one of the most common causes for prolonged labour, makes cesarean section necessary less frequently than it did a decade ago because of the widespread use of very weak solutions of oxytocin to stimulate uterine contractions in such cases.

(Oxytocin is a hormone produced by the nerve cells of the hypothalamus, a centre at the top of the brainstem; the hormone is stored in the posterior lobe of the pituitary.)

Prolonged or difficult labour resulting from either a small maternal pelvis, a large fetus, or a malposition or malpresentation of the fetus is one of the most frequent reasons that some women have their first, or primary, cesarean section.

As a general rule after a woman has undergone one abdominal delivery, she is delivered thereafter in the same fashion. The principle of "once a cesarean, always a cesarean" came about because of the danger of rupture of the uterine scar, with loss of the baby's and often the mother's life if she is permitted to deliver vaginally after a previous cesarean section.

The woman who suffers from obstructed labour is delivered abdominally if labour cannot be terminated vaginally without danger to her or the baby. Threatened rupture of the uterus is treated by immediate cesarean section. Ordinarily the patient in labour who has been neglected and for this reason is actually or potentially infected is delivered by some type of cesarean section.

A number of conditions that would not be considered imperative reasons for abdominal delivery may, at times, be factors influencing the choice of cesarean section. Breech presentation by itself is not a reason for cesarean section; a large baby, however, that is presenting by the breech in a woman past her middle 30s who is bearing a child for the first time could quite possibly be considered an indication for cesarean section because of the increased hazard to a large baby in a breech delivery and the possibility that it might be the patient's only opportunity to bear a child. Absolute or relative indications for cesarean section include a number of uncommon conditions, such as multiple pregnancy; prolonged pregnancy; a malignant tumour of one of the pelvic organs; a previous operation, the results of which interfere with normal function of the uterus; an anomaly of the genitalia; a benign pelvic tumour that obstructs the birth canal; a paralytic neuromuscular disorder, such as poliomyelitis, that prevents the mother from exercising her voluntary expulsive forces; or death of fetuses before or during earlier childbirths.

Cesarean section is often necessary when the mother is diabetic or has toxemia of pregnancy, a complex series of metabolic disorders that involve or may involve excessive vomiting, convulsions, and coma. The procedure is also resorted to in some instances when a woman has her first child late in her child-bearing years. Cesarean section may seem necessary if the mother has not only chronic high blood pressure and disease of the blood vessels but also pre-eclampsia, a condition in which there is a sudden rise in blood pressure, fluid accumulates in the tissues, and protein in the blood reaches abnormal heights. Premature expulsion of the umbilical cord may call for cesarean section if the child is alive and immediate vaginal delivery is not possible.

In rare instances the obstetrician may make incisions in the incompletely dilated uterine cervix. The incisions permit vaginal delivery in those cases in which labour is unduly prolonged and the incomplete dilation of the cervix is the only thing that is delaying delivery.

Procedures now rarely used

Three procedures formerly employed but now seldom used are (1) internal podalic version, an operation in which the obstetrician inserts his hand into the uterus and turns the fetus around so that it delivers by the breech (see above); (2) symphysiotomy; and (3) pubiotomy. Symphysiotomy is a surgical incision through the symphysis pubis, the joint between the two pubic bones of the pelvis at the front midline of the body; and pubiotomy is cutting through a pubic bone. Symphysiotomy and pubiotomy were formerly used when the fetus was too large for the mother's pelvis but have now been largely abandoned, at least in the United States, in favour of cesarean section.

Another procedure, formerly necessary in emergencies but now never obligatory, is the destruction of a living, normal infant, because its delivery intact would be incompatible with preservation of the mother's life. Today, modern techniques and antibiotics make possible the delivery of any infant intact, alive or dead, by methods that are likely to be safer for the mother than a difficult, destructive operation.

ACCIDENTS DURING LABOUR

Lacerations. *Lacerations of the perineum, vulva, and vagina.* Vaginal lacerations usually make themselves known by profuse bleeding after delivery of the baby. Not all extensive lacerations cause bleeding, however, and a large tear in the vaginal wall may not be discovered until the obstetrician inspects the vagina after the placenta is delivered. There is no difficulty in diagnosing lacerations near the external opening of the birth canal, because they are easily seen by the obstetrician. Even minor lacerations are repaired, because, if they are not, granulation tissue may form in the wounds and delay healing. Deep lacerations require anatomical reconstruction of the torn tissues. Extensive tears of the perineum (the tissues between the genital organs and the anus) can often be avoided by performing an episiotomy—an incision in the vulvar orifice, the external genital opening—before delivery of the infant's head. Also, attention on the obstetrician's part to the mechanism of labour, manual assistance in delivery of the head and shoulders, avoidance of too rapid delivery, delivery between pains, and the proper use of the forceps are some of the many measures that help to avoid injuries not only to the perineum but to all of the genital tissues.

Cervical lacerations. The cervix, the lower end of the uterus that projects into the vagina, is usually inspected after the placenta has been delivered. Superficial tears look somewhat like a frayed edge on the cuff-like cervix. Deeper lacerations usually cause serious bleeding immediately before or after delivery of the placenta.

Small cervical lacerations are not repaired; they heal spontaneously. Deeper tears are sutured. The management of extensive tears into the body of the uterus or the broad ligaments that support the uterus depends on the extent of the injury and its location; an abdominal operation is sometimes required to control the bleeding and to repair the uterus. Occasionally hysterectomy—removal of the uterus—is necessary.

Other accidents. *Rupture of the uterus.* Rupture of the uterus may occur spontaneously; it may be caused by trauma, or it may occur when a cesarean-section scar gives way. The classical signs of impending spontaneous rupture are gradually increasing, constant, severe pain in the lower part of the abdomen, restlessness, a rising temperature, an increasing pulse rate, and a tense, tender uterus that does not relax between strong contractions. When rupture occurs, the patient complains, usually, of extreme pain and then a sensation of something tearing or giving way. Uterine contractions stop. There is extensive internal bleeding. The baby's body can be felt in the mother's abdomen beside the contracted uterus.

Signs of impending rupture

Prompt delivery, almost always by cesarean section, is the treatment of impending rupture. The patient is anesthetized to stop uterine contractions as soon as the diagnosis is made.

An immediate abdominal operation follows the diagnosis of uterine rupture. Bleeding from the torn uterine walls must be stopped as promptly as possible. The fetus is removed. A hysterectomy is usually performed, because the ragged uterine scar is likely to rupture again if the patient has another term pregnancy, and bleeding from the torn uterus is difficult to control. Such patients often require generous quantities of transfused blood. Antibiotics are given, because infection is or may be present.

Injuries to the pelvic supporting tissues. Injuries to the pelvic supporting tissues may not be evident during labour. Months or years later the diagnosis will be made, because the patient complains of something bulging from the vagina, involuntary loss of urine while coughing or laughing, a sensation of things falling down, dragging pelvic discomfort, and difficulty in emptying the lower bowel. The bulging mass formed by a cystourethrocele or rectocele, when seen at vaginal examination, confirms it.

(A cystourethrocele is a sagging of the urethra and bladder out of position; a rectocele is a protrusion of the rectum into the vagina.) At times the result of the injuries to the pelvic supporting ligaments and muscles may be so severe that the uterus lies completely outside the vagina, and the vagina is turned inside out, forming a huge ball-shaped mass lying between the patient's thighs.

Treatment depends on the severity of the symptoms. Many women live out their lives without much distress from small cystourethroceles and rectoceles. Larger lesions are repaired surgically.

Inversion of the uterus. Another accident that may occur during labour is inversion of the uterus. The uterus turns inside out and upside down so that its inner surface lies outside and against the wall of the vagina. Inversion causes sudden shock. There may be severe bleeding. The diagnosis is made by noting the pear-shaped mass, covered by a shaggy, dark-red, bleeding surface, filling the vagina or hanging outside. The placenta may be still attached to it.

Restoration of a uterus to its normal position is accomplished after the patient's shock and hemorrhage are treated, and she is anesthetized. The obstetrician inserts his hand into the patient's vagina and lifts up the uterus. The tension applied to the uterine ligaments by this procedure usually reinverts the uterus.

Embolisms. Embolisms may occur. (An embolism is a blockage of a blood vessel, as by a blood clot or bubble of air.) Amniotic fluid embolism causes sudden, severe respiratory distress, signs of shock, cyanosis (blueing of the skin), heart collapse, and circulatory failure. If the diagnosis is made promptly, oxygen, blood transfusion, and the injection of fibrinogen, a clotting factor, into a vein may be lifesaving.

Effects of amniotic fluid embolism

Air embolism causes the patient to become suddenly short of breath and cyanotic. She may have heart pain and show signs of shock. The heart beats irregularly, and swishing sounds, caused by the presence of air mixed with blood in the heart, can often be heard. Death follows quickly unless the diagnosis is made at once. Treatment consists of drawing the air from the heart with a needle and syringe.

Fibrinogenopenia. Fibrinogenopenia, a shortage of fibrinogen, which causes defective blood clotting and serious bleeding, may result from a number of circumstances, including premature separation of the placenta and a hard, forceful labour. The diagnosis is confirmed by testing the mother's blood. It lacks fibrinogen if it does not clot firmly in ten minutes or if the clot that does form dissolves when incubated at 37° C (98.6° F) for one hour. Treatment includes management of the condition responsible for the lack of fibrinogen, replacement of blood lost through bleeding, and the administration of fibrinogen intravenously.

Placenta accreta. Abnormal adherence of the placenta to the uterus, a condition called placenta accreta, is suspected when the placenta cannot be expelled. If the adherence is only partial, there is usually brisk bleeding from the remainder of the placental site. Formerly, placenta accreta was treated by immediate removal of the uterus. In the late 1960s it was suggested that the placenta should be left in place to disintegrate, in which case the patient is protected from infection with antibiotics.

Abruptio placentae

Genital bleeding during labour. Genital bleeding during labour is a symptom of a number of obstetrical complications in addition to those discussed above. The diagnosis of premature separation of the placenta (abruptio placentae) is made when the patient complains of sudden abdominal pain and when there is uterine tenderness and vaginal bleeding. The mother may go into shock, and the fetus may die. There may be signs of hidden bleeding and concealed blood within the uterus. This condition is differentiated from placenta previa by the fact that the placenta is not in the lower uterine segment.

In cases of suspected placenta previa, the placenta can be located with considerable accuracy, as by X-ray. The definitive diagnosis of placenta previa is made, however, when vaginal examination, which is not performed until everything is in readiness for immediate vaginal or abdominal delivery, reveals part of the placenta in the lower uterus.

In every case of serious blood loss, bleeding must be controlled and lost blood replaced in amounts sufficient to protect the mother. Most patients with placenta previa and premature detachment of the placenta are treated by cesarean section. Cesarean section is not performed for premature detachment of the placenta (abruptio placentae) until a shortage of fibrinogen is corrected. Removal of the uterus may be necessary in rare cases of abruptio placentae when the uterine wall has been so infiltrated by blood that it cannot contract.

Severe bleeding not related to the pregnancy, such as that resulting from rupture of one of the pelvic veins or rupture of the spleen, may occur during labour. When it occurs, it must be treated regardless of the pregnancy.

Accidents to the umbilical cord. An accident to the umbilical cord is suspected when there is marked irregularity in the fetal heart rate and particularly when the irregularity is accentuated by uterine contractions. A prolapsed cord—that is, a cord lying below the head—can be felt through the membranes on vaginal examination. After the membranes have ruptured, the cord can be felt and seen in the vagina. It may hang out of the vulva. The patient is delivered by cesarean section if the infant is alive and if the head can be prevented from pressing on the cord while preparations are made for the operation. The baby is delivered vaginally if the cervix is completely dilated and if conditions are favourable for prompt vaginal delivery. Attempts to replace the cord in the uterus are seldom successful. Vaginal delivery is allowed to continue if the infant is dead.

True knots in the cord and rupture of the cord with bleeding are seldom diagnosed until after delivery. They are usually associated with sudden and, at the time, inexplicable fetal death. (J.W.Hu.)

NATURAL CHILDBIRTH

In the 1940s Grantly Dick-Read, a British obstetrician, developed a technique of delivery called natural childbirth that minimized the surgical and anesthetic aspects of delivery and concentrated upon the mother's conscious effort to give birth to her child. Although opposed by many physicians who felt that it denied the progress of modern medicine and needlessly primitivized the process of birth, the method was gradually accepted and by the late 1950s was practiced by a sizable percentage of women, especially in the United States and England.

Arguments for natural childbirth

Natural childbirth, as formulated by Dick-Read, stems from his premise that childbirth need not be accompanied by excessive pain and that labour pains are the result of unnatural physical tension caused by fear. Dick-Read maintains that fear can be counteracted by understanding and an ability to relax, and his method prescribes for the expectant mother a lengthy course of instruction in the mechanics of labour and birth as well as exercises to strengthen the musculature and to encourage proper breathing. During her labour the mother is aided by trained personnel so that she does not forget her training, and small quantities of anesthetic are made available to her when needed. No claims are made that natural childbirth is totally painless; it rather enables the mother's physical response to transcend discomfort.

Natural childbirth is not considered advisable for women in poor health or for those who have physical defects or psychological problems. For the healthy, determined young mother, it presents the advantage of allowing her to participate actively, rather than passively, in labour and to experience the actual moment of birth. A disadvantage is the amount of time required for the prenatal instruction course, which is impractical for many mothers. (Ed.)

PUERPERIUM OR PERIOD OF INVOLUTION

Within six to eight weeks after childbirth, most of the structures of the maternal organism that underwent change during pregnancy return more or less to their prepregnancy state. The enlarged uterus, which at the end of gestation weighed about 1,000 grams (35 ounces),

shrinks to a weight of about 60 grams (two ounces). Along with this process of uterine involution, the lining membrane of the uterus is almost completely shed and replaced by a new lining, which is then (six to eight weeks after delivery) ready for the reception of another fertilized ovum (egg). The greatly dilated neck of the womb and lower birth passage likewise undergo marked and rapid involution, but they seldom return exactly to their prepregnancy condition. As a rule examination of a woman who has given birth accordingly reveals evidence of this. The markedly stretched abdominal wall also undergoes considerable involution, particularly if abdominal exercises are carried out. Although the intradermal tears (striae gravidarum) become smaller and silvery white, they do not completely disappear but remain as evidence of the marked and rapid stretching of the skin that took place during pregnancy. The breasts, unlike most of the other organs, continue to increase in size. By the second or third day after childbirth, they become so distended that they are painful. After the milk comes in on the third day, this distension recedes, but the breast enlargement persists as long as lactation continues. If the child is not allowed to nurse on its mother's breasts, lactation ceases within a short time, and mammary involution follows (see also LACTATION, HUMAN).

Pascal, Blaise

Blaise Pascal, a mathematician, physicist, religious philosopher, and master of French prose, laid the foundation for the modern theory of probabilities, formulated what came to be known as Pascal's law of pressure, and propagated a religious doctrine that taught the experience of God through the heart rather than through reason. The establishment of his principle of intuitionism had an impact on such later philosophers as Jean-Jacques Rousseau and Henri Bergson and also on the Existentialists.

Pascal, red crayon drawing by Jean Domat, c. 1649. In the Bibliothèque Nationale, Paris.

Pascal's life to the Port-Royal years. He was born on June 19, 1623, at Clermont-Ferrand, France, where his father, Étienne Pascal, was presiding judge of the tax court. Pascal's mother died in 1626, and in 1631 the family moved to Paris. Étienne, who was respected as a mathematician, devoted himself henceforth to the education of his children. While his sister Jacqueline (born in 1625) figured as an infant prodigy in literary circles, Blaise proved himself no less precocious in mathematics. In 1640 he wrote an essay on conic sections, *Essai pour les coniques,* based on his study of the now classical work of Girard Desargues on synthetic projective geometry. The young man's work, which was highly successful in the world of mathematics, aroused the envy of no less a personage than the great French Rationalist and mathematician René Descartes. Between 1642 and 1644, Pascal conceived and constructed a calculating device to help his father—who in 1639 had been appointed intendant (local administrator) at Rouen—in his tax computations. The machine was regarded by Pascal's contemporaries as his main claim to fame, and with reason, for in a sense it was the first digital calculator.

Until 1646 the Pascal family held strictly Roman Catholic principles, though they often substituted *l'honnêteté* ("polite respectability") for inward religion. An illness of his father, however, brought Blaise into contact with a more profound expression of religion, for he met two disciples of the abbé de Saint-Cyran, who, as director of the convent of Port-Royal, had brought the austere moral and theological conceptions of Jansenism into the life and thought of the convent. Jansenism was a 17th-century form of Augustinianism in the Roman Cathòlic Church. It repudiated free will, accepted predestination, and taught that divine grace, rather than good works, was the key to salvation. The convent at Port-Royal had become the centre for the dissemination of the doctrine. Pascal himself was the first to feel the necessity of entirely turning away from the world to God, and he won his family over to the spiritual life in 1646. His letters indicate that for several years he was his family's spiritual adviser, but the conflict within himself—between the world and ascetic life—was not yet resolved. Absorbed again in his scientific interests, he tested the theories of Galileo and Evangelista Torricelli (an Italian physicist who discovered the principle of the barometer). To do so, he reproduced and amplified experiments on atmospheric pressure by constructing mercury barometers and measuring air pressure, both in Paris and on the top of the Puy de Dôme, a mountain overlooking Clermont-Ferrand. These tests paved the way for further studies in hydrodynamics and hydrostatics. While experimenting, Pascal invented the syringe, refined Torricelli's barometer, and created the hydraulic press, an instrument based upon the principle that became known as Pascal's law: pressure applied to a confined liquid is transmitted undiminished through the liquid in all directions regardless of the area to which the pressure is applied. His publications on the problem of the vacuum (1647–48) added to his reputation. When he fell ill from overwork—he was of a weak constitution—his doctors advised him to seek distractions; but what has been described as Pascal's "worldly period" (1651–54) was, in fact, primarily a period of intense scientific work, during which he composed treatises on the equilibrium of liquid solutions, on the weight and density of air, and on the arithmetic triangle: *Traité de l'équilibre des liqueurs et de la pesanteur de la masse de l'air* (Eng. trans., *The Physical Treatises of Pascal,* 1937) and also his *Traité du triangle arithmétique.* In the last treatise, a fragment of the *De Alea Geometriae,* he laid the foundations for the calculus of probabilities. By the end of 1653, however, he had begun to feel religious scruples; and the "night of fire," an intense, perhaps mystical "conversion" that he experienced on November 23, 1654, he believed to be the beginning of a new life. He entered Port-Royal in January 1655, and though he never became one of the solitaries, he thereafter wrote only at their request and never again published in his own name. The two works for which he is chiefly known, *Les Provinciales* and the *Pensées,* date from the years of his life spent at Port-Royal.

Contributions to physics and mathematics

Association with the Convent of Port-Royal

"Les Provinciales." Written in defense of Antoine Arnauld, an opponent of the Jesuits and a defender of Jansenism who was on trial before the faculty of theology in Paris for his controversial religious works, Pascal's 18 *Lettres écrites par Louis de Montalte à un provincial* deal with divine grace and the ethical code of the Jesuits. They are better known as *Les Provinciales.* They included a blow against the relaxed morality that the Jesuits were said to teach and that was the weak point in their controversy with Port-Royal; Pascal quotes freely Jesuit dialogues and discrediting quotations from their own works, sometimes in a spirit of derision, sometimes with indignation. In the two last letters, dealing with the question of

grace, Pascal proposed a conciliatory position that was later to make it possible for Port-Royal to subscribe to the "Peace of the Church," a temporary cessation of the conflict over Jansenism, in 1668.

The *Provinciales* were an immediate success, and their popularity has remained undiminished. This they owe primarily to their form, in which for the first time bombast and tedious rhetoric are replaced by variety, brevity, tautness, and precision of style; as Nicolas Boileau, the founder of French literary criticism, recognized, they marked the beginning of modern French prose. Something of their popularity, moreover, in fashionable, Protestant, or skeptical circles, must be attributed to the violence of their attack on the Jesuits. In England they have been most widely read when Roman Catholicism has seemed a threat to the Church of England. Yet they have also helped Catholicism to rid itself of laxity; and, in 1678, Pope Innocent XI himself condemned half of the propositions that Pascal had denounced earlier. Thus, the *Provinciales* played a decisive part in promoting a return to inner religion and helped to secure the eventual triumph of the ideas set forth in Antoine Arnauld's treatise *De la fréquente communion* (1643), in which he protested against the idea that the profligate could atone for continued sin by frequent communion without repentance, a thesis that thereafter remained almost unchallengeable until the French church felt the repercussion of the revocation of the Edict of Nantes (which had granted religious freedom to French Protestants) in 1685. Whereas the Jesuits seemed to represent a Counter-Reformation predominantly concerned with orthodoxy and obedience to ecclesiastical authority, the *Provinciales* advocated a more spiritual approach, emphasizing the soul's union with the Mystical Body of Christ through charity.

Morality and spirituality

Further, by rejecting any double standard of morality and the distinction between counsel and precept, Pascal aligned himself with those who believe the ideal of evangelical perfection to be inseparable from the Christian life. Although there was nothing original in these opinions Pascal nevertheless stamped them with the passionate conviction of a man in love with the absolute, of a man who saw no salvation apart from a heartfelt desire for the truth, together with a love of God that works continually toward destroying all self-love. For Pascal, morality cannot be separated from spirituality. Moreover, his own spiritual development can be traced in the *Provinciales*. The religious sense in them becomes progressively refined after the first letters, in which the tone of ridicule is smart rather than charitable.

"Pensées." Pascal finally decided to write his work of Christian apologetics, *Apologie de la religion chrétienne*, as a consequence of his meditations on miracles and other proofs of Christianity. The work remained unfinished at his death. Between the summers of 1657 and 1658, he put together most of the notes and fragments that editors have published under the inappropriate title *Pensées* ("Thoughts"; Eng. trans., *Pensées*, 1962). In the *Apologie*, Pascal shows the man without grace to be an incomprehensible mixture of greatness and abjectness, incapable of truth or of reaching the supreme good to which his nature nevertheless aspires. A religion that accounts for these contradictions, which he believed philosophy and worldliness fail to do, is for that very reason "to be venerated and loved." The indifference of the skeptic, Pascal wrote, is to be overcome by means of the "wager": if God does not exist, the skeptic loses nothing by not believing in him; but if he does exist, the skeptic gains eternal life by believing in him. Pascal insists that men must be brought to God through Jesus Christ alone, because a creature could never know the infinite if Jesus had not descended to assume the proportions of man's fallen state.

The second part of the work applies the Augustinian theory of allegorical interpretation to the biblical types (*figuratifs*); reviews the rabbinical texts, the persistence of true religion, the work of Moses and the proofs concerning Jesus Christ's God-like role; and, finally, gives a picture of the primitive church and the fulfillment of the prophecies. The *Apologie* (*Pensées*) is a treatise on spirituality. Pascal was not interested in making converts if they were not going to be saints.

Pascal's apologetics

Pascal's apologetic, though it has stood the test of time, is primarily addressed to individuals of his own acquaintance. To convert his libertine friends, he looked for arguments in their favourite authors: in Michel de Montaigne, in the Skeptic Pierre Charron, in the Epicurean Pierre Gassendi, and in Thomas Hobbes, an English political philosopher. For Pascal, Skepticism was but a stage. Modernist theologians in particular have tried to make use of his main contention, that "man is infinitely more than man," in isolation from his other contention, that man's wretchedness is explicable only as the effect of a Fall, about which a man can learn what he needs to know from history. In so doing, they sacrifice the second part of the *Apologie* to the first, keeping the philosophy while losing the exegesis. For Pascal as for St. Paul, Jesus Christ is the second Adam, inconceivable without the first.

Finally, too, Pascal expressly admitted that his psychological analyses were not by themselves sufficient to exclude a "philosophy of the absurd"; to do so, it is necessary to have recourse to the convergence of these analyses with the "lines of fact" concerning revelation, this convergence being too extraordinary not to appear as the work of providence to an anguished seeker after truth (*qui cherche en gémissant*).

He was next again involved in scientific work. First, the "Messieurs de Port-Royal" themselves asked for his help in composing the *Élements de géométrie*; and second, it was suggested that he should publish what he had discovered about cycloid curves, a subject on which the greatest mathematicians of the time had been working. Once more fame aroused in him feelings of self-esteem; but from February 1659, illness brought him back to his former frame of mind, and he composed the "prayer for conversion" that the English clergymen Charles and John Wesley, who founded the Methodist Church, were later to regard so highly. Scarcely capable of regular work, he henceforth gave himself over to helping the poor and to the ascetic and devotional life. He took part intermittently, however, in the disputes to which the "Formulary"—a document condemning five propositions of Jansenism that, at the demand of the church authorities, had to be signed before a person could receive the sacraments—gave rise. Finally a difference of opinion with the theologians of Port-Royal led him to withdraw from controversy, though he did not sever his relations with them.

Pascal died on August 19, 1662, after suffering terrible pain, probably from carcinomatous meningitis following a malignant ulcer of the stomach. He was assisted by a non-Jansenist parish priest who found him to be "most submissive to the Sovereign Pontiff and to the Church."

Assessment. At once a physicist, a mathematician, an eloquent publicist in the *Provinciales*, and an inspired artist in the *Apologie* and in his private notes, Pascal was embarrassed by the very abundance of his talents. It has been suggested that it was his too concrete turn of mind that prevented his discovering the infinitesimal calculus; and in some of the *Provinciales* the mysterious relations of human beings with God are treated as if they were a geometrical problem. But these considerations are far outweighed by the profit that he drew from the multiplicity of his gifts; his religious writings are rigorous because of his scientific training; and his love of the concrete emerges no less from the stream of quotations in the *Provinciales* than from his determination to reject the vigorous method of attack that he had used so effectively in his *Apologie*.

MAJOR WORKS

MATHEMATICS, LOGIC, AND THE FOUNDATIONS OF SCIENCE: *Essai pour les coniques* (1640); *Lettre sur le sujet de la machine inventée par le sieur B.P. pour faire toutes sortes d'opération d'arithmétique* (1645); *De l'autorité en matière de philosophie*, the first editor's title of Pascal's preface to a projected *Traité du vuide*, consisting of a general statement of the principle of scientific research (written 1647, printed 1779); *Traité du triangle arithmétique avec quelques autres petits traités sur la même matière* (written 1654, printed 1665); *De l'esprit géométrique—de l'art de persuader* (written *c.* 1658, first printed in two parts 1728 and 1776);

Histoire de la roulette, appellée autrement trochoïde ou cycloïde (1658); *Lettres de A. Dettonville, contenant quelques-unes de ses inventions de géométrie* (1658–59).

PHYSICS: *Expériences nouvelles touchant le vuide* (1647); *Récit de la grande expérience de l'équilibre des liqueurs* (1648); *Traites de l'équilibre des liqueurs et de la pesanteur de la masse de l'air* (written 1651, printed 1663; *The Physical Treatises of Pascal: The Equilibrium of Liquids and the Weight of the Mass of the Air*, 1937).

RELIGIOUS PHILOSOPHY AND CONTROVERSY: *Abrégé de la vie de Jésus-Christ* (written 1654 or 1655, printed 1846); *Lettre escritte à un Provincial par un de ses amis sûr le sujet des disputes présentes de la Sorbonne* (January 1656, followed by 17 more pamphlets on the same themes down to March 1657), all 18 being subsequently republished together as *Les Provinciales* (1657; augmented edition, with supplementary pamphlets, 1659); *Projet de mandement contre l'Apologie pour les casuistes* (written 1658, printed 1779); *Ecrits sur la grâce* (four treatises drafted between 1656 and 1658 and printed from 1779 onward); *Pensées de M. Pascal sur la religion et sur quelques autres sujets* (1670; the first Eng. trans. was *Monsieur Pascal's Thoughts, Meditations, and Prayers*, 1688; numerous new translations and versions have appeared since then); *Prière pur demander à Dieu le bon usages des maladies* (written 1659, printed 1666 and 1670).

OTHER WORKS: *Trois discours sur la condition des grands* (comprised 1660, printed 1670). Collected editions of Pascal's works also include several private letters of mathematical or spiritual interest.

COLLECTED EDITIONS: Considerable editions of Pascal's *Oeuvres complètes* were undertaken by the Abbé Charles Bossut, 5 vol. (1779); and by Léon Brunschvicg, Pierre Boutroux, and Félix Gazier, 14 vol. (1908-25). The handiest edition is by LOUIS LAFUMA, *l'Intégrale* (1960). Collections in English include *The Miscellaneous Writings of Pascal* (1849); *Thoughts, Letters, Minor Works* (1910); and *Provincial Letters, Pensées, Scientific Treatises*, Encyclopædia Britannica "Great Books of the Western World" (1952).

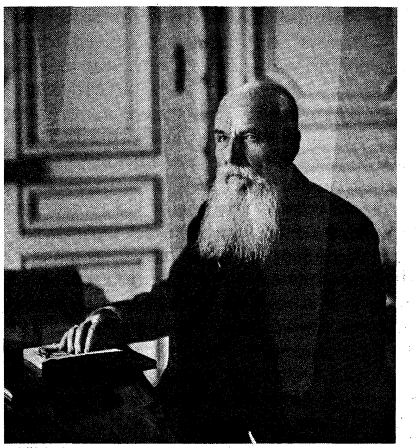
BIBLIOGRAPHY. The standard edition of Pascal's works is that by LEON BRUNSCHVICG, PIERRE BOUTROUX, and FELIX GAZIER, 14 vol. (1908–25); in part replaced by the edition of JEAN MESNARD, 2 vol. (1964–72); and by *Pensées sur la religion*, ed. by LOUIS LAFUMA, 3rd ed., 3 vol. (1960); also editions by H.F. STEWART of *Pensées* (1950; with Eng. trans.) and of *Provinciales* (1920, reissued 1951). Biographical and critical studies include: JEAN MESNARD, *Pascal, l'homme et l'oeuvre* (1951; Eng. trans., *Pascal: His Life and Works*, 1952), an excellent biography, with bibliography; *Pascal* (1965; Eng. trans., 1969); and *Pascal et les Roannez*, 2 vol. (1965); LUCIEN JERPHAGNON, *Le Caractère de Pascal* (1962); PHILIPPE SELLIER, *Pascal et saint Augustin* (1970); EMILE CAILLIET, *The Clue to Pascal* (1943, reprinted 1970); and *Blaise Pascal, l'homme et l'oeuvre*, "Cahiers de Royaumont" (1956), a collection of articles and discussions from the proceedings of a congress on Pascal held at Royaumont in 1954.

(J.Or./L.J.)

Pašić, Nikola

A statesman of remarkable foresight and tenacity, Nikola Pašić was one of the founders of the Kingdom of the Serbs, Croats, and Slovenes (later Yugoslavia). The leader of Serbia's Radical Party from 1881, he played a major role in politics under both the Obrenović and the Karageorgević dynasties. The Balkan Wars (1912–13) and World War I (1914–18) brought his ideas of Pan-Serb nationalism to fruition; but his insistence on Serbian hegemony in the multinational state that he brought into being sowed seeds of domestic dissension that were greatly appeased by the federalization of Yugoslavia, long after his death.

Early career. Nikola Pašić was born on December 19 (old style; December 31, new style), 1845, into a commercial family of modest means at Zaječar. He studied engineering in Belgrade, then graduated from the Zürich Polytechnikum, where his interest in contemporary liberalism and democratic institutions was stimulated by the Russian anarchist Mikhail Bakunin. Returning to Serbia (1873), he joined the Socialist group led by Svetozar Marković and, as editor of the newspaper *Oslobodjenje* ("Liberation"), became an important exponent of Marković's views. But participation in the wars against Turkey (1876–78) led Pašić to revise his political thinking, and, having concluded that King Milan Obrenović's oligarchy was depriving Serbia both of progressive leadership and of national perspective, Pašić decided to enter politics actively. Elected to parliament in 1878, he worked, as leader of the opposition, against the authoritarian monarchy in an endeavour to establish a parliamentary democracy. He also helped to found the Radical Party (1881).



Pašić.
H. Roger-Viollet

When a popular rising instigated against Milan's government by the Radicals in Zaječar (1883) led to further repression and to the severe punishment of many Radical leaders, Pašić was forced to flee through Austria to Bulgaria. Condemned to death in his absence, he plotted with other émigré leaders to unite Serbia and Bulgaria in a war of liberation. After Milan's abdication in favour of his son Alexander (1889), Pašić returned to Serbia with both his political convictions and his determination much strengthened. He was elected president of the Skupština (Parliament) and, on two occasions, mayor of Belgrade. Pašić was appointed premier for the first time from February 1891 to August 1892 and as foreign minister accompanied the new king, Alexander Obrenović, on a state visit to Russia (1892), where he established firm personal and political ties with the tsarist regime. He became Serbian minister to St. Petersburg (Leningrad) in 1893 but resigned in protest at former king Milan's recall to Serbia (1894).

The attempt on Milan's life in 1899 resulted in trumped-up charges of regicide being brought against the members of the Radical Party. Pašić, who was among those sentenced to death and who was unaware of the forceful Russian interventions being made on his behalf, won himself an amnesty by making a humiliating confession in which he implicated many of his former colleagues. He then left the country voluntarily to return only when Milan had finally withdrawn.

The Karageorgević restoration

When the Karageorgević dynasty, in the person of King Peter I, was restored by the bloody coup d'etat of 1903, Pašić, as leader of the Radical Party, concentrated his efforts on establishing the party both as the backbone of the new regime and as the moving force in Serbian politics. The methods by which he strove to preserve his leadership often seemed ruthless and opportunistic, for he never hesitated to adapt his policies or to sacrifice his personal relationships to the political necessity of the moment. (This led, not unnaturally, to acrimonious conflicts with the party in opposition and to schisms within his own.) From December 1904 to May 1905 he served as premier and as minister for foreign affairs—displaying great skill by counteracting Austria-Hungary's attempts to impose a tariff war on Serbia. He held both posts again from May 1906 to June 1908 but was occupying only a minor governmental position in October 1908, when Austria-Hungary's annexation of the Turkish provinces of Bosnia and Hercegovina provoked a major international crisis. He was reappointed premier in October 1909, only to be replaced in 1911 by Milan Milovanović, his greatest political rival. Though he cooperated with Milovanović in concluding a pact with Bulgaria—from which was eventually to develop the Balkan League,

whose aim was war against Turkey—younger politicians and many military leaders continually conspired to remove him from his position as party leader, and in 1912 his imminent dismissal was avoided only by Milovanović's sudden death. Thenceforth reinstated as premier and minister for foreign affairs, Pašić led Serbia through two victorious wars: the first against Turkey (1912) and the second against Bulgaria (1913).

Despite his increased prestige, a further attempt was made to oust Pašić from office when the opposition parties joined the military leaders in an attempt to overthrow the ruthless Radical-controlled administration in Macedonia, and it was only as a result of direct Russian intervention that King Peter was prevailed upon, albeit grudgingly, to grant Pašić a mandate for new elections. The accession as regent of Prince Alexander (King Peter's younger son) on June 24, 1914, gave Pašić some support, and his position was further confirmed when the threat of war with Austria-Hungary prevented the elections from being held.

Leadership during World War I. After the murder of Archduke Francis Ferdinand by a Serb nationalist at Sarajevo on June 28, 1914, Pašić was most compliant in dealing with the formidable terms of Austria-Hungary's ultimatum to Serbia but was nevertheless unable to avert the declaration of war on June 28. World War I initially silenced Serbian political discord: parliament, which had already been dissolved, reassembled at Niš, and in November 1914 a coalition government under Pašić's premiership was formed. In this situation Pašić shrewdly played on heightened nationalistic sentiments in order to transform Serbia's war into his own dream of liberating all the Serbs—and even other South Slavs—in Austria-Hungary. He strongly opposed the secret Treaty of London, whereby Russia, France, and Great Britain promised much South Slav territory to Italy.

Withdrawal to Corfu

The Austro-German conquest of Serbia forced Pašić's government and the army to withdraw from Serbia to Corfu (winter 1915). When in 1917 the government executed leaders of the Black Hand, a clandestine military organization, on charges of plotting the assassination of the regent and of seeking actively to participate in politics, a lasting schism in Serbian politics was created; but, though the coalition government broke up, Pašić continued to govern with a homogeneous Radical Cabinet. When his position was still further weakened by the fall of Russia's tsarist regime (1917), he was obliged temporarily to abandon his strict Pan-Serbian attitude and to negotiate on equal terms with Ante Trumbić's Yugoslav Committee, a body of South Slav exiles from Austria-Hungary with its seats in London and Paris. The resulting Corfu Declaration (July 1917) laid down the broad lines for a postwar unified Yugoslav state.

Postwar career. As World War I neared its end, Pašić began to claim that Serbia, as the dominant political and military force among the South Slavs, had the exclusive right to speak on the Allied side on their behalf. As a result, the Triple Entente governments withheld from the Yugoslavs the recognition that they accorded to the much less favourably situated Czechoslovaks in August 1918. On November 9, 1918, at Geneva, Pašić, under pressure from the Serbian opposition and from the Allied governments, joined delegates from the Yugoslav Committee, from the National Council recently formed in Zagreb, and from the Serbian opposition in signing a declaration that provisionally envisaged a Yugoslavia in which the Serbian government (Belgrade) should share power with the representatives of Austria-Hungary's former South Slav subjects (Zagreb). The Serbian government, which Pašić himself had secretly dissuaded, rejected the declaration. As a result, when Austria-Hungary collapsed, the Allies were unable to agree on a solution for the relations of the South Slavs with Serbia, while Italy reasserted its territorial claims under the Treaty of London. Despite the danger, Pašić persevered in his obstructive tactics toward the Yugoslav Committee and to the National Council in Zagreb.

Nevertheless, an uneasy compromise was finally achieved when Serbia and the South Slav provinces were united on December 1, 1918, as the Kingdom of the Serbs, Croats, and Slovenes. Though he was denied the premiership of the kingdom, Pašić went with Trumbić and Vesnić as one of the new state's delegates to the Peace Conference at Versailles (1919).

Pašić failed fully to comprehend the fateful difference between Serbia's homogeneity and the complexity of the new kingdom, which comprised several nations, each with its own distinct historical development and cultural identity. Ignoring requests for individual recognition from Croats, Slovenes, Macedonians, and Bosnian Muslims, he continued to regard them simply as Serbs—albeit Serbs of three religions and several names. When, therefore, he was reappointed premier in 1921 he immediately pushed through parliament a unitary constitution that, under the guise of establishing a homogeneous nation, actually confirmed the existing Serbian hegemony and, by abolishing historic and autonomous provinces, established a strongly centralized regime under a powerful monarchy. He eliminated the Democrats from the government (winter 1921) and formed an entirely Radical Cabinet. He failed to secure a majority in the elections of March 1923 but stayed safely in office, thanks to blunders by the opposition. Though from July to October 1924 he had to give way to a coalition government under Ljubomir Davidović, by adroit interparty manoeuvring he was able immediately afterward to return to power much stronger than before. His relations with King Alexander and with the Anticentralist Croats and Slovenes nevertheless became increasingly strained. In February 1925 Pašić was forced to dissolve parliament, but by adopting drastic measures—among them the imprisonment of Stjepan Radić and other Croatian Peasant Party leaders—he secured a small working majority. A temporary political collaboration with Radić later the same year failed to produce a stable government; and, when Radić publicly criticized the still-increasing tendency toward centralization and unification, Pašić had to resign in March 1926. He died on December 10, 1926, at Belgrade, three weeks before his 81st birthday.

The Serbian hegemony

BIBLIOGRAPHY. CARLO SFORZA, *Pachitch et l'union des Yougoslaves* (1938; Eng. trans., *Fifty Years of War and Diplomacy in the Balkans: Pashich and the Union of the Yugoslavs,* 1940), the only known biography of Pašić in English, written by a prominent Italian diplomat and author who was Pašić's personal friend; H. WICKHAM STEED, *Through Thirty Years, 1892–1922* (1924), memoirs of an outstanding British political observer and writer who cooperated with R.E. Seton-Watson to promote the Yugoslav cause during World War I; PAVLE D. OSTOVIC, *The Truth About Yugoslavia* (1952), an informative work on Yugoslav politics by an observer who served as the secretary of the Yugoslav Committee from 1914 to 1918.

Passage Rites

Passage rites are ceremonial events, existing in all historically known societies, that mark the passage from one social or religious status to another. This article describes these rites among various societies throughout the world, giving greatest attention to the most common types of rites, and discusses their purposes from the viewpoints of the people observing the rites, and their social, cultural, and psychological significance as seen by scholars seeking to gain an understanding of human behaviour.

NATURE AND SIGNIFICANCE

Many of the most important and common rites of passage are connected with the biological crises of life—birth, maturity, reproduction, and death—all of which bring changes in social status and, therefore, in the social relations of the people concerned. Other rites of passage celebrate changes that are wholly cultural, such as initiation into societies composed of people with special interests—for example, fraternities. Rites of passage are universal, and presumptive evidence from archaeology in the form of burial finds strongly suggests that they go back to very early times. The worldwide distribution of these rites long ago attracted the attention of scholars, but the first substantial interpretation of them as a class of phenomena

was presented in 1909 by the French anthropologist and folklorist Arnold van Gennep (1873–1957), who coined the name rites of passage. Van Gennep saw the rites as means by which individuals are eased, without social disruption, through the difficulties of transition from one social role to another. On the basis of an extensive survey of preliterate and literate societies, van Gennep held that the rites consist of three distinguishable, consecutive elements, called in French *séparation, marge,* and *agrégation,* which may be translated as separation, transition, and reincorporation, or as preliminal, liminal, and postliminal stages (before, at, and past the threshold). The person (or persons) on whom the rites centre is first symbolically severed from his old status, then undergoes adjustment to the new status during the period of transition, and is finally reincorporated in society in his new social status. Although the most commonly observed rites relate to crises in the life cycle, van Gennep saw the significance of the ceremonies as being social or cultural, celebrating important events that are primarily sociocultural or man-made rather than biological. The British anthropologist A.M. Hocart (1884–1939) held that the passage from one status to another was the result rather than the cause of these ceremonies; thus the rites both induced and allayed personal and social stress rather than merely allaying it. Basing his views on circumstances in a few ancient civilizations, Hocart thought that all rites of passage were based on the model of ritual of investiture of kings, in which symbolic killing and rebirth of the new ruler, and sometimes actual killing of the old, were required. Later scholarship has shown that symbolic death and rebirth into the new status are common forms of symbolism in rites of passage of various kinds and that the symbolic killing and rebirth of rulers is therefore not appropriately viewed as the prototype of all rites.

Arnold van Gennep's theory

FUNCTIONS

Modern scholars in the social sciences characteristically accept the views of van Gennep about the social and psychological significance of rites of passage; that is, passage rites are seen to have positive value for the individual in relieving stress at times when great rearrangements in his life occur, such as are brought by coming of age, entering marriage, becoming a parent, or at the death of a close relative, and in providing instruction in and approval of his new roles. The rites are seen also to be socially supporting in various ways. Such support includes roles of the rites in preventing social disruption by relieving the psychological stress of the individuals concerned; providing clear instruction to all members of societies to continue life in normal fashion with new social alignments, the affirmation they provide of social and moral values expressed and thus sanctioned as part of the ceremonies; and the social unity they foster by joint acts and joint expression of social values. During most of man's history, rites of passage have generally been religious events; that is, they have been conducted in a religious framework and regarded as religious acts and hence possessed special authority. From the viewpoint of modern social science, however, their nature is generally seen as being fundamentally secular. Mankind gives social attention to all events regarded as being socially important. Until recent times, religion was intimately connected with most aspects of life, and events of such social importance as the changes in society that the rites celebrate were most frequently incorporated in the system of religious belief and act. The tendency of recent decades toward secularization of rites of passage strongly suggests that the primary significance of most rites is social or secular rather than religious. In the modern, scientifically minded nations of the world many rites of passage, such as rites of initiation into fraternal and honorary societies are wholly secular; others have only small elements of religion, and even marriage may be a wholly secular rite.

Rites as entertainment

One of the primary functions of rites of passage that is often overlooked by interpreters, perhaps because it appears obvious, is the role of the rites in providing entertainment. Passage rites and other religious events have in the past been the primary socially approved means of participating in pleasurable activities, and religion has been a primary vehicle for art, music, song, dance, and other forms of aesthetics.

From its beginning, the study of the significance of rites as a class of phenomena has attempted to account for similarities and differences in the rites among societies of the world. The similarities are striking and doubtless reflect the close similarity in ways of human thought. Modern attempts to account for similarities and differences have generally given little attention to and reached no consensus concerning the nature of the innate psychological factors involved in the genesis of the rites. Attempts to understand rites of passage have instead generally been sociocultural interpretations that view the rites as part of an integrated sociocultural system, the man-made part of human life. Religion and rites of passage are thus seen as elements in this system that affect and are affected by other elements in the system such as means of gaining a livelihood and the manner in which society is aligned in groups. Most modern analysts accordingly have interpreted both differences and similarities in rites of passage on the basis of their sociocultural context. The inventive and symbolic capabilities of mankind are treated as a constant factor, and analytic attention is given to differences and similarities in the sociocultural contexts in which rites are found. In attempting to understand why marriage is an extremely elaborate rite in one society and very simple in another society, for example, scholars have looked to the social order and to the manner of gaining a livelihood to judge the relative importance of the enduring unions of spouses. Following the view that culture, including the social order, composes a coherent, inclusive system, modern scholarship has, in short, most commonly interpreted rites of passage in terms of their functional significance in the social system.

The significance or stated goals of rites of passage as these exist in the minds of the actors are regarded as quite inadequate for gaining an understanding of the functional significance of the rites. Very often, rites of passage are said to have goals such as dispatching the spirit of a dead person to another world, protecting the newborn, the new adult, and the newlywed from evil influences. Often the explicit goals of the rites have been forgotten and their continuation is a matter of following tradition, so that means have become goals. Although scholars have noted the explicit goals of these rites, they have characteristically given greatest emphasis to inferring functional significances that are not obvious to the actors in the rites. In so doing they have broadened their investigations from observations of the symbolism of rites to include prominently all of the behaviour during the rites and their social contexts, learning the social identities of the performers and their relationships to other performers and the entire society.

CLASSIFICATIONS OF RITES

No scheme of classification of passage rites has met with general acceptance, although many names have been given to distinguishable types of rites and to elements of rites. The name purification ceremonies, for example, refers to an element of ritual that is very common in rites of passage and also in other kinds of religious events. In most instances, the manifest goal of purification is to prepare the individual for communication with the supernatural, but purification in rites of passage may also be seen to have the symbolic significance of erasing an old status in preparation for a new one (see also PURIFICATION RITES).

Other names that have been given to passage rites often overlap. Life-cycle ceremonies and crisis rites are usually synonymous terms referring to rites connected with the biological crises of life, but some modern scholars have included among crisis rites ritual observances aimed at curing serious illnesses. Ceremonies of social transformation and of religious transformation (for both see this section, below) overlap and similarly overlap crisis rites. Religious transformations, such as baptism and rites of ordination, always involve social transformations; social transformations such as at coming-of-age and induction

into office may also bring new religious statuses, and life-cycle ceremonies similarly may or may not involve changes in religious statuses. It is nevertheless sometimes useful to distinguish the various rites by these names.

Life-cycle ceremonies. Life-cycle ceremonies are found in all societies, although their relative importance varies. The ritual counterparts of the biological crises of the life cycle are the numerous kinds of rites celebrating childbirth, ranging from baby "showers" to pregnancy rites to rites observed at the actual time of childbirth and, as exemplified by Baptism and the fading Christian rite of Churching of Women, a ceremony of thanksgiving for mothers soon after childbirth. These rites involve the parents as well as the child and in some societies include the couvade, which in its so-called classic form centres ritual attention at childbirth upon the father rather than the mother. At this time the father follows elaborate rules of ritual procedure that may include taking to bed, simulating labour pains, and symbolically enacting the successful birth of a child. In all societies some ritual observances surround childbirth, marriage, and death, although the degree of elaboration of the rites varies greatly even among societies of comparable levels of cultural development. Rites at coming-of-age are the most variable in time in the life span and may be present or absent. In some societies such rites are observed for only one sex, are elaborate for one sex and simple for the other, or are not observed for either sex. Characteristically, rites at coming-of-age are not generally observed in the modern industrial civilizations or, as in the Jewish Bar Mitzwa and the Protestant confirmation of the United States, exist today more or less as vestiges of formerly important religious rites. Among the elaborate civilizations of Asia, rites at coming-of-age have similarly waned in recent times. The elaborate rites observed a century ago in Japan when young men and young women reached social maturity are only rarely observed today and are virtually unknown to the general population. Death is given social attention in all societies, and the observances are generally religious in intent and import. In societies that fear dead bodies the deceased may be abandoned, but they are nevertheless the focus of ritual attention. Most commonly, rites at death are elaborate, and they include clearly all of the stages of separation, transition, and reincorporation first noted by van Gennep (see also DEATH RITES AND CUSTOMS).

The couvade

Ceremonies of social transformation. Ceremonies of social transformation include all of the life-cycle ceremonies, since these involve social transitions for the subjects of the ritual and also for other persons. When a man or woman dies, for example, he assumes a new social role as a spirit that may be socially important to the living; the bereaved spouse becomes a widow or widower; and the children have an unnamed but changed status as lacking one parent. A vast number of rites of social transformation, such as rites of initiation into common-interest societies, have no direct or primary connection with biological changes. These are abundant in the United States and European nations, usually as secular ceremonies. In primitive societies, rites of this kind mark induction into age-graded societies, principally limited to males, and a variety of common-interest societies such as warrior societies, curing societies (special groups whose purpose is to cure illnesses), and graded men's societies that are hierarchically ranked in prestige. Whether hereditary or achieved by appointment or election, assumption of important office in various kinds of societies is often observed by elaborate ritual. Any other events involving changes in social status tend to become the subjects of institutionalized ritual, which is then a prerequisite for the new status. Common examples are initiation ceremonies of college fraternities, sororities, and honorary societies; adult fraternal societies, and social groups of other kinds centred on common interests. Other social changes of importance that apply to a substantial number of people but do not involve initiation into organized social groups are also given ritual attention. Common among these are graduation exercises, festivities marking retirement from work, and various kinds of award ceremonies.

Ceremonies of religious transformation. Religious-transformation ceremonies signal changes in religious statuses, which may be matters of the greatest importance to the people. Performing ritual such as making sacrifices and offerings may be required in the normal course of life, and these acts may be regarded as conferring a new religious status or state of grace. Sacrifices are a frequent feature of rites of passage, and for important ceremonies such as coronations and funerals of rulers, have sometimes required the sacrifice of many human beings (see also SACRIFICE). Among the laity, entry into a religious society or the assumption of any other new religious role is customarily an event celebrated by rites such as those of baptism and confirmation. Among professional religious personnel, the achievement of any distinct status of specialization is ordinarily observed by rites corresponding to the Christian rites of ordination—the rites through which religious functionaries become entitled to exercise their respective functions. As with other rites of passage, these rites may be simple or complex, and their degree of complexity may generally be easily seen as reflecting the religious and social importance of the newly acquired status. A single element of an elaborate rite in one society, such as circumcision or the dressing of the hair in a distinctive way, may in another society be the central or sole event of rites of either social or religious transformation. These ceremonies may, accordingly, be called rites of circumcision or be identified by the name of the style of hairdress.

Sacrifices

Ordination of a Lutheran pastor by the laying on of hands.

Other ceremonies. The term rites of passage is occasionally applied to institutionalized rites for curing serious illness and, rarely, to cyclic ceremonies such as harvest festivals. No new social or religious status is ordinarily gained by recovery from illness or participation in harvest rites, however, and these ceremonies have probably been included among the rites of passage because of similarities in their ritual procedures. In some societies, recovery from a very critical illness is regarded as a divine sign that the erstwhile invalid should assume the role of a religious specialist, but rites of ordination are quite separate. Some elements of ceremonies pertaining to changes in the seasons may be seen as incorporating acts of separation and incorporation, symbolically saying goodbye to the old season and welcoming the new, but these are not customarily called rites of passage. Although clearly denoting a change in social status, divorce has rarely been regarded as a rite of passage. Festive observances at this time are perhaps common in some societies, but they are often informal practices of the individual or simple acts

of local custom, such as discarding wedding rings, that are not institutionalized in the entire society. The absence of divorce from the conventional roster of rites of passage illustrates an outstanding characteristic of this class of rites: all celebrate events that are either socially approved or, like death and illness, unavoidable. Rites of passage that signal the assumption of social statuses disapproved by society are both out of keeping with the prevailing interpretation of the rites as being socially supportive and would broaden them to cover such events as trials by jury and commitment to prison for serious crimes.

Symbolic aspects of ceremonies. Whatever their subclassification, elaborate rites of passage are commonly rich in symbolism that prominently includes representations of the states of separation and transition and, especially, insignia of the new status. Most common among these markers of new status are alterations and embellishments of visible or invisible parts of the body, distinctive garments and bodily decorations, and insignias corresponding to symbols of office. All parts of the body that may be altered or embellished without ordinarily causing serious disability have served as the symbols of social statuses and have been elements of rites of passage. Outstanding among these insignias are special styles of hairdress, clothing, and ornaments; the filing, staining, and removal of teeth; the wearing of ornaments in pierced ears, noses, or lips; tattoos and, among dark-skinned people upon whom tattoos would not be visible, their counterpart of scarification, which produces designs in relief; and circumcision or other genital operations (see also RELIGIOUS DRESS AND VESTMENTS).

Insignia and body decorations

Several motifs or themes of symbolism commonly recur among societies widely separated from each other geographically and culturally. One such theme symbolizes death and rebirth into the new status. Initiates may be ceremonially killed and then made symbolically to act like infants who, during the rites, are made to mature into their new statuses. Another common form of symbolism makes use of doors or other portals that signify entry into the new social domain. Ordeals are a rather common feature of coming-of-age ceremonies for both males and females, and they are also used in rites of initiation into men's societies of various kinds. Success in passing the ordeals is customary and signifies mastery of the roles that are to be assumed.

A universal feature of rites of passage is the proscription of certain kinds of ordinary behaviour. Sexual continence is a common rule, as is the prohibition of ordinary work such as farming, hunting, and fishing. Many rites prohibit certain behaviour or prescribe the reverse of ordinary behaviour. Among Indians of the western United States, for example, a taboo against scratching the body with the fingers was common during ritual periods. In other societies, ritual behaviour required that the subjects of ritual sit in a remarkable fashion, wear articles of clothing inside out or backward, or wear the clothing of the opposite sex. These acts all may be seen as dramatizations, by contrast, of the events that they celebrate, thereby making them memorable.

A representative example. Rites of passage marking very important events customarily include all of the three stages described by van Gennep. A representative example is afforded by the traditional rites surrounding childbirth as these were commonly observed in Japan until recent years. Observances began when a woman learned she was pregnant. Partly for stated reasons of promoting health and partly for supernaturalistic reasons, she thenceforth abstained from certain foods and ate others. During the fifth month of pregnancy she donned a special girdle, ordinarily procured from a Buddhist temple and supernaturally blessed. Relatives offered prayers for the well-being of the woman and her child. When birth seemed imminent, she was isolated from all other persons except the women who attended her and remained in isolation for a fixed number of days after parturition. This period was most commonly 33 days, which was divided into stages preceeding from severe restriction of her acts to final complete resumption of all normal activities. She had at first to follow a number of special rules of diet and could not perform normal household tasks. During the period of isolation, the mother was regarded as polluted from the flow of blood during childbirth and therefore dangerous to other people and dangerous or offensive to supernatural beings of the Shintō religious pantheon. She could not make the usual offerings or say prayers before the household shrines to Shintō gods or have any other kind of contact with them. To avoid offending the sun goddess, her clothing and that of her child when laundered could never be hung in direct sunlight to dry but instead were placed in the shadows of the eaves of the house. For the same reason, she covered her head with a cloth when she stepped outside the house near the end of the period of isolation. Water and cloths used in washing the mother after parturition were considered to be polluted and were buried in the ground beneath the floor of the room of confinement. After a fixed number of days passed, the mother was permitted to resume bathing and again perform some but not all of her ordinary work in the house. Other restrictions on behaviour were removed at fixed times, and when the full period passed, the mother and her female aides performed a ceremony of purification by sprinkling salt on the mother and on the floors of the dwelling. The beginning of a new, normal period free from pollution also was symbolized by kindling a new fire in the household cooking stove. Now ready to return to normal life, the mother ate a ceremonial meal with other members of the family and resumed ordinary relationships with supernatural beings and other human members of the community.

Japanese passage rites

PASSAGE RITES IN THE CONTEXT OF THE SOCIAL SYSTEM

Most of the scholarly interpretations of rites of passage of the 20th century have considered their relation to the social system and have seen the functional significance of the rites as a contribution to the maintenance of society as a system of congruent parts. Explicit or implicit in this line of reasoning is the idea of equilibrium found in any scientific theory concerned with systems. For the system to operate effectively, its elements must be mutually supportive or congruous, and the system is then described as being in a state of equilibrium. Social systems embrace a fixed number of people and a fixed number of roles. Changes in either the number of the people or in the proportions of statuses disturb social equilibrium. When a child is born, a new member is added to society; the social behaviour and statuses of its parents change, and these changes also affect other members of society. Other social changes that are the subjects of passage rites similarly disrupt the state of social equilibrium. Rites of passage are seen to foster the development of a new state of equilibrium in adjustment to the social changes upon which the rites focus. By means of the rites, members of society are informed of the new social circumstances and at the same time give social approval to them. Individuals upon whom the rites focus are assured of success in their new roles by the ritual observances and are given psychological reassurance in a number of other ways. They and all other members of society are instructed by the ritual enactment of their new social relations to return to normal behaviour incorporating the added or lost personnel and the added, lost, or changed social statuses. The same general kind of reasoning is applied to various other religious ceremonies. The anthropologists Eliot D. Chapple and Carleton S. Coon interpret all rites of passage and other group rites as "rites of intensification." Calling special attention to the ritual depiction of habitual relationships for the statuses involved, Chapple and Coon state that this behaviour "has the effect of reinforcing or intensifying their habitual relations, and thus serves to maintain their conditioned response . . . In the technical (physiological) sense, the performance of these rites prevents the extinction of habits . . . to which the individual has been trained."

Changes of status and social equilibrium

Closely related to the function of passage rites in restoring social equilibrium, in the anthropologists' interpretation, are a group of additional effects or functions, some of which apply first to the individuals whose statuses

change and, through their behaviour, to the entire social group. Other functional effects apply directly to the entire society. By allaying the anxiety of individuals who are undergoing change, social disruption is avoided. Rites of passage characteristically give assurance of mastery of the new roles and often include instruction in the new roles. In the many societies in which statuses and roles are clearly distinguished by sex, the rites symbolically emphasize these differences, thereby instructing the initiates and aiding them in sexual identification. The anxiety and potential social disruption caused by death and the grief of the bereaved are similarly held in check. Funeral rites customarily point up grief and then firmly instruct the bereaved to resume normal behaviour that is not disruptive to others. The joint performance of rites and the joint expression of moral and other social values that are included among ritual acts may be seen as directly promoting group solidarity through communion with one's fellows and affirmation or reaffirmation of rules and ideals that foster social harmony.

Rites of passage and all other group rites are seen to be socially supporting in still another implicit way. The joint rites are customarily a rehearsal or dramatization, with supernatural sanction, of a part or all of the social order of the society. Relatives have special roles that are congruent with, or enactments of, their positions in normal social life, and the entire social hierarchy may be on display during the rites through the assignment of ritual roles. Thus statuses of kinship, caste, social equality, and hierarchy are all seen to be reinforced by dramatic presentation of them.

Accepting this group of interpretations of the social significance of rites of passage, anthropologists have also attempted to understand variations in the degree of elaboration of rites of passage among societies of the world. A fundamental assumption is the commonplace idea that the greater the importance of a social change the greater the ritual attention will be. The birth, marriage, and death of a ruler obviously are more important to the entire society than these events in the life of a commoner. The importance of such events is not always obvious, however, and their relative importance is often difficult to see when different societies are compared. Rites of marriage, for example, may be very simple or very elaborate in different societies of the same economic base and comparable levels of cultural development. Recourse to consideration of features of the social order has allowed a reasonable explanation of the differences. Marriage rites in matrilineal societies, for example, which are organized into subgroups primarily upon a principle of descent through female lines only, tend to be simple, and divorce in these societies is also simple. Marriage rites in patrilineal societies (in which descent is through male lines), however, tend to be elaborate, and divorce initiated by females is difficult.

Marriage rites in matrilineal and patrilineal societies

In matrilineal societies, the social core is composed of groups of male and female relatives united by female lines, which are economically distinct from other groups and self-sufficient. Where the matrilineal principle of organization is strong, the role of the husband and father, who belongs to a matrilineal group different from that of his wife, is not that of economic provider for his wife and children. Instead, he is the economic mainstay for his sister and her children, and his contact with his wife may be limited to spending nights with her. The brothers or other male relatives of a mother not only provide economically for her children but also assume what is elsewhere the role of the father in socializing children. Enduring unions of marriage are not vital to such matrilineal societies. If marriages end in divorce, the matrilineal ordering of society assures approved social identification, economic support, and affective ties for the children and their mother and also assures continuance of the society as long as males are available as procreators. In patrilineal societies, however, the role of the mother, who is the outsider in the group, is vital for the birth and rearing of the children, and she and her children are dependent upon her husband for economic support. Strong sanctions are placed upon marriages in these societies to help ensure lasting unions. Marriage ceremonies are correspondingly elaborate, often involving the transfer of property, which among some African societies is called marriage insurance for the reason that it must be returned if the marriage falls asunder.

In societies such as those of the United States and European nations, where the important unit of kinship is ordinarily limited to the nuclear family of parents and children and where important social affiliation does not depend upon descent through one sex of progenitors, enduring unions of marriage are also vitally important. Rites of passage at marriage traditionally have been required by law as well as by the church, and many other sanctions on lasting marriages are imposed by laws concerning divorce, communal property, and the care of children. The bride and groom who have undergone the whole series of traditional rites of passage from engagement parties to the religious ceremony may reasonably be seen as more firmly married than couples united by a simple civil ceremony (see also SOCIAL DIFFERENTIATION AND STRATIFICATION; CASTE SYSTEMS; KINSHIP).

PSYCHOLOGICAL ASPECTS OF PASSAGE RITES

Less scholarly attention has been given to psychological than to social or cultural aspects of rites of passage, in large part because the scholars concerned with such rites in world societies have been principally anthropologists, who lean toward sociocultural interpretations. As the foregoing discussion of passage rites in social context illustrates, psychological aspects of rites nevertheless enter strongly if often implicitly into anthropological interpretations as fundamental matters in social solidarity and social disorder. Emotional ties to kin and other members of society, personal identification with social groups and religious statuses, and commitment to religious ideology and other values are reinforced and sometimes created by rites of passage. In a realistic sense, the rites serve as blueprints for social relations and religious behaviour that make clear the acceptable ways to act and at the same time point up and reinforce affective relations with other people and with the supernatural. Familial rites of ancestor worship, for example, are not only reinforcements of familial solidarity but also have psychological value in reinforcing emotional ties among relatives.

Psychological interpretations of passage rites have given greatest emphasis to their value in allaying personal anxiety. A recurrent feature of the rites are acts of magic that assure that the outcome of the endeavour will be successful. In the words of the anthropologist Bronisław Malinowski these acts serve symbolically and psychologically "to bridge over the dangerous gaps in every important pursuit or critical situation" that exist because of man's lack of control of the universe. By such magical means as miniature boats floated in streams or carried away by the tide, the dead are shown symbolically to go successfully to the other world, and childbirth and successful maturation are similarly depicted magically. The subjects of rites of passage frequently act out their future roles to the approval of all others. Numerous acts of magic that are not essential to changes in social status may be incorporated in rites of passage and may be seen to give psychological assurance relating to the future life of the individual. Traditional Japanese practices at childbirth, for example, required that when a girl was born, the placenta be buried in the ground outside the entrance to the dwelling to insure that the girl, when mature, marry in normal fashion and leave the family. When a boy was born, the placenta was buried inside the house to ensure that he remain at home when mature. The ordeal that a young man or young woman must often undergo during rites of coming-of-age may similarly be seen to provide psychological assurance of success in the new status. Ordeals of this kind are characteristically uncomfortable or frightening, but they are events that any human being ordinarily can endure.

Psychotherapeutic value of rites

The psychotherapeutic value of passage rites surrounding events in which stress may be acute, such as childbirth, death, and serious illness, is clearly apparent and essentially follows the principles of modern secular psy-

chotherapy. The subject is made the centre of concentrated attention by many people, is given reassuring evidence of their regard for him, and, by means of magic and the intervention of supernatural beings, is assured of a successful outcome. These events are carried out on a high emotional pitch, which gives them added force. When anxiety is induced by religious beliefs themselves, such as by ideas that if ritual acts are not performed calamitous results will follow, the rites of passage may be said both to create and to allay anxiety.

Where particular social statuses have special honour and prestige, the mere existence of these statuses offers opportunities for gaining psychological satisfaction, and the requirements for gaining these statuses serve to guide behaviour in socially approved channels that offer psychological satisfaction.

Other interpretations of psychological aspects of passage rites have relied upon ideas derived from or inspired by the psychoanalyst Sigmund Freud (1856–1939). These have sometimes concerned the symbolism involved in the rites and, in anthropological interpretations, have dealt with both Freudian ideas of symbols and the social order. The psychologist Bruno Bettelheim has interpreted cicatrization (inducement of scars) of males in rites at coming-of-age as symbolic wounds indicating subconscious male envy of the vagina, the counterpart of Freud's idea of penis envy. A psychologically oriented anthropologist J.M. Whiting, and others have combined sociological and psychoanalytic theories in attempting to explain why male initiation ceremonies are conducted in some societies and not in others. Harsh rites, sometimes including genital operations, are held to be correlated with societies in which infant males have long and intimate contact with their mothers, and husbands are prohibited from sexual intercourse with their wives for a period of two years or more. The long and exclusive relationship between mother and son is assumed to lead to strong emotional dependence upon the mother by the son, which becomes potentially disruptive at the time the son reaches puberty. The harsh rites are seen to break the bond of dependency and avoid potential social disruption that might otherwise result from discord between son and father at this time.

PASSAGE RITES IN THE CONTEXT OF THE RELIGIOUS SYSTEM

Certain passage rites represent first and foremost transformations in the religious statuses or circumstances of the people concerned. As already noted, rites of passage are customary upon the assumption of a new status as a religious professional. During most of man's history, however, rites of passage have carried among their implications a change to a new religious state for the ordinary members of society as well as for the professional religious person. Among the culturally advanced societies of the world with orders of priests, ideas of the significance of symbolism in passage rites may be elaborate and sophisticated, representing the rites as different states of grace or, as in Hinduism, cyclic states involving death and rebirth. In many societies, one is not fully or properly a human being until he has undergone the rites of passage appropriate for his age and sex. In some societies, fully human status is not reached until the rite of Baptism has been performed, and children who die before that time may be interred with special rites in places separate from those of the dead who have been baptized. When passage rites are religious ceremonies, as has generally been the circumstance until modern times, some state of sacrament or divine blessing, vaguely or clearly defined, is entailed. At the time of death, rites of passage placing the deceased in the realm of the supernatural customarily have been required. Symbolism in many rites of passage denotes communion with the supernatural. In common with many other kinds of religious events, then, passage rites relate the individual and the society to the sacred world, conferring benefit upon him thereby (see also SACRED OR HOLY).

Rites of passage frequently have ethical import of value for the maintenance of social equilibrium. Where ethical or moral codes and religious beliefs are intimately connected or identified as one and the same, as in Christianity, Judaism and Islām, the role of religious beliefs and acts may be seen to have strong value as social sanctions since the moral injunctions apply to human relations as well as to man's relations with the supernatural world. All societies have moral or ethical codes, rules of what is appropriate and inappropriate in human relations, and these are enforced by various means. Rites of passage, as noted above, commonly incorporate statements or dramatizations of moral values, and rites at coming-of-age often give moral instruction in highly explicit terms. No necessary or inherent connection exists, however, between morality and religious beliefs. Any serious breach of proper moral conduct results in the imposition of a network of sanctions, many of them secular. In some societies, religious beliefs have little bearing on morality in relations with one's fellow men, although violations of rules applying to relations with supernatural beings and supernatural forces may be regarded as bringing inevitable punishment or misfortune through the supernatural agency. Whenever morality is a part of religious precepts, the direct sanctioning force of passage rites stressing moral rules may be powerful and important to the maintenance of society. In other societies, the ethical import of passage rites and other features of religion may operate less directly. An example is provided by societies that revere but do not deify ancestors. Any breach of morality reflects unfavourably upon the ancestors, who may undertake no action of censure but nevertheless serve as a sanctioning force that is reinforced by death rites.

Morality and religious beliefs

PRIMARY PASSAGE RITES

In simple, primitive societies dependent for subsistence upon hunting and gathering, in which social groups are small and specialization in labour is limited to distinctions by sex and age, no social statuses may exist except those of child, adult, male, female, and disembodied spirit. Among primitive societies somewhat more advanced technologically and culturally, however, specialized groups based upon common interests appear, and these customarily require rites of induction or initiation. In culturally sophisticated societies, with elaborate divisions of labour, social statuses of leadership and specialized occupation are multiple. If all societies of the world, preliterate and literate, are considered, the most commonly recurrent rites of passage are those connected with the normal but critical events in the human life span—birth, attainment of physical maturity, mating and reproduction, and death.

Birth rites. Rites surrounding the birth of a child are often a complex of distinct rituals that prescribe different behaviour on the part of the mother, the father, other relatives, nonfamilial members of the society, and with respect to the newborn. Observances may begin when pregnancy is first noted and may continue until the time of delivery, when the full rite of passage is observed, and for a variable period of time afterward. In many simple societies and in European societies of the past, the expectant mother is isolated from other members of society at this time for the stated reason that the blood that flows during childbirth has inherently harmful qualities. Where this belief is strong, the classic couvade may be practiced. Regions of the world in which this practice was formerly common include the Amazon Basin of aboriginal South America, Corsica, Spain, among the Basques of France and Spain, and among various societies of Asia. Old ethnological writings have created the impression that ritual attention is limited entirely to the father. Later investigations have made it appear doubtful that the mother in any society is free from ritual requirements. In many societies, rites that have been called the couvade are observed by both parents. The anthropologist Alfred L. Kroeber (1876–1960) reported that among most of the many tribes of aboriginal California, rites at childbirth were much alike for both mother and father. To prevent harm to their child and to other people during the ritual period, the parents observed food taboos; ate in seclusion; avoided contact with other people; did as little work as possible; and refrained from various other acts of ordinary

Isolation of expectant mothers

behaviour that included cooking, touching tools, and eating salt, meat, and fish. Women often were under injunctions to scratch themselves only with a stick or a bone for fear that their nails at this time would leave permanent scars on their bodies.

Practices of sympathetic and contagious magic relating to birth and the later well-being of both child and mother are abundant and diverse. Among Indians of aboriginal British Columbia, the mother inserted a smooth beachstone, an eel, or other slippery object under her garment at the neckline, permitting it to slide to the ground to symbolize and insure quick and successful childbirth. In societies of Southeast Asia and Indonesia, religious specialists dressed as women simulated successful delivery. Rites directed toward the newborn similarly symbolize or ensure health and well-being and, after some days, weeks, or months have passed, often include Baptism or other ritual acts that introduce the child to supernatural beings. Both child and mother are often regarded as being defenseless at this time, and many ritual acts have the purpose of protecting them from harmful supernatural beings and forces. In Southeast Asia and Indonesia, a practice called mother roasting, which requires that the mother be placed for some days over or near a fire, appears once to have had the goal of protecting the mother from such evil influences. This practice survives today in altered form in the rural Philippines, where it is regarded as having therapeutic value.

Mother roasting

Native explanations of the ritual procedures at childbirth reflect beliefs of a mystic affinity between parent and child, and many of the prescriptions have the manifest goals of preventing harm to the infant until it is able to fend for itself. Among South American Indians practicing the classic couvade, this belief of affinity between father and child relates to the soul, which is not fully transmitted to the child until the end of the ritual period.

In addition to the social (communal) and psychological significances of birth rites already noted, scholars have offered interpretations of these ceremonies as reinforcing familial ties. The classic couvade has been seen by Malinowski as a sympathetic symbolic stressing of the relationship between the husband and the wife and her kin, which is instituted when the child is born. In addition to serving as a means of allaying husbandly anxiety over the welfare of the wife, the practices of the couvade establish social paternity, which, in turn, promotes familial and societal solidarity.

Initiation rites. The most prevalent of rites of initiation among societies of the world are those observed at coming-of-age. These have frequently been called puberty rites, but, as van Gennep argued long ago, this name is inappropriate. Puberty among females is often defined as the time of onset of menses (the menstrual flow), but no such clearly identifiable point exists in the sexual maturation of males. Moreover, the age at which rites of attaining maturity are observed vary greatly from society to society, going far beyond the normal range of years at which sexual maturity is attained. The definition of maturation is thus seen to be largely social or cultural rather than solely biological.

The full range of stages of passage rites is often followed in rituals at coming-of-age. Ordeals or other tests of manhood and womanhood are also common. Some of these practices in preliterate societies seem incomprehensible or absurd until their nature as evidence of qualification for the new social statuses is understood. Among the Bemba tribe of Africa, for example, girls were required to catch water insects with their mouths and to kill a tethered chicken by sitting on its head. Circumcision or other genital operations are also a fairly common feature of rites celebrating the attainment of maturity. Although most commonly applying to males, genital operations are performed on females in a few societies. It seems quite clear that circumcision and other alterations of the sexual organs have not until modern times been regarded as therapeutic surgery. These operations may have psychological significance following Freudian lines of interpretation, but it seems clear that they are also significant as insignia of social status. Where circumcision is the practice for male initiates, the uncircumcised male is not a full-fledged adult. It may be remembered that at this time other parts of the body are also modified, by incision, piercing, filing, tattooing, and by other kinds of practices that are not painful. Circumcision may in fact have no direct relation to the attainment of sexual maturity. In native Samoa, boys were circumcised at any age from 3 to 20.

Ordeals and other practices

Henri Stierlin—Ziolo

An outstanding feature of rites at coming-of-age, which is generally less prominent or absent from other rites of passage, is their emphasis upon instruction in behaviour appropriate to the status of adults. Instruction in dress, speech, deportment, and morality may be given over a period of months. Very commonly, instruction is first given at this time in matters of religion that have heretofore been kept secret, and initiates may at this time be expected or required to commune with the supernatural, sometimes by means of revelatory trances induced by fasting, violent physical exertion, or the consumption of plant substances that produce hallucinations or otherwise alter the sensibilities.

Separation of male initiates from their mothers and all other females is also common, and ritual events may dramatize the transition from a world of women and children to one that is ideally male. Symbolism of these rites dramatizes the separation in such ways as by requiring the young men temporarily to wear the clothing of women and by rigid exclusion of all females from participation in the rites.

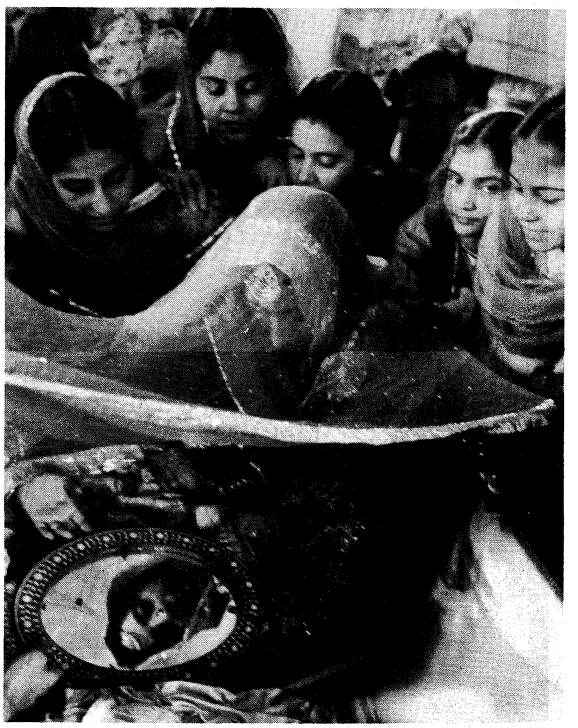
Among the technologically and scientifically advanced societies of the world, initiation rites have become increasingly secular. The great religions of the world all included rites at coming-of-age, but for much of the modern population of these nations, the rites are either not observed or are simpler vestiges of the old religious ceremonies. The most common rites of initiation are predominantly or wholly secular ceremonies conducted to celebrate such events as entry into a common-interest association or graduation from school. Rites of initiation such as into age-graded groups or common-interest societies follow essentially the same pattern as those at coming-of-age, and their simplicity or elaboration may be correlated with the importance of the new statuses.

As seen by social analysts, the significance of initiation rites of all kinds is the same as that of other rites of passage. Some emphasis is given to their didactic value and to their significance in sex-role identification. One question that has not been answered is why rites at coming-of-age are so poorly developed today among the technologically advanced societies of the world. Many factors, including changed views of the nature of the universe and changed social conditions, appear to have contributed to the decline of rites of passage. The super-

Rites at coming-of-age in modern times

naturalism traditionally present in the rites is no longer acceptable to many people, and in the United States and parts of Europe the association of adult status with sexual maturity as expressed in the term puberty rites has been unwelcome, a matter that should be excluded from notice rather than celebrated. Probably far more important in discouraging the rites has been the extreme variation in these nations in the age of social maturity. In the United States, the ages differ at which one may legally drive a car, enter marriage, own and control property, buy alcoholic drinks and tobacco, enter military service, and vote; and in some of these matters the ages differ from state to state. The demands of modern civilization have, moreover, lengthened the age of social maturity, the time at which one is an economically productive member of society, and, dependent upon the number of years of formal education, have produced great variation in the age of full social maturity. The social and psychological value of rites of coming-of-age in making the transition to adulthood seem substantial, but it seems certain that modern cultural circumstances are incompatible with the conduct of such rites.

Frank Horvat—Black Star



Hindu wedding custom; the bride regards her reflection in a mirror.

Marriage rites. It is assumed by anthropologists that marriage is one of the earliest social institutions invented by man, and, as already noted, rites of marriage are observed in every historically known society. These rites vary from extremes of elaboration to utmost simplicity, and they may be secular events or religious ceremonies. Subclasses of rites of marriage, named and unnamed, exist in many societies, beginning with ceremonies of betrothal that require complex formalities of transfer and exchange of goods, which are often regarded as compensation to the bride's kin group for their loss of the bride. Ceremonies of dramatic, sham "capture" of the bride by the groom and his relatives and friends have been common in both preliterate and literate societies. Marriage in these societies is seen by social analysts as a cooperative liaison between two different groups of kin, between which some feelings of hostility exist. Ceremonies of token capture are conducted even when betrothal and all other arrangements for marriage have long been completed to the expressed satisfaction of both sides, and the sham captures are interpreted as socially sanctioned channels or the expression and relief of feelings of hostility between the two kin groups. In some historically known societies of Africa such sham battles between kin of brides and grooms may occur, with full societal approval, for years after a marriage during any kind of religious rite.

Sham capture of brides

Like rites at coming-of-age, ceremonies at marriage have often included clearly visible insignia of the new social status, in such forms as wedding rings, distinctive hair dress and garments, and tattoos, ornaments, or other embellishments that are regarded also as being decorative. Traditionally, preliminary rites have often provided instruction in the wifely role. Such instruction might be informal or conducted as a part of ritual. Rites of marriage proper also often give instruction through mimicry, dancing, and other symbolic acts that dramatically depict the woman's proper role in society, expressing her economic and social obligations and privileges with reference to her children, husband, other relatives, and still other members of society. Tests of maturity and rites with the purpose of promoting fertility have also commonly been included.

In addition to sharing the functional significances of other passage rites, marriage ceremonies may be seen especially to stress social bonds between husband and wife and their kin groups. In most societies and during most of human history, romantic love has not been the means by which spouses are selected. Convention, often strongly sanctioned, has limited marriage to only certain classes of people. Mutual attraction between the spouses has been a matter of little or no importance. The importance of marriage with respect to spouses, children, other kin, and the orderly maintenance of society is readily inferrable. Rites of marriage place a sanction on unions of marriage that may be very powerful and thus serve as both a means of conducting an orderly and satisfying human life and also as sanctions for the orderly maintenance of society. A general correlation may be seen between the degree of elaboration of marriage rites and the social importance of enduring marriages in the society in question. Where, as in some of the large, industrial nations of the world, marriage rites are simple and sometimes secular, a host of other sanctions operate similarly to foster lasting unions.

Death rites. All human societies have beliefs in souls or spirits and an afterlife, and all conduct rituals when people die. The earliest archaeological evidence of rites of passage comes in the form of deliberate burials of Neanderthal man, interments that included ornament shells and stone implements. Like other passage rites, ceremonies at death vary greatly but have much in common. Attention centres upon the deceased and upon the bereaved. The body of the deceased must be disposed of. This is most commonly done by interment, although other practices are also followed, such as cremation, abandonment, natural decomposition and later burying of the bones, and mummification. Special symbolic attention is given to allow or induce the soul of the deceased to enter the spirit world, and in societies where the souls of the dead are feared as being potentially malevolent, special ritual measures are taken to safeguard the living. The dead remain indefinitely as members of society, and where reverence for or worship of ancestors is a religious practice, the social affinity with deceased is close.

The bereaved

Pointed ritual attention is given to the bereaved, who at this time must observe many special rules of behaviour. In many societies, funerals are joyous rather than solemn affairs, but where lighthearted festivities are conducted they customarily appear as a final stage of the rite of passage. The bereaved are everywhere in some degree isolated from other members of society and prohibited from many normal activities. These and other features of the rites point up the transition the bereaved is undergoing, dramatize grief at the climax of the ceremonies, and by final ceremonies symbolically instruct the bereaved to set excessive grief behind and return to normal social life in the new role. Climaxes of grief are dramatically portrayed by such events as gashing the body, wailing and weeping, and the use of hired mourners, all conducted on signal for fixed intervals. A joyous celebration may fol-

low, involving song, dance, feasting, and other pleasurable activities, in which the bereaved prominently participates and is thereby reincorporated into the normal social system.

More than other passage rites, ceremonies at death are closely identified with religion, and many of the acts of these rites have explicit religious goals. Prominent among these is the assurance of a continuation of existence in an afterlife, in which the deceased in some measure continue to be members of living societies (see also DEATH RITES AND CUSTOMS).

Passeriformes

The order Passeriformes, the passerines, or perching birds, is the dominant avian group on Earth today. Considered the most highly evolved of all birds, passerines have undergone an explosive evolutionary radiation in relatively recent geological time and now occur in abundance on all continents except Antarctica and on most oceanic islands. Their rapid evolution and adaptation to virtually all terrestrial environments have resulted in a large number of species, some 5,100, compared to only about 3,500 species for all other birds.

The order Passeriformes is divided by most taxonomists into four suborders: Eurylaimi, Tyranni, Menurae, and Passeres. The first three, containing about 1,100 species, are considered more primitive and are often grouped informally as the "suboscines" for convenient comparison with the very large fourth suborder, the oscines, or songbirds (about 4,000 species).

GENERAL FEATURES

Size range and structural diversity. Passerines are small to medium-sized land birds, ranging from about 7.5 to about 117 centimetres (three to 46 inches) in overall length. Among the tiniest species are the New World flycatchers (Tyrannidae), New Zealand wrens (Xenicidae), titmice (Paridae), flowerpeckers (Dicaeidae), tanagers (Thraupidae), and waxbills (Estrildidae). The heaviest are the lyrebirds (Menuridae) of Australia and the ravens (*Corvus*). The longest species, the ribbon-tailed bird of paradise (*Astrapia mayeri*), is actually not so large in body bulk but has extremely long tail feathers. Most passerine species fall within the range of about 12.5 to 20 centimetres (five to eight inches) in length and from 15 to 30 grams (0.5 to one ounce) in weight. A house sparrow (*Passer domesticus*), for example, is 12 to 15 centimetres (five to six inches) long and weighs about 26 grams (0.9 ounce); a cardinal (*Cardinalis cardinalis*) 20 to 23 centimetres (eight to nine inches) and approximately 44 grams (1.5 ounces).

Passerines have evolved a great diversity of feeding adaptations. The majority are insectivorous, at least at certain times of their lives. Members of the order have evolved many ways for finding insect food: swallows (Hirundinidae) are aerial feeders; New World flycatchers "hawk" insects by flying out from a perch; vireos (Vireonidae) glean insects from small twigs and foliage; woodcreepers (Dendrocolaptidae), nuthatches (Sittidae), and creepers (Certhiidae) search for insects in crevices in tree bark; and many other species pick and scratch on the ground and in leaf litter. More specialized passerines eat aquatic insects (dippers: Cinclidae), fish (some New World flycatchers: Tyrannidae), fruit (cotingas: Cotingidae; and many others), leaves (plantcutters: Phytotomidae), nectar (sunbirds: Nectariniidae), small land vertebrates (shrikes: Laniidae), and seeds (finches and many others). For these different food habits, various structural specializations have developed, especially in the bill and feet (see below *Form and function*).

Importance to man. *Aesthetic and economic importance.* Since prehistoric times people have enjoyed watching and listening to songbirds. The almost infinite variety of colours, patterns, behavioral traits, songs, and calls found in these birds appeals to man's aesthetic tastes. As objects of beauty and interest passerines have been incorporated into human culture, folklore, poetry, music, sculpture, and painting. Songbirds have also been used as symbols, such as the European goldfinch (*Carduelis carduelis*), which represented the Passion of Christ in Renaissance art, or the raven (*Corvus corax*), which sometimes has signified a messenger for the devil, an evil omen.

Songbirds as religious symbols

Passerines are widely kept as cage birds. The origins of this practice are lost in antiquity, but it is known that by the 5th century BC the Greeks kept a variety of songbirds, including finches, nightingales and other thrushes, magpies (*Pica*), and starlings (*Sturnidae*). Canaries (*Serinus canaria*) were brought to Europe from their native Canary Islands in the 16th century and have since been developed by domestication and breeding into many varieties. Other passerines now widely kept as pets are the cardueline and estrildine finches and the starlings (particularly Asian mynahs, *Gracula*). The magnitude of the cage-bird "fancy" is indicated by importation statistics on wild and semidomestic birds: in one recent year alone, over 420,000 passerines (excluding canaries) were legally imported into the United States as cage birds, a number far exceeding that of parrots, the only other bird group whose members are commonly kept as pets. Many countries, including the United States and Great Britain, prohibit the capture and sale of nearly all native songbirds.

Songbirds are also economically important in other ways. Although seldom considered food in economically advanced areas, they are nonetheless important dietary items in many rural or heavily populated countries. China, Japan, and other Oriental countries, for instance, have highly developed techniques for catching small birds, and in cities such as Hong Kong and Tokyo passerines are commonly sold in food markets. In Italy, France, and Belgium the capture of migratory songbirds for the pot or for cage birds is still extensive. Laws against such activities are difficult to enact or enforce in areas in which the habit has become part of the culture; hence, for example, more than 10,000,000 passerines were still being caught annually in Italy in the late 1960s.

Fortunately, killing songbirds for their feathers is no longer as prevalent as it once was. Until the early 20th century, however, there were few protective laws, and the wearing of birds (especially on women's hats) was common. In 1886 a young ornithologist reported that he had counted feathers from no fewer than 40 bird species, including 22 kinds of passerines, on hats seen on two afternoon walks in a fashionable part of New York City.

Other cultures have used songbird feathers for personal adornment, but usually for men rather than women. This practice often came about not only for the beauty of the feathers themselves but also because the feathers were used as symbols of such bird qualities as speed and aggressiveness. Most noteworthy are the feathers of male birds of paradise (Paradiseidae) used as headdresses by tribesmen of New Guinea. An estimated 80,000 adult birds are still being killed annually for this purpose. Other ancient uses of passerine feathers have now largely been terminated, either because the birds are extinct (in the case of Hawaiian feather cloaks) or because more suitable modern substitutes have been found (Melanesian feather money).

Songbirds as agricultural pests

Some passerines, on the other hand, are serious economic pests. In areas in which one-crop agriculture is extensive, certain bird species have undergone population explosions because of almost unlimited food availability; in turn, their crop depredations can be serious. One example of this is in Africa, where immense flocks of a small weaver, the red-billed quelea, or Sudan dioch (*Quelea quelea*), numbering as many as 20,000,000 birds in one flock, do millions of dollars worth of damage to various small grain crops each year. Other serious pests are the Java sparrow (*Padda oryzivora*) in Asian rice fields and mixed flocks of New World blackbirds (*Icteridae*) and European starlings (*Sturnus vulgaris*) in grainfields in the United States. The same starling and the house sparrow, both introduced to the United States from Europe, have become urban pests by fouling buildings with excrement and blocking rain gutters and ventilators with their nests. Starlings occasionally also have been implicated in accidents; in 1960 a flock at the airport in Boston was sucked into a jet's engines and the resultant crash killed 61 people.

Ecological importance. The greatest importance of passerines is ecological. As the dominant form of birdlife in virtually all terrestrial environments, the perching birds are a major component of the world's ecosystems. They consume great quantities and varieties of food—grains, fruits, insects and other invertebrates, small amphibians and reptiles, and even small mammals—and in turn serve as food for other animals; they act as hosts for parasites and are occasionally parasitic themselves; they both propagate and distribute plants by pollinating flowers and carrying viable seeds to new locations; and they have the mobility (through migration) to utilize habitats that are available only at certain times of the year. A few aspects of the ecological impact of passerines are known, but, until the science of ecology has advanced, the true magnitude of their importance cannot be evaluated with precision.

NATURAL HISTORY

Types of territories

Reproduction. *Territoriality and courtship.* The breeding behaviour of passerines is diverse. Most species are solitary nesters, a single monogamous pair of birds maintaining a territory that is large enough to support all their activities during the breeding season: courtship, mating, nesting, and food gathering. Others have similar territories, but the birds forage outside the defended area for most of their food (*e.g.*, the North American red-winged blackbird, *Agelaius phoeniceus*). Still others are colonial nesters, defending only the nest site and a small area immediately adjacent to it. Some species build individual nests close together in a colony (oropendolas, Icteridae; some swallows; the house sparrow), and others construct massive communal nests in which the breeding pair defends only its own nest cavity (palm chat, *Dulus*; several weaverbirds, Ploceidae). In a few species polygynous (polygamous) males establish special display territories (leks) for courtship and mating in which no nesting takes place. In these courtship arenas the males, usually brilliantly coloured, attract females through song and posturing and sometimes by dancing, manipulation of objects, and other elaborate displays. The best known arena-displaying males are the cocks of the rock (*Rupicola*), manakins (Pipridae), birds of paradise, and bower-birds (Ptilonorhynchidae). After mating in or near the lek, a female leaves to build a nest and raise the young without assistance from the male. Still other species build no nest at all, but are brood parasites (some cowbirds, Icteridae; whydahs, Ploceidae); the female lays her eggs in the nests of other (usually smaller) species, and the young are raised entirely by the foster parents.

Nesting. Nest sites are varied: they include holes in the ground, trees, banks, and rock crevices; on ledges; on the surface of the ground; within the larger nests of other species (including nonpasserines) or near wasp nests (presumably for the protection the wasps afford); and in a wide variety of vegetation—grasses, shrubs, and trees.

Passerine nests are usually elaborately constructed and may contain many different kinds of materials: mud, grasses, hair and feathers, strips of bark, plant fibres and downs, rootlets, twigs and sticks, leaves, string, spider webs, cast snake skins, lichens, and many other substances. Most species build open nests, usually cup-shaped. Others form domed or ball-shaped closed nests, with an entrance at the side (occasionally at the top or bottom). One of the most famous closed nests is that of the South American ovenbirds of the genus *Furnarius* (Furnariidae), whose name derives from its thick-walled mud "oven" nest, often built on top of a fence post or some other exposed site. The North American ovenbird, *Seiurus aurocapillus* (a wood warbler, Parulidae), also builds a domed oven-shaped nest, but of plant materials on the forest floor. Some species, especially members of the Icteridae, make soft hanging nests that range to two feet or more in length. The thorn birds (*Phacellodomus*), as well as many other Furnariidae, build huge nests of twigs suspended from the ends of tree branches; these nests, which may be more than two metres (nearly seven feet) long and contain many compartments, are used by only a single nesting pair, sometimes with nonbreeding helpers (probably the young of the previous season). These nests are often appropriated by troupials (*Icterus icterus*), which evict the owners, even destroying the eggs and young in the process. A few other species also take over nests for their own use, notably the piratic flycatcher (*Legatus leucophaius*, a tyrannid) and the bay-winged cowbird (*Molothrus badius*).

Woven nests

Nests of many passerines are constructed with amazing skill. The tailorbirds of Asia (*Orthotomus*) are noted for nests built in a pocket that the birds make by sewing together the edges of one or more leaves, using plant fibres or other materials. Some species, especially the weavers, are able to tie knots with strips of grass or palm leaves and thus weave an exceptionally tight and compact nest. Others build equally firm nests by felting the materials together. In contrast, a few passerines build flimsy nests (some Cotingidae), apparently as an adaptation toward lessened visibility to predators, for such nests are attended minimally by the parents, seemingly to draw as little attention to the site as possible. Other birds excavate their nests in soft earthen banks, use old woodpecker holes, or find natural crevices in trees or rocks. The type of nest built by the members of a single family may be varied (extremely so in the Furnariidae) or consistent: all woodcreepers nest in holes; all vireos weave a cup between the arms of a forked branch.

Incubation and parental care. Passerines lay clutches of one to 14 eggs, clutch size being unrelated to the size of the bird. The largest species, the two lyrebirds (*Menura*), lay a single egg; some of the smaller titmice (*Parus*) have been recorded with the biggest clutches. In most passerines the female incubates the eggs alone,

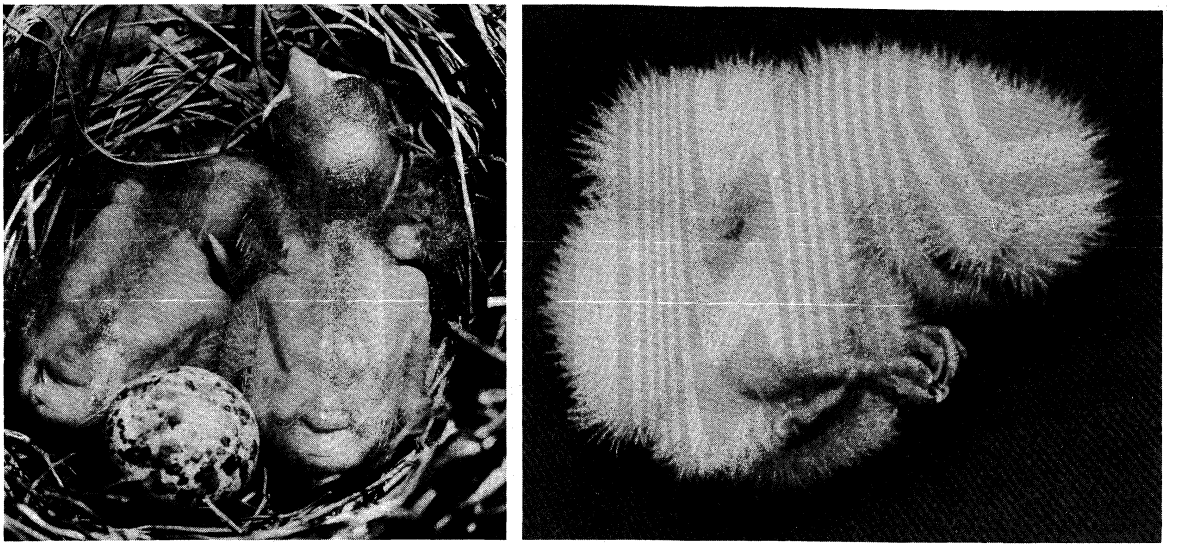

Figure 2: *Two main types of young.*

(Left) Root Resources—EB Inc., (right) David W. Snow

but in some groups—such as the antbirds (Formicariidae), certain grosbeaks (*Pheucticus*), and others—the male shares equally in incubation. Males of most species help to feed the young. Some passerines have only one nest per breeding season, but others may have two or more, especially if one nest is destroyed before the young fledge. The incubation period generally varies from 11 to 21 days depending on the species but is well over a month in lyrebirds. The hatchlings are typically blind, sparsely covered with down, and helpless; some species hatch completely naked, and a very few are densely covered with down at hatching (some cotingas, antbirds of the genus *Formicarius*, and some Campephagidae). The young remain in the nest for eight to 30 or 35 days (about 42 in the lyrebirds) but most commonly from ten to 15 days. After they fledge, they require some days or weeks to become fully independent of their parents.

Variety of vocalizations among passerines

Sound production. An outstanding aspect of passerine behaviour is the ability to sing. Song is best developed in the oscines, which have a highly complex vocal organ or syrinx, but even the more primitive suboscines are capable of a variety of vocal sounds. The woodcreepers (Dendrocolaptidae), ovenbirds (Furnariidae), and antbirds (Formicariidae) sing relatively simple songs, consisting of a few notes or whistles, often repeated rapidly in a trill, roll, or rattle. Manakins (Pipridae) also utter simple trills or whistles: in addition, some species are capable of a loud nonvocal snapping sound, which is produced by specialized wing feathers. The cotingas sing a wider variety of songs, from quiet musical notes to the incredibly loud and far-carrying "gongs" of the bellbirds (*Procnias*). The New World flycatchers are well-known for their range of distinctive call notes, and many species sing well and melodiously. In some groups (notably the *Empidonax* complex), the plumages of closely related species are so similar that the birds can be distinguished in the field only by their calls and songs. Both the lyrebirds and scrub-birds (Atrichornithidae) have syringes more like those of oscines and are known for their loud and complicated songs. They are also accomplished mimics; lyrebirds mimic the songs of almost all birds within their hearing, as well as many mechanical sounds. Many species of oscines have complicated and beautiful songs, notable examples being the nightingales (*Luscinia*) and some other thrushes, larks (Alaudidae), mimic thrushes (Mimidae), and wrens (Troglodytidae). The possession of the complex oscine syrinx does not guarantee a complex song, however, and many "songbirds," such as waxwings (*Bombycilla*) and swallows, utter simpler sounds than do many suboscines.

Only the male of most passerine species sings a true song, although the female can produce a variety of call notes and other sounds. In some species in which the female sings, she seldom does so during the breeding season unless it is a duet with her mate. Such duetting or antiphonal singing of paired birds is so well developed in certain species that it is difficult to determine that the song is coming from two individuals. In the African black-and-red shrike (*Laniarius barbarus erythrogaster*) the reaction time between the male's start of song and the female's response has been timed at 0.135 second.

Interactions with ants. *Anting.* A characteristic but poorly understood behaviour pattern of passerines is the practice of anting. This peculiar ritual has two forms: active anting, in which a bird picks up worker ants in its bill and wipes them on its feathers in a stereotyped manner, and passive anting, in which the bird squats or lies down in a group of ants and assumes an exposing stance so that the ants will crawl up into its feathers. Birds may also apply ants to their plumage while passively anting, but species that use the active stance (the majority of recorded passerines) apparently never use the passive stance. Birds show definite discrimination in the type of ants used, avoiding stinging species and selecting those that exude or spray formic acid or other defense fluids (ants of the subfamilies Formicinae and Dolichoderinae of the family Formicidae). A great deal of controversy has existed over the function of anting. Some authorities have theorized that it is a form of self-stimulation, but British ornithologist K.E.L. Simmons has argued convincingly that it is a type of feather maintenance. Formic acid and other ant fluids are known to be insecticidal; dressing the feathers with ants would thus kill or deter avian parasites, such as lice and mites. Additional components of ant fluids include essential oils, which could be used by birds to supplement the oils from their own uropygial (preen) gland. After a bout of anting, birds often continue feather-maintenance activities by bathing, oiling (from the uropygial gland), and preening. Recent studies have shown anting to be most prevalent during molt, when the bird's skin is irritated by the growth of new feathers. Anting clearly is innate behaviour, and its remarkable uniformity in at least 30 passerine families, both oscine and suboscine, implies that it has real importance to the bird. Some individuals have been seen to ant with such things as cigarette butts, orange peels, mothballs, and smoke, apparently reacting to the pungent fumes of these objects in the same way as they do to the strong odours of ants. A few nonpasserines have also been observed going through motions that are similar to anting, but as yet true anting is known only in the Passeriformes.

Active versus passive anting

Ant-following. Another specialized form of behaviour, also associated with ants, is the practice known as ant-following. In the New World tropics, nomadic army

ants move in huge troops, swarming over the forest floor in columns as wide as ten metres (more than 30 feet) or more. Because the ants devour all the small animal life in their path, a moving column of them is edged by fleeing insects, spiders, millipedes, isopods, small frogs, and lizards. The ant columns are accompanied by troops of birds that seize the fugitives. Ant-following birds apparently do not eat the ants but only the insects and other small animals trying to escape. A number of passerine species, notably several antbirds, are believed to be entirely dependent on army ants for finding food. Many other birds also follow ants when they come upon them; these include woodcreepers, manakins, New World flycatchers, tanagers, wrens, and occasional ovenbirds. Even some nonpasserines may join a troop of ant-followers—motmots (Momotidae), tinamous (Tinamidae), and hawks—although the hawks may be more attracted by the ant-following birds than by the insects. The same ant-dependent species have also been known to follow large animals, including man, that stir up insects with their feet.

Popperfoto, London

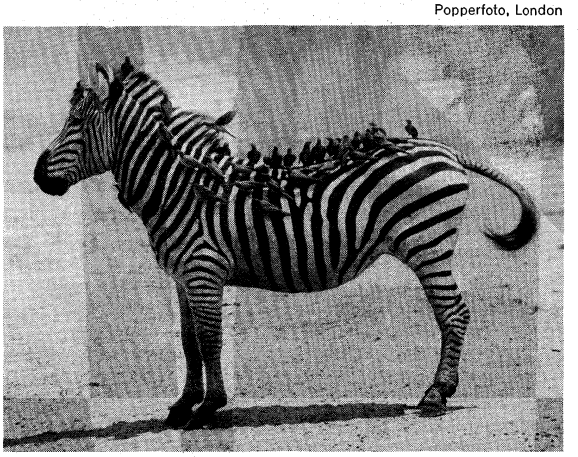

Figure 3: A zebra covered by a large number of oxpeckers.

Association of passerines with large animals

A few passerines, although not ant followers, will escort large quadrupeds, such as cattle, buffalo, and deer, to catch the insects that fly up around them and to feed on the ticks and flies parasitizing the animals themselves; especially noted for this behaviour are the cattle tyrant (*Machetornis rixosa*, Tyrannidae) tickbirds or oxpeckers (*Buphagus*, Sturnidae), and several cowbirds. In Australia yellow robins (*Eopsaltria*, Muscicapidae) will follow the much larger lyrebirds as they scratch and feed along the ground.

FORM AND FUNCTION

External features. *Feet and legs.* The single feature that distinguishes passerines from all similar birds is their "perching" foot. In this foot type, all four toes are well developed and free from one another; in some families (wrens and most suboscines) the front toes may be partially fused at the base, but the distal portions (extremities) are functionally free. The hindtoe (hallux) is joined on the same level with the front toes and opposes them, so that the foot can grip a perch. The only exception to this passerine foot type is found in the well-named *Paradoxornis paradoxus*, or three-toed parrotbill (Panuridae), in which the outer toe is reduced to a short clawless stump, fused to the middle toe; other species of *Paradoxornis* have normal feet.

Modifications of the foot

Although all passerines can perch, not all do so habitually. A number of species (some tapaculos, Rhinocryptidae; larks; pipits, Motacillidae) are largely terrestrial and have feet modified for walking and running; the terrestrial foot is differently proportioned from the typical perching one, often with longer toes and longer, straighter claws (particularly on the hallux), probably as an aid in maintaining balance when running. The dippers, or water ouzels (*Cinclus*), are semi-aquatic, but although they successfully swim on the water surface and walk under water searching for food on stream bottoms, they have retained the typical passerine foot. The single slight difference in the *Cinclus* foot is that the claw of the middle toe sometimes has a thin horny flap (of unknown function) on its inner border. Some other passerines, notably swallows, live a largely aerial life and have small and weak feet. The typical arboreal songbird has a well-developed foot, with the middle front toe longer than the others. Birds such as woodcreepers and nuthatches that often cling to vertical surfaces have strong, curved, sharp claws. Those that spend much of their time walking and scratching on the ground (although not limited to terrestrial activity) tend to have heavy, straighter, and rather blunt claws. Most passerines, however, have moderately curved sharp claws that are suited to grip a variety of rounded or rough surfaces.

The lower leg of passerines, the tarsometatarsus (usually called simply the tarsus), is normally covered by a horny sheath (podotheca). Exceptions include some swallows, which have feathered tarsi. Although the various different patterns of scale size and distribution of the normal unfeathered podotheca have been used by some taxonomists to differentiate families or groups of families, study has revealed so much variability in the tarsal patterns of certain families that it is no longer considered a reliable family character; it may still be useful as a generic or specific character. In most oscines the posterior (plantar) surface of the tarsus is bilaminate—*i.e.*, covered by two long plates, or laminae.

Bill. The bills of passerines are extraordinarily diverse in size, shape, and proportions. This diversity was long thought to be indicative of the birds' relationships and so was used as a prime taxonomic character. It is now believed, however, that bills are evolutionarily plastic, reacting with relative ease to selective pressures, particularly to changes in feeding habits. Thus on a broad scale a passerine's bill shape reveals less about its family affinities than it does about its food preferences, and, although bill shape may be an aid to determining a bird's relationships, it must be considered in the light of other features and of the degree of variation found in the family. Two often-cited examples of the adaptiveness of bills are the geospizine, or Darwin's finches (Fringillidae) of the Galápagos Islands, and the Hawaiian honeycreepers, Drepanididae (see EVOLUTION). Each is a closely interrelated group of birds with different kinds of bills in the several species and genera. Those of drepanidids range from heavy, seed-cracking, grosbeak-like bills through thin, pointed insectivorous types to the long, decurved (curved downward) bills of nectar feeders. These Hawaiian birds are now thought to be closely related members of a single family of nine genera. On the basis largely of bill shape, they were once classified into four different families and 18 genera.

Most birds, including passerines, show little sexual dimorphism (difference between sexes) in bills except for minor differences in size (reflecting general body size differences) and sometimes in colour. The most outstanding exception is the extinct huia (*Heteralocha acutirostris*, Callaeidae), originally classified as two different species. The male of this New Zealand bird had a strong, chiselling bill, whereas the female had a long, decurved, pliable bill. Reportedly the two sexes fed cooperatively, the male digging in decaying wood and the female probing in crevices to extract grubs. The species unfortunately was prized by the Maoris, who used the white-tipped tail feathers in ceremonial headdresses, as well as by Europeans, and, after most of its habitat had been destroyed, the huia was hunted to extinction about the end of the 19th century.

Specializations of the bill

Passerine bills may be broadly classified into eight morphological and functional types:

1. Insectivorous: a generalized type found in many passerines, ranging from relatively straight and pointed (as in the wood warblers, Parulidae), through bills with a slight or pronounced hook (some New World flycatchers), to those that are short, with a wide gape and usually surrounded by rictal bristles (stiff hairlike feathers)—*e.g.*, in aerial feeders, such as swallows. Most insectivorous

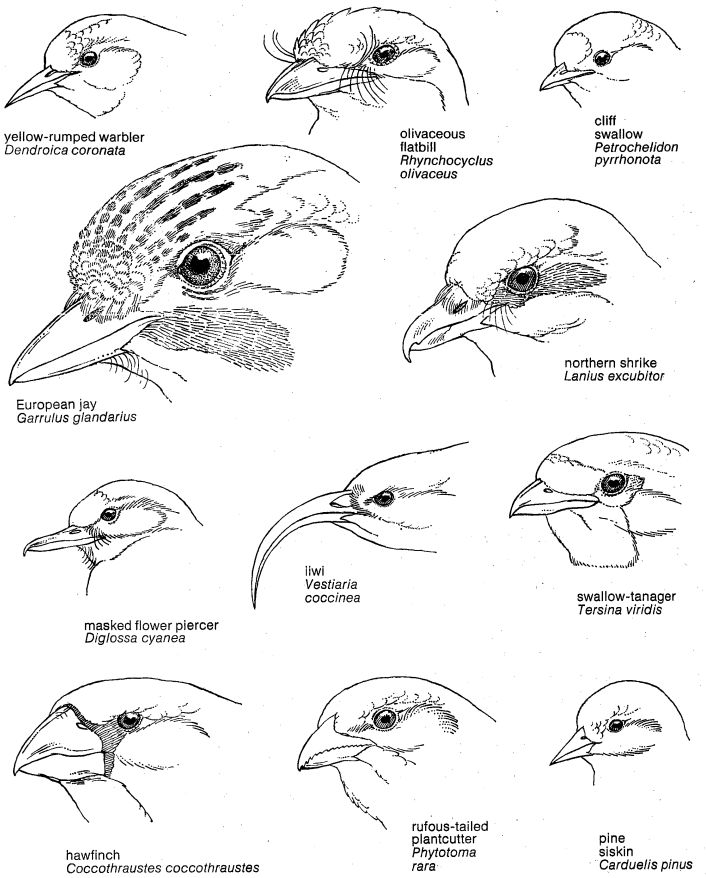

Figure 4: Types of bills found among passerine birds.
Drawing by R. Keane

bills are relatively light in build, but this depends on the type of insect usually taken by the species and also on how generalized a feeder it is.

2. Omnivorous: unspecialized in shape and function but usually strongly built, as in crows and jays (Corvidae).

3. Toothed: strongly hooked at the tip and with a "tooth" (notch) on either tomium (cutting edge) of the upper mandible; adapted to tearing up large, relatively soft prey. This is the typical bill of shrikes (Laniidae) but is also found in some unrelated birds, such as the Australian bellmagpies (Cracticidae) and some tanagers.

4. Tearing: a relatively light bill with a strong hook at the tip, for tearing open objects, such as flowers, to obtain the insects and nectar within. Found in flower piercers (*Diglossa*, Thraupidae).

5. Probing: relatively narrow and often downcurved; slender in species that probe flowers for tiny insects and nectar (sunbirds; some Hawaiian honeycreepers) but more heavily constructed in those that probe in wood or under tree bark (creepers, *Certhia*; some woodcreepers).

6. Frugivorous: variable but usually rather wide; ranges from lightly built with a wide gape for swallowing whole fruits (found in some cotingas, and in the swallow-tanager, *Tersina*) to more heavily built for tearing apart tougher fruits (some tanagers).

7. Serrated: conical, with a finely serrated edge, adapted for feeding on leaves, buds, shoots, and fruit. Found only in the plant cutters (Phytotomidae).

8. Conical: Adapted for seed eating. Ranges from exceedingly stout and blunt (*e.g.*, the hawfinch, *Coccothraustes*, which can crack remarkably hard objects, such as cherry pits) to relatively small and pointed (siskins, *Carduelis*). Some forms specialized for particular kinds of seed extraction (*e.g.*, crossbills, *Loxia*, which feed on pine seeds).

This classification indicates morphological and functional types of bills, but it does not imply that a species with a particular type of bill will feed only on the food for which it is best adapted. Although some birds are extremely specialized in their feeding habits, most are opportunistic feeders, seizing upon whatever food is readily available and can be "handled" with the bill. Hence many basically granivorous or frugivorous birds catch insects, especially when feeding nestlings, and many insectivorous species exploit seasonally available plant food. Myrtle warblers (*Dendroica coronata*) and tree swallows (*Iridoprocne bicolor*), for example, feed on bayberries in fall and winter, and eastern kingbirds (*Tyrannus tyrannus*) and other New World flycatchers will eat a variety of fruits and berries in season.

The mandibles of passerines, like those of all other birds, are composed of bone covered with a horny sheath, the ramphotheca. The ramphotheca is worn down by normal use and, in most birds, is capable of growing to replace the lost material. In individuals with damaged bills or those (such as cage birds) that do not have the opportunity to wear down the constantly growing ramphotheca, the bills overgrow at the tip.

Plumage and pterylosis. The colours, patterns, and textures of passerine feathers are considered important taxonomic characters, especially in determining genera, species, and subspecies. Plumage is also occasionally used in a very broad way to indicate evolutionary levels. Spots, streaks, and dull colours are generally considered more primitive than bold or complicated patterns and bright colours, but there are many exceptions to this rule.

Passerines often are sexually dimorphic in their plumage, with adult males wearing brighter colours and more striking patterns than do females. In some families, notably tanagers (Thraupidae), wood warblers (Parulidae), and New World orioles (Icteridae), the temperate zone species show more sexual dimorphism than do tropical members of the same families. In addition, many species (especially those in temperate climates) are seasonally dimorphic, with a bright plumage during the breeding season and a dull one in winter. Juvenile plumages of both sexes tend to be cryptically coloured (*i.e.*, adapted for concealment), as is that of the adult female.

Colour varieties in passerines

Virtually any colour may be found in one passerine or another, and the order offers a wide array of specialized feather types, such as the waxlike tips on the flight feathers of waxwings (Bombycillidae); the tufts of stiff feathers in some honeyeaters (Meliphagidae); iridescent "spangles" in some manakins, sunbirds, and tanagers; and the almost unbelievable array of "wires," iridescent gorgets, velvety ruffs, racquet tails, and filamentous plumes of the birds of paradise.

Another taxonomically important character is the number and distribution of feathers (pterylosis) on the bodies of passerines. From external appearance all birds seem to be more or less evenly covered by feathers; in actual fact, however, most birds have their feathers growing from relatively narrow tracts (pterylae) in the skin. From the pterylae the feathers fan out and cover the remainder of the bird's body. In passerines, the feathers are arranged in eight distinguishable tracts, with apteria (relatively bare skin) between them. Variations in tract width and length and especially differences in feather number and distribution are often useful in determining relationships. Of particular interest are the occurrence of apteria within tracts and the configuration of the ventral tract. Also used in classification are the numbers of flight feathers. The remiges (flight feathers on the wings) of most passerines consist of ten primaries on the "hand" (manus) and nine secondaries on the forearm (ulna). In all perching birds the tenth (outermost) primary is reduced to some degree, and in many families only nine may be found. The number of secondaries is more variable, with some species having as many as 14 (the satin bowerbird, *Ptilonorhynchus violaceus*). Tail feathers (rectrices) are also variable; most passerines have 12, but the number ranges from six to 16.

Of importance in some species is the relative length of the primaries. This "wing formula" is often useful in distinguishing between species of such difficult groups as the New World flycatchers and the Old World warblers (Sylviidae).

Internal features. *Syrinx.* In a group of birds as vocal as the passerines, it is natural that the structure of the vocal apparatus should have evolutionary significance. Differing from the mammalian larynx in both location and structure, the syrinx consists of a resonating chamber at the lower end of the windpipe (trachea), with associated membranes, cartilages, and muscles. These modifications involve elements of the bronchi (the two tubes connecting the trachea with the lungs) as well as those of the trachea. Since the mid-19th century the basic subdivisions of the order Passeriformes have been based primarily on the structure of the syrinx. Some of the features of the syrinx long thought to be indicators of relationships have recently been shown to have little taxonomic validity. Other taxonomic characters now must be studied and evaluated before the classification can be adjusted.

Syringeal muscles are classified into two groups: extrinsic muscles, which connect the syrinx with other parts of the anatomy, and intrinsic muscles, which extend from one part of the syrinx to another. The number, shape, and attachments of the intrinsic muscles are likely to remain important in passerine classification. Those birds in which the muscles are inserted on the middle of the bronchial semi-rings (C-shaped cartilages that strengthen the bronchi) are sometimes called mesomyodian (most members of the suborder Tyranni) and those with the insertion on the ends of the semi-rings are acromyodian (Menurae, Passeres). The Eurylaimi and a few others have no intrinsic muscles. Further distinction is made in the number of pairs of intrinsic muscles, most importantly in the Passeres, which have four.

Vocal-organ specializations

The passerine syrinx exists in four basic types:

1. Unspecialized: relatively little modification of the tracheobronchial region; few, if any, cartilaginous specializations, and no intrinsic muscles; found in broadbills (Eurylaimidae), pittas (Pittidae), New Zealand wrens, asities (Philepittidae), plantcutters, most cotingas, and a few manakins and tyrant flycatchers.
2. Tracheophone: most of the specializations limited to the tracheal region; intrinsic muscles number none to two pairs; pessulus (a bony bar lying at the junction of the bronchi) absent; found in all members of the Furnarioidea (South American ovenbirds, woodcreepers, antbirds, and tapaculos).
3. Intermediate tracheobronchial: various modifications of cartilages and membranes; one or two pairs of intrinsic muscles; pessulus present or absent; found in the sharpbill (*Oxyruncus*) and most manakins and tyrant flycatchers.
4. Oscine (acromyodean): complex musculature involving four pairs of intrinsic muscles (but three pairs in lyrebirds and scrub-birds); some cartilaginous specializations; pessulus present (except in larks).

Despite the rather extensive knowledge of the morphology of the syrinx and its importance in passerine classification, very little is known about how it functions to produce sounds. Several theories have been proposed, but none has yet been proved wholly satisfactory.

Skeleton. Of the many variations in passerine skeletal structure, only a few that are important in classification are mentioned here.

In the skull the bony palate, composed of a number of small bones, is termed aegithognathous; also found in swifts (Apodiformes), this palatal type is characterized by the shape and type of fusion of the small bones of the palate. Within this basic type the many minor variations in shape, size, and position of the component bones are useful in delimiting closely related groups of birds, especially suboscines.

Elsewhere on the head, variations in the hyoid apparatus, a complex of small bones that supports the tongue, have been used in passerine classification.

In the sternum (breastbone) the shape of the anteriormost spine (spina sternalis) and the number of notches in the posterior border are of great interest. The spina sternalis, short and forked in most passerines, is long and simple in the Eurylaimidae (one exception), Philepittidae, and a few Cotingidae. All oscines and most suboscines have a single pair of posterior sternal notches; only the tapaculos and certain of the terrestrial antbirds (*Conopophaga, Pittasoma, Hylopezus, Myrmothera*) have two pairs. The sternum of lyrebirds differs from all others in the order in being exceptionally thick, long, and narrow; it may have no posterior notches at all, or it may have a single shallow pair.

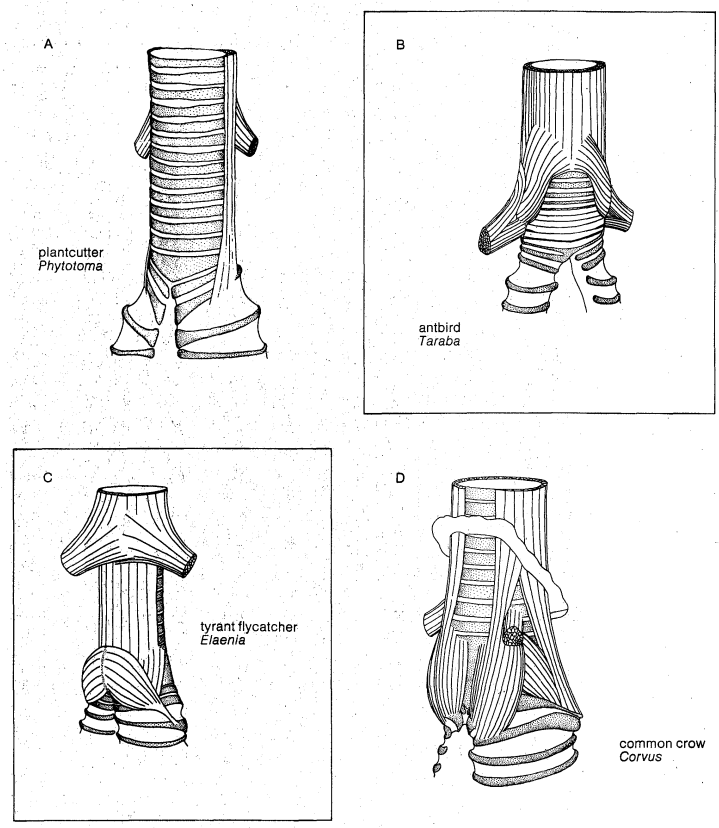

Figure 5: *Four major syrinx types of passerine birds.* Figures show lower trachea, upper bronchi, and attached muscles, seen from the ventral side. (A) unspecialized; (B) tracheophone; (C) intermediate tracheobronchial; (D) oscine.
From P.L. Ames in (A,B,C) *Bulletin of the Peabody Museum of Natural History*, no. 37 (1971), Yale University; (D) J.C. George and A.J. Berger, *Avian Myology* (1966), Academic Press

Musculature. A number of different muscle systems have been important in passerine classification. Important examples, in addition to those of the syrinx, are the muscle complexes controlling the tongue, the jaws, the wings and pectoral girdle, and the legs and pelvic girdle. One character that has been used for over a century is the condition of the deep plantar tendons. These narrow straps extend from the bellies of the two deep flexor muscles on the leg, down the back of the tarsometatarsus, and attach to the toes. They act to close the toes (hence to grasp a perch). In the Eurylaimidae these tendons are connected by a short band (vinculum), but in all other passerines they are entirely separate. This difference has been used by some to divide the passerines into two major groups: the Desmodactyli (vinculum present) and the Eleutherodactyli (vinculum absent).

EVOLUTION AND PALEONTOLOGY

Origins of perching birds

Passerines, like other small land birds with fragile bones and arboreal habits, are rarely fossilized; hence the fossil record gives few clues to their evolution. Their origins, both in time and ancestral type, can only be guessed. Some authorities believe that passerines arose during the Early Cretaceous Era (about 120,000,000 years ago); others believe that it was much later, not until the Late Cretaceous or even Paleocene Epoch (perhaps 65,000,000 years ago).

The earliest known passerine fossils are from the upper Eocene Epoch (about 40,000,000 years ago). One of these is an extinct genus assigned to the modern family of tapaculos (Rhinocryptidae), another is thought to be related to the titmice (Paridae), and still another to the starlings (Sturnidae). *Palaeospiza*, a primitive oscine

classified as a separate family (Palaeospizidae) between the larks and the swallows, is known only from the Colorado Oligocene Epoch (about 35,000,000 years ago). As drying conditions during the Miocene Epoch (26,000,000 to 7,000,000 years ago) reduced the forests and encouraged the spread of grasslands, bird families exploited the newly appearing drier and less forested habitats and radiated into them. There for the first time appear remains of crows (Corvidae), thrushes (Turdidae), wagtails (Motacillidae), shrikes (Laniidae), and wood warblers (Parulidae).

During the Pliocene Epoch (from 7,000,000 to 2,500,000 years ago) the warm, dry conditions continued, and most paleornithologists now believe that all of the living passerine families were in existence by its close. They also believe that most modern species of birds arose during the Pleistocene Epoch (about 2,500,000 to 10,000 years ago), a period of almost constant change during which there were four major advances and retreats of the glaciers. Most of the passerines in the fossil record are from the Pleistocene or Recent epochs and represent either living species or close relatives. Evolution since the retreat of the last ice sheet (about 11,000 years ago) has been mainly at the subspecies level.

With the lack of a significant fossil record, nothing is known of the type or types of birds from which passerines arose. Studies of the anatomy of modern forms have led to a general agreement that the perching birds developed from more than one ancestral type (polyphyletic origin). But until more evidence is unearthed, nothing further can be said.

CLASSIFICATION

Distinguishing taxonomic features. The classification of passerines is probably the single most vexing problem in avian taxonomy today. Few of the subgroupings (especially oscine families) have strikingly different characteristics, the fossil record is inadequate, and the order has undergone an explosively radiative evolution that has resulted in a large number of anatomically similar species. Classification is further complicated by the persistence of intermediate and relict forms and a high degree of convergence (similarity due to different lines being subject to the same types of natural selection) among distantly related groups. It is therefore necessary to examine each passerine species in careful detail (including its anatomy) to be certain of its affinities. With some 5,100 species in the order, this is a monumental task, one that is by no means complete. Traditionally, passerine families have been defined on the basis of a careful (usually anatomical) study of only a few individuals; the great majority of the birds have been assigned to established families solely because they externally resemble the studied species in plumage, bill, leg, and foot characters, as well as in what is known of their life history, behaviour, geographical distribution, etc. It is unfortunate that in the early years of avian taxonomy there was a strong tendency to try to include each newly discovered species, regardless of its geographical range, in some previously defined palearctic family.

Re-evaluation of early taxonomic characters

In the mid-20th century, taxonomists began re-examining the generally accepted 19th-century groupings of birds into families. In these investigations some of the features on which earlier classifications were based have been found to be convergent or too variable to be useful in certain groups (*e.g.*, bill shape, tarsal scutellation). Consequently, passerine taxonomists have been left with a rather sparse body of morphological information upon which to base a classification. In recent years ornithologists have made a concerted effort both to augment some of the century-old work on passerine anatomy and to explore new avenues of morphology, behaviour, reproductive patterns, biochemistry, and zoogeography to help define and relate the many families of perching birds. Much of this work is still in progress and has not yet been incorporated into classification systems. Among traditional and newly studied taxonomic features are external characters—such as rictal bristles and other specialized feathers, colours and patterns of the fleshy parts of the mouth, morphology of the bill and nostrils, colour patterns of adults and young; internal anatomical characters—such as the number of cervical (neck) vertebrae, the condition of the deep plantar tendons, anterior and posterior spines and processes of the sternum, syringeal muscles, palatal and other bones of the skull, feather tracts, jaw and tongue musculature, hyoid (tongue) apparatus, aortic-arch system, pneumatic fossa (cavity) of the humerus, and types of spermatozoa; biochemical analysis of substances—such as egg white, eye lens, plasma proteins, and hemoglobins; and an array of behavioral traits—such as reproductive behaviour, nest building, methods of scratching, etc. Thus, although the current system is by no means satisfactory, improvement is in the offing, and it is hoped that in the near future modern studies will lead to a more firmly drawn passerine classification.

Annotated classification. The classification and sequence of families given here is essentially that proposed in 1971 by American ornithologist Oliver L. Austin, Jr., based on a 1960 classification by Alexander Wetmore, with certain changes (see *Critical appraisal*). Some of the traditional diagnostic characters have been omitted because they have proved unreliable or because preliminary restudy indicates that the old generalizations do not hold true.

ORDER PASSERIFORMES (perching birds, or passerines)

Land birds with a characteristic "perching" foot; 4 toes (never webbed) joined at the same level, with the 1st toe (hallux) directed backward and never reversible. Oil gland unfeathered. Wing eutaxic (no gap between the 4th and 5th secondaries), usually with 9 or 10 primaries. The young altricial—*i.e.*, hatched almost or completely naked of feathers (a few exceptions), helpless, and requiring a considerable period of parental care. Groups marked with a dagger (†) are extinct and known only from fossils.

Suborder Eurylaimi

Syrinx simple, tracheobronchial, lacking intrinsic muscles and cartilaginous specialization; pessulus present. Sternum with anterior spina sternalis long and simple (exceptions) and with one pair of notches in posterior border. Hallux weak but about as long as the other toes. Clavicles well developed. Usually 15 cervical vertebrae (all other passerines have 14). Deep plantar tendons of different type than all other passerines.

Family Eurylaimidae (broadbills). Generally brightly coloured, chunky birds, with large heads, short necks; 12.5 to 28 cm (5 to 11 in.) in length. Bill broad and flattened, covered with a crest in some; gape wide. Front toes partially joined; 10 or 11 primaries. Other characters as in subordinal definition above; 14 species, primarily in forests or cloud forests. Indo-Malaya, Africa, Philippines.

Suborder Tyranni (majority of suboscines)

Syrinx usually more complex; muscles variable; pessulus present or absent. Sternum with short spina sternalis, forked (exceptions noted below); posterior border with one or two pairs of notches. Hallux strong. Clavicles well developed.

Superfamily Furnarioidea

Syrinx complex, tracheal; pessulus absent. Pterylosis (distribution of feathers) variable. Sternum with one or two pairs of notches.

Family Dendrocolaptidae (woodcreepers). Characteristically slender arboreal birds, olive brown to rufous, usually streaked or barred; 14.5 to 37 cm (5.5 to 15 in.). Strong probing bills, laterally compressed, short and straight to long and downcurved; nares holorhinal (see Furnariidae). Short legs, powerful feet; front toes partially joined at base. Tail stiff with spiny tips. Posterior border of sternum with one pair of notches. Syrinx with cartilaginous specializations and two pairs of intrinsic muscles. Pterylosis with distinctive ventral tract type. Forty-eight species, forest or brushland. Mexico through South America.

Family Furnariidae (ovenbirds). A large and extraordinarily diverse group, an excellent example of adaptive radiation. In South America, especially in the southern Brazil–Argentina–Chile region, this family has evolved to fill a broad range of ecological niches; various furnariids look and behave like wrens, thrushes, dippers, creepers, larks, wood warblers, titmice, nuthatches, and even the nonpasserine woodpeckers (Picidae) and sandpipers (Scolopacidae). If such diversity can be summarized, ovenbirds are generally small, dull brown birds, darker above and paler below; 12 to 28 cm (about 5 to 11 in.). One distinctive character is the shape of the

external nares (nostrils), which are schizorhinal (slitlike) at their posterior border rather than holorhinal (rounded), as in other passerines. Front toes partially joined at base. Sternum with one pair of notches (some exceptions). Syrinx with two pairs of intrinsic muscles. Pterylosis distinctive within suboscines but of same type as many oscines. Approximately 215 species, wide variety of habitats; Mexico through South America.

Family Formicariidae (antbirds). A large and diverse family, with loose-webbed plumage, generally in browns, grays, black, and white. Overall size range 9.5 to 37 cm (less than 4 to nearly 15 in.), including several large terrestrial species with long legs but very short tails (hence a deceptively short "body length"). Bill strong, hooked to variable degrees. Front toes slightly joined at base. Sternum with one or two pairs of notches, the two pairs found in most but not all of the long-legged terrestrial species. Syrinx of two types: the first with one pair of ventrally originating intrinsic muscles (largely the arboreal species), the second with no intrinsic muscles. Pterylosis variable; dorsal tract with reduced or absent posterior element (primarily the arboreal species); several different dorsal types among the terrestrial species. Wings generally short and rounded, flight weak; about 231 species, largely in dense forests and brushland. Neotropical; Mexico to northern Argentina.

Family Rhinocryptidae (tapaculos). A small, little-known group. Plumage dull, generally in grays, browns, and black; 9 to 25.5 cm (less than 4 to more than 10 in.). Bill distinguished by a movable flap (operculum) over the nostrils. Legs, feet, and claws strong. Wings short and rounded, flight feeble. Sternum with two pairs of notches. Syrinx with one pair dorsally originating intrinsic muscles (some exceptions). Pterylosis distinctive in ventral tract (exceptions). Twenty-seven species, grasslands, scrublands, and dense forest undergrowth. Central and South America, especially Chile and Patagonia.

Superfamily Tyrannoidea

Syrinx tracheobronchial; pessulus present or absent. Pterylosis: dorsal saddle with full-length apterium (exceptions). Sternum with one pair of posterior notches.

Family Cotingidae (cotingas). An extremely diverse, probably composite family; ranges from plain-coloured flycatcher-like to bright, extravagantly adorned birds: 9 to 45.5 cm (about 4 to 18 in.). Some with extraordinary plumes and lappets (the crow-sized umbrella bird, *Cephalopterus*); others renowned for their loud voices, fleshy wattles, and white plumage (white being unusual in land birds). The family as traditionally constituted can no longer be characterized anatomically: the syrinx is of two types; the tarsal envelope is of several different kinds; the joining of the front toes is variable; the dominant artery of the thigh is either the sciatic or femoral; the spina sternalis is forked except in some bell birds (*Procnias*). Several species with powder downs, a specialized type of feather otherwise known in passerines only in the oscine wood-swallows (Artamidae); 91 species, forests. United States–Mexico border to Bolivia, Peru, and Argentina.

Family Pipridae (manakins). Most piprids are fairly uniform in external appearance; generally small (8.5 to 16 cm [3.5 to 6.5 in.]), rather stubby, with short wings and tail (a few long-tailed species). Most males black with patches of brilliant colour (red, yellow, blue, etc.); females are generally drab olive green. Several species, such as the broad-billed manakin (*Sapayoa aenigma*), are externally and anatomically unlike the majority of manakins and may not be properly included in this family. Bill short, rather broad at base, notched, with a slight hook at tip. Some species with specialized feathers, particularly in the wings (also true of some cotingas and tyrannids). Third toe partially fused at base to 2nd or 4th. Syrinx highly variable, as family is presently constituted; 59 species, tropical and subtropical forest. Southern Mexico to Paraguay and northern Argentina.

Family Tyrannidae (New World, or tyrant, flycathers). Large family of generally (but not exclusively) arboreal birds with plumage in grays, browns, olive greens, some with black, white, and yellow, occasionally brighter colours. Many with erectile crowns or crests, often more colourful than the rest of the plumage; length 7.5 to 40.5 cm (3 to 16 in.). Bill extremely variable but commonly broad, somewhat flattened, and hooked at tip; nostril rounded without an operculum or narrow with membranous operculum; most species with well-developed rictal bristles (stiff hairlike feathers around the mouth). Feet weak except in the few terrestrial species; front toes variably but never strongly fused. Syrinx characterized by 1 pair of intrinsic muscles (none or 2 in some), generally variable in other features. About 367 species, with a wide range of habitats. Northern Canada and Alaska through North and South America to Tierra del Fuego, also Falkland and Galápagos Islands. (The family common name of New World flycatchers serves to distinguish it from the large oscine family of Old World flycatchers, Muscicapidae.)

Family Oxyruncidae (sharpbill). A single, rare, little-known species, sometimes placed in the Tyrannidae. Length about 17 cm (7 in.); externally very much like flycatchers, with the same basic syringeal structure. Differences include a long, straight, and sharply pointed bill, surrounded at the base with short, fine, stiff feathers (not rictal bristles). Nostril narrow, covered by a broad horny operculum. Feet strong. Locally distributed in humid forest from Costa Rica to southeastern Brazil and Paraguay.

Family Phytotomidae (plantcutters). A small family of finchlike birds, gray or brown streaked with black, with areas of rusty red; about 17 cm (7 in.) long. Bill distinctive, stout and conical with a finely serrated edge. Legs short, feet large and strong. Syrinx simple, similar to that of some Cotingidae. Pterylosis: flank margin of ventral tract oblique, contrasting with truncated margin in other New World Tyrannoidea; 3 species, open brush and cultivated regions (where it is often considered a pest). Peru to Argentina and Chile.

Family Pittidae (pittas). A relatively homogeneous family; stout-bodied, long-legged, largely terrestrial, 15 to 28 cm (6 to 11 in.); with a wide range of colours in the loose-webbed plumage: reds, greens, blues, as well as browns, black, and white. Wings short and rounded but strong; tail very short. Syrinx simple, lacking intrinsic muscles and cartilaginous modifications; pessulus absent in most species. Egg white protein pattern differs from that of all other suboscines. Twenty-three species, Old World tropics in forests and scrublands. Africa through Malaysia, Australia, Solomon Islands.

Family Xenicidae (*Acanthisittidae* of many authors; New Zealand wrens). Small birds, 7.5 to 10 cm (3 to 4 in.), look and act much like true wrens (Troglodytidae). Considered evolutionary relicts, 2 species are strongly arboreal, the other 2 terrestrial. One of the latter, the now-extinct Stephen Island rock wren (*Xenicus lyalli*), was markedly terrestrial and may have been flightless; if so, it would have been the only known passerine to have completely lost the ability to fly. The 3 extant species are very weak flyers, with short wings and very short tails. Legs long and slender; 3rd and 4th toes fused basally, and all toes (especially the hallux) with long claws. Forest and scrub; New Zealand.

Family Philepittidae (asities and false sunbirds). The two species of asities (*Philepitta*) are black or yellowish green, rather pitta-like, with stout bodies and long legs. The two false sunbirds (*Neodrepanis*) are very different externally, looking much like true sunbirds (Nectariniidae), with which they were long classified; small, blue, yellow, and greenish with short tails and long, slender, curved bills. All philepittids have bare skin or wattles around the eyes or both. Currently classified in the Tyranni, but the simple structure of the syrinx and the unforked spina sternalis have led some recent authorities to suggest they are more closely allied to the Eurylaimi. Forests of Madagascar.

Suborder Menurae

Syrinx tracheobronchial, acromyodian, with 2 or 3 pairs of muscles inserted on the ends of the bronchial semi-rings; pessulus present. Sternum with short, forked spina sternalis, 1 pair of notches or none. Hallux strong. Clavicles not well-developed.

Family Menuridae (lyrebirds). Among the largest members of the order in length, 75 to more than 100 cm (30 to 40 in.), with some weighing over 1,100 grams (about 2½ pounds), lyrebirds are aberrant passerines in virtually all features. In size, brownish plumage, and terrestrial habits, they look much like pheasants. The tail of 16 feathers is extraordinary: in males of *Menura superba* the outermost pair of feathers is curved like a lyre, the next 6 pairs are light and filamentous, and the innermost pair is modified into narrow "wires"; the tail of *M. alberti* is shorter and simpler; females of both species have rather long but not extremely modified tails. The alula (free digit on the leading edge of the wing) on the short rounded wings has 6 feathers rather than the usual 3 or 4. Rictal bristles present. Legs and feet strong and heavy. Sternum long, narrow, and thick, unique within passeriines; posterior border may be entire or with 1 pair of shallow notches. Syrinx of the oscine type, but with only 3 pairs of intrinsic muscles; it is capable of a remarkable variety of loud ringing calls and the birds are famous for their vocal mimicry. Two species, dense forests; Tasmania (introduced) and eastern Australia.

Family Atrichornithidae (scrub-birds). Wholly unlike lyrebirds in external appearance, rather like large wrens, long-tailed, brownish, and terrestrial; 16.5 to 23 cm (6.5 to 9 in.).

One species, *Atrichornis clamosus*, long thought to be extinct but recently rediscovered. Both species virtually flightless, with very small wings and clavicles small and separated (not fused into a furcula, "wishbone"), a condition unique within passerines. Sternum unlike *Menura*, with 1 pair of deep posterior notches. Legs and feet very strong. Rictal bristles lacking. Similar to lyrebirds in the quality of their strong voices, nesting habits, and basic syringeal structure. Scrub-birds, however, have only 2 pairs of intrinsic muscles in the syrinx. Two species, scrublands; in western and eastern Australia.

Suborder Passeres (songbirds, or oscines)

Syrinx with 4 pairs of intrinsic muscles. Sternum with spina sternalis short and forked, and posterior border with 1 pair of notches. Hallux variable in strength. Clavicles well-developed. All with same complex of syringeal muscles, with only minor variations.

Family Alaudidae (larks). A distinctive and well-defined group, the only oscines with back of tarsus rounded and scaled instead of sharp and unsegmented. Syrinx also unique among Passeres in lacking the usual bony pessulus. Small ground birds, 12 to 23 cm (about 5 to 9 in.), usually cryptically coloured in browns and grayish buffs, plain or streaked, lighter below (several species black below); sexes similar. Bill usually pointed, slightly downcurved; wings long, pointed; legs rather long, hindtoe usually with long, straight claw. About 75 species inhabit open fields, plains, beaches of Old World, with only 1 species, the horned lark (*Eremophila alpestris*), also in North America south to Colombia. Many species migratory. Food: seeds, insects, and other invertebrates. Sing beautifully, often a soaring flight song.

†*Family Palaeospizidae* (*Palaeospiza*). A single fossil species known only from Oligocene of Colorado.

Family Hirundinidae (swallows, martins). A distinctive family placed low on the oscine family tree because of primitive syringeal characters, particularly the double bronchial rings, unique in Passeres. Small birds, 9.5 to 23 cm (about 4 to 9 in.), with compact plumage, often with metallic sheen, usually lighter below; sexes usually alike or nearly so. Wings long, pointed, primaries reduced to 9. Tail medium to long, truncate to forked. Legs short, feet small, weak. Bill short, flat, but wide gape enhanced by rictal bristles. Walk with difficulty but fly strongly, feed on insects caught in flight. Voice usually a twittering or squealing, sometimes melodious. The river martins of Africa and Thailand differ by large, brightly coloured bills, stronger feet, and syringeal characters. The 79 living species are found worldwide except polar regions and certain oceanic islands; all or nearly all migratory.

Family Dicruridae (drongos). Small to medium-sized birds, 18 to 63.5 cm (7 to 25 in.), the longest being those with exceptionally long tails; usually black with purple or greenish sheen, some crested or with spangled neck and head feathers, iris of eye usually red; sexes alike. Bill stout, arched, slightly hooked and notched; long, strong rictal bristles; legs short, feet stout. Wings long; tail variable, of 10 or 12 feathers, usually forked; some species with racquet tails. Arboreal birds that fly well but seldom long or far. Food mostly insects caught on the wing. Voice varied, melodious; capable mimics. The 20 species range through Africa, southern Asia, Malaysia, northern Australia, east to Solomons, in woodlands, savannas, cultivated regions.

Family Oriolidae (forest orioles, fig-birds). Medium-sized birds, 18 to 30.5 cm (7 to 12 in.); brightly coloured, predominantly in yellows, greens, and black; sexes unlike, female duller, young streaked below. Bill strong, pointed, slightly hooked; long, pointed wings with 10 primaries; medium to long tail of 12 feathers. Strictly arboreal birds that feed on insects, fruit; 28 species in forest and open woodland across Eurasia, in Africa, East Indies, Australia, Philippines. Flight strong, undulating. Voices loud, with harsh calls, but melodious songs.

Family Corvidae (crows, jays, ravens, rooks, choughs, nutcrackers, and magpies). Medium to large passerines, including the heaviest oscines, the ravens (*Corvus*); 17.5 to 70 cm (7 to 28 in.). Ten primaries, the 10th (outer) always much shorter than 9th, but longer than primary coverts. Bill strong, powerful, longer than rest of head or nearly so; nostrils usually covered with bristles. Crows (*Corvus*) and allies, large, black or black and gray or white; wings long, tail shorter than wing. Jays generally smaller, often coloured in blues, greens, yellows; wings rounded; tail sometimes two-thirds of total length. About 102 species, almost cosmopolitan (absent from southernmost South America, Antarctica, some oceanic islands, introduced to New Zealand); varied habitats, prefer woodlands, open brushlands. Voices harsh, loud.

Family Callaeidae (wattlebirds). Medium-sized, 25.5 to 53.5 cm (10 to 21 in.); black, brown, or blue-gray, with fleshy blue or orange wattles at the gape; sexes may differ in size, wattles, and bill shape. Weak fliers but hop strongly. Sternum weak; 10-primaried wings short, rounded; tail long. Bill stout and short to long and curved; legs long, feet stout. Eat fruit, nectar, insects. A variety of musical notes and whistles. Three species limited to primeval forests of New Zealand; huia (*Heteralocha*) extinct; wattlebird (*Callaeas*) and saddleback (*Creadion*) rare.

Family Grallinidae (mudnest builders). Ten-primaried oscines of medium size, 19 to 50 cm (7.5 to 20 in.). Differ from most corvids in lacking nasal bristles. Legs long, strong; wings long and pointed to short and rounded. Black and white or dark gray; sexes alike or unlike. Four species limited to Australia, western New Guinea, in woodlands, marshes, cultivated lands, usually near water. Weak fliers with peculiar jumping gait; all build deep, open-bowl nests of mud, stiffened with hair, feathers, grass. Eat insects, snails, seeds, soft fruit. Melodious whistles, harsh and plaintive notes.

Family Cracticidae (bellmagpies). Ten species of medium to large oscines, 25 to 58 cm (10 to 23 in.). Most black, white, and gray; some have brown phase; sexes alike or unlike. Large heavy bill, slightly to strongly hooked; nostrils bare. Wings long, pointed; legs strong, medium to long. Australia, New Guinea, and nearby islands; gregarious inhabitants of brushy plains, open forests, mangrove shores, cleared lands. Eat insects, small animals, some fruit and seeds. Fine singers with ringing, gonglike calls.

Family Ptilonorhynchidae (bowerbirds). Ten-primaried oscines of medium size, 23 to 37 cm (about 9 to 15 in.); sexes alike in a few, but males usually much brighter coloured, often with nuchal (neck) crest but never with plumes or facial wattles. Stout bill, straight to slightly curved; wings rounded; legs and feet stout, hindtoe shorter than middle toe. Seventeen species, in forests of New Guinea and northern Australia. Solitary, largely terrestrial birds; eat berries, seeds, fruits, insects, small animals. Males of most species build elaborate stages or bowers for display and courtship. Loud ringing calls, good mimics.

Family Paradisaeidae (birds of paradise). Small- to medium-sized, 10-primaried, 14 to 117 cm (about 5.5 to 46 in.), greatest length due to streaming tail feathers; greatly varied colours, most males with spectacular plumes on head, flanks, wings, or tail; some with wattles or bare skin on the head; females plain browns or grays. Bill slender to rather heavy, hooked or sickle-shaped in some. Wings rounded; legs short; feet rather stout. About 40 species, New Guinea, northern and eastern Australia, Moluccas, and adjacent islands. Solitary forest birds, rather weak fliers; males of most species have elaborate courtship displays. Eat fruit, seeds, insects, small animals. Prolonged whistles, loud shrill calls.

Family Paridae (titmice and chickadees). Ten-primaried oscines with short to medium, rounded wings; tail short to long; bill rather stout, pointed, shorter than remainder of head; nonoperculate nostrils concealed by thick feathers. Small birds, 7.5 to 20 cm (3 to 8 in.), with thick plumage usually strongly patterned in grays, yellows, brown, black, or white, never streaked, barred, or spotted; sexes usually alike. About 64 species in forests and brushlands of the Philippines, Malaysia, Eurasia, Africa, and North America to Guatemala. Active, gregarious little birds; feed on insects, seeds. Chattering notes, whistled calls.

Family Certhiidae (creepers). Small, slender, climbing birds, 9.5 to 19 cm (3.5 to 7.5 in.), with curved bills as long or longer than rest of head; operculate nostrils free of bristles or feathers; rictal bristles absent. Legs short, thin, outer toe always shorter than middle toe but much longer than inner toe; claws long, hindclaw as long or longer than hindtoe; wings rounded or pointed; tail feathers long, stiff, with pointed tips. Brownish above, streaked with black or light brown, white below; sexes alike. Six species (with the inclusion of the African spotted creeper, *Salpornis*, a controversial point) in temperate woodlands of Eurasia, Africa, North America, south to Nicaragua. Solitary birds, spiral up tree trunks from base probing bark for insects; two species inhabit rocky cliffs. Soft calls, sweet but weak songs.

Family Sittidae (nuthatches). Small, stocky, climbing birds, 9.5 to 19 cm (3.5 to 7.5 in.) with thin, pointed, usually straight bills; rounded, nonoperculate nostrils partly concealed by feathers; short rictal bristles present; tarsus short; long laterally compressed claws on large toes, hallux equal to outer toe, inner toe reaching only to second joint of middle toe; wings rather long, pointed; tail short, square, soft. Typically gray to blue above, white or brownish below; sexes alike or nearly so. About 22 species; typical nuthatches (*Sitta*) distributed across North America and Eurasia to Malaysia and the Philippines, aberrant forms in Philippines, Australo-

Papuan region. Typically in forests, a few in rocky areas. Forage on tree trunks and large branches for insects, eat some seeds and small fruits. Simple call notes and songs.

Family Climacteridae (Australian treecreepers). Six species of small, creeper-like climbing birds, 12.5 to 17.5 cm (5 to 7 in.); of uncertain ancestry and affinities. Legs short; toes long, claws long, curved, strong, especially that of hallux; tail rounded, soft; bill long, somewhat downcurved. Grayish-brown to black above, streaked below, often a lighter eye stripe and wing bar; sexes similar but with slight recognizable differences. Forests of Australia and New Guinea; rather solitary, sedentary birds; feed by spiralling up tree trunks, some forage for insects on ground. Voice high-pitched whistles.

Family Panuridae (bearded tits, parrotbills). Small, titmouse-like birds, 10 to 17.5 cm (4 to 7 in.), distinguished (with one exception, the bearded tit, *Panurus biarmicus*) from all other oscines by the strongly compressed bill, much shorter than head, markedly curved convexly, both tomia (cutting edges) sinuated; nostrils concealed by feathers; wings short, rounded; tail rather long, graduated. Plumage soft, fluffy, plain brownish above, lighter below; sexes alike or nearly so. About 19 species in brushy grasslands, scrublands, and thickets of temperate Eurasia; active, gregarious, travel in small flocks searching for seeds, insects, berries. Low twittering call notes.

Family Chamaeidae (wrentit). Small bird about 16.5 cm (6.5 in.) long, with thick fluffy plumage; plain brown above, lighter and streaked below. Bill short, rounded, pointed, slightly downcurved; nostrils exposed, operculate; rictal bristles distinct; wings short, rounded; tail long, graduated; sexes alike. The single species ranges in brushlands and forest edges from Oregon to northern Baja Californai; usually in pairs. Eats insects, small berries. Voice: a loud whistle on one pitch. Often classified in the Timaliidae.

Family Timaliidae (babblers). A poorly defined, diverse group of more than 250 species, with uncertain affinities and lineage. Small to medium-large, 9 to more than 40 cm (3.5 to 16 in.). Plumage soft, fluffy; bill highly varied, small and weak to long, straight, downcurved, often hooked. Wings short, rounded, fit close to body; legs rather large, strong. Mostly dull coloured, a few brightly coloured; sexes alike and unlike. In woodlands, scrub, and brushlands of eastern and central Eurasia, Africa, Madagascar, Philippines, Malaysia, and Australia; solitary or gregarious, usually arboreal, some terrestrial; all insectivorous, some also eat fruit, berries. Many species with noisy, harsh calls, musical songs.

Family Campephagidae (cuckoo-shrikes and minivets). About 70 species of small- to medium-sized, forest-living birds, 12.5 to 35.5 cm (5 to 14 in.). Africa, India to Japan, East Indies, Australia. Rather stout, slightly downcurved bill, notched, hooked at tip; nostrils partly concealed by short bristles; wings medium, pointed; long tail rounded or graduated; legs short, feet weak to strong. Feathers of back and rump usually with heavy shafts, thickly matted and loosely attached. Cuckoo-shrikes plain gray, black, or whitish birds, often with barred underparts; minivets brightly coloured in reds, yellows. Sexes often completely dissimilar. Eat insects, berries, small fruits. Noisy birds, with whistles and harsh calls.

Family Pycnonotidae (bulbuls). Medium-sized birds, 14 to 28 cm (5.5 to 11 in.), with soft, fluffy plumage, especially soft on lower back and rump; many species with hairlike, vaneless feathers on nape of neck. Bill usually slender, slightly downcurved; rictal bristles well-developed; feet and legs rather small; wings short; tail medium to long. Usually drably coloured in gray, brown, greenish, some with yellow, white, or red patches on head and under tail; sexes alike. About 119 species in Africa and across southern Asia to Japan, Philippines, Moluccas, Borneo; in woodlands, brushlands, cultivated regions. Eat berries, fruit, some insects. Noisy, some good singers, mimics.

†*Family Palaeoscinidae* (*Palaeoscinis*). A fossil species known only from the Miocene of California.

Family Irenidae (leafbirds, ioras, fairy bluebirds). Small to medium birds, 13 to 25 cm (5 to 10 in.); bill fairly long, slightly downcurved or hooked; legs short; wings rounded; tail square to rounded. Like bulbuls, some have hairlike feathers on nape and long fluffy rump feathers but are more brightly coloured, brown or black with contrasting yellow, green, or blue; sexes usually dissimilar. About 14 species in forests and cultivated lands from India to Philippines, south to Borneo, Java, Sumatra. Eat fruit, berries, buds, some insects. Good singers, musical whistles and flutey notes.

Family Cinclidae (dippers). The only largely aquatic oscines; small, 14 to 19 cm (5.5 to 7.5 in.), birds with plump bodies, short concave wings, short, square or rounded tail. Tarsi and toes long and stout. Bill slender, straight, pointed; nostrils with broad operculum; rictal bristles absent. Dense compact plumage plain gray, brown, or black, some with white patches on throat, breast, head; sexes alike. Four species, found along swift, rocky streams in Eurasia, North Africa, and North and South America, south to Argentina. Food: insects, aquatic larvae, and other organisms gleaned from stream bottoms. Have shrill penetrating whistled calls and chattering songs.

Family Troglodytidae (wrens). Small, 9.5 to 22 cm (3.5 to 8.5 in.), chunky birds, mostly brown, usually barred, spotted, or streaked, with white, black, or browns; sexes alike. Bill slender, medium to long, often downcurved; nostrils with operculum; rictal bristles usually indistinct but sometimes obvious with 1 or 2 well-developed. Stout legs and feet, front toes partly joined at base. Wings short, rounded, well-developed 10th (outermost) primary, at least half as long as 9th; tail short, square to rounded, often carried cocked up. The 59 species range through most of North and South America; 1 also found in Eurasia and North Africa; inhabit brushlands, forests, forest edges, rocky slopes, deserts, grassy marshes. Most forage on or near ground in undergrowth for insects, worms, other invertebrates. Highly developed song, musical, variety of bubbling, flutelike to growling notes, harsh chattering calls; some species duet.

Family Mimidae (mockingbirds, catbirds, thrashers). Slender, medium-sized, 20 to about 30 cm (8 to 12 in.); bill medium to long, nearly straight to strongly downcurved; nostrils always exposed, with overhanging membrane; rictal bristles present, but few and somewhat weak. Legs rather long, feet strong, middle toe joined at base to outer toe but not to inner toe. Wings short, rounded; tail long. Coloured brown, gray, black, bluish, underparts usually pale, often white, spotted, or streaked, some solidly coloured, some with white in wings or tail; sexes alike. Exclusively New World, the 31 species range from southern Canada, the West Indies, Galápagos, to southern Argentina and Chile. Eat fruit, seeds, insects. Famous as fine singers and mimics.

Family Turdidae (thrushes, bluebirds, nightingales, wheatears, robins, chats). A large, almost cosmopolitan group of about 305 species of small- to medium-sized birds, 11.5 to 33 cm (4.5 to 13 in.). Bill rather slender; legs and feet fairly stout, tarsus usually booted (smooth sheath, not divided into scales); 10-primaried wing rounded to pointed; tail medium, truncate or graduated, forked in a few. Colours brown, blue, gray, often blended, or in bold black, white, yellow, or red patterns; sexes alike or unalike; young usually spotted below. Virtually worldwide; absent originally only from New Zealand (now introduced there), some oceanic islands, Antarctica, and parts of the Arctic. Usually arboreal, many terrestrial, in varied habitats—forests, deserts, brushlands, grasslands, cultivated fields. Eat mostly fruit, insects, also seeds, leaves, worms, and mollusks. Most are fine singers.

Family Sylviidae (Old World warblers, kinglets). Typically small, 9 to 26 cm (3.5 to 10 in.), with slender bill; longitudinal nostrils with an operculum; medium rounded wings of 10 primaries; short to medium legs. Plumage usually browns, grays, olive greens with little pattern; some streaked or barred; some brightly, boldly marked; sexes alike or similar, young never spotted below. Nearly 300 species, worldwide except in polar regions, South America, some oceanic islands, mostly in woodlands, some in brushlands, marshes. Food essentially insects; voices pleasant, varied, well-developed song in some.

Family Polioptilidae (gnatcatchers, gnatwrens). Dainty, slender, tiny, 10 to 14 cm (4 to 5.5 in.), with long, thin, pointed bills, operculate nostrils partly exposed, and rictal bristles. Rounded wing with 10th primary much less than half as long as 9th; long rounded tail constantly moving. Blue-gray or brown above, lighter below, most with white in outer tail feathers, some with black markings on head; sexes alike or nearly so. The 11 species are active arboreal birds of open forests and semi-arid deserts from southern Canada to Argentina. Food essentially small insects. Rather weak songs of trills and warbles, simple short call notes.

Family Pachycephalidae (whistlers, shrike-thrushes, thickheads). Small- to medium-sized, stout-bodied, 13 to 28 cm (5 to 11 in.); roundish heads, rather heavy bill sometimes hooked at the tip. Wings rather long, pointed, with very short 10th primary; tail medium long, usually rounded. A few species crested or with wattles or bare patches at base of bill. Most are greenish gray to brown above, lighter below, many with yellow or dull red markings; sexes alike, a few unalike; many juvenile plumages spotted or like that of female. About 42 species in Australo-Papuan region, Malaya, Philippines, Oceania; in forests, brushlands, mangroves, savannas. Diet predominantly insects with some fruit. Melodious flutey calls, pairs often duet.

Family Maluridae (wren-warblers, emu-wrens). Small-bodied birds, 7.5 to 25 cm (3 to 10 in.), that carry the long tail cocked up over the back. Bill small, weak; wings short, rounded; legs and feet medium. Emu-wrens (*Stipiturus*) have rectrices reduced to 6 loose-barbed shafts. Most species are brightly patterned in contrasting browns, reds, shiny blues, black, and white; sexes alike or unalike. About 83 species in Australo-Papuan region, including New Zealand; in forests, scrublands, heaths. Food largely insects and other invertebrates. Many are good singers, mimics.

Family Muscicapidae (Old World flycatchers). A large (about 340 species) family of small insectivores, 7.5 to 22.5 cm (3 to 9 in.); the paradise flycatchers (*Terpsiphone*) with long tails, to 53.5 cm (21 in.). Typically with flat, broad bills, well-developed rictal bristles; short, weak legs and feet. Wings short and rounded to long and pointed; tail short and narrow to long and fanned or with long central plumes. Varied colours, many plain browns, grays, some with bright blues, reds, and black and white; some crested or with facial wattles; sexes alike and unalike, young usually spotted. Eurasia from tree line south through Africa, Australia, and in Pacific Islands to Hawaii; forests, scrublands, cultivated and riverine areas. Voices usually weak, monotonous, but well-developed song in a few.

Family Prunellidae (accentors, hedge sparrows). Small, drab, 12.5 to 17.5 cm (5 to 7 in.); slender, pointed bills, wide at base, culmen (ridge of upper bill) slightly rounded. Tarsus rather short, feet strong. Wings rounded to pointed with very short 10th primary; tail shorter than wing, square or emarginate. Colour browns or grays, usually streaked or spotted; sexes similar. Twelve species across Eurasia and northern Africa; various habitats, parks and gardens, brushlands, barren mountain slopes below snow line. Feed on or near ground on insects, berries, seeds. Thin chattering, twittering songs, metallic calls, often in flight.

Family Motacillidae (pipits, wagtails). Small, slender-bodied ground birds, 12.5 to 23 cm (5 to 9 in.). Pipits similar to larks in appearance but differ in having a bilaminate tarsus and pointed wing with 9 primaries. Wagtails have longer tails, brighter colours. Bill thin, pointed; legs long, slim, with elongated hindtoe and hindclaw (with some exceptions); tail usually edged with white or yellow. Plumage brown, streaked, mottled, sexes similar (pipits); or marked in bold black, white, or yellow patterns, sexes unalike (wagtails). About 53 species, worldwide except polar regions and some oceanic islands; in open grasslands, deserts, shores, cultivated areas. Feed on insects, spiders, mollusks, some vegetable matter. Simple repetitive song often given in flight, and short, sharp call notes.

Family Bombycillidae (waxwings). Small, arboreal, soft-plumaged, crested, 15.5 to 19 cm (6 to 7.5 in.); distinguished by waxy red "droplets" at tips of secondary wing feathers of most individuals. Bill short, swollen, slightly hooked; nostrils almost concealed by feathers, rictal bristles absent. Long pointed wing with rudimentary 10th primary; square to slightly rounded, short tail. Velvety plumage blended with browns, grays, and yellow; tail tipped with yellow or red; sexes alike. Three species in temperate Northern Hemisphere, in evergreen or birch forests. Eat berries, fruit, buds, flowers, insects. Weak chattering song, soft lisping calls.

Family Ptilogonatidae (silky flycatchers). Small, arboreal, crested, 18 to 24.5 cm (7 to 9.5 in.). Bill short, broad, deeply cleft; nostrils exposed, bordered by membrane, rictal bristles present. Wings and legs rather short; 10th primary well-developed; tail long. Soft silky plumage of solid grays, black, brown, white spots in wings and tail, some with yellow markings. Four species, found from southwestern U.S. to Panama; in brush country, desert scrub, open forest. Rather shy, active birds that feed on berries and on insects caught in flight. Weak warbling song.

Family Dulidae (palm chat). Medium-sized about 19 cm (7.5 in.); deep laterally compressed bill, strongly curved culmen, circular nostrils wholly exposed. Wings rounded, 10th primary less than half as long as 9th; tail longish; legs and toes stout. Plumage stiff and harsh, olive brown above, yellowish-white streaked with brown below; sexes alike. The single species limited to cultivated areas and open woodlands of Hispaniola and Gonave Island, West Indies. Lives on fruits and flowers. Noisy, gregarious birds with harsh chattering notes.

Family Hypocoliidae (hypocolius). Medium-sized, 17.5 cm (7 in.); short, broad bill, moderately curved culmen, operculate nostrils; nasal bristles lacking and rictal bristles poorly developed. Tarsus rather short, heavily scutellated (scaled). Soft plumage blue-gray above, lighter below, with black facial, wing, and tail markings, white wing tips, slightly crested; sexes alike. The single species inhabits semi-arid scrublands, palm groves, gardens in Tigris-Euphrates valley of Iraq, wanders to Afghanistan, western India, Arabia, Red Sea coast. Fruit eater with low calls and weak song.

Family Artamidae (wood-swallows or swallow-shrikes). Chunky-bodied, medium-sized; 15 to 21 cm (6 to 8.5 in.); unique among oscines in having powder downs. Bill stout; broad at base, moderately long, decurved, pointed; legs short; feet strong. Wings long, pointed; tail short, nearly square. Plumage compact, soft, in plain solid browns, grays, or black above, usually lighter below; sexes similar. Ten species in open lands, forest clearings, Australia east to Fiji Islands, north to Philippines, Indochina, India. Live on insects caught in flight. Voice a harsh nasal twittering.

Family Vangidae (vanga shrikes). Small- to medium-sized, 12.5 to 32.5 (5 to 13 in.), 10-primaried, arboreal oscines of varied aspect; some resemble flycatchers, thrushes, nuthatches, or typical shrikes. Bill stout, heavy, hooked, notched; with enlarged ridge in one, thin, downcurved in another; legs and feet strong; wings fairly long, rounded; tail square or rounded, moderately long. Plumage rather soft, loose, typically black or blue above, white below, some with brown or gray patches; sexes alike or unalike. Thirteen species, restricted to forests, scrublands, mangrove swamps, of Madagascar. Eat insects, small reptiles, amphibians. Chattering calls, harsh notes, shrill whistles.

Family Laniidae (shrikes). Rather small- to medium-sized 15 to 36 cm (6 to 14 in.); 10-primaried, with proportionately large heads; stout, strong, sometimes toothed, sharply hooked bills; strong legs with sharp claws; tarsus scutellate anteriorly, lamellate (plated) laterally; wings medium; tail usually long, narrow. Plumage soft, black, gray, or brown above, usually paler below in true shrikes; yellows, reds, greens in some African bush shrikes; sexes alike or unalike. Essentially Old World, 64 species across temperate Eurasia, Africa, east to Philippines, and south to New Guinea and Timor; 2 species in North America to southern Mexico; usually solitary birds, in open forests, clearings, brushlands, cultivated areas. Food large insects, small vertebrates; some impale prey on thorns for storage and to tear apart. Voices varied, some with well-developed song, several species sing antiphonally.

Family Prionopidae (helmet shrikes). Medium-sized, 19 to 25.5 cm (7.5 to 10 in.); distinguished from preceding family by their fully scutellate tarsus and stiff forehead feathers projecting forward, almost concealing the nostrils; most with conspicuous wattles surrounding the eyes. Bill stout, hooked; legs short, strong; wings and tail medium to long. Plumage black above, white or buffy below in bold patterns; sexes similar. Nine species, in brushlands, scrub, and forests of Africa, south of the Sahara. Gregarious arboreal birds that hunt in small flocks for insects. Harsh chattering notes, nasal humming sounds, snap bills audibly.

Family Sturnidae (starlings, mynas, oxpeckers). Stocky, medium-sized, 16.5 to 42 cm (6.5 to 16.5 in.); very short but visible 10th primary. Bill pointed, straight, or slightly arched, swollen near the tip in oxpeckers (*Buphagus*); tongue flat, not tubular (as in some relatives). Legs and feet stout, strong, tarsus with unbroken plates behind. Typically dark coloured with metallic sheen, some brown or gray with white, yellow, or red markings, some with facial wattles, a few crested; sexes alike or unalike. About 107 living, 4 recently extinct species in all types of wooded and agricultural lands; temperate Eurasia through Africa, northern Australia, East Indies, east to Tuamotu Archipelago; a few introduced widely elsewhere (*e.g.*, North America). Almost omnivorous; wide range of vegetable and animal foods. Garrulous, varied notes, calls, whistles, some excellent mimics.

Family Meliphagidae (honeyeaters). Small- to medium-sized, 10 to 40 cm (4 to 16 in.); long, protractile, brush-tipped tongue curled at the sides to form a tube. Bill slender, pointed, downcurved, upper cutting edge serrated; nostrils unfeathered, with leathery operculum. Wings long, pointed, 10th primary about half the length of 9th; tail medium to long. Legs short to medium, tarsus scaled anteriorly. Drab browns, yellows, grays, or bold patterns of black, red, white; sexes alike or unalike. About 168 living, 4 recently extinct species, from Australia and New Zealand through the Papuan region, north to Marianas, east to Hawaii, 2 species in southern Africa. Habitat forests, brushlands, cultivated lands. Food chiefly nectar, insects, some fruit. Voices loud, varied; musical song in many.

Family Nectariniidae (sunbirds, spider hunters). Small, 9 to 22 cm (3.5 to 8.5 in.). Long, slender, downcurved, pointed bill, finely serrated near tip; tongue not brush-tipped but partly tubular, projectile, divided at tip; nostrils rounded, open, operculate; no rictal or nasal bristles. Wings rounded, short, 10th primary variable in length but always present; tail square,

medium to long, pointed, sometimes with elongated central feathers. Legs short, stout, tarsus with anterior transverse scales; hallux and claws short. Many sunbirds with vivid colours, metallic sheens, and bright patches in male; females much duller; other sunbirds and spider hunters dully coloured in both sexes. About 116 species, in forests, scrub country, mangroves; Asia and Africa south of Sahara, east to central China, Philippines, Solomons, south through Malaya to northern Australia. Active arboreal birds, sunbirds are Old World counterparts of New World hummingbirds but not as skilled fliers. Feed on nectar, insects, some small fruit. Weak call notes, faint songs.

Family Dicaeidae (flowerpeckers, pardalotes, diamond birds). Small chunky birds 7.5 to 18 cm (3 to 7 in.), with short necks, legs, tails. Bill usually short, stout, relatively straight; slender and curved in a few, edges of distal (outer) 3rd serrated; distal half of short tongue deeply cleft, the edges curled into 2 slender semitubular tips. Wings rather long, 10th primary usually vestigial, absent in a few. Bright-coloured males dark, glossy (rarely metallic) above, lighter below, often with red or yellow patches on crown, rump, breast; females usually much duller; some species dull-coloured in both sexes. About 58 species in forests, scrublands; India to southern China, Philippines, east through Solomons, and south to Australia. Active arboreal birds, feed around flowers on nectar, small insects, berries (particularly mistletoe). Sharp metallic twittering calls, a few have warbling song.

Family Zosteropidae (white-eyes). Relatively uniform group of little birds, 10 to 15 cm (4 to 6 in.) long, yellowish- or reddish-brown to olive green above, lighter below, typically with a conspicuous white eye-ring; sexes alike. Bill short, slender, pointed, slightly decurved; tongue brush-tipped; rictal and nasal bristles absent. Wings short, rounded, 10th primary usually lacking; tail medium, square; legs and claws short, feet strong. About 90 species in forests, brush country, mangroves; Africa south of Sahara, across southern Asia to Korea, Japan, south to Australia, New Zealand, east to Carolines, Samoa. Travel in restless flocks, feed on nectar, insects, fruit. Weak voices, pleasant twittering, warbling songs.

Family Cyclarhidae (pepper-shrikes). Rather heavily built, medium-sized, 14.5 to 17.5 cm (5.5 to 7 in.), with large heads; stout, strongly hooked, laterally compressed bills; nostrils rounded, exposed; rictal bristles present but weak. Wings short, rounded, 10th primary half length of 9th; tail medium; legs and feet strong. Loose-webbed plumage olive green above, yellow to buffy-white or gray below, rufous stripe over eye; sexes similar. One species southern Mexico to Guianas, Uruguay, northern Argentina; a second in Colombia and Ecuador; open forest, brushland. Weak fliers, travel singly or in pairs, moving deliberately through foliage. Eat large insects, fruit. Repetitive warbling song, harsh scolding calls.

Family Vireolaniidae (shrike-vireos). Small, poorly known; 14.5 to 18.5 cm (5.5 to 7 in.). Rather stout, hooked bill; nostrils oval, exposed; rictal bristles inconspicuous. Wings short, rounded, 10th primary reduced to half length of 9th; tail short to medium; legs short, stout. Plumage silky, loose-webbed, greenish above, yellowish to white below, head marked with yellow, gray, blue, black, or white; sexes similar. Three species; in rain-forest treetops from southern Mexico to central Brazil. Food fruits, insects. Loud repetitive whistled song.

Family Vireonidae (vireos, greenlets). Rather plainly coloured, small arboreal birds, 10 to 17.5 cm (4 to 7 in.), mostly brownish-gray to olive green above, yellow, grayish, or white below; plumage never streaked or spotted; some with light eye-rings, eye stripes, wing bars; sexes alike. Bill fairly heavy, slightly hooked and notched; nostrils ovate, operculate, partly exposed; rictal bristles inconspicuous; legs short, strong. Wings long, pointed to short, rounded, 10th primary very short or vestigial. About 37 species in all types of woodlands from central Canada to Uruguay and Argentina. Usually solitary inhabitants of forest edges; seek insects on leaves and branches, eat some berries, fruit. Compulsive singers; songs of repeated, often melodious, phrases; harsh scolding notes.

Family Drepanididae (Hawaiian honeycreepers). Small forest birds, 11.5 to 22 cm (4.5 to 8.5 in.), limited to the Hawaiian Islands; 14 species living, 10 of them rare and local, 8 species recently extinct. Bill extremely varied, short to long, thin to thick, straight to extremely downcurved, pointed to hooked, but never serrate or notched. Wings pointed, 10th primary vestigial or absent; tail medium, truncate or slightly forked; legs short to medium; feet strong. Plumage plain brown, olive green, yellow, red, gray, or black, never metallic or glossy; sexes unlike or similar with female smaller. Solitary or in small flocks; eat nectar, insects, seeds, fruit. Warbling songs, clear calls.

Family Parulidae (wood warblers, bananaquits). Dainty, small, 10 to 18.5 cm (4 to 7.5 in.); pointed wings of 9 primaries, medium 12-feathered tail. Bill usually slender, pointed, culmen slightly downcurved, flattened with pronounced rictal bristles in a few but never notched or hooked; tongue moderately slender, tip variably bifid (divided) or fimbriate (fringed). Legs medium, hindclaw never elongated. Colours varied but never metallic or glossy; grays and olive browns dominant ground colours, often brightly patterned with yellows, reds, blue, black, or white; sexes alike or unlike. About 119 species in forests and brushlands from tree line of North America to southern South America. Active, arboreal (a few terrestrial); feed mostly on insects, occasional fruits, berries, seeds, 1 group (bananaquits) sip nectar. Voices typically weak, thin, high-pitched; a few with loud and well-developed songs.

Family Zeledoniidae (wrenthrush). The single species is small, 11.5 (4.5 in.), with 9 primaries. Bill weak and flattened vertically; legs long, feet large, strong; wings and tail short, rounded. Plumage soft, olive brown above, slate gray below, crown black-bordered orange; sexes alike. Resident in humid cloud forests of Costa Rican, western Panamanian highlands. Shy, retiring birds with weak, fluttery flight, seldom fly more than 20 m (65 feet), creep and hop on forest floor. Food mainly insects. Voice thin, high-pitched, repetitive whistles.

Family Icteridae (orioles, troupials, oropendolas, caciques, blackbirds, grackles, cowbirds, meadowlarks). A heterogeneous group, medium to large, 16 to 54 cm (about 6 to 21 in.). Straight, pointed, unnotched, conical bill, with culmen extending more or less onto forehead; operculate nostrils, never concealed; rictal bristles lacking. Wings mostly long, pointed; tail short to rather long; legs and feet strong. Plumage often solid black with metallic gloss, or multicoloured in bold patterns of black and red, orange, yellow, brown; sexes usually differ, female smaller. About 88 species, throughout Western Hemisphere (except polar regions), in a wide variety of habitats. Many species gregarious; some colonial or semicolonial nesters. Eat a wide range of animal and vegetable foods. Usually loud-voiced, with harsh, whistling, or bubbling calls; well-developed song in some.

Family Tersinidae (swallow-tanager). Single tanager-like species, 15 cm (6 in.), differing from Thraupidae mainly in peculiar palate, expandable throat, and broad, flat, swallowlike bill; longer wings, shorter legs. Male shining turquoise with black throat, face, sides barred black, white below; female green with grayish-white barring. Lowland and mountain forests; Panama, Trinidad, south into Argentina. Somewhat gregarious; strong fliers; feed on insects, fruit. Voice monotonous chirps, almost no song.

Family Thraupidae (tanagers, euphonias, honeycreepers, and diglossas). Small to medium, compactly built, 9 primaries; 8 to 30 cm (about 3 to 12 in.), most under 20 cm. Bill with commissure (meeting of edges) not abruptly angled or bent at the base; mandibular tomium not distinctly angled (never toothed) near the base. Bill usually conical, short to medium, generally notched, toothed, or hooked at tip; rictal bristles present. Nectar-feeding species with specialized bill and brush-tipped tongue. Wings pointed, short to long; tail short to medium, truncate, emarginate, or rounded. Generally brightly coloured, in contrasting patterns of black, white, yellow, red, blue, green, brown; sexes alike or unalike. About 223 species in forests, brushlands; temperate North America to Brazil, Argentina. Arboreal birds; flight strong but not sustained in non-migratory species. Eat berries, fruit, insects, nectar. Voices varied, song well-developed in a few but usually short calls and warblings.

Family Catamblyrhynchidae (plush-capped finch). Finch-like, 9 primaries, 15 cm (6 in.), with stubby, conical, slightly hooked bill and a distinctive patch of short, stiff, velvety tipped, orange-yellow feathers on the forecrown. Wings short, rounded; tail medium; legs stout, feet strong. Male bluish-gray above, chestnut below, nape and sides of head black; female similar but duller. Mountain forests of Colombia, Venezuela south to Peru, Bolivia. A little-known species of uncertain relationships and systematic position.

Family Fringillidae (New World seedeaters). Small, 9 primaries; 10 to 27 cm (4 to 11 in.), with short, stout, conical, pointed bills. Commissure distinctly angled or deflexed at the base, mandibular tomium elevated, often toothed, gonys (midline ridge of lower bill) more than half length of upper bill; rictal bristles usually obvious. Wings short, rounded to long, pointed; tail short to long, tarsus relatively long. Colours and patterns varied; sexes alike or unlike. About 315 species almost cosmopolitan (absent from Oceania, East Indies, Madagascar, Antarctica; introduced in Australia, New Zealand) in all terrestrial habitats. Gregarious or solitary, terrestrial or arboreal birds; food mainly seeds, some other vegetable mat-

ter, insects. Call a simple chirp, often well-developed song; flight song rare. Family includes buntings, juncos, towhees, grosbeaks, cardinals, longspurs, Darwin's finches, chaffinch, yellow hammer, most sparrows.

Family Carduelidae (goldfinches, siskins, rosefinches, redpolls, crossbills, bullfinches, hawfinches, canaries). Small to medium-sized, 10 to 25 cm (4 to 10 in.), with short, stout to slender pointed bills (mandibles crossed in one genus); gonys less than half length of upper bill. Wings somewhat rounded, medium length, 10th primary present but less than half length of 9th; tarsus relatively short. Colours variable but browns, reds, and yellows predominate; some streaked or mottled, some plain patterns; sexes alike or unalike. About 112 species in woodlands, brushlands, worldwide except Pacific Islands; introduced in Australia. Gregarious birds with strong, undulating flight. Eat seeds, buds, berries, some insects. Highly developed songs, sing in flight.

Family Estrildidae (waxbills, some finches). Small, 7.5 to 15 cm (3 to 6 in.), bill stout, short, pointed; gonys less than half the length of upper bill. Wings rounded, short to pointed, medium length; 10th primary present but almost vestigial; tarsus relatively short. Great variety of bright and somber colours and patterns; sexes alike or unalike. About 107 species; forest edges, clearings, grasslands, and marshes of Africa, southern Asia, East Indies, Australia, some South Pacific islands. Highly gregarious, active, ground feeders. Food: seeds, some berries, insects. Song poorly developed, weak chirps, chatterings, buzzes.

Family Ploceidae (weaverfinches). Small, stoutly built seed-eaters, mostly 10 to 25 cm (4 to 10 in.), a few long-tailed species to 50 cm (males only). Short, stout, conical, pointed bills; gonys less than half length of upper bill; rictal bristles lacking; tarsus relatively short. Wings short to long, rounded to pointed, 10th primary present, much reduced; tail short to very long. Colours, patterns widely varied; sexes alike or unalike. About 156 species in all terrestrial habitats, mainly in Africa, also in Eurasia, Madagascar, Malaysia; a few (*e.g.*, the house sparrow, *Passer domesticus*) widely introduced elsewhere. Usually gregarious; food mainly seeds, some other vegetable matter, insects. Harsh, monotonous voices, song poorly developed.

Critical appraisal. The classification of the Passeriformes is currently in a state of flux. Of the several major works on the order since 1950, no two have agreed on the sequence of families, and each author has proposed innovations of his own. Ornithologists who are principally concerned with arranging museum displays, preparing national lists, or studying avian biology in the field may regard any change in classification as an unnecessary and unmitigated nuisance, and a few such workers have tried to prevent further change by having avian taxonomy formally "standardized." An attempt to do so at the XIVth International Ornithological Congress in 1966 failed in part because taxonomists opposed it vigorously and in part because its proponents could not agree on which of the several passerine sequences currently in use should be adopted.

Difficulties in preparing a lineal sequence

A main difficulty with any lineal sequence is the impossibility of making it reflect evolution's three-dimensional development, and it will be many years before enough evidence is in to satisfy all taxonomists. Most taxonomists place adjacent in the linear order those groups that they believe to be most closely related, but if three groups are believed to be equally interrelated, no linear sequence can express the relationship. The simplest solution for those who want a rigid, nonvarying sequence is to list all families alphabetically, and under each the genera and species alphabetically in turn. Even this system, which of course gives no indication of relationships, is not foolproof, for all scientific names are subject to change through the laws of priority as well as by inevitable changes in various taxa as more is learned about them. Hence it seems far better to retain the systems currently in use, leaving them fluid enough to be changed when changes are shown justifiable.

Since the late 19th century, when the many advances in taxonomic thought of the previous century began to crystallize and bear fruit, three main passerine sequences have dominated the world bird lists. The first, proposed originally by R.B. Sharpe of the British Museum in 1877, but based in part on the published and unpublished work of others, places the crows at the summit of avian evolution (hence at the end of a modern lineal sequence), ostensibly (although never so stated directly) on the basis of their alleged high intelligence. This sequence was adopted by the German ornithologist Ernst Hartert in his monumental *Die Vögel der paläarktischen Fauna*, published in 1903, and subsequently by most other European ornithologists.

The second sequence, placing the thrushes at the end, was in general usage, particularly in North America, until the late 1920s.

The third sequence, originally proposed in 1926 by two Americans, Alexander Wetmore and Waldron DeWitt Miller, but also based partly on the earlier work of others, places the crows, actually a rather generalized group, near the base of the oscine family tree, and in top place puts the so-called nine-primaried oscines, dominated by the seed-eating fringillids, because, as Wetmore explained in a 1960 paper (*A Classification for the Birds of the World*),

> this group is the modern expression of a main core or stem that through the earlier Tertiary periods has given rise to more specialized assemblages. . . . Further specialization is apparent in some parts of the existing fringilline assemblage that, if undisturbed, may lead to further differentiation.

This sequence immediately became standard for North American works and has remained so for these and certain international lists ever since, with only minor departures and rearrangements.

Within the suboscines, research is beginning to suggest that the three Old World families long included within the suborder Tyranni should be removed, leaving that suborder purely New World in distribution. It has been suggested that the asities (Philepittidae) may be more closely related to the broadbills, with which they share some features of the syrinx and sternum, than to the New World tyrannoid groups. The relationships of the asities, pittas, and New Zealand wrens will remain uncertain until further study can provide a better understanding of their biology and anatomy.

Nearly all recent classifications have grouped the eight to ten families of New World suboscines in a suborder, Tyranni, based on syringeal features studied by the 19th-century anatomist A.H. Garrod. An American ornithologist, P.L. Ames, following a re-examination of the syringeal anatomy, suggested in 1965 that one superfamily of the suborder, Furnarioidea (the antbird–ovenbird group), should not be united to the other, Tyrannoidea (tyrant flycatchers and allies), on the basis of the syrinx but should be elevated to subordinal rank, a view supported by features of the pterylosis and sternal and cranial osteology. This suggestion, made initially in 1907 by a British anatomist, W.P. Pycraft, but without supportive evidence, was taken up in a classification by R.W. Storer in 1971 (see the Table).

As more suboscines are studied in detail, some genera may be found to have been misclassified; particularly vulnerable are certain forms in the woodcreeper–ovenbird (Dendrocolaptidae–Furnariidae), antbird–tapaculo (Formicariidae–Rhinocryptidae), and cotinga–manakin–flycatcher (Cotingidae-Pipridae-Tyrannidae) complexes. A group of small South American ground birds known as gnateaters and antpipits was separated from the antbirds in 1882 as a family, Conopophagidae, and generally recognized for nearly 90 years. Careful study in 1968, however, revealed that the family was an artificial one; one genus (*Conopophaga*) has been returned to the Formicaridae, the other (*Corythopis*) placed in the Tyrannidae. Recent studies of egg white proteins by American biologist C.G. Sibley and colleagues suggest that the palm chat (*Dulus*) may be closer to the weaverfinches than to the waxwings; that the Cape sugarbird (*Promerops*) may be a starling rather than a honeyeater; and that the phainopepla (*Phainopepla*) may be most closely related to the solitaires (*Myadestes*), which are currently placed in the thrush family. A number of widely accepted oscine families invite similar examination. Only additional study will solve these problems and (hopefully) provide a better understanding of the position of aberrant genera, such as *Rupicola* and *Menura*.

Comparison of Systems of Passeriform Classification

Encyclopaedia article	Wetmore, 1960	Peters Checklist	Storer, 1971
Order Passeriformes	**Passeriformes**	**Passeriformes**	**Passeriformes**
Suborder Eurylaimi	*Eurylaimi*	*Eurylaimi*	*Eurylaimi*
Family Eurylaimidae (broadbills)	Eurylaimidae	Eurylaimidae	Eurylaimidae
Suborder Tyranni	*Tyranni*	*Tyranni*	*Furnarii*
Superfamily Furnarioidea	Furnarioidea	Furnarioidea	
Family Dendrocolaptidae (woodcreepers)	Dendrocolaptidae	Dendrocolaptidae	Dendrocolaptidae (incl. Furnariidae)

Estrildidae (waxbills)		Paradisaeidae	
Ploceidae (weaverfinches)		Corvidae	

Within the oscines, one of the greatest problems is a satisfactory delineation and arrangement of the many superficially similar groups. Most taxonomists agree that the oscines contain three large groups (see the Table): (1) the crows, Old World orioles, birds of paradise, and allies; (2) the thrushes, babblers, Old World flycatchers, Old World warblers, kinglets, and allies; and (3) the finches, icterids, tanagers, and allies. Authorities disagree on how to subdivide these groups into "manageable" sections, precisely where to draw the lines between

some families, and even whether to assign them familial or lesser taxonomic rank. Other groups, currently assigned family rank, are still of moot affinities and defy all efforts to place them in a linear sequence completely acceptable to everyone; among these are the larks, swallows, titmice, wrens, dippers, mimid thrushes, honeyeaters, waxwings, and the palm chat.

As present-day students are delving more deeply into and reassessing the anatomical evidence on which most passerine families were erected a century ago, they are finding that much oscine classification was based originally on a few basic characters, weighted too strongly by the opinions of individual taxonomists. Bringing to bear such existing new lines of evidence as ethology, serology, parasitology, and protein analysis is helping to clear some of the long unchallenged beliefs that have clouded the main issues. Hopefully these developments will encourage taxonomists to abandon some of their tenacious opinions—*e.g.*, that the crows represent the apex of passerine evolution. They should then be able to draw familial lines at the point at which the evidence indicates they should be, regardless of the relative size of each group.

BIBLIOGRAPHY. General works, written in a popular style, containing a wealth of information on the biology of passerines, include O.L. AUSTIN, JR., *Birds of the World* (1961) and *Families of Birds* (1971); JAMES FISHER and R.T. PETERSON, *The World of Birds* (1964); and E.T. GILLIARD, *Living Birds of the World* (1958). Some regional faunal works contain much information on passerines. For the Eurasian region, see D.A. BANNERMAN, *The Birds of the British Isles*, vol. 6–12 (1957–63); CHARLES VAURIE, *The Birds of the Palearctic Fauna: A Systematic Reference, Order Passeriformes* (1959); H.F. WITHERBY *et al.*, *The Handbook of British Birds*, 5 vol. (1938–41). For tropical Asia, see E.C. STUART BAKER, *The Fauna of British India, Including Ceylon and Burma*, vol. 1–4 (1922–27); SALIM ALI and S.D. RIPLEY, *Handbook of the Birds of India and Pakistan, Together with Those of Nepal, Sikkim, Bhutan and Ceylon*, vol. 4 ff. (1970–); A.L. RAND and E.T. GILLIARD, *Handbook of New Guinea Birds* (1968); B.E. SMYTHIES, *The Birds of Burma* (1940) and *The Birds of Borneo* (1960). For Australasia, see G.M. MATHEWS, *The Birds of Australia*, 12 vol. (1910–26); D.L. SERVENTY and H.M. WHITTELL, *Birds of Western Australia*, 3rd ed. (1962); W.R.B. OLIVER, *New Zealand Birds*, 2nd ed. rev. (1955); ERNST MAYR, *Birds of the Southwest Pacific* (1945); J.E. DU PONT, *Philippine Birds* (1972). For Africa, see D.A. BANNERMAN, *The Birds of Tropical West Africa*, 8 vol. (1930–51) and *The Birds of West and Equatorial Africa*, 2 vol. (1953); J.P. CHAPIN, "The Birds of the Belgian Congo," *Bull. Am. Mus. Nat. Hist., 65, 75*, 4 pt. (1932–54); C.W. MACKWORTH-PRAED and C.H.B. GRANT, *Birds of Eastern and North-eastern Africa* (1955) and *Birds of the Southern Third of Africa* (1963). For North America, see A.C. BENT, "Life Histories of North American Birds . . . ," 8 *Bulletins* of the United States National Museum (1942–68); E.H. FORBUSH, *Birds of Massachusetts and Other New England States*, vol. 2–3 (1927–29); I.N. GABRIELSON and F.C. LINCOLN, *The Birds of Alaska* (1959); W.E. GODFREY, *The Birds of Canada* (1966); and volumes on birds of individual states. For the Caribbean and Central and South America, see ALEXANDER WETMORE and B.H. SWALES, "The Birds of Haiti and the Dominican Republic," *Bull. U.S. Natn. Mus. 155* (1931); JAMES BOND, *Birds of the West Indies*, 2nd ed. (1971); R. MEYER DE SCHAUENSEE, *The Birds of Colombia, and Adjacent Areas of South and Central America*, 2nd ed. (M.H.C./O.L.A.)

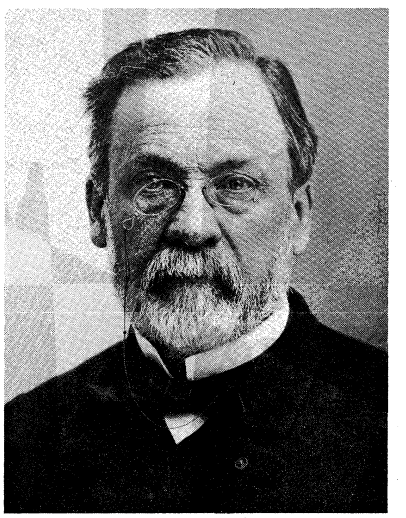
Pasteur, Louis

The scientific contributions of Louis Pasteur, French chemist and microbiologist, were among the most varied and valuable in the history of science and industry. It was he who proved that micro-organisms cause fermentation and disease; he who originated and was the first to use vaccines for rabies, anthrax, and chicken cholera; he who saved the beer, wine, and silk industries of France and other countries; he who performed important pioneer work in stereochemistry; and he who originated the process known as pasteurization.

Archives Photographiques



Pasteur.

Born December 27, 1822, at Dole in eastern France, Pasteur was the descendant of generations of tanners. His great-grandfather had been an indentured labourer who had purchased his freedom. In his youth Pasteur showed little interest in anything but drawing and produced a number of pastels, portraits of his parents and friends. After attending primary and secondary schools in Arbois where his family had moved, and then in Besançon, Pasteur earned his *bachelier ès lettres* (bachelor of arts) in 1840 and *bachelier ès sciences* (bachelor of science) at the Royal College in Besançon in 1842. The following year he was admitted to the École Normale Supérieure, the famous teachers' college in Paris. He became *licencié ès sciences* (master of science) in 1845 and after acquiring an advanced degree in physical sciences, he won his *docteur ès sciences* (doctor of philosophy) in 1847. On May 22, 1848, at the age of 26, he presented before the Paris Academy of Sciences a paper reporting a remarkable discovery he had just made—that certain chemical compounds were capable of splitting into a "right" component and a "left" component, one component being the mirror image of the other. His discoveries arose out of a crystallographic investigation of tartaric acid, an acid formed in grape fermentation that is widely used commercially, and racemic acid—a new, hitherto unknown acid that had been discovered in certain industrial processes in the Alsace region. Both acids not only had identical

Stereochemical investigations

chemical compositions but also had the same structure; yet they showed marked differences in properties. The German chemist Eilhardt Mitscherlich (1794–1863) had shown that while ordinary commercial tartaric acid affects the rotation of plane polarized light, the unknown acid had no such effect. With the help of his own chemical methods Pasteur supplied the clue to this enigma by showing that the salts of the racemic acid consisted of two types of crystals that were mirror images of one another (like right- and left-hand gloves). When separated the two types of crystals rotated plane polarized light to the same degree but in opposite directions (one to the right, or clockwise, and the other to the left, or counterclockwise). One of the two crystal forms of racemic acid proved to be identical with the tartaric acid of the fermentation. As Pasteur showed further, one component of the racemic acid (that identical with the tartaric acid from fermentation) could be utilized for nutrition by micro-organisms, whereas the other, which is now termed its optical antipode, was not assimilable by living organisms. On the basis of these experiments, Pasteur elaborated his theory of molecular asymmetry, showing that the biological properties of chemical substances depend not only on the nature of the atoms constituting their molecules but also on the manner in which these atoms are arranged in space.

In 1848 Pasteur was appointed professor of physics at the Dijon Lycée (secondary school) but was shortly called to the University of Strasbourg as professor of chemistry. There, on May 29, 1849, he married the daughter of the rector of the university, Marie Laurent, by whom he was to have five children, only two of whom survived childhood.

In 1863 Pasteur became dean of the new science faculty at the University of Lille, where he initiated a highly modern educational concept: by instituting evening classes for the many young workmen of the industrial city, conducting his regular students around large factories in the area, and organizing supervised practical courses, he demonstrated the relationship that he believed should exist between theory and practice, between university and industry. At Lille, after receiving a query from an industrialist on the production of alcohol from grain and beet sugar, Pasteur began his studies on fermentation. In the course of his analysis he once again encountered—though in liquid form—new "right" and "left" compounds. From studying the fermentation of alcohol he went on to the problem of lactic fermentation, showing yeast to be an organism capable of reproducing itself, even in artificial media, without free oxygen—a concept that became known as the Pasteur effect.

Fermentation research

In 1857 he was named Director of Scientific Studies at the École Normale Supérieure. He continued his researches and announced that fermentation was the result of the activity of minute organisms and that when fermentation failed, either the necessary organism was absent or was unable to grow properly. Before this discovery, all explanations of fermentation had lacked experimental foundation; Pasteur showed that milk could be soured by injecting a number of organisms from buttermilk or beer but could be kept unchanged if such organisms were excluded.

He was elected to the Academy of Sciences in 1862, and the following year a chair at the École des Beaux-Arts was established for him for a new and original program of instruction in geology, physics, and chemistry applied to the fine arts.

As a scholar engaged in research, Pasteur eventually found his administrative duties as Director of Scientific Studies at the École Supérieure too irksome. He gave up the post in 1867 and, thanks to the support of Emperor Napoleon III, a laboratory of physiological chemistry was created for him at the same institution. As a logical sequel to his work on fermentation, he began research on spontaneous generation (the concept that bacterial life arose spontaneously), a question which at that time divided scientists into two opposing camps. Pasteur's recognition of the fact that both lactic and alcohol fermentations were hastened by exposure to air led him to wonder whether his invisible organisms were always present in the atmosphere or whether they were spontaneously generated. By means of simple and precise experiments, including the filtration of air and the exposure of unfermented liquids to the air of the high Alps, he proved that food decomposes when placed in contact with germs present in the air, which cause its putrefaction, and that it does not undergo transformation or putrefy in such a way as to spontaneously generate new organisms within itself.

After laying the theoretical groundwork, Pasteur proceeded to apply his findings to the study of vinegar and wine, two commodities of great importance in the economy of France; his pasteurization process, the destruction of harmful germs by heat, made it possible to produce, preserve, and transport these products without their undergoing deterioration.

Pasteurization

In 1865 he undertook a government mission to investigate the diseases of the silkworm, which were about to put an end to the production of silk at a time when it comprised a major section of France's economy. To carry out the investigation, he moved to the south of France, the centre of silkworm breeding. Three years later he announced that he had isolated the bacilli of two distinct diseases and had found methods of preventing contagion and of detecting diseased stock.

In 1870 Pasteur devoted himself to the problem of beer. Following an investigation conducted both in France and among the brewers in London, he devised, as he had done for vinegar and for wine, a procedure for manufacturing beer that would prevent its deterioration with time. British exporters, whose ships at the time had to sail entirely around the African continent, were thus able to send British beer as far as India without fear of its deteriorating.

Although Pasteur was partially paralyzed in 1868 and applied for retirement from the university, he continued his researches. In 1873 he was elected a member of the Academy of Medicine, and in 1874 the French Parliament provided him with an award that would ensure his material security while he pursued his work.

When, in 1881, he had perfected a technique for reducing the virulence of various disease-producing microorganisms, he succeeded in vaccinating a herd of sheep against the disease known as anthrax. Likewise, he was able to protect fowl from chicken cholera, for he had observed that once animals stricken with certain diseases had recovered, they were later immune to a fresh attack. Thus by isolating the germ of the disease and by cultivating an attenuated, or weakened, form of the germ and inoculating fowl with the culture, he could immunize the animals against the malady. In this he was following the example of the English physician Edward Jenner in his method for vaccinating animals against cowpox.

On April 27, 1882, Pasteur was elected a member of the Académie Française, at which point he undertook research that proved to be the most spectacular of all—the preventive treatment of rabies. After experimenting with inoculations of saliva from infected animals, he came to the conclusion that the virus was also present in the nerve centres, and he demonstrated that a portion of the medulla oblongata of a rabid dog when injected into the body of a healthy animal produced symptoms of rabies. By further work on the dried tissues of infected animals and the effect of time and temperature on these tissues, he was able to obtain a weakened form of the virus that could be used for inoculation. Having detected the rabies virus by its effects on the nervous system and attenuated its virulence, he applied his procedure to man; on July 6, 1885, he saved the life of a nine-year-old boy, Joseph Meister, who had been bitten by a rabid dog. The experiment was an outstanding success, opening the road to protection from a terrible disease. In 1888 the Pasteur Institute was inaugurated in Paris for the purpose of undertaking fundamental research, prevention, and treatment of rabies. Pasteur, although in failing health, headed the institute until his death on September 28, 1895.

Assessment

Louis Pasteur brought about a veritable revolution in the 19th-century scientific method. By abandoning his laboratory and by tackling the agent of the disease in its

natural environment, he was able through his investigations to supply the complete solution to a given question, not only identifying the agent responsible for a disease but also indicating the remedy.

A skillful experimenter, endowed with a great curiosity and a remarkable gift of observation, Pasteur devoted himself with immense enthusiasm to science and its applications to medicine, agriculture, and industry. He was prompt to defend his ideas with courage and often with considerable harshness—in writings as well as in speech—toward his opponents. It was chiefly in his work on spontaneous generation and on rabies that he encountered the strongest opposition to his ideas (which were, for the time, revolutionary) from medical circles and a section of the press. He was happy to accept the glory and honours that came his way, for he was well aware of his own value and of his scientific successes. A great friendship developed between Pasteur and the renowned British surgeon Sir Joseph Lister (1827–1912), who was quick to apply to his own discipline the discoveries of his eminent French colleague.

ROUX, "L'oeuvre médicale de Pasteur," in *Centième Anniversaire* (1922), a very interesting work written by one of Pasteur's collaborators; R. VALLERY-RADOT, *Histoire d'un savant par un ignorant* (1884), a very interesting work written by Pasteur's son-in-law, who was also his secretary, and *La vie de Pasteur* (1899; Eng. trans., 1960), a fundamental work on the life of Pasteur, but weak from the scientific point of view.

(J.M.R.N.)

Patagonian Desert

The Patagonian Desert covers the greater part of the region of Patagonia, that is to say, nearly all of the southern portion of mainland Argentina. With an area of about 260,000 square miles (673,000 square kilometres), it is the largest desert in the Americas, extending from latitudes 37° S to 51° S. It is bounded, approximately, by Andean Patagonia (the southern extension of the Andes mountains) to the west; by the Río Colorado to the north, except where the desert extends beyond the river into the borderlands of Mendoza and La Pampa provinces; by the Atlantic Ocean to the east; and by the Río Coig to the south. The desert thus covers most of the provinces of Neuquén, Río Negro, Chubut, and Santa Cruz; some geographers also include the area north of the island of Tierra del Fuego, which lies at the southern tip of South America and is divided between Argentina and Chile.

Origin of the name

The name Patagonia is derived from the Patagones, as the original inhabitants were called by Spanish explorers in the 16th century. It appears that Ferdinand Magellan, the Portuguese navigator and first European to reconnoitre the coast in that era, coined that name because the natives, with their thick furs, bushy hair, and painted faces, reminded him of Patagon, a dog-headed monster of the Spanish 16th-century romance *Amadís de Gaula.* The phrase *Patagonia, tierra maldita* ("Patagonia, land accursed") is proverbial. For an associated physical feature, see ANDES MOUNTAIN RANGES.

Landscape and environment. *Relief.* The desert covers the Patagonian tableland that extends from the Andes to the Atlantic Ocean. The general aspect of the tableland is one of vast steppelike (virtually treeless) plains, rising terrace fashion from high coastal cliffs to the foot of the Andes; but the true aspect of the plains is by no means as simple as such a general description would imply. Along the Río Negro, the land rises in a series of fairly level plains from about 300 feet (90 metres) at the coast to about 1,300 feet at the junction of the Limay and Neuquén rivers and 3,000 feet at the base of the Andes. The tableland region rises to an altitude of 5,000 feet. South of the Río Negro, the plains are much more irregular; volcanic eruptions have occurred in this area down to fairly recent times. Basaltic sheets, apparently only recently cooled, cover the tableland east of lakes Buenos Aires and Pueyrredón. On the Chico and Santa Cruz rivers, the plains have spread to within about 50 miles (80 kilometres) of the coast and reach almost to the coast south of the Coig and Gallegos rivers. In places, basaltic massifs (mountainous masses) are the salient features of the landscape.

The coast consists largely of high cliffs separated from the sea by a narrow coastal plain. Thus, the plateaus are formed of horizontal strata, some of sedimentary rocks, others of lava flows. Areas of hilly land, composed of resistant crystalline rocks, stand above the plateaus.

Rivers and lakes

Drainage. The deep, wide valleys bordered by high cliffs that cut the tablelands from west to east are all beds of former rivers that flowed from the Andes to the Atlantic, but only a few now carry permanent streams of Andean origin (the Colorado, Negro, Chubut, Senguerr, Chico, and Santa Cruz). The majority either have intermittent streams such as the Shehuen, Coig, and Gallegos, which have their sources east of the Andes, or, like the Deseado, are completely dry, except for salt ponds in the deeper depressions, and so altered by the combined effect of wind and sand as to afford little surface evidence of the rivers that once flowed in them. They serve an important purpose in the collection of the scanty surface water. Alluvial soils of considerable depth have been built up in them.

The line of contact between the Patagonian tableland and the folds of the Andes is marked by a chain of lakes, their upper ends deep in mountain canyons, their lower ends held in by glacial moraines.

From Lago Nahuel Huapí northward, the lakes—except for Lago Lácar—still drain to the Atlantic. South of Lago Nahuel Huapí, all of the lakes except Viedma and Argentino now drain to the Pacific through deep canyons cut across the Andean cordillera.

Climate. Patagonia is influenced by the South Pacific air current, which brings humid winds from the ocean to the continent. The winds, however, lose their humidity as they blow over the west coast of South America and over the Andes and are thus quite dry when they reach the Patagonian Desert.

The two climatic zones

Climatologically, the Patagonian Desert can be divided into two main zones, the northern and the southern, by a line drawn from the western half of Neuquén province to a point just south of the Península Valdés in northeastern Chubut province.

The northern zone, semi-arid, has annual mean temperatures between about 54° and 68° F (12° and 20° C); recorded maximum temperatures vary between about 106° and 113° F (41° and 45° C), and minimum temperatures vary between 12° and 23° F (−5° and −11° C). Sunshine, minimal along the coast, is most plentiful inland to the northwest. The rainfall varies from 3.5 to 17 inches a year. The prevailing winds, from the southwest, are dry, cold, and strong.

The climate of the southern zone of the Patagonian Desert is sharply distinct from the humid one of the Andean cordillera. In the north of this zone, the influence of the Atlantic is practically nonexistent—probably because of the heights of the coastal region (which reach 900 to 1,800 feet around the Golfo San Jorge)—although cold winds coming from the west and the cold Falkland Current both make themselves felt. In the southern part, which is practically peninsular, the Atlantic exerts some influence. The zone has a cold, dry climate, with temperatures that are higher along the coast than they are inland and with strong west winds. Mean annual temperatures range from 43° to 55° F (6° to 13° C), with maximum

temperatures at about 108° F (42° C), and minimum temperatures between 16° and −27° F (−9° and −33° C). There are heavy snows in winter and frosts throughout the year; and spring and autumn are so short that summer and winter are the only seasons worth counting. Average annual precipitation (rain and snow) ranges between about 4.5 and eight inches, though as much as 18.5 inches has been recorded. In the central areas of the desert there is less precipitation, and there is more sunshine than on the coast or in the Andean cordillera.

Vegetation and animal life. Whereas the long, narrow strip of Patagonia's western border has a vegetation like that of the adjacent cordillera, the arid region of the Patagonian Desert comprises two zones, each with its own characteristic vegetation.

The northern zone includes most of Neuquén province, most of Río Negro province, and the northeasternmost part of Chubut. About 84,000,000 acres (34,000,000 hectares) in area, it consists of open bushland, covered with widely spaced thickets between about three and seven feet high. Grasses flourish in the sandy areas, while salt-tolerant grasses and shrubs predominate in the salt flats. In irrigated areas profitable crops can be grown; these include peaches, plums, damsons, almonds, apples, pears, olives, grapes, hops, dates, vegetables, aromatic plants, and alfalfa. In the north, the zone merges into one of wooded steppe.

Crops of the irrigated areas

The second zone, covering the southwesternmost parts of Neuquén and Río Negro provinces, three-quarters of Chubut, and nearly all Santa Cruz province, has an area of 116,000,000 acres. The vegetation is low and very sparse and needs almost no water.

Among the birds of the desert are herons and other waders; predators such as the shielded eagle, the sparrow hawk, and the chimango (beetle-eater); and the almost extinct ñandú, or choique, a flightless bird similar to the African ostrich but not so tall.

The typical marsupial (animal having a pouch for carrying young) of the desert is the comadreja (a member of the weasel family). Species of bats include a long-eared variety. Armadillos, pichis (small armadillos), foxes, ferrets, skunks, mountain cats, and pumas are to be found, as also are maras, or Patagonian hares, and different kinds of burrowing rodents, such as the vizcacha and the tuco-tuco. Of the larger mammals, the most interesting is the guanaco, a kind of llama, hunted almost to extermination. There are a number of poisonous snakes as well as tortoises and lizards.

Vinchucas (winged bugs), bloodsucker insects (transmitters of American trypanosomiasis, or Chagas' disease), scorpions, and 14 kinds of spiders (including one kind called *Mecysmanchenius*, not found elsewhere) are also to be encountered.

The rivers and lakes are poor in fish, but sea fish and crustaceans and mollusks are plentiful off the coast.

The Patagones

Population. The original inhabitants of Patagonia seem to have been Indians from Tierra del Fuego. The most ancient artifacts, such as harpoons, found in the caves along the Strait of Magellan suggest that these people were moving up the mainland coast about 5,100 years ago. Robust and very tall, they constituted the two principal ethnic groups of Patagones—the Puelche-Guennakin in the north, and the Chonik or Tehuelche in the south. The surviving descendants of these Patagones, namely the Yámanes and the Alacalufes, are few in number; a kindred people, the Chono, died out in recent times. The Spanish explorers found the Patagones living as nomadic hunters of guanaco or of ñandú.

Toward the end of the 16th century the Spaniards attempted to colonize the Patagonian coastal region to clear it of English pirates; but a Jesuit settlement on the Golfo San Matías came to nothing. In 1778, however, the English tried to settle on the same bay, and the Spaniards reacted by founding Patagonia's first two towns, San José and Viedma (originally named Nuestra Señora del Carmen). A Spanish settlement at Puerto Deseado lasted from 1780 to 1807; but three years later this region was again devoid of European settlement.

After Argentina became independent, an attempt was made to populate Patagonia to make it part of the national state. Immigration, however, was not massive, though people came for various reasons: some to exploit the economic resources, others (for instance, the Welsh) to enjoy religious or political liberties. By the 1970s most of the immigrants were Chileans seeking temporary work rather than a fixed domicile. Such transitory immigrants form about 20 percent of the population. Apart from major concentrations at Comodoro Rivadavia and in the towns strung out along the upper valley of the Río Negro, Patagonia's sparse population is mostly rural.

Natural resources and their exploitation. Oilfields around Comodoro Rivadavia, Plaza Huincul, and Catriel are Patagonia's most conspicuous asset, apart from the great deposits of ore at Sierra Grande in Río Negro province, which supply all Argentina with iron. Río Negro province also has deposits of manganese, wolfram (or tungsten), fluorite (calcium fluoride, used as a flux in metallurgy), lead, and heavy spar (barite, the principal ore of barium); Neuquén province has deposits of copper and gold, vanadium (used to toughen steel), and zinc-lead; Chubut province has uranium and manganese in moderate quantities. There are also deposits of kaolin and gypsum.

Hydroelectric development

To exploit the hydroelectric potential of the Neuquén and Limay rivers, construction of a generating station to produce an estimated 1,650,000 kilowatts—the future centre of the El Chocón–Cerros Colorados complex—has been begun and is scheduled for completion by 1978. The project is also designed to irrigate the Comahue region, thus promoting farming and industry.

Transport. Argentina's National Route No. 3 runs for more than 1,860 miles from Buenos Aires and Bahía Blanca through the Patagonian coastal region southward to Comodoro Rivadavia. The roads of the desert proper, however, are few and of poor quality. Four railroads run east–west from the coastal region; two, which reach the foothills of the Andean cordillera, are connected with the Bahía Blanca–Buenos Aires line. Air services are based chiefly on the towns of the coastal region.

The chief ports are Rawson, Deseado, Santa Cruz, and Río Gallegos (south of the Río Coig); San Antonio Este, Puerto Madryn, Camarones, and San Julián, all on protected bays; and Comodoro Rivadavia, an outlet for petroleum products. San Antonio Este and Puerto Madryn are being developed for overseas traffic.

The economic potential

Prospects. The development of the Neuquén and Limay rivers has already been mentioned; the potential energy of other rivers could also be exploited. Better roads and a co-ordinated policy for the ports are also desirable. Fisheries could be organized on an economic basis. The wool trade, however, requires protection against unfavourable trends in the international market. The clay deposits of Neuquén province, on the Meseta de la Barda Negra, around Picún Leufú, and around Cerro Bandera, could provide the basis for a ceramics industry; an aluminum plant at Puerto Madryn could process imported ores and also Patagonia's own aluminum minerals. Patagonia's oilfields are capable of greater production.

It is also to be noted that the Patagonian Desert region, in general, and its arid subregion, in particular, are in the process of expanding. This is due to the destruction of the vegetational cover by animals pastured on the land, which in turn leads to erosion (gullying). Because of the lack of control over the land being used for pasture, the advance of this destruction is rapid.

BIBLIOGRAPHY. ANSELM WINDHAUSEN, "The Birth of Patagonia," *Rev. Soc. Arg. Geol.*, vol. 2 (1947), is a relatively nontechnical article on the geological history of Patagonia, with emphasis on the more prominent geological stratifications and tectonic events that led to the present configuration of the region. On the general structure, see A.D. YGOBONE, *Planificación general de la Patagonia* (1947).

(E.F.G.D.)

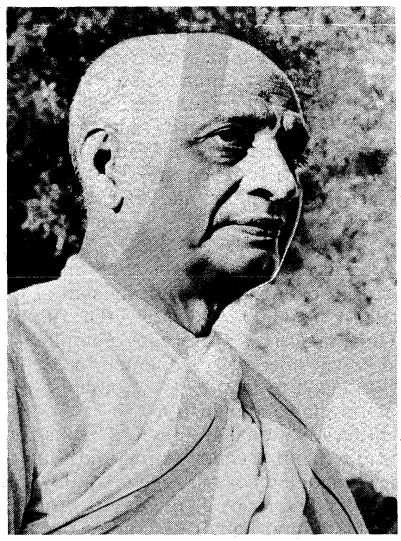
Patel, Vallabhbhai Jhaverbhai

Vallabhbhai Jhaverbhai Patel, barrister and statesman, stood in the forefront leadership of the Indian National Congress in the struggle for Indian independence; as

home minister and deputy prime minister of independent India, he smoothed the integration of the Indian states and helped mold the Indian Union.

Patel was born in Nadiād, near Surat, in Gujarāt, India, on October 31, 1875, into a self-sufficient landowning family of the Leva Patidar caste, renowned for their assertiveness and resourcefulness. Reared in an atmosphere of traditional Hinduism, he attended primary school at Karamasad and high school at Petlād, but was mainly self-taught. In contrast to many of his fellow students, Patel was of strong constitution; he enjoyed athletics and expressed a self-confident and stubborn leadership.

By courtesy of the Information Service of India, London



Patel.

Legal career

He married at the age of 16, matriculated at 22, and passed the district pleader's examination, which enabled him to practice law. In 1900 he set up an independent office of district pleader in Godhra, and two years later he moved to Borsad, in Kheda District.

As a lawyer, Patel distinguished himself in presenting an unassailable case in a precise manner, and in challenging police witnesses and British judges. He was immune to flattery and aloof from servile Indian lawyers. In 1908 Patel lost his wife, who had borne him a son and daughter, and thereafter remained a widower.

Determined to enhance his career in the legal profession, Patel travelled to London in August 1910 to study at the Middle Temple. There he studied diligently and passed the final examinations with high honours.

Returning to India in February 1913, he settled in Ahmadābād, rising rapidly to become the leading barrister in criminal law at the Ahmadābād bar. Reserved and courteous, he was noted for his superior mannerisms, his smart, English-style clothes, and his championship in bridge at Ahmadābād's fashionable Gujarāt Club. He was, until 1917, indifferent to Indian political activities.

In 1917 Patel, like many other Indians at the time, found the course of his life changed after having been influenced by Mahatma Gandhi. Patel adhered to Gandhi's *satyāgraha* (policy of nonviolence) insofar as it furthered the Indian struggle against the British. But he did not identify himself with Gandhi's moral convictions and ideals, and he regarded Gandhi's emphasis on their universal application as irrelevant to India's immediate political, economic, and social problems. Nevertheless, having resolved to follow and support Gandhi, Patel changed his style and appearance. He quit the Gujarāt Club, dressed in the white cloth of the Indian peasant, and ate in the Indian manner.

From 1917 to 1924 Patel served as the first Indian municipal commissioner of Ahmadābād and was its elected municipal president from 1924 to 1928. Patel first made his mark in 1918, when he planned mass campaigns of peasants, farmers, and landowners of Kaira District, Gujarāt, against the decision of the Bombay government to collect the full annual revenue taxes despite crop failures caused by heavy rains.

In 1928 Patel successfully led the landowners of Bārdoli in their resistance against increased taxes. His efficient leadership of the Bārdoli campaign earned him the title *sardār* (leader), and henceforth he was acknowledged as a nationalist leader throughout India. He was considered practical, decisive, and even ruthless; and the British recognized him as a dangerous enemy.

Political philosophy

Patel, however, was no revolutionary. In the crucial debate over the objectives of the Indian National Congress during the years 1928 to 1931, Patel believed (like Gandhi and Motilal Nehru, but unlike Jawaharlal Nehru and Subhas Chandra Bose) that the goal of the Indian National Congress should be dominion status within the British Commonwealth—not independence. In contrast to Jawaharlal Nehru, who condoned violence in the struggle for independence, Patel ruled out armed revolution, not on moral but on practical grounds. Patel held that it would be abortive and would entail severe repression. Patel, like Gandhi, saw advantages in the future participation of a free India in a British Commonwealth, provided that India was admitted as an equal member. He emphasized the need to foster Indian self-reliance and self-confidence, but, unlike Gandhi, he did not regard Hindu–Muslim unity as a prerequisite for independence.

Patel disagreed with Jawaharlal Nehru on the need to bring about economic and social changes by coercion. A conservative rooted in traditional Hindu values, Patel belittled the usefulness of adapting Socialist ideas to the Indian social and economic structure. He believed in free enterprise, thus gaining the trust of conservative elements and thereby collected the funds that sustained the activities of the Indian National Congress.

Patel was the second candidate after Gandhi to the presidency of the 1929 Lahore session of the Indian National Congress. Gandhi shunned the presidency in an attempt to prevent the adoption of the resolution of independence and exerted pressure on Patel to withdraw, mainly due to Patel's uncompromising attitude towards the Muslims; Jawaharlal Nehru was elected. During the 1930 Salt Satyāgraha, Patel served three months' imprisonment. In March 1931 Patel presided over the Karāchi session of the Indian National Congress. He was imprisoned in January 1932. Released in July 1934, he marshalled the organization of the Congress Party in the 1937 elections and was the main contender for the 1937–38 Congress presidency. Again, because of Gandhi's pressure, Patel withdrew and Jawaharlal Nehru was elected. Along with other Congress leaders, Patel was imprisoned in October 1940, released in August 1941, and imprisoned once more from August 1942 until June 1945.

During the war Patel rejected as impractical Gandhi's nonviolence in the face of the then expected Japanese invasion of India. On the transfer of power, Patel differed with Gandhi in realizing that the partition of the subcontinent into Hindu India and Muslim Pakistan was inevitable, and he asserted that it was in India's interests to part with Pakistan.

Patel was the leading candidate for the 1945–46 presidency of the Indian National Congress, but Gandhi once again intervened for the election of Nehru. Nehru, as president of the Congress, was invited by the British viceroy to form an interim government. Thus, in the normal course of events, Patel would have been the first prime minister of India. During the first three years of independence, Patel was deputy prime minister, minister of home affairs, minister of information, and minister of states; above all his enduring fame rests on his achievement of the peaceful integration of the princely Indian states into the Indian Union and the political unification of India. He died in Bombay on December 15, 1950.

BIBLIOGRAPHY. D.V. TAHMANKAR, *Sardar Patel* (1970), provides the most comprehensive biography of Patel to date. MICHAEL BRECHER, *Nehru: A Political Biography* (1959), includes the best analysis of the confrontation between Nehru and Patel. V.P. MENON, *The Story of the Integration of the Indian States* (1956), highlights the role of Patel.

Patent Law

The word patent is derived from "letters patent," which earlier designated the document by which a sovereign conferred a privilege or right on someone. The name was a reference to the fact that the document, addressed to the public at large, was sealed with the great seal in such a way that the document could be unfolded and read without breaking the seal ("patent," from the Latin meaning "opened" or "exposed"). Modern usage of the term is confined primarily to grants of certain rights in inventions, and the solemn formalities of a royal grant generally no longer exist.

The patent of invention is a grant of specified rights by the government of a particular country. These rights generally consist in the exclusive right to make (that is, manufacture) and to deal with the subject matter of the patent for a limited period of time. A distinction must be drawn between the grant of the positive right to make and the grant of the right to exclude others from making. In older times probably both were usually intended, since restrictions existed on the freedom of anyone to engage in particular occupations. Modern development, however, has been toward the concept that only the right to exclude others is granted by the patent, since the patentee's own right to make and deal with the subject matter exists without any grant, subject to any superior rights of others or any applicable statutes.

The "exclusive" rights of patents

The right to exclude, conferred by the patent, is expressed in various ways and may differ somewhat in scope in the statutes of different countries. In the United States, for example, it is specifically expressed as "the right to exclude others from making, using or selling the invention." In the United Kingdom the granting document gives the patentee the sole right to "make, use, exercise and vend" the invention. Some statutes—*e.g.*, that of France in 1968—list specific acts, such as manufacturing, making use of, introducing into the country, selling, offering for sale, putting on the market, etc. Hence, the person granted the patent has a monopoly over the specific subject matter of the grant for a period of time.

The system of granting patents for inventions has developed with a complex of objectives including rewarding the inventor and thereby stimulating inventive activity; encouraging the disclosure of the subject matter so that the public will be in possession of the knowledge; and encouragement to produce the item. By having the exclusive right, the patentee is encouraged to manufacture and put the invention into use since he is free of competition for a time; and investment in such enterprises is also stimulated. And, incidentally, some competition in making inventions may be introduced.

HISTORY OF PATENTS

Italian origin of patents

Patents for inventions were first introduced in the 15th century in certain Italian states—the first known grant by a state to an inventor having occurred in the Republic of Florence in 1421 and an ordinance relating to patents having been enacted in Venice in 1474. The concept spread to other European states, and during the following two centuries the grant of invention patents became more and more common and regular. At first these grants were ordinarily made without any specific statutes on the subject but by virtue of the general authority and power of the ruler. In England, for example, Queen Elizabeth I issued grants relating to inventions, grants of exclusive rights and privileges regarding the importation and establishment of industries new to the realm, and monopoly grants relating to known commodities. Dissatisfactions over the monopoly grants led to the Statute of Monopolies of 1623, an act of Parliament that declared such grants to be unlawful but, as an exception, confirmed the authority to grant exclusive rights for new inventions for a term of 14 years. Thereafter, invention patents were granted fairly continuously in England (more so than in other European countries) under a general system developed by custom, rather than by statute.

First comprehensive patent statutes

Formal, comprehensive patent statutes did not appear until near the close of the 18th century—in the United States in 1790 and in Revolutionary France in 1791. The former was an expression of democratic action by the new republic and the latter a change from what had been a royal prerogative to one of the rights of man. The French statute of 1791 was explicit in declaring the natural right of an inventor to the exclusive right to his invention. In the United States it was necessary, when the individual states formed the union, to confer the authority to grant patents specifically upon the central government. The Constitution of 1787 gave to the Congress the power "to promote the progress of . . . the useful arts, by securing for limited times to . . . inventors the exclusive right to their . . . discoveries." In accordance with this provision, the first federal patent law was enacted. In the 19th century the enactment of specific statutes continued elsewhere. Early ones include those in the Netherlands (1809), Austria (1810), Russia (1812), Bavaria (1812), Prussia (1815), Sweden (1826), Spain (1826), two Canadian provinces (1823, 1826), Mexico (1832), Brazil (1840), Chile (1840), and even the Republic of Texas (1839) before it joined the United States. There was no general statute in Great Britain until 1852. Eventually, most of the individual German states enacted provisions for the granting of patents, and, after unification, the new Germany passed a general patent law (effective in 1877). The Sardinian patent law of 1859 was extended to the rest of Italy in stages as the country became unified from 1860 to 1870.

By the end of the 19th century a large number of countries had enacted patent laws and some had even revised earlier laws to improve them. At present there are about 100 independent jurisdictions having separate patent statutes. In addition, about 20 countries rely solely on the registration therein of a patent obtained in a specified other country; for most, this is the United Kingdom, of which they were formerly colonies, and about two dozen British colonies have patent ordinances that provide for registering British patents therein and, in some instances, for independent patents also. Only about a half-dozen countries have no patent law.

THE GRANTING OF PATENTS

Types of patents

The most common type of patent is one granted to an inventor for an invention or one granted to another person (including a "legal person" or corporation) who derives rights from the inventor. A "patent of addition" refers to an improvement on a patented invention; it is issued to the same patentee and expires with the main patent. So-called secret patents may be issued for inventions that are to be kept secret for purposes of national security, but usually in such cases the patent is withheld; the invention is simply kept secret. A small number of countries, including Germany, Italy, Japan, Spain, Poland, and the Philippines, provide for a kind of second-class patent for inventions of useful articles, referred to as a *Gebrauchsmuster* in Germany or, generally, as a utility-model patent. Its chief distinction is that its term is usually much shorter and processes and compositions may be excluded. Some countries provide for what are called confirmation, revalidation, or importation patents, whereby a person who has obtained a patent in a foreign country may more easily obtain a local patent. The chief advantage is that all the procedural efforts toward issuing the patent having already occurred, the second country can merely enter a record of the first patent. A number of former British colonies provide only for the recording of a British patent. It is possible in a few countries for one who is not the inventor or who did not derive the rights from the inventor to obtain a patent by importing the invention into the country; this is the case in the United Kingdom.

Inventors' certificates in Socialist countries

A different system exists in the U.S.S.R. and in several other Socialist countries (Albania, Bulgaria, China, Romania), which provides not only patents of the usual kind but also what are referred to as authors' or inventors' certificates. The author's certificate does not confer any exclusive rights to the invention but records the inventor's contribution, recognizes his authorship, and entitles him to receive some compensation for the use of the invention (if it is used) and also to receive some per-

quisites. Nationals of these countries obtain very few or no patents; and the right conferred by a patent, though it may be expressed in terms of exclusive rights, does not really have the same effect as in other countries because of the absence of private enterprise.

Subject matter for patents. The subject matter for which patents can be obtained, as has been stated, relates to inventions. In general, this includes practically every type of invention of an industrial character. Different statutes express the subject matter in various ways—in the United States as "any new and useful process, machine, manufacture, composition of matter or improvement thereof," and in the United Kingdom as "any manner of new manufacture" (with certain elaborations).

In a few countries, such as the United States, patents may also be granted for new and distinct varieties of plants, which the inventor, or discoverer, himself has asexually reproduced. Various items, such as scandalous or immoral matter, matter contrary to law, scientific principles, and so on, commonly cannot be patented; indeed, processes involving only mental steps are not ordinarily considered proper subject matter for patent at all. Some countries exclude the patenting of substances produced by chemical action and of medicines, although the process for making such substances can be patented and the patent would cover the product when made by the process. This type of exclusion was removed recently in Germany and in the Scandinavian countries, and its removal is finding greater support elsewhere. It does not appear in the laws of France, the United States, the United Kingdom, and many other countries.

Principle of novelty

To qualify for a patent, an invention must be new, and novelty is ordinarily defined by the statute. In most countries, if the invention has become known to the public (*e.g.*, by having been described in a printed publication, by having been put into public use or otherwise having become known to the public) before the application for patent is made, it is no longer considered novel and a valid patent cannot be obtained. In a few countries the inventor's own publication of his invention for a limited period of six months or a year is not considered derogatory to his rights. In only a few countries, too, is there a period within which any publicity relating to the invention will not defeat the right of an inventor to a patent. Usually, any prior use outside the country concerned, without printed publicity, is not considered as defeating novelty. In the United Kingdom all relevant events occurring outside the kingdom are disregarded.

Principle of inventive merit

In addition to the requirement for novelty, there has developed, primarily in the more industrialized countries, a further requirement of a somewhat subtle character concerning the "inventiveness," "unobviousness," or, in Germany, "inventive level" or "inventive height" in comparison with the "state of the art" or "prior art." In other words, the new subject matter must sufficiently advance the state of the art for a patent to be warranted.

The form of language proposed by the Council of Europe and coming into use in European countries is that an invention, to be patentable, must be new and "involve an inventive step," with the further definition that an inventive step is involved if the subject matter is "not obvious having regard to the state of the art." The intention of these provisions, of course, is to exclude slight or trivial changes and obvious changes from the protection of patents; however, the determination of adequate inventiveness has been one of the most difficult aspects of patent law and has involved the greatest number of conflicts of opinion.

Application for patents. In most countries the inventor or person (including companies) deriving the right from the inventor may apply for a patent; in the United States usually only the inventor may apply, although the patent may be granted to the assignee. The application for a patent must comply with the formal requirements of the country, including specified forms, documents, procedures, and fees. The application must contain a description of the invention so presented that it can be accomplished through its directions; and it must conclude with one or more statements referred to as "claims," which define the invention succinctly and serve to delimit the scope of the rights requested.

Formal requirements and filing dates

An application for patent must be directed to one invention, but several related inventions, linked by a single inventive concept or otherwise closely related and interdependent, may be permitted in the same application. Practices vary on this point. If the application violates the rules or practices relating to unity of invention, the applicant will be required to "divide" or "restrict" the application to but one invention.

The filing date of the application is important since, in general, it marks the point in time at which novelty of the invention must exist and also determines who obtains the valid patent in cases in which two or more different persons make application for the same invention. Although the filing date is controlling in most countries, a few countries, such as the United States, Canada, and the Philippines, permit recourse to the date of invention.

In general, applications for patent are maintained in confidence by the patent office until after the patent is granted, or at a certain stage in the proceedings, or after a certain time interval from the filing date of the application, as may be specified in the statute.

The practice of opening applications to public inspection at a certain time after the filing date, 18 months, was first followed in Australia and has spread to such countries as The Netherlands (1964), Denmark, Finland, Norway, and Sweden, Germany (1968), France (1969), and Japan (1970). In The Netherlands, Germany, and Japan, this practice was adopted as part of the deferred examination system referred to below. In these countries, as well as in France, the specification is issued in printed form at or about the same time; in the other countries, lists may be published, with the public then being able to inspect or obtain copies. The practice was adopted in the Scandinavian countries in view of the long period of pendency of applications before the patent is issued in order that domestic industry would not be taken by surprise. The applicant has provisional patent rights on the publication of his application, which become ineffective if a patent is not ultimately obtained.

Administrative procedure. Broadly, two main types of administrative procedures govern the granting of patents. Under the first system, called the registration system, if the application papers are deemed to be formally in order, the patent is granted in due course. Whether the patent complies with substantive provisions of the law is determined later by a court if the question arises, as in a suit on the patent. This system is followed in Belgium, Italy, Spain, Switzerland (except for certain classes of inventions), and a large number of other countries. In some countries there may be a refusal of a patent for reasons apparent on the face of the papers (that the invention is scandalous, for example) or an objection based on a charge of lack of unity. The French law of 1844 was the prototype of this system.

The registration and the examination systems

The United States adopted the French system in 1793, but a new patent law in 1836 introduced what is usually referred to as the examination, or pre-examination, system. This was adopted by Germany in 1877 and since then by many other countries. Under this system, an attempt is made in advance to determine whether or not the application complies with the substantive requirements for patents. An examiner searches through relevant prior patents, possibly including those of other countries, and publications available to him to determine whether or not the invention being claimed is, in fact, new and also whether or not the degree of novelty is sufficient to support a patent. The U.S., Germany, The Netherlands, Sweden, Austria, Japan, the U.S.S.R., and a few other countries make the fullest pre-examination in this respect. But even in these countries the examination cannot be exhaustive, and matters such as the existence of prior public use are not investigated before grant.

Typically, under the examination system, an examiner, after making a search of the prior art, writes to the applicant communicating the results and indicating whatever action is considered appropriate at that time. All or some claims may be indicated as not patentable (the precise

terminology and procedure differ according to different national laws), which means that a patent cannot be granted on the stated claims; and specific formal objections can be raised. If the decision is adverse in any respect, the applicant may present arguments and amendments (though in general new matter cannot be introduced) seeking to overcome the examiner's position. The application is then re-examined. There may be several of these exchanges of actions and responses. If the examiner concludes in the re-examination that all or some of the claims cannot be allowed, the applicant can appeal to a higher body—such as the patent office's board of appeals and then the courts (as in the United States) or to a federal patent court (as in West Germany).

The French system

Under a new French law that came into effect in 1969, a search of the prior art is made for the French office by the International Patent Institute (referred to below) and a report on the results made. The applicant may amend and comment on the report, and members of the public can also file statements, after which the patent office draws up a final report and issues the patent. There is no refusal of a patent even if the report is adverse, in strict conformity with traditional French principles, but the patent with its record is left to be adjudicated by the courts. The 1969 law also introduced a second type of patent, called a "utility certificate," which an applicant obtains at his own option; this patent does not involve a search and report, and its term is six years instead of 20.

Most countries employing the examination system carry out merely a limited examination, searching primarily only through their own prior patents; few countries have arrangements for obtaining the results of searches made in other countries. The chief reason for this is the formidable expenditure of time and effort involved in such full searches. A complex of documentation must be built up and maintained, and a staff of persons skilled in science and technology is needed to conduct the examinations. In the United Kingdom only a limited search and a limited examination are made through initial reluctance to give public officials too much authority.

In most examining countries (the United States and Canada excluded), when the examiner concludes that a patent may be granted, the application is published; and the public, during a period of generally three or four months, is given an opportunity to oppose the granting of the patent. In West Germany and some other countries, any person, regardless of his interest, may oppose; whereas in the United Kingdom the opposer must have an interest for so doing. But, in any event, the opposer can object on virtually any grounds and produce evidence additional to what the examiner had considered or could consider.

Systems of deferred examination

Because of the heavy workload and increasing backlog of applications, various schemes have been developed to alleviate or expedite the process of examination. In The Netherlands, a procedure introduced in 1964 represents an attempt to reserve examinations only for applications that prove to have enduring importance or interest. Under this system, an application is published 18 months after the filing date, and the applicant receives certain provisional rights. To maintain these rights he must pay an annual fee. At any time during a period of seven years after the filing date, the applicant may request initiation of the examination procedure, paying a special examination fee. If the seven-year period elapses, however, without any such request, the application is considered no longer pending, and the provisional rights disappear retroactively. In this manner, only those applications in which the applicant demonstrates a persistent interest are examined, and considerable work on the part of the patent office is saved. The deferred examination system was adopted in Germany in 1968 and in Japan in 1970. Other efforts to relieve procedural pressures, particularly with respect to the time required for searching, continue; the possibility of mechanical or computer searching, under study for some time, has as yet yielded inadequate results.

Publication of specifications. About two dozen countries that grant patents publish the specification (and drawings) in printed form—either some time during or before examination or at the time the patent is granted or shortly thereafter. These publications constitute a large body of published technology. Patent offices in some countries have put considerable effort into developing and maintaining classifications of this material so that it may be consulted not only by their official examiners but also by the public generally. Many countries exchange copies of their printed specifications, which enables them conveniently to build up their files. Most countries publish an official journal in which notices and other information relating to patents and allied subjects appear.

Term and maintenance fees. A patent is granted for a limited period of time that varies among different countries. The most common practice is for the patent to expire a certain number of years after the filing date—16 years in the United Kingdom, Australia, Ireland, New Zealand, and South Africa; 17 years in Denmark, Finland, Norway, and Sweden; 18 years in Germany and Switzerland; and 20 years in Belgium, France, Hungary, Israel, and a number of other countries. In some countries, however, the term is a specified number of years from the granting date (in the United States and Canada, 17 years; in Spain, 20 years; and in some other countries, 14 or 15 years) or from the date of publication of the application (in Austria, 18 years).

Renewal fees

A fee is required when an application is filed and, in general, at some later stage also. The large majority of countries (the United States and Canada excepted) require the payment of periodical fees to maintain a patent in force. These fees may become due beginning one, two, three, or four years from the filing date and annually thereafter. One result of the renewal-fee system is that patents in which the owner is no longer interested drop out of consideration as subsisting monopolies. If a renewal fee is not paid, the patent lapses, but usually a period of grace for late payment of a fee is provided; and in some countries (the United Kingdom for one) restoration of a lapsed patent is possible.

PATENTS AS PROPERTY

Patents constitute objects of intangible personal property, and this is expressly stated in some statutes. A patent can be transferred to another owner by assignment or passed to another by inheritance or bequest.

Licensing

The patentee may grant licenses to others to use his invention or discovery; this license, being a contract, is governed by the laws relating to contracts (see CONTRACTS, LAW OF). Customarily, the license is based upon royalty payments, though there may be some other consideration. Terms and conditions of various kinds can be included, but here violation of other laws, such as antitrust laws, must be avoided. A "tying clause," whereby the licensee is required to purchase materials and supplies from the licensor (patentee), may be illegal.

Patent infringement. Infringement of a patent consists in the unauthorized performance of any of the acts reserved for the patentee—such as manufacturing, using, and selling and, in some countries, other activities such as importing or stocking for trade. The laws of some countries—Germany, for example—specifically state that the activities must be for industrial or commercial purposes and that personal use of a patented invention for noncommercial purposes would not constitute infringement. When his exclusive rights have been infringed, the owner of the patent may file suit in the appropriate court and recover damages as well as obtain an injunction prohibiting future infringements. In some countries a criminal action may also be taken against the infringer, although this is not often done. The government may itself exercise the right to use the patented invention but with just compensation to the patentee; the latter may usually file suit in an attempt to adjust a compensation that he considers unsatisfactory.

The court, in a suit for infringement, may not only adjudicate the infringement question but also consider the validity of the patent itself. A few countries (West Germany, for example) separate the two questions: one court handles the infringement suit; the federal patent court considers the question of validity—in a separate suit to

revoke or nullify the patent. Specific actions in court to revoke a patent are possible in many countries. In the United Kingdom an interested party can seek revocation in the patent office itself during the first year after the patent is granted.

Working and compulsory licenses. In the 19th century, in most countries, the patentee was obliged to "work" his invention fairly continuously within a specified period, such as two or three years; if he did not, the patent became void or was revoked (provided the patentee offered no adequate excuse). "Working" meant either some measure of actual manufacture within the country or some public offer to grant licenses. Later, however, there developed a compromise procedure: the patent is not revoked for nonworking; it simply, after a specified period, becomes subject to the issuing of what are called *compulsory* licenses. If the invention has not been worked, then a qualified applicant may seek the award of a license from the patent office or a court. He must pay the patentee whatever royalties may be determined, and he cannot transfer his license to another. After two years, if the compulsory licenses themselves do not prove adequate to encourage production, the patent can finally be revoked for nonworking.

Compulsory licenses

Compulsory licenses serve a number of purposes. They may be intended to advance the public good, by making certain that an invention that is deemed useful is indeed used. Several countries—France, the United Kingdom, Canada, and the Philippines, for instance—specifically provide that medicines or inventions useful in preparing medicines be subject to compulsory licenses. The United States has such a provision for patents relating to atomic energy (though atomic weapons are not patentable at all). They may be provided for in cases of abuse of patent rights. Although the United States has no general law relating to working or compulsory licenses, the courts have used the device of compulsory licenses in deciding antitrust suits; a corporation judged monopolistic can be forced, as part of the remedy, to grant licenses to others. Finally, compulsory licenses are often issued to those who have dependent patents—patents, that is, that cannot be worked without using someone else's patent. A compulsory license is granted for the main patent so that the dependent one can be properly worked. Although it can be said that the frequency of recourse to the provisions of compulsory license laws is not very great, such laws may serve as safeguards.

In the United Kingdom, West Germany, and a few other countries, the patentee can file a declaration stating that he will grant licenses to anyone, whereupon his annual fees are reduced by half. Some countries contain a provision for the expropriation of a patent when required in the public interest, with the payment of compensation to the patentee. Such provisions are seldom, if ever, invoked, however.

INTERNATIONAL DEVELOPMENTS IN PATENT LAW

International Convention for the Protection of Industrial Property. Although there are a number of bilateral treaties on patent matters and a few treaties involving several countries, the most important general patent treaty is the International Convention for the Protection of Industrial Property, first signed in Paris in 1883 and coming into effect on July 7, 1884, between 11 countries. This treaty was revised at Brussels in 1900, at Washington in 1911, at The Hague in 1925, at London in 1934, and at Lisbon in 1958, each revision superseding the former version. A further revision at Stockholm in 1967 related mainly to organizational matters. By 1970 the number of participating countries had reached 78. The large increase in recent decades was due mainly to the adherence of newly established countries, but the normal increase continued as well, the U.S.S.R. adhering in 1965 and Argentina in 1967. Under the first article of the convention the countries constituted themselves a Union for the Protection of Industrial Property.

The convention establishes rights in industrial property —namely patents, designs, trademarks, unfair competition, and related matters—of the nationals (and residents) of the participating countries and in some respects has the aspect of international legislation on these subjects. One of the basic articles of the convention provides that the nationals (and residents) of each country enjoy in the other countries the same advantages that the other countries grant to their own nationals, without prejudice to any rights specially provided for by the convention.

Major provisions of the International Convention

One of the most important articles of the convention deals with what is called the "right of priority." By the operation of this provision, a person who has duly applied for a patent in one of the countries of the union and then, later, within 12 months, applies for a patent for the same invention in another of the countries can be considered to have applied in the second country on the earlier date. This article is important to inventors in view of the fact that in most countries publication of the invention before applying for a patent will defeat the right to a patent.

Other articles of the convention provide that patents obtained in the different countries of the union shall be independent of one another; that the inventor shall have the right to be named in the patent (this being important in those countries in which the owner, as distinguished from the inventor, may apply for the patent); that a period of grace shall be provided for the payment of the fees for maintaining a patent in force; that the use of an invention on board ships or on land vehicles or aircraft temporarily or accidentally in the territory of a country shall not be considered as infringing the rights of a patentee in that country, and so on. One article prescribes certain criteria that must be observed if a patent is to be revoked or if compulsory licenses are to be granted. The convention also includes provisions dealing with trademarks, trade names, and unfair competition.

Under the convention, a central office known as the International Bureau for the Protection of Industrial Property, located in Geneva and under the general supervision of the Swiss government, serves as a clearinghouse of information on patent and trademark laws and issues a monthly periodical in French and English, *La Propriété industrielle*, or *Industrial Property*, dealing with patents, trademarks, and related matters. It issues other publications, arranges and serves as the secretariat for international conferences and meetings, and engages in other activities relating to patents and trademarks. A similar bureau was established under the Berne Copyright Convention of 1886, which is administered jointly with the patent bureau—the combined administration being called the United International Bureaux for the Protection of Intellectual Property (BIRPI). The Stockholm Conference of 1967 also produced a new treaty establishing a World Intellectual Property Organization (WIPO), which entered into force in 1970. This new organization is to replace the earlier administrative framework and is somewhat wider in scope.

International Patent Institute

Another intergovernmental organization is the International Patent Institute (Institut International des Brevets) at The Hague, established in 1949 by agreement between Belgium, France, Luxembourg, and The Netherlands, with the object of maintaining a central place that would preserve documents and perform the function of making a search of the prior art for member countries. Since 1949, Monaco, Switzerland, Turkey, and the United Kingdom have also joined. At present the institute performs searching work for the Swiss, French, and Dutch patent offices. It also makes searches for private parties, for a fee.

Numbers of patents. The ten countries that in recent years have issued the greatest number of patents are, in alphabetical order, Belgium, Canada, France, Federal Republic of Germany, Italy, Japan, Switzerland, the Soviet Union (inventor's certificates), the United Kingdom, and the United States. The numbers for these countries range from 65,000 to 15,000 per year, though the numbers are not strictly comparable owing to the different systems. Countries issuing from 5,000 to 15,000 patents per year in recent years include Argentina, Australia, Austria, India, Mexico, South Africa, Spain, and

Sweden. Countries issuing from 1,000 to 5,000 include Brazil, Chile, Denmark, Finland, Greece, Hungary, Israel, Luxembourg, The Netherlands, New Zealand, Norway, Pakistan, Poland, Portugal, and Romania.

During the decade before World War II, the total number of patents granted by all countries averaged approximately 180,000 a year. This number decreased considerably during the war and the years immediately following, sinking to less than half; but by 1950 the number had risen again to above the prewar average. The increase continued sharply until by 1970 over 400,000 patents were being issued annually. The increase is attributable partly to a gradual increase in the total number of inventions being patented; but more largely it is due to the expansion in international patenting. Of the more than 400,000 patents issued in 1969, 40 percent were granted to residents of the countries issuing them and 60 percent to residents of other countries. Thus a large proportion of the 400,000 patents were simply duplications of the same essential invention patented in different countries. Whereas on the national level the increase in patent applications has led to attempts to ease the increasing burdens by changes in systems, on the international level there has been an attempt among countries to increase cooperation and develop various plans for curtailing the considerable duplication of effort.

International duplication of patents

International patents. The rights granted by a patent extend only within the territorial jurisdiction of the state granting the patent, and thus one who desires patent rights in a number of different countries must obtain a separate patent in each of them. The burden of obtaining international protection can become quite heavy.

Although the laws of some countries provide that under certain conditions a patent granted in another country may be registered and become effective without the usual patenting procedures, there is no international patent law—with one exception. In 1964, 13 French African countries concluded a treaty adopting a common patent law, with a single patent office issuing patents, each patent effective in all countries of the group. The countries—Cameroon, Chad, Central African Republic, Congo (Brazzaville), Dahomey, Gabon, Ivory Coast, Malagasy Republic, Mauritania, Niger, Senegal, Togo, and Upper Volta—maintain their common patent office at Yaoundé, Cameroon, and have a patent law that is nearly the same as the French law before the recent changes. The countries also provide for a common trademark registration.

The Council of Europe early considered the question of a common patent but decided first to take up problems involving the lack of uniformity in national laws. The first result, in 1955, was a treaty governing the formalities required in filing applications; it has since been adhered to by 18 countries, two outside Europe. Next, again in 1955, was a treaty providing for an international classification of patents (now adhered to by 15 countries and also adopted by others). Third was a Convention on the Unification of Certain Points on Substantive Law on Patents for Inventions, signed in 1963 by 11 countries, which envisioned uniform provisions relating to the subject matter for patents and to such substantive conditions of patentability as novelty and inventiveness. Although this treaty never went into effect, it influenced several countries to enact laws following its provisions.

After World War II, the Scandinavian countries, Denmark, Finland, Norway, and Sweden, commenced efforts toward greater cooperation in patent matters, as in other affairs. The first part of the plan involved enactment of uniform patent laws, accomplished finally in 1967; these are still separate national laws, however. Under the second part of the plan, not yet achieved, there will be an international law and treaty, and it will be possible to obtain a single patent valid in all of the member countries.

Although the treaty establishing the Common Market, or European Economic Community, recognized the existence of separate national patent laws, there have also been efforts to internationalize patent rights in these countries. Early efforts failed by reason of various disagreements, but negotiations begun in 1968 among a larger number of European countries led to the publication in 1971 of the second preliminary draft of a treaty establishing a European patent. The general plan is for the creation of a European patent office in which applications for patents, filed by anyone, can be examined in accordance with the patent law and procedure embodied in the treaty. The single patent, when issued, will operate as a national patent in each of the participating countries, subject to respective national laws but bound by the law of the treaty with regard to certain basic requirements. The single patent will represent a bundle of separate patents, issued, however, as a single act by one authority and bound by common conditions for patentability. Each country may still issue national patents to persons who apply directly in that country. A second treaty between the Common Market countries alone is part of the plan; as to these countries the European patent will operate as a single patent for a combined territory.

Patent Cooperation Treaty of 1970

A new treaty called the Patent Cooperation Treaty was drawn up and signed in Washington in June 1970 by 20 adherents of the International Convention. Its main objective is to facilitate the filing of patent applications in a number of countries. A single application can be filed in a single office (branch offices existing in each nation), and the application can be effective in any of the participating countries that the applicant designates. The application will be subject to an initial examination as to form and will then receive a search of the prior art, with a report on the results. After this stage, the individual countries take over, having been supplied official copies; and they proceed with their own further steps toward granting the patent. A separate chapter of the treaty provides for examination by a single examining office, but this provision is optional and pertains only to those countries that may elect to have such a service. One chapter relates to supplying information services and technical services in patent matters. The treaty will come into force when ratified by eight countries, at least four of which meet certain conditions as to the volume of patent activity.

BIBLIOGRAPHY. There is no recent general legal treatise on patent law on an international and comparative level. The *Manual for the Handling of Applications for Patents, Designs, and Trademarks Throughout the World*, 2 vol. (looseleaf with annual replacement pages); WILLIAM WALLACE WHITE and BYFLEET G. RAVENSCROFT, *Patents Throughout the World* (looseleaf); and KONSTANTIN KATSAROV, *Manual and Directory on Industrial Property All Over the World*, 7th ed. (1970), are established works presenting summaries of the patent laws of every country, concentrating on details and procedures for obtaining and maintaining patents; the first one mentioned is probably the fullest. J.W. BAXTER, *World Patent Law and Practice* (1971, looseleaf), is a topical compilation. HOBART NOBLE DURHAM, *World Patent Litigation* (1967, looseleaf), separately treats patent suits in 18 countries.

Articles of international scope are published in *International Review of Industrial Property and Copyright Law* (quarterly since 1970), which also includes a section of abstracts of decisions and articles. *Industrial Property*, official publication of the United International Bureau for the Protection of Intellectual Property (English-language edition monthly since 1962), includes articles relating to individual countries and general studies from time to time, in addition to official notices and texts, and annual statistical reports.

The UNITED NATIONS publication, *The Role of Patents in the Transfer of Technology to Developing Countries: Report* (1964), is an economic study focussed on the problems of developing and underdeveloped countries. The most comprehensive and scholarly work on the Paris Convention is STEPHAN P. LADAS, *The International Protection of Industrial Property* (1930), but it is quite out of date. G.H. BODENHOUSEN, *Guide to the Application of the Paris Convention for the Protection of Industrial Property* (1968), is a short explanatory treatment.

There is no recent one-volume legal treatise on patent law in the United States; the section on "Patent Law" in *Corpus Juris Secundum*, vol. 69, pp. 49–59, 160–1126, 1134–1211, with cumulative annual pocket parts, can serve this purpose for want of one. Legal works on British patent law are *Terrell on the Law of Patents*, 11th ed. (1965); and THOMAS ANTHONY BLANCO WHITE, *Patents for Inventions and the Registration of Industrial Designs*, 3rd ed. (1962).

The most recent Canadian text is HAROLD D. FOX, *The Canadi-*

an Law and Practice Relating to Letters Patent for Inventions, 4th ed. (1969). Textbooks in English, other than compendia of the type first mentioned, on the laws of non-English-language countries are scarce. For Japan there is ROBERT WHEELER RUSSELL, *Patent and Trademarks in Japan*, 2nd ed. (1966); and KUKIMOTO, *Summary of the Japanese Patent Law* (1971). There is a good deal of patent law writing in French and considerable in German. The Max-Planck Institute for Foreign and International Patent, Copyright, and Competition Law, in Munich, is responsible for the publication of many studies.

(P.J.F.)

Patna and Pāṭaliputra

Patna is the capital of the state of Bihār in northern India; it is located in the district of the same name. The ancient city of Pāṭaliputra, capital of the Maurya and Gupta empires, occupied approximately the same site between the 6th century BC and the 6th century AD.

History. Pāṭaliputra was founded by Ajātaśatru, king of Magadha (South Bihār) in the 5th century BC. He built a fort there named Pāṭaligrāma to repel the possible attack of the Vṛjjis from the other side of the river Ganges. In the time of his son Udāya (Udāyin), the capital of Magadha was moved there from Rājagṛha (Rājgīr in Bihār subdivision). Between the mid-4th and the late 1st century BC, Pāṭaliputra was the metropolis of three successive Magadha dynasties: the Nanda, Maurya, and Śuṅga.

The Mauryan period

No descriptions of the city survive from the Nanda Period. The Greek ambassador Megasthenes, who stayed there for a number of years in the time of Candragupta Maurya (*c.* 321–*c.* 297 BC), describes the location of Palibothra (Pāṭaliputra) at the confluence of the river Ganges with Erannaboas. According to him, its shape was that of a parallelogram, and it was surrounded by a wooden wall, pierced with loopholes for the discharge of arrows. In his words, "even Susa and Ecbatana could not rival the beauty and grandeur of Pāṭaliputra." The city was the scene of the third Buddhist Council during the reign of the Maurya emperor Aśoka (*c.* 265–238 BC). Pāṭaliputra was sacked by Indo-Greek forces under Demetrius about 185 BC. Their retreat, caused by trouble at home, was immediately followed by a coup organized by the Brahmin commander in chief Puṣyamitra, who killed his master Bṛhadratha (the last Maurya ruler) and ascended the throne as founder of the Śuṅga dynasty. The city lost its political importance after the fall of the Śuṅga (*c.* 73 BC) but continued to be a centre of learning.

Early in the 4th century AD, Pāṭaliputra became the capital of the Gupta state. According to the Chinese traveller Fa-hsien, who visited the city during the reign of Candra Gupta II (reigned *c.* AD 380–*c.* 415), "the royal palace and the halls in the midst of the city, the walls and the gates with the inlaid sculpture work seemed to be the work of superhuman spirits." Shortly thereafter the capital was shifted westward. Pāṭaliputra once again declined and was finally deserted. At the time of the Chinese writer Hsüan-tsang's visit in AD 637, the city lay in ruins. Ashy patches noticed in excavated sites suggest that it may have been destroyed by fire.

Nothing is known of its history from the 7th century until 1541, when it was refounded as Patna by the Āfghan ruler Sher Shāh. Under the Mughals, it regained its old status as the metropolis of Bihār. The Englishman Ralph Fitch, who visited Patna in 1586, described it as "a very long and great town." The emperor Aurangzeb (1659–1707) renamed it ʿAzīmābād for his grandson, ʿAzīm. The city passed into the hands of the British East India Company in 1765 and became the seat of the provincial council for the collection of the company's revenue. In 1865 Patna and Gayā formed the two districts of Bihār. When the new province of Bihār and Orissa was carved out of the old presidency of Bengal in 1912, Patna was selected as its capital. Orissa, however, became a separate province in 1936, and since then Patna has been associated with Bihār alone. The greater part of the city proper, stretching along the river bank for nine miles, has considerably increased in population and expanded in size within the last 50 years. A high Court was set up here for the new province in 1916, followed by a university in 1917.

The modern city

Prominent among its modern structures are the Government House, the Assembly Chambers, the Oriental Library, a medical college, and an engineering college. Its historic monuments include the mosque of Ḥusayn Shāh of Bengal (1499); the Sikh Temple associated with the tenth Gurū, Govinda Singh; and the granary at Bankipore (now Bānkipur; 1786), popularly called the Golghar.

Archaeology. Excavations at Bulandibagh and Kumrahar near Patna have partly exposed the ancient sites of Pāṭaliputra and the Mauryan Palace. L.A. Waddell in 1893 found fragments of a polished column, carved stones, and certain other objects on the basis of which he presumed that Kumrahar represented the site of the palace. His work was continued by D.B. Spooner, who carried out excavations at both sites between 1912 and 1915, locating remains dating from four ancient periods between *c.* 600 BC and AD 600. The earliest period included the characteristic Northern Black Polished Pottery (NBP), with red and grey wares, iron implements, and terra-cotta figurines. Fragmentary architectural pieces bearing the high Mauryan polish were also found in this period. In the second period the same ceramic industries continued, with some deterioration in workmanship. In the third period (AD 100–300), NBP pottery disappears altogether, red and grey ware predominating. A gold amulet modelled on the coins of the Kuṣāṇa king Huviṣka with the legend on one side and Ardochṣo, goddess of abundance, on the other, was also found at this level. The last period (*c.* AD 300–600) yielded plain red ware, terra-cotta figurines, and certain objects of Gupta workmanship. This was followed by a long break until 1600, when the site again showed habitation with finds of glazed pottery, glass beads, ivory dice, and a coin of Shāh ʿĀlam.

Spooner's excavations at Kumrahar led to the discovery of the Mauryan Pillared Hall. Here eight heaps of polished stones in eight rows of ten each were discovered amidst a deposit of charcoal and ash, suggesting that the wooden structure of the hall had been destroyed by fire. Spooner also exposed structures from the post-Mauryan and Gupta periods. Some brick construction of the latter period also was uncovered at Bulandibagh in 1926–27, with a unique wooden construction of long planks at the bottom. A similar one, without the wood planks, was traced at Goshain-Khan, half a mile east of Bulandibagh.

Further excavations were carried out in 1951–55 at Kumrahar in an effort to trace the extension of the Pillared Hall, but all that was found was the remains of several monasteries. The hall was probably burned early in the Śuṅga period, as the structural remains of this period were traced over the ashy layer. The entire area was in continuous occupation from the Mauryan period until *c.* AD 600.

The surrounding district of Patna also has many ancient sites. These include Rājgīr, associated with the life of Buddha; Pāvāpurī, where Mahāvīra, the founder of Jainism, died; and Nālandā, the great intellectual centre of the early medieval period in India. Excavations here revealed seven levels of occupation and buildings of nine different periods from the 5th to 12th centuries AD. The division of Patna includes the area to the south of the Ganges covering 11,336 square miles comprising the districts of Patna, Gayā, and Shāhābād.

BIBLIOGRAPHY. L.A. WADDELL, *Pāṭaliputra* (1892), and his *Report on the Excavations at Pāṭaliputra* (1903), are the two pioneer works. D.B. SPOONER'S fairly exhaustive report on his excavations is published in the *A. Rep. Archaeol. Surv., India* pp. 55–61 (1912–13). The results of the excavations at Kumrahar (1951–55) are published by A.S. ALTEKAR and V. MISHRA in their *Report on Kumrahar* (1959). The history of the Patna district and city is given in the *Imperial Gazetteer of India*, vol. 20 (1908), and also in the Bihār Census Report (Patna District) of 1961. The history of the city and excavations at Pāṭaliputra are also described in B.N. PURI, *Cities of Ancient India* (1966).

(B.N.P.)

Patrick, Saint

The last missionary enterprise of the British church before it sank under the impact of the Anglo-Saxon inva-

sion was the firm establishment of the Christian faith in Ireland. The leader and moving spirit of this undertaking was the bishop Patricius, or Patrick, who thus may also be credited with having made possible the Christianizing by the Irish of their Pictish and Anglo-Saxon neighbours. Accordingly, St. Patrick is venerated in ecclesiastical and popular tradition as the national apostle of Ireland.

Confessio and *Epistola*

Patrick is known only from his own two short works, the *Confessio* ("Confession," or spiritual autobiography), set down in his old age, and his *Epistola* ("Letter"), written in denunciation of the ill-treatment inflicted on some Irish Christian captives by the soldiers of a British chieftain, Coroticus. The authenticity of these sources is unquestioned.

Born in Britain of a Romanized family, at the age of 16 he was torn by Irish raiders from the villa of his father, Calpurnius, a deacon and minor local official, and carried into slavery in Ireland, where, during six bleak years spent as a herdsman, he turned with fervour to the Lord. Hearing at last in a dream that the ship in which he was to escape was ready, he fled his master and found passage to Britain. There he came near to starvation and suffered a second brief captivity before he was finally reunited with his family.

The best known passage in the *Confessio* tells of a dream, after his return to Britain, in which one Victoricus delivered him a letter headed "The Voice of the Irish." As he read it he seemed to hear a certain company of Irish beseeching him to walk once more among them. "Deeply moved," he says, "I could read no more." Nevertheless, because of the shortcomings of his education he was reluctant for a long time to respond to the call. Even on the eve of re-embarkation for Ireland he was beset by doubts of his fitness for the task. Once in the field, however, his hesitations vanished. Utterly confident in the Lord, he journeyed far and wide, baptizing and confirming with untiring zeal. In diplomatic fashion he brought gifts to a kinglet here and a lawgiver there but accepted none from any. On at least one occasion he was cast into chains. On another, he addressed with lyrical pathos a last farewell to his converts who had been slain or kidnapped by the soldiers of Coroticus. Careful to deal fairly with the heathen, he nevertheless lived in constant danger of martyrdom. The evocation of such incidents of what he called his "laborious episcopate" was his reply to a charge, to his great grief endorsed by his ecclesiastical superiors in Britain, that he had originally sought office for the sake of office. In point of fact, he was a most humble-minded man, pouring forth a continuous paean of thanks to his Maker for having chosen him as the instrument whereby multitudes who had worshipped "idols and unclean things" had become "the people of God."

The phenomenal success of Patrick's mission is not, however, the full measure of his personality. Since his writings have come to be better understood, it is increasingly recognized that, despite their occasional incoherence, they mirror a truth and a simplicity of the rarest quality. No diarist has ever bared his inmost soul to the same degree as did the patron saint of Ireland. As D.A. Binchy, the most austerely critical of Patrician scholars, has put it, "The moral and spiritual greatness of the man shines through every stumbling sentence of his 'rustic' Latin."

Uncertainty about the exact dates of his birth and death

It is not possible to say with any assurance when Patrick was born. There are, however, a number of pointers to his missionary career having lain within the second half of the 5th century. In the Coroticus letter, his mention of the Franks as still heathen indicates that the letter must have been written between 451, the date generally accepted as that of the Franks' irruption into Gaul as far as the Somme River, and 496, when they were baptized en masse.

Patrick, who speaks of himself as having evangelized heathen Ireland, is not to be confused with Palladius, sent by Pope Celestine in 431 as "first bishop to the Irish believers in Christ."

Before the end of the 7th century Patrick had become a legendary figure, and the legends have continued to grow. One of these would have it that he drove the snakes of Ireland into the sea to their destruction. Another, probably the most popular, is that of the shamrock, which has him explain the concept of the Holy Trinity, three Persons in one God, to an unbeliever by showing him the three-leaved plant with one stalk. Today Irishmen wear shamrocks, the national flower of Ireland, in their lapels on St. Patrick's Day, March 17.

BIBLIOGRAPHY. For particulars as to the extant manuscript sources, see the definitive edition by L. BIELER of the *Confessio* and *Epistola* in *Libri Epistolarum Sancti Patricii Episcopi*, 2 vol. (1952), and for an English translation of the writings, Bieler's *Works of St. Patrick* (1953). Bibliographical references are covered exhaustively up to 1929 in J.K. KENNEY (ed.), *Sources for the Early History of Ireland*, vol. 1 (1929); studies published from then till 1962 are amply treated in D.A. BINCHY, "Saint Patrick and His Biographers, Ancient and Modern," *Studia Hibernica*, 2:7–173 (1962), an incomparable critical analysis of the Patrician problem. Useful works appearing since 1962 include: L. BIELER, *St. Patrick and the Coming of Christianity* (1967); R.P.C. HANSON, *Saint Patrick: His Origins and Career* (1968); and T. O'RAIFEARTAIGH, "Saint Patrick's Twenty-Eight Days Journey," *Irish Historical Studies*, vol. 16, no. 64 (1969).

(T.O'R.)

Patristic Literature

Patristic literature includes the writings, both orthodox and heretical, of the Fathers of the early Christian Church, from the late 1st century AD to the early 8th century.

This article is divided into the following sections:

NATURE AND SIGNIFICANCE

The concept and periodization of patristic literature. Patristic literature is generally identified today with the entire Christian literature of the early Christian centuries, irrespective of its orthodoxy or the reverse. Taken literally, however, patristic literature should denote the literature emanating from the Fathers of the Christian Church, the Fathers being those respected bishops and other teachers of exemplary life who witnessed to and expounded the orthodox faith in the early centuries. This would be in line with the ancient practice of designating as "the Fathers" prominent church teachers of past generations who had taken part in ecumenical councils or whose writings were appealed to as authoritative. Almost everywhere, however, this restrictive definition has been abandoned. There are several reasons why a more elastic usage is to be welcomed. One is that some of the most exciting Christian authors, such as Origen, were of questionable orthodoxy, and others—Tertullian, for example—deliberately left the church. Another is that the undoubtedly orthodox Fathers themselves cannot be properly understood in isolation from their doctrinally unorthodox contemporaries. Most decisive is the consideration that early Christian literature exists, and deserves to be studied, as a whole, and that much will be lost if any sector is neglected because of supposed doctrinal shortcomings.

Reasons for a broad concept of patristic literature

There has been much difference of opinion about the period that the patristic literature, understood in this more flexible sense, should be held to cover. The editor of

the largest and best known collection of Greek and Latin patristic texts took an exceptionally inclusive line, carrying his Latin series down to the time of Pope Innocent III (d. 1216), and his Greek series down to approximately the fall of Constantinople (1453). It seems more realistic, however, to make the patristic epoch coterminous with the life of the ancient, or premedieval, Catholic Church. Leaving out the New Testament itself, this scheme takes Clement of Rome (bishop, *c.* 95) as a starting point and concludes in the West with Pope Gregory the Great (d. 604) and in the East with John of Damascus (d. *c.* 749). For convenience it is useful to treat the ecumenical Council of Nicaea (325) as dividing this vast stretch of centuries into two manageable sections. Such a cleavage is by no means arbitrary, for the council was much more than a watershed in the evolution of dogmatic theology. In the ante-Nicene era (before 325) the church was relatively unimportant in the Roman empire and perforce on the defensive, but the emperor Constantine's convening of the council was itself a token of the triumph of Christianity and foreshadowed the increasingly influential role it was to play in the post-Nicene era (after 325).

Languages and types of patristic literature. *Languages.* The language of the earliest patristic writings, as of the primitive liturgy, was Greek in both West and East. This is explained partly by the wide diffusion of Greek throughout the whole Mediterranean basin and the prestige it enjoyed in the larger western towns, partly by the fact that Greek-speaking missionaries had first carried the new religion westward. Only toward the end of the 2nd century did Latin make headway, first in North Africa and then in Rome; but after a hesitant start it completely ousted Greek in the West. In the East, Greek was liable to be displaced by Syriac, Coptic, and Armenian, where these were the languages spoken by the educated. The Greek of the Fathers, though incorporating biblical expressions and impressing fresh meanings on certain terms, was substantially identical with contemporary secular Greek; but Christian Latin differed rather more, in vocabulary if not in syntax, from the everyday speech. This was because, being less rich and flexible than Greek, Latin needed a great importation of new words and adaptation of old ones to become an adequate vehicle for Christians.

Almost all of the writings classified as patristic either are theological in content or have a theological colouring. The modern reader who feels put off by this should reflect that the ante-Nicene authors were in the main striving to defend, understand, and explain their faith, while in the post-Nicene period the interest of people of all sorts and conditions in theology and theological debate reached a pitch unparalleled except, perhaps, at the Reformation. Though this theological preoccupation is everywhere evident, the patristic writings exhibit an extraordinary variety of literary types.

Apologetic and polemical literature

Types. From the pre-Nicene centuries there have survived specimens of the early apologetical and polemical literature of the church, the first tentative essays in constructive theology and Christian philosophizing, official and personal letters, and essays in biblical interpretation; there are also fragments of liturgy and hymnody, accounts of martyrdoms, and blueprints for the organization of church life. The post-Nicene literature, considered as literature, reaches a much higher level; this was to be expected, for Christianity by this time was attracting the highly educated and sophisticated in increasing numbers. In both East and West a literary golden age dawned, and even though commonplace works of ecclesiastical controversy and biblical exegesis (critical interpretation) abound, these later centuries can boast magnificent examples of dogmatic expositions, set-piece sermons, historiography, exchanges of correspondence, mystical treatises of elaborate artfulness, and religious poetry.

In the past, classical students were sometimes inclined to dismiss the patristic literature as secondary, the product of a decadent age, but the shortsightedness of this judgment is now generally realized. The writings of the Fathers make a special appeal to Christians because they so graphically recall the development of ecclesiastical institutions and doctrines, indeed the whole life of the adolescent church. But they are equally interesting both to those who explore the ancient Greco-Roman world for its own sake and to those who are attracted to it as the womb out of which Western civilization was to emerge. The interplay of pagan and Christian cultures in these fateful centuries makes a fascinating study; if Christian thinkers were sometimes more powerfully affected by the secular intellectual environment than they cared to acknowledge, those who upheld the views of this latter-day paganism, with its insecurity and yearning for salvation, had more in common with them than appeared on the surface. But the slow, all-embracing transformation of society which, through the medieval milieu and the Renaissance, was to issue in the modern world was already underway. The writings of the Fathers uniquely illuminate both the germinative ideas at work in the process and the new structures that were taking shape.

THE ANTE-NICENE PERIOD

During the first three centuries of its existence, the Christian Church had first to emerge from the Jewish environment that had cradled it and then come to terms with the predominantly Hellenistic (Greek) culture surrounding it. Its legal position at best precarious, it was exposed to outbursts of persecution at the very time when it was working out its distinctive system of beliefs, defining its position vis-à-vis Judaism on the one hand and Gnosticism (a heretical movement that upheld the dualistic view that matter is evil and the spirit good) on the other, and constructing its characteristic organization and ethic. It was a period of flux and experiment, but also one of consolidation and growing self-confidence, and these are all mirrored in its literature.

Earliest patristic writings

The Apostolic Fathers. According to conventional reckoning, the earliest examples of patristic literature are the writings of the so-called Apostolic Fathers; the name derives from their supposed contacts with the Apostles (intimate disciples of Jesus) or the apostolic community. These writings include the church order called the *Didachē*, or *Teaching of the Twelve Apostles* (dealing with church practices and morals), the *Letter of Barnabas*, and the *Shepherd of Hermas*, all of which hovered at times on the fringe of the New Testament canon in that they were used as sacred scripture by some local churches; the *First Letter of Clement*, the seven letters that Ignatius of Antioch (d. *c.* 110) wrote when being escorted to Rome for his martyrdom, the related *Letter to the Philippians* by Polycarp of Smyrna (d. *c.* 156 or 168), and the narrative report of Polycarp's martyrdom; some fragmentary accounts of the origins of the Gospels by Papias (fl. late 1st or early 2nd century AD), bishop of Hierapolis in Phrygia, Asia Minor; and an ancient homily (sermon) known as the *Second Letter of Clement*. They all belong to the late 1st or early 2nd century and are all to a greater or lesser extent influenced (sometimes by way of reaction) by the profoundly Jewish atmosphere that pervaded Christian thinking and practice at this primitive stage. For this reason alone, modern scholars tend to regard them as a somewhat arbitrarily selected group. A more scientific assessment would place them in the context of a much wider contemporary Jewish-Christian literature that has largely disappeared but whose character can be judged from apocryphal (or noncanonical) works such as the *Ascension of Isaiah*, the *Odes of Solomon*, and certain extracanonical texts modelled on the New Testament.

Even with this qualification, the Apostolic Fathers, with their rich variety of provenance and genre (types), illustrate the difficult doctrinal and organizational problems with which the church was grappling in those transitional generations. Important among these problems were the creation of a ministerial hierarchy and of an accepted structure of ecclesiastical authority. The *Didachē*, which is Syrian in background and possibly the oldest of these documents, suggests a phase when Apostles and prophets were still active but when the routine ministry of bishops and deacons was already winning recognition. The *First*

Letter of Clement, an official letter from the Roman to the Corinthian Church, reflects the more advanced state of a collegiate episcopate, with its shared authority among an assembly of bishops. This view of authority was supported by an emergent theory of apostolic succession in which bishops were regarded as jurisdictional heirs of the early Apostles. The *First Letter of Clement* is also instructive in showing that the Roman Church, even in the late 1st century, was asserting its right to intervene in the affairs of other churches. The letters of Ignatius, bishop of Antioch at the beginning of the 2nd century, depict the position of the monarchical bishop, flanked by subordinate presbyters (priests) and deacons (those serving priests in the liturgy), which had been securely established in Asia Minor.

Relationship of Judaism and Christianity

Almost more urgent was the question of the relation of Christianity to Judaism, and in particular of the Christian attitude toward the Old Testament. In the *Didachē* there is little sign of embarrassment; Jewish ethical material is taken over with suitable adaptations, and the Jewish basis of the liturgical elements is palpable. But with *Barnabas* the tension becomes acute; violently anti-Jewish, the Alexandrian author substitutes allegorism (use of symbolism) for Jewish literalism, and thus enables himself to wrest a Christian meaning from the Old Testament. The same tension is underlined by Ignatius' polemic against Judaizing tendencies in the church. At the same time all these writings—especially those of Ignatius, Polycarp, and Papias—testify to the growing awareness of a specifically Christian tradition embodied in the teaching transmitted from the Apostles.

Almost all the Apostolic Fathers throw light on primitive doctrine and practice. The *Didachē*, for example, presents the Eucharist as a sacrifice, and *I Clement* incorporates archaic prayers. *II Clement* invites its readers to think of Christ as of God, and of the church as a preexistent reality. Hermas seeks to modify the rigorist view that sin committed after Baptism cannot be forgiven. But the real key to the theology of the Apostolic Fathers, which also explains its often curious imagery, is that it is Jewish-Christian through and through, expressing itself in categories derived from latter-day Judaism and apocalyptic literature (that depicting the intervention of God in history in the last times), which were soon to become unfashionable and be discarded.

The Gnostic writers. Hardly had the church thrown off its early Jewish-Christian idiosyncrasies when it found itself confronted by the amorphous but pervasive philosophical-religious movement known as Gnosticism. This movement made a strong bid to absorb Christianity in the 2nd century, and a number of Christian Gnostic sects flourished and contributed richly to Christian literature. Although the church eventually maintained its identity intact, the confrontation forced it to clarify its ideas on vital issues on which it differed sharply from the Gnostics. Chief among these were the Gnostics' distinction between the unknown supreme God and the Demiurge (identified with the God of the Old Testament) who created this world; their dualist disparagement of the material order and insistence that the Redeemer became incarnate in appearance only; their belief in salvation by esoteric knowledge; and their division of mankind into a spiritual elite capable of achieving salvation and, on a lower plane, inferior grades of "psychic" and "material" men.

Gnostic emphasis

Among the leading 2nd-century Christian Gnostics were Saturninus and Basilides, reputedly pupils of Menander, a disciple of Simon Magus (late 1st century), the alleged founder of the movement; they worked at both Antioch and Alexandria. But most famous and influential was the Egyptian Valentinus, who acquired a great reputation at Rome (*c.* 150) and founded an influential school of thought. Basilides and Valentinus are reported to have written extensively, and their systems can be reconstructed from hostile accounts by Irenaeus (*c.* 120/140–*c.* 200/203), Clement of Alexandria (*c.* 150–*c.* 215), and other orthodox critics. But the Gnostics generally seem to have been prolific writers, and as they needed their own distinctive scriptures they soon created a body of apocryphal books patterned on the New Testament. It was a Syrian Gnostic convert, Tatian, who compiled (late 2nd century) the first harmony of the Four Gospels (the *Diatessaron*)—a single gospel using the material from the Gospels; and an Italian Gnostic, Heracleon (2nd century), who prepared the earliest commentary on St. John's Gospel (extracts from it have been preserved by Origen). Epiphanius (*c.* 315–403) preserved a *Letter to Flora*, by the Valentinian Gnostic Ptolemaeus (late 2nd century), supplying rules for interpreting the Mosaic Law (the Torah) in a Christian sense; and another disciple of Valentinus, Theodotus (2nd century), published an account of his master's system that was excerpted by Clement of Alexandria.

Anti-Gnostic sources

Almost the entire vast literature of Gnosticism has perished, and until recently the only original documents available to scholars (apart from extracts like those already mentioned which were preserved by orthodox critics) were a handful of treatises in Coptic contained in three codices (manuscript books) that were discovered in the 18th and late 19th centuries. The most interesting of these are *Pistis Sophia* and the *Apocryphon of John*, the former consisting of conversations of the risen Jesus with his disciples about the fall and redemption of the aeon (emanation from the Godhead) called Pistis Sophia, the latter of revelations made by Jesus to St. John explaining the presence of evil in the cosmos and showing how man can be rescued from it.

The Naj' Ḥammādī codices

Since 1946, however, this meagre store has been richly supplemented by the discovery near Naj' Ḥammādī, in Egypt on the Nile about 78 miles northwest of Luxor, of 13 codices containing more than 100 Christian Gnostic treatises in Coptic translations. The best known of these, the Jung Codex (named in honour of the psychoanalyst Carl Jung by those who purchased it for his library), includes four important items: a *Letter of James*, recording revelations imparted by the risen Christ to the Apostles; the *Gospel of Truth*, perhaps to be identified with the work of this name attributed by Irenaeus to Valentinus; the *Letter to Rheginus*, a Valentinian work, possibly by Valentinus himself, on the Resurrection; and a *Treatise on the Three Natures*, also Valentinian. Of the other documents from the Naj' Ḥammādī library thus far published, the one that has attracted most attention is the *Gospel of Thomas*, a collection of sayings and parables that are ascribed to Jesus.

A figure of immense significance who is often, though perhaps mistakenly, counted among the Gnostics was Marcion, who after breaking with the Roman Church in 144 set up a successful organization of his own. Teaching that there is a radical opposition between the Law and the Gospel, he refused to identify the God of love revealed in the New Testament with the wrathful Creator God of the Old Testament. He set forth these contrasts in his *Antitheses*, and his adoption of a reduced New Testament consisting of St. Luke's Gospel and certain Pauline epistles, all purged of presumed Jewish interpolations, had an important bearing on the church's formation of its own fuller canon.

Characteristics of apologetic literature

The Apologists. Meanwhile, the orthodox literature of the 2nd and early 3rd centuries tends to have a distinctly defensive or polemical colouring. It is the age of Apologists, and these Apologists had to engage in battle on two fronts. First, there was the hostility and criticism of pagan society. Because of its very aloofness the church was popularly suspected of sheltering all sorts of immoralities and thus of threatening the established order. At a higher level, Christianity, as it became better known, was being increasingly exposed to intellectual attack. The physician Galen of Pergamon (d. *c.* 200) and the Middle Platonist thinker Celsus, who followed the religiously inclined form of Platonism that flourished from the 3rd century BC to the 3rd century AD (*cf.* his devastating *Alēthēs logos*, or *True Word*, written *c.* 178), were only two among many "cultured despisers." But, secondly, orthodoxy had to take issue with distorting tendencies within, whether these took the form of Gnosticism or of other heresies, such as the so-called semi-Gnostic Marcion's rejection of the Old Testament revelation or the claim of

the ecstatic prophet from Phrygia, Montanus (*c.* 157), to be the vehicle of a new outpouring of the Holy Spirit. Christianity had also to define exactly where it stood in relation to Hellenistic culture.

The early Apologists (2nd century). Strictly speaking, the term Apologists denotes the group of 2nd-century writers who defended Christianity against external critics, pagan and Jewish. The earliest of this group was Quadratus, who in about 124 addressed an apology for the faith to the emperor Hadrian; apart from a single fragment, it is now lost. Other early 2nd-century Apologists who are mere names known to scholars are Aristo of Pella, the first to prepare an apology to counter Jewish objections; and Apollinaris, bishop of Hierapolis, said to be the author of numerous apologetic works and also of a critique of Montanism. An early apology that has survived intact is that of Aristides, addressed *c.* 140 to the emperor Antoninus Pius; after being completely lost, the text was rediscovered in the 19th century. The most famous Apologist, however, was Justin, who was converted to Christianity after trying various philosophical schools, paid lengthy visits to Rome, and was martyred there (*c.* 165). Justin's two *Apologies* are skillful presentations of the Christian case to the pagan critics; and his *Dialogue with Trypho* is an elaborate defense of Christianity against Judaism.

Relationship to philosophy

Justin's attitude to pagan philosophy was positive. His pupil Tatian could see nothing but evil in the Greco-Roman civilization. Indeed, Tatian's *Discourse to the Greeks* is less a positive vindication of Christianity than a sharp attack on paganism. His contemporary Athenagoras of Athens, author of the apologetic work *Supplication for the Christians* and a treatise *On the Resurrection of the Dead*, is as friendly as Justin to Greek culture and philosophy. Two others who deserve mention are Theophilus of Antioch, a prolific publicist whose only surviving work is *To Autolycus*, prepared for his pagan friend Autolycus; and the anonymous author of the *Letter to Diognetus*, an attractive and persuasive exposition of the Christian way of life that is often included among the Apostolic Fathers.

As stylists the Apologists reach only a passable level; even Athenagoras scarcely achieves the elegance at which he obviously aimed. But they had little difficulty in refuting the charges of atheism, cannibalism, promiscuity, and other spurious charges popularly brought against Christians, or in mounting a counterattack against the debasements of paganism. More positively, they strove to vindicate the Christian understanding of God and specific doctrines such as the divinity of Christ and the resurrection of the body. In so doing, most of them exploited current philosophical conceptions, in particular that of the *Logos* (Word), or rational principle underlying and permeating reality, which they regarded as the divine reason, become incarnate in Jesus. They have been accused of Hellenizing Christianity (making it Greek in form and method), but they were in fact attempting to formulate it in intellectual categories congenial to their age. In a real sense they were the first Christian theologians.

Eristic (missionary) Apologists. As the 2nd century advanced, a more confident, aggressive spirit came over Christian Apologists, and their intellectual and literary stature increased greatly. Clement of Alexandria (150–215), for example, while insisting on the supremacy of faith, freely draws on Platonism and Stoicism to clarify Christian teaching. In his *Protrepticus* ("Exhortation") and *Paedagogus* ("Instructor") he urged pagans to abandon their futile beliefs, accept the Logos as guide, and allow their souls to be trained by him. In interpreting scripture he used an allegorizing method derived from a Jewish philosopher, Philo (*c.* 15 BC–after AD 40), and against Gnosticism he argued that the baptized believer who studies the Scriptures is the true Gnostic, faith being at once superior to knowledge and the beginning of knowledge.

Rapprochement with and reaction to Greco-Roman culture

The critique of Gnosticism was much more systematically developed by Clement's older contemporary, Irenaeus (*c.* 120/140–*c.* 200/203) of Lyons, in present-day France, in his voluminous *Against Heresies.* While countering the Valentinian dualism that asserted that spirit was good and matter evil, this treatise makes clear the church's growing reliance on its creed or "rule of faith," on the New Testament canon, and on the succession of bishops as guarantors of the true apostolic tradition. Irenaeus was also a constructive theologian, expounding ideas about God as creator, about the Son and the Spirit as his "two hands," about Christ as the new Adam who reconciles fallen man with God, and about the worldwide church with its apostolic faith and ministry, a concept which theology was later to take up eagerly.

More brilliant as a stylist and controversialist, the North African lawyer Tertullian (*c.* 160–after 220) was also the first Latin theologian of considerable importance. Unlike Clement, he reacted with hostility to pagan culture, scornfully asking, "What has Athens to do with Jerusalem?" His *Apology* remains a classic of ancient Christian literature, and his numerous moral and practical works reveal an uncompromisingly rigid moral view. Although later becoming a Montanist himself (a follower of the morally rigorous and prophetic sect founded by Montanus), he wrote several antiheretical tracts, full of abuse and biting sarcasm. Yet, in castigating heresy he was able to formulate the terminology, and to some extent the theory, of later Trinitarian and Christological orthodoxy; his teaching on the fall of man, aimed against Gnostic dualism, in part anticipates Augustine.

Roughly contemporary with Tertullian, and like him an intellectual and a rigorist, was Hippolytus (*c.* 170–*c.* 235), a Greek-speaking Roman theologian and antipope. He, too, had a vast literary output, and although some of the surviving works attributed to him are disputed, it is probable that he wrote the comprehensive *Refutation of All Heresies,* attacking Gnosticism, as well as treatises denouncing specifically Christian heresies. He was also the author both of numerous commentaries on scripture and (probably) of the *Apostolic Tradition*, an invaluable source of knowledge about the primitive Roman liturgy. His *Commentary on Daniel* (*c.* 204) is the oldest Christian biblical commentary to survive in its entirety. His exegesis (interpretive method) is primarily typological; *i.e.*, treating the Old Testament figures, events, and other aspects as "types" of the new order which was inaugurated by Christ.

Late 2nd to early 4th century. *Alexandria.* Meanwhile, a brilliant and distinctive phase of Christian literature was opening at Alexandria, the chief cultural centre of the empire and the meeting ground of the best in Hellenistic Judaism, Gnosticism, and Neoplatonism. Marked by the desire to present Christianity in intellectually satisfying terms, this literature has usually been connected with the Catechetical School, which, according to tradition, flourished at Alexandria from the end of the 2nd through the 4th century. Except for the brief period, however, when Origen was in charge of it (202/203–230/231), it may be doubted whether the school was ever itself a focus of higher Christian studies. When speaking of the School of Alexandria, some scholars claim that it is better to think of a distinguished succession of like-minded thinkers and teachers who worked there, and whose highly sophisticated interpretation of Christianity exercised for generations a formative impact on large sectors of eastern Christendom.

The Catechetical School of Alexandria

The real founder of this theology, with its Platonist leaning, its readiness to exploit the metaphysical implications of revelation, and its allegorical understanding of scripture, was Clement, the Christian humanist whose welcoming attitude to Hellenism and critique of Gnosticism were noted above. His major work, the *Stromata* ("Miscellanies"), untidy and deliberately unsystematic, brings together the inheritance of Jewish Christianity and Middle Platonism in what aspires to be a summary of Christian gnosis (knowledge). All his reasoning is dominated by the idea of the Logos who created the universe and who manifests the ineffable Father alike in the Old Testament Law, the philosophy of the Greeks, and finally the incarnation of Christ. Clement is also a mystic for whom the higher life of the soul is a continuous moral and spiritual ascent.

Significance and influence of Origen

But it is Origen whose achievement stamps the Alexandrian school. First and foremost, he was an exegete (critical interpreter), as determined to establish the text of scripture scientifically (*cf.* his *Hexapla*) as to wrest its spiritual import from it. In homilies, scholia (annotated works), and continuous commentaries he covered the whole Bible, deploying a subtle, strongly allegorical exegesis designed to bring out the several levels of significance it contains. As an apologist, in his *Contra Celsum*, he refuted step-by-step the pagan philosopher Celsus' damaging onslaught on Christianity. In all his writings, but especially his *On First Principles*, Origen shows himself to be one of the most original and profound of speculative theologians. Neoplatonist in background, his system embraces both the notion of the pre-existence of souls, with their fall and final restoration, and a deeply subordinationist doctrine of the Trinity: *i.e.*, one in which the Son is subordinate to the Father. For his spiritual teaching, with its emphasis on the battle against sin, on freedom from passions, and on the soul's mystical marriage with the Logos, his *Commentary on Canticles* provides an attractive introduction.

Origen's influence on Christian doctrine and spirituality was to be immense and many-sided; the orthodox Fathers and the leading heretics of the 4th century alike reflect it. Meanwhile, the Alexandrian tradition was maintained by several remarkable disciples. Two of these whose works have been entirely lost but who are reported to have been polished writers were Theognostus (fl. 250–280) and Pierius (fl. 280–300), both heads of the Catechetical School and apparently propagators of Origen's ideas. But there are two others of note, Dionysius of Alexandria (*c.* 200–*c.* 265) and Gregory Thaumaturgus (*c.* 213–*c.* 270), of whose works some fragments have survived. Dionysius of Alexandria wrote on natural philosophy and the Christian doctrine of creation but is chiefly remembered for his dispute with Pope Dionysius (d. 268) of Rome on the correct understanding of the Trinity. In this Dionysius of Alexandria is revealed as a faithful exponent of Origen's pluralism and subordinationism. Gregory Thaumaturgus has left a fascinating *Panegyric to Origen*, giving a graphic description of Origen's method of instruction, as well as a dogmatically important *Symbol* and a *Canonical Epistle* that is in effect one of the most ancient treatises of casuistry (*i.e.*, the application of moral principles to practical questions).

Anti-Origenist reaction. If Origen inspired admiration, his daring speculations also provoked criticism. At Alexandria itself, Peter, who became bishop *c.* 300 and composed theological essays of which only fragments remain, attacked Origen's doctrines of the pre-existence of souls and their return into the condition of pure spirits. But the acutest of his critics was Methodius of Olympus (d. 311), of whose treatises *The Banquet*, exalting virginity, survives in Greek, and others mainly in Slavonic translations. Although indebted to Alexandrian allegorism, Methodius remains faithful to the Asiatic tradition (literal and historical) of Irenaeus—who had come to France from Asia Minor—and his realism, and castigates Origen's ideas on the pre-existence of souls, the flesh as the spirit's prison, and the spiritual nature of the resurrected body. As a writer he strove after literary effect, and Jerome, writing a century later, praises the excellence of his style.

Pre-Nicene Latin literature. Latin Christian literature was slow in getting started, and North Africa has often been claimed as its birthplace. Tertullian, admittedly, is the first Christian Latinist of genius, but he evidently had his humbler predecessors. Latin versions of the Bible, recoverable in part from manuscripts, were appearing in Africa, Gaul, and Italy during the 2nd century. In that century, too, admired works like *I Clement*, *Barnabas*, and the *Shepherd of Hermas* were translated into Latin. The oldest original Latin texts are probably the Muratorian Canon, a late 2nd-century Roman canon, or list of works accepted as scripture, and the *Acts of the Scillitan Martyrs* (180) of Africa.

Origin and gradual emergence of Latin patristic literature

The first noteworthy Roman Christian to use Latin was Novatian (*c.* 200–*c.* 258), the leader of a rigorist schismatic group. His surviving works reveal him as an elegant stylist, trained in rhetoric and philosophy, and a competent theologian. His doctrinally influential *De trinitate* ("Concerning the Trinity") is basically apologetic: against Gnostics it defends the oneness and creative role of Almighty God, against Marcion it argues that Christ is the Son of God the Creator, against Docetism (the heresy claiming that Jesus only seemed the Christ) that Christ is truly man, and against Sabellianism (the denial of real distinctions in the Godhead) that in spite of Christ's being fully divine there is but one God. His rigorous moralism comes out in his *On Public Shows* and *On the Excellence of Chastity* (both once attributed to Cyprian); in *On Jewish Foods* he maintains that the Old Testament food laws no longer apply to Christians, the animals which were classified as unclean having been intended to symbolize vices.

A much greater writer than Novatian was his contemporary and correspondent, Cyprian (*c.* 200–*c.* 258), the statesmanlike bishop of Carthage. A highly educated convert to Christianity, Cyprian left a large corpus of writings, including 65 letters and a number of moral, practical, and theological treatises. As an admirer of Tertullian, he continued some of his fellow North African's tendencies, but his style is more classical, though much less brilliant and individual. Cyprian's letters are a mine of information about a fascinating juncture in church history. His collections of *Three Books of Testimonies to Quirinus*, or authoritative scripture texts, illustrate the church's reliance on these in defending its theological and ethical positions. A work that has been of exceptional importance historically is his *Unity of the Catholic Church*, in which Cyprian contends that there is no salvation outside the church and defines the role of the Roman see (episcopal authority). His *To Demetrianus* is an original, powerful essay refuting the allegation of pagans that Christianity was responsible for the calamities afflicting society.

Defense of Roman episcopal authority

Three writers from the later portion of this period deserve mention. Victorinus of Pettau, converted about 335 from Neoplatonism, was the first known Latin biblical exegete; of his numerous commentaries the only one that remains is the commentary on Revelation, which maintained a millenarian outlook—predicting the 1,000-year reign of Christ at the end of history—and was clumsy in style. Arnobius the Elder (converted by 300) sought in his *Adversus nationes* ("Against the Nations"), like Tertullian and Cyprian before him, to free Christianity from the charge of having caused all the evils plaguing the empire, but ended up by launching a violent attack on the contemporary pagan cults. A surprising feature of this ill-constructed, verbose apology is Arnobius' apparent ignorance concerning several cardinal points of Christian doctrine, combined with his great enthusiasm for his newfound faith.

By contrast, his much abler pupil Lactantius (*c.* AD 240–*c.* 320), like him a native of North Africa, was a polished writer and the leading Latin rhetorician of the day. His most ambitious work, the *Divine Institutes*, attempted, against increasingly formidable pagan attacks, to portray Christianity as the true form of religion and life, and is in effect the first systematic presentation of Christian teaching in Latin. The later *Deaths of Persecutors*, now generally recognized as his, describes the grim fates of persecuting emperors; it is a primary source for the history of the early 4th century and also represents a crude attempt at a Christian philosophy of history.

THE POST-NICENE PERIOD

The flowering of early Christian literature

The 4th and the first half of the 5th century witnessed an extraordinary flowering of Christian literature, the result partly of the freedom and privileged status now enjoyed by the church, partly of the diversification of its own inner life (*cf.* the rise of monasticism), but chiefly of the controversies in which it hammered out its fundamental doctrines.

Arianism, which denied Christ's essential divinity, aroused an all-pervasive reaction in the 4th century; the task of the first two ecumenical councils, at Nicaea (325)

and Constantinople (381), was to affirm the orthodox doctrine of the Trinity. In the 5th century the Christological question moved to the fore, and the Council of Chalcedon (451), completing that of Ephesus (431), defined Christ as one person in two natures. The Christological controversies of the 5th century were extremely complex, involving not only theological issues but also issues of national concerns—especially in the Syrian-influenced East, where the national churches were called non-Chalcedonian because they rejected the doctrinal formulas of the Council of Chalcedon.

Involved in the 5th-century Christological controversy were many persons and movements: Nestorius, consecrated patriarch of Constantinople in 428, and his followers, the Nestorians, who were concerned with preserving the humanity of Christ as well as his divinity; Cyril (*c.* 375–444), patriarch of Alexandria, and his followers, who were devoted to maintaining a balanced emphasis on both of the natures of Christ, divine and human; Eutyches (*c.* 378–after 451), a muddleheaded archimandrite (head of a monastery) who affirmed two natures before and one nature after the incarnation; the Monophysites, who (following Eutyches) stressed the one unified nature of Christ; the moderates and those who sought theological, ecclesiastical, and even political solutions to this highly complex doctrinal dispute, such as Pope Leo I (d. 461). It was a time when the Alexandrian and Antiochene theological schools vied with each other for the control of the theology of the church. In the Syrian East the Antiochene tradition continued in the schools of Edessa and Nisibis, which became centres of a non-Greek national renaissance. The issues of grace, free will, and the fall of man concerned the West mainly. Meanwhile, old literary forms were developing along more mature lines, and new ones were emerging, including historiography, lives of saints, set piece (fixed-form) oratory, mystical writings and hymnody.

Literature of the Arian controversy

The Nicene Fathers. A seesaw struggle between Arians and orthodox Christians dominated the immediate post-Nicene period. Arius (d. 336) himself, Eusebius of Nicomedia (d. *c.* 342), and other radicals occupied the extreme left wing, carrying Origen's views on the subordination of the Son to what became dangerous lengths. Apart from a few precious letters and fragments, their writings have perished. On the extreme right Athanasius (*c.* 293–373), Eustathius of Antioch (d. *c.* 337), and Marcellus of Ancyra (d. *c.* 374 and strongly anti-Origenist) tenaciously upheld the Nicene decision that the Son was of the same substance with the Father. Again, the writings of the two latter figures, except for scattered but illuminating fragments, have disappeared. Most churchmen preferred the middle ground; loyal to the Origenist tradition, they suspected the Nicene Creed of opening the door to Sabellianism (the heresy that defended the oneness of God and viewed the Father, Son, and Holy Spirit as three successive modes of revelation), but were equally shocked by Arianism in its more uncompromising forms. Eusebius of Caesarea (*c.* 260/264–*c.* 340) was their spokesman, and for decades the eastern emperors supported his mediating line.

Eusebius is chiefly known as a historian; his *Ecclesiastical History*, with its scholarly use of documents and guiding idea that the victory of Christianity is the proof of its divine origin, introduced something novel and epoch-making. But he also wrote voluminous apologetic treatises, biblical and exegetical works, and polemical tracts against Marcellus of Ancyra. From these can be gathered his theology of the Word, which was Origenist in inspiration and profoundly subordinationist and which made the strict Nicenes suspect him as an ally of Arius. Such suspicions were unjust, for he upheld Origen's doctrine of eternal generation (*i.e.*, that the Word is generated outside the category of time) and rejected the extreme Arian theses. His influence can be studied in the works of Cyril of Jerusalem (*c.* 315–386?), whose *Catecheses*, or introductory lectures on Christian doctrine for candidates for Baptism, exemplify a pastoral type of Christian literature. Though critical of the Arian positions, Cyril remained reserved in his attitude toward the Nicene theology and at several other points showed affinities with Eusebius.

Significance of Athanasius

Athanasius bestrides the 4th century as the inflexible champion of the Nicene dogma. He had been present at the council, defending Alexander, the theologian-bishop of Alexandria from 313 to 328, who had exposed Arius; and after succeeding Alexander in 328 he spent the rest of his stormy life defending, expounding, and drawing out the implications of the Nicene theology. His most thorough and effective exposition of the Son's eternal origin in the Father and essential unity with him is contained in his three *Discourses Against the Arians;* but in addition he produced a whole series of treatises, historical or dogmatic or both, as well as letters, covering different aspects of the controversy.

It would be misleading, however, to delineate Athanasius exclusively as a polemicist. First, even in his polemical writings he was working out a positive doctrine of the triune God that anticipated later formal definitions. His *Letters to Bishop Serapion*, with their persuasive presentation of the Holy Spirit as a consubstantial (of the same substance) person in the Godhead, are an admirable illustration. Also, his noncontroversial works, such as the relatively early but brilliant apologies, *Discourse Against the Pagans* and *On the Incarnation*; the attractive and influential *Life of St. Antony*, which was to give a powerful impulse to monasticism (especially in the West); and his numerous exegetical and ascetic essays, which survive largely in fragments, sometimes in Coptic or Syriac translations, should not be overlooked.

Contributions to theology and monasticism

The Cappadocian Fathers. Although Athanasius prepared the ground, constructive agreement on the central doctrine of the Trinity was not reached in his lifetime, either between the divided parties in the East or between East and West with their divergent traditions. The decisive contribution to the Trinitarian argument was made by a remarkable group of philosophically minded theologians from Cappadocia (in eastern Turkey)—Basil of Caesarea (*c.* 330–379), his younger brother Gregory of Nyssa (*c.* 335–*c.* 394), and his lifelong friend Gregory of Nazianzus (*c.* 329–*c.* 389/390). Of aristocratic birth and consummate culture, all three were drawn to the monastic ideal, and Basil and Gregory of Nazianzus achieved literary distinction of the highest order. While their joint accomplishments in doctrinal definition were indeed outstanding, each made a noteworthy mark in other fields as well.

So far as Trinitarian dogma is concerned, the Cappadocians succeeded, negatively, in overthrowing Arianism in the radical form in which two acute thinkers, Aëtius (d. *c.* 366) and Eunomius (d. *c.* 394), had revived it in their day, and, positively, in formulating a conception of God as three Persons in one essence that eventually proved generally acceptable. The oldest of Basil's dogmatic writings is his only partially successful *Against Eunomius*, the most mature his essay *On the Holy Spirit*. Gregory of Nyssa continued the attack on Eunomius in four massive treatises and published several more positive dogmatic essays, the most successful of which is the *Great Catechetical Oration*, a systematic theology in miniature. The output of Gregory of Nazianzus was much smaller, but his 45 *Orations*, as well as being masterpieces of eloquence, contain his classic statement of Trinitarian orthodoxy. Basil's vast correspondence testifies to his practical efforts to reconcile divergent movements in Trinitarian thinking.

Basil is famous as a letter writer and preacher and for his views on the appropriate attitude of Christians toward Hellenistic culture; but his achievement was not less significant as a monastic legislator. His two monastic rules, used by St. Benedict and still authoritative in the Greek Church, are tokens of this. Gregory of Nazianzus, too, was an accomplished letter writer, but his numerous, often lengthy poems have a special interest. Dogmatic, historical, and autobiographical, they are often intensely personal and lay bare his sensitive soul. On the other hand, Gregory of Nyssa, much the most speculative of the three, was an Origenist both in his allegorical interpretation of scripture and in aspects of his eschatology. But he is chiefly remarkable as a pioneer of Christian

mysticism, and in his *Life of Moses, Homilies on Canticles,* and several other books he describes how the soul, in virtue of having been created in the divine image, is able to ascend, by successive stages of purification, to a vision of God.

Uncritical theological views

A figure who stood in sharp contrast, intellectually and in temperament, to the Cappadocians was their contemporary, Epiphanius (*c.* 315–403) of Salamis, in Cyprus. A fanatical defender of the Nicene solution, he was in no sense a constructive theologian like them, but an uncritical traditionalist who rejected every kind of speculation. He was an indefatigable hammer against heretics, and his principal work, the *Panarion* ("Medicine Chest"), is a detailed examination of 80 heresies (20 of them pre-Christian); it is invaluable for the mass of otherwise unobtainable documents it excerpts. Conformably with Epiphanius' contempt for classical learning, the work is written in Greek without any pretension to elegance. His particular *bête noire* was Origen, to whose speculations and allegorism he traced virtually all heresies.

Monastic literature. From the end of the 3rd century onward, monasticism was one of the most significant manifestations of the Christian spirit. Originating in Egypt and spreading thence to Palestine, Syria, and the whole Mediterranean world, it fostered a literature that illuminates the life of the ancient church.

Both Anthony (*c.* 250–355), the founder of eremitical, or solitary, monasticism in the Egyptian desert, and Ammonas (fl. *c.* 350), his successor as leader of his colony of anchorites (hermits), wrote numerous letters; a handful from the pen of each is extant, almost entirely in Greek or Latin translation of the Coptic originals. Those of Ammonas are particularly valuable for the history of the movement and as reflecting the uncomplicated mysticism that inspired it. The founder of monastic community life, also in Egypt, was Pachomius (*c.* 290–346), and the extremely influential rule that he drew up has been preserved, mainly in a Latin translation made by Jerome.

Though these and other early pioneers were simple, practical men, monasticism received a highly cultivated convert in 382 in Evagrius Ponticus. He was the first monk to write extensively and was in the habit of arranging his material in groups of a hundred aphorisms, or "centuries," a literary form that he invented and that was to have a great vogue in Byzantine times. A master of the spiritual life, he classified the eight sins that undermine the monk's resolution, and also the ascending levels by which the soul rises to wordless contemplation. Later condemned as an Origenist, he was deeply influential in the East, and, through John Cassian (360–435), in the West as well.

Influence of monastic literature on ethics and mysticism

Side by side with works composed by monks there sprang up a literature concerned with them and the monastic movement. Much of it was biographical, the classic example being Athanasius' *Life of St. Antony.* Sulpicius Severus took this work as his model when early in the 5th century he wrote his *Life of St. Martin of Tours* (*c.* 330–397), the first Western biography of a monastic hero and the pattern of a long line of medieval lives of saints. But it was Palladius (*c.* 363–before 431), a pupil of Evagrius Ponticus (d. 399), who proved to be the principal historian of primitive monasticism. His *Lausiac History* (so called after Lausus, the court chamberlain to whom he dedicated it), composed about 419/420, describes the movement in Egypt, Palestine, Syria, and Asia Minor. Since much of the work is based on personal reminiscences or information received from observers, it is, despite the legendary character of many of its narratives, an invaluable source book.

Finally, no work so authentically conveys the spirit of Egyptian monasticism as the *Apophthegmata Patrum* ("Sayings of the Fathers"). Compiled toward the end of the 5th century, but using much older material, it is a collection of pronouncements of the famous desert personalities and anecdotes about them. The existing text is in Greek, but it probably derives from an oral tradition in Coptic.

The School of Antioch. Antioch, like Alexandria, was a renowned intellectual centre, and a distinctive school of Christian theology flourished there and in the surrounding region throughout the 4th and the first half of the 5th century. In contrast to the Alexandrian school, it was characterized by a literalist exegesis and a concern for the completeness of Christ's manhood. Little is known of its traditional founder, the martyr-priest Lucian (*d.* 312), except that he was a learned biblical scholar who revised the texts of the Septuagint and the New Testament. His strictly theological views, though a mystery, must have been heterodox, for Arius, Eusebius of Nicomedia, and other Arians claimed to be his disciples ("fellow Lucianists"), and Bishop Alexander of Alexandria, who denounced them, lists Lucian among those who influenced them. But Eustathius of Antioch (d. *c.* 337), the champion of Nicene orthodoxy, is probably more representative of the school, with his antipathy to what he regarded as Origen's excessive allegorism and his recognition, as against the Arians, of the presence of a human soul in the incarnate Christ.

Literalistic views of the School of Antioch

It was, however, much later in the 4th century, in the person of Diodore of Tarsus (*c.* 330–*c.* 390), that the School of Antioch began to reach the height of its fame. Diodore courageously defended Christ's divinity against Julian the Apostate, the Roman emperor (361–363) who attempted to revive paganism, and in his lifetime was regarded as a pillar of orthodoxy. Later critics detected anticipations of Nestorianism (the heresy upholding the division of Christ's Person) in his teaching, and as a result his works, apart from some meagre fragments, have perished. They were evidently voluminous and wide-ranging, covering exegesis, apologetics, polemics, and even astronomy; and he not only strenuously opposed Alexandrian allegorism but also expounded the Antiochene *theoria,* or principle for discovering the deeper intention of scripture and at the same time remaining loyal to its literal sense.

Significant Antiochene theologians

In stature and intellectual power Diodore was overshadowed by his two brilliant pupils, Theodore of Mopsuestia (*c.* 350–428/429) and John Chrysostom (*c.* 347–407). Both had also studied under the famous pagan Sophist rhetorician Libanius (314–393), thereby illustrating the cross-fertilization of pagan and Christian cultures at this period. Like Diodore, Theodore later fell under the imputation of Nestorianism, and the bulk of his enormous literary output—comprising dogmatic as well as exegetical works—was lost. Fortunately, the 20th century has seen the recovery of a few important texts in Syriac translations (notably his *Commentary on St. John* and his *Catechetical Homilies*), as well as the reconstruction of the greater part of his *Commentary on the Psalms.* This fresh evidence confirms that Theodore was not only the most acute of the Antiochene exegetes, deploying the hermeneutics (critical interpretive principles) of his school in a thoroughly scientific manner, but also an original theologian who, despite dangerous tendencies, made a unique contribution to the advancement of Christology. His *Catechetical Homilies* are immensely valuable both for understanding his ideas and for the light they throw on sacramental doctrine and liturgical practice.

In contrast to Theodore, John was primarily a preacher; indeed he was one of the most accomplished of Christian orators and amply merited his title "Golden-Mouthed" (*Chrysostomos*). With the exception of a few practical treatises and a large dossier of letters, his writings consist entirely of addresses, the majority being expository of the Bible. Here he shows himself a strict exponent of Antiochene literalism, reserved in exploiting even the traditional typology (*i.e.*, treatment of Old Testament events, etc., as prefigurative of the new Christian order) but alert to the moral and pastoral lessons of his texts. This interest, combined with his graphic descriptive powers, makes his sermons a mirror of the social, cultural, and ecclesiastical conditions in contemporary Antioch and Constantinople, as well as of his own compassionate concern as a pastor. Indefatigable in denouncing heresy, he was not an original thinker; on the other hand, he was outstanding as a writer, and connoisseurs of rhetoric have always admired the grace and simplicity of his style in some moods, its splendour and pathos in others.

The last noteworthy Antiochene, Theodoret (*c.* 393–*c.* 458) of Cyrrhus, in Syria, was also an elegant stylist. His writings were encyclopaedic in range, but the most memorable perhaps are his *Remedy for Greek Maladies,* the last and in some respects most effective of ancient apologies against paganism; and his *Ecclesiastical History,* continuing Eusebius' work down to 428. His controversial treatises are also important, for he skillfully defended the Antiochene Christology against the orthodox Bishop Cyril of Alexandria (*c.* 375–444) and was instrumental in getting its more valuable features recognized at the Council of Chalcedon. He was a scholar with a comprehensive and eclectic mind, and his large correspondence testifies to his learning and mastery of Greek prose as well as illustrating the history and intellectual life of the age.

The schools of Edessa and Nisibis. Parallel with its richer and better known Greek and Latin counterparts, an independent Syriac Christian literature flourished inside, and later outside (in Persia), the frontiers of the Roman Empire from the early 4th century onward. Aphraates, an ascetic cleric under whose name 23 treatises written between 336 and 345 have survived, is commonly considered the first Syriac Father. Deeply Christian in tone, these tracts present a primitive theology, with no trace of Hellenistic influence but a firm grasp and skillful use of scripture. But it was Edessa and Nisibis (now Urfa and Nusaybin in southeast Turkey) that were the creative centres of this literature. Edessa indeed had been a focus of Christian culture well before 200; the old Syriac version of the New Testament and Tatian's *Diatessaron,* as well as a mass of Syriac apocryphal writings, probably originated in its neighbourhood.

Syriac Christian literature

The chief glory of Edessene Christianity was Ephraem (*c.* 306–373), the classic writer of the Syrian Church, who established his school of theology there when Nisibis, its original home and his own birthplace, was ceded to Persia under the peace treaty of 363, after the death of Julian the Apostate. In his lifetime Ephraem had a reputation as a brilliant preacher, commentator, controversialist, and above all, sacred poet. His exegesis shows Antiochene tendencies, but as a theologian he championed Nicene orthodoxy and attacked Arianism. His hymns, many in his favourite seven-syllable metre, deal with such themes as the Nativity, the Epiphany, and the Crucifixion, or else are directed against skeptics and heretics. His *Carmina Nisibena* make a valuable source book for historians, especially for information about the frontier wars.

After Ephraem's death in 373, the school at Edessa developed his lively interest in exegesis and became increasingly identified with the Antiochene line in theology. Among those responsible for this was one of its leading instructors, Ibas (d. 457), who worked energetically translating Theodore of Mopsuestia's commentaries and disseminating his Christological views. His own stance on the now urgent Christological issue was akin to that of Theodoret of Cyrrhus—roughly midway between Nestorius' dualism and the Alexandrian doctrine of one nature—and he bluntly criticized Cyril's position in his famous letter to Mari (433), the sole survivor (in a Greek translation) of his abundant works; it was one of the Three Chapters anathematized by the second Council of Constantinople (553).

Influence of the Antiochene school of thought in the Syrian East

The frankly Antiochene posture typified by Ibas brought the school into collision with Rabbula, bishop of Edessa from 412 to 435, an uncompromising supporter of Cyril and the Alexandrian Christology. As well as writing numerous letters, hymns, and a sermon against Nestorius, Rabbula translated Cyril's *De recta fide* (*Concerning the Correct Faith*) into Syriac and also probably compiled the revised Syriac version of the Four Gospels (known as the Peshitta) in order to oust Tatian's *Diatessaron.* On his death he was succeeded by Ibas, who predictably exerted his influence in an Antiochene direction.

Another eminent Edessene writer was Narses (d. *c.* 503), who became one of the formative theologians of the Nestorian Church. He was the author of extensive commentaries, now lost, and of metrical homilies, dialogue songs, and liturgical hymns. In 447, when a Monophysite (a heretical view that Christ had one nature) reaction set in, he was expelled from Edessa along with Barsumas, the head of the school, but they promptly set up a new school at Nisibis on Persian territory. The school at Edessa was finally closed, because of its Nestorian leanings, by the emperor Zeno in 489, but its offshoot at Nisibis flourished for more than 200 years and became the principal seat of Nestorian culture. At one time it had as many as 800 students and was able to ensure that the then prosperous church in Persia was Nestorian. On the other hand, Philoxenus of Mabbug, who had studied at Edessa in the second half of the 5th century and was one of the most learned of Syrian theologians, was a vehement advocate of Monophysitism. His 13 homilies on the Christian life and his letters reveal him as a fine prose writer; but he is chiefly remembered for the revision of the Syriac translation of the Bible (the so-called Philoxenian version) for which he was responsible and which was used by Syrian Monophysites in the 6th century.

The Chalcedonian Fathers. From about 428 onward Christology became an increasingly urgent subject of debate in the East, and excited interest in the West as well. Two broad positions had defined themselves in the 4th century. Among Alexandrian theologians the "Word-flesh" approach was preferred, according to which the Word had assumed human flesh at the incarnation; Christ's possession of a human soul or mind was either denied or ignored. Antiochene theologians, on the other hand, consistently upheld the "Word-man" approach, according to which the Word had united himself to a complete man; this position ran the risk, unless carefully handled, of so separating the divinity and the humanity as to imperil Christ's personal unity.

Apollinarius the Younger (*c.* 310–*c.* 390) had brilliantly exposed the logical implications of the Alexandrian view; although condemned as a heretic, he had forced churchmen of all schools to recognize, though with varying degrees of practical realism, a human mind in the Redeemer. His writings were systematically destroyed, but the remaining fragments confirm his intellectual acuteness as well as his literary skill. The crisis of the 5th century was precipitated by the proclamation by Nestorius (d. *c.* 451), patriarch of Constantinople—pushing Antiochene tendencies to extremes—of a Christology that seemed to many to imply two Sons. Nestorius held that Mary was not only *Theotokos* ("God-bearing") but also *anthropotokos* ("man-bearing"), though he preferred the term *Christotokos* ("Christ-bearing"). In essence, he was attempting to protect the concept of the humanity of Christ. The controversy raged with extraordinary violence from 428 to 451, when the Council of Chalcedon hammered out a formula that at the time seemed acceptable to most and that attempted to do justice to the valuable insights of both traditions.

The rise of the Christological crisis

A number of theologians and ecclesiastics either prepared the way for or contributed to the Chalcedonian solution. Three who deserve mention are Theodoret of Cyrrhus, Proclus of Constantinople, and John Cassian. The first was probably responsible for drafting the Formula of Union (433) that became the basis of the Chalcedonian Definition. Proclus was an outstanding pulpit orator, and several of his sermons as well as seven letters concerned with the controversy have been preserved; he worked indefatigably to reconcile the warring factions. Cassian prepared the West for the controversy by producing in 430, at the request of the deacon (later pope) Leo, a weighty treatise against Nestorius.

But much the most important, not least because they approached the debate from different standpoints, were Cyril (*c.* 375–444), patriarch of Alexandria, and Pope Leo the Great (d. 461). Cyril had been the first to denounce Nestorius, and in a whole series of letters and dogmatic treatises he drove home his critique and expounded his own positive theory of hypostatic (substantive, or essential) union. He secured the condemnation of Nestorius at the Council of Ephesus (431), and his own letters were canonically approved at Chalcedon. A convinced adherent of the Alexandrian Word-flesh Christol-

Contributions of Cyril of Alexandria and Leo the Great

ogy, he deepened his understanding of the problem as the debate progressed; but his preferred expression for the unity of the Redeemer remained "one incarnate nature of the Word," which he mistakenly believed to derive from Athanasius. Leo provided the necessary balance to this with his famous *Dogmatic Letter*, also endorsed at Chalcedon, which affirmed the coexistence of two complete natures, united without confusion, in the one Person of the Incarnate Word, or Christ.

In patristic literature, however, the interest of both Cyril and Leo extends far beyond Christology. Cyril, for example, published lengthy essays on the Trinitarian issue against the Arians, and also enormous commentaries on Old and New Testament books. If the former show little originality, his exegesis marked a reaction against the more fanciful Alexandrian allegorism and a concentration on the strictly typological significance of the text. Leo, for his part, was a notable preacher and one of the greatest of popes. His short, pithy sermons, clear and elegant in style, set a fine model for pulpit oratory in the West; and his numerous letters give an impressive picture of his continuous struggle to promote orthodoxy and the interests of the Roman see.

Non-Chalcedonian Fathers. The Chalcedonian settlement was not achieved without some of the leading participants in the debate that preceded it being branded as heretics because their positions fell outside the limits now accepted as permissible. It also left to subsequent generations a legacy of misunderstanding and division.

5th-century heretical literature

The outstanding personalities in the former category were Nestorius and Eutyches (*c.* 378–after 451). It was Nestorius whose imprudent brandishing of extremist Antiochene theses—particularly his reluctance to grant the title of "Mother of God" (*Theotokos*) to the Blessed Virgin—had touched off the controversy. Only fragments of his works remain, for after his condemnation their destruction was ordered by the Byzantine government, but these have been supplemented by the discovery, in a Syriac translation, of his *Book of Heracleides*. Written late in his life, when Monophysitism had become the bogy, this is a prolix apology in which Nestorius pleads that his own beliefs are identical with those of Leo and the new orthodoxy. Eutyches, on the other hand, an over-enthusiastic follower of Cyril, was led by his antipathy to Nestorianism into the opposite error of confusing the natures. He contended that there was only one nature after the union of divinity and humanity in the Incarnate Word, and he was thus the father of Monophysitism in the strict, and not merely verbal, sense.

After the Council of Ephesus in 431 the eastern bishops of Nestorian sympathies gradually formed a separate Nestorian Church on Persian soil, with the see of its patriarch at Ctesiphon on the Tigris. Edessa and then Nisibis were its theological and literary centres. But a much wider body of eastern Christians, particularly from Egypt and Palestine, found the Chalcedonian dogma of "two natures" a betrayal of the truth as stated by their hero Cyril. For the next two centuries the struggle between these Monophysites and strict Chalcedonians to secure the upper hand convulsed the Eastern Church. Among the Monophysites it produced theologians of high calibre and literary distinction, notably the moderate Severus of Antioch (465–538), who while contending stoutly for "one nature after the union" was equally insistent on the reality of Christ's humanity. His contemporary Julian of Halicarnassus taught the more radical doctrine that, through union with the Word, Christ's body had been incorruptible and immortal from the moment of the incarnation.

In the 7th century, inspired by the need for unity in the face of successive Persian and Arab attacks, an attempt was made to reconcile the Monophysite dissenters with the orthodox Chalcedonians. The formula, which it was thought might prove acceptable to both, asserted that though Christ had two natures, he had only one activity; *i.e.*, one divine will. This doctrine, Monothelitism, stimulated an intense theological controversy but was subjected to profound and far-reaching criticism by Maximus the Confessor (*c.* 580–662), who perceived that, if men are to find in Christ the model for their freedom and individuality, his human nature must be complete and therefore equipped with a human will. The formula was condemned as heretical at the third Council of Constantinople of 680–681.

The post-Nicene Latin Fathers. Latin Christian literature in this period was slower than Greek in getting started, and it always remained sparser. Indeed, the first half of the 4th century produced only Julius Firmicus Maternus, author not only of the most complete treatise on astrology bequeathed by antiquity to the modern world but also of a fierce diatribe against paganism that has the added interest of appealing to the state to employ force to repress it and its immoralities. From Africa, rent asunder by Donatism, the heretical movement that rejected the efficacy of sacraments administered by priests who had denied their faith under persecution, came the measured anti-Donatist polemic of Optatus of Milevis, writing in 366 or 367, whose line of argument anticipates Augustine's later attack against the Donatists.

Much more significant than either, however, was Gaius Marius Victorinus, the brilliant professor whose conversion in 355 caused a sensation at Rome. Obscure but strikingly original in his writings, he was an effective critic of Arianism and sought to present orthodox Trinitarianism in uncompromisingly Neoplatonic terms. His speculations about the inner life of the triune Godhead were to be taken up by Augustine.

Three remarkable figures, all different, dominate the second half of the century. The first, Hilary of Poitiers (*c.* 315–*c.* 367), was a considerable theologian, next to Augustine the finest produced by the West in the patristic epoch. For years he deployed his exceptional gifts in persuading the anti-Arian groups to abandon their traditional catchwords and rally round the Nicene formula, which they had tended to view with suspicion. Often unfairly described as a popularizer of Eastern ideas, he was an original thinker whose scriptural commentaries and perceptive Trinitarian studies brought fresh insights. The second, Ambrose of Milan (*c.* 339–397), was an outstanding ecclesiastical statesman, equally vigilant for orthodoxy against Arianism as for the rights of the church against the state. Both in his dogmatic treatises and in his largely allegorical, pastorally oriented exegetical works he relied heavily on Greek models. One of the pioneers of Catholic moral theology, he also wrote hymns which are still sung in the liturgy.

Significance of Hilary, Ambrose, and Jerome in the Western Church

The third, Jerome (*c.* 347–419/420), was primarily a biblical scholar. His enormous commentaries are erudite but unequal in quality; the earlier ones were greatly influenced by Origen's allegorism, but the ones written later, when he had turned against Origen, were more literalist and historical in their exegesis. Jerome's crowning gift to the Western Church and Western culture was the Vulgate translation of the Bible. Prompted by Pope Damasus (*c.* 304–384), he thoroughly revised the existing Latin versions of the Gospels; the Old Testament he translated afresh from the Hebrew. His historical and polemical writings (the latter full of sarcasm and invective) are all interesting, and his rich correspondence supremely so. As a stylist he wrote with a verve and brilliance unmatched in Latin patristic literature.

The two foremost Christian Latin poets of ancient times, Prudentius (348–after 405) and Paulinus of Nola (*c.* 353–431), also belong to this half-century. Both used the old classical forms with considerable skill, filling them with a fresh Christian spirit. Prudentius' work is both the finer in quality and the more wide-ranging; in his *Battle for the Soul* he introduced an allegorical form that made an enormous appeal to the Middle Ages. Paulinus is also interesting for his extensive correspondence, much admired in his own day, which kept him in close touch with many leading Christian contemporaries.

Augustine as the major theologian of the West

All these figures are overshadowed by the towering genius of Augustine (354–430). The range of his writings was enormous: they comprise profound discussions of Christian doctrine (notably his *De Trinitate*); sustained and carefully argued polemics against heresies (Manichaeism, a dualistic religion; Donatism; and Pelagian-

ism, a view that emphasized man's free will); exegesis, homilies, and ordinary sermons; and a vast collection of letters. His two best known works, the *Confessions* and *The City of God*, broke entirely fresh ground, the one being both an autobiography and an interior colloquy between the soul and God, the other perhaps the most searching study ever made of the theology of history and of the fundamental contrast between Christianity and the world. On almost every issue he handled—the problem of evil, creation, grace and free will, the nature of the church—Augustine opened up lines of thought that men still debate. The prose style he used matched the level of his argument, having a rich texture, subtle assonance, and grave beauty that were new in Latin.

In part recovered in recent years, the works of Pelagius (fl. 405–418) show him to have been a writer and thinker of high quality. Early in the 5th century, when the monasteries of southern Gaul became active intellectual centres, Vincent of Lérins (d. *c.* 450) and John Cassian published critiques of Augustine's extreme positions on grace and free will, proposing the alternative doctrine called Semi-Pelagianism, which held that man by his own free will could desire life with God. This in turn was criticized by able writers like Prosper of Aquitaine (*c.* 390–*c.* 463) and the celebrated preacher Caesarius of Arles (470–542) and was condemned at the Council of Orange (529). Cassian, however, a firsthand student of Eastern monasticism, is chiefly important for his studies of the monastic life, based on material collected in the East. The rules he formulated were freely drawn upon a century later by St. Benedict of Nursia (*c.* 480–547), the reformer of Western monasticism, when Benedict composed his famous and immensely influential rule at Monte Cassino.

The decline of Latin and Greek patristic literature

The 6th century marks the final phase of Latin patristic literature, which includes several notable figures, of whom Boethius (480–524), philosopher and statesman, is the most distinguished. His *De consolatione philosophiae* (Concerning the Consolation of Philosophy) was widely studied in the Middle Ages, but he also composed technically philosophical works, including translations of, and commentaries on, Aristotle. Beside him should be set his longer lived contemporary, Cassiodorus (*c.* 490–*c.* 585), who, as well as encouraging the study of Greek and Latin classics and the copying of manuscripts in monasteries, was himself the author of theological, historical, and encyclopaedic treatises. Also notable is Venantius Fortunatus (*c.* 540–*c.* 600), an accomplished poet whose hymns, such as "Vexilla regis" ("The royal banners forward go") and "Pange lingua" ("Sing, my tongue, the glorious battle"), are still sung. Finally, Gregory the Great (*c.* 540–604) was so prolific and successful an author as to earn the title of Fourth Doctor of the Latin Church. Although unoriginal theologically and reflecting the credulity of the age, his works (which include the earliest life of St. Benedict) made an enormous appeal to the medieval mind.

Later Greek Fathers. The closing phase of patristic literature lasted longer in the Greek East than in the Latin West, where the decline of culture was hastened by barbarian inroads. But even in the East a slackening of effort and originality was becoming perceptible in the latter half of the 5th century. A clear illustration of this is provided by the practice of substituting chain commentaries composed of excerpts from earlier exegetes and anthologies of opinions of respected past theologians for independent exposition and speculation.

Yet the picture was not altogether dim. In the strictly theological field, Leontius of Byzantium (d. *c.* 545) showed ability and originality in reinterpreting the Chalcedonian Christology along the lines of St. Cyril with the aid of the increasingly favoured Aristotelian philosophy. Two other writers, very different from him and from each other, revived in the late 5th and early 6th centuries the brilliance of past generations. One was the figure who called himself Dionysius the Areopagite (*c.* 500), the still unidentified author of theological and mystical treatises that were destined to have an enormous influence. Based on a synthesis of Christian dogma and Neoplatonism, his work exalts the negative theology (God is understood by what he is not) and traces the soul's ascent from a dialectical knowledge of God to mystical union with him. The other is Romanos Melodos (fl. 6th century), greatest hymnist of the Eastern Church, who invented the kontakion, an acrostic verse sermon in many stanzas with a recurring refrain. The sweep, pathos, and grandeur of his compositions give him a high place of honour among religious poets.

With Maximus the Confessor and John of Damascus the end of the patristic epoch is reached. Maximus was a major critic of Monothelitism; he was also a remarkable constructive thinker whose speculative and mystical doctrines were held in unity by his vision of the incarnation as the goal of history. Writing early in the 8th century, John was chiefly influential through his comprehensive presentation of the teaching of the Greek Fathers on the principal Christian doctrines. But he was more than a mere systematizer. In constructing his synthesis he added at many points a finishing touch of his own; his writings in defense of images, prepared to counter the Iconoclasts (those who advocated destruction of religious images, or icons), were original and important; and he was the author of striking poems, some of which found a place in the Greek liturgy.

CONCLUSION

The vitality of patristic literature

Even such a survey as the present, concerned rather to highlight the most significant movements and figures than to provide an exhaustive catalog of writers and their works, brings out the extraordinary vitality of the patristic literature. For four or five hundred years, when secular culture was slowly but steadily in decline, the patristic writers breathed new life into the Greek and Latin languages and created Syriac as a literary medium. Even when the period came to an end, the halt was really only a temporary pause until the impulses behind it could force other outlets. The literature of the later Byzantine Empire looked back to and drew nourishment from the golden centuries of the Fathers, while Latin Christian letters experienced more than one renascence in the Middle Ages.

The range and variety, too, of the literature are impressive. Its overwhelmingly theological concern necessarily imposed understandable but serious limitations, but, when these have been allowed for, the Christian writers must be acknowledged to have been remarkably successful at molding the traditional literary forms to their new purposes and also at improvising fresh ones adapted to their special situations. Aesthetically considered, patristic literature contains much that is mediocre and even shoddy, but also a great deal that by any standards reaches the heights. And it has a unique interest as the creation of an immensely dynamic and far-reachingly important religious movement during the centuries when it could dominate the whole of life and society.

BIBLIOGRAPHY

Texts: The most complete collection of Greek and Latin patristic writings in the original is J.P. MIGNE, *Patrologiae cursus completus*; there is a Greek series with Latin translations, 161 vol. (1857–66), and a Latin series, 221 vol. (1844–55). More modern collections, less complete to date but providing better critical texts, are: for the Greek Fathers, *Die griechischen christlichen Schriftsteller der ersten drei Jahrhunderte* (1897–); for the Latin Fathers, *Corpus scriptorum ecclesiasticorum latinorum* (1866–), and *Corpus Christianorum* (1954–); for both, *Sources chrétiennes* (1941–), with French translations. Translations of Greek works into Oriental languages are published in *Corpus scriptorum christianorum orientalium* (1903–), and in *Patrologia orientalis* (1907–). Many texts are published in critical editions in *Texte und Untersuchungen zur Geschichte der altchristlichen Literatur* (1882–).

Translations: The following series, while consisting only of selections, provide English translations of patristic works: "Library of the Fathers," 43 vol. (1839–81); "The Ante-Nicene Christian Library" (1864–); "Select Library of Nicene and Post-Nicene Fathers of the Christian Church" (1887–92); "Ancient Christian Writers: The Works of the Fathers in Translation" (1946–); and "The Fathers of the Church" (1947–).

General: The most important of the systematically arranged manuals on the patristic literature available in English are: B. ALTANER, *Patrologie*, 7th ed. (1966; Eng. trans., 1960); F.L. CROSS, *The Early Christian Fathers* (1960); and J. QUASTEN, *Patrology*, 3 vol. (1950–60). See also P. DE LABRIOLLE, *Latin Christianity* (Eng. trans. 1924); H. VON CAMPENHAUSEN, *The Fathers of the Greek Church* and *The Fathers of the Latin Church* (Eng. trans., 1963 and 1964).

(J.N.D.K.)

Paul III, Pope

Alessandro Farnese, a scion of one of the great *condottieri* families of Tuscany, reigned as Pope Paul III from October 13, 1534, to November 10, 1549. Known as the "Farnese pope," he was—in his secular life-style, in his promotion of family interest, and in his patronage of the arts—a typical representative of the Renaissance papacy. He nevertheless manifested a true piety and a concern for church reform that culminated in the calling of the Council of Trent in 1545, inaugurating the resurgence of the Roman Catholic Church after the Protestant Reformation.

Paul III, contemporary medallion. In the coin collection of the Vatican Library.

The Farnese family

Background and early years. Born at Canino, February 29, 1468, Alessandro was the son of Pier Luigi Farnese and Giovannella Gaetani. In service to the papacy since the 12th century, the Farnese family had extended its possessions from a stronghold on Lake Bolsena south and westward to include most of the fiefs between Perugia, Orvieto, Sermoneta, and the sea. In 1417 Ranuccio Farnese (the Elder), one of the most celebrated *condottieri* (mercenary soldiers) of his time, had been made a Roman senator by Pope Martin V. Ranuccio's son Pier Luigi, by marriage with the Gaetani heiress, solidified the Farnese position in the Roman nobility. In 1489, Pier Luigi's daughter Giulia la Bella married Orsino Orsini, a relative of the Spanish cardinal Rodrigo Borgia (Borja), and became a favourite at the papal court. Her brother Bartolommeo became lord of Montalto; her other brother, Alessandro, was destined for the church.

Sensitive and talented, Alessandro Farnese was entrusted to the Humanist Pomponio Leto for his early education and then joined the Medici circle in Florence under Lorenzo the Magnificent. There he was associated with Giovanni de' Medici (the future Pope Leo X) and attended the University of Pisa.

Because of an obscure family quarrel, Alessandro's early sojourn in Rome was interrupted by a short prison term under Pope Innocent VIII. But his career was assured when Cardinal Rodrigo Borgia became his patron. On Rodrigo's election to the papacy (taking the name Alexander VI), he made Alessandro treasurer of the Roman Church, and a year later, on September 20, 1493, created him a cardinal deacon. Gossip traced Alessandro's rapid preferment to the intimacy between his sister Giulia and the Borgia pope, and Alessandro was referred to as the "petticoat cardinal."

Although a prelate, Alessandro did not become an ordained priest until 1519. Meanwhile, he conducted himself like a Renaissance nobleman. Of wide artistic tastes and philosophic interests, he increased his revenues with multiple benefices. He travelled on diplomatic missions, enjoyed the hunt, and delighted in majestic religious and secular ceremonies. Favoured also by Pope Leo X, he used his wealth to enhance his family position and constructed the famous Palazzo Farnese, on the Via Giulia in Rome. Moreover, despite his unfeigned personal piety, the Farnese cardinal kept a wellborn Roman mistress by whom he fathered four children—Pier Luigi, Paolo, Ranuccio, and Costanza. (Later, as Pope Paul III, he provoked serious charges of nepotism by using his papal influence to further the interests of his children and their families, going so far in one celebrated incident as to appoint two of his grandchildren, still in their teens, to the cardinalate.)

Reform of his private life

In 1509 Pope Julius II invested Cardinal Alessandro Farnese with the bishopric of Parma. Selecting Bartolomeo Giudiccioni as his vicar general, the Cardinal took seriously the obligation of governing the diocese and decided to change his private way of life. In May 1512, he served as Julius' legate for the Fifth Lateran Council in Rome; then, having discontinued his liaison with his mistress in 1513, he put the reform decrees of that council into effect in Parma with a visitation in 1516 and, three years later, with a synod. In June 1519 he was ordained a priest and said his first mass on Christmas of that year. Thereafter, his private life was without reproach, and the Cardinal was identified with the reform party in the Roman Curia.

Achievements as pope. The Farnese cardinal's diplomatic skills made him an invaluable aid to the five pontiffs in whose election he participated—Pius III, Julius II, Leo X, Adrian VI, and Clement VII—before he himself emerged as the Roman pontiff on October 13, 1534. At the age of 67, Pope Paul, though apparently frail, was a man of great charm and determination. He was described in diplomatic reports as shrewd and affable, deliberately slow of speech yet loquacious, expressing himself in an elegant Italian or Latin with learned allusions, and scrupulously refraining from tying himself down to a definite "yes" or "no" until the final settlement of an issue—but then able to act with swift, uncompromising dispatch.

Of medium height, spare of figure, with an aquiline nose, ruddy complexion, and aristocratic hands, Paul III was portrayed by Titian in 1543 at age 75 in the full vigour of his pontificate. Two later Titian portraits depict the ravages of age on the pontiff but reveal the depth of intelligence and strength that accompanied him to his last breath at 82.

The pontiff kept himself in good health by frequent excursions in Rome and the countryside, supervising urban projects and fortifications. He encouraged agriculture and provided for new food supplies. His coronation was accompanied by tournaments and pageants, signalling the end of the austerity imposed by the sack of Rome in 1527. In 1536, he authorized the revival of the carnival and rearranged the main thoroughfare in Rome for the visit of the Emperor Charles V, restoring the panoply of traditional ceremonies for the reception of princes and ambassadors. His lavish policies brought prosperity to Rome and the Papal States.

Despite charges of paganism levelled against his pontificate for its secular extravagances—even astrologers were admitted to the papal court—Pope Paul was determined to reform the church. Aware, however, of the setback suffered by Pope Adrian VI's precipitate reform policy a decade earlier, he proceeded, in the face of great internal opposition, with a slow but deliberate call for conversion of the Roman clergy and curia, as well as a reorganization of the papal offices. Immediately upon his election he announced his intention to hold a council and summoned the papal ambassadors Girolamo Aleandro and Pietro Paolo Vergerio from Venice and Vienna, respectively, for consultation about the dangerous state of the church in the north. He then dispatched Vergerio to Austria and Germany on a two-year sojourn to enlist prelates and

The plan for a reform council

princes in the project of holding a council in Mantua or Turin. The Protestants for years had been clamouring for such an assembly on German soil, free of Roman domination. The papacy, however, had feared the calling of a general council would compromise its authority. Paul, however, proceeded with preparations for the council even after it was rejected by Martin Luther and the Protestant leaders.

In a series of consistories, or consultative assemblies, he created cardinals of proven virtue throughout Europe. He also encouraged the foundation of new religious orders and congregations, such as the Theatines, Somaschi, Barnabites, and the Ursuline nuns. Particularly important was his confirmation of the new Jesuit order, which was to provide the papacy with one of its principal instruments in promoting the Counter-Reformation.

Pope Paul's greatest problems were caused by his relations with Emperor Charles V and the French king Francis I, whom he tried to persuade to cease their inveterate wars and turn their forces against the Ottoman Turks, who menaced the coasts of Italy as well as the outposts of Christendom in the East. He encouraged the Emperor to suppress the Lutheran Schmalkaldic League, urged the French king to eliminate the Huguenots, and employed tortuous diplomatic skill to avoid siding with either monarch. In 1538 he journeyed to Nice in an attempt to bring them together. That same year, he excommunicated the English king Henry VIII, who had declared himself head of the English Church. (An earlier sentence of excommunication under Clement VII had been suspended.) Using the military skill of Pier Luigi (his son by his former mistress) and the diplomacy of his grandson Cardinal Alessandro, Paul asserted papal control over central Italy, skillfully avoiding encirclement by both the imperial and French forces.

In May 1536 Pope Paul published a bull of convocation for his proposed council to be held in Mantua. He also authorized a select group of cardinals to draw up a report on the abuses within the church. Guided by Cardinal Gasparo Contarini, this group denounced the ordination of poorly prepared priests, the selection of incompetent bishops, the accumulation of benefices, and the decadence of the religious orders, preaching, and the care of souls. The report, however, fell into Protestant hands and was used by Luther in a violent attack on the Roman Church and the papacy. Nevertheless, the Pope pursued his plans to hold the council, scheduled to open on May 23, 1537, at Mantua. With infinite patience, Paul sought to overcome the opposition of Emperor, kings, prelates, and princes, proroguing and postponing the council's opening again and again over the course of nine years, but finally succeeding in having it inaugurated by his legate, Cardinal Giovanni del Monte, in Trent on December 13, 1545.

In deference to the clamouring of the Protestants, the Emperor insisted that the council confine itself mainly to dealing with discipline and reform. Nevertheless, the Pope's decision that doctrinal matters be given precedence prevailed, and, in its early sessions, the Council of Trent hammered out decrees on the canon of the Scriptures, original sin, justification, and the sacraments, as well as on reform. Fears of the plague and the menace of an attack by armed Protestant forces induced the Pope to accept the council's transfer to Bologna in February 1548. But the Emperor forbade the Spanish and German prelates to go to Bologna, and the Pope had to suspend the Council on September 17, 1549. Nevertheless, this first phase of the Council of Trent had achieved a substantial step forward, leading to a thorough reform of the Church's teaching and discipline.

Throughout his pontificate, Pope Paul frequently visited trouble spots in the Papal States and beyond. He was in Civitavecchia in 1535 and 1537; visited Lucca and Piacenza on his way to Nice in 1538; appeared in Perugia to pacify the city after his forces broke the power of the Colonna family in 1540; and in 1543 he visited Bologna on his way to Busseto to meet the Emperor.

Patronage of the arts

As a patron of the arts, Pope Paul restored the University of Rome, increased the subsidies and importance of the Vatican Library, and showed favour to theologians and canonists but did not neglect the fine arts. He cajoled Michelangelo into finishing the fresco "The Last Judgment" in the Sistine Chapel, decorating the Pauline Chapel, and completing the plans for the construction of the new St. Peter's Basilica. He used Antonio da Sangallo the Younger and a host of architects to renew the fortifications of Rome and the Papal States, continued the construction of the Sala Regia (Royal Hall) in the Vatican, and ordered the reconstruction of the buildings on the Capitoline Hill.

In the midst of grave family, political, and military setbacks, the Pope visited the Quirinal Palace in Rome in early November 1549 and was taken with a raging fever. Clear-minded to the end, he received the last sacraments and died on November 10, in his 82nd year. On his deathbed he is reported to have repented of his nepotism.

Whatever the faults of his early career and the political intrigues of his pontificate, Pope Paul III was remembered by contemporaries as "good hearted, obliging and supremely intelligent . . . worthy to be described as magnanimous." He led the Church out of the decadent splendour of the Renaissance into the austere rejuvenation of the post-Reformation epoch. His grandiose tomb in St. Peter's by Michelangelo's pupil Guglielmo della Porta befits the place he occupies in the church's history.

Paul VI, Pope

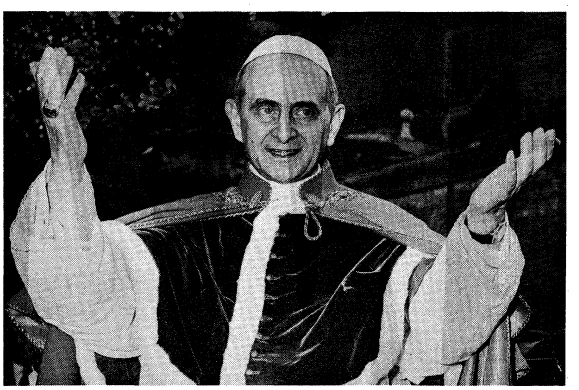
Pope Paul VI (Giovanni Battista Montini), 262nd pope of the Roman Catholic Church, governed through most of the second Vatican Council (1962–65) and in the immediate postconciliar period. His pontificate was confronted with the many problems and uncertainties of a church facing a new position and role in the contemporary world.

Early Vatican career

Early life and career. Born at Concesio (Brescia), September 26, 1897, the son of a middle class lawyer—who was also a journalist and local political figure—and of a mother belonging to the same social background, young Montini was in his early years educated mainly at home because of frail health and later in Brescia. Ordained priest on May 29, 1920, he was sent by his bishop to Rome for higher studies and was eventually recruited for the Vatican diplomatic service. His first assignment, in May 1923, was to the staff of the apostolic nunciature (papal ambassador's post) in Warsaw, but persistent ill-health brought him back to Rome before the end of that same year. He then pursued special studies at the Ecclesiastical Academy, the training school for future Vatican diplomats, and at the same time resumed work at the Vatican Secretariate of State, where he remained in posts of increasing importance for over 30 years.

Leisure moments away from the office were dedicated to the spiritual care of young students from the University of Rome. He thus formed close personal contacts and friendships with many promising young men who later emerged as prominent leaders on the Italian political scene after World War II. Among these were: Giovanni Gronchi, later president of Italy; the future prime ministers of Italy Mario Scelba and Aldo Moro; and future governmental cabinet members. This university student group, under the guidance of their young chaplain Montini, undertook visits to the poor and practical efforts to assist the poor in their needs.

In 1939 Montini was appointed papal undersecretary of state and later, in 1944, acting secretary for ordinary (or nondiplomatic) affairs. He declined an invitation to be



Paul VI.

elevated to the Sacred College of Cardinals in 1953. In the beginning of November 1954, Pope Pius XII appointed him archbishop of Milan and Pope John XXIII named him cardinal in 1958. He was elected pope on June 21, 1963, choosing to be known as Paul VI.

Social and ecclesiastical concerns

Vatican II and Paul VI's pontificate. The Montini pontificate began in the period following the difficult first session of the second Vatican Council, in which the new pope had played an important, though not spectacular, part. His lengthy association with university students in the stormy atmosphere of the early days of the Fascist regime in Italy, plus the generally philosophical bent of his mind—developed by a long-standing habit of extensive and reflective reading—enabled him to bring to the perplexing problems of the times an academic understanding, coupled with the knowledge derived from long years of practical diplomatic experience. Paul VI guided the three remaining sessions of the second Vatican Council, often developing points he had first espoused as cardinal archbishop of Milan. His chief concern was that the Roman Catholic Church in the 20th century should be a faithful witness to the tradition of the past, except when tradition was obviously anachronistic.

Upon the completion of the council (December 8, 1965), Paul VI was confronted with the formidable task of implementing its decisions, which affected practically every facet of church life. He approached this task with a sense of the difficulty involved in making changes in centuries-old structures and practices—changes rendered necessary by many rapid transformations in the social, psychological, and political milieu of the 20th century. Montini's approach was consistently one of careful assessment of each concrete situation, with a sharp awareness of the many varied complications that he believed could not be ignored. This prevalently philosophical attitude was often construed by his critics as timidity, indecision, and uncertainty. Nonetheless, many of Paul VI's decisions in these crucial years called for courage. In July 1968, he published his encyclical *Humanae Vitae* ("Of Human Life"), which reaffirmed the stand of several of his predecessors on the long-smoldering controversy over artificial means of birth prevention, which he opposed. In many sectors this encyclical provoked adverse reactions that may be described as the most violent attacks on the authority of papal teaching in modern times. Similarly, his firm stand on the retention of priestly celibacy (*Sacerdotalis Caelibatus*, June 1967) evoked much harsh criticism. Paul VI later likened the large numbers of priests leaving the ministry to a "crown of thorns." He also was disturbed by the growing numbers of religious men and women asking for release from vows or who were abandoning out of hand their religious vows.

From the very outset of his years as pope, Paul VI gave clear evidence of the importance he attached to the study and the solution of social problems and to their impact on world peace. Social questions had already been prominent in his far-reaching pastoral program in Milan (1954–63). During those years he had travelled extensively in the Americas and in Africa, centring his attention mainly on concern for workers and for the poor. While visiting the United States in 1960, the then Cardinal Archbishop of Milan presented to Pres. Dwight D. Eisenhower a statue of an angel shattering the chains of a captive, thus indicating his constant interest in the relief of oppression in any form. Such problems dominated his first encyclical letter *Ecclesiam Suam* ("His Church"), August 6, 1964, and later became the insistent theme of his celebrated *Populorum Progressio* ("Progress of the Peoples"), March 26, 1967. This encyclical was such a pointed plea for social justice that in some conservative circles the Pope was accused of Marxism.

Apostolic journeys. In an address to the council fathers at the end of the first session of the second Vatican Council, the then Cardinal Montini formulated a question that may be called the theme of his pastoral service as pontiff: "Church of Christ, what say you of yourself?" In an effort to answer this fundamental question, Paul VI undertook a series of apostolic journeys that were unparalleled occasions for a pope to set foot on every continent. His first journey was a pilgrimage to the Holy Land (January 1964), highlighted by his historic meeting with the Greek Orthodox patriarch of Constantinople, Athenagoras, in Jerusalem. At the end of that same year he went to India, the first pope to visit Asia. The following year (October 4, 1965) he travelled to the headquarters of the United Nations in New York where he delivered a moving plea for peace to the General Assembly in special session. In 1967 he undertook short visits to Fátima (Portugal) and to Istanbul and Ephesus (Turkey), a journey that had special ecumenical significance: a second meeting with Athenagoras in the patriarch's own episcopal city (Constantinople). In August 1968, the Pope went to Bogotá (Colombia), with a brief stopover in the Bermudas on the return flight to Rome. He appeared before the International Labour Organisation and the World Council of Churches in Geneva (Switzerland), in June 1969. The following month he was in Uganda, East Africa. In the autumn of 1970, he undertook the longest papal journey in modern history: ten days spent in visits to Teheran (Iran), East Pakistan, the Philippines, Western Samoa, Australia, Indonesia, Hong Kong, and Ceylon, each stop bringing Paul VI into personal contact with different peoples of the world. His arrival in Manila almost ended in tragedy when an attempt was made on his life within minutes of his descent from the plane, but with no serious injury.

Papal journeys and concerns

The themes treated by Paul VI on these trips were basically the same: world peace, social justice, world hunger, illiteracy, the brotherhood of man under God, and international cooperation. These subjects reflect the character and the ideals of Paul VI, often called the "pilgrim pope," for whom "peace and brotherhood are synonymous."

Social and ecumenical interests. On January 6, 1971, in the Clementine Hall in the Vatican, Paul VI conferred the Pope John XXIII Peace Prize on the Albanian-born Mother Mary Teresa Bojaxhiu, who had spent most of her life in India, where she had founded a special religious congregation of women dedicated to the alleviation of the countless ills of the poorest classes in the country, gathering the dying off the streets and doing what she could to assist them in every way possible. Paul VI declared on this occasion that the award was intended to centre attention on how even a humble individual without means can further world peace without fanfare, simply by proving in day-to-day action that "every man is my brother," the theme that he himself had chosen for the observance of the 1971 Day for World Peace. Here, as in other instances, Paul's aim was to confront the world at large with the inescapable problems of justice and peace while at the same time proving conclusively that even these apparently insoluble problems can and must be settled with realistic courage and individual perseverance. He was relentlessly anxious to arouse the universal conscience of mankind to the practical solution of the problems involved in the realization of the ideal of charity and justice. As archbishop of Milan, he had been accustomed to go out every Friday afternoon, in memory of the Passion of Christ, to visit some poor invalid or someone tried by suffering, to make his own personal contribution to helping his fellowmen.

Ecumenical concerns

Paul VI's human concern found further expression in his efforts to lessen the long-standing tensions between the church of Rome and other churches and even with those professing no religion at all. He sought out closer understanding with numerous religious leaders throughout the world, both Christian and non-Christian, placing more emphasis on those aspects that unite the churches rather than on those that divide. To show that mutual acquaintance is at the very foundation of any plans or hopes for unity, Pope Paul met with prominent religious leaders from various communities in Great Britain, the United States, and the Soviet Union, as well as other countries. Paul VI also set up a special secretariat for nonbelievers, stressing the need of understanding and endeavouring to solve the problems posed by atheism. Under his guidance the Roman Catholic Church drastically revised its legislation governing marriages between its own members and those who profess other faiths, expressing a firm desire to diminish the threat of human tragedy following possible clashes of individual consciences. For this reason Paul VI's *motu proprio* (a type of papal document) was welcomed and praised for its understanding of human problems and its desire to find a satisfactory solution to the problem of mixed marriages without demanding of either side any renunciation of basic principles of conscience. In the rise of modern ecumenism, Paul VI saw excellent opportunities to encourage world brotherhood, which, he hoped, might enable all men to continue their efforts for human well-being in their pursuit of happiness in unity of faith in God. On May 15, 1971, commemorating the 80th anniversary of Pope Leo XIII's encyclical *Rerum Novarum* on the reform of the social order, Pope Paul issued a forceful apostolic letter, "Octogesima Adveniens" with particular insistence on the necessity of involvement of all men in the solution of the problems of justice and peace. He died at Castel Gandolfo on August 6, 1978.

(E.L.H.)

Paul the Apostle, Saint

Paul was a 1st-century Jew who, after being the bitterest enemy of the Christian Church, became its leading missionary and possibly its greatest theologian. His letters, the earliest extant Christian documents, antedate the Gospels of the New Testament. More than half of the Acts of the Apostles deals with his career, and this, together with the letters written by him or in his name, comprises one-third of the New Testament. His efforts and his vision of a world church were responsible for the rapid spread of Christianity and for the speed with which it became a universal religion. None of the followers of Jesus did more than he to establish the patterns of Christian thought and practice.

Sources. For Paul's life there are no reliable sources outside the New Testament. The primary source is his own correspondence, of which Romans, I and II Corinthians, and Galatians are acknowledged to be genuine by all scholars; Philippians, Colossians, I and II Thessalonians, and Philemon by most. About Ephesians, opinion is divided, but it contains little biographical material. The Pastoral Letters (to Timothy and Titus) were written by a disciple of Paul but probably contain Pauline fragments. The letters alone, however, provide no connected story. For that it is necessary to rely on Acts, written some 30 years after Paul's death. Because its evidence sometimes conflicts with that of the letters, some scholars question the historicity of Acts. The general belief is, however, that Acts was written by Paul's companion the evangelist Luke, who drew on his own diary for much of the story.

Life. *Early life.* Paul's birthplace, Tarsus in Cilicia, a district of Asia Minor lying on the main trade route between East and West, was a cosmopolitan university city, which had been the home of famous Stoic philosophers. Paul was proud of his native city and manifested his debt to its Greek culture in his command of idiomatic Greek, in the occasional use of philosophical terms, and in a wealth of metaphors drawn from city life. He was proud, too, of the Roman citizenship inherited from his father; he used his Roman name Paulus in preference to his Jewish name Saul, and he found in the world empire of Rome a model for his later faith in a universal Christian commonwealth. Yet his formal education must have been strictly Jewish. He grew up with a knowledge of Hebrew and under the scrupulous regimen of the Pharisees, a religious and political Jewish party that emphasized moral purity and reinterpreted the Torah, or Law, according to the needs of the time. His subsequent conversion never robbed him of his pride in the ancestral traditions absorbed in childhood.

St. Paul, from the Pisa polyptych by Masaccio, 1426. In the Museo Nazionale di San Matteo, Pisa, Italy. His attributes, the book and the sword, symbolize the word of God (the book), which is the weapon (the sword) employed by the Holy Spirit.
Alinari

The notion that Paul had an unhappy adolescence, tortured by religious doubts and an uneasy conscience, is based on a misunderstanding of the Letter of Paul to the Romans, chapter 7. Though in the guise of autobiography, this chapter is a Christian analysis of religious legalism. Paul's explicit references to his early life are free from any suggestion of inner struggle. He excelled all his contemporaries in his zeal for the Law of Moses, and by its standards his life was blameless. His picture—in Romans, chapter 2, verses 17–20—of the pious Jew exulting in the Law, proud of his God, confident of being guide to the blind, is a self-portrait.

Paul's training as a rabbi

According to Acts, Paul was trained as a rabbi under Gamaliel I, a renowned teacher of the Law, and this is borne out by his frequent use of rabbinic methods of exegesis (*i.e.*, interpretation of a scriptural text) and his knowledge of midrashic legends (*i.e.*, commentaries or explanations of a scriptural text in the form of edifying lessons). Like most rabbis he also learned a trade—tentmaking—by which throughout his missionary career he was regularly to earn his own living. It is unlikely that he ever met Jesus. In Jerusalem, however, he learned enough about Jesus to regard him as a menace to Pharisaic Judaism, for Paul first appears on the scene of history as a persecutor of the Christian Church. In the judgment of Paul the Pharisee, Jesus had broken the Law and taught others to break it and had been justly condemned under the curse that the Old Testament book of Deuteronomy pronounces on lawbreakers.

Conversion. Through a vision on the road to Damascus, Paul became convinced that this crucified Jesus was alive again, vindicated by the Resurrection. Paul came to believe that the curse of crucifixion had been real enough, but it had been borne vicariously. Out of love for men Christ had identified himself with them and now invited them to be identified with him in his new life. In Galatians, he says: Christ "loved me and gave himself for me." For Paul, Christ, not the Law, was the full, final revelation of God's nature and purpose; and all of his passionate devotion was transferred to this new centre. Along with his conversion came his call to be Apostle to the Gentiles and to break down the barrier of prejudice and hostility that the Law had erected between the Jewish people and their neighbours.

Immediately after this experience, Paul withdrew into solitude in Arabia, no doubt to think over the implications of what had happened to him. In later controversy, he insisted that he had received directly from Christ not only his apostleship but his gospel, which declared that a man's standing with God depends solely on his faith in what God has done in Christ and not in any sense on his own effort or achievement. He also referred, however, to traditions received from those who were Christians before him and displayed a full acquaintance with the teaching of Jesus recorded in the Gospels. Much of this he must have learned at Damascus after his return from Arabia.

Visits to Jerusalem and Antioch. Three years later Paul spent two weeks in Jerusalem visiting Peter and James. According to Acts he was forced to leave Damascus by a threat against his life and escaped over the wall of the city in a basket. He himself mentions this escape in II Corinthians, adding that the threat came from a governor appointed by the Nabataean king, Aretas. The difficulty with this account is that Damascus was under Roman rule at least until AD 37, and it is not possible to defer Paul's first visit to Jerusalem as late as that without throwing the chronology of his career into confusion. Possibly the escape belongs to a later, unrecorded visit to Damascus.

From Jerusalem Paul returned to his native Cilicia. It was 14 years later (or possibly 14 years from his conversion) before he was to be in Jerusalem again. If this information from the Letter of Paul to the Galatians is fitted into the framework of Acts, Paul is out of view for ten years, until—according to Acts, chapter 11—the missionary Barnabas finds him and takes him to Antioch. This hiatus can be avoided only by abandoning the order of Acts altogether and assuming that the second visit took place after his missionary work in Asia Minor and Greece. This radical solution, however, creates more problems than it purports to solve and has won little support from biblical scholars. Rather, it seems necessary to imagine Paul engaged in strenuous missionary work in Cilicia and Syria and to assign to this period many of the experiences listed in II Corinthians, chapter 11, verses 23–27, for which no place can be found in the subsequent narrative of Acts.

The first planned Christian missions

Thus far, Christianity had been disseminated beyond Palestine without plan or direction from its leaders. Christians had been scattered by persecution and had carried the gospel with them, preaching at first to fellow Jews but finding a growing response also among Gentiles. The idea of a planned mission first arose at Antioch. The missionaries, Barnabas and Paul, before setting out on their travels, went to Jerusalem, accompanied by Titus. They had a private consultation with the leaders of the Christians there—James, Peter, and John—and reached agreement on future missionary policy. In view of Paul's vehement assertion that nobody else was party to the discussion, this meeting cannot be identified with the public conference of Acts, chapter 15. Acts, chapter 11, mentions an earlier visit of Paul and Barnabas to Jerusalem to deliver a relief fund for a famine that occurred probably in AD 46, and it is best to assume that they took advantage of that occasion to lay their plans before their Jerusalem colleagues.

Shortly after this Peter visited Antioch. One question that had not been discussed at Jerusalem was the relationship between Jewish and Gentile Christians in the new community. Jews were forbidden by their Law to eat with Gentiles. The church at Antioch had been disregarding this rule and holding common meals and Eucharists, until a protest came from James that this practice at Antioch was making things difficult and even dangerous for the church in Jerusalem. The Jewish members, including Peter and Barnabas, accordingly abandoned their liberalism for fear of Jewish reprisals against the mother church. According to Galatians, it was left for Paul to show his mettle by insisting that not only church unity but the very truth of the gospel was at stake.

First missionary journey. Paul and Barnabas, accompanied by Barnabas' cousin John Mark, now set out for Cyprus on a preaching tour, beginning at Salamis, the principal city of the island, and ending at Paphos, the seat of government, where they had an encouraging interview with the governor, Sergius Paulus. They then crossed to the mainland and landed at Perga (near modern Murtana, Turkey). There, to Paul's annoyance, Mark left the party for home. Paul himself was ill, probably with an attack of the recurrent illness that in II Corinthians he called his "thorn in the flesh." He had to change his plans (presumably, in view of his later history, he already had his sights on Ephesus—an ancient Ionian city in western Asia Minor) and go to recuperate in the more healthful uplands of Anatolia, or Asia Minor. This reconstruction of events is known as the "South Galatia" theory—*i.e.*, that Galatians was written to the churches founded during the mission of Acts, chapters 13 and 14—in contrast to a "North Galatia" theory that is no longer held by many scholars.

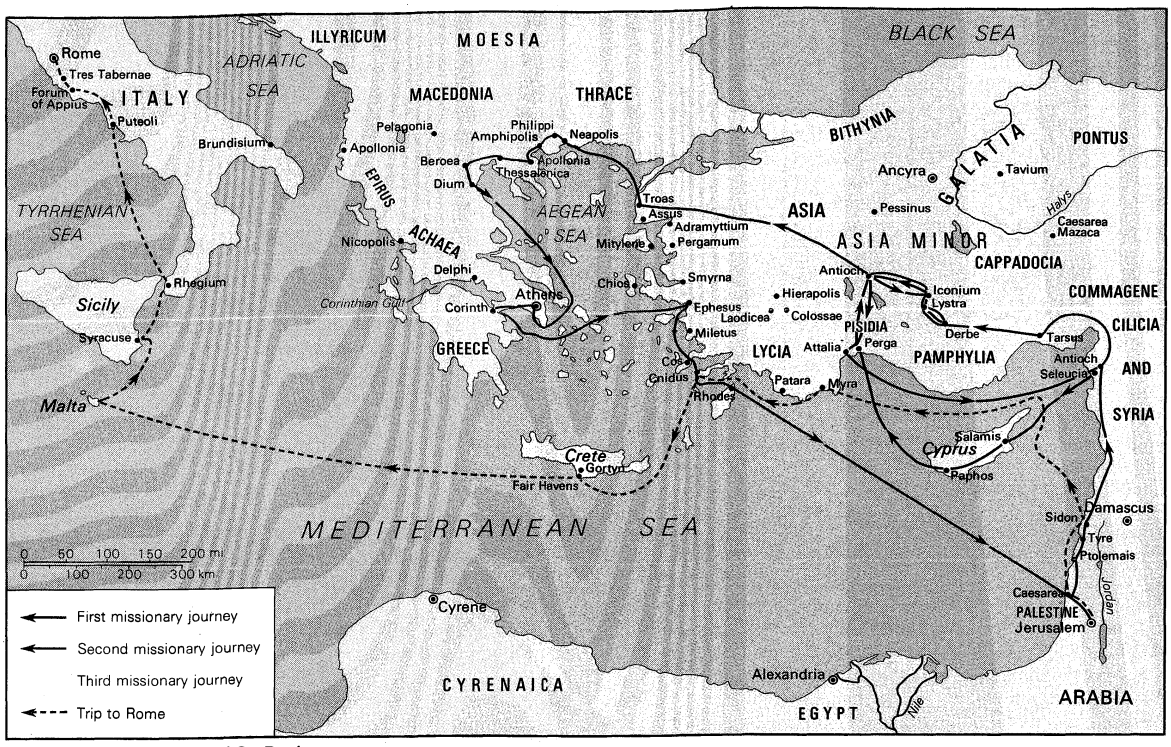
The Galatian mission started in the Roman colony of Pisidian Antioch (near modern Yalvaç, Turkey), where the missionaries preached in the synagogue until Jewish hostility first compelled them to turn to the Gentiles and finally drove them from the city. Their visit to Iconium (modern Konya, Turkey) followed the same pattern. At Lystra (near modern Hatunsaray, Turkey) they were first mistaken for local gods, but subsequently Paul was stoned and left for dead. Yet, after reaching Derbe (the site is disputed), they were able to retrace their steps and revisit the churches they had founded before returning to Syrian Antioch.

The Jerusalem conference

The success of this tour in gaining Gentile converts made a settlement of the dispute over table fellowship more urgent than ever; and so a conference was held in Jerusalem, which issued a letter asking Gentile Christians to relieve Jewish Christians of embarrassment by observing some of the Jewish rules of ceremonial purity. The historicity of this conference, or at least of Paul's participation in it, has been impugned on the grounds that Paul never mentions the apostolic letter or the solution propounded in it. Nevertheless, the probability is that events were moving so fast that this compromise was out-of-date almost as soon as it was promulgated.

Second missionary journey. Paul now proposed a new tour but refused to take Mark. Barnabas stood by his cousin, and the partners separated. Barnabas and Mark returned to Cyprus, and Paul chose as his new colleague Silas, who like himself was a Roman citizen, bearing the Roman name of Silvanus. Together they visited the churches of Syria, Cilicia, and Galatia. At Lystra they were joined by Timothy, a young Christian with a Jewish mother and a Gentile father. At this point it is possible to begin to see emerge Paul's missionary strategy of concentrating on large centres of Roman influence. Aiming again for Ephesus, he was prevented "by the Holy Spirit" from entering the Roman province of Asia, turned north toward the large cities of Bithynia (northwestern Asia Minor), was diverted a second time, and so came to Troas, where he had a vision of a Macedonian asking for help.

So Christianity gained its first foothold in Europe, with the formation of a small church in the Roman colony of Philippi in Macedonia. From the serene letter written to this church at the end of his life, it seems that they never caused him any of the ethical, theological, or disciplinary difficulties he had had to face elsewhere. Instead, they fre-



The missionary journeys of St. Paul.

quently sent money out of slender resources to help with the expenses of his work in other cities and ultimately for his own relief in prison in Rome. After the cure of a psychic slave girl, Paul and Silas were imprisoned on a charge of anti-Roman practices but were released with apologies when they revealed their Roman citizenship and complained of the illegality of their treatment. At Thessalonica (modern Thessaloníki, Greece) they preached for three weeks before being interrupted by a riot and a charge of treasonable adherence to a rival emperor, from which they escaped by discreet departure. Hostile Jews, however, pursued them to the neighbouring town of Beroea and cut short their work there also. Paul went on to Athens, leaving Silas and Timothy to follow later.

Work at Athens and Corinth

At Athens, Paul addressed the council of the Areopagus (formerly the supreme court of Athens; at the time of Paul a body with wider and vaguer powers) and converted one of its members, but nothing is said about a church. The reason appears in the letter that he wrote soon afterwards to Thessalonica. He was deeply concerned about the fate of the recent converts he had left behind there, exposed to persecution and without adequately instructed leadership. He was prevented from going back "by Satan," probably a return of his recurrent illness. When Timothy arrived, Paul, with no thought for his own condition, sent him back for news. He himself went on to Corinth, still convalescent.

In Corinth, Paul lodged with a Christian couple, Aquila and Priscilla, tentmakers like himself. Aquila was a Jew from Pontus (northeastern Asia Minor), but he and his wife had been living in Rome until the previous year, when an edict of the emperor Claudius had expelled all Jews from the capital. These two became lifelong friends of Paul and on one occasion risked their lives for him. Soon Silas and Timothy arrived with the cheering news that the Christians in Thessalonica were loyal and in good heart. The only cause for anxiety was that some of them had misunderstood Paul's preaching about the advent of Christ, taking his language about its imminence with a literalness he never intended. To deal with this situation, he wrote his first letter to them. Some weeks later, when he heard that members of the church had actually given up their daily work to prepare for the end, he wrote his second, somewhat sterner, letter accusing them of truancy.

After a year and a half in Corinth, Paul was arraigned before the new governor Gallio on a charge of practicing an illicit religion. The case was dismissed, and for the author of Acts this episode was the strongest argument in his apology for the Christian religion. For the historian it has an even greater importance, providing the one fixed date in Paul's biography, from which the rest of the chronology has to be worked out, backward and forward. An inscription found at Delphi proves that Gallio's year of office began on July 1, AD 51. Paul must have arrived in Corinth early in 50. "Some time afterwards" (the author of Acts has a tantalizing way of adding vague indications of time to precise ones) Paul left Corinth for Ephesus, Caesarea (on the coast of Palestine), and Jerusalem and so returned to base at Antioch. Of Silas no more is heard until he reappears in the final salutation of the First Letter of Peter.

Third missionary journey. From Antioch Paul set out on a further tour of the Galatian churches, after which he at last succeeded in reaching Ephesus. Here he was to stay for three years, longer than he devoted to any other city. At first he taught in the synagogue, then, when that was closed to him, in a hired lecture hall. Luke was not with him and records in Acts none of the events of this long period except the discrediting of a Jewish exorcist and a dangerous riot started by the silversmiths' guild because Paul's success was having an adverse effect on their market. From Paul's letters, however, some of the gaps can be filled. He gathered around him a team of colleagues who evangelized the surrounding province of Asia. It must have been at this time, for example, that the churches of the Lycus Valley were founded, at Colossae, Hierapolis, and Laodicea. Here, as elsewhere, missionary work had its dangers. Aquila and Priscilla, who seem to have made their home in Ephesus, "risked their necks" for Paul. He speaks, too, in II Corinthians, of a mysterious "trouble" that made him despair of life and, in I Corinthians, of fighting with wild beasts at Ephesus. It is possible that he spent some of the time in prison.

Much of his attention was taken up with the church in Corinth, to which he wrote four letters and paid one visit, unrecorded in Acts. The first letter has not survived, but in reply to it he received a letter that raised questions about various matters of faith and conduct, marriage and divorce, the eating of meat slaughtered in pagan ritual, the right of women to lead public worship, ecstatic speech, and the resurrection of the body. The writers seem to

Letters to the church in Corinth

have been those whom Paul refers to as "the strong party," and they did not simply invite instruction but stated a case and expected him to agree with it. Paul had also received a verbal report of a more disquieting nature from "Chloe's people," who told him of party divisions within the church, litigation between its members, disorderly conduct at the Lord's Supper, or Eucharist, and a case of incest that had gone unrebuked. Paul's answer to all this was the letter known as I Corinthians. Before long the troubles in Corinth were exacerbated by the arrival of newcomers with letters of introduction from another church, who questioned Paul's credentials and undermined his authority. Paul decided to deal with this crisis in person; but his visit was not a success, and he came out of the encounter badly. Back in Ephesus he wrote a third letter (of which II Corinthians, chapters 10–13 may be a part), so severe that he regretted it as soon as Titus, his courier, had left. Titus was to return through Macedonia, and Paul was to meet him at Troas, where he planned to spend some time in evangelism. So great, however, was his anxiety about Corinth that he could not settle there. He went on to Macedonia, where Titus met him with the good news that the severe letter had had its desired effect. All the pent-up feelings of the past weeks were then poured out in the letter known as II Corinthians (or perhaps only chapters 1–9).

Another of Paul's concerns during his stay in Ephesus was the organization of a relief fund for the impoverished church in Jerusalem. Many of his own churches were poor, but he encouraged them to be generous because he saw in this collection a demonstration of unity between Jewish and Gentile churches.

It is notoriously difficult to date Paul's letter to the Galatians; but arguments from language, style, and theology would place it between II Corinthians and Romans, and in that case it must have been written from Macedonia. Acts gives the impression that, after meeting Titus, Paul hurried on to Corinth, stopping only to visit the Macedonian churches in passing. But in Romans Paul claims to have preached the gospel "from Jerusalem as far round as Illyricum"; *i.e.*, the Yugoslav coast. The closing paragraph of the letter to Titus mentions a plan to spend a winter in Nicopolis, at the western end of the Corinthian gulf. If this last passage is one of the genuine Pauline fragments embedded in the Pastoral Letters, these two pieces of evidence together would seem to point to an extended ministry in the northwest part of the Balkan Peninsula.

Letter to the church in Rome

Early in AD 57 Paul paid his last visit to Corinth, and it was probably during the three months he spent there that he wrote his letter to the church in Rome. If chapter 16 of Romans is an integral part of that letter, this origin is certain because that chapter is a letter of introduction for Phoebe, a deacon from Cenchreae, the port of Corinth. Even if that chapter is a separate note addressed to the church of Ephesus, Paul's account of his plans makes it almost certain that he was in Corinth when he wrote. He had not founded the church in Rome (there had been a church there by AD 49 when Aquila and Priscilla were forced to leave); and he wrote this full statement of his faith to prepare the way for a visit, in the hope that the church would then sponsor his projected mission to Spain related in Romans. First, however, he had to go to Jerusalem to accompany the relief fund raised by the Gentile churches.

Paul had intended to travel by ship, but a plot against his life dictated a partial change of plans. He went overland to Troas, stopping for a week in Philippi for the Passover. He then took a passage on a ship that stopped at several ports along the coast and enabled him to meet the Ephesian elders at Miletus (modern Saraylar, Turkey) and take leave of them. After a week's stay with the deacon Philip at Caesarea, he reached Jerusalem.

Arrest and imprisonment. On his last journey to Jerusalem, Paul had been accompanied by representatives of the churches that had contributed to the relief fund. One of these, Trophimus, a Gentile from Ephesus, was recognized by some Asian Jews, who jumped to the conclusion that Paul had taken him into the part of the Temple forbidden to Gentiles. Paul had to be rescued from the ensuing riot by Roman soldiers and escaped further ill-treatment by informing the commanding officer that he was a Roman citizen. While still in protective custody he heard of a plot on his life and informed the commanding officer, who sent him under guard to the governor Felix at Caesarea. Having no evidence for a conviction but unwilling to antagonize the Jewish authorities, Felix kept Paul in prison for two years. When his successor, Festus, arrived, rather than be sent to Jerusalem for trial, Paul appealed to the Emperor.

Paul in Rome

The journey to Rome began in late autumn, and a shipwreck delayed the travellers for three months in Malta, so that they arrived in Rome in the spring of AD 60. There Paul remained for two further years, in house custody awaiting trial. At this point the narrative of Acts comes to an abrupt end, without disclosing the outcome of the trial. As long as the Pastoral Letters were accepted as Pauline, their evidence demanded the hypothesis of an acquittal and second imprisonment. By this theory, Paul must have spent two or three further years in missionary work in Greece, Macedonia, Epirus (northwestern Greece), Asia Minor, and Crete before being arrested again, taken to Rome a second time, and this time sentenced to death. Now that these letters are recognized to be pseudonymous, however, there is no reason to suppose that the verdict at the first trial was favourable. There is good evidence from later authors that Paul died a martyr's death in Rome sometime during the reign of the emperor Nero (AD 54–68).

It is usually assumed, and with good reason, that Paul's remaining letters, Philippians, Colossians, Philemon, and Ephesians (if the last is his), were written from his Roman prison. If so, they provide some evidence to fill out the story of his last years. A slave from Colossae, called Onesimus, had run away from his master Philemon (who happened to be a Christian and a friend of Paul); he came to Rome, met Paul, and was converted by him. Reluctantly, Paul decided he must send him back to his master and wrote a letter to Philemon asking him to receive his former slave as a brother. At about the same time he had another contact with the church in Colossae through its leader Epaphras, who came to consult him about an unorthodox "philosophy" that was gaining some following among Christians at Colossae. To refute this aberrant form of Christianity, Paul wrote his letter to the Colossians. At the same time he wrote a letter that has not survived to the church in Laodicea. If the letter that is known as Ephesians is by him, it was a circular letter to Gentile churches he had not founded or visited, written at the same time as the three letters mentioned above and carried by the same courier, Tychicus.

The church of Philippi, which had sent Paul money in the past to help with the expenses of his missions, now sent one of its members, Epaphroditus, with a further gift. Epaphroditus fell ill on the way and nearly killed himself by completing the journey with the illness upon him. He had intended to stay with Paul and look after him; but Paul, hearing that his friends at home were anxious about his state of health, sent him back and wrote his letter to the Philippians to send with him. The rest is silence, except perhaps for a little farewell note to Timothy, preserved in II Timothy, chapter 4, verses 6–8.

Vivid contrasts of Paul's character

Character. Paul was a man of vivid contrasts. Small and unimpressive in physical stature, he must have had immense stamina to withstand the rigours of travel, beatings, and imprisonments, bouts of intermittent illness, and not least "the anxiety for all the churches" (II Corinthians). Though not a natural orator, he could dominate an audience by incandescence of spiritual power. He was capable both of coarseness and of delicate sensitivity.

Paul's favourite metaphors from athletic stadium, law court, and battlefield reveal him as every inch a competitor, debater, and fighter. He aimed at excellence, whether as a Pharisee or as a servant of Christ. He "gave himself to the Lord" (I Corinthians), determined only to "spend and be spent" (II Corinthians), and to repay "to Greek and barbarian, to wise and foolish" the debt he owed to Christ (Romans). He must always be breaking new

ground (Romans), always pressing on to new discoveries of the mysteries of God (Philippians). Yet he gained the strength that was required for this restless activity from an inner peace that the outside world could not disturb (Philippians).

He could be violent in the assertion of his rugged independence (Galatians), acknowledging no superiors except Christ himself. Yet he had many friends and was never happier than when others shared with him his work, his enthusiasms, and his faith. He calls them fellow workers, fellow soldiers, fellow slaves, yokefellows. In a life devoted to the service of others, he had the grace to accept their service in return and to demand from his colleagues the same high standards that he demanded from himself.

Paul had an eye for detail and would take endless pains over matters of conduct that others thought trivial. Yet he combined with this a comprehensive grasp of the significance of his new faith, believing that it was God's purpose to bring the warring powers of the universe to unity in Christ (Ephesians). It was clear to him that the mighty plan that embraced the whole of history and all nature could yet be reduced to microcosm in God's love for one man.

He could be both stable and volatile, at one time wielding a massive common sense, at another, borne aloft on the wings of ecstasy. He had the gift of tongues (I Corinthians) and of prophecy (Acts) and underwent occasional experiences of vision or trance (II Corinthians). Yet he did not base either his faith or his authority on these but believed that God's activity was most clearly to be seen in normal life and above all in human weakness. He dominates the apostolic age not as a saint or superman but as a normative Christian in whom ordinary human nature was raised to its highest powers. This same contrast characterizes his writing. From humdrum details of conduct he can elicit universal principles and can move in a moment from the prose of argument to the poetry of worship.

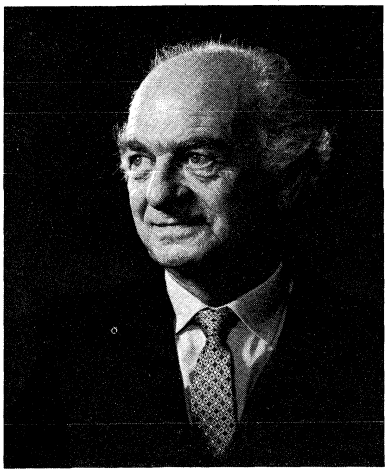
Above all, Paul was a man of God. He saw the hand of God in his own early life, in his conversion, in his apostleship, in his ministry, and even in his illness. His theology is an exposition of the hidden wisdom of God, which had lain behind all history but was now disclosed in Christ. For him, God had been, in Christ, reconciling the world to himself; and man's salvation was God's work from start to finish.

BIBLIOGRAPHY. From the immense bibliography, which includes many commentaries on the Acts and letters, only a small representative selection can be chosen. G.A. DEISSMANN, *St. Paul* (1912); T.R. GLOVER, *Paul of Tarsus* (1925); and J.S. STEWART, *A Man in Christ* (1935), are the most illuminating biographies—the first more social, the second more personal, and the third more theological. H.J. SCHOEPS, *Paul* (1961), tells the story from a radically different point of view. J. KNOX, *Chapters in a Life of Paul* (1954), offers a drastic solution to problems of chronology. W.M. RAMSAY, *St. Paul the Traveller and the Roman Citizen* (1896), is a valuable contribution to historical geography. P.N. HARRISON, *The Problem of the Pastoral Epistles* (1921), is a classic treatment of authorship. W.L. KNOX, *St. Paul and the Church of Jerusalem* (1925); A.M. HUNTER, *Paul and His Predecessors* (1940); and J. MUNCK, *Paulus und die Heilsgeschichte* (1954; Eng. trans., *Paul and the Salvation of Mankind*, 1959), deal with different aspects of Paul's relationship with the other Apostles. ALBERT SCHWEITZER, *The Mysticism of Paul the Apostle* (1931); and W.D. DAVIES, *Paul and Rabbinic Judaism* (1948), are important specialist studies. D.E.H. WHITELEY, *The Theology of St. Paul* (1964), is the most recent comprehensive work on Paul's teaching.

(G.Cai.)

Pauling, Linus

Linus Carl Pauling, American chemist and crusader for peace, achieved scientific renown for his contributions to the understanding of molecular structure, particularly types of chemical bonding (forces holding molecules together) and their relations to the properties of matter and to living organisms. After World War II he became a leader in peace movements, especially in the campaign for nuclear weapons disarmament. He received the Nobel Prize for Chemistry for 1954, "for his research into the nature of the chemical bond and its application to the elucidation of the structure of complex substances," and the Nobel Prize for Peace for 1962, thus becoming the second person to be honoured twice by Nobel awards.



Pauling.

Pauling was born in Portland, Oregon on February 28, 1901, the son of Herman William Pauling, a pharmacist, and his wife Lucy Isabelle (Darling). He received his B.S. in chemical engineering at Oregon State Agricultural College (now Oregon State University), Corvallis, in 1922, then became a graduate assistant at California Institute of Technology, Pasadena, where he took his Ph.D. in physical chemistry in 1925. For two years he was a postdoctoral fellow in Europe, working in the laboratories of such noted scientists as Arnold Sommerfeld in Munich, Niels Bohr in Copenhagen, Erwin Schrödinger in Zürich, and Sir William Henry Bragg in London. He returned to California Institute of Technology as assistant professor of chemistry in 1927, becoming full professor in 1931 and serving as director of the Gates and Crellin Laboratories of Chemistry between 1936 and 1958.

Application of quantum physics to molecular structure

Pauling's chemical work dealt with the many aspects of molecular structure, ranging from simple molecules to proteins. He was among the first to apply the principles of quantum mechanics to the structure of molecules and effectively utilized X-ray diffraction (the alteration of the straight course of X-rays by the interference of an atom or group of atoms), electron diffraction (interference with the course of electrons by atoms), magnetic effects, and the heat involved in forming chemical compounds for the calculation of interatomic distances and the angles between chemical bonds. He was successful in relating the distances and angles between chemical bonds to molecular characteristics and to interaction between molecules.

In order to account for the equivalency of the four bonds around the carbon atom, he introduced the concept of hybrid orbitals, in which electron orbits are moved from their original positions by mutual repulsion. Pauling also recognized the presence of hybrid orbitals in the coordination of ions or groups of ions in a definite geometric arrangement about a central ion. His theory of directed (positive and negative) valence (the capacity of an atom to combine with other atoms) was an outgrowth of his early work, as was the concept of the partial ionic character of covalent bonds—*i.e.*, atoms sharing electrons. His empirical concept of electronegativity, the power of attraction for electrons in a covalent bond, was useful in further clarification of these problems. In the case of compounds the molecules of which cannot be represented unambiguously by a single structure, he introduced the concept of resonance hybrids whereby the true structure of the molecule is regarded as an intermediate state between two or more depictable structures. The resonance theory came under heavy but unsuccessful attack in the U.S.S.R.

in 1951 when doctrinaire scientists of the Communist Party argued that it conflicted with dialectical materialist principles. The ideas on bonding were developed serially in his numerous journal articles during his early career and were consolidated in his book, *The Nature of the Chemical Bond, and the Structure of Molecules and Crystals* (1939), which grew out of lectures he gave in 1937 and 1938. The textbook proved to be one of the most influential of the century.

In 1934 Pauling began to apply his knowledge of molecular structure to the complex molecules of living tissues, particularly in connection with proteins. His studies of the magnetic susceptibility (the ease with which something can be magnetized) of the hemoglobin (the red protein in the red cells of the blood) molecule during oxygenation inaugurated a succession of studies that led to a theory of native (active proteins as found in living organisms), denatured (proteins that through heat or chemical action have broken some of their bonds), and coagulated (solidified) proteins. He became interested in proteins involved in immunological reactions and in 1940, with a German-born biologist, Max Delbrück, developed a concept of molecular complementarity in antibody-antigen reactions (in which the production of antibodies is stimulated in an organism when foreign substances called antigens are introduced). He recognized the importance of hydrogen bonding in protein structure and in interactions between macromolecules (extremely large molecules usually built from repeating groups of smaller molecules). His work with a U.S. chemist, Robert B. Corey, on the structure of amino acids and polypeptides (the chief components of proteins) led him to recognize that certain proteins have structures that resemble a spiral staircase and are called helices.

Late in the 1940s Pauling became interested in sickle-cell anemia when he learned that the red blood corpuscles show their abnormal crescent shape only in venous blood. Intuitively, he reasoned that the cause of the cell deformity must lie in a genetic defect associated with hemoglobin formation. His studies showed that the sickling effect was nullified by the presence of oxygen in the arterial blood.

Pauling also developed a molecular model for the explanation of anesthesia that was made public in 1961, introduced ideas toward the understanding of memory processes, and in 1965 postulated a theory of the atomic nucleus that had certain advantages over other models. His scientific career has been characterized by the application of intuitive hunches aided by a phenomenal memory of chemical facts. Pauling refers to this as the stochastic method (from the Greek "apt to divine the truth by conjecture").

Following the development of nuclear weapons, Pauling became deeply concerned about the possible hazards of exposure to radiation associated with weapons testing. He expressed his view in his book *No More War!* (1958). In January 1958 he brought to the United Nations a petition signed by 11,021 scientists from all over the world urging an end to nuclear weapons tests. In 1963 he left the California Institute of Technology to become a staff member of the Center for the study of Democratic Institutions at Santa Barbara where he largely devoted himself to the study of problems of peace and war. No official reason was given for the award of the Peace Prize for 1962 to Pauling in 1963, but it is widely assumed that he received it for his efforts in behalf of the test ban treaty that was concluded in the same year. His pacifist views estranged him from many scientists with whom he had been closely associated during the years of World War II, when he had served as a civilian with the Office of Scientific Research and Development. Though he was equally opposed to nuclear testing by the United States and the Soviet Union, his loyalty to the U.S. was questioned in some conservative political circles.

Nobel Peace Prize

In 1969 he resigned a position he had held for two years with the University of California, Santa Barbara, in protest against the educational policies of the governor of California and joined the chemistry department of Stanford University, Stanford, California. In addition to winning two Nobel Prizes, an honour that has been conferred on only one other person—Marie Curie, the French physicist—he has been widely honoured in scientific and pacifist circles. He has held guest appointments in many other universities, both at home and abroad. His success as a scientist is based on his capacity for quick insight into new problems, his ability to recognize interrelationships, and the courage to put forward unorthodox ideas. While his concepts have not always been correct, they have always stimulated discussion and investigation.

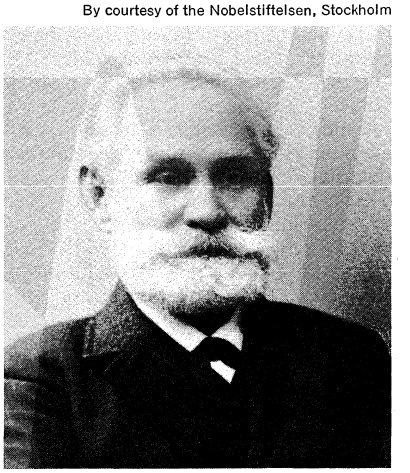
BIBLIOGRAPHY. Pauling's scientific work is stressed by J.H. STURDIVANT in A. RICH and N. DAVIDSON (eds.), *Structural Chemistry and Molecular Biology*, pp. 3-9 (1968). This commemorative volume prepared for Pauling's 65th birthday also has a complete bibliography of his scientific papers and his books. For his Nobel Awards, see *Le prix Nobel en 1954*, pp. 29-32, 66-67 (1955), and the address "Modern Structural Chemistry," pp. 91-99; and *Le prix Nobel en 1963*, pp. 70-82, 113-114 (1964), and the address "Science and Peace," pp. 296-312.

(A.J.I.)

Pavlov, Ivan Petrovich

The Russian physiologist Ivan Petrovich Pavlov is chiefly known for his development of the concept of the conditioned reflex. In a now classic experiment, he trained a hungry dog to salivate at the sound of a bell, which was previously associated with the sight of food. He developed a similar conceptual approach, emphasizing the importance of conditioning, in his pioneering studies relating human behaviour to the nervous system. His Nobel Prize, however, was awarded for his research on the physiology of digestion. After the Bolshevik Revolution and until two years before his death, Pavlov bitterly opposed the Soviet bureaucracy and Marxism.

By courtesy of the Nobelstiftelsen, Stockholm



Pavlov.

Pavlov was born on September 26 (September 14, old style), 1849, the first son of the village priest and the grandson of a peasant, and spent his youth in his native village (Ryazan) in central Russia. He attended a church school and theological seminary, where his seminary teachers impressed him by their devotion to imparting knowledge. In 1870 he abandoned his theological studies to enter the University of St. Petersburg (Leningrad), where he studied chemistry and physiology. After receiving the M.D. at the Imperial Medical Academy in St. Petersburg (graduating in 1879 and completing his dissertation in 1883), he studied during 1884–86 in Germany under the direction of the cardiovascular physiologist Carl Ludwig (in Leipzig), and the gastrointestinal physiologist Rudolf Heidenhain (in Breslau).

Having worked with Ludwig, Pavlov's first independent research was on the physiology of the circulatory system. From 1888–90, in the laboratory of Botkin in St. Petersburg, he investigated cardiac physiology and the regulation of blood pressure.

Experimental physiology

He became so skillful a surgeon that he was able to introduce a catheter into the femoral artery of a dog almost painlessly without anesthesia and to record the influence

on blood pressure of various pharmacological and emotional stimuli. By careful dissection of the fine cardiac nerves he was able to demonstrate the control of the strength of the heartbeat by nerves leaving the cardiac plexus; by stimulating the severed ends of the cervical nerves, he showed the effects of the right and left vagal nerves on the heart.

Pavlov married an attractive pedagogical student in 1881, a friend of the author Fyodor Dostoyevsky, but he was so impoverished that at first they had to live separately. He attributed much of his eventual success to his wife, a domestic, religious, and literary woman, who devoted her life to his comfort and work. In 1890 he became professor of physiology in the Imperial Medical Academy, where he remained until his resignation in 1924. At the newly founded Institute of Experimental Medicine, he initiated precise surgical procedures for animals, with strict attention to their postoperative care and facilities for the maintenance of their health; this excellent care enabled many of them to live for ten to 14 years.

During the years 1890–1900 especially, and to a lesser extent until about 1930, Pavlov studied the secretory activity of digestion. While working with Heidenhain, he had devised an operation to prepare a miniature stomach, or pouch; he isolated the stomach from salivary and pancreatic secretions, while preserving its vagal nerve supply. The surgical procedure enabled him to study the gastrointestinal secretions in a normal animal over its life-span. This work culminated in his book *Lectures on the Work of the Principal Digestive Glands* in 1897. For his advances in the physiology of digestive secretions, Pavlov was awarded the Nobel Prize for Physiology in 1904.

The conditioned reflex

By observing irregularities of secretions in normal unanesthetized animals, Pavlov was led to formulate the laws of the conditioned reflex, a subject that occupied his attention from about 1898 until 1930. He used the salivary secretion as a quantitative measure of the psychical, or subjective, activity of the animal, in order to emphasize the advantage of objective, physiological measures of mental phenomena and higher nervous activity. He sought analogies between the conditional (commonly though incorrectly translated as "conditioned") reflex and the spinal reflex. According to the physiologist Sir Charles Sherrington, the spinal reflex is composed of integrated actions of the nervous system involving such complex components as the excitation and inhibition of many nerves, induction (*i.e.*, the increase or decrease of inhibition brought on by previous excitation), and the irradiation of nerve impulses to many nerve centres. To these components, Pavlov added cortical and subcortical influences, the mosaic action of the brain, the effect of sleep on the spread of inhibition, and the origin of neurotic disturbances principally through a collision, or conflict, between cortical excitation and inhibition.

Beginning about 1930, Pavlov tried to apply his laws to the explanation of human psychoses. He assumed that the excessive inhibition characteristic of a psychotic person was a protective mechanism—shutting out the external world—in that it excluded injurious stimuli that had previously caused extreme excitation. In Russia this idea became the basis for treating psychiatric patients in quiet and nonstimulating external surroundings. During this period Pavlov announced the important principle of the language function in the human as based on long chains of conditioned reflexes involving words. The function of language involves not only words, he held, but an elaboration of generalizations not possible in animals lower than the human.

Opposition to Communism

Pavlov's relationships with the Communists and the Soviet government were unique not only for Russia but also for the history of science. Although he was never a politician, he spoke fearlessly for what he considered the truth. In 1922, during the distressing conditions in the aftermath of the Revolution, he requested permission from Lenin to transfer his laboratory abroad. Lenin denied this request, saying that Russia needed scientists such as Pavlov and that Pavlov should have the same food rations as an honoured Communist. Although it was a period of famine, Pavlov refused: "I will not accept these privileges unless you give them to every one of my collaborators!" In spite of many honours granted him by Soviet officials, he upbraided them openly. After returning from his first visit to the United States in 1923 (the second was in 1929), he publicly denounced Communism, stated that the basis for international Marxism was false, and said that, "For the kind of social experiment that you are making, I would not sacrifice a frog's hind legs!" In 1924, when the sons of priests were expelled from the Military Medical Academy in Leningrad (the former Imperial Medical Academy), he resigned his Chair of Physiology announcing "I also am the son of a priest, and if you expel the others I will go too!" In 1927, distressed that his was the only negative vote in the Academy of Sciences against the newly recommended "Red professors," he wrote to Stalin, protesting that "On account of what you are doing to the Russian intelligentsia—demoralizing, annihilating, depraving them—I am ashamed to be called a Russian!" In the late 1920s, as an anti-Communist gesture, he refused Bukharin, the Communist Commissar of Education, admission to his laboratory, though the laboratory was supported by government funds administered by Bukharin.

During the last two years of his life, Pavlov gradually ceased these excoriations and even stated that he hoped to see the success of the government, at the helm of his country. This change of heart may have been a result of increased government support of science and of his own feelings of patriotism when war with Japan seemed imminent. He was never a Communist, however, nor was he responsible for the technique of brainwashing that has sometimes been ascribed to him.

In personal habits Pavlov was extremely punctual, never missing an appointment, it was claimed, and arriving on time in the laboratory even when there was revolutionary activity on the streets. To a collaborator, who explained his ten-minute delay as a result of the shooting, Pavlov exclaimed, "What difference does a Revolution make when you have experiments to do in the laboratory!" He was a bold, vehement nonconformist both in science and in his personal life; he fiercely took up the cudgel for what he believed regardless of the force of his opposition. Although Pavlov held to scientific agnosticism, he considered true religion beneficial; he said that he envied no one anything except his wife her devout religious faith.

Contributions to science

Pavlov's method of studying the normal, healthy animal in natural conditions made possible his contributions to science. He was able to formulate the idea of the conditioned reflex because of his ability to reduce a complex situation to the simple terms of an experiment. Recognizing that in so doing he omitted the subjective component, he insisted that it was not possible to deal with mental phenomena scientifically except by reducing them to measurable physiological quantities.

Although Pavlov's work laid the basis for the scientific analysis of behaviour, and notwithstanding his stature as a scientist and physiologist, his work was subject to certain limitations. Philosophically, while recognizing the preeminence of the subjective and its independence of scientific methods, he did not, in his enthusiasm for science, clarify or define this separation. Clinically, he accepted uncritically psychiatric views concerning schizophrenia and paranoia, and he adopted such neural concepts as induction and irradiation as valid for higher mental activity. Many psychiatrists now consider his explanations too limited, and some neurophysiologists have taken greater interest in other developments, such as electrophysiology and biochemistry. In contrast to Sherrington, he has had few prominent students outside Russia. His method of working with the normal, healthy, unanesthetized animal over its entire life has not been generally accepted in physiology.

He worked regularly in the laboratory or clinic until his death, from pneumonia, on February 27, 1936, in Leningrad.

BIBLIOGRAPHY. BORIS P. BABKIN, *Pavlov: A Biography* (1949), based on personal and professional knowledge of the author, one of Pavlov's oldest pupils, is the most complete

and reliable account until World War I. In dealing with Pavlov's later life Babkin depends upon a Russian monograph by A.A. Savich, another colleague, and the memoirs of his widow. I.P. PAVLOV, *Lectures on Conditioned Reflexes*, 2 vol., trans. by W.H. GANTT (1929–41), contains a biographical sketch, including personality characteristics, dealing mainly with his career after the Soviet Revolution, based on the translator's six years of professional association with Pavlov. Discussions of Pavlov's scientific achievements and independent attitude to government bureaucracy also by W.H. GANTT are "Physiology Since Pavlov," *New Republic*, 105:728–731 (1941); "Pavlov Through Red-Colored Glasses," *Contemp. Psychol.*, 2:273–274 (1957); and "Ivan Petrovich Pavlov," *Recent Adv. Biol. Psychiat.*, vol. 4 (1962). Gantt's *Russian Medicine* (1937), shows the relation of Pavlov to prominent Russian figures in medicine.

(W.H.G.)

Pavlova, Anna

Only rarely do the great personalities of classical ballet become part of world history; one of the few whose genius was known widely in her lifetime and then did pass into general legend is Anna Pavlova.

Anna Pavlovna Pavlova was of Polish origin but was born in St. Petersburg (now Leningrad). The actual date has been variously quoted; the most authoritative is perhaps the one given in the Russian edition of her husband's biography of her—January 31, 1882.

Culver Pictures

Anna Pavlova.

The place and time could hardly have been better for a child with an innate talent for dancing. Tsarist Russia maintained magnificent imperial schools for the performing arts. Entry was by examination, and, although Pavlova's mother was poor—her father had died when she was two years old—the child was accepted for training at the Imperial School of Ballet at the Mariinsky Theatre (now the Kirov State Theatre) in St. Petersburg in 1891.

Prima ballerina of the Imperial Ballet

Following ballet tradition, Pavlova learned her art from teachers who were themselves great dancers. She graduated to the Imperial Ballet in 1899 and rose steadily through the grades to become prima ballerina in 1906. By this time she had already danced *Giselle* with considerable success.

Almost immediately, in 1907, the pattern of her life began to emerge. That year, with a few other dancers, she went on a tour to Riga, Stockholm, Copenhagen, Berlin, and Prague. She was acclaimed, and another tour took place in 1908. In 1909 the impresario Sergey Diaghilev staged a historic season of Russian ballet in Paris, and Pavlova appeared briefly with the company there and later in London. But her experience of touring with a small group had given her a taste for independence, and she never became part of Diaghilev's closely knit Ballets Russes. Her destiny was not, as was theirs, to innovate but simply to show the beauties of classical ballet throughout the world. While she was still taking leave from the Mariinsky Theatre, she danced in New York and London in 1910, where she was partnered with Mikhail Mordkin.

Once she left the Imperial Ballet in 1913, however, her frontiers were extended. For the rest of her life, with various partners (including Laurent Novikov and Pierre Vladimirov) and companies, she was a wandering missionary for her art, giving a vast number of people their introduction to ballet. Whatever the limitations of the rest of the company, which inevitably was largely a well-trained, dedicated band of young disciples, Pavlova's own performances left those who watched them with a lasting memory of disciplined grace, poetic movement, and incarnate magic. Her quality was, above all, the powerful and elusive one of true glamour.

Pavlova's independent tours, which began in 1914, took her to remote parts of the world. These tours were managed by her husband, Victor Dandré. The repertoire of Anna Pavlova's company was largely conventional. They danced excerpts or adaptations of Mariinsky successes such as *Don Quixote*, *La Fille mal gardée*, *The Fairy Doll*, or *Giselle*, of which she was an outstanding interpreter. The most famous numbers, however, were the succession of ephemeral solos, endowed by her with an inimitable enchantment: *The Dragonfly*, *Californian Poppy*, *Gavotte*, and *Christmas* are names that lingered in the hearts of her audiences, together with her single choreographic endeavour, *Autumn Leaves* (1918).

Famous roles

Pavlova's enthusiasm for ethnic dances was reflected in her programs. Polish, Russian, and Mexican dances were performed. Her visits to India and Japan led her to a serious study of their dance techniques. She compiled these studies into *Oriental Impressions*, collaborating on the Indian scenes with Uday Shankar, later to become one of the greatest performers of Indian dance, and in this way playing an important part in the renaissance of the dance in India.

Since she was the company's raison d'être, the source of its public appeal, and therefore its financial stability, Pavlova's burden was extreme. It was hardly surprising, therefore, that, by the end of her life, her technique was faltering, and she was relying increasingly on her unique qualities of personality. She died on January 23, 1931, at The Hague, in The Netherlands, of pneumonia.

Pavlova's personal life was undramatic apart from occasional professional headlines, as when, in 1911, she quarrelled with Mordkin. She kept her marriage secret for some time, and there were no children; her maternal instincts spent themselves on her company and on a home for Russian refugee orphans, which she founded in Paris in 1920. She loved birds and animals, and her home in London, Ivy House, Hampstead, became famous for the ornamental lake with swans, beside which she was photographed and filmed, recalling her most famous solo, *The Dying Swan*, which the choreographer Michel Fokine had created for her in 1905. These film sequences are among the few extant of her and are included in a compilation called *The Immortal Swan*, together with some extracts from her solos filmed one afternoon in Hollywood, in 1924, by the actor Douglas Fairbanks, Sr.

BIBLIOGRAPHY. VICTOR DANDRE, *Anna Pavlova* (1932), a tribute from her husband written immediately after her death; THEODORE STIER, *With Pavlova Round the World* (1927); and WALFORD HYDEN, *Pavlova* (1931), two accounts of touring with Pavlova written by her musical directors; HARCOURT ALGERANOFF, *My Years with Pavlova* (1957), one of Pavlova's leading dancers writes of his time with her company; A.H. FRANKS (ed.), *Pavlova* (1956), a symposium contributed by people who knew Pavlova, compiled for the 25th anniversary of her death; CYRIL W. BEAUMONT, *Anna Pavlova* (1932); VALERIAN SVETLOV, *Anna Pavlova* (1930); and PAUL D. MAGRIEL (ed.), *Pavlova* (1947), three monographs on her life and work—the last is fully illustrated.

(K.S.W.)

Pedagogy

Traditionally regarded as the art and practice of teaching, pedagogy, because of the growing scientific study of children and the human learning processes and the increasingly numerous analytical studies of educational objectives and curricula, now includes also the notion of the science of teaching. The focus of this article will be on the scientific basis of pedagogy; that is, on principles and ideas supported by objective study.

GENERAL CHARACTERISTICS OF TEACHING

Elements to consider in the teaching situation. In the act of teaching there are two parties (the teacher and the taught) who work together in some program (the subject matter) designed to modify the learners' behaviour and experience in some way. It is necessary to begin, therefore, with observations about the learner, the teacher, and the subject matter and then to consider the significance of group life and the school. It will then be possible to consider the factors and theories involved in modifying a person's behaviour and understanding. These include theories of learning in education, of school and class organization, and of instructional media.

Characteristics of the child and the teacher

A child enters school with little if any attainment in written expression and leaves it capable of learning much from human culture. It was thought originally that this progress was just a matter of learning, memorizing, associating, and practicing. The work of psychologists has revealed, however, that the growth of the pupil's intellectual powers must include a large element of development through different phases, beginning with simple sensorimotor coordination; going on to the beginnings of symbolizing, helped by the growth of language and play; and then on to logical thought, provided the material is concrete; and, finally, in midadolescence, on to the power to examine problems comprehensively, to grasp their formal structure, and to evoke explanation. In his emotional life, the child progresses from direct, immediate, uninhibited reactions to more complex, less direct, and more circumspect responses. The physical growth of the child is so obvious as to need no comment. Any attempt to educate the child intellectually and emotionally and for action must take account of these characteristics. Education must pace development, not follow it and not ignore it. The components in the child's overall educational growth are physical and mental maturation, experience, formal teaching through language, and an urge in the learner to resolve discrepancies, anomalies, and dissonances in his experience.

What is required of a teacher is that he enjoy and be capable of sharing work programs with children, designed to modify their behaviour and experience. This means making relevant experience available to the student at the right time. The teacher must be mature, have humour with a sense of status, be firm yet unruffled, and be sympathetic but not overpersonal. With large classes, the teacher becomes a leader of a group, providing stimulating learning situations.

The subject matter taught also has a marked influence on the total teaching situation. It may be conveniently divided into broad headings of languages, humanities, sciences, mathematics, and arts. Although each group of subjects has something in common with others in terms of the demands it makes on the thinker, each area has also something quite specific in its mode of development. Languages call for verbal learning and production based on oral work, particularly during the early phases. The humanities call for an understanding of cause–effect relations of immediate and remote connections between persons and institutions and man in his environment. The sciences call for induction from experience, though deductive processes are required when the laws of science are formalized into mathematical terms. The humanities and sciences both depend on the ability of the learner to hypothesize. Mathematics calls for the ability to abstract, symbolize, and deduce. An interest in the formal and structural properties of the acts of counting and measuring is fundamental. Arts and literature call for a fairly free opportunity to explore and create.

Characteristics of the school community

A large part of the teacher's role is as a group leader, and the group life of the school and the classroom must influence the teaching situation. Group life shows itself in the dynamic structure of the class—including its manner of reaching group decisions, the hierarchy of its members, the existence of cliques and of isolated individuals —and in its morale and overall response to the school and the rest of the staff. The individual pupil also conducts himself under the influence of the group to which he belongs. His achievements and attitudes are subject to evaluation by the group, leading to support or ostracism, and he sets his standards according to these influences.

In many schools, the range of ages in any class is about one year, and the narrow range makes for some uniformity of subject-matter coverage. But in rural one- and two-teacher schools, groups of children may be heterogeneous by age and ability, and the mode of teaching has to cope with a number of smaller subunits moving along at different rates. The teacher's problem is to coordinate the work of these small, dissimilar groups in such a way that all get attention. Creative free activity has to be practiced by one group while another has more formal instruction from the teacher.

The effect of "streaming," or "tracking"—that is, selecting homogeneous groups by both age and intellectual ability—has promoted much inquiry. The practice evokes extreme opinions, ardent support, and vociferous condemnation. The case for uniformity is that putting a pupil with his intellectual peers makes teaching more effective and learning more acceptable. The case against it draws attention to its bad effects on the morale of those children in the lower streams. This view supports the heterogeneous class on the grounds that the strongest are not overforced, and the weakest gain from sharing with their abler fellows. Experimental evidence on the problem is bewilderingly diverse.

The school community is housed in a physical complex, and the conditions of classrooms, assembly places, and play areas and the existence (or nonexistence) of libraries, laboratories, art-and-craft rooms, and workshops all play their part in the effectiveness of the teaching–learning situation. Severe restrictions may be caused by the absence of library and laboratory services.

The social forces immediately outside the school community also influence the teaching situation. These emanate from home, neighbourhood, and wider social groupings. Teaching is a compact among several groups, including teachers, students, and parents, in the first place, with youth organizations and religious and lay groups playing a secondary role. The overall neighbourhood youth subculture also sets standards and attitudes that a teacher has to take into account in his work.

General objectives of teaching. The classification of the general objectives of teaching in terms of school subject matter is not sufficient to explain the ultimate ends of education. These include, essentially, the promotion of a well-integrated person capable of taking a responsible, active role in society. With such a purpose in mind, one may achieve more insight by choosing a psychological analysis of the objectives into the attainment of intellectual abilities and social insights (cognition), the learning of practical active skills (psychomotor learning), and the development of emotions, attitudes, and values (affective learning).

Development of cognitive, affective, and psychomotor learning

Cognitive growth begins at the level of the infant school, with the acquisition of early language and numerical capabilities, and continues increasingly to dominate education to the secondary and higher levels. But the learner is more than an enlarging reservoir of information. With this acquisition goes a growing power to generalize, abstract, infer, interpret, explain, apply, and create. Cognitive training produces a thinker–observer aware of the modes of thought and judgment making up human intellectual activity. In the final stages, the teacher aims at a thinker, critic, organizer, and creator.

In the development of psychomotor learning, the teacher is concerned with the promotion of coordinated skills and their creative use. Instruction begins with the acts of handwriting and plastic art play, characteristic of earlier

years of schooling. It includes painting, games, workshop skills, and practical science. It has a high prestige value among the pupils themselves and the wider community.

The permeation of emotional learning throughout the whole educative process is not always obvious, in part because very often it is brought about incidentally. Teachers may be self-conscious and self-critical about the deliberate inculcation of emotional responses, which will provide the energy and a mainspring of social life. The acquisition and application of values and attitudes are most marked by the time of adolescence and dominate the general life of the young individual. Theoretical, aesthetic, social, economic, political, hedonistic, and religious values pervade the school curriculum. Literature, art, the humanities, and religious teaching are all directly involved, and the teaching of science and mathematics can bring about a positive attitude toward cognitive and theoretical values.

A person's emotional structure is the pattern of his values and attitudes. Under the influence of instruction and experience, this structure shows three kinds of change. First, the pupil learns to select those situations and problems to which he will make appropriate emotional responses. Second, in general, an increasing range of situations includes happenings more remote from the learner. At first, emotions are aroused by situations directly affecting the child, but as he becomes more mature he is increasingly involved in affairs and causes far removed from his own personal life. Third, his repertoire of emotional responses gradually becomes less immediate, expressive, and linked with physical activity.

The general design of instruction. The scientific analysis of educative processes has led to a more detailed examination of the total act of teaching, which is intended to make the teacher more aware of all that is involved in a piece of instruction.

Foreknowledge about students and objectives. The complete act of teaching involves more than the presentation and development of lesson material. Before he embarks on a fresh stage of instruction, the teacher must be reasonably clear about two things: (1) the capabilities, achievements, strengths and weaknesses, background, and interests of his learners; and (2) the short- and long-term objectives he hopes to achieve in his lesson and series of lessons. These curricular strategies will have to be put into effect in the light of what is known about the students and will result in the actual tactics of the teaching-learning situation.

Educational psychologists give much attention to diagnosing preinstructional achievements, particularly in the basic subjects of language and number, and to measuring intellectual ability in the form of reasoning power. There has been special emphasis on the idea of the student's readiness at various ages to grasp concepts of concrete and formal thought. Numerous agencies produce test material for these purposes, and in many countries the idea has been widely applied to selection for entry to secondary and higher schools; one of the purposes of so-called leaving examinations is to grade students as to their suitability for further stages of education. The teacher himself, however, can provide the most sensitive diagnoses and analyses of preinstructional capacity, and the existence of so much published material in no way diminishes the effectiveness of his responsibility.

The teaching–learning situation. In the actual instruction, a single lesson is usually a part of a longer sequence covering months or more. Each lesson, however, stands to some extent as a self-contained unit within a sequence. In addition, each lesson itself is a complex of smaller teaching–learning–thinking elements. The progress of a lesson may consist of a cycle of smaller units of shorter duration, each consisting of instruction by the teacher and construction by the learner—that is, alternating phases in which first the activity of the teacher and then that of the learner predominates.

The progress of lessons

The lesson or syllabus proper is thus not to be narrowly conceived of as "chalk and talk" instruction. It is better seen as a succession of periods of varying length of instruction by the teacher and of discovery, construction, and problem solving by the pupil. Although the student's own curiosity, experience, and observation are important, so is the cyclic activity of teacher and learner. The teacher selects, arranges, and partially predigests the material to be learned, and this is what is meant by guiding the learner's discovery and construction activity. It is a role the teacher cannot abrogate, and, even in curricula revised to give the learner greater opportunity to discover for himself, there is concealed a large degree of selecting and decision making by the teacher. This is what teaching is about.

Teachers must face the problem of how to maintain curiosity and interest as the chief motivative forces behind the learning. Sustained interest leads the student to set himself realistic standards of achievement. Vital intrinsic motivation may sometimes be supplemented by extrinsic rewards and standards originating from sources other than the student himself, such as examinations and outside incentives, but these latter are better regarded as props to support the attention of the learner and to augment his interest in the subject matter.

Assessment of results. At the end of the lesson proper or of any other unit or program of instruction, the teacher must assess its results before moving to the next cycle of teaching events. Assuming the occurrence of teaching–learning cycles of instruction-construction activity, it follows that there is a built-in process of frequent assessment during the progress of any period of teaching. The results of the small phases of the learner's problem solving provide at the same time both the assessment of past progress and the readiness for further development.

Progress over longer intervals of learning can be measured by more formal tests or examinations within the school or at local administrative level. Postinstructional assessment may have several purposes: to discover when classes or year groups have reached some minimum level of competence, to produce a measure of individual differences, or to diagnose individual learning–thinking difficulties. A wide variety of assessment can be used for this purpose, including the analysis of work produced in the course of learning, continuous assessments by the teachers, essay-type examinations, creative tasks, and objective tests. The content of the assessment material may also vary widely, ranging from that that asks for reproduction of learned material to that that evokes application, generalization, and transfer to new problem situations.

GENERAL THEORIES OF LEARNING IN EDUCATION

Traditional theories. *Mental-discipline theories.* The earliest mental-discipline theories of teaching were based on a premise that the main justification for teaching anything is not for itself but for what it trains—intelligence, attitudes, and values. By choosing the right material and by emphasizing rote methods of learning, according to this theory, one disciplines the mind and produces a better intellect.

In classical times, the ideal product of education was held to be a citizen trained in the disciplined study of a restricted number of subjects—grammar, logic, rhetoric, arithmetic, geometry, music and astronomy. The mode of learning was based on imitation and memorizing, and there was heavy emphasis on the intellectual authority of the teacher, as in the socratic method of question and answer. In later centuries, it was further taken for granted that the study of Greco-Roman literature and philosophy would have a liberalizing effect on the student.

In the hands of the Renaissance Dutch philosopher Erasmus and the Jesuit Fathers, this method of instruction took more sensitive account of the psychological characteristics of young learners. Understanding had to precede learning, and, according to the Jesuits, the teacher's first task was careful preparation of the material to be taught (the prelection). But even with this greater awareness of the learner's needs, the concept of mental discipline still underlay the whole process of instruction. Present-day critics of this classical humanistic approach would challenge the alleged power of mental discipline and the rather exclusive value of Greco-Roman thought.

The theory of "faculty psychology"

The theory of learning involving mental discipline is more commonly associated with Aristotle's "faculty psychology," by which the mind is understood to be composed of a number of faculties, each relatively independent of the others. The principle had its origin in a theory that classified mental and spiritual life in terms of functions of the soul: knowing, feeling, hungering, reasoning, and doing. From the Middle Ages to the early 19th century, the number of recognized faculties grew and included those of judgment, duty, perception, and conception. Since these were associated with certain parts of the cranium by the phrenologists, it was a natural step to assume that learning would consist of the exercise of these "parts," or mental capabilities (though the education of the senses also had a role, in initiating the rational cognitive processes). Certain school subjects were thought to have particular value as agents for exercising certain faculties. Geometry trained the faculty of reason, and history trained the memory. School subjects came to be valuable as much for what faculties they trained as for their own intrinsic worth. This is the learning theory of formal discipline.

Psychological faculties, used as categories, no doubt influenced the study of so-called mental factors. When different cognitive tests are given and the results compared, similarities are found among all the tests and among smaller groups of them. The bases for the similarities are identified as mental factors, including the ideas of intelligence, reasoning, memory, verbal ability, number capacity, and spatial intelligence. The existence of common mental factors underlying different school subjects would support the idea of formal discipline and would lead to the notion of transfer of training, by which exercise in one school subject leads to improvements in learning of another. The transferred elements could be common facts, learning habits, methods of thinking, attitudes, and values. Though much empirical research has been done on transfer of learning, it has yielded mixed results. Some workers hold that transfer has been possible only insofar as there have been identical elements, and even those who claim a transfer of methods generally insist that transfer has little chance of success unless it is actively explained and applied. Learners have to apply methods consciously to the new field in order to succeed. The opposing view would be that each subject is unique and requires its own mode of thought. A more realistic view may be intermediate—namely, that there is both a common and a specific element in each intellectual field, that mental discipline or transfer of training is to some degree possible but only insofar as the similarities and analogies are utilized, that the process is deliberate, and that a residue of specific subject matter remains in each field. This requires specific learning.

Naturalistic theories. A few educational theorists view the education of the child as an unfolding process. The child develops inevitably as a product of nature, and the main function of the teacher is to provide the optimum conditions for this development. This leads to the theory that the child's experience is the essential thing. A Swiss educator, J.H. Pestalozzi, was a leading theorist in this field, and his practical schemes were designed to provide the most appropriate experience for the child's development. In a sense, the modern revival of the potency of experience is an acknowledgement of the developmental element in learning.

Naturalistic emphasis is on creativity

Jean-Jacques Rousseau also started from the assumption that man conforms to nature. Since, more than Pestalozzi, he assumed the certainty of a spontaneous development of powers and faculties, he urged that any form of constraint was to be avoided. Thus it has been held that he saw man as a noble savage growing in isolation in a state of nature. But nature also means a social life. The consequences of Rousseau's basic view have been (1) a reduced emphasis on knowing and greater emphasis on acting and doing, (2) a promotion of positive interests in learning, and (3) an encouragement of the child to depend on his own resources. In their purest form, naturalistic theories are clearly inadequate in the modern world of technology, but their emphasis on spontaneous child activity, as opposed to excessive formal instruction, is a valuable component of the educational process.

Apperception theories. Another theory assumed that human learning consisted essentially of building up associations between different ideas and experiences; the mind, in accordance with the ideas of the 17th-century English philosopher John Locke, was assumed to be at first devoid of ideas. The 19th-century German philosopher Johann Herbart made an important contribution by providing a mental mechanism that determined which ideas would become conscious and which would be left in the subconscious, to be called upon if circumstances warranted it. This was the mechanism of apperception, by which new ideas became associated with existing ideas to form a matrix of association ideas called the apperception mass. New ideas were thus assimilated to the old. A Swiss psychologist, Jean Piaget, argued that such assimilation was not enough, that accommodation of the established ideas to the new experiences was also required.

In any event, ideas such as Herbart's were translated into a sequence of steps presumed to be required to carry out a lesson:

1. Preparation, whereby the teacher starts the lesson with something already known to the class
2. Presentation, introducing new material
3. Association, whereby the new is compared with the old and connected (the stage of apperception)
4. Generalization, whereby the teacher presents other instances of the new idea
5. Application, whereby the ideas are applied to further material, carried out by the child individually (a problem-solving phase)

Though these five steps give the teacher a clear role, they constitute a form of intellectual dominance and could lead to stereotyped lessons restricting the spontaneous creative learning by the pupil. Contemporary curricular revisions, on the contrary, aim at promoting pupil activity.

Conditioning and behaviourist theories. *Classical and operant conditioning.* In the act of classical conditioning, the learner comes to respond to stimuli other than the one originally calling for the response (as when dogs are taught to salivate at the sound of a bell). One says in such a situation that a new stimulus is learned. In the human situation, learning to recognize the name of an object or a foreign word constitutes a simple instance of stimulus learning. Such an event is called sign learning, because, in knowing the sign for something, a person to some extent makes a response to the sign similar to that that he would make to the object itself. Learning new vocabularies, new terms and conventions, or algebraic and chemical symbols all involve some degree of classical conditioning. It is thought probable that one trains the emotions in the same way, for a person may learn to feel pleasure not only when he meets the original situation causing the pleasure but also when he sees some wider context associated with it. This idea is important in school teaching and helps in a general way to explain children's positive and negative feelings toward school, feelings that may have arisen originally from difficulties in learning specific school subjects.

Stimulus learning

Operant, or instrumental, conditioning is so-called because, in making his response, the learner provides the instrument by which a problem is solved. This learning is more important to schoolwork, for teachers are concerned ultimately with drawing forth new responses from their students. Learning is active, and, after the early acquisition of vocabulary, terminology, and rules (by stimulus learning), the learner must use this material in problem-solving responses. By reinforcement (*e.g.*, a reward), both sorts of learning can be combined.

Conditioning theories are not wholly adequate to explain school learning, since the learner is not simply a responder. Intervening between the stimulus and the response is the learner's total conscious structure, made up of the results of experience, previous teaching, attitudes, and his own capacity to comment upon and edit his own response. Simple reinforcement is also inadequate in that

the stimulus and the response are not linked in an exclusive one-to-one basis. Several stimuli may evoke a single response, and several responses may be made to a particular stimulus. These form the behavioral bases for the formation of concepts and transfer effects from one topic to another. The two basic modes of stimulus-response learning provide a ground analysis of school learning, but the complexity of academic achievement calls for much elaboration on the simple model.

Cognitive theories of learning. Cognitive theories are appropriate to the school situation, for they are concerned with knowing and thinking. They assume that perceiving and doing, shown in manipulation and play, precede the capacity to symbolize, which in turn prepares for comprehensive understanding. Although the sequence of motor-perceptual experience followed by symbolic representation has been advocated for a long time, Jean Piaget offered the first penetrating account of this kind of intellectual growth. His views have exercised great influence on educators.

Cognitive theories of learning also assume that the complete act of thought follows a fairly common sequence, as follows: arousal of intellectual interest; preliminary exploration of the problem; formulation of ideas, explanations, or hypotheses; selection of appropriate ideas; and verification of their suitability.

The emphasis of optimum sequence and pacing of learning

Teaching based on cognitive theories of learning recognizes, first, the growth in quality of intellectual activity and capitalizes on this knowledge by organizing instruction to anticipate the next stage in development but does not await it; otherwise there would be no instruction; *i.e.*, instruction should pace development but not outstrip it. Second, it seeks to tune the learning situation to the sequences of the complete act of thought and to arrange, simplify, and organize the subject matter accordingly. Some educators emphasize strongly the arousal phase; in many modern science curricula there is, thus, the idea of inquiry training, which tries to arouse in the child a spontaneous rather than a directed interest. Other educators are concerned more with the middle intellectual phases of the thinking sequence—especially the playing with hypotheses or hunches and the working with organizing ideas and concepts.

Once started, the motivation of cognitive learning depends less on notions of reinforcement and more on standards of intellectual achievement generated by the learner himself. Accordingly, the learner may begin to have aspirations and to set himself future standards that are influenced by his past performances and those of his fellows.

Maturation and readiness theories. Readiness theories of learning lean heavily on the concept of maturation in stages of biological and mental development. It is assumed that a child passes through all stages of development in reaching maturity. The teacher finds out what a child is ready for and then devises appropriate materials and methods. Much of the work on reading skills, for instance, makes use of the readiness concept. The Italian educator Maria Montessori claimed that "periods of sensitivity," corresponding to certain ages, exist when a child's interest and mental capacity are best suited to acquiring knowledge of such things as textures and colours, tidiness, and language.

Insofar as Piaget offered a learning theory, it was based on the idea of readiness. But his approach to development does not overemphasize maturation and readiness, for he pointed out that, after the first few months of life, maturation is marginal in its effects, whereas experience is essential. Development through different intellectual phases, he believed, is necessarily coincident with relevant active experience; readiness is actively promoted, not passively entered, and the teacher must endeavour to be a step ahead of any particular level of readiness.

Structural theories of learning. The second half of the 20th century saw a revival of the concept of the structured wholeness of experience, which Gestalt psychologists had first introduced early in the century. The whole of experience, in this view, is more than the sum of its parts. In educational terms, a new experience—such as a new historical text, an exposition in science, or a problem rider in geometry—begins by seeming relatively formless and unstructured. The learner, who does not yet know his way about the material, begins by seizing upon what appear to him to be important features or figures. He then reformulates the experience in these new terms. The insight gradually becomes more and more structured until finally he reaches an understanding or a solution to the problem. It may be that, in all these processes, the learner may try anything he can think of, usually in a haphazard way.

Learning as an act of structuring and relating

Piaget improved upon Gestalt notions by suggesting a thought structure of a more adaptable nature—one that becomes more differentiated and intuitive with experience. He listed three psychological properties of a structure: wholeness, relationship between parts, and the principle of homeostasis, whereby a mental structure adjusts itself to new experience by assimilation and accommodation. This kind of structuralism found quite independent advocates in other fields. In language, for example, an American, Noam Chomsky, believes that there are innate language structures in the young individual, just as Piaget insists that there are thought structures.

A belief in the structural nature of experience would conceive of the teacher as an encourager, example provider, coanalyzer, and cobuilder of mental structures that originate in the learner in a relatively undifferentiated state. The learner is assumed to be active in forming structures and to be making the best he can of the situation he experiences. The teacher's task is to help and moderate this process of the learner's active construction. This notion works easily and well with able children but entails careful selection with less able students.

Others have also stressed the structural nature of advanced cognitive learning. Each area of human knowledge, in this view, is said to have its own unique structure composed of its concepts and their relationships and its own basic modes of progress. It is suggested that teaching a school subject should not lead to too much tampering with the inherent structural order of the subject but should follow the structure and lines of development of the subject itself. Teaching should not be contrived and artificial. Thus, economics should be taught as an economist views it or physics as a physicist views it or language as a linguist views it. Although such ideas are generally attractive, they have not been widely translated with any success into actual school practice.

GENERAL THEORIES OF EDUCATIONAL ORGANIZATION

Educational organization rests to some extent on psychological views about learning, but explicitly it is concerned with the grouping of pupils for educational experience and instruction.

Grading and streaming

Pupils in general are organized by age into what are usually termed grades, classes, or forms. Each school is also usually either comprehensive (containing students pursuing various academic, commercial, and vocational curricula) or based on the so-called dual plan (containing only students pursuing a particular curriculum). In some countries, this dual system is actually tripartite: there may be schools for classical academic study, schools for technical or vocational study, and schools for more generalized, "modern," diversified study. Whether comprehensive or dual-plan, schools frequently have some kind of streaming or multitracking whereby students are grouped according to ability so that there are separate classes for the less able and the more able (see also ELEMENTARY AND SECONDARY EDUCATION).

Grading and streaming have recently come in for much criticism. There is a rigidity in the two systems that causes some educators uneasiness, particularly since total education is seen as more than achievement in school subjects. Some countries, notably the United States, have made a start in trying to solve this difficulty by introducing the nongraded school, in which grades are abolished and students are placed individually in "phases" for each subject, through which they progress at their own pace. A similar solution has been to ungrade students for certain basic subjects, such as mathematics and native language,

but to have them rejoin their age peers for other school activities. In such systems there is, nevertheless, a kind of grading by intellectual ability, and egalitarians are apt still to be suspicious of them. There is scarcely any clear evidence of the effectiveness of the wholly nongraded system. It would seem probable that the optimum organization may be to combine grading with nongrading. Although this will involve constructing complex timetables, it will also offer the advantages of other, more rigid systems without introducing too many of their disadvantages. For one thing, retaining some grouping by age seems important as a link to extramural activities, in which age peers tend spontaneously to come together.

The modern interest in resources for learning has led to the concepts of general-purpose classrooms, open-plan teaching, and team teaching. The idea of general-purpose classrooms starts from the assumption that the school curriculum can be divided into a few large areas of allied intellectual interests, such as the humanities, languages, and sciences. The total resources available for teaching in each of these areas, including teachers, are then made available in one common teaching space, and ordinary classroom and lesson-period divisions disappear, to be replaced by a real mobility between teachers and learners as they make use of the different resources available, including library and laboratory facilities and various educational hardware (see below *Instructional media*). In the infant and primary schools, similar ideas are introduced in the open-plan system. At both the primary and the secondary levels, however, there is insufficient evidence on the effectiveness of the systems. The attitude and action of the teacher remains the strongest factor, and he may still require some privacy for his teaching.

Team teaching

Team teaching represents an attempt to make better use of every teacher's potential in any subject area, to create a flexible learning situation, and to make nonstreaming more effective. The normal class of 30 pupils with an individual subject teacher is replaced by a larger group of pupils and a team of teachers, who pool their efforts. Although the team plan may take several forms, it generally assumes some variety of the following elements: (1) large-group instruction, in which the total complement of some 50 to 150 students in the program is periodically taught by one teacher (either the same teacher or several teachers in rotation) in a lecture hall; (2) small-group instruction, which alternates with large-group instruction so as to allow small numbers of students and a member of the teaching team to discuss, report, and exchange ideas; (3) independent study, whereby students are given individual projects or library work; and (4) team planning sessions, in which, daily or weekly, the teachers plan, coordinate, report on, and evaluate their programs. The presumed benefits of team teaching are that it makes better use of each teacher's individual interests and strengths; that it avoids unnecessary replication, particularly in such basic subjects as native literature, in which ordinarily several classes led by different teachers cover the same ground; and that teaching in front of one's colleagues is a beneficial practice providing some evaluative feedback. Also, it is said that the less able children do not feel so segregated as in ordinary streamed classes; although they may gain little from the large-group sessions and individual projects, they seem to make real progress in the small seminar groups, without becoming overaware of their more limited capabilities. The reasons for this are obscure. In any event, the most obvious advantage of team teaching is its flexibility, in affording a great variety of possible combinations of student groupings and of educational resources. The major problem is that team teaching cannot be used in all subject areas. Although it may be useful in such areas as the humanities and the social sciences, its provision for lecture-size audiences does not aid the teaching of such subjects as mathematics, in which there are too many individual differences in ability. The same is true of arts and other subjects. Furthermore, without expert leadership, seminars are apt to degenerate into scenes of rather woolly discussions.

The grouping of children by ability, though still practiced, remains a problem. Formal tests are used to separate students according to their ability, and many people feel that separations by such means are neither reliable nor socially desirable. Even with regard to separating the mentally handicapped, there is growing opinion that wherever possible these children should be given basic instruction in special centres and remedial classes in schools for normal children. Handicapped and normal children would thereby share much of their education. Separation of the sexes is also declining in most countries, as the mixing of girls and boys comes to be recognized as healthy and socializing.

INSTRUCTIONAL MEDIA

In general, instructional media are seen by educators as aids rather than substitutions for the teacher. A teacher spends a disproportionate amount of his time in routine chores—in collecting and assigning books and materials and in marking—that could be partly obviated if aids could be so constructed as to free him to concentrate on the central job of promoting understanding, intellectual curiosity, and creative activity in the learner.

Speaking–listening media. In lectures and recordings, the teacher is able to set out his material as he thinks best, but usually the audience reception is weakly passive since there is not much opportunity for a two-way communication of ideas. Furthermore, in lectures, much of the students' energies may be taken up with note writing. This inhibits thinking about the material. Recordings enable one to store lecture material and to use it on occasions when a teacher is not available, but they are rather detached for young learners and seem to evoke better results with older students.

Language laboratories

Language laboratories are study rooms equipped with electronic sound-reproduction devices, enabling students to hear model pronunciations of foreign languages and to record and hear their own voices as they engage in pattern drills. Most laboratories provide a master control board that permits a teacher to listen to and correct any student individually. Many are equipped to use filmstrips or motion pictures simultaneously with the tape recorders. These laboratories are effective modes of operant learning, and, after a minimum vocabulary and syntax have been established, the learning can be converted into a stimulating form of problem solving.

Visual and observational media. Useful visual materials include objects and models, diagrams, charts, graphs, cartoons, and posters; maps, globes, and sand tables for illustrating topographical items; pictures, slides, filmstrips, motion pictures, and television. Facilities include blackboards, bulletin boards, display cases, tables and areas, museums, flannel boards, and electric boards. Such activities as field trips and the use of visiting authorities (usually called resource people) are considered part of visual and observational programs, and even demonstrations, dramatizations, experiments, and creative activities are usually included.

In general, pictures and diagrams, fieldwork, and contrived experiments and observations are all used as concrete leads to the generalizing, abstracting, and explaining that constitutes human learning. To fulfil this function, however, their use must be accompanied by interpretation by an adult mind.

The teacher must offer careful elaboration and discussion, for children's and adolescents' powers to interpret and infer often go astray and thus must be carefully guided. Visual material by itself may even be a hindrance; a scattering of pretty pictures through a history text, for example, does not necessarily produce a better understanding of history. Similar difficulties are inherent in fieldwork—geographical, biological, archaeological, and geological. What is observed rarely gives the whole story and, in the case of archaeological and geological fieldwork, provides an incomplete picture of the past. The teacher must fill in the gaps or somehow lead his students to do so.

Reading–writing media. Reading and writing have formed the staple of traditional education. This assumes sophisticated language attainments and the capacity to think formally and respond to another mind, for a text-

book is essentially a mode of communication between a remote teacher and a reader. The material in a textbook is a sample of a subject area, simplified to a level suitable for the reader. Because the sampling in both the text and the exercise might be haphazard, and there can be no feedback to the writer, the teacher has to take on the writer's responsibilities.

Programmed instruction

Programmed learning is a newer form of reading and writing. The most basic form of programmed instruction —called linear programming—analyzes a subject into its component parts and arranges the parts in sequential learning order. At each step in his reading, the student is required to make a response and is told immediately whether or not the response is correct. The program is usually structured so that right answers are apt to be extremely frequent (perhaps 95 percent of the time)—in order, so the theory goes, to encourage the student and give him a feeling of success. In another kind of programmed instruction—called branching programming—the student is given a piece of information, provided with alternative answers to questions, and, on the basis of his decision, detoured, if necessary, to remedial study or sent on to the next section of the program. The two types of program differ fundamentally in their attitudes toward errors and the use of them. The brancher uses them to further the learning; the linearist avoids them. The chief value of programmed instruction in general is that it allows a student to learn at his own pace, without much teacher supervision. Its chief defect is that it can quickly become dull and mechanical for the student.

Computer-based instruction. The large storage and calculating capacities of the computer suggest great potential for its use in the classroom. It can give instructions to the learner, call for responses, feed back the results, and modify his further learning accordingly. The computer can also be used to measure each student's attainments, compare them with past performances, and then advise teachers on what parts of the curriculum they should follow next.

In a fully computer-assisted instruction program, the computer takes over from the teacher in providing the learner with drill, practice, and revision, as well as testing and diagnosis. The form of the teaching may be simply linear or branching, or it can be extended to thinking and problem solving by simulation. The limitations at the moment centre on the learner's responses, which are limited to a prescribed set of multiple choices. Free, creative responses, which one associates with the best of classroom situations, cannot yet be accommodated.

(E.A.P.)

Pediments

A pediment is a piedmont plain (one lying near a highland) formed by the bevelling of bedrock that may be mantled with alluvium (unconsolidated sediments) or exposed. The pediment surface generally makes an abrupt angle with a mountain mass or backing hillslope and pediment embayments may extend into the uplands along valleys. The term was first applied by W.J. McGee in 1897, when writing of the Sonoran Desert, and was adopted for general usage in 1922 by Kirk Bryan, a U.S. geomorphologist, who described landforms in Arizona.

Comparable forms occur in humid areas but pediments are characteristic of arid lands, where they accentuate the separateness of island-like ranges and surrounding plains. Well-developed pediments give a high-set appearance to desert uplands. Although the dispersed surface drainage and shallow detrital cover do not favour local water supplies nor irrigation agriculture, smooth, firm pediment surfaces are readily traversed by vehicles and provide good access across the important piedmont tracts.

This article treats the physical characteristics of pediment surfaces and some views on the origin of these features, which is still a matter of some dispute. For discussion of related forms, see ALLUVIAL FANS and DESERTS. For information on processes involved in pediment formation, see FLUVIAL PROCESSES; WEATHERING; and DURICRUSTS. See also LANDFORM EVOLUTION for discussion of the Davisian cycle of erosion, equilibrium of process and form, and other ideas on the origins of landforms.

FORM OF PEDIMENTS

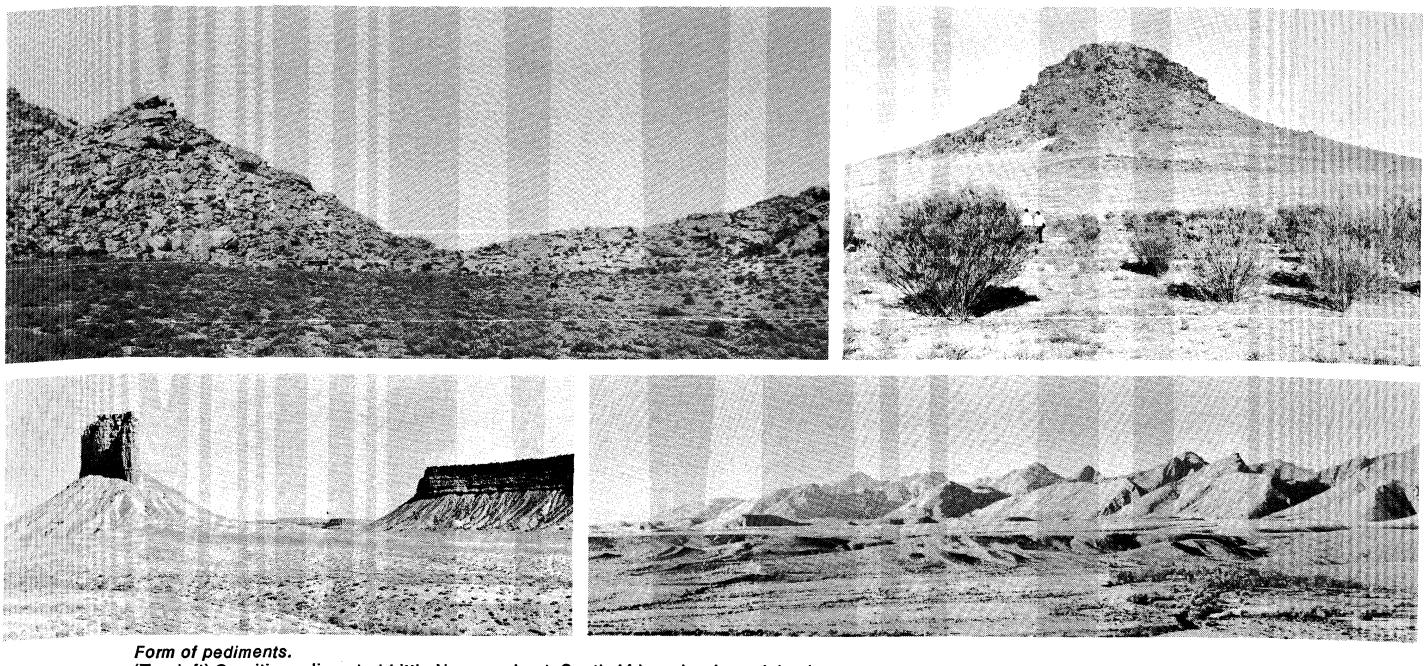
The longitudinal profile of pediments is typically concave; the gradient decreases with distance downslope and approximates a logarithmic curve. Pediment gradients range between 1 in 250 and 1 in 6, and often the smoothness of the slope belies the appreciable steepness of its upper part. Convexity in the lower sector can result from incision of trunk drainage, whereas local convexity in the upper part has been attributed to regrading at a late stage. The uppermost sector may be interrupted by rock outcrops and by small outliers of the upland.

Cross-gradients of undissected pediments are generally small and surfaces are at most smoothly and broadly undulating, with low rises between drainage tracts. Some upper sectors of pediments, however, exhibit as much as 15 metres transverse relief, and gradients are as steep as 1 in 10.

Pediment profile and rock type

The pediment profile is influenced directly by the underlying rock and indirectly by the calibre of detritus yielded from the backing hillslope. The most widespread and best developed pediments are on granite and similar massive rocks; these break down from joint blocks to sand and grit with few intermediate-sized particles. Such pediments have moderate slopes of limited concavity, which persist to the head of the pediment where there is an angular junction with the hill. A mantle of grit and sand usually is present, broken by minor outcrops and tors that are not necessarily concentrated towards the head. Pediments in mixed rocks, and in soft fine-grained rocks with a hard capping, exhibit a smooth and marked concavity. The slope steepens rapidly near the head and passes into the hillslope through a short transitional sector. Such profiles are commonly associated with a mantle of stone derived from the hill and the particle size decreases progressively downslope. Steepening at the head of the pediment is linked with the appearance of coarser colluvial debris. There are few interruptions of profile by rock outcrops, and these generally occur near the head of the pediment. This distinction between granitic and nongranitic pediments is fundamental.

Other differences of gradient express contrasts in erosional and transportive balances and in the stage of pediment evolution. Pediments at the foot of high mountains that yield much coarse debris are generally steeper than those flanking uplands of reduced relief. There is an inverse relation between pediment length and average slope, which suggests the occurrence of regrading during pediment extension. In Arizona, bare rock pediments are steeper than those that are mantled. Pediment slopes in intercanyon sectors are steeper than those along drainage lines, and those along minor channels are steeper than those flanking major channels.



Form of pediments.
(Top left) Granitic pediment at Little Namaqualand, South Africa, showing subdued concavity of profile, angular piedmont junction, and thin mantle without stone. (Top right) Middle Pinnacle, a nongranitic pediment on mixed rocks near Broken Hill, New South Wales, showing markedly concave profile into the hillslope, abundant outcrop, and widespread stone mantle. (Bottom left) Soft rock pediments cut in Mancos shale with a flat capping of Mesa Verde sandstone near Mesa Verde National Park, Colorado. Note the short transitional concavity at the heads and the shallowly dissected lower pediment slopes. (Bottom right) Dissected pediments in the Flinders Range, South Australia, which have a gravel mantle up to ten feet (three metres) thick, across shales and carbonate rocks; steeply dipping limestones and sandstones form the ranges.

It is claimed that pediment slopes are gentler where aridity is more marked, due to sparser vegetation, and that the slope break against the hill is accentuated. An extreme arid form may be the pinnacle landscapes of the Saharan Tibesti. In this area, hills of horizontally bedded sandstone tower with sheer sides above thinly veneered rock plains, and pediment slopes are absent or limited to a narrow fringe.

Pediment slopes on homogeneous rock tend to be radial in plan view, as on an alluvial cone, and there are fine map examples of arcuate parallel contours with a regular increase in spacing downslope. Where such ideal pediments narrow upslope to an apex in an upland re-entrant, they constitute rock fans. Pediments have been linked to such forms but they are relatively rare. Pediment outlines are variable and are dependent on structural controls. A pediment may open out on softer shale and then narrow to a rock bench where the drainage transverses a resistant sandstone, for example. Some pediment embayments taper gradually upslope whereas many others are blunt-headed. The upper limits of granitic pediments are characteristically regular, with few stream indentations, but the surfaces are smooth and well planed below spurs, in unindented sectors, and in stream embayments.

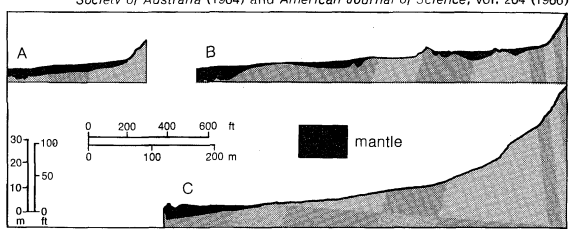
SURFACE FEATURES OF PEDIMENTS

The surfaces first described as pediments were veneered with a metre or so of overburden, such as might be considered to be in transit across the slope. Later workers, particularly those who accept a fluvial origin for pediments, have argued that mantles tens of metres thick can represent the depth of channel scour during floods. In extreme cases, surfaces with a cover of 60 metres have been described as pediments, as along the east front of the Rocky Mountains in Colorado. All agree, however, that the pediment should owe its form predominantly to erosion and that the diagnostic feature is the rock floor.

The pediment mantle

The mantle may occur throughout the slope, as on many granitic pediments, or the rock floor may be exposed near the hill foot. Where depositional basins occur, as in the southwestern United States, the mantle thickens away from the hill base and the mantled pediment passes into an alluvial apron; the term peripediment is used for a locally intervening sector cut across basin fill.

From T. Langford-Smith and G.H. Dury, "A pediment survey at Middle Pinnacle, near Broken Hill, New South Wales," *Journal of the Geological Society of Australia* (1964) and *American Journal of Science*, vol. 264 (1966)



Pediment mantles; mountain front at right.
(A) Complete mantle cover, extending from mountains to lower end of pediment. (B) Mantle filling in irregular pediment surface. (C) Stripped pediment surface with mantle near lower end.

Pediment mantles include a range of materials that reflect the various depositional environments and the source rocks. In interstream sectors the cover tends to be poorly sorted and crudely layered because it is carried from the hillslope and deposited by wash processes, but the mantle becomes finer grained and better sorted downslope. It may include fine aeolian material. Such deposits, termed pedisediments, may grade laterally into typical alluvium near stream channels. On nongranitic pediments there is a mixture of stone from the hill with finer, wash-derived material, and the stone tends to accumulate in a protective surface layer; the mantle on granitic pediments consists chiefly of sand and grit, with stone restricted to the hill margins.

The mantle commonly is weathered, an indication of relatively stable conditions following deposition. Clay enrichment and well-developed soil profiles are common, as are calcareous and gypseous crusts. These duricrusts may protect pediment slopes from dissection.

The upper level of a mantle, or depositional cover, controls pedimentation by restricting downcutting on the ex-

posed slopes above. Rapid accumulation of debris results in burial of the rock plane and rapid removal leads to its dissection. A stable depositional margin allows extension of the subaerial pediment as the hillslope retreats, whereas gentle lowering of the mantle, as in the later stages of diminished relief and sediment yield, favours the exhumation of a suballuvial pediment. Ideal conditions for pediment formation therefore include a subsiding or slowly accumulating basin fill with interior drainage, or a stable or slowly lowering surface adjusted to outgoing drainage, but pedimentation in fact occurs over a wide range of baselevel situations.

Surficial drainage on pediments

There are three characteristic types of surface drainage on pediments. Shallow rills linked in close distributary meshes and slightly impressed in mantle material occupy the upper sectors and tributary embayments of mantled granitic pediments. They head at the hillslope base, where they may connect with slope runnels. Such a rill zone may extend a few hundred metres downslope, depending upon the prominence of the mountain mass, and it generally narrows as the upland is diminished by erosion. The rills transport and deposit material derived from the hillslope.

Small linked channels incised a metre or so into the bedrock or mantle of the pediment form subparallel, slightly anastomosing (braided) systems. On granitic pediments they head at the lower margins of the rill zone and progressively encroach on it; on nongranitic pediments they can occupy the entire surface. They may feed downslope into a depositional plain or into the larger channels described below, and their essential role appears to be the transportation of debris and erosion.

Larger individual channels also occur and they characteristically exhibit shallow trench profiles and the rather straight courses of bedload streams. These channels have sandy floors and loose sandy banks, and have a tendency to braid. On granitic pediments they arise mainly from the confluence of minor channels on the pediment itself; on nongranitic pediments they more commonly form extensions of upland drainage.

MULTIPLE PEDIMENTS

A change from planation to incision in the piedmont can result in the dissection of pediments. Such is the origin of many flat-topped spurs, mesas, and benches with thin cappings of mantle material, as in strike lowlands of the Flinders Ranges of South Australia, where they stand up to 50 metres above the base plains of today. Staged or multiple pediments form spectacular benchlands below some regional escarpments, along the east front of the Colorado Rockies and in some dry intermont basins further west, for example. The succession there has been attributed to uplift and to Pleistocene climatic changes, with pediments planed in drier interglacials and mantled and incised in the wetter glacial periods. In a subhumid nonglaciated environment with intermittent uplift, as in the Canberra region of the Southern Tablelands of southeastern Australia, staged pediments have been described, the lowest of them passing into strath terraces of the incised Murrumbidgee drainage.

PEDIMENT EXTENSION AND PEDIPLANATION

Many desert mountains show evidence of reduction and disintegration by the encroachment of pediments. Comparison of forms indicates that pediment embayments extend headward and eventually link as pediment passes across divides, breaking the upland into isolated smaller masses. Such passes extend the pediment slopes but are generally smoothly convex across the crest. The elimination of an upland watershed should result in a pediment dome with rounded crest and radially concave flanks, as described from the Mojave Desert of California and from Namaqualand in South Africa.

Pediment-like slopes are not restricted to piedmont settings, however, and need not necessarily have resulted from the destruction of upland masses. They have been described along valley sides in the High Plains of eastern Colorado and Kansas, for example.

The term pediplain was introduced for erosional surfaces that formed through the coalescence of pediments, or that were presumed to have formed by the processes of pedimentation. The term has since been extended to describe erosional plainlands of continental extent that are identified with pediments by their multiconcave profiles, absence of deep mantling or weathering, and the persistence of steep hillslopes that are independent of the stage of planation achieved. Such planation has been termed pediplanation, as in southern Africa, and the inference is made that it involves the elimination of relief by retreat of hillslopes, and the extension of piedmont plains by processes seen now to operate on pediments. Pediplanation is held to contrast with the downwearing, rounding, and mantling processes of peneplanation, as envisaged by W.M. Davis, an American geographer.

PEDIMENT-LIKE FORMS IN HUMID REGIONS

Although features accepted as characteristic of pediments attain their best development in deserts, bevelled rock surfaces also occur in humid regions. In humid areas the surfaces are more commonly mantled with deposits and soils and are obscured to greater degree by vegetation. Davis considered rock basements beneath marginal valley-floor strips to be homologous with pediments and he used this similarity to support his view of arid terrain as a variant of the humid model. The differences cited, namely less steep and less rectilinear backing hillslopes, thicker overburden, more deeply weathered bedrock, and lower surface gradients adjusted to finer weathering products, were held to be of degree only. Davis described the Piedmont below the Appalachian Blue Ridge as the humid equivalent of a pediment.

L.C. King, a South African geologist, stressed the uniformitarian nature of hillslopes and maintained that pediments, although best exemplified on hard rocks and in semi-arid environments, appear with varying prominence in all landscapes. He cited the scarp-foot vales of the English Lowlands as pediment forms. J.T. Hack described gravel-capped benches of the Virginia Piedmont as dissected pediments and claimed that the control of piedmont slopes was lithologic rather than climatic, with gentler gradients on shales and carbonate rocks, and steeper slopes on sandstone and quartzite. Hack stressed the similarity of forms in Virginia to those on comparable rocks in the Henry Mountains of Utah, where the climate is much drier.

THEORIES OF PEDIMENT DEVELOPMENT

There are two components in the development of a pediment: the trimming back of the hill and the grading of the rock slope below. The existence of a pediment does not necessarily mean that the hill face has retreated across its length. Where an upland margin accords with a steeply inclined break in rock hardness, it is clear that downwearing at the discontinuity has predominated over slope retreat. Similarly, in granitic terrain, where the uplands are commonly compartmented by steep joints, the piedmont may correspond with a less massive and more readily degraded rock. Most soft-rock pediments, however, are formed on flattish structures with hard rock cappings, such that retreat can occur without changing the lithology of the slope. With these qualifications, it is possible to distinguish between theories of pediment formation that stress backweathering of the hillslope, areal erosion by diffuse runoff, or planation and trimming by laterally migrating stream channels.

Backweathering. Backweathering of the hillslope, with concommitant extension of a rock bench below, was stressed by A.C. Lawson as the dominant factor in pedimentation. The processes invoked in slope retreat were subaerial weathering and the removal of detrius by hillwash and mass movement. The hillslope was predicted to assume and maintain a constant angle during retreat, which was controlled by structure or by the angle of rest of the dominant size of slope debris. The junction of the bench and hill foot, which may have originated as a fault scarp, was determined by the growing detrital apron supplied from above. This apron was held to protect the underlying rock from further degradation. Lawson postulated that the apron must advance more slowly with in-

creasing extent, so restricting its protective role that the rock bench would flatten proportionally and a convex rock profile would result. He claimed that this suballuvial surface would be exposed as a subaerial bench or pediment at a later stage, with decreasing detritus from the diminishing upland. Sheetfloods were held responsible for the transport of debris across the apron and for the ultimate exposure of the rock bench.

Lawson's theory seems applicable in southwest Arizona, where there has been widespread stripping of mantle from rock surfaces, but there is considerable evidence that it by no means offers a universal explanation. Suballuvial profiles, for example, show a range of forms; indentation of the upland front locally at drainage outlets implies a significant role for water action; and soft-rock pediments, which evince the best evidence of slope retreat, are characteristically unmantled in their upper sectors at all stages.

Planation by diffuse runoff. This view received its impetus through the linking of W.J. McGee's early description of pediment landforms with an account of a sheetflood for which an erosive role was claimed. The paucity of subsequent observations suggests that sheetfloods are rare and localized, however, and the commonest form of overland flow on the upper parts of pediments is probably in the many small rills. Rillwash is claimed to be capable of removing and transporting weathered rock with a planatory effect, and combined with weathering, it is also held responsible for the removal of debris from the hillslope and for occasional undercutting at the base.

Lateral planation. The work of migrating stream channels was stressed by Douglas Johnson, who maintained that a zone of predominant transport and planation should exist between the zones of degradation in the upland and deposition in the lowland basin. Swinging of a stream channel about its outlet should form a rock fan similar to an alluvial cone, but such features have rarely been recorded. In granitic terrain, where the piedmont angle is most abrupt and the pediment at its smoothest, lateral planation is particularly weak; hillslopes are rarely undercut, pediment embayments are blunt-headed rather than apical, the slope-pediment contrast is strongest in the straight interstream sectors, and there is restricted channelling in the critical uppermost parts that are mantled with unsorted material. Even on soft-rock pediments traversed by large channels there is little indentation of the hill front, and major outlets are marked by alluvial fans rather than by rock fans. Furthermore, because desert channels are remarkably straight in piedmont sectors, there is restricted scope for planation in the intervening stretches.

Composite explanations. Many would argue that all these processes can act together, with rillwash and backweathering predominant in granitic terrain and stream planation of greater importance on nongranitic and particularly on soft-rock pediments, as attested by the alluvial character of their mantles. Further, the distinction between rillwash and lateral planation by minor channels is easily overdrawn because erosion by the shifting, interbranching, slightly incised rills, which characterize upper pediment sectors, tends to produce some degree of planation.

Control of pedimentation by the mantle. Important problems remain unanswered, particularly the relationship between the mantle and the rock floor, the role of the mantle in pedimentation, and the significance of buried or stripped rock surfaces with respect to changes in régime. The widespread stripped and dissected pediments of southeast Arizona have prompted a suggestion that all the regional pediments are exhumed suballuvial benches, their exposure resulting from a general swing from sheetflooding to channel flow, perhaps due to earth movement. Similarly, pediment mantles in the Rockies have been interpreted as due to a change from drier interglacial to more humid outwash conditions, or to shifts of drainage that bring coarser debris to fine-grained rock environments. Constant invocation of changed environmental conditions to reconcile field evidence becomes unconvincing, however, particularly in areas such as central Australia, where different parts of a single pediment may show signs of active stripping and of burial.

In an arid environment the mantle is not merely protective, for it enhances weathering by retaining moisture beneath the surface. This is particularly true of the piedmont sector, where runoff from the hillslope may cause notching of the hill base and rotting of protrusions of a buried rock floor. A mantle thus forms a weathering level; episodes of stripping will carry away weakened rock and this will lead to planation. Further, a partial mantle provides a smoothly graded surface to which protruding ribs of weathered granite or schist can be trimmed by rillwash.

Such mantle-controlled processes are most important on granitic pediments, where the rock is physically resistant above ground but susceptible to chemical weathering below, and where piedmont lowering is a function of long-continued downwearing under stable conditions rather than of hillslope retreat.

Soc.*, 17:81–102 (1957), a discussion of the claim that pediments and pedimentation are worldwide, despite modification by climate and rock type.

(J.A.M.)

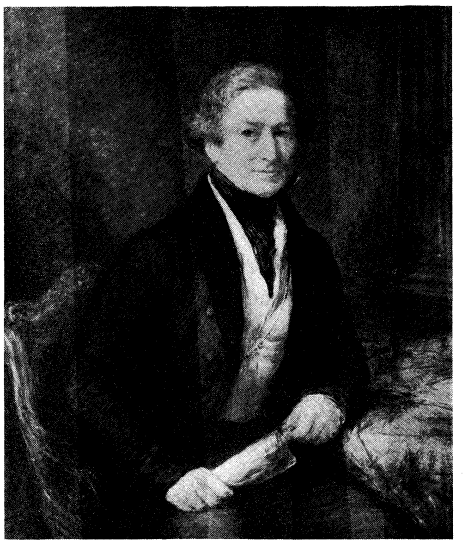
Peel, Sir Robert

British prime minister, founder of the Conservative Party, and the man responsible for the repeal, in 1846, of the Corn Laws that, by imposing heavy tariffs on imported grain, kept farm prices high in England, Sir Robert Peel was one of the outstanding English statesmen of the 19th century. He was born on February 5, 1788, at Bury in Lancashire, the eldest son of a wealthy cotton manufacturer, who was made a baronet by William Pitt the Younger. Robert was educated at Harrow and at Oxford, and, with his father's money, a parliamentary seat was found for him as soon as he came of age, in 1809.

Early political career

As an able young government supporter, Peel received appointment as undersecretary for war and colonies in 1810. Two years later he accepted the difficult post of chief secretary for Ireland. There he made his reputation as an able and incorruptible administrator and at the end of his Irish secretaryship was marked out for early promotion. He had also distinguished himself as the ablest of the "Protestant" party that resisted the admittance of Roman Catholics to Parliament, and in 1817 he gained the coveted honour of election as member of Parliament for Oxford University. Though declining immediate office after his return from Ireland, he was made chairman, in 1819, of the important currency commission that brought about a return to the gold standard.

In the 1822 ministerial reconstruction pursued by Robert Banks Jenkinson, 2nd earl of Liverpool, Peel accepted the post of secretary of state for the home department and a seat in the Cabinet. His first task was to meet the long-standing demands in Parliament for a radical reform of the criminal laws. He then proceeded to a comprehensive reorganization of the criminal code. Between 1825 and



Peel, oil painting by John Linnell, 1838. In the National Portrait Gallery, London.

1830 he effected its fundamental consolidation and reform, covering three-quarters of all criminal offenses. The rising statistics of crime convinced him that legal reform should be accompanied by improved methods of crime prevention. In 1829 he carried through the Metropolitan Police Act that set up the first disciplined police force for the Greater London area.

When George Canning succeeded Liverpool as prime minister in 1827, Peel resigned on the issue of Catholic emancipation. He returned to office under Arthur Wellesley, 1st duke of Wellington, early in 1828 as home secretary and leader of the House of Commons. Differences with Wellington led to the resignation of several followers of Canning after only four months in office, thus considerably weakening the government. This was followed by the Catholic crisis of 1828–29 that grew out of the renewal of the Irish movement for emancipation in 1823 with the formation of the Catholic Association. Its growing strength culminated in the victory of Daniel O'Connell, the Irish "Liberator," at a by-election for County Clare in 1828. Convinced that further resistance was useless, Peel proffered his resignation and urged the Prime Minister to make a final settlement of the Catholic question. Faced with severe opposition from the King and the Anglican Church, Wellington persuaded Peel, in 1829, to remain in office and assist in carrying through the policy of concession to the Catholics on which they now both agreed. Peel was bitterly attacked for his sudden change of heart and lost his seat for Oxford. Wellington's declaration against parliamentary reform in November 1830 finally brought about the fall of his weak and unpopular government.

Prime minister and Conservative leader

In the reform crisis following Wellington's fall, Peel's position was difficult and ambiguous. Though not opposed to moderate parliamentary reform, he was shocked by the sweeping measure introduced by the ministry of Charles Grey, 2nd Earl Grey, in March 1831. But, on the other hand, he made no effort to conciliate the ultra-Tories, and his refusal to form a new ministry with Wellington and pass a Tory reform bill in 1832 further weakened his standing with his former followers. Yet he was already looking to the growth of conservative opinion in the country, and his moderation in the first reformed Parliament (1833–34) did much to restore his political stature. The premature dismissal of the ministry of William Lamb, 2nd Viscount Melbourne, in November 1834 and Peel's appointment as prime minister gave him an impossible task because he did not possess, and the Conservative Party lacked the organization and men necessary to procure, a majority in the House of Commons (even though the general election of 1835 added considerably to their numbers). Nevertheless, his Tamworth Manifesto was an epoch-making statement of the new Conservative reform principles, and for the first time the party came under his acknowledged leadership. In April 1835, defeated by a combination of Whigs, radicals, and Irish nationalists, he resigned his office. During the next six years, aided by his astute and cautious tactics, the Conservative Party steadily increased in numbers and confidence. Following the general election of 1841, in which he gained a majority of over 70 in the House of Commons, Peel formed an administration that was one of the most memorable of the century.

Peel was faced with war in China and Afghanistan, strained relations with France and the United States, severe commercial distress at home, agitation by the workingmen's reform movement of the Chartists and the Anti-Corn Law League, O'Connell's campaign for the repeal of the union of Ireland and Great Britain, and a five-year accumulation of budgetary deficits. His policy aimed at peace and security abroad, a reduction in the cost of living for the working classes, and encouragement to trade and industry. On the controversial issue of the Corn Laws, to which the landed interest in his party was very sensitive, he brought forward as one of his first measures a new bill drastically reducing the scale of protective duties. In the same year, the bold reintroduction of the income tax (originally instituted during the Napoleonic Wars) established the internal revenue on a sound footing and enabled him to make sweeping reductions of duties on food and raw materials entering the country. The Bank Charter Act of 1844, establishing a tight connection between note issue and gold reserves, completed the foundations of the Victorian banking and currency system. The success of these measures encouraged Peel to launch a second great free-trade budget in 1845. The income tax was renewed, and there was another even more massive round of tariff reductions.

With the return of prosperity, Chartism died down and the Anti-Corn Law League turned to more constitutional methods of agitation. Abroad, a firm but conciliatory policy led to better relations with France. The boundary disputes with the United States were settled by the mission of Alexander Baring, 1st Baron Ashburton, in 1842 and the Oregon treaty of 1846. The same combination of firmness and conciliation was followed in Ireland. Once the threatening campaign for repeal of the union was brought to a halt in 1843 with O'Connell's trial for conspiracy, Peel turned to more constructive measures. A commission was set up to inquire into the relations between landlord and tenant, and a wide scheme for Irish university education was passed into law in 1845.

The liberality of Peel's Irish policy, especially the greatly increased grant to the Catholic seminary of Maynooth, aroused strong Protestant feeling in England, severely straining relations with his own party. The potato disease in 1845, bringing with it the certainty of widespread famine in Ireland, completed the breach. Peel had already come to the conviction that the Corn Laws would have to be abolished sooner or later. His decision in the autumn of 1845 that a relief program for Ireland must be accompanied by the repeal of the Corn Laws split his Cabinet and led to his resignation. But, when Lord John Russell failed to form a free-trade ministry in December 1845, Peel returned to office. After savage parliamentary debates the repeal of the Corn Laws was finally carried through in June 1846. Peel believed that the attempt to preserve the Corn Laws in the changed social and political conditions of Britain would imperil the rule of the aristocracy. Nevertheless, a majority of his party voted against him, and a smaller number joined the opposition to bring about his defeat and resignation later the same month. For the rest of his career he dedicated himself to the support of free-trade principles and the maintenance of Russell's Whig ministry as the only safeguard against a protectionist government. He died on July 2, 1850, as a result of a riding accident.

Assessment

A proud, shy person, Peel was by nature quick-tempered, courageous, stubborn, and often autocratic. With a first-class intellect, an exact memory, and great capacity for work, he was a superb administrator and an outstanding parliamentary debater. Though he has an unchal-

lenged place as founder of the modern Conservative Party, his political outlook was formed in the pre-reform era. He regarded ministers of the crown as servants of the state rather than as mouthpieces for sectional or party views. By insisting on fundamental changes in the national interest, he did much to preserve the continuity of aristocratic parliamentary government in an age of rapid industrial change, social distress, and class conflict. More than any other man, he was the architect of the mid-Victorian age of stability and prosperity that he did not live to see.

(N.G.)

Peirce, Charles Sanders

In the half-century preceding World War I, the pioneering researches of Charles Sanders Peirce, generally known as the founder of Pragmatism, ranged widely in the sciences, mathematics, logic, and philosophy. Most of his work is now known only to specialists, each grasping a small part of it, severed from its connections with the rest. Even his Pragmatism is viewed in relation to that of other Pragmatists rather than to other parts of his own work. A philosopher will know him also for his evolutionary metaphysics (theory of basic reality) of chance and continuity. A mathematician may known him for his contributions to linear algebra. A logician will know him as one of the creators of the algebra of logic—including the logic of relations; quantification theory (on the usages of "every . . . ", "no . . . ", and "some . . . "); and three-valued logic, which admits a third truth value between true and false—and may know him also for his two systems of logical graphs, which he called entitative and existential. A psychologist may discover in him the first modern psychologist in the United States. A worker in semiotic—the general theory of signs—will know him as cofounder of that science. A philologist may encounter him as an authority on the pronunciation of Elizabethan English. A computer scientist may find in one of his letters the first known sketch of the design and theory of an electric switching-circuit computer. But all of this, and much besides, lay beyond the scope of his professional career, which was that of a physical scientist in the service of the United States government. In that capacity, he was known to his contemporaries for his contributions to astronomy, gravimetry (the measurement of weight or density), spectroscopy, metrology (of weights and measures), geodesy, and the mathematical theory of map projections.

Range of his intellectual creativity

Work in the physical sciences for the Coast Survey. Peirce was born in Cambridge, Massachusetts in September 1839, one of the four sons of Sarah Mills and Benjamin Peirce, who was Perkins professor of astronomy and mathematics at Harvard University. After graduating from Harvard College in 1859 and spending one year with field parties of the U.S. Coast and Geodetic Survey, Peirce entered the Lawrence Scientific School of Harvard University, from which, in 1863, he graduated summa cum laude in chemistry. Meanwhile, he had reentered the Survey in 1861 as a computing aide to his father, who had undertaken the task of determining, from observations of occultations of the Pleiades (by the Moon's passing in front of them), the longitudes of American survey points with respect to European ones. Much of his work, at first chiefly astronomical, was done, on assignment by the superintendent of the Survey, in the Harvard College Observatory, in whose *Annals* (1878) his *Photometric Researches* (toward a more precise determination of the shape of the galaxy of stars to which the solar system belongs) appeared.

Work in astronomy and geodetics

Peirce, 1891.

Peirce's father, who was then superintendent of the Survey, obtained an appropriation from Congress to send parties to the Mediterranean Sea to observe the solar eclipse of December 22, 1870. Several months in advance, Charles, who had already observed an earlier eclipse, was sent to look for suitable observational sites along the expected path of totality. He himself then became a member of the party at one of the Sicilian sites.

In 1871 his father obtained an appropriation to initiate a geodetic connection between the surveys of the Atlantic and Pacific coasts. This cross-continental triangulation lent urgency to the need for a gravimetric survey of North America directed toward a more precise determination of the Earth's ellipticity, a project that Charles was to supervise. For that purpose, he returned to Europe four times to obtain apparatus, to conduct experiments, to participate in meetings of the European Geodetic Association and of its permanent commission, and to consult observers and instrument makers. In pursuit of this project, he contributed to the theory and practice of pendulum swinging as a means of measuring the force of gravity. The need to make accurate measurements of lengths in his pendulum researches, in turn, led him to take home with him the so-called Berlin Meter No. 49—the first authoritative line-metre (a metre standardized by matching with the standards of the Normaleichungsamt Imperial Standards Commission, in Berlin) to be received in the United States—and to make a pioneer determination of the length of the metre in terms of a wavelength of light (1877–79). Between 1873 and 1886 Peirce conducted pendulum experiments at about 20 stations in Europe and the United States and (through deputies) at several other places, including Grinnell Land in the Canadian Arctic.

Peirce was, for a time, in charge of the Office of Weights and Measures, in which capacity he recommended to a Congressional committee that the office be expanded, a step toward the eventual establishment of the National Bureau of Standards in 1901.

Though his experimental and theoretical work on gravity determinations had won international recognition for both him and the Survey, he was in frequent disagreement with its administrators from 1885 onward. The amount of time he took for careful preparation of reports was ascribed to procrastination. His "Report on Gravity at the Smithsonian, Ann Arbor, Madison, and Cornell" (written 1889) was never published because of differences concerning its form and content. When consulted about a proposed new apparatus with a short invariable pendulum, he objected that its invariability was not amenable to confirmation. He finally resigned as of the end of 1891, and, from then until his death in 1914, he had no regular employment or income. For some years he was a consulting chemical engineer, mathematician, and inventor; he played a modest part, for example, in the development of the St. Lawrence Power Company at Massena, New York.

Participation in scientific societies

Peirce was elected a fellow of the American Academy of Arts and Sciences in 1867, a member of the National Academy of Sciences in 1877. He presented 34 papers before the latter from 1878 to 1911, nearly a third of them in logic (others were in mathematics, physics, geodesy, spectroscopy, and experimental psychology). He was elected a member of the London Mathematical Society in 1880. He was active in the 1870s in the Philosophical (*i.e.*, scientific) Society of Washington, in the 1870s and 1880s in the American Metrological Society, and in the 1890s in the New York Mathematical Society (later the American Mathematical Society).

Work in logic. Though Peirce's career was in physical science, his ambitions were in logic. By the age of 31, he had published eight papers, a monograph, and a pamphlet—all of them technical—in that field, besides papers and reviews in chemistry, philology, the philosophy of history and of religion, and the history of philosophy. He had also given two series of Harvard University lectures and one of Lowell Institute lectures, all in logic. Though Peirce aspired to a university chair of logical research, no such chair existed, and none was created for him: the day of logic had not yet come. His nearest approach to this ambition occurred at Johns Hopkins University, where he held a lectureship in logic from 1879 to 1884 while retaining his position in the Survey.

Semiotic and logic

Logic in its widest sense he identified with semiotic, the general theory of signs. He laboured over the distinction between two kinds of action: sign action or semiosis, and dynamic or mechanical action. In 1907 he said,

> I am, as far as I know, a pioneer, or rather a backwoodsman, in the work of clearing and opening up what I call *semiotic*, that is, the doctrine of the essential nature and fundamental varieties of possible semiosis.

His major work, unfinished, was to have been entitled *A System of Logic, Considered as Semiotic.*

Though he made eminent contributions to deductive or mathematical logic, he was a student primarily of "the logic of science"; *i.e.*, of induction and of what he called "retroduction" or "abduction," the forming and accepting on probation of a hypothesis to explain surprising facts. His lifelong ambition was to establish abduction and induction firmly and permanently along with deduction in the very conception of logic—each of them clearly distinguished from the other two, yet positively related to them.

It was for the sake of logic that Peirce diversified his scientific researches so extremely, for the logician, he thought, should ideally have an insider's acquaintance with the methods and reasonings of all the sciences.

Peirce gave two further series of Lowell lectures, on the history of science (1892–93) and on "Some Topics of Logic Bearing on Questions Now Vexed" (1903); a series of Cambridge lectures on "objective logic" (1898); a series of Harvard lectures on Pragmatism (1903); and three on "Logical Methodeutic" (1907). He was a principal contributor on many subjects to *The Century Dictionary* (1889–91) and on logic to James Mark Baldwin's *Dictionary of Philosophy and Psychology* (1901–02). He reviewed for *The Nation* (1869–1908).

Work in philosophy. Peirce's Pragmatism was first elaborated in a series of "Illustrations of the Logic of Science" in the *Popular Science Monthly* in 1877–78. The scientific method, he argued, is one of several ways of fixing beliefs. Beliefs are essentially habits of action. It is characteristic of the method of science that it makes its ideas clear in terms first of the sensible effects of their objects, and second of habits of action adjusted to those effects. Here, for example, is how the mineralogist makes the idea of hardness clear: the sensible effect of x being harder than y is that x will scratch y and not be scratched by it; and believing that x is harder than y means habitually using x to scratch y (as in dividing a sheet of glass) and keeping x away from y when y is to remain unscratched. By the same method Peirce tried to give equal clarity to the much more complex, difficult, and important idea of probability. In his Harvard lectures of 1903, he identified Pragmatism more narrowly with the logic of abduction. Even his evolutionary metaphysics of 1891–93 was a higher order working hypothesis by which the special sciences might be guided in forming their lower order hypotheses; thus, his more metaphysical writings, with their emphases on chance and continuity, were but further illustrations of the logic of science.

When Pragmatism became a popular movement in the early 1900s, Peirce was dissatisfied both with all of the forms of Pragmatism then current and with his own original exposition of it, and his last productive years were devoted in large part to its radical revision and systematic completion, and to the proof of the principle of what he by then had come to call "pragmatism."

His "one contribution to philosophy," he thought, was his "new list of categories" analogous to Kant's a priori forms of the understanding, which he reduced from 12 to three: Quality, Relation, and Representation. In later writings he sometimes called them Quality, Reaction, and Mediation; and finally, Firstness, Secondness, and Thirdness. At first he called them concepts; later, irreducible elements of concepts—the univalent, bivalent, and trivalent elements. They appear in that order, for example, in his division of the modalities into possibility, actuality, and necessity; in his division of signs into icons, indexes, and symbols; on the division of symbols into terms, propositions, and arguments; and in his division of arguments into abductions, inductions, and deductions. The primary function of the new list was to give systematic support to this last division. (For the philosophy of Peirce, especially as it relates to Pragmatism, see PRAGMATISM: *History of Pragmatism: The classical Pragmatists.*

Peirce was twice married: first in 1862 to Harriet Melusina Fay, who left him in 1876, and second in 1883 to Mme Juliette Pourtalai (*née* Froissy). There were no children of either marriage. For the last 26 years of his life, he and Juliette lived on a farm on the Delaware River near Milford, Pennsylvania. He called himself a bucolic logician, a recluse for logic's sake. He lived his last years in serious illness and in abject poverty relieved only by aid from such friends as William James—in whose honour Peirce added Santiago (St. James) as his middle name. He died of cancer on April 19, 1914, on his farm. The Peirce house, acquired by the National Park Service in 1972, was to become a national memorial.

Peirce is now recognized as the most original and the most versatile intellect that the Americas have so far produced. The recognition was slow in coming, however, and much of his work is still unexplored.

BIBLIOGRAPHY

The Peirce papers: Collected Papers, ed. by CHARLES HARTSHORNE, PAUL WEISS, and ARTHUR W. BURKS, 8 vol. (1931–58), with a bibliography of Peirce's writings in vol. 8, pp. 249–330. The Peirce papers in the Houghton Library at Harvard University are listed and described by RICHARD S. ROBIN in his *Annotated Catalogue of the Papers of Charles S. Peirce* (1967), and in "The Peirce Papers: A Supplementary Catalogue," *Transactions of the Charles S. Peirce Society*, 7:35–57 (1971). A microfilm edition of the greater part of the collection is available from the Harvard University Library microreproduction service. CAROLYN EISELE has prepared an edition of his mathematical writings (forthcoming).

Studies: Studies in the Philosophy of Charles Sanders Peirce (1952), was edited by PHILIP P. WIENER and FREDERIC H. YOUNG. The *Second Series*, ed. by EDWARD C. MOORE and RICHARD S. ROBIN (1964), contains a supplement to Burks's bibliography of Peirce's own writings (pp. 477–485) and also a bibliography of writings about Peirce (pp. 486–514). There are further supplements in *Transactions . . .*, 2:51–59 (1966). CAROLYN EISELE and VICTOR F. LENZEN have published numerous studies of Peirce's work in the sciences, mathematics, and in the history of science (see the bibliographies mentioned above). Of the many books on Peirce's philosophy, the one that makes most use of unpublished materials and has greatest biographical value is MURRAY G. MURPHEY, *The Development of Peirce's Philosophy* (1961).

Peisistratus

Peisistratus, who was born around the beginning of the 6th century BC, was a major figure in the political, economic, religious, and cultural life of Athens during that century.

Rise to power. In 594 his mother's relative, the reformer Solon, had improved the economic position of the Athenian lower classes, but the Solonian reorganization of the constitution had not eliminated bitter aristocratic contentions for control of the archonship, the chief executive post. As Peisistratus reached manhood, the two major vying factions were called the Plain, led by Lycurgus, and the Coast, led by Megacles.

During a war with the city of Megara about 565, Peisistratus gained military fame by taking the Megarian harbour. He organized his own faction, named the Hillsmen, a group that included noble families from his own district, the eastern part of Attica, and also a very considerable part of the growing population of the city of Athens. At one point Peisistratus slashed himself and the mules of his chariot and made a dramatic entrance into the agora (marketplace) to show how his enemies had wounded him. The people voted him a bodyguard of citizens armed with clubs, with the aid of which he seized the Acropolis and held power briefly in 561. To increase his support he contracted a short-lived marriage with the daughter of Megacles and again acquired temporary power in Athens (probably 556–555), but Lycurgus and Megacles united to force him out.

For several years Peisistratus was an exile in northern Greece. He laid a solid base for his return, exploiting the silver and gold mines of Mt. Pangaeum and gaining the support of conservatives in Thebes, Argos, Naxos, and elsewhere. In 546 he went to Eretria on the island of Euboea, with the force provided by his own funds and by his friends, and from this base invaded Attica. At Pallene, near Mt. Hymettus, he launched a surprise attack on the Athenian army in the heat of midday, while his enemies were gambling or sleeping. After a complete victory, Peisistratus became master of Athens for the third time and remained in power until his death in 527. His sons Hippias and Hipparchus succeeded him.

The occasional modern efforts to interpret the factions involved in the rise of Peisistratus as representing simply different economic interests or purely geographical blocs seem misconceived, nor can one hope to penetrate the legends about Peisistratus to discern his personality. His career down to 546 shows persistence, dexterity, and diplomatic ability; once master, he followed a program that pleased the city population especially but that also appealed to the rural majority.

Tyrant of Athens. Peisistratus was master of Athens by the use of force, so in Greek terms he was a *tyrannos.* He maintained a mercenary bodyguard, composed in part of Scythian archers; he may have disarmed the citizens; and he certainly placed hostages from major families in safekeeping on the island of Naxos. Yet he preserved the constitutional forms of government and made them operate more efficiently. Some aristocrats cooperated and were permitted to hold the yearly post of archon; others went into exile. Once Peisistratus, accused of homicide, appeared before the court on the day of the trial; but his accuser dared not press the charge.

Religious and other developments

His internal policies appear to have been designed to increase the unity and majesty of the Athenian state. Since religion was closely interwoven with the structure of the Greek *polis* or city-state, many of his steps were religious reforms. He brought the great shrine of Demeter at Eleusis under state control and constructed the first major Hall of the Mysteries (Telesterion) for the annual rites of initiation into the cult. Many local cults of Attica were either moved to the city or had branch shrines there. Artemis, for instance, continued to be worshipped at Brauron, but now there was also a shrine to Artemis on the Acropolis. Above all, Athena now became the main deity to be revered by all Athenian citizens. Peisistratus constructed an entry gate (Propylaea) on the Acropolis and perhaps built an old Parthenon under the temple that now stands on the crest of the Acropolis. Many sculptured fragments of limestone from Peisistratid buildings have been found on the Acropolis, and the foundations of a major, unfinished temple can still be seen.

Festivals and literature also flourished in Peisistratid times. The tyrant enhanced the glory of the Panathenaea, a yearly festival to Athena, by accentuating the Great Panathenaea (every four years) with athletic contests and prizes for bards who recited the Homeric epics. After the cult of Dionysus was placed under state sponsorship, prizes were awarded at the yearly Dionysia for the singing of dithyrambs and, from 534, for the performance of tragedies. Poets such as Anacreon lived at the court of Peisistratus and his sons, who also encouraged the collection of oracles and supported the famous soothsayer Onomacritus.

Contribution to the growth of Athens. At this time Athens itself was becoming a city, rather than an agglomeration of villages. Peisistratus improved its water supply by building an aqueduct that fed the Enneakrounos fountain on the edge of the agora. He also beautified and systematized the marketplace itself; 6th-century markers of its borders have been found in agora excavations. Just outside the city, on the banks of the Ilissus stream, he began a temple to Olympian Zeus, but this was not finished until the reign of the Roman emperor Hadrian.

In the countryside, Solon had encouraged the growing of olive trees and vines to produce cash crops; Peisistratus made loans to small farmers for tools and equipment. In a few cases the estates of exiled aristocrats appear to have been broken up, but the major force in reducing aristocratic control over rural Attica seems to have been the regularization of government. Peisistratus instituted a system of travelling judges to provide state trials of rural cases on the spot; he himself made inspection tours.

This extensive cultural and political activity was financed by Peisistratus' revenues from the mines of Mt. Pangaeum and from internal sources. The silver mines of Laurium were state property, and dues were exacted from the growing trade at Athenian harbours. Peisistratus instituted a tax, probably of 10 percent, on agricultural production. On one tour of inspection, according to a famous story, he saw a farmer digging in a field of stones and asked what his income was. When the farmer replied, "Just so many aches and pains; and of these aches and pains Peisistratus ought to take his ten percent," the tyrant remitted all taxes to the frank farmer.

Athenian industry and commerce expanded tremendously in the latter half of the 6th century; the main contribution of Peisistratid rule to these developments was probably the guarantee of internal tranquility and the protection of foreign immigrants.

External policy

Externally, the tyrant pursued a policy of peace, probably because he dared not allow the Athenian citizenry to bear arms in a major war. But at this time the Greek world was also in a temporary state of balance. In the Aegean, Peisistratus helped such friends as Lygdamis of Naxos to become local tyrants. He purified the sacred island of Delos by removing the old graves near its temple of Apollo. His main efforts, however, were concentrated in gaining control of the Hellespont, through which came the exported grain of south Russia. To this end he secured command of Sigeum and installed a younger son, Hegesistratus, as its ruler. More important, he encouraged the Athenian Miltiades to lead a private venture that gained mastery over the Chersonesus.

On the death of Peisistratus, Athens was still much less important politically and militarily than was Sparta. Commercially, states such as Miletus, Corinth, and Aegina were at least as active, and the contemporary tyrant Polycrates of Samos was as important a patron of the arts and letters. Nonetheless, the religious and patriotic unification of Athens had made great progress during Peisistratus' calm, even rule. As Aristotle reports, it became a common saying that the tyranny of Peisistratus had been the age of Cronus, the golden age.

BIBLIOGRAPHY. The main ancient sources are HERODOTUS, bk. 1, ch. 59–64; and ARISTOTLE, *Constitution of Athens*, ch. 13–17. N.G.L. HAMMOND, *A History of Greece to 322 B.C.*, 2nd ed., ch. 6 and 8 (1967), cites other minor sources and gives the political development. On the constitutional side, see C. HIGNETT, *A History of the Athenian Constitution to the End of the Fifth Century B.C.*, ch. 5 (1952). A. ANDREWES, *The Greek Tyrants* (1956), thoughtfully compares Peisistratus with other Greek tyrants.
