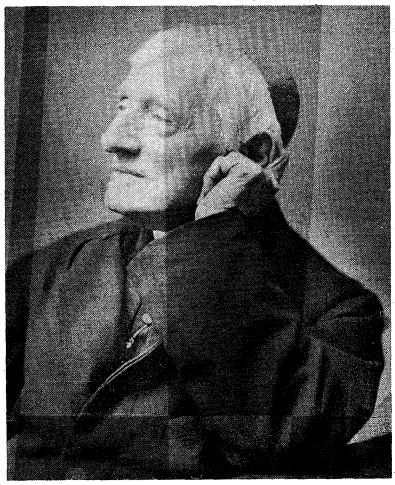
Newman, John Henry

A leader of the Oxford Movement in the Church of England and then, after his conversion, a leader of the Roman Catholic Church, Cardinal Newman was one of the most remarkable churchmen and men of letters of the 19th century.

By courtesy of the Gernsheim Collection, the University of Texas at Austin



Newman, photograph by Herbert Barraud.

Life before conversion. Newman was born in London on Feb. 21, 1801. After pursuing his education in an evangelical home and at Trinity College, Oxford, he was made a fellow of Oriel College, Oxford, in 1822; vice principal of Alban Hall in 1825; and vicar of St. Mary's, Oxford, in 1828.

Under the influence of the clergyman John Keble and Richard Hurrell Froude, Newman became a convinced high churchman (one of those who emphasized the Anglican Church's continuation of the ancient Christian tradition, particularly as regards the episcopate, priesthood, and sacraments).

The Oxford Movement

When the Oxford Movement began he was its effective organizer and intellectual leader, supplying the most acute thought produced by it. A high church movement within the Church of England, the Oxford Movement was started at Oxford in 1833 with the object of stressing the Catholic elements in the English religious tradition, and of reforming the Church of England after the pattern of the Church of the first five centuries AD. Newman's editing of the *Tracts for the Times* and his contributing of 24 tracts among them were less significant for the influence of the movement than his books, especially the *Lectures on the Prophetical Office of the Church* (1837), the classic statement of the Tractarian doctrine of authority; the *University Sermons* (1843), similarly classical for the theory of religious belief; and above all his *Parochial and Plain Sermons* (1834–42), which in their published form took the principles of the movement, in their best expression, into the country at large. In 1838 and 1839 Newman was beginning to exercise far-reaching influence in the Church of England, because the stress upon the dogmatic authority of the church was felt to be a much-needed re-emphasis in a new liberal age, because he seemed so decisively to know what he stood for and where he was going, because in the quality of his personal devotion his followers found a man who practiced what he preached, and because he had been endowed with the gift of writing sensitive and sometimes magical prose.

Newman was contending that the Church of England represented true catholicity and that the test of this catholicity (as against Rome upon the one side and what he termed "the popular Protestants" upon the other) lay in the teaching of the ancient and undivided church of the Fathers. From 1834 onward this middle way was beginning to be attacked on the ground that it undervalued the Reformation; and when in 1838–39 Newman and Keble published Froude's *Remains*, in which the Reformation was violently denounced, moderate men began to suspect their leader. Their worst fears were confirmed in 1841 by Newman's *Tract 90*, which, in reconciling the Thirty-Nine Articles with the teaching of the ancient and undivided church, appeared to some to assert that the articles were not incompatible with the doctrines of the Council of Trent; and Newman's extreme disciple, W.G. Ward, claimed that this was indeed the consequence. Bishop Richard Bagot of Oxford requested that the tracts be suspended; and in the distress of the consequent denunciations Newman increasingly withdrew into isolation, his confidence in himself shattered and his belief in the catholicity of the English church weakening. He moved out of Oxford to his chapelry of Littlemore, where he gathered a few of his intimate disciples and established a quasi-monastery.

Newman's conversion

He resigned St. Mary's, Oxford, on Sept. 18, 1843, and preached his last Anglican sermon ("The Parting of Friends") in Littlemore Church a week later. He delayed long, because his intellectual integrity found an obstacle in the historical contrast between the early church and the modern Roman Catholic Church; but meditating upon the idea of development, a word then much discussed in connection with biological evolution, he applied the law of historical development to the Christian society and tried to show (to himself as much as to others) that the early and undivided church had developed rightly into the modern Roman Catholic Church and that the Protestant churches represented a break in this development, both in doctrine and in devotion. These meditations removed the obstacle and on Oct. 9, 1845, he was received at Littlemore into the Roman Catholic Church, publishing a few weeks later his *Essay on the Development of Christian Doctrine*.

Life after conversion. Newman went to Rome to be ordained to the priesthood and after some uncertainties founded the Oratory at Birmingham in 1848. He was suspect to the more rigorous among Roman Catholic clergy because of the quasi-liberal spirit that he seemed to have brought with him (his mode of expressing the idea of doctrinal development, his teaching on the nature of faith); and therefore, though in fact he was no liberal in any normal sense of the word, his early career as a Roman Catholic priest was marked by a series of frustrations, as he at least felt them to be. In 1852–53 he was convicted of libelling the apostate former Dominican priest Achilli. He was summoned to Ireland to be the first rector of the new Catholic university in Dublin, but the task was in the conditions impossible, and the only useful result was his lectures on the *Idea of a University* (1852). His role as editor of the Roman Catholic monthly, the *Rambler*, and in the endeavour of Lord Acton to encourage critical scholarship among Catholics, rendered him further suspect and caused a breach with H.E. Manning, once himself a Tractarian and soon to be the new arch-

bishop of Westminster. One of Newman's articles ("On Consulting the Faithful in Matters of Doctrine") was reported to Rome on suspicion of heresy. He attempted to found a Catholic hostel at Oxford but was thwarted by the opposition of Manning.

Apologia pro Vita Sua and *Grammar of Assent*

From the sense of frustration engendered by these experiences Newman was delivered in 1864 by an unwarranted attack from Charles Kingsley upon his moral teaching. Kingsley in effect challenged him to justify the honesty of his life as an Anglican. And though he treated Kingsley more severely than some thought justified, the resulting history of his religious opinions, *Apologia pro Vita Sua* (1864), was read and approved far beyond the limits of the Roman Catholic Church and by its fairness, candour, interest, and the beauty of some passages recaptured the almost national status that he had once held. Though the *Apologia* was not liked by Manning and those who thought as he did, because it seemed to show the quasi-liberal spirit that they feared, it assured Newman's stature in the Roman Catholic Church. In 1870 he expressed opposition to a definition of papal infallibility, though himself a believer in the doctrine. In the same year he published his most important book of theology since 1845, *An Essay in Aid of a Grammar of Assent* (commonly known as *The Grammar of Assent*), which contained a further consideration of the nature of faith and an attempt to show how faith can possess certainty when it rises out of evidence that can never be more than probable. In 1879 Pope Leo XIII made him cardinal-deacon of St. George in Velabro. He died at Birmingham on Aug. 11, 1890, and is buried (with his closest friend, Ambrose St. John) at Rednal, the rest house of the Oratory.

Mind and character

Newman's portraits show a face of sensitivity and aesthetic delicacy. He was a poet—most famous are his contributions in the *Lyra Apostolica* of his Anglican days, including the hymn "Lead, kindly light," written in 1833 when he was becalmed in the strait between Sardinia and Corsica, and *The Dream of Gerontius* (1865), based upon the requiem offices and including such well-known hymns as "Praise to the holiest in the height" and "Firmly I believe and truly"—and his thought as a philosopher or theologian was never far from the poetic apprehension. He was always conscious of the limitations of prose and aware of the necessity for parable and analogy, and logical theologians sometimes found him elusive or thought him muddled.

But his was a mind of penetration and power, trained upon Aristotle, David Hume, Bishop Joseph Butler, and Richard Whately, and his superficial contempt for logic and dialectic blinded some readers into the error of thinking his mind illogical. His intellectual defect was rather that of oversubtlety; he enjoyed the niceties of argumentation, was inclined to be captivated by the twists of his own ingenuity, and had a habit of using the *reductio ad absurdum* in dangerous places. Newman's mind at its best is probably to be found in parts of the *Parochial and Plain Sermons* or the *University Sermons*, at its worst in the *Essay on Ecclesiastical Miracles* of 1843.

His sensitive nature, though it made him lovable to his few intimates, made him prickly and resentful of public criticism, and his distresses under the suspicions of his opponents, whether Anglicans defending the Reformation or ultramontanes (exponents of centralized papal power) attacking his Roman theology, weakened his confidence and prevented him from becoming the leader that he was otherwise so well equipped to be. Nevertheless, as the effective creator of the Oxford Movement he helped to transform the Church of England; and as the upholder of a theory of doctrinal development he helped Catholic theology to become more reconciled to the findings of the new critical scholarship, while in England the *Apologia* was important in helping to break down the cruder prejudices of Englishmen against Catholic priests. In both the Catholic Church and the Church of England his influence has been momentous.

MAJOR WORKS

Theological Works:

Tracts for the Times, nos. 1–3, 6, 7, 8 (with R.H. Froude), 10, 11, 15 (with Sir W. Palmer), 19–21, 31, 33, 34, 38, 41, 45, 47, 71, 73, 74 (with B. Harrison), 75, 76, 79, 82, 83, 85, 88, 90, 1833–41 (all edited by Newman); *Parochial and Plain Sermons*, 1834–42; *Lectures on the Prophetical Office of the Church*, 1837; *University Sermons*, 1843; *An Essay on the Development of Christian Doctrine*, 1845; *On Consulting the Faithful in Matters of Doctrine*, 1859; *An Essay in Aid of a Grammar of Assent*, 1870.

Miscellaneous:

Remains of the Late R.H. Froude, 1838–39 (ed. with J. Keble); *The Idea of a University*, 1852; *Apologia pro Vita Sua*, 1864 (Newman's account of his conversion to Roman Catholicism); *Essays Critical and Historical*, 1872; *Meditations and Devotions of the Late Cardinal Newman*, 1893.

Novels:

Loss and Gain, 1848 (anon.; signed and with subtitle *The Story of a Convert*, 1853); *Callista: A Sketch of the Third Century*, 1856 (anon.). (VERSE): *Lead, Kindly Light*, 1834 (anon.; reprinted in Newman's *Verses on Various Occasions*, 1868; *The Dream of Gerontius*, 1865.

BIBLIOGRAPHY. The most important works by Newman have been reprinted, a few of them often; but as Newman was in the habit of making substantial alterations when re-editing, their text history needs care: see J. RICKABY, *Index to the Works of John Henry Cardinal Newman* (1914).

Many of his letters as an Anglican were edited by ANNE MOZLEY, *Letters and Correspondence of J.H. Newman During His Life in the English Church*, new ed., 2 vol. (1898); the *Correspondence of John Henry Newman with John Keble and Others 1839–1845* was edited at the Birmingham Oratory (1917). See also *Cardinal Newman and William Froude, F.R.S.: A Correspondence*, ed. by G.H. HARPER (1933). C.S. DESSAIN and V.F BLEHL (eds.), *Letters and Diaries of John Henry Newman*, vol. 11– (1961–), is definitive. The best edition of the *Apologia* is by M.J. SVAGLIC, *Apologia pro vita sua* (1967). The official biography is W.P. WARD, *The Life of John Henry Cardinal Newman, Based on His Private Journals and Correspondence*, 2 vol. (1912, reissued 1927); less critical, but well-based on the archives and very readable is M. TREVOR, *Newman*, 2 vol. (1962–63); a short modern life is C.S. DESSAIN, *John Henry Newman* (1966).

For Newman's thought and philosophical theology, see M. NEDONCELLE, *La philosophie religieuse de John Henry Newman* (1946); for theology in general, J.H. WALGRAVE, *Newman: le développement du dogme* (1957; Eng. trans., *Newman the Theologian*, 1960); for the idea of development and its background, O. CHADWICK, *From Bossuet to Newman* (1957); for Newman and education, A.D. CULLER, *The Imperial Intellect* (1955); and F. MCGRATH, *Newman's University: Idea and Reality* (1951). Useful articles appear in *Newman Studien* (1948–).

(W.O.C.)

New Mexico

A state of the American Southwest, New Mexico is an integral part of the "Old West" of cattle drives, cowboys, and clashes with Apache Indians. In the vast flatness of its Great Plains and the rough, weather-scored peaks of its mountain ranges, it still retains much of its frontier flavour. The severe tensions and increasingly frequent confrontations between its Spanish-American, Indian, and "Anglo," or English-speaking, population are a continuing reminder of the bitter antagonisms that characterized its long history and were little resolved when it became the 47th state in the Union in 1912.

The 121,666 square miles (315,115 square kilometres) of New Mexico make it the fifth largest of American states, with only 254 square miles (658 square kilometres) of water area. Rectangular in shape except for a small panhandle in the southwestern corner, New Mexico is bounded on the north by Colorado, on the east by Oklahoma and Texas, on the south by Texas and the Mexican state of Chihuahua, and on the west by Arizona, which, from 1850 to 1863, was part of the Territory of New Mexico. At its northwestern corner it joins Arizona, Utah, and Colorado in the only four-way meeting of states in the United States.

Despite the traditionally agrarian nature of the state, augmented by successful irrigation methods, by the early 1970s, New Mexico had become highly urbanized. Seventy percent of its population of 1,016,000 were living in urban areas—nearly one-third in Albuquerque and surrounding Bernalillo County. The capital, Santa Fe, is a much smaller city, but its founding in 1610 preceded that

of Albuquerque by 96 years, and it is the oldest continuously used seat of government in North America. It was also the southwestern terminus of the Santa Fe Trail, a wagon trail that was a major commercial and migration route from Missouri to the Southwest from 1821 to 1880, when the last section of the railroad was completed. (For information on related topics, see the articles UNITED STATES; UNITED STATES, HISTORY OF THE; NORTH AMERICA; ROCKY MOUNTAINS; and GREAT PLAINS.)

THE HISTORY OF NEW MEXICO

New Mexico was peopled by various Indian cultures, who farmed and hunted on the land for at least 10,000 years before white explorers appeared. The more peaceful agriculturists, including the later groups, whose pueblo ruins dot the state, held the longer sway and had well-developed irrigation systems by the time the more aggressive and nomadic Navajo and Apache arrived from the north, probably in the 15th century.

Spanish and Mexican rule. Reports of the fabled seven cities of gold brought the first white explorers into New Mexico in 1540, led by the Spanish adventurer Francisco Coronado. The journey fruitless, they returned to Mexico. After several decades of desultory exploration by soldiers and friars, Juan de Oñate was given contracts for colonization in 1595 and made the first permanent white settlements during the following years, founding Santa Fe in 1610.

Colonial period

For the next century, missionary work predominated, but the attempts to eradicate Indian religion and culture brought on an uprising and massacre in 1680 that cleared out the white man for some years. By 1700, Spanish arms had reasserted themselves, and for the next century there was considerable settlement. Albuquerque, founded in 1706, was the focal point in the south, and the older Santa Fe was that of the north. When New Mexico became a part of the Republic of Mexico, newly founded in 1821, it already had begun the trade with the United States over the Santa Fe Trail that would lead to still another allegiance 25 years later.

Territory and state. During the Mexican War, which began in 1846, New Mexico was taken by the Army of the West under Gen. Stephen Kearny. All residents were granted amnesty and citizenship in return for an oath of allegiance to the United States. The Territory of New Mexico was established by Congress in 1850. During the Civil War an invading Confederate force was driven out by the Colorado Volunteers.

The Navajo tribes were quelled and, in 1868, given a large reservation, but the Apaches, settled on two reservations in 1880, continued their struggles until 1886. The burgeoning cattle industry was the main development of these decades, and the territory often was bloodied by battles between cattlemen and sheepmen, large landowners and homesteaders. The legendary Billy the Kid and his lawman-nemesis, Pat Garrett, were products of this struggle. The Apache leaders Geronimo, Cochise, and Victorio, though mainly active in Arizona, made forays into southwestern New Mexico. The Atlantic and Pacific Railroad (later the Atchison, Topeka, and Santa Fe), which reached Albuquerque in 1880, brought new immigration, and farming grew rapidly with the development of new irrigation methods and resources.

Following admission as a state on January 6, 1912, New Mexico retained its agricultural bases until World War II, when atomic research opened a new era in the state's life. The most famous scientific installation is at Los Alamos, centre of the project that created the first atomic bomb in 1945.

The gradual development of mineral resources also helped the economy and income of the state.

THE NATURAL AND HUMAN LANDSCAPE

The natural environment. New Mexico has some of the flattest land in the world and also some of the most rugged mountains. Some portions are blessed with pine forests, rich meadows, and fish-laden mountain streams, while other areas are devoid of streams, and even cacti struggle to survive. The eastern third of the state is an extension of the Great Plains. The central third is the southern extension of the Rocky Mountains, with the ranges interspersed by valleys and running in a north–south direction. The western third is high-plateau country, but it also contains many short mountain ranges and plains.

Surface features

Mountains. Average elevation ranges from 5,000 to 8,000 feet (1,500 to 2,500 metres) above sea level in the northwest to less than 4,000 feet (1,200 metres) in the southeast, with 85 percent of the state in excess of 4,000 feet (1,200 metres). The highest mountain peaks, Wheeler Peak (13,161 feet [4,011 metres]) and Truchas Peak (13,102 feet [3,993 metres]), are in the Sangre de Cristo range in the north central part of the state. The numerous valleys between the ranges are indispensable to agriculture and grazing. Unique volcanic formations abound as reminders of past lava flows. The caverns near Carlsbad are among the most spectacular natural formations in the world.

Rivers. Five major river systems—the Rio Grande, Pecos, Canadian, San Juan, and Gila—drain the state. The Rio Grande, which has played an influential role in New Mexico's history, virtually bisects the state. Agriculture in its floodplain has been significant from prehistoric times, and, before American settlement, white men lived exclusively in its valleys and those of its tributaries. The Pecos, east of the Rio Grande and approximately parallel to it, was also a popular route for explorers. The Canadian River, rising in the Sangre de Cristo Range and flowing due east across the arid plains, was a useful avenue for explorers despite its deep canyons. The San Juan and Gila rivers lie west of the Continental Divide, in the northwest and southwest respectively. All but the Gila, which is not dammed in New Mexico, provide water for irrigation, recreation, and flood control.

Climate. Though New Mexico's mean annual temperature is 53° F (12° C), extremes range from 110° F (43° C) to −29° F (−2° C). Variations are caused more by altitude than latitude, temperatures rising or falling by 5° F with every 1,000 feet of elevation. Nighttime temperatures tend to fall sharply. The average annual rainfall is 15 inches (380 millimetres), though precipitation tends to increase with elevation. About 40 inches (1,000 millimetres) of rain falls in the higher mountains, whereas lower areas may get no more than eight to ten (200 to 250 millimetres). Generally, precipitation is greatest in the eastern third of the state, least in the western.

Vegetation. New Mexico has six vegetation zones, which are also determined mainly by altitude. The Lower Sonoran zone, in southern sections of the Rio Grande and Pecos valleys and in the southwestern corner, usually occurs at altitudes below 4,500 feet. It embraces nearly 20,000 square miles of the best grazing area and irrigated farmland. The Upper Sonoran, comprising about three-fourths of the state and including most of the plains, foothills, and valleys above 4,500 feet, is a zone of prairie grasses, low piñon pines, and juniper shrubs. At higher altitudes, better stands reflect the more abundant rainfall. The Transition zone, covering some 19,000 square miles, is identified chiefly with the ponderosa pine. The Canadian zone, embracing 4,000 square miles at elevations of 8,500 to 9,000 feet, contains blue spruce and Douglas fir. The Hudsonian and Arctic-Alpine zones, above 9,500 feet, are too small in area and too sparsely covered to be of great importance.

Zones of vegetation

Animal life. The diversity of natural vegetation and elevation affect the wildlife, and the inaccessibility of much of New Mexico has helped preserve its abundance. Mule deer, brown bear, bighorn sheep, mink, muskrat beaver, fox, mountain lion, and bobcat live in the mountain and forest areas above 7,000 feet, while at lower elevations antelope are still found, along with coyote and jackrabbit. Barbary sheep from North Africa were introduced into several mountain areas. Many species of trout are common in the mountain streams, and warm-water fish abound in lower streams. Approximately 300 species of birds can be found at almost any time, including various game birds. The rattlesnake and the black widow

spider are most feared by man among the many lower forms.

Patterns of human settlement. The first Spanish settlements were in the central Rio Grande Valley and its tributaries. The Spanish-speaking inhabitants are still concentrated in the north central portion of the state. The eastern third of the state is frequently referred to as "Little Texas" or the "East Side." It is an extension of the Great Plains of western Texas and was originally settled as a cattle frontier expanding westward from Texas after the Civil War. It has continued to attract Protestant Anglos from Texas as ranchers, farmers, or oil-field workers, and they often have been at odds with the Spanish-American Catholics of Albuquerque and Santa Fe. The southwestern corner of the state, settled by Anglo miners after the coming of the railroads, also has little in common with the central area. The northwest corner received Mormon settlers from Colorado, but the greatest growth of this area resulted from oil and natural-gas discoveries after World War II.

Early settlers remained along streams because of the scarcity of water elsewhere. In a typical community, adobe houses opened onto a plaza from which four streets ran outward, and the entire enclave was enclosed by a wall for defense. Nearby were small agricultural plots and orchards owned by individuals. Just beyond, in a great circle, was the ejido, land for communal grazing, recreation, or firewood. Despite fear of Indian attack, individual ranches away from settlements often were established. At the time of the American conquest, New Mexico was a self-sufficient agrarian community, with most people residing in small villages.

Spanish villages

After the Civil War, vast cattle ranches appeared on the East Side, their size limited only by the availability of water. The coming of the railroad in 1879 brought several waves of Anglo farmers, but frequent droughts ruined many who tried to till the soil as they had in their more humid homelands. Dry farming—tilling that uses drought-resistant crops or otherwise conserves soil moisture—saved many who remained, but today irrigated farming is the most important form of agriculture.

THE PEOPLE OF NEW MEXICO

Ethnic composition. The people of New Mexico are primarily Anglos, Spanish-Americans, or Indians, and there are few Negroes or Orientals. The original Spanish settlers intermarried with the Indians, and their descendants are designated as Spanish-Americans or Hispanos rather than Mexican-Americans, as elsewhere in the Southwest. The numerical superiority of Spanish-Americans lasted until the 1940s, but by 1970 persons with Spanish surnames made up only slightly more than 25 percent of the population. After World War II an influx of Anglos contributed to a widespread desertion of small agricultural villages by their traditional Spanish-speaking residents, who moved to urban centres or to California. Many such villages became ghost towns.

The Indian population has grown from 34,510 in 1940 to about 73,000 in 1970. A large Navajo reservation extends over the northwest corner into Arizona, and nearby Gallup is famous as "the Indian capital of America." There are also reservations for the Utes, Jicarilla, and Mescalero Apaches, and in 1968 more than 20,000 Pueblo Indians lived on 19 scattered land grants. The Indians preserve many of their ancient ways, tending flocks of sheep and producing numerous handicraft items. In recent years, however, dissatisfaction with their low income, inadequate housing, poor health standards, and lack of educational opportunity has led to a growing militancy and an increasing exodus from their reservations or pueblos to urban centres.

Indian population

Demography. Traditionally rural New Mexico has joined the national trend toward urbanization, and since 1920 its rate of population growth has exceeded that of the United States as a whole. A growth rate of nearly 40 percent during the 1950s was in large part the result of a proliferation of federal expenditures in the state for defense and research and of the discovery of oil and other minerals. The reduction of federal outlays and the leveling off of mining booms, however, caused the rate to plunge to only 7 percent in the 1960s, and in both decades half of the state's counties declined in population. Urbanization has involved a number of factors: the movement of Spanish-Americans away from their rural homes, the consolidation of farms and the increasing inclination of many farmers to abandon their isolation for the larger towns and commute to their fields and flocks.

THE STATE'S ECONOMY

New Mexico's economy is similar to that of the developing nations of the world in that it is largely at the mercy of forces over which it has little control. Relying heavily on the export of raw materials and on federal expenditures for programs of no certain permanence, it is subject to shifting demands from the outside. Over-all, government spending accounts for nearly one-third of the state's economy. New Mexico is a comparatively poor state, in 1970 ranking 44th nationally in per capita income. During the 1960s the income of the average New Mexican fell from about 85 percent to 79 percent of the national figure.

Agriculture. Though gross farm income continues to rise slowly, in 1970 it accounted for only 7 percent of the state's income. Under Spain and Mexico, Nueva Méjico was self-sufficient, growing beans, corn, cotton, and squash on the alluvial plain of the Rio Grande. Sheep prospered in the arid land and remained important until the 20th century. The Anglos brought cattle raising from Texas, and the sale of beef now accounts for more than one-half of marketing receipts from agricultural products. Cotton is the leading cash crop, with hay second. Wheat and sorghum grains are raised on the dry farms of the eastern part of the state, but the irregularity of rainfall makes this type of agriculture hazardous. Half of the total cropland of 1,117,000 acres (452,000 hectares) is under irrigation, and it is such lands that furnish the overwhelming share of the crop dollar.

Major crops

Mining. The mining industry, contributing 6 percent of the state's economy, brought many settlers and attracted outside capital in territorial days. Gold and silver mining began in the 19th century, reached its peak in 1915, and has declined since. Copper mining continues in importance, and coal mining, which went into decline with increased use of other fuels, expanded in the 1960s as the result of improved technology. New Mexico produces some 85 percent of the nation's potash and since discovery of uranium deposits in 1950, has led the nation in uranium production. Iron, lead, zinc, manganese, and molybdenum are also mined, but oil and natural gas account for some 65 percent of the state's mineral income. Production of the latter is mainly in the southeast corner and in the San Juan Basin in the northwest.

Manufacturing. Originally limited to the production of consumer goods, manufacturing has increased rapidly since World War II and accounts for 7 percent of the economy. Food processing, petroleum refining, smelting, construction materials, and railroad maintenance are leading manufacturing activities. Basic atomic research is carried on at the Los Alamos Scientific Laboratory, with testing taking place at Sandia Military Base, in Albuquerque, or at the White Sands Missile Range, near Alamogordo. An offshoot of this is private manufacturing of ordnance, electronics, precision instruments, and the like. Because of the limited development of industry, unionism has never been important, and it is confined largely to the mining, smelting, and petroleum industries.

Tourism and trade. In 1968 wholesale and retail trade contributed 21 percent and services 18 percent of the state's economy. The figure for services chiefly reflects the increasingly important development of recreation and tourism. The distinctive Indian and Hispanic cultures continue to draw countless visitors. State and national parks and monuments, historic sites, hunting and fishing, skiing, and Indian ceremonials are important attractions.

Transportation. Geographic isolation was a basic cause of New Mexico's slow economic development. In the Spanish and Mexican periods, it was often a six-month trip between Mexico City and Santa Fe. The Santa

Fe Trail route was much shorter, and American consumer goods helped prepare the way for conquest. This isolation was ended when the railroads reached Albuquerque and Santa Fe in 1880, and today an extensive rail network unites the state. New Mexico has highways linking major population centres, three of them part of the federal interstate system. Mountainous terrain has made road construction expensive, and, although secondary road building has lagged, it is adequate. Air transportation provides a vital link with the distant centres of the nation.

ADMINISTRATION AND SOCIAL CONDITIONS

Governmental structure. In most instances the state's constitution can be amended by a majority vote of the legislature and by a majority vote of the electorate. A public referendum on major issues is permitted, but public initiative on legislative matters is not. Nomination to office is by closed primary.

Executive. The governor has the usual powers of pardon, reprieve, and veto, but he has more authority than executives of most states. Since he appoints most of the state boards, departments, agencies, and commissions, he is the virtual master of patronage and the political organization. Like the lieutenant governor and other executive officials, he is elected for a two-year term and can serve two consecutive terms but is ineligible for all state elective offices for two years thereafter.

Legislature and judiciary. A legislature composed of 42 members of the Senate, elected to four-year terms, and 70 members of the House, elected to two-year terms, meets annually for a 60-day session. Heading the judiciary are five Supreme Court justices elected individually for eight years, with overlapping terms. Judges of the 11 judicial districts are elected for six years and serve ex officio as judges of juvenile courts.

Local government and politics. Each of New Mexico's 32 counties is administered by three commissioners elected for two years. Other county elective officers are assessor, clerk, sheriff, surveyor, treasurer, and probate judge. In the territorial era, citizens usually favoured Republicans, but since statehood Democrats have tended to dominate. The state voted for the winner in every presidential election from admission through 1972.

Education. A public school system was established in 1891, and, since statehood, educational improvement has been phenomenal. In 1968 the educational attainment of the Anglo adult population averaged 12.1 years—compared however, to only 8.1 for Spanish-Americans. Per-pupil expenditure in 1970 was more than $600 and average teaching salaries nearly $7,800. Most of the improvement in education has been in the urban centres, however, and many rural and small-town schools remain substandard. As Hispanos are dominant in these areas, this has meant a poorer education for their children. Legalized segregation for the Hispano minorities on the East side ended in the 1950s, but *de facto* segregation, primarily on the elementary level, remains.

Colleges and universities

Higher education is led by the University of New Mexico, in Albuquerque, established in 1888. Other state-supported institutions include New Mexico State University (1889), in University Park; Eastern New Mexico University (1934), in Portales; New Mexico Highlands University (1893), in Las Vegas; Western New Mexico University (1893), in Silver City; and New Mexico Institute of Mining and Technology (1889), in Socorro. Northern New Mexico State School at El Rito, originally established in 1909 to train Spanish-speaking teachers, is today a resident high school. In addition, the state universities have established branch campuses, while some cities have organized junior colleges. There are several private colleges as well.

Health and welfare. Other state institutions include a penitentiary, a hospital and training school, an industrial school for boys, a girl's welfare home, the Carrie Tingley Crippled Children's Hospital (1937), a school for the visually handicapped, a school for the deaf, and a miner's hospital. The state Department of Health, created in 1919, administers an extensive social-service program, often in collaboration with federal agencies. Medical services in rural areas are rarely adequate. State expenditures for health were $5.52 per capita in 1969.

Intergroup relations. The greatest single problem that New Mexico faces is the cultural clash between Spanish-Americans, once dominant in the state, and the now-dominant Anglo. Distrust and sometimes hostility, prejudice, and discrimination exist between the two groups. Efforts in 1967 of an Hispanic group, the Alianza de los Pueblos Libres (Alliance of Free City-States), to regain lost land was a result of the frustration growing out of their declining social, educational, and economic status, for which demands for land grants became a symbol. The Hispano has equality before the law, but in all practical matters he is a second-class citizen in his homeland. His income averages little more than half that of the Anglo, his education is much less, and he is under-represented in the professions. The percentage of Spanish-Americans living in substandard housing is not only above that of the Anglo but is also above that of the few blacks in the state. Desertion of the native villages for urban centres creates problems of social and economic adjustment that will take years to resolve.

Status of Spanish-Americans

CULTURAL LIFE AND INSTITUTIONS

The arts. Writers and architects have been influenced by New Mexico's Indian and Spanish heritages and the Anglo impact upon the two. The appearance of the cowboy and the miner and the conflicts of the frontier territory in the 19th century also have been dominant cultural themes. Painters have been concerned especially with the unique landscape, since no other area of the United States presents such a variety of scenery or so many modes of life side by side. Attracting artists in all fields from many parts of the nation and of the world, Taos was the first to have an important art community, but it is now rivalled by Santa Fe and Albuquerque. The state institutions of higher education, through their libraries and their departments of art, music, dance, and theatre, have played a key role in the dissemination of cultural knowledge. This has been accomplished directly and through the training of public-school teachers. The success of the Santa Fe Opera Association, organized in 1956, reflects the growth of musical appreciation. Performing in an outdoor theatre in the Sangre de Cristo Mountains near the city, the company has presented a repertory that has won it worldwide acclaim.

The historical atmosphere of New Mexico and its fusion of three cultures is represented by its unique architecture. Indian pueblo buildings were modified by the Spanish when they built Santa Fe and many of these original structures have been restored. The statehouse, most public buildings, and many private ones have recently been constructed in the modified Spanish mission style.

Folk culture. Local Indians produce pottery of high quality and authentic beauty. Each village has its own design to identify the work of its people. Navaho blankets are famous the world over. Today, many Indians make buttons, beads, pins, rings, necklaces, earrings, and belts, mainly for sale to the growing number of tourists. The United States Indian Arts and Crafts Board has attempted to preserve the authenticity of Indian jewelry by establishing standards in handworked silver. Individual pueblos preserve native dances by performing at numerous fiestas, the most important being the Inter-Tribal Ceremonial, which draws thousands of visitors to Gallup every summer.

Indian arts

Spanish folk art has been preserved largely by the Penitentes, a religious group within the Roman Catholic Church. In rural areas, medieval Spanish music and art have been preserved against modern influences.

Museums. The Museum of New Mexico, housed in the Palace of the Governors in Santa Fe, helps preserve archaeological sites, mementos, and folk arts of the past, as well as the state archives. The Museum of Navaho Ceremonial Art is in Santa Fe, and in Taos is the Kit Carson Home and Museum.

Communications. In 1971, New Mexico had 19 daily newspapers, 70 radio stations, and seven commercial and

educational television stations. The *New Mexico Historical Review*, a quarterly established in 1926, publishes scholarly articles on the state's history, while the University of New Mexico Press publishes books in many fields related to the Southwest.

Prospects. New Mexico's major problems lie, first, in its intergroup relations and, second, in its slight and uncertain economic base. Certain unique advantages are available, however, to meet these problems. The scientific talent at Los Alamos and elsewhere in the state could play a vital role in expanding peacetime uses of nuclear energy. The state's natural beauty and climate can be utilized better to expand the already important tourist industry. The success in luring movie producers to take advantage of the unequalled landscape and the ability of cities like Roswell to bring in new industries to offset the loss of federal installations suggest that existing economic problems can be solved. The social problem can be eased greatly by providing more economic and educational opportunity for the Hispano and Indian minorities, but this must be done in an atmosphere of trust and goodwill on all sides.

SMITH, *New Mexico Indians* (1966), an analysis of the economic, educational, and social problems of the state's Indians, with a summary by tribes.

(W.A.B.)

New Orleans

Unquestionably one of the most distinctive cities of the New World, New Orleans was established at great cost in an environment of conflict. Its strategic position, commanding the mouth of the great Mississippi–Missouri river system, which drains the rich interior of North America, made it a pawn in the struggles of Europeans for the control of North America. As a result, its peoples evolved a unique culture and society, blending many heritages. Its citizens of African descent—who have represented from a fourth to a half of the population of the city since its inception—have provided a special contribution in making New Orleans the birthplace of Dixieland jazz. New Orleans is a city of paradox and contrast: while it shares the urban problems afflicting other North American cities, it has nevertheless preserved the exuberant and uninhibited spirit exemplified by its carnival season, culminating in the annual Mardi Gras, when more than 1,000,000 persons throng the streets. The city also has a solid economic base: it is the largest city in Louisiana, the second port of the United States in value of foreign commerce, a major tourist resort, and a medical, industrial, and educational centre.

Historical and cultural heritage

The city and Orleans Parish (county) are coextensive, covering an area of almost exactly 200 square miles (518 square kilometres). The boundaries are formed by the Mississippi River and Jefferson Parish to the west and Lake Pontchartrain to the north. The latter is connected by the Rigolets Channel to Lake Borgne on the east, and the southern boundary is made up of St. Bernard Parish and, again, the Mississippi River. The city is divided by the Mississippi, with the principal settlement on the east bank. The west bank, known as Algiers, has grown rapidly in recent years. It is connected to eastern New Orleans by the Greater New Orleans Bridge. The bridge, completed in 1958, has proved to be an increasingly painful bottleneck to the city's traffic.

The early city was located on the east bank along a sharp bend in the river, from which its popular name "Crescent City" is derived. The modern metropolis has spread far beyond this original location. Because its saucer-shaped terrain lies as low as five feet below sea level and experiences an average rainfall of 57.45 inches, a levee, or embankment, system and proper drainage have always been of prime importance to the city. New Orleans has a moderate climate, the average daily temperature from October through March being 60° F (16° C) and from April through September, 77° F (25° C). Freezing weather is rare, and the temperature goes above 95° F (35° C) only about six days a year. (For further information see LOUISIANA; UNITED STATES, HISTORY OF THE; and MISSISSIPPI RIVER).

THE GROWTH OF THE METROPOLIS

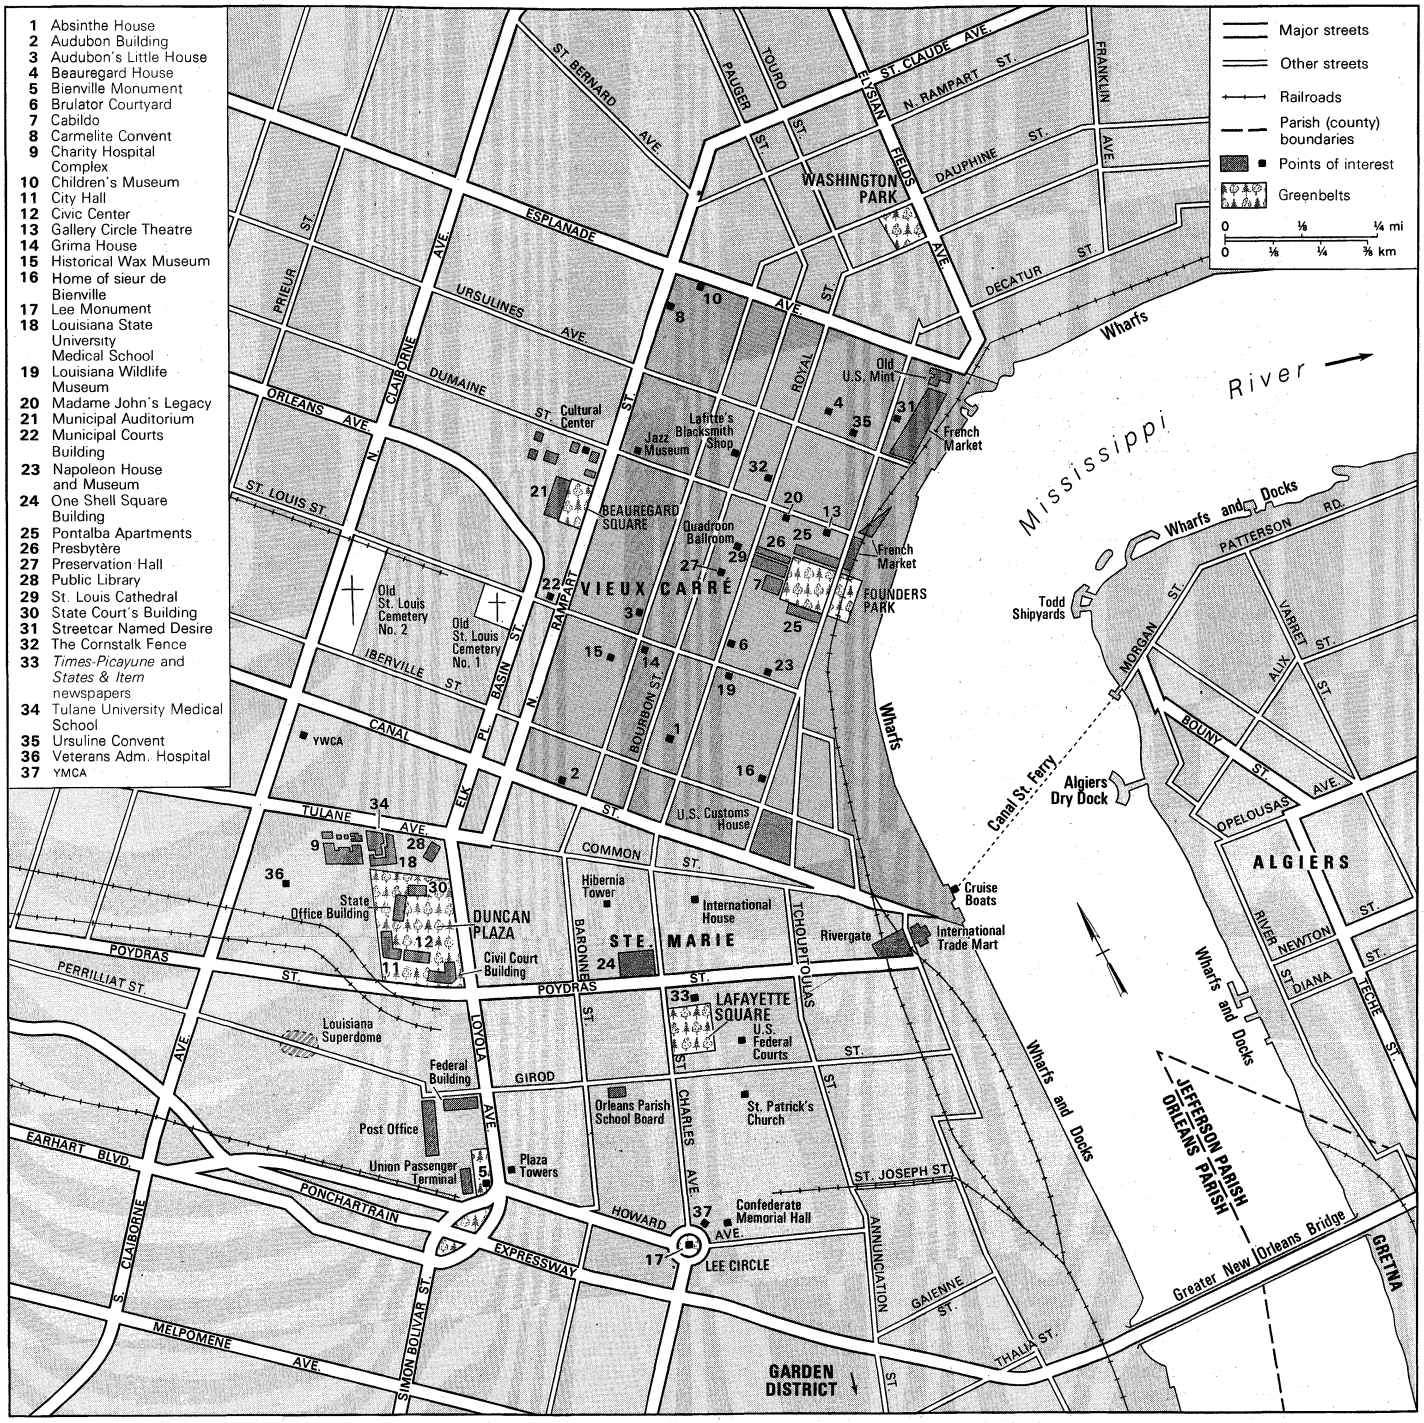
Foundation and early settlement. The decision to found New Orleans was made in Paris in 1717 by John Law's Company of the West, which had taken control of Louisiana that year. The colony's new proprietors envisioned New Orleans (named for the French regent, the Duc d'Orléans) as a "port of deposit," or transshipment centre, for future trade from upriver in the Mississippi Valley. Jean-Baptiste le Moyne, sieur de Bienville, the man who suggested the site, was entrusted with the actual foundation of the city. Clearing of underbrush for the new city probably began in March 1718. The engineers charged with this task met with problems arising from uncooperative convict labour, a shortage of supplies, two severe hurricanes (in 1721 and 1722), and the unpleasant physical conditions of swamps and mosquitoes as they set up the first crude dwellings covered with bark and reeds. An engineer, Adrien de Pauger, drafted the first plan for the town, encompassing the section known today as the Vieux Carré and consisting of 66 squares forming a parallelogram.

Hostility of the environment

The first residents were a colourful mixture of Canadian backwoodsmen, company craftsmen and troops, convicts, slaves, women of uncertain virtue, and indigents. In a census taken in November 1721, New Orleans had a population of 470 persons: 277 whites and 172 Negro and 21 Indian slaves. In 1722 New Orleans was designated the capital of Louisiana, and in 1731 the city returned to the control of the French crown. More respectable colonists began to arrive, but growth continued to be precarious. The main economic staples grown in the vicinity of New Orleans were tobacco and indigo for export and rice and vegetables for local consumption. Naval stores was also an export. French ships were, however, reluctant to call at New Orleans to pick up such cargo: its value did not match its bulk.

In 1762 France, ready to part with its unprofitable port, secretly agreed to cede Louisiana to Spain, and by the Treaty of Paris (1763) Spain received New Orleans and the Louisiana Territory west of the Mississippi. After a brief rebellion—which was sternly suppressed—the inhabitants of New Orleans enjoyed peace and a growing prosperity under Spanish law, while trade arose with the British colonies in spite of Spanish restrictions. At the same time English-speaking colonists were moving west to settle along the tributaries of the Mississippi. In the decade of the American Revolution, these "Kaintucks," as they were called, began floating their cargoes downriver to New Orleans: several times Spanish officials suspended the right of deposit of American goods at New Orleans in response to the boisterous conduct of American frontiersmen along the city's upper levee.

In 1800 Louisiana was secretly returned to Napoleon's



Central New Orleans.

France, and by 1803 the French emperor had negotiated for its sale to the United States. The ceremonies transferring Louisiana to France and later to the United States took place in New Orleans' Cabildo and main square, the Place d'Armes (now Jackson Square) in the winter of 1803.

The Louisiana Purchase

The early 19th century. New Orleans' population in 1803 was aproximately 8,000—4,000 whites and 2,700 enslaved and about 1,300 free "persons of colour." Its prosperity was reflected in its 1803 exports, which had a value approaching $2,000,000, and were bound mainly for American ports. In 1805, when it was incorporated as a municipality, New Orleans took on an identity separate from that of Louisiana's territorial government. As the city expanded out of its original limits, one of the first new tracts of land to be added was the Faubourg Ste. Marie, a suburb lying on the uptown side of the Vieux Carré and separated from it by a broad "commons" (today Canal Street, New Orleans' main street). It became the "American section" in the early 19th century and the hub of most business activities. Other *faubourgs* (lit., outskirts, or suburbs) were laid out above and below the two nuclear settlements and across the river and were finally absorbed into the city by the 1870s.

During the War of 1812, New Orleans was threatened by a British invasion force, which approached the city from the Gulf of Mexico. Gen. Andrew Jackson, with his army of frontiersmen and local volunteers, won a smashing victory on January 8, 1815, saving the city, though, unknown to him, the war already had been concluded.

The era of cotton

The next 40 years constituted the golden age of New Orleans as a great cotton port. The first steamboat to reach the city, in 1812, was appropriately called the "New Orleans." Mississippi River steamboats increased to 400

by 1840, and local commerce skyrocketed in value, reaching $54,000,000 by 1835. By 1840 the city was rated the fourth port in the world: after the 1840s canals and railroads diverted produce eastward to New York City.

German and Irish immigrants arrived in New Orleans in large numbers in the 1840s. By 1850 the city's total population had swelled to 116,375. New Orleans, however, had not learned to cope with the health hazards of its mushrooming growth; drinking water came from the river or cisterns; no sewerage system existed; drainage was deficient; and flooding was common after heavy rains. The results were sporadic outbreaks of cholera and yellow fever, the worst of which was the yellow fever epidemic of 1853, accounting for more than 8,000 deaths.

The Civil War and its aftermath. During the Civil War, the strategic location of the city was inadequately appreciated by the Confederate military. The Union fleet of Admiral David Farragut was able to capture New Orleans in April 1862. The city was placed under the military command of Gen. Benjamin Butler, and city officials were removed from office. Although Butler was replaced as commander by Nathaniel Banks by the end of 1862, his brief régime became infamous in local history for his roughshod handling of the population.

During the period of Reconstruction, 1865–77, racial tensions ran high. "Scalawags" (white Southerners who cooperated with Republican forces) and "carpetbaggers" (Northerners accused of exploiting the situation for personal gain) cooperated to gain political control of the city and state, with the support of black voters. By 1872 amnesty had been granted to the ex-Confederates, and the municipal government returned to traditional white control, although state government, and the city police force, remained under Radical Republican control until 1877. In the 1880s the debt of $24,000,000, incurred under carpetbag régimes, increased steadily with each subsequent administration. This municipal debt had to be paid before the city could undertake any new bond issues for sorely needed municipal improvements.

In the last 20 years of the 19th century, therefore, New Orleans made limited, though steady, progress. Between 1840 and 1900, it had dropped from third to 12th place in national rank, although its population had increased to 287,104.

Yellow fever was sharply curtailed after the Civil War through fumigation of ships at a quarantine station on the lower Mississippi and was finally eradicated by 1906. By the early 20th century, the river steamboats, unable to compete with railroads in bulk carried or in rates, disappeared; the Port of New Orleans, attracting less railroad freight than Eastern ports, reached a low ebb shortly before World War I. With the development of towboats and barges large enough to hold almost an entire trainload of cargo, however, cheap river transportation revived the river commerce, and the port again surged forward, becoming the second port in the nation after World War II. Substantial progress, at least in physical improvements, came to the city in the 1950s. During the administration of Mayor DeLesseps S. Morrison, a vast railroad consolidation program was achieved, and a $15,000,000 railroad terminal constructed. Streets were widened, railroad ground crossings were spanned with overpasses, and a $20,000,000 civic center built, which includes the 11-story City Hall.

20th-century growth

THE CONTEMPORARY CITY

The people. New Orleans' population in 1970 was almost 600,000, a 5.4 percent decline from 1960. Of this figure, 323,000 were white; 267,000, black; and 2,700 persons of other races. Whites accounted for scarcely more than half of the total, whereas in 1960 they had made up almost two-thirds. In contrast to the population decline in Orleans Parish, the adjacent parishes—which, together with Orleans, compose one of the national Standard Metropolitan Statistical Areas—showed big increases. The parishes of Jefferson, St. Bernard, and St. Tammany—the latter across Lake Pontchartrain from New Orleans—all showed an increase of around 60 percent. Since the black population in these three parishes is quite small, these figures indicate a white move to the suburbs, a trend common to major United States cities. The total population of the four parishes in the Greater New Orleans Standard Metropolitan Statistical Area was just over 1,000,000.

The shift in population to the suburbs was less motivated by racial tension (although this may play a part) than by desires for better and more modern living facilities. The fact that a large segment of the black population resides in declining neighbourhoods (some segregated, some integrated) has spurred both black and integrated political, social, and religious organizations to work either independently or with city and federal agencies in projects to improve the quality of life for lower-income citizens. The additional fact that New Orleans has an upper-class and a middle-class black population has been a significant factor in such projects.

The city's economy. *The port and its facilities.* New Orleans has always been primarily a commercial centre, with manufacturing playing a secondary role in its economic life. The busy harbour, besides adding to the city's cosmopolitan atmosphere, is the foundation of the metropolitan economy, influencing many aspects of urban life.

The era of the modern Port of New Orleans began in 1879 with the construction of jetties in South Pass, one of three passes that flow from the river into the Gulf. Sandbars had formed at intervals in these passes and had hindered ships entering the river since the city's founding. The jetties narrowed South Pass, forcing the river to cut a deeper channel to a depth of 30 feet. Later, a second channel, Southwest Pass, was deepened to 40 feet by installing jetties; it is now the main pass used by seagoing vessels entering and leaving the river. The distance from New Orleans to the Gulf is about 110 miles.

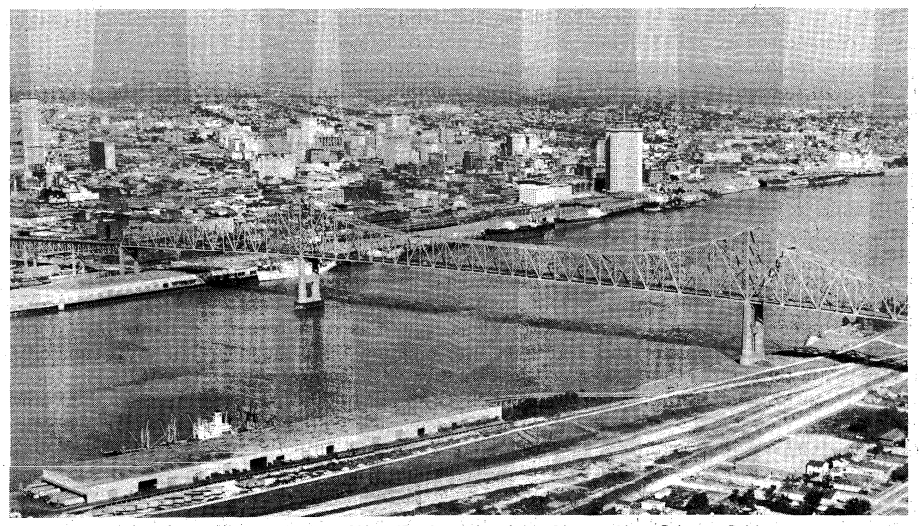
Another major step forward for the port was taken in 1896, when the state legislature removed wharf facilities from the control of private contractors and created the Board of Commissioners of the Port of New Orleans (the Dock Board), a body charged with administering the public wharves. In 1908 the Dock Board was authorized to issue negotiable bonds for the improvement of port facilities. The projects subsequently accomplished included the rebuilding and expansion of public wharves and the construction (in partnership with the Board of Levee Commissioners of the Orleans Levee District) of the five-and-a-half mile Industrial Canal, which links the river to Lake Pontchartrain, the Intracoastal Waterway, and the Mississippi River–Gulf Outlet. In 1963 the Mississippi River–Gulf Outlet, a ship channel shortening the passage to the Gulf by 40 miles, was opened to maritime traffic. Tonnage handled at this terminal grew at an average rate of 80 percent annually.

Legislative control of the port

The Dock Board has formulated a 30-year plan (1970-2000) called Centroport U.S.A. by which much of the port's activities will be switched from the Mississippi River to wharves and industrial complexes along the Gulf Outlet. The river frontage thus retired from maritime use will be diverted to such projects as high-rise apartments and public recreation areas.

New Orleans is a major grain port both in the United States and worldwide; other exports include raw and processed agricultural products, fabricated metals, chemicals, textiles, oils, petroleum and petroleum products, tobacco, and paper board. New Orleans' imports and exports have a high value, about twice the national average, which helps to account for its national ranking.

Manufacturing. The greater New Orleans' four-parish Standard Metropolitan Statistical Area is one of the fastest growing industrial areas in the nation. A concentration of petrochemical plants, representing a capital investment of about $1,000,000,000, has sprung up along the Mississippi River above New Orleans. The National Aeronautics and Space Administration established the Michoud Assembly Facility in New Orleans in 1961 to produce the giant Saturn rocket boosters used in flights to the moon. The major goods manufactured in the greater New Orleans area are food products, clothing and related items, stone, clay and glass articles, primary metal and fabricated metal items, and transportation equipment.



New Orleans from across the Mississippi River. To the right of the Greater New Orleans Bridge is the International Trade Mart.
Charles E. Rotkin—P.F.I.

In recent years, petrochemical industries along the Mississippi above New Orleans and offshore oil rigs in the Gulf have become serious polluters through oil-rig fires and oil slicks and discharges of mercury, arsenic, and lead, threatening the city's drinking water, ruining the taste of river fish, and endangering the ecology of the Gulf. Despite federal actions against the offending industries, much remains to be done.

Transportation. The transportation facilities of New Orleans include three airports. The New Orleans International Airport accounts for well over 300 commercial-flight arrivals and departures daily. The New Orleans Airport on the lakefront is devoted to private and corporate plane use, while the U.S. Naval Air Station serves air reserve units of the various armed services. The centre of railroad activity is the Union Passenger Terminal—eight railroads operate out of New Orleans with direct connections to cities in 28 states. Two passenger bus lines also use the Union Passenger Terminal, whereas more than 60 truck lines and barge lines operate to and from the city. Regular express sailings by more than 100 scheduled steamship lines also offer passenger- and cargo-carrying service. The major access bridges serving the Greater New Orleans area, in addition to the Greater New Orleans Bridge, are the Huey P. Long Bridge, which crosses the river above the city, and the Pontchartrain Causeway, a twin span that is the world's longest bridge, stretching over 23 miles.

Politics and government. *The political framework.* Both the political life and the municipal government of 20th-century New Orleans have been dominated by factions of the Democratic Party. The question of state interference in city affairs versus home rule is one of the major issues. In 1954, New Orleans finally received a strong home rule charter, which substituted a mayor-council form of government for the mayor-commission form that had existed since 1912.

Municipal management

In addition to the mayor and seven councilmen—five elected from districts and two at large—who serve four-year terms, the position of chief administrative officer to the mayor was created. The mayor is the top administrator over the 13 municipal departments and oversees the affairs of various commissions and boards. A chief administrative officer is charged with supervision of city departments, the preparation of the annual budgets, and the coordination of city relations with state and federal agencies. The seven councilmen are strictly a legislative body.

Political issues have changed. Gone is the antagonism between city and state governments that spanned the eras from governors Huey Long in the 1920s, through Earl Long in the 1940s. Political corruption is no longer an issue in city politics, and segregation also has deteriorated as a defensible position for whites to espouse. (The local White Citizens Council, which was strong in the 1950s, has all but disappeared.) On the other hand, blacks have become more politically articulate. Several black political organizations participate actively in local and state political campaigns.

Although most city and parish government has been consolidated in New Orleans, Orleans Parish officials continue to play an important role. These officials include the district attorney, the board of assessors, and the Orleans Parish School Board, who supervise public education under the state department of education.

Municipal services. In the 1960s, expansion of new residential areas in New Orleans, combined with the spiralling cost of services, caused the operating budget for municipal services almost to double. New Orleans government entered the early 1970s suffering from a grave lack of the funds necessary to carry out its work effectively and to provide an appropriate income for the employees of its various departments. One of the major problems is the low assessment of taxes on both residential and industrial property and the loss of taxpayers to the suburban parishes.

Drainage has always been the number-one problem among municipal services. Virtually surrounded by levees—25 feet high on the Mississippi River and 10 feet high on Lake Pontchartrain—the below-sea-level city has 14 major drainage pumping stations, with the average capacity of a single station being 2,500 cubic feet per second. The drainage machinery used at these stations is among the largest found in the world. Following the disaster of 1965, when Hurricane Betsy flooded the city's lower Ninth Ward, the Sewerage and Water Board operating the pumping stations drafted a plan to make these facilities hurricane safe. Further improvements in drainage canals and pumping equipment are planned in the older section of the city for completion by 1980.

Drainage and flood-control systems

Flood control along 129 miles of the river, Lake Pontchartrain, and secondary waterways in the city is under the direction of the Board of Levee Commissioners of the Orleans Levee District. In addition to its primary job of flood control, the board has, since the 1920s, reclaimed some 2,000 acres of Lake Pontchartrain bottom land and developed it into one of the most scenic lakefront areas in the United States. Approximately 60 percent of the land is dedicated to public facilities, which include an amusement park, sandy beaches, a marina, a cement seawall from which fishing and swimming can be enjoyed, picnic grounds, parkways with flower beds, fountains, and shelter houses. The remaining 40 percent of this reclaimed land has been turned into four residential subdivisions, which are among the finest in the city.

Police and crime

In the fight against the steadily rising crime rate in the city, the police department has, since 1961, introduced a guard-dog corps, reorganized its patrol system to increase

its effectiveness by 60 percent, created two new police districts, built new stations in older districts, more than doubled its automotive equipment, established a community relations division, and put into operation a communication van, which acts as a field command post in time of emergency.

In spite of the increase in the proportion of the black population and a high arrest rate for black youth, racial violence has been less troublesome in New Orleans than in many other cities. A racial confrontation with police occurred in 1970 when Black Panthers took over an unoccupied apartment in the densely populated black Desire housing project. Since 1970 the Urban Squad, about evenly divided between volunteer black and white policemen, has been markedly successful in securing the trust of Desire residents, and with the help also of a community centre and swimming pool, crime in the area has decreased significantly.

The social milieu. *Health.* New Orleans has become a medical and educational centre in the 20th century. Its 19-story Charity Hospital of Louisiana, with over 2,477 beds, is the teaching hospital for two adjacent institutions, the Tulane and the Louisiana State University medical schools, with which the nearby Veterans Administration Hospital is also affiliated. There are 21 hospitals within the metropolitan area containing a total bed capacity of more than 6,300. In addition to serving local residents of this area, specialists frequently treat patients from Latin America.

Education. New Orleans has nine institutions of higher learning: The Tulane University of Louisiana and its affiliate, The H. Sophie Newcomb Memorial College for Women; Loyola University; Louisiana State University in New Orleans; St. Mary's Dominican College; three primarily black schools, Dillard University, Xavier University of Louisiana, and Southern University in New Orleans; and a trade school, Delgado College. The city also has many private, parochial, and business schools. The public school system, which began in 1841 with 83 pupils and four teachers, had by the 1970s an enrollment in excess of 100,000 and some 4,500 teachers. In 1960 a public school crisis, attracting international attention, developed when an attempt was made at the token integration of two white schools. Despite this, within ten years the school system was substantially integrated at both student and teacher levels.

Racial relations. By 1970 the population of New Orleans was 45 percent black. Relations between the races, though certainly not ideal, proved less turbulent than in many other cities. Historically, racial segregation in New Orleans differed from that of other Southern cities; for example, free persons of colour always were an important minority in antebellum days. Mixed neighbourhoods, or scattered groups of blacks living near whites, have been the rule rather than the exception in housing. School integration has presented problems, particularly in the early 1960s, but these are gradually being solved. The city has an interracial Human Relations Committee, whose members work with the mayor. By the early 1970s two black judges were serving in local courts, one of whom was the first black man to be elected to the state legislature since Reconstruction. Other black Orleanians have served in administrative posts in city government.

Cultural life and institutions. The cultural life of New Orleans is a synthesis of contributions by both whites and blacks. The white American heritage is reflected in the public school system and the business and commercial life of the city, while the immigrant heritage—Irish societies, German Volkfests, Italian St. Joseph Day altars, and the like—added ethnic colour to urban conformity. The black heritage is particularly rich. In antebellum days, free persons of colour were musicians, poets, journalists, business entrepreneurs, and landlords. Both black freemen and slaves were famed for their craftsmanship in such trades as bricklaying, iron grillwork, and carpentry. The contribution of black musicians to the birth of jazz out of black blues and "field hollers" and white dance tunes and hymns is well known. New Orleans, therefore, is one American city in which the black as well as the white cultural contribution is abundantly clear and acknowledged.

Facilities for recreation and relaxation in New Orleans are justly famous. Often referred to as "the city that care forgot," New Orleans has always been a town for those seeking a good time. Its residents love music, dancing, and a "Continental Sunday" spent in amusements. The three factors that have contributed to its popularity with tourists are the Old World charm of the Spanish-French architecture in its Vieux Carré, the gay abandon of its carnival and Mardi Gras, and its reputation as the birthplace, between the 1880s and World War I, of Dixieland jazz.

The Vieux Carré: Creole architecture and ironwork

The Vieux Carré is a sightseer's delight. Its Creole architecture, creating the atmosphere of a foreign city, combines native architectural ingenuity with adaptations of French colonial traditions of eastern Canada and West Indian Spanish colonial styles. Typical are one-story cottages opening directly on the sidewalks, with high-pitched roofs and windows reaching to the ground. Another style is the L-shaped two-story dwelling with a side entrance to an inner patio. Also built to the sidewalk, it has a roof that extends out over balconies on both the street and patio sides. Iron grillwork, designs for which were created locally and executed to a high perfection by slave craftsmen, decorates these balconies and also supports the roof. Such houses are built side by side with no openings between them, but the patios offer space for trees, flowers, and fountains and ensure privacy for the occupants.

Central to the Vieux Carré is Jackson Square, facing which are the Cabildo and Presbytère (former governmental centres, but now state museums) and St. Louis Cathedral. All date from colonial times, but considerable stylistic changes have been made on these buildings since they were erected.

On either side of this square are the Pontalba Apartments, built between 1849 and 1851, while nearby is the historic French Market. Curio and antique collectors throng the many shops on Royal Street. Side streets are lined with art galleries, perfume shops, sidewalk cafés, and tearooms. Bourbon Street is famous for its nightclubs, where jazz and risqué floor shows are a specialty. Devotees of jazz may also visit Preservation Hall and Dixieland Hall, where revivals of traditional styles may be heard. The New Orleans Jazz Club has established a Jazz Museum, which is open to the public; and each spring the city puts on an International Jazz and Heritage Festival.

Every April the New Orleans Spring Fiesta Association sponsors walking tours of private homes and patios in the Vieux Carré and also of the spacious Garden District uptown, the elite 19th-century neighbourhood. Boats tour the extensive harbour facilities and the magnificent scenery of nearby waterways. The observation point atop the International Trade Mart (400 feet, or 122 metres) at the foot of Canal Street offers a panoramic view of the river and city. Adjacent to this commercial centre is The Rivergate, a mammoth exhibition hall. The world renowned Creole cuisine may be sampled in numerous restaurants, ranging from elegant dining rooms with French menus and waiters, to small cafés with checkered tablecloths, serving red beans and rice.

The sporting life and the lively arts

Sports share an honoured position with jazz and carnival activities in New Orleans. The city is the home of the New Orleans Saints, a member of the National Football League, and a dome stadium, to be known as the Superdome, is scheduled for completion in the 1970s. Located near the Civic Center, it will be one of the world's largest sports arenas. Crowds up to 82,000 may be seated in this structure. Racing has a 100-day season at the local Fair Grounds Race Track, while golf, a popular pastime, attracts top golfers every year to the $100,000 Greater New Orleans Open Golf Tournament held at Lakewood Country Club. Boating, fishing, and swimming are popular pastimes on the city's many waterways. The city's Southern Yacht Club, on Lake Pontchartrain, is the second oldest in the country. In addition to the lakefront, popular recreation areas include the city's two largest parks,

Audubon and City. The New Orleans Recreation Department operates more then 100 playgrounds and directs organized recreation activities for thousands of youngsters. At the end of each year the Mid-Winter Sports Carnival is held in the city, featuring amateur competition in all major sports. It concludes on New Year's Day with the Sugar Bowl football contest between outstanding college teams.

Since World War II, New Orleans has become an art centre, with many artists and art galleries offering original works to collectors. The New Orleans Museum of Art is a public museum displaying many art treasures. Live theatre is represented by several "little theatre" groups. Musical events include eight operas staged annually by the New Orleans Opera House Association, the 16 concerts a year given by the New Orleans Philharmonic-Symphony Society, a summer pops concert series, and concerts presented by the New Orleans Jazz Club and the New Orleans Recreation Department.

Mardi Gras

The New Orleans carnival season, one of the events lending character to the contemporary city, begins after Christmas with local carnival organizations holding balls almost every night until Mardi Gras, the "Fat Tuesday" before Ash Wednesday. The two weeks before Mardi Gras are filled with parades, both day and night, climaxing on Mardi Gras with the Rex parade. The first parading carnival group (called a "krewe") was the "Mystick Krewe of Comus," which appeared in 1857, though celebrations by masked students go back to 1827. The krewe of Rex came into existence in 1872. Krewes, parades and carnival crowds have been growing ever since.

In the latter half of the 19th century, there were about a half dozen leading newspapers including one in French. Today, through a process of gradual consolidation, New Orleans has two major daily newspapers: The *Times-Picayune* (morning) and the *New Orleans States-Item* (afternoon). Though both are owned by the same company, keeping competition minimal, they maintain high standards of journalism. Competitive journalism is kept alive among the city's five television stations, four of which are commercial and one educational. In addition, there are 15 local radio stations.

Problems and prospects. The major problem facing New Orleans is its lack of financial resources to maintain many vital city services, a situation directly linked to the faulty tax base heavily dependent upon traditionally low property assessments, and the move to neighbouring parishes of prospective taxpayers. In addition to the possibility of revisions in the total taxation structure, a further hope for the future is the development of tracts of untouched land within the city limits for new suburban-like neighbourhoods and the urban renewal of old neighbourhoods. The crime rate appears to be levelling off, but drug addiction, associated with such crimes as shoplifting, pickpocketing, and robbery, has increased and become a problem among high school students. The efforts of police, school officials, and drug clinics toward prevention and rehabilitation, however, are showing favourable results.

Racial tension is a problem that a city almost equally divided must live with for years to come. Aside from violence associated with black militants in 1970, the high crime rate among lower-income black youth that grows out of their slum environment, and some minor racial altercations in high schools, the two races coexist fairly amiably in New Orleans. With the continuing rise in black population and the broader opportunities opening up for blacks in education and professions, blacks are destined to play a much more prominent part in the future economic and political life of the city than ever before.

Tourism, one of New Orleans' major industries, faces two challenges for the future: it must regulate Mardi Gras more rigidly to ensure a safer and more pleasant holiday for tourists, and it must provide more entertainment for its youth. Already a mecca of sophisticated adult entertainment, the "Crescent City" hopes to add more child-oriented entertainment such as children's museums, amusement parks, and a modern zoo.

RIGHTOR (ed.), *Standard History of New Orleans, Louisiana* (1900); and G.E. KING, *New Orleans: The Place and the People* (1895, reprinted 1928). Popular general histories that include surveys of the modern city are O.W. EVANS, *New Orleans* (1959); and H. SINCLAIR, *The Port of New Orleans* (1942). A topical history that includes modern data is H. CARTER (ed.), *The Past As Prelude: New Orleans, 1718–1968* (1968). Detailed period studies are J.G. CLARK, *New Orleans, 1718–1812: An Economic History* (1970); R.C. REINDERS, *End of an Era: New Orleans, 1850–1860* (1964); G.M. CAPERS, *Occupied City: New Orleans Under the Federals, 1862–1865* (1965); and J.J. JACKSON, *New Orleans in the Gilded Age: 1880–1896* (1969). Port history and activity is discussed in R.W. BRADBURY, *The Water-Borne Commerce of New Orleans* (1937); A.I. WARRINGTON, *Economic Geography of New Orleans and the Middle South* (1952); *New Orleans Port Handbook and Manual: A Reference Book on a Major World Port* (1961); and the *Annual Report of the Board of Commissioners of the Port of New Orleans.* For politics and government, see L.V. HOWARD and R.S. FRIEDMAN, *Government in Metropolitan New Orleans* (1959); and M. INGER, *Politics and Reality in an American City: The New Orleans School Crisis of 1960* (1969). The best sources for detailed descriptions of historic places in the Vieux Carré are S.C. ARTHUR, *Old New Orleans* (1936) and *New Orleans City Guide* (1938). Detailed statistical information on city services is in the *Louisiana Almanac* (annual); the reports of the Mayor of New Orleans, of the Board of Levee Commissioners of the Orleans Levee District (1956), of the Sewerage and Water Board (1969), and in the *National Atlas of the United States of America* (1970). Population and manufacturing statistics are in the UNITED STATES DEPARTMENT OF COMMERCE, BUREAU OF THE CENSUS publications: *Louisiana General Population Characteristics* (1970); *Louisiana Final Population Counts* (1970), and *1967 Census of Manufactures, Louisiana* (1967).

(J.J.J.)

New South Wales

The first British colony in Australia, New South Wales is the oldest, richest, and most industrialized state of the Australian Commonwealth. Originally, the name New South Wales was applied to the entire east coast of Australia when the British explorer Capt. James Cook claimed the territory for the British crown in 1770. The separate colonies of Tasmania, South Australia, Victoria, and Queensland were proclaimed in the 19th century, and in 1911 and 1915 the Australian Capital Territory around Canberra and Jervis Bay was ceded to the commonwealth. New South Wales was thus gradually reduced to its present area of 309,433 square miles (801,428 square kilometres). It is bounded by the Pacific Ocean to the east, the states of Victoria to the south, South Australia to the west, and Queensland to the north. By no means the largest Australian state, it is the most populous, with over 4,500,000 inhabitants by the early 1970s. Its capital, Sydney, is the nation's largest city. Lord Howe Island, a dependency of New South Wales, is administered as part of the state.

New South Wales reflects the dynamism and the growth problems of a fast-developing country. It is Australia's focal point of commercial farming, industry, and cultural development. It is also plagued by an imbalance between its urban and rural populations and often chafes under the financial restrictions of the commonwealth government. (For a discussion of the capital city, see SYDNEY.)

THE LANDSCAPE

The Great Dividing Range

The natural environment. *Relief.* The dominant geographical feature is the Great Dividing Range which separates the narrow coastal strip from the great plains to the west. The coastal strip varies from 10 to 50 miles in width and is bounded along its entire length by a natural barrier of steep mountains. Beyond this barrier, however, the Great Dividing Range consists not of true mountains but of a series of high plateaus, or Tablelands, which slope gently to the west until they merge imperceptibly into the plains beyond. The average height of these Tablelands is about 2,500 feet. In some areas they rise to 5,000 feet, and they attain a height of 7,328 feet (2,234 metres) at Mt. Kosciusko—the highest mountain in Aus-

tralia—in the Australian Alps in the south. The gentle western side of the Tablelands is known as the Western Slopes. The plains cover nearly two-thirds of the state. Lying below 1,000 feet, they are interrupted only by the elevated country between Orange and Cobar in the east and by the Main Barrier and Grey ranges in the west.

Drainage. The Great Dividing Range is the state's main watershed. Numerous rivers flow eastward from the range to the Pacific Ocean. Though often beautiful, they are too short and rapid to be of much economic value. The major rivers that flow west—the Namoi, the Macquarie, the Lachlan, and the Murrumbidgee—cross some 500 miles of sunburned plains before joining the Murray and Darling rivers. These brown, muddy, inland rivers meander across the plains and lose a great deal of their water by evaporation. Over 1,600 miles of the Darling River, which rises in Queensland, flow to the southwest across the plains to join the Murray. Rising in Victoria, the Murray runs for over 1,200 miles along the southern border of New South Wales before crossing South Australia to reach the Pacific Ocean.

Soils. A great deal of New South Wales is naturally fertile, and the red and black soil plains are extremely rich. The coastal strip, however, consists mostly of poor and sandy soils. Agricultural potential is severely limited by inadequate and uncertain rainfall and intense evaporation.

Climate. About 19 percent of the state receives less than ten inches of rain a year, and approximately 23 percent receives only ten to 15 inches. The coastal districts have the most annual rainfall, varying from about 30 inches in the south to about 75 inches in the north. Precipitation diminishes progressively away from the coast. The average annual rainfall in the northwest is only eight inches, and some of the land beyond the Darling River merges into desert.

Rainfall

If the dry climate and brilliant sunshine present severe agricultural problems, they are yet attractive to the inhabitants of the coastal cities. Newcastle, Sydney, and Wollongong have a delightful climate. It is rarely too hot in summer or too cold in winter, and Sydney is without sunshine for an average of only 23 days a year. Inland it is both hotter in summer and colder in winter. Average temperatures range from 74° to 83° F (24° to 29° C) in the summer months and from 49° to 54° F (7° to 13° C) in winter. Temperatures of over 100° F (38° C) are frequent in summer, and frost at night is common in winter. Heavy snow falls on the southern mountains and, more rarely, on the northern and central Tablelands. On Mt. Kosciusko snowdrifts linger throughout the summer.

The seasons are fairly well defined; autumn begins in March, winter in June, spring in September, and summer in December.

Vegetation. The natural vegetation ranges from the dense semitropical forest of the northern coast to the sparse plant life of the western plains. Nearly one-tenth of the state is forested, and, except for the plains, a much larger area is covered with bush and scrub. The forests, concentrated mainly on the coast and Tablelands, give way to shrub eucalyptus on the Western Slopes and to salt bush and spinifex (a spiny grass) in the far west. The predominant tree is the eucalyptus, which is the state's chief source of hardwood. Smaller quantities of softwoods, such as the red cedar, the hoop pine, and the rosewood, are found on the northern coast, while the cypress pine grows on the Western Slopes. Native grasses are found everywhere but in the extreme west, and there are many wild flowers.

Animal life. The rich birdlife includes many species of parrot and cockatoo, the flightless emu, and the mound-building scrub turkey and mallee bird. Most of the species of marsupials, mammals that do not develop a placenta and that carry their young in an external pouch, are represented. These include the wombat, the koala, the common and ring-tailed opossum, the common and long-nosed bandicoot, and a variety of kangaroos and wallabies. Many of the smaller marsupials, diminished by agriculture and forestry, are retreating into uninhabited regions. The platypus and spiny anteater are common.

Marsupials

Several species of poisonous snakes, including black, brown, and tiger snakes, are found throughout the state. The best known fish is the Murray cod, which is found in the western rivers and is an excellent food source. Trout have been introduced into the streams of the Great Dividing Range.

Traditional regions. There are four regions of traditional activity. The coastal strip is mostly used for dairy farming, the Tablelands for sheep and cattle raising, and the Western Slopes for wheat cultivation. The plains are the site of the great sheep stations, for over 100 years the basis of the state's economy. They still provide almost 40 percent of Australia's wool.

There are also four distinct political regions. The northern Tableland is known as New England. Its population, almost entirely rural, tends to resent the government's preoccupation with Sydney. There has long been an unsuccessful movement to form a new state. Similar feelings can be found in the Riverina district, located between the Murray and Murrumbidgee rivers. There, too, people tend to favour separatism; in practical matters, they look toward Melbourne, the capital of Victoria, rather than to Sydney. The Monaro sheep country comprises the windy, upland district of the southern Tableland, including what is now the Australian Capital Territory. The sheep graziers of the Western plains, living a remote and lonely life, feel a common loyalty born of common interests.

The landscape under human settlement. *Rural settlement.* Climatic conditions have also dictated the size of landholdings. The smallest are in the coastal strip, where dairy and fruit farming are the chief occupations. Holdings are considerably larger—between 500 and 5,000 acres—on the Tablelands and Western Slopes, where mixed farming is the normal practice. Further west they grow larger still; in the dry lands of the Western Division, many sheep stations cover over 100,000 acres. The exception to this general rule is in irrigated areas along the Murrumbidgee and other inland rivers, where diversified cultivation makes small holdings possible.

Landholdings

The tenure of landholdings in New South Wales is mostly either freehold or leasehold from the crown. Tenancy, as understood in Europe, is uncommon, and, except in the Western Division, most land is occupied by the owners.

Because of the large size of the average field, or paddock, and the relatively uncultivated appearance of the land, a typical sheep station presents a characteristic appearance. The heart of each property is the homestead, with its cluster of low buildings and well-watered trees and gardens, surrounded by bare, brown paddocks. There are no villages, and the nearest country town may be 30 or 40 miles away. In spite of the severe problems faced by sheep graziers because of the unstable price of wool and the constant threat of drought, life on the larger properties is still considered a pleasant and privileged one.

Urban settlement. The largest industrial urban area is the coastal complex of Newcastle, Sydney, and Wollongong. There are several towns of 30,000 or fewer inhabitants in the interior, such as Albury and Wagga Wagga in the southeast and Orange and Tamworth in the east central region. These are essentially country towns serving the surrounding rural population. The only interior industrial town is Broken Hill, in the far west, which depends upon the rich mineral deposits in the Barrier Range.

THE PEOPLE

Population groups. *Ethnic origins.* The people of New South Wales are in no way different from those of Australia as a whole. Nearly 80 percent are of British origin, and over 20 percent are of Irish descent. The small remainder is composed mainly of continental Europeans. There are also some 24,000 native tribesmen, or Aborigines, and a few thousand Chinese.

Religious groups. Almost the entire population professing a religion is Christian. The largest groups are Anglicans (Church of England), 42 percent, and Roman Catholics, 31 percent. Other groups are Presbyterians, Methodists, Greek Orthodox, and Baptists. Lutherans and Congregationalists each comprise less than 1 percent of the population.

Demography. The birthrate and deathrate and other vital statistics do not vary substantially from those of the rest of Australia. Since 1960, however, New South Wales has had a slightly lower birthrate than the other states, presumably because of the higher proportion of people living in cities. The birthrate in 1965 had fallen to 18.6 per 1,000 but has since risen slightly. Since 1947, immigration has accounted for over one-third of the total population increase.

The most striking feature of the population is the disparity between those living in the rural areas and those in the cities. Three-fourths of the state's 4,500,000 people are crowded into 2 percent of its area in Newcastle, Sydney, and Wollongong. This urban population increased by over 400,000 from 1966 to 1971, while that of the rest of the state declined by more than 126,000. The state government has long been concerned by this trend, and various schemes have been proposed to correct it. If it continues, by the end of the 20th century 82 percent of the population will be crammed into the central-coast industrial area.

THE ECONOMY

Economically the most important state in Australia, New South Wales contains about one-half of the country's sheep, one-quarter of its cattle, and one-third of its pigs. It produces a large share of the nation's grain, dairy products, and wool and mines most of its black coal and silver, lead, and zinc. It is also the country's most industrialized area and produces over two-fifths of the nation's manufactured goods.

The extent and distribution of resources. *Biological resources.* In 1970 there were about 70,000,000 sheep, 150,000 horses, and 5,500,000 cattle grazing on the state's vast grasslands. There were also about 500,000 pigs. The state forests provide an important natural resource of hardwood timber, although the percentage of forest land —12 percent—is low by international standards. The Pacific Ocean provides valuable fish.

Mineral resources. The most important mineral resource is the vast black-coal deposits of the central coastal region. The main silver, lead, and zinc deposits are located at Broken Hill. Large copper deposits have been discovered at Cobar. Other mineral resources include tin from the Ardlethan and Tallebong fields and rutile (a red or black mineral cut into gems), found in the coastal sands. By the early 1970s, no iron ore, nickel, uranium, oil, or natural gas had been discovered.

Power resources. Coal is the most developed power resource, while the Snowy River offers important hydroelectric potential.

Sources of income. *Agriculture, forestry, and fishing.* Agriculture is spread throughout the state. About half of the acreage under crops is devoted to wheat, which is grown for both domestic consumption and export. Other grains grown include oats, maize (corn), and rice; fodder, potatoes, grapes, sugarcane, and fruit are also raised. Excellent wine is produced in the Hunter Valley and cotton is grown on the Namoi River. Sheep are raised mainly for their wool, which is also exported. Both slaughter and dairy cattle are important.

Wheat and wool

New South Wales is the most important timber-producing state, accounting for about one-third of Australia's production. Hardwoods and softwoods are exploited, and there is a regular pine reforestation program.

Tuna fishing is the most important marine industry, and mullet, shark, and Australian salmon are also caught in significant numbers. The state provides about one-third of the national fish catch, as well as all of the oysters consumed domestically.

Mining and quarrying. The most important coalfields are in Hunter Valley above Newcastle, around Wollongong, and at Lithgow. Silver, lead, and zinc are mined at Broken Hill. Copper is mined chiefly near Cobar, and tin is mined in the central and northern Tablelands.

Industry. About two-thirds of the manufacturing industries are located in Sydney. Other important industrial centres are Newcastle, Wollongong, Lithgow, and Broken Hill. The fastest growing industry is the manufacture of iron and steel and metal goods. Other important products are textiles, food, beverages, tobacco, chemicals, paints, paper, and printed material. Factories are mainly small, and only a few employ over 1,000 persons. A very few large concerns, such as the Broken Hill Proprietary Company Ltd. (iron and steel) and the Australian Consolidated Industries Ltd. (glass), employ over half the industrial workers.

Power. Electricity is generated and distributed by the Electricity Commission of New South Wales. Power is sold to local authorities, the state railways and tramways, and large industrial users. Almost all the state's electricity is generated by thermal-power stations. The Snowy Mountains hydroelectric scheme, begun in 1949 and to be completed in 30 years, has diverted the waters of the Snowy and other rivers westward into the Murrumbidgee. After its completion, about 20 percent of the state's electricity will be generated by waterpower.

Finance. Since 1942 the commonwealth has collected all income taxes and reimbursed the states on an agreed formula. As a result, New South Wales is almost entirely dependent upon commonwealth grants for its revenue. In 1971 the states were given the right to levy a payroll tax, but it was not clear that this "growth tax" would be sufficient for their mounting needs.

Management of the economy. Like the rest of Australia, the state has essentially a capitalist economy, with the great majority of industry owned by public companies. The state government, however, owns and manages the railways, some coal mines, and the production of electricity. There is a vigorous trade-union movement. The Chamber of Manufacturers and other employers' organizations represent the interests of private enterprise.

Transportation. New South Wales has excellent internal air services. The state railways provide an adequate link between Sydney and larger population centres. They have suffered, however, from competition with air and road transport. Sydney has Australia's only underground rail network, and electric rail services connect the city with many of its suburbs.

Metro services in Sydney

Roads. There are 131,330 miles of public roads, including 22,410 miles of state highways and main roads. Most of these are paved, but many, including the main highways to Brisbane and Melbourne, are too narrow for the traffic they now bear. Most country roads are surprisingly good, though not all are yet paved.

Inland waterways. There are no commercial waterways, although before the railways were built the Murray and Darling rivers and their tributaries were used extensively for carrying freight.

Ports. The four major ports are Sydney, Newcastle, Port Kembla, and Botany Bay. Together they handle approximately 40,000,000 tons of cargo each year. All ports are administered by the Maritime Services Board of New South Wales.

Railways. The railways cover over 6,000 miles and centre upon Sydney. They also provide adequate facilities to the other major urban centres including Broken Hill, 700 miles to the southwest. The lines run from north to south along the coast and roughly from east to west in the Tablelands and plains.

Air services. Air services, largely for passenger traffic, are provided by a number of lines. Air links are operated to all the major towns, and the airport at Sydney can accommodate jet aircraft.

ADMINISTRATION AND SOCIAL CONDITIONS

Government. *Constitutional framework.* The state government administers internal matters, while the national government (commonwealth) is responsible for defense, foreign policy, immigration, trade, customs and excise, post and telegraph services, and air and sea transport. Within those limitations, the state is sovereign and has powers to make laws for the welfare and good government of New South Wales. It has no armed forces other than the police.

The Parliament consists of two houses—the lower house, or Legislative Assembly, of 94 members who are directly elected by the people, and the 60-member upper

Houses of Parliament

house, or Legislative Council, one-fourth of whose members are elected by both houses every three years. The Cabinet is chosen from the party that commands a majority in the Legislative Assembly; it is headed by a premier. Parliament meets for three years but can be dissolved earlier.

The state also has its own governor, who is appointed by the Queen on the recommendation of the government. The titular head of the government, he is now always an Australian, and his duties are almost entirely formal.

Local government. New South Wales is divided into more than 200 local-government areas, which are controlled by councils. These councils are elected every three years by adult residents of their areas.

Elections. All elections are by universal adult suffrage; the voting age is 18 years. Voting for the Legislative Assembly is compulsory, but voting for local councils is not.

Political parties. Political parties are usually state branches of the federal political parties and tend to have the same policies and interests. The three principal parties are the Liberal Party, the Country Party, and the Australian Labor Party. There is also a branch of the Australian Democratic Labor Party, without a seat in either house, and a small Communist Party, which still retains some influence in a few trade unions. Elections are fought on state issues, but the fortunes of the parties are often affected by the fortunes of the same parties in the commonwealth.

Justice. State law and its administration are largely based upon the British system. Legal procedure includes trial by jury in criminal cases, the right of appeal, and an independent judiciary. The highest state court is the Supreme Court, against which appeals can be made to the High Court of Australia and, in certain cases, to the Privy Council in London. Minor offenses are dealt with by magistrates in the Courts of Petty Sessions, while more serious cases are brought before a judge and jury in the Courts of Quarter Sessions.

Administration. *Education.* Education is compulsory for all children between the ages of six and 15. Most children are educated in free, nondenominational primary and secondary schools. A minority go to private schools, most of them administered by the Roman Catholic Church. There are also a few denominational secondary schools for the children of the wealthy. There are five universities in the state; the cost of administration is shared with the commonwealth.

Health and welfare. The state government is responsible for the supervision of public health, hospitals, and medical services. There are almost 270 public and a large number of private hospitals. The national health-insurance scheme is financed and administered by the commonwealth, as are the social services such as family allowances, child endowment, unemployment benefits, and pensions.

Standard of living

Social conditions. New South Wales shares in the high standard of living and generous social services enjoyed by all Australians. The state has its own Industrial Commission to settle industrial disputes, though here, too, the Commonwealth Arbitration system has become predominant. The basic wage—adopted from time to time by the Commonwealth Conciliation and Arbitration Commission—is adopted for state awards and agreements. The 40-hour workweek is now standard.

CULTURAL LIFE AND INSTITUTIONS

The state cannot claim a unique culture that distinguishes it from the rest of Australia. It is perhaps the most representative and typical of all the states, and its greater population and wealth give it a leading position over all but Victoria.

The state of the arts. Sydney has the oldest and reputedly the best of the symphony orchestras. There are many small theatres, but no professional drama company of first-class quality was established by the early 1970s. Sydney's Opera House, which opened in 1973, is a major arts centre with a concert hall, a large theatre for opera and ballet, and a small theatre.

Many of Australia's leading poets and novelists were either born in the state or live there. Sydney is the centre of a school of contemporary painting that looks toward the United States and Europe for its inspiration. The Art Gallery of New South Wales has the best collection of Australian painting in Australia. In general, the cultural climate is marked more by a healthy and democratic vitality rather than by any special distinction. This is equally true of the popular arts, where there are large audiences for and keen interest in both Australian and foreign folk singers and jazz and rock groups.

The mass media. Sydney has three morning papers, including the *Australian*, which has a national circulation, and the *Sydney Morning Herald*, which is the oldest paper in Australia. There are also two evening papers and four Sunday papers. Many weeklies and magazines are also published there. Most country towns, even those of medium size, also have their own newspapers. In both television and radio broadcasting, the Australian Broadcasting Commission competes with a number of commercial stations.

Prospects for the future. Because of its wealth, geographical position, and mixed economy, New South Wales is well placed to share in the progress and prosperity of Australia. It is likely to remain, for some time to come, the most important state in the commonwealth. Whether it will also remain a distinct political entity is more doubtful and must depend on the future of federalism in the country. Though there is a certain loyalty to their state among New South Welshmen, this more often finds expression in sports than in politics. The Australian Labor Party openly and some Liberals secretly are centralists who would like to abolish the states or at least reduce them to administrative units. It can be argued that the state governments and parliaments are in any case likely to lose their reason for existence if they are not given back the power to raise their own revenue to meet their own expenditures.

BIBLIOGRAPHY. The best source for up-to-date facts and statistics on New South Wales is the *Official Year Book*, issued annually by the government of New South Wales in conjunction with the Commonwealth Bureau of Census and Statistics. Historical, as well as other, information on New South Wales may be found in books on Australia, such as C.M.H. CLARK, *A History of Australia*, 2 vol. (1962–68); G. GREENWOOD (ed.), *Australia: A Social and Political History* (1955 and 1966); and A.G.L. SHAW, *The Story of Australia* (1955).

(J.D.Pr.)

New Thought

New Thought, a mind-healing movement based on religious and metaphysical (concerning the nature of ultimate reality) presuppositions, originated in the United States in the 19th century. Involving both individuals and denominations, it maintains an influence beyond the particular organizations associated with the movement. The diversity of views and styles of life represented in various New Thought groups are difficult to describe because of their variety, and the same reason makes it virtually impossible to determine either membership or adherents. The influence of the various New Thought groups has been spread by its leaders through lectures, journals, and books not only in the United States but in the United Kingdom, in Europe, Asia, Africa, and Australia. Many adherents of New Thought consider themselves to be Christian, though generalizations about their relations to Christianity have been questioned.

History of the New Thought movement. *Origins.* The origins of New Thought may be traced to a dissatisfaction on the part of many persons with scientific empiricism and their reaction to the religious skepticism of the 17th and 18th centuries. The romanticism and idealism of the 19th century also influenced the New Thought movement, of which Phineas P. Quimby (1802–66) is usually cited as the earliest proponent. From Portland, Maine, Quimby practiced mesmerism (hypnotism) and developed his concepts of mental and spiritual healing and health based on the view that illness is a matter of the mind. Quimby's influence may be seen in the writings

Influence of Phineas P. Quimby

of Mary Baker Eddy and in the development of Christian Science (which she founded), although Mrs. Eddy retracted acknowledgment of dependence on her teacher. Quimby's influence has been readily acknowledged by Warren F. Evans (1817–89) and by Julius A. Dresser (1838–1893) and his son Horatio W. Dresser (1866–1954). Evans, a Methodist and then a Swedenborgian minister (leader of a theosophical movement based on the teachings of the 18th-century Swedish scientist and theologian Emanuel Swedenborg), published a number of works exploring and systematizing the ideas of Quimby. These included *Mental Cure* (1869), *Mental Medicine* (1872), and *Soul and Body* (1876). Julius Dresser was a popular lecturer who emphasized the theories of Quimby, and his son Horatio spread the elder Dresser's teachings and later edited *The Quimby Manuscripts* (1921).

Organization of New Thought groups. As the ideas of Quimby and his students began to spread, those interested began to gather in congregations. They organized New Thought congresses (the first in 1894), the National New Thought Alliance in 1908, and the International New Thought Alliance (INTA) in 1914. In the Alliance are (or have been) such groups as the Unity School of Christianity (founded by former Methodists Charles and Myrtle Fillmore), Divine Science (founded by Nona L. Brooks), the Church of Religious Science (founded by Ernest Holmes), and others, such as the Home of Truth, the Church of Truth, the Christ Truth League, the Society of the Healing Christ, and the Christian Assembly. The Alliance has depended for its continuity upon presidents, two of whom have had long tenures (James A. Edgerton, 1915–23, and again 1934–37; and Robert H. Bitzer, 1949–63), and upon the cooperation of the leaders of various schools of New Thought recognized by the Alliance. Its headquarters has been in Washington, D.C., in New York City, and in Hollywood, California, where it is now located. Smaller groups have often gathered around teachers noted for their powers of healing and have organized themselves in rather loose congregational patterns. There is no single organizational structure.

Member groups of the New Thought Alliance

New Thought teachings and practices. New Thought represents the influence of Platonism (based on the views of the 5th–4th century BC Greek philosopher Plato, involving the view that the realm of ideas is more real than that of matter), Swedenborgianism, (especially Swedenborg's view that the material realm is one of effects whose causes are spiritual and whose purpose is divine); Hegelianism (based on the views of the 18th–19th century German philosopher G.W.F. Hegel, especially those concerning the external world, mental phenomena, and the nervous organism as the meeting ground of the body and the mind); Orientalism (involving spiritually-oriented teachings of Eastern religions; *e.g.*, Hinduism); and, particularly, the Transcendentalism (a form of Idealism) of the 19th-century American philosopher and poet Ralph Waldo Emerson. Though a summary of New Thought beliefs is difficult to make, since it is to a large degree individualistic in outlook, it is possible to summarize some of the more prevalent views. As far as Christian Science is concerned, New Thought adherents do not accept Mrs. Eddy's teaching or any other formulation as the final revelation. Rather, truth is viewed as a matter of continuing revelation, and no one leader or institution can declare with finality what is its nature. Moreover, New Thought does not oppose medical science, as Mrs. Eddy did, and it is essentially positive and optimistic about life and its outcome.

Basic views. In 1916 the Alliance agreed upon a purpose that embraces some central ideas of most groups:

> To teach the Infinitude of the Supreme One; the Divinity of Man and his Infinite Possibilities through the creative power of constructive thinking and obedience to the voice of the indwelling Presence which is our source of Inspiration, Power, Health and Prosperity.

Views on the divinity of man and his potentialities

In 1917, at the St. Louis (Missouri) Congress, the Alliance adopted a "Declaration of Principles." It was modified in 1919 and was printed in *New Thought* until revised in the 1950s. This purpose and these Principles emphasized the immanence of God, the divine nature of man, the immediate availability of God's power to man, the spiritual character of the universe, and the fact that sin, human disorders, and human disease are basically matters of incorrect thinking. Moreover, according to New Thought, man can live in oneness with God in love, truth, peace, health, and plenty. Many New Thought groups emphasize Jesus as teacher and healer and proclaim his kingdom as being within a person. Reference to Jesus or the Christ is totally omitted in the Principles, however, as revised in 1954. New Thought leaders, unlike Quimby, it should be noted, have increasingly stressed material prosperity as one result of New Thought. New Thought implies a kind of monism (oneness of the world), but it also has strong Gnostic (an esoteric dualism in which matter is opposed to spirit) undertones; that is, though New Thought is open to all, spiritual healing and strength of mind and body are only available to those who have the insights and who have been initiated into the movement at some point. There are no established patterns of worship, although the services often involve explication of New Thought ideas, testimony to healing, and prayer for the sick.

Spread of New Thought ideas. New Thought conceptions have been spread by a wide variety of periodicals, the following of which are still being published: *New Thought* (INTA); *Unity*, *Weekly Unity*, and *Christian Business* (Unity School of Christianity); *Divine Science Monthly*, *Science of Mind*, *Religious Science*, and *Crusader*, (published by Brother Mandus, English leader of the World Healing Crusade). New Thought ideas have also been spread by a number of writers who have produced several religious books with significant popular appeal: Ralph W. Trine, *In Tune with the Infinite* (1897); Orison Swett Marden, *Pushing to the Front* (1894); Robert Collier, *The Secret of the Ages* (1926); and Emmet Fox, *Power Through Constructive Thinking* (1940), and *The Sermon on the Mount* (1934). More recently, clergymen outside the movement, such as Glenn Clark, in *How to Find Health Through Prayer* (1940), and Norman Vincent Peale, in *The Power of Positive Thinking* (1952), have contributed to the distribution of some New Thought ideas. Though it is very difficult to generalize about the social and ethical consequences of New Thought, there is evidence, as suggested by this popular literature, that New Thought has been individualistic in its ethical concerns. It has attempted to promote a positive personal attitude toward life and to encourage a success mentality in an industrialized and urbanized America. This has made it appealing to middle and upper class clientele and has reinforced the suspicion of its adherents concerning those who attempt to deal with the corporate problems of life by means of political power. The general Methodist orientation of persons such as Evans and the Fillmores suggests a source of the perfectionist aspects of New Thought views.

Promotion of positive personal attitudes

New Thought groups. *Unity*. Among the most prominent groups spreading New Thought motifs is Unity; *i.e.*, the Unity School of Christianity, which was organized by Myrtle (1845–1931) and Charles (1854–1948) Fillmore. Both were originally Methodists, and both suffered from physical and emotional troubles. The Fillmores came under the influence of Emma Curtis Hopkins, a former follower of Mrs. Eddy, at the Christian Science Theological Seminary in Chicago. They started publishing *Modern Thought* in 1889 and *Unity* in 1891 and expanded their influence greatly through a ministry they called Silent Unity, which involved an affirmative prayer and counselling service on request. At first this type of healing and spiritual ministry was carried on through correspondence and later by telegraph and telephone. From small beginnings in Kansas City, Missouri, Unity expanded, with Unity Centers developing elsewhere; the Fillmores also founded a Unity Village, several miles outside of Kansas City on about 1,400 acres of farmland, in order to coordinate the work of followers. Unity developed into a publishing organization of remarkable size, distributing the writings of the Fillmores (in books,

pamphlets, and magazines) on healing, prosperity, success, prayer, and numerous other subjects. Unity publications included *Unity*, *Weekly Unity*, *Daily Word*, and *Wee Wisdom* for children; the publications have been supplemented with an extensive use of radio programs. Unity stresses its agreement with Christianity, and the Fillmores attempted to harmonize its several distinctive teachings with orthodoxy. Unlike recent tendencies in INTA and within New Thought groups, they continued to stress the teaching of Jesus Christ. According to their teaching, they revived his healing methods, but, in contradistinction to orthodox Christian churches, they teach a belief in reincarnation and the regeneration of the body in a succession of rebirths. Salvation is finally attained by breaking out of the cycle of rebirths and by reaching a true spiritual nature and Christ-consciousness. Unity allows sexual intercourse for procreation only and urges abstention from the use of meat, tobacco, intoxicants, and drugs. In 1922 Unity left the INTA, although some individuals in local Unity Centers have remained in the Alliance. Since the 1920s, Unity has developed some denominational characteristics with an accredited ministry in association with the parent body in Kansas City. Since the death of Charles Fillmore in 1948, Unity has continued under the leadership of his son, Rick, and a grandson, Charles. Unity claims to have received 650,000 contacts for a prayer a year.

Teachings of Unity differing from orthodox Christian churches

Psychiana. Though Unity is considered as Christian by its adherents, other groups promoting New Thought motifs find themselves at odds with, and even hostile to, Christianity. One such group, Psychiana (a healing cult promoted by advertisement and direct mail), was founded by Frank B. Robinson (1886-1948) of Moscow, Idaho. Robinson, son of a Baptist minister, one time student at the Bible Training School in Toronto, Canada, and pharmacist, began to advertise "God-power" in 1929. Rejecting the orthodox Christian Trinitarian beliefs in God the Father, the Son, and the Holy Spirit—and also the established Christian organizations—he stressed that the power of God was freely available for individual use. He advertised, "I talked with God," and circulated a series of "Psychiana Lessons" (1932), which demonstrated how others might also bring from the realm of the spirit of God anything needed for complete physical and material happiness. In his book, *Your God-Power* (1943), Robinson systematized some of his thoughts and showed some influence from Theosophy (a religious movement containing Hindu, Buddhist, and Western religious ideas that originated in the 19th century under the Polish-American Madame Helena Blavatsky). He called himself the archbishop of Psychiana, and, though he did head a corporation that sent out an estimated 1,000,000 sets of lessons, he headed no permanent or widespread organization.

The I Am movement. The I Am movement, also associated with New Thought, was founded in the 1930s by Guy Ballard (1878–1939), a mining engineer, and his wife, Edna (d. 1971). The I Am movement was based upon the teachings expounded in Ballard's books, including *Unveiled Mysteries* (1934), *The Magic Presence* (1935), and *The I Am Discourses. The Voice of the I Am* was the monthly periodical of the movement. Drawing upon classical mythology, astronomy, astrology, the Bible, and theosophy, Ballard taught that there were numerous Ascended Masters, who themselves had broken the bonds of human limitations. Among these, at the beginning, was Jesus, and then, most important of all, Comte de St. Germain, an 18th-century European necromancer and occultist. Persons could turn to these various masters for vast cosmic power. Furthermore, through successive reincarnations every member of the movement could become an Ascended Master. By employing such affirmation every member could be assured of health, prosperity, and happiness. To these benefits was added freedom from the fear of death because of the presence of the Mighty I Am in every man. The Ballards were known for their superpatriotism, their condemnation of Liberal causes in the 1930s, and mail fraud, for which Edna served a jail sentence after her husband's death. The fact that the I Am Movement and Psychiana declined in influence and numbers shortly after their leaders died indicates the ephemeral character of some New Thought groups.

Conclusion. New Thought has spread widely throughout the United States and the world and has contributed to the increased interest in what has been called faith healing, or better, the healing ministry, within the larger denominations of Christians. The development of this interest within these bodies may curb some of the influence of New Thought, but New Thought seems to continue because of man's apparently keen desire to assert his own value and to overcome his psychic and physical limitations, frailties, and finitude. New Thought gives expression to the desire for health and wholeness and also to the desire to realize a harmony, according to its teachings, of man's little mind with the Great Mind. It allows its adherents and those influenced by its leadership and widespread literature a buoyant optimism about themselves and the cosmos.

Influence on the larger Christian denominations

BIBLIOGRAPHY. The most helpful bibliography of books, pamphlets, magazines, and New Thought archives, as well as the best volume for the history and thought of the movement is CHARLES S. BRADEN, *Spirits in Rebellion* (1963). Primary sources are: HORATIO W. DRESSER (ed.), *The Quimby Manuscripts* (1921), and *History of the New Thought Movement* (1919); WARREN FELT EVANS, *The Mental Cure: Illustrating the Influence of the Mind on the Body, Both in Health and Disease and the Psychological Method of Treatment* (1869); CHARLES FILLMORE, *Metaphysical Bible Dictionary* (1931); and RALPH WALDO TRINE, *In Tune with the Infinite* (1897). See also *New Thought* and *Unity*, two of the most important periodicals still being published.

Secondary works that treat the subject sympathetically and place it in larger context are: DONALD MEYER, *The Positive Thinkers* (1965); ROBERT PEEL, *Christian Science: Its Encounter with American Culture* (1958); and LOUIS SCHNEIDER and SANFORD M. DORNBUSCH, *Popular Religion: Inspirational Books in America* (1958).

(J.H.Sm.)

Newton, Sir Isaac

Isaac Newton, English physicist and mathematician, was the culminating figure of the scientific revolution of the 17th century. In optics, his discovery of the composition of white light integrated the phenomena of colours into the science of light and laid the foundation for modern physical optics. In mechanics, his three laws of motion, the basic principles of modern physics, resulted in the formulation of the law of universal gravitation. In mathematics, he was the original discoverer of the infinitesimal calculus. Newton's *Philosophiae Naturalis Principia Mathematica* (*Mathematical Principles of Natural Philosophy*), 1687, was one of the most important single works in the history of modern science.

EARLY YEARS

Formative influences. Born on December 25, 1642 (January 4, 1643, new style), in the hamlet of Woolsthorpe, Lincolnshire, Newton was the only son of a local yeoman, also Isaac Newton, who had died three months before, and of Hannah Ayscough. That same year, at Arcetri near Florence, Galileo Galilei had died; Newton would eventually pick up his idea of a mathematical science of motion and bring his work to full fruition. A tiny and weak baby, Newton was not expected to survive his first day of life, much less 84 years. Deprived of a father before birth, he soon lost his mother as well, for within two years she married a second time; her husband, the well-to-do minister Barnabas Smith, left young Isaac with his grandmother and moved to a neighbouring village to raise a son and two daughters. For nine years, until the death of Barnabas Smith in 1653, Isaac was effectively separated from his mother, and his pronounced psychotic tendencies have been ascribed to this traumatic event. That he hated his stepfather we may be sure. When he examined the state of his soul in 1662 and compiled a catalog of sins in shorthand, he remembered "Threatning my father and mother Smith to burne them and the house over them." The acute sense of insecurity that rendered him obsessively anxious when his work was published and irrationally violent when he defended it accompanied Newton throughout his life and can plausibly be traced to his early years.

After his mother was widowed a second time, she determined that her first-born son should manage her now considerable property. It quickly became apparent, however, that this would be a disaster, both for the estate and for Newton. He could not bring himself to concentrate on rural affairs—set to watch the cattle, he would curl up under a tree with a book. Fortunately, the mistake was recognized, and Newton was sent back to the grammar school in Grantham, where he had already studied, to prepare for the university. As with many of the leading scientists of the age, he left behind in Grantham anecdotes about his mechanical ability and his skill in building models of machines, such as clocks and windmills. At the school he apparently gained a firm command of Latin but probably received no more than a smattering of arithmetic. By June 1661, he was ready to matriculate at Trinity College, Cambridge, somewhat older than the other undergraduates because of his interrupted education.

Influence of the scientific revolution. When Newton arrived in Cambridge in 1661, the movement now known as the scientific revolution was well advanced, and many of the works basic to modern science had appeared. Astronomers from Copernicus to Kepler had elaborated the heliocentric system of the universe. Galileo had proposed the foundations of a new mechanics built on the principle of inertia. Led by Descartes, philosophers had begun to formulate a new conception of nature as an intricate, impersonal, and inert machine. Yet as far as the universities of Europe, including Cambridge, were concerned, all this might well have never happened. They continued to be the strongholds of outmoded Aristotelianism, which rested on a geocentric view of the universe and dealt with nature in qualitative rather than quantitative terms.

Like thousands of other undergraduates, Newton began his higher education by immersing himself in Aristotle's work. Even though the new philosophy was not in the curriculum, it was in the air. Some time during his undergraduate career, Newton discovered the works of the French natural philosopher René Descartes and the other mechanical philosophers, who, in contrast to Aristotle, viewed physical reality as composed entirely of particles of matter in motion and who held that all the phenomena of nature result from their mechanical interaction. A new set of notes, which he entitled "Quaestiones Quaedam Philosophicae" ("Certain Philosophical Questions"), begun sometime in 1664, usurped the unused pages of a notebook intended for traditional scholastic exercises; under the title he entered the slogan "Amicus Plato amicus Aristoteles magis amica veritas" ("Plato is my friend, Aristotle is my friend, but my best friend is truth"). Newton's scientific career had begun.

Importance of the "Quaestiones"

The "Quaestiones" reveal that Newton had discovered the new conception of nature that provided the framework of the scientific revolution. He had thoroughly mastered the works of Descartes and had also discovered that the French philosopher Pierre Gassendi had revived atomism, an alternative mechanical system to explain nature. The "Quaestiones" also reveal that Newton already was inclined to find the latter a more attractive philosophy than Cartesian natural philosophy, which rejected the existence of ultimate indivisible particles. The works of the 17th-century chemist Robert Boyle provided the foundation for Newton's considerable work in chemistry. Significantly, he had read Henry More, the Cambridge Platonist, and was thereby introduced to another intellectual world, the magical Hermetic tradition, which sought to explain natural phenomena in terms of alchemical and magical concepts. The two traditions of natural philosophy, the mechanical and the Hermetic, antithetical though they appear, continued to influence his thought and in their tension supplied the fundamental theme of his scientific career.

Although he did not record it in the "Quaestiones," Newton had also begun his mathematical studies. He again started with Descartes, from whose *La Géometrie* he branched out into the other literature of modern analysis with its application of algebraic techniques to problems of geometry. He then reached back for the support of classical geometry. Within little more than a year, he had mastered the literature; and, pursuing his own line of analysis, he began to move into new territory. He discovered the binomial theorem, and he developed the calculus, a more powerful form of analysis that employs infinitesimal considerations in finding the slopes of curves and areas under curves.

Development of the calculus

By 1669 Newton was ready to write a tract summarizing his progress, *De Analysi per Aequationes Numeri Terminorum Infinitas* ("On Analysis by Infinite Series"), which circulated in manuscript through a limited circle and made his name known. During the next two years he revised it as *De methodis serierum et fluxionum* ("On the Methods of Series and Fluxions"). The word fluxions, Newton's private rubric, indicates that the calculus had been born. Despite the fact that only a handful of savants were even aware of Newton's existence, he had arrived at the point where he had become the leading mathematician in Europe.

Work during the plague years. When Newton received the bachelor's degree in April 1665, the most remarkable undergraduate career in the history of university education had passed unrecognized. On his own, without formal guidance, he had sought out the new philosophy and the new mathematics and made them his own, but he had confined the progress of his studies to his notebooks. Then, in 1665, the plague closed the university, and for most of the following two years he was forced to stay at his home, contemplating at leisure what he had learned. During the plague years Newton laid the foundations of the calculus and extended an earlier insight into an essay, "Of Colours," which contains most of the ideas elaborated in his *Opticks*. It was during this time that he examined the elements of circular motion and, applying his analysis to the Moon and the planets, derived the inverse square relation that the radially directed force acting on a planet decreases with the square of its distance from the Sun—which was later crucial to the law of universal gravitation. The world heard nothing of these discoveries.

CAREER

The optics. *Inaugural lectures at Trinity.* Newton was elected to a fellowship in Trinity College in 1667, after the university reopened. Two years later, Isaac Barrow, Lucasian professor of mathematics, who had transmitted Newton's *De Analysi* to John Collins in London, resigned the chair to devote himself to divinity and recommended Newton to succeed him. The professorship exempted Newton from the necessity of tutoring but im-

posed the duty of delivering an annual course of lectures. He chose the work he had done in optics as the initial topic; during the following three years (1670–72), his lectures developed the essay "Of Colours" into a form which was later revised to become Book One of his *Opticks*.

Beginning with Kepler's *Paralipomena* in 1604, the study of optics had been a central activity of the scientific revolution. Descartes's statement of the sine law of refraction, relating the angles of incidence and emergence at interfaces of the media through which light passes, had added a new mathematical regularity to the science of light, supporting the conviction that the universe is constructed according to mathematical regularities. Descartes had also made light central to the mechanical philosophy of nature; the reality of light, he argued, consists of motion transmitted through a material medium. Newton fully accepted the mechanical nature of light, although he chose the atomistic alternative and held that light consists of material corpuscles in motion. The corpuscular conception of light was always a speculative theory on the periphery of his optics, however. The core of Newton's contribution had to do with colours. An ancient theory extending back at least to Aristotle held that a certain class of colour phenomena, such as the rainbow, arises from the modification of light, which appears white in its pristine form. Descartes had generalized this theory for all colours and translated it into mechanical imagery. Through a series of experiments performed in 1665 and 1666, in which the spectrum of a narrow beam was projected onto the wall of a darkened chamber, Newton denied the concept of modification and replaced it with that of analysis. Basically, he denied that light is simple and homogeneous—stating instead that it is complex and heterogeneous and that the phenomena of colours arise from the analysis of the heterogeneous mixture into its simple components. The ultimate source of Newton's conviction that light is corpuscular was his recognition that individual rays of light have immutable properties; in his view, such properties imply immutable particles of matter. He held that individual rays (that is, particles of given size) excite sensations of individual colours when they strike the retina of the eye. He also concluded that rays refract at distinct angles—hence, the prismatic spectrum, a beam of heterogeneous rays, *i.e.*, alike incident on one face of a prism, separated or analyzed by the refraction into its component parts—and that phenomena such as the rainbow are produced by refractive analysis. Because he believed that chromatic aberration could never be eliminated from lenses, Newton turned to reflecting telescopes; he constructed the first ever built. The heterogeneity of light has been the foundation of physical optics since his time.

Analysis of colour

There is no evidence that the theory of colours, fully described by Newton in his inaugural lectures at Cambridge, made any impression, just as there is no evidence that aspects of his mathematics and the content of the *Principia*, also pronounced from the podium, made any impression. Rather, the theory of colours, like his later work, was transmitted to the world through the Royal Society of London, which had been organized in 1660. When Newton was appointed Lucasian professor, his name was probably unknown in the Royal Society; in 1671, however, they heard of his reflecting telescope and asked to see it. Pleased by their enthusiastic reception of the telescope and by his election to the society, Newton volunteered a paper on light and colours early in 1672. On the whole, the paper was also well received, although a few questions and some dissent were heard.

Controversy. Among the most important dissenters to Newton's paper was Robert Hooke, one of the leaders of the Royal Society who considered himself the master in optics and hence he wrote a condescending critique of the unknown parvenu. One can understand how the critique would have annoyed a normal man. The flaming rage it provoked, with the desire publicly to humiliate Hooke, however, bespoke the abnormal. Newton was unable rationally to confront criticism. Less than a year after submitting the paper, he was so unsettled by the give and take of honest discussion that he began to cut his ties, and he withdrew into virtual isolation.

In 1675, during a visit to London, Newton thought he heard Hooke accept his theory of colours. He was emboldened to bring forth a second paper, an examination of the colour phenomena in thin films, which was identical to most of Book Two as it later appeared in the *Opticks*. The purpose of the paper was to explain the colours of solid bodies by showing how light can be analyzed into its components by reflection as well as refraction. His explanation of the colours of bodies has not survived, but the paper was significant in demonstrating for the first time the existence of periodic optical phenomena. He discovered the concentric coloured rings in the thin film of air between a lens and a flat sheet of glass; the distance between these concentric rings (Newton's rings) depends on the increasing thickness of the film of air. In 1704 Newton combined a revision of his optical lectures with the paper of 1675 and a small amount of additional material in his *Opticks*.

Colours in thin films

A second piece which Newton had sent with the paper of 1675 provoked new controversy. Entitled "An Hypothesis Explaining the Properties of Light," it was in fact a general system of nature. Hooke apparently claimed that Newton had stolen its content from him, and Newton boiled over again. The issue was quickly controlled, however, by an exchange of formal, excessively polite letters that fail to conceal the complete lack of warmth between the men.

Newton was also engaged in another exchange on his theory of colours with a circle of English Jesuits in Liège, perhaps the most revealing exchange of all. Although their objections were shallow, their contention that his experiments were mistaken lashed him into a fury. The correspondence dragged on until 1678, when a final shriek of rage from Newton, apparently accompanied by a complete nervous breakdown, was followed by silence. The death of his mother the following year completed his isolation. For six years he withdrew from intellectual commerce except when others initiated a correspondence, which he always broke off as quickly as possible.

Influence of the Hermetic tradition. During his time of isolation, Newton was greatly influenced by the Hermetic tradition with which he had been familiar since his undergraduate days. Newton, always somewhat interested in alchemy, now immersed himself in it, copying by hand treatise after treatise and collating them to interpret their arcane imagery. Under the influence of the Hermetic tradition, his conception of nature underwent a decisive change. Until that time, Newton had been a mechanical philosopher in the standard 17th-century style, explaining natural phenomena by the motions of particles of matter. Thus, he held that the physical reality of light is a stream of tiny corpuscles diverted from its course by the presence of denser or rarer media. He felt that the apparent attraction of tiny bits of paper to a piece of glass that has been rubbed with cloth results from an ethereal effluvium that streams out of the glass and carries the bits of paper back with it. This mechanical philosophy denied the possibility of action at a distance; as with static electricity, it explained apparent attractions away by means of invisible ethereal mechanisms. Newton's "Hypothesis of Light" of 1675, with its universal ether, was a standard mechanical system of nature. Some phenomena, such as the capacity of chemicals to react only with certain others, puzzled him, however, and he spoke of a "secret principle" by which substances are "sociable" or "unsociable" with others. About 1679, Newton abandoned the ether and its invisible mechanisms and began to ascribe the puzzling phenomena—chemical affinities, the generation of heat in chemical reactions, surface tension in fluids, capillary action, the cohesion of bodies, and the like—to attractions and repulsions between particles of matter. More than 35 years later, in the second English edition of the *Opticks*, Newton accepted an ether again, although it was an ether that embodied the concept of action at a distance by positing a repulsion between its particles. The attractions and repulsions of Newton's speculations were direct transpositions of the occult sym-

pathies and antipathies of Hermetic philosophy—as mechanical philosophers never ceased to protest. Newton, however, regarded them as a modification of the mechanical philosophy that rendered it subject to exact mathematical treatment. As he conceived of them, attractions were quantitatively defined, and they offered a bridge to unite the two basic themes of 17th-century science—the mechanical tradition, which had dealt primarily with verbal mechanical imagery, and the Pythagorean tradition, which insisted on the mathematical nature of reality. Newton's reconciliation through the concept of force was his ultimate contribution to science.

The Principia. *Planetary motion.* Newton originally applied the idea of attractions and repulsions solely to the range of terrestrial phenomena mentioned in the preceding paragraph. But late in 1679, not long after he had embraced the concept, another application was suggested in a letter from Hooke, who was seeking to renew correspondence. Hooke mentioned his analysis of planetary motion—in effect, the continuous diversion of a rectilinear motion by a central attraction. Newton bluntly refused to correspond but, nevertheless, went on to mention an experiment to demonstrate the rotation of the Earth: let a body be dropped from a tower; because the tangential velocity at the top of the tower is greater than that at the foot, the body should fall slightly to the east. He sketched the path of fall as part of a spiral ending at the centre of the Earth. This was a mistake, as Hooke pointed out; according to Hooke's theory of planetary motion, the path should be elliptical, so that if the Earth were split and separated to allow the body to fall, it would rise again to its original location. Newton did not like being corrected, least of all by Hooke, but he had to accept the basic point; he corrected Hooke's figure, however, using the assumption that gravity is constant. Hooke then countered by replying that, although Newton's figure was correct for constant gravity, his own assumption was that gravity decreases as the square of the distance. Several years later, this letter became the basis for Hooke's charge of plagiarism. He was mistaken in the charge. His knowledge of the inverse square relation rested only on intuitive grounds; he did not derive it properly from the quantitative statement of centripetal force and Kepler's third law, which relates the periods of planets to the radii of their orbits. Moreover, unknown to him, Newton had so derived the relation more than ten years earlier. Nevertheless, Newton later confessed that the correspondence with Hooke led him to demonstrate that an elliptical orbit entails an inverse square attraction to one focus—one of the two crucial propositions on which the law of universal gravitation would ultimately rest. What is more, Hooke's definition of orbital motion—in which the constant action of an attracting body continuously pulls a planet away from its inertial path—suggested a cosmic application for Newton's concept of force and an explanation of planetary paths employing it. In 1679 and 1680, Newton dealt only with orbital dynamics; he had not yet arrived at the concept of universal gravitation.

Correspondence with Hooke

Universal gravitation. Nearly five years later, in August 1684, Newton was visited by the British astronomer Edmond Halley, who was also troubled by the problem of orbital dynamics. Upon learning that Newton had solved the problem, he extracted Newton's promise to send the demonstration. Three months later he received a short tract entitled *De Motu* ("On Motion"). Already Newton was at work improving and expanding it. In two and a half years, the tract *De Motu* grew into *Philosophiae Naturalis Principia Mathematica*, which is not only Newton's masterpiece but also the fundamental work for the whole of modern science.

Significantly, *De Motu* did not state the law of universal gravitation. For that matter, even though it was a treatise on planetary dynamics, it did not contain any of the three Newtonian laws of motion. Only when revising *De Motu* did Newton embrace the principle of inertia (the first law) and arrive at the second law of motion. The second law, the force law, proved to be a precise quantitative statement of the action of the forces between bodies that had become the central members of his system of nature. By quantifying the concept of force, the second law completed the exact quantitative mechanics that has been the paradigm of natural science ever since.

The quantitative mechanics of the *Principia* is not to be confused with the mechanical philosophy. The latter was a philosophy of nature that attempted to explain natural phenomena by means of imagined mechanisms among invisible particles of matter. The mechanics of the *Principia* was an exact quantitative description of the motions of visible bodies. It rested on Newton's three laws of motion: (1) that a body remains in its state of rest unless it is compelled to change that state by a force impressed on it; (2) that the change of motion (the change of velocity times the mass of the body) is proportional to the force impressed; (3) that to every action there is an equal and opposite reaction. The analysis of circular motion in terms of these laws yielded a formula of the quantitative measure, in terms of a body's velocity and mass, of the centripetal force necessary to divert a body from its rectilinear path into a given circle. When Newton substituted this formula into Kepler's third law, he found that the centripetal force holding the planets in their given orbits about the Sun must decrease with the square of the planets' distances from the Sun. Because the satellites of Jupiter also obey Kepler's third law, an inverse square centripetal force must also attract them to the centre of their orbits. Newton was able to show that a similar relation holds between the Earth and its Moon. The distance of the Moon is approximately 60 times the radius of the Earth. Newton compared the distance by which the Moon, in its orbit of known size, is diverted from a tangential path in one second with the distance that a body at the surface of the Earth falls from rest in one second. When the latter distance proved to be 3,600 (60 x 60) times as great as the former, he concluded that one and the same force, governed by a single quantitative law, is operative in all three cases, and from the correlation of the Moon's orbit with the measured acceleration of gravity on the surface of the Earth, he applied the ancient Latin word *gravitas* (literally, "heaviness" or "weight") to it. The law of universal gravitation, which he also confirmed from such further phenomena as the tides and the orbits of comets, states that every particle of matter in the universe attracts every other particle with a force that is proportional to the product of their masses and inversely proportional to the square of the distance between their centres.

When the Royal Society received the completed manuscript of Book I in 1686, Hooke raised the cry of plagiarism, a charge that cannot be sustained in any meaningful sense. On the other hand, Newton's response to it reveals much about him. Hooke would have been satisfied with a generous acknowledgment; it would have been a graceful gesture to a sick man already well into his decline, and it would have cost Newton nothing. Newton, instead, went through his manuscript and eliminated nearly every reference to Hooke. Such was his fury that he refused either to publish his *Opticks* or to accept the presidency of the Royal Society until Hooke was dead.

Charge of plagiarism

International prominence. The *Principia* immediately raised Newton to international prominence. In their continuing loyalty to the mechanical ideal, Continental scientists rejected the idea of action at a distance for a generation, but even in their rejection they could not withhold their admiration for the technical expertise revealed by the work. Young British scientists spontaneously recognized him as their model. Within a generation the limited number of salaried positions for scientists in England, such as the chairs at Oxford, Cambridge, and Gresham College, were monopolized by the young Newtonians of the next generation. Newton, whose only close contacts with women were his unfulfilled relationship with his mother, who had seemed to abandon him, and his later guardianship of a niece, found satisfaction in the role of patron to the circle of young scientists. His friendship with Fatio de Duillier, a Swiss-born mathematician resident in London who shared Newton's interests, was the most profound experience of his adult life.

Warden of the mint. Almost immediately following the *Principia*'s publication, Newton, a fervent if unorthodox Protestant, helped to lead the resistance of Cambridge to James II's attempt to Catholicize it. As a consequence, he was elected to represent the university in the convention that arranged the revolutionary settlement. In this capacity, he made the acquaintance of a broader group, including the philosopher John Locke. Newton tasted the excitement of London life in the aftermath of the *Principia*. The great bulk of his creative work had been completed. He was never again satisfied with the academic cloister, and his desire to change was whetted by Fatio's suggestion that he find a position in London. Seek a place he did, especially through the agency of his friend, the rising politician Charles Montague, later Lord Halifax. Finally, in 1696, he was appointed warden of the mint. Although he did not resign his Cambridge appointments until 1701, he moved to London and henceforth centred his life there.

In the meantime, Newton's relations with Fatio had undergone a crisis. Fatio was taken seriously ill; then family and financial problems threatened to call him home to Switzerland. Newton's distress knew no limits. In 1693 he suggested that Fatio move to Cambridge, where Newton would support him, but nothing came of the proposal. Through early 1693 the intensity of Newton's letters built almost palpably, and then, without surviving explanation, both the close relationship and the correspondence broke off. Four months later, without prior notice, Samuel Pepys and John Locke, both personal friends of Newton, received wild, accusatory letters. Pepys was informed that Newton would see him no more; Locke was charged with trying to entangle him with women. Both men were alarmed for Newton's sanity; and, in fact, Newton had suffered at least his second nervous breakdown. The crisis passed, and Newton recovered his stability. Only briefly did he ever return to sustained scientific work, however, and the move to London was the effective conclusion of his creative activity.

Nervous breakdown

As warden and then master of the mint, Newton drew a large income, as much as £2,000 per annum. Added to his personal estate, the income left him a rich man at his death. The position, regarded as a sinecure, was treated otherwise by Newton. During the great recoinage, there was need for him to be actively in command; even afterward, however, he chose to exercise himself in the office. Above all, he was interested in counterfeiting. He became the terror of London counterfeiters, sending a goodly number to the gallows and finding in them a socially acceptable target on which to vent the rage that continued to well up within him.

Interest in religion and theology. Newton found time now to explore other interests, such as religion and theology. In the early 1690s he had sent Locke a copy of a manuscript attempting to prove that Trinitarian passages in the Bible were latter-day corruptions of the original text. When Locke made moves to publish it, Newton withdrew in fear that his anti-Trinitarian views would become known. In his later years, he devoted much time to the interpretation of the prophecies of Daniel and St. John, and to a closely related study of ancient chronology. Both works were published after his death.

Leader of English science. In London, Newton assumed the role of patriarch of English science. In 1703 he was elected President of the Royal Society. Four years earlier, the French Académie des Sciences (Academy of Sciences) had named him one of eight foreign associates. In 1705 Queen Anne knighted him, the first occasion on which a scientist was so honoured. Newton ruled the Royal Society magisterially. John Flamsteed, the Astronomer Royal, had occasion to feel that he ruled it tyrannically. In his years at the Royal Observatory at Greenwich, Flamsteed, who was a difficult man in his own right, had collected an unrivalled body of data. Newton had received needed information from him for the *Principia*, and in the 1690s, as he worked on the lunar theory, he again required Flamsteed's data. Annoyed when he could not get all the information he wanted as quickly as he wanted it, Newton assumed a domineering and condescending attitude toward Flamsteed. As president of the Royal Society, he used his influence with the government to be named as chairman of a body of "visitors" responsible for the Royal Observatory; then he tried to force the immediate publication of Flamsteed's catalog of stars. The disgraceful episode continued for nearly ten years. Newton would brook no objections. He broke agreements that he had made with Flamsteed. Flamsteed's observations, the fruit of a lifetime of work, were, in effect, seized despite his protests and prepared for the press by his mortal enemy, Edmond Halley. Flamsteed finally won his point and by court order had the printed catalog returned to him before it was generally distributed. He burned the printed sheets, and his assistants brought out an authorized version after his death. In this respect, and at considerable cost to himself, Flamsteed was one of the few men to best Newton. Newton sought his revenge by systematically eliminating references to Flamsteed's help in later editions of the *Principia*.

Difficulties with Flamsteed

In Gottfried Wilhelm Leibniz, the German philosopher and mathematician, Newton met a contestant more of his own calibre. It is now well established that Newton developed the calculus before Leibniz seriously pursued mathematics. It is almost universally agreed that Leibniz later arrived at the calculus independently. There has never been any question that Newton did not publish his method of fluxions; thus, it was Leibniz's paper in 1684 that first made the calculus a matter of public knowledge. In the *Principia* Newton hinted at his method, but he did not really publish it until he appended two papers to the *Opticks* in 1704. By then the priority controversy was already smouldering. If, indeed, it mattered, it would be impossible finally to assess responsibility for the ensuing fracas. What began as mild innuendoes rapidly escalated into blunt charges of plagiarism on both sides. Egged on by followers anxious to win a reputation under his auspices, Newton allowed himself to be drawn into the centre of the fray; and, once his temper was aroused by accusations of dishonesty, his anger was beyond constraint. Leibniz's conduct of the controversy was not pleasant, and yet it paled beside that of Newton. Although he never appeared in public, Newton wrote most of the pieces that appeared in his defense, publishing them under the names of his young men, who never demurred. As president of the Royal Society, he appointed an "impartial" committee to investigate the issue, secretly wrote the report officially published by the society, and reviewed it anonymously in the *Philosophical Transactions*. Even Leibniz's death could not allay Newton's wrath, and he continued to pursue the enemy beyond the grave. The battle with Leibniz, the irrepressible need to efface the charge of dishonesty, dominated the final 25 years of Newton's life. It obtruded itself continually upon his consciousness. Almost any paper on any subject from those years is apt to be interrupted by a furious paragraph against the German philosopher, as he honed the instruments of his fury ever more keenly. In the end, only Newton's death ended his wrath.

Priority dispute with Leibniz

Final years. During his final years Newton brought out further editions of his central works. After the first edition of the *Opticks* in 1704, which merely published work done 30 years before, he published a Latin edition in 1706 and a second English edition in 1717–18. In both, the central text was scarcely touched, but he did expand the "Queries" at the end into the final statement of his speculations on the nature of the universe. The second edition of the *Principia*, edited by Roger Cotes in 1713, introduced extensive alterations. A third edition, edited by Henry Pemberton in 1726, added little more. Until nearly the end, Newton presided at the Royal Society (frequently dozing through the meetings) and supervised the mint. During his last years, his niece, Catherine Barton Conduitt, and her husband lived with him. He died on March 20 (March 31, N.S.), 1727, in London.

MAJOR WORKS

Philosophiae Naturalis Principia Mathematica (1687; *Mathematical Principles of Natural Philosophy*, 1729); *Opticks* (1704); *Arithmetica Universalis* (1707; *Universal Arithmetick*, 1720); *The Chronology of Ancient Kingdoms Amended*

(1728); *Observations Upon the Prophecies of Daniel and the Apocalypse of St. John* (1733).

BIBLIOGRAPHY. The standard biography of Newton is DAVID BREWSTER, *Memoirs of the Life, Writings, and Discoveries of Sir Isaac Newton*, 2nd ed., 2 vol. (1855). A more modern work by LOUIS T. MORE, *Isaac Newton: A Biography* (1934), does not succeed in replacing Brewster. FRANK MANUEL, *A Portrait of Isaac Newton* (1968), offers a fascinating Freudian analysis of him. The best general treatment of the major problems in Newtonian science is found in I. BERNARD COHEN, *Franklin and Newton* (1956). Two recent works have explored the development of Newton's mechanics: JOHN W. HERIVEL, *The Background to Newton's Principia* (1966); and RICHARD S. WESTFALL, *Force in Newton's Physics* (1971). I. BERNARD COHEN, *Introduction to Newton's Principia* (1971), a history of the development and modification of Newton's major work, is the first volume of Cohen's edition of the *Principia* with variant readings. A.I. SABRA, *Theories of Light from Descartes to Newton* (1967), is the leading authority on Newton's work in optics. ALEXANDRE KOYRE, *Newtonian Studies* (1965), contains a collection of essays by one of the master historians of science. In addition to Cohen's edition of the *Principia*, there are collections of Newtonian materials, all with valuable introductory essays: *The Mathematical Papers of Isaac Newton*, ed. by D.T. WHITESIDE, 5 vol. (1967–72, in progress); *Unpublished Scientific Papers of Isaac Newton*, ed. by A.R. and M.B. HALL (1962); *Isaac Newton's Papers & Letters on Natural Philosophy and Related Documents*, ed. by I. BERNARD COHEN (1958); and *The Correspondence of Isaac Newton*, ed. by H.W. TURNBULL and J.F. SCOTT, 4 vol. (1959–).

(R.S.W.)

New York (State)

One of the 13 original states of the United States, New York was until the 1960s the nation's first state in nearly all population, cultural, and economic indexes. Its displacement by California around mid-decade was caused by the enormous growth rate that had persisted on the West Coast for several decades, rather than by any decline by New York. Although the state's percentage growth between the 1960 and 1970 censuses was well below the national average, it gained more people—to more than 18,000,000 inhabitants—than any of the states except California, Florida, and Texas, and its gross economic product exceeded that of all but a handful of nations in the world.

An overview of the state

This great population and economic base exists in a region of substantial contrast—from the Atlantic Ocean shores of Long Island and the skyscrapers of Manhattan through the rivers, mountains, and lakes of Upstate New York to the plains of the Great Lakes. By means of this pathway from ocean to inland seas, the canals, railroads, and highways of New York made it a principal gateway to the west for the Middle Atlantic and New England states and a continuing point of union for much of the nation. Along the way grew the cities—from New York City through Albany (the state capital), Utica, and Syracuse to Buffalo and Rochester on the lakes—that, with their suburbs, today hold more than four-fifths of all New Yorkers.

New York's central role in the development of the American nation was a slow-maturing phenomenon, and both the New England and Southern colonies had more to do with the movement toward revolution and with stabilizing the new nation in its early decades. Once under way, however, New York's growth attained a breakneck pace. Today, the state—and New York City, in particular—remains the focus of much of the nation's economy and finance, as well as of many formative impulses in U.S. arts and culture. The overwhelming presence of New York City actually has tended to divide the state socially and politically, causing long-standing problems for both city and state, but the influence and image of the state is a major element of national political life.

The 49,576 square miles (128,401 square kilometres) of New York are bounded, from west to north, by Lake Erie, the Canadian province of Ontario, Lake Ontario, and Quebec Province; on the east by the New England states of Vermont, Massachusetts, and Connecticut; on the southeast by the Atlantic Ocean and New Jersey; and on the south by Pennsylvania. (For information on related topics, see the articles UNITED STATES OF AMERICA; UNITED STATES, HISTORY OF; AMERICAN REVOLUTION; NEW YORK (CITY); NORTH AMERICA; APPALACHIAN MOUNTAINS; GREAT LAKES; and NIAGARA RIVER AND FALLS.)

THE HISTORY OF NEW YORK

Two major groupings of Indian tribes were living in the region when the white man arrived: the Mohegan (Mohican) and Munsee tribes of the Algonkian family near the coast and, inland, the five tribes of the Iroquois—Mohawk, Oneida, Onondaga, Cayuga, and Seneca—which formed the League of Five Nations about 1570. This confederacy, with advanced social and governmental institutions, reached the height of its power around 1700. When these tribes later aligned themselves with the British against the French and the Algonkians, they probably provided the balance of power needed for the British to emerge victors in the nearly 150 years of struggle between the two European powers in North America.

Settlement and colonial period. New York was settled originally as a colony of the Netherlands following Henry Hudson's exploration in 1609 of the river later named for him. In 1624 the Dutch established Fort Orange at present-day Albany as the first permanent European settlement in New York. One year later, a similar colony, New Amsterdam, was established at the foot of Manhattan Island. To legalize the settlement, Peter Minuit, Dutch governor, paid the Indians 60 Dutch guilders—about $24—in the form of merchandise. Although the Dutch established several settlements along the Hudson, their interest was more in trade than in permanent agricultural development. Thus, while these trading posts prospered and aided the general expansion of the empire of the Netherlands, no deep roots of permanent colonization were planted. The likely explanation for this lies in the general economic prosperity and social stability of the homeland. The Dutch citizens had no strong economic motivations to move overseas, nor were there sufficient religious quarrels at this time to promote such movement. When an English fleet sailed into New York harbour in 1664, Peter Stuyvesant, the governor, surrendered without a fight. Although controversy ensued for several years, the colony was clearly in English hands by 1669. It was renamed New York after the Duke of York.

Slowness of growth in colonial period

Despite this change in ownership and sovereignty, however, the colony did not develop rapidly. Like the Dutch, the English crown granted large tracts of land to private individuals. This system of landownership was not attractive to settlers such as the farmer-colonists who had settled New England, and agricultural development, particularly in the Hudson Valley, remained slight.

Further, the European war between France and England had its counterpart in North America. The French, established along the St. Lawrence and in Quebec, made many forays into northern and central New York. The relatively strong Five Nations federation of the Iroquois aligned itself with the English in New York and New England because of earlier French aid to the rival Algonkians. This warfare discouraged settlement beyond Albany. The military situation was brought to a conclusion by the Treaty of Paris in 1763, which confirmed English dominance of the New York region. A gradual but steady movement of settlers from New England began New York's population explosion. The New Englanders moved across the borders of Connecticut and Massachusetts, some remaining on the east bank of the Hudson, others passing through Albany to the interior.

In 1698 the colony's population was about 18,000, two-thirds of it in and around New York City. By the eve of the American Revolution, however, the numbers had grown to 163,000, and the concentration was nearly exactly reversed; but New York still ranked only seventh among the colonies. The cosmopolitan and heterogeneous character of its population was already well established. Dutch culture remained strong in New York City and Albany, while most of the settlements in the interior possessed—and possess to this day—a flavour and dialect of the New England Yankee, with the addition of several German communities. This emerging pattern of cultural

heterogeneity was to have a considerable impact on the politics of the state, as were the waves of immigration from Europe that followed the war and continued well into the 20th century.

Revolution, statehood, and growth. New York contains many of the battlegrounds of the American Revolution, suffering invasions from both north and east. The war in New York took on many of the characteristics of a civil war, since the state probably had a higher proportion of persons loyal to the crown than did any other.

After the war, a part of the state's political leadership aligned itself with like-minded leaders from other colonies to urge establishment of a strong central government for the new nation rather than the loose confederation then existing. New York delegates participated vigorously in the Constitutional Convention, one of the leaders of which was New Yorker Alexander Hamilton. Despite the role of Hamilton and other New York delegates in drafting the new document, the politics of ratification within the state legislature were intense and bitter; and New York was the 11th state to endorse the Constitution.

Improvements in transportation, and the movement westward

Both the American Revolution and the War of 1812 interrupted New York's expansion westward, but, thereafter, the movement began in earnest. Turnpikes spread westward from Albany and other points along the Hudson River, and settlers spread across the state. The opening of the Erie Canal in 1825 confirmed New York's position as the gateway to the west from the Atlantic Coast. Railroads followed in quick order and tended to follow the pattern of trade established by the turnpikes and the canal.

By 1800 New York state had become the second largest state in the Union, trailing only Virginia, and 10 years later it had surpassed all other states. Its leadership was not only in population, size, and growth but also in manufacturing, trade, and transportation—and in the increasing heterogeneity of its population.

Growth and change were reflected as well in the political and governmental history of the state. The original state constitution restricted the suffrage to property holders and established a governing system dominated by large property holders and leading commercial interests. The change in population composition, as well as shifting political attitudes in the nation, soon caused New York to move in a more democratic direction. In the 1830s, a vigorous campaign was launched against the system of landownership in the Hudson Valley, with renters eventually being given the opportunity to own the land they tilled. The constitutional convention of 1846 confirmed these democratic moves by expanding the suffrage and restricting the power of both legislature and governor.

Emergence of political divisions. Over the next century and more, New York grew in virtually every measurable dimension, but its political development centred on the increasing chasm of interest and affection between New York City and Upstate. The issue of "home rule," the demands of the city for total powers of self-government against claims that the city was the creature of the state, remained central to the conflict that continued into the 1970s.

As early as the 1780s, an organization eventually to be known as Tammany Hall was formed in the city to combat attempts by propertied Revolutionary leaders to limit the franchise in the new state. Largely middle class in membership, it did not extend its democratic principles to the lower classes or immigrants. By mid-19th century, however, through workers' and equal-rights parties, Irish politicians dominated the organization and the office of mayor, culminating in the control of the Democratic machine after 1868 by William "Boss" Tweed.

Well into the 20th century, the name Tammany was an international byword for municipal corruption at the highest levels. City–state antagonism was fuelled by Democratic domination in the city and Republican domination of areas Upstate and, in most years, of the statehouse and legislature as well. Investigations of Tammany Hall and city politics in general were highlighted by those of the Seabury Commission (1931–32), which brought about the resignation of Mayor James Walker and led to the reform administration of Fiorello H. La Guardia (1933–45) and the efforts of subsequent mayors to tread the line between Tammany's power in municipal elections and an image of political incorruptibility.

Much of Tammany Hall's power was based on its social services to the waves of immigrants that inundated New York City until changes in immigration laws slowed the tide in the 1920s. When state and federal government began to take over such services as social security, workmen's compensation, and unemployment, welfare, and health benefits, notably during the Depression of the 1930s, Tammany's hold began slowly to erode. By the 1970s the state and city remained in difficult confrontation no matter what the party of mayor and governor, though ironically home rule and increased state financial assistance had become joint demands. It seemed likely that the focus would remain on the need for the state to provide a growing proportion of services.

THE NATURAL AND HUMAN LANDSCAPE

Although to many non-New Yorkers—and actually to many residents of the New York City metropolitan area as well—New York state and New York City are synonymous, the state has a great range of geographical and climatic conditions. During at least part of the Ice Age New York was covered almost entirely by glaciers, the only exceptions being southern Long Island, all of Staten Island, and the far southeastern corner of the state.

Geological regions. The movement of the glaciers over long time periods left New York with nine distinct geological regions and, within these, 28 subregions. Each possesses its own landform, with distinctive geological structures and patterns of erosion. In the northeast, the Adirondack upland is characterized by the highest and most rugged mountains in the state, reaching 5,344 feet (1,629 metres) in Mt. Marcy and 5,114 feet (1,559 metres) in Algonquin Peak of Mt. McIntyre. Except for some forestry activities, the region is without economic value other than for recreation. A large part of it has been designated as a wilderness preserve by the state.

The St. Lawrence–Champlain Lowlands extend northeastward from Lake Ontario to the ocean along the boundary with Canada. Within this area are three subdivisions: the St. Lawrence marine plain, a flat to gently rolling strip along the St. Lawrence River; the St. Lawrence hills south of this plain; and, farther south, the Champlain Lake Plain.

The routes of settlement and commerce

Another region, the Hudson–Mohawk Lowland, follows the Hudson River from New York City to Albany then turns west along the Mohawk River. The Hudson Valley portion, between the Catskill Mountains on the west and the Taconic Range on the east, is from ten to 20 miles wide; the Mohawk Valley portion is ten to 30 miles wide. These routes provided easy access from both New York City and New England into the hinterland of the state and formed the natural paths for canal, railroad, and highway. Cutting natural pathways through the mountains of central and western New York, these rivers became the state's major avenues of commerce, serving first as the basis of the Erie Canal and later as the route of the New York Central Railroad and of the New York State (now Thomas E. Dewey) Thruway.

To the east of the Hudson River lies the New England Upland, extending eastward into Massachusetts and Connecticut and southward across the Lower Hudson Valley into Pennsylvania.

Two small regions complete the geologic picture in southeastern New York. The Atlantic Coastal Plain, which extends from Massachusetts to Florida, takes in Long Island and Staten Island. A small finger of the eastern Piedmont region juts up from New Jersey for some distance along the west bank of the Hudson.

The Appalachian Highlands

The largest region in New York, the Appalachian Highlands, occupies about one-half of the state, extending westward from the Hudson Valley to the state's southern and western boundaries. Located within it are the Catskill Mountains, the peaks of which reach 2,000 to 4,000 feet, the Finger Lakes hills area, and the Delaware Basin. The Catskills, with their mountains and lakes, are primarily a

recreation area. The Finger Lakes area also provides many opportunities for summer and winter sports, and its valleys provide excellent grasslands for dairying. The Delaware Basin, drained by the Delaware River, is a mixed-farming area.

Lying to the north of the Appalachian Upland and to the west of the Mohawk Valley and extending along the southern shores of the Great Lakes is a plateau-like region known as the Erie–Ontario Lowlands. It is composed of lake plains bordering the Great Lakes that extend between five and 30 miles inland from the lakes. Because of the moderating influence of the lakes on the weather, the region has become an important fruit-growing area. Finally, between the lake lowlands and the western reaches of the Adirondacks and north of Oneida Lake lies the Tug Hill Upland, which is one of the least settled parts of the state because of its poor soil and drainage and its severe climatic conditions.

Waters. Among New York's special geographical features are its two major shorelines: 127 miles bordering the Atlantic, 371 miles on Lakes Erie and Ontario. In addition, it has some 8,000 lakes and nine major rivers. The Hudson and Mohawk rivers have played the most significant roles in the state's history, but the Genesee and Oswego, flowing northward into Lake Ontario, also have been important. The Delaware, Susquehanna, and Allegheny drain the southern and western portions of the state and provide a large part of New York City's water supply. Connecting Long Island Sound with New York Bay and separating Long Island and Manhattan is the tidal estuary known as the East River. The most dramatic of the waterfalls that dot the state is Niagara Falls, a source of much hydroelectric power as well as one of the chief scenic attractions of the Northeast.

Climate. New York's climate proved a great disappointment to the early Dutch settlers. Since Manhattan was actually Mediterranean in latitude, it was rather bewildering to them to find that "it freezes and snows severely in winter." If Manhattan was uncomfortably cold and wet in the winter months, the rest of the state must have been an even greater disappointment.

The mean monthly temperature ranges from a high of 54° F (12.2° C) in New York City's Central Park to a low of 40° F (4.4° C) at Lake Placid in the Adirondacks. Average August temperatures range from 73° F (23° C) in New York City to 62° F (17° C) at Indian Lake in the Adirondacks; in February, from 33° F (0.5° C) on Long Isand to 14° F (−10° C) at Stillwater Reservoir in the Adirondacks. These figures represent the extremes, but substantial differences exist between New York City and Upstate Albany, Buffalo, Rochester, and Syracuse. A tendency to cloudiness across the state produces few completely clear days. New York City has about 100 such days during the average year, Syracuse and Buffalo have 72, Binghamton 68, and Albany 73.

The growing season also varies substantially: Long Island has the longest, with 200 days, while in the extreme north central region there are only 85. Rainfall and melted snow produce a range of precipitation from 32 to 45 inches a year, with the coastal plain receiving the greatest amount of precipitation, while the Erie–Ontario lowland receives the least. Nearly all parts of the state, however, receive sufficient rainfall for adequate crop growing, with the occasional exception being parts of the Erie–Ontario lowland. The Buffalo region receives an unusual amount of snow since it is on the eastern shore of Lake Erie.

The human regions. The cultural and social distinctions among various parts of New York state have tended to decline. Upstate cities, for example, are nearly as ethnically varied as New York City. Certain cultural and social characteristics brought by early settlers remain visible and, to some degree, still influence life-styles. During the Colonial period and for a number of years after the American Revolution, New England was a major source of immigrants; and traces of the New England influence are still present, particularly in the architecture and small-town planning of the north shore of Long Island and in northern Westchester County. The Dutch influence around Albany is now little more than place-names and street names, plus some preserved or rehabilitated Dutch architecture. German and Scottish settlers have left their mark in the Schoharie Valley; parts of the Hudson and Mohawk valleys (German); and in Orange and Ulster counties and in the Cherry Valley area (Scots).

Diversity of ethnic, national, and regional influences

The basic distinction between Upstate and Downstate is normally related to political differences—Upstate, conservative; Downstate, liberal. These political differences are matched by and interact with social ones. Downstate must be divided between New York City and the suburbs, and, within the city, differences among the boroughs are significant. Manhattan, although containing many low-income residents, is the centre for sophisticated life-styles and liberal politics, the home of the "limousine liberals." The outer boroughs are characterized by relatively stable ethnic neighbourhoods and "communities in transition," more conservative in social attitude but oriented to the Democratic Party. The suburbs are dominated by white middle- and high-income families living in detached houses, though in recent years the income spread in the suburbs has increased, and the inner suburbs are beginning to resemble the city's outer boroughs.

The rural Upstate areas must be distinguished from the Upstate cities and their suburbs. Rural New York remains conservative both politically and socially. The city regions vary from relatively sophisticated Rochester, with its heavy concentration of white-collar technical and managerial employees, to the more conservative Syracuse–central New York area. Buffalo, with its emphasis on heavy industry, has a large blue-collar population.

THE PEOPLE OF NEW YORK

The growth of the population. Since the Colonial period, much of New York's growth has resulted from immigration, both from other states and from abroad. Before the American Revolution, the Dutch, English, Scots, and Germans were the primary settlers, to be followed in the first half of the 19th century by New Englanders spreading across developing parts of Upstate and into Westchester and northern Long Island. The influx of European immigrants came first from the northern and central parts of the Continent, later from the southern countries.

Patterns of immigration

In the early 1970s, nearly one out of eight New Yorkers was foreign born, and 33 percent of the population was either foreign born or had one or both parents born abroad. The nations of origin of this stock are, in order, Italy, the Soviet Union, Poland, Germany, Ireland, the United Kingdom, and Canada, while nearly 1,000,000 persons are from a great diversity of other countries.

Related to this concentration of foreign origin is the state's religious composition. About one-third of the population is Roman Catholic, while 15 percent is Jewish.

The growth of the non-white portion of the population in the 20th century is of particular significance. The first large-scale influx of blacks from Southern states occurred during World War I, but it was small compared to that during and following World War II. In 1940, only 4.4 percent of the population was non-white, but by 1970 the percentage had increased to 12.9. The non-white population is concentrated in the state's metropolitan areas and, within those areas, in the central cities. In 1970 the non-white percentage reached 18 percent in the New York City metropolitan area, 29 percent in the city's borough of Manhattan. Other urban areas show smaller percentages, the Buffalo area, at 8.8, having the highest.

The non-whites

Another immigrant group that has had a significant impact on the economy and culture of New York since World War II is the Puerto Ricans. In 1970 over 870,000 Puerto Ricans resided in the state, over 90 percent of them in New York City. Following a heavy immigration of Puerto Ricans in the 1950s and early 1960s, the growing economic strength of Puerto Rico caused a considerable reduction, with those entering the state being largely offset by those returning to Puerto Rico.

Population concentration and movement. Overall, New York's population density in the early 1970s—380 people per square mile, compared to the national average of 58—is exceeded only by New Jersey, Rhode Island, Massachusetts, Connecticut, and Maryland. The distribu-

tion is uneven, with densities much higher in urban areas. In New York City, the density was 26,316; and for the entire New York City metropolitan area, 5,415.

The population of the state's seven metropolitan areas accounted for 87 percent of all New Yorkers, with 64 percent in the New York City metropolitan area. In line with national trends, most of the cities continued to lose population to surrounding suburban areas during the 1960s. The slight increase in New York City was concentrated in the outlying, suburb-like boroughs of Queens and Richmond (Staten Island), whereas both Manhattan and Brooklyn lost residents.

This shifting, far from being random, represents a sorting out of the population, with middle- and higher-income whites moving to the suburbs, leaving low-income groups and blacks within the central cities. Many economic activities, particularly manufacturing and headquarters of corporations, have moved to the suburbs as well. This movement of people and economic activity resulted in the urban crisis that was becoming familiar across the United States in the 1960s and 1970s: the increasing needs of the cities to combat crime and other symptoms of the poverty concentrated within them at the same time that their social and economic resources to do so were being removed. While the total economic strength of the metropolitan areas was growing rapidly, the cities were increasingly unable to participate in the prosperity and seemed likely to slip increasingly further behind.

THE STATE'S ECONOMY

New York's economy possesses characteristics similar to those of the other Northeastern states. The economies of other states—in the South, the Middle West, and the Far West—are growing more rapidly than the Northeast, but this more mature region still possesses great economic strength. New York has a complex network of nearly every form of transportation. Its resources of electrical power for domestic and commercial use are enormous, including conventional coal- and oil-burning plants, hydroelectricity from the Niagara region, and a small but growing nuclear source; however, at least 10,000,000,000 kilowatt-hours must be imported from other states.

Components of the economy. New York is represented in every economic category designated by the federal Bureau of the Census. In comparison to the rest of the United States, New York's economy has a disproportionately large share of the country's economy in the fields of wholesale–retail trade, finance–insurance–real estate, transportation–communications–public utilities, and services; it is under-represented in farming, mining, manufacturing, construction, and government. Even within these latter fields, it is over-represented in manufacturing, for example, in instruments production (three times the national average), wearing apparel, leather and leather products, and printing, publishing, and related industries.

Economic strengths and weaknesses

In spite of these strengths, New York, like the nation as a whole, has a declining proportion of its population engaged in manufacturing. In 1947, more than one-third of its employed population were in manufacturing, while by 1969 the figure had shrunk to about one-fourth. Between 1958 and 1970, actual manufacturing employment in New York increased only 1 percent, whereas the nation had a 25 percent growth. Thus, New York leads the nation in this fundamental economic change, which will find a decreasing portion of the nation's work force engaged in manufacturing. The growth sectors of the economy are nonmanufacturing ones. Employment increases in the 1960s came in finance–insurance–real estate, in services, and in government, approximately doubling wage and salary disbursements in these fields.

Areas of economic specialization. Some economic specialization exists within different parts of the state. Manufacturing, for example, is more highly concentrated in the Upstate metropolitan areas than in the New York City area, whereas such activities as services and finance–insurance–real estate are much larger in the New York City metropolitan area than Upstate. Further specialization exists among the Upstate areas. Buffalo is strong in heavy industry, while Rochester, with a national dominance in the manufacture of photographic and optical equipment, is primarily responsible for the state's strong position in instrument production.

Syracuse is substantially over-represented, relative to both the nation and the rest of New York, in the production of primary metals, machinery, and paper and allied products, as well as in educational employment. The Utica–Rome area specializes in machinery and transportation equipment, while the Albany–Troy–Schenectady area is strong in the field of paper and allied products. Albany, as the state capital, leads in government employment. The state's smallest metropolitan area, Binghamton, is the original site of the International Business Machine Corporation (IBM) and thus has a concentration of employment in the computer and business-machine field.

Incomes. In 1970, per capita income of New York workers was 22 percent above the national figure and about 13 percent above that in neighbouring North Atlantic states. The income growth rate increased significantly during the 1960s, no doubt a reflection of unusually high inflationary trends. This growth rate is about the same in the New York City area and Upstate; in both regions, personal incomes doubled between 1950 and 1970. Figures for 1950 and 1968 show also that the relative positions of the seven metropolitan areas in regard to percent share of the economy was virtually identical: in order, New York City, Buffalo, Rochester, Albany–Schenectady–Troy, Syracuse, Utica–Rome, and Binghamton. Nonmetropolitan areas accounted for about one-third of Upstate New York's economic incomes; just over 3 percent of income in such areas was from farms, in contrast to a figure of just over 0.5 percent statewide.

Economic management. The state plays both regulatory and promotional roles in the economy. The Public Service Commission controls the rates charged by the public utilities, and the Urban Development Corporation encourages the production of housing and other community facilities. The Department of Commerce aids in attracting new economic activity to the state, providing information and assistance to industries seeking to locate there, giving some financial support to local communities interested in developing industrial parks, and offering other incentives to encourage the location of new industries within such areas.

The state's role in the economy

New York tends to have somewhat lower unemployment rates during downturns in the national economy than does the rest of the nation, but it also recovers less rapidly. This behaviour results in large measure from the state's economic mix and its heavy dependence on nonmanufacturing activities.

New York has one of the most highly unionized work forces of any state. The most rapidly growing unionization is in the service sector, particularly among such government workers as teachers, sanitation men, police, and firemen. The nature of labour–management relations varies considerably from industry to industry, with workers in construction and the garment and apparel industries wielding great power. Nearly every session of the state legislature devotes attention to the field of labour relations, particularly public-sector employee relations, in which no satisfactory means of settling disputes has yet emerged. Simple "no-strike" statutes do not work, and the arbitration devices used thus far remain unsatisfactory to both workers and management.

As the country's economy shifts increasingly from manufacturing to nonmanufacturing, the strength of New York in service and related activities will continue to serve it well. Although definite economic problems exist in various parts of the state, primarily in its central cities, the overall economic outlook is good.

Transportation. Underlying the economic activity of New York state is its transportation system. New York's early economic advantages were themselves a product of its location relative to the country's natural transportation routes, and its current position remains heavily dependent on their continuing to tie together the centres of population within and without the state.

The Erie Canal, opened in 1825, tied New York City and its port to Buffalo and the westward-expanding na-

Waterways and railways

tion. The main railroad system followed the route of the canal, with feeder lines jutting north and south into the rest of the state. Following World War II, the limited-access Thomas E. Dewey Thruway stretched from New York to the Pennsylvania state line, passing through Albany, Utica, Syracuse, Rochester, and Buffalo. The basic paths of these main transportation routes are not substantially different from those trod by the state's original settlers.

With the completion in 1918 of the New York State Barge Canal System, which incorporated the old Erie Canal, New York had the country's most extensive inland-waterway system. Although still an important means for moving goods—particularly petroleum products, which provide nearly half the tonnage—the present annual tonnage carried on the system is a considerable drop from earlier decades.

The railways first challenged the supremacy of the canal. Beginning in the mid-19th century with the establishment of the New York Central Railroad, a system was built that tied New York's major cities to Chicago, Boston, Montreal, and other urban centres. Although declining in the number of passengers carried, the railroads remain important handlers of freight. Much of this freight originates at the Port of New York, still the largest port in the United States, handling in 1970 approximately 15 percent of all the nation's imports. Nearly one-half of all passengers to and from the United States pass through this port.

Highways

Central to the highway system are the limited-access highways. The Thruway connects at Albany to the Northway, which extends northward to Canada. In central New York, a major highway runs from the Pennsylvania state line to Canada, passing through Binghamton, Syracuse, and Watertown. At Syracuse, this route intersects with the Thruway, causing the city to remain a transportation hub and accounting, in large part, for its economic viability. Another limited-access expressway extends across the southern tier of the state. On Long Island a set of east–west highways ties the entire island to New York City, New England, and Upstate New York.

The most complex commuting system exists in the New York metropolitan area, with its combination of subways, buses, and railroads. The nearly 800-mile-long New York transit system provides intra-city passenger transport. Commuter railroads serve suburban Long Island, New Jersey, Connecticut, and Westchester County. Many of these transportation networks were brought under the control of a single agency, the New York Metropolitan Transportation Authority, in 1968.

In 1971, New York had 446 airfield facilities, including 20 major municipal airports. The three largest are in the New York City metropolitan area—John F. Kennedy International, La Guardia, and Newark (New Jersey)—with a combined total of nearly 14,000,000 passenger enplanements in 1970.

ADMINISTRATION AND SOCIAL CONDITIONS

Structure of government. New York's constitution prescribes the distribution of powers among the branches of state government as well as the system of local government throughout the state. As is the case in some other states, however, the document is excessively detailed, including provisions that most constitutional scholars consider more appropriately treated in legislative statutes than in a constitution. Because of this detail, articles tend to become outdated rapidly, requiring fairly frequent conventions for constitutional revision. Since the first convention in 1777, eight others have been held at roughly 20- to 25-year intervals, the last in 1967. The present document requires that the question of holding a convention be placed before the voters every 20 years.

The constitutional framework

Shifting constitutional forms. The first constitution established a bicameral legislature and provided for the first popularly elected governor in the United States, but it restricted the suffrage to male property holders. Veto power over legislation was vested in a Council of Revision, comprising the governor and justices of the Supreme Court, while the appointment of nearly all state and local officials lay with the Council of Appointment, comprising the governor and four senators. These councils represented an effort to avoid the autocratic rule that New Yorkers had experienced at the hands of the colonial governors appointed by the British crown. The convention of 1821 abolished the bodies, extended the franchise, and introduced a formal bill of rights.

The convention of 1846, influenced heavily by the populist spirit of Jacksonian democracy, imposed financial limitations on the legislature, which often had extended state credit to private ventures in such areas as railroad and canal building. Many state offices, including the judiciary, were made elective.

The constitution of 1894 remains New York's basic law today, but it has been amended more than 160 times. Its new provisions included a merit civil-service system, limitations on disposal of the state's forest preserve, a commitment to public education, and the first constitutional definition of state–local relations.

Earlier and later conventions produced documents that were rejected by the voters or sets of amendments reflecting the spirit of the times. If not accepted, such amendments often were introduced into law through legislation. The conventions of 1938 and 1967 were concerned primarily with social issues—of welfare, labour, and other rights during the Depression years, of aid to parochial schools and the solution of urban social and economic crises more recently. Whereas the voters accepted most of the 1938 amendments, they soundly rejected the 1967 document.

Contemporary executive, legislature, and judiciary. Emerging from these various constitutional revisions and amendments is a state government characterized by a strong governorship based on power over appointments and budget. The governor normally has the upper hand in contests with the legislature.

He is somewhat restricted in his executive authority, however, by a number of independently appointed or elected officials. The Board of Regents, for example, which presides over the education establishment of the state, is appointed by the legislature. An independently elected comptroller acts as auditor for both state and local governments.

The legislature, found recently by an independent analysis of legislative structure and process to be the second most effective in the country, comprises a Senate of 58 members and an Assembly of 150. Each house has standing committees concerned with broad issues of public policy. Several committees composed of both senators and assemblymen study specific policy issues and make recommendations to the legislature. The state also uses numerous nonlegislative commissions—appointed by the governor, by the legislature, or by both—to investigate such problems as education-aid formulas, state–local relations, the judicial process, welfare administration, and basic governmental organization.

Legislative and paralegislative committees

For judicial purposes, New York is divided into 14 districts. Called the Supreme Court, each district has several elected judges. Four judicial departments act as appeal divisions from the Supreme and inferior courts. The highest court is the Court of Appeals. The governor appoints the judges to the appellate departments from those elected to the Supreme Court, while those serving on the Court of Appeals are elected for 14-year terms. At the state level, the Court of Claims hears cases against the state. A variety of local bodies functions, including county courts and the court system of New York City. Other local courts include family and surrogate courts.

Local government. Much legislative debate revolves around the allocation of state aid to local jurisdictions. The constitution has contained a home-rule provision since 1896, but court interpretations of the provision, which gives the state the power to act in any matter in which there is a state concern, have tended to weaken the home-rule concept and continue Albany's domination of local governments. Moreover, the increasing interdependence of the state and its parts caused by metropolitanization and industrialization inevitably has reduced the autonomy of local jurisdictions.

Local jurisdictions consist of five types of governments; counties (62), towns (well over 900), villages (over 550), cities (62), and special districts (almost 1,000). The entire state is covered by county jurisdictions, which are divided into towns. Urban areas may be incorporated as either cities or villages. When it incorporates as a city, the town jurisdiction is eliminated, but villages remain a part of the town in which they are located and residents pay town as well as village taxes.

Unlike states in which either town or county government is weak, New York has strong jurisdictions of both types. This situation often leads to considerable overlapping in the provision of governmental services outside of cities. Special districts include those for schools (encompassing the entire state) and such urban services as sewers, water, and streetlighting. The largest regional district is the Port of New York Authority, which operates bridges, harbours, and related facilities throughout the New York City metropolitan area, including those in northern New Jersey.

The decision of the United States Supreme Court in 1965 requiring legislative districts to be roughly equal in population brought new life into New York's county government, since town supervisors were no longer able to have dual responsibility as county supervisors as well. Many counties, including the most urban outside New York City, have opted for single-executive systems.

Cities and villages generally are governed by a mayor and a council, with only a few cities, the largest being Rochester, using the city-manager plan. Some of the larger cities have a second legislative body, often called the Board of Estimate. In New York City, the mayor, the president of the City Council, the comptroller, and the five borough presidents serve on this body. In other cities, membership usually includes the mayor, the president of the city council, and one or more high-ranking fiscal officers.

State financial aid to local governments

The state–local governing system of New York places heavy responsibilities on local governments. To help them function, more than one-half of the state budget consists of aid to local government. Nearly one-half of this is for public schools; other major aid categories include welfare, health, highways, and housing and urban renewal.

Current debate indicates that the state will soon be playing a larger and perhaps exclusive role in financing education, perhaps using a statewide property tax for part of the revenue. If the federal government assumes a much larger share in financing welfare, the local governments in New York will become concerned primarily with providing only traditional municipal services. Such changes would go far toward solving the severe financial pressures now felt by the state's major cities.

Taxation. To finance such services, New York's relatively healthy economic base provides the source of the highest per capita taxation in the United States. In fiscal 1970–71 the figure for state and local taxes was $689, compared to second-place Hawaii's $614 and the national average of $460. State impositions include income, sales, business, and excise taxes; local revenues are derived mainly from property and sales taxes. New York City is the sole local jurisdiction imposing an income tax. The broad state base plus the widespread use of local sales taxes allows New York to rely less on local property taxes than do such other large or heavily populated states as California, Massachusetts, and New Jersey.

Political life. The political struggles between Upstate and New York City cannot be reduced entirely to a matter of Democratic-Republican hostility. New York City's politics has been characterized until recently by strong Democratic (Tammany) leaders of the city's five counties, especially New York (Manhattan) and Bronx counties, but the leaders of these organizations often had as much difficulty dealing with Democratic governors in Albany as with Republican ones. The Republican Party, generally controlling the state legislature, if not the governorship, remained strongly conservative until its traditional leadership was threatened around 1900 by Theodore Roosevelt and Charles Evans Hughes.

The four major political parties in state politics

Although both the Democrats and Republicans have strong statewide party organizations, New York is one of the few states in which third and fourth parties have thrived and often played significant roles in elections. Originally confined to New York City, where the Liberal Party has at times endorsed Republican candidates and in 1969 slated and won re-election for Mayor John Lindsay after he was rejected by his former Republican sponsors, the splinter movement produced in the 1960s the statewide Conservative Party, which in 1970 saw its candidate elected to the U.S. Senate.

Since 1920 the governorship has been about equally divided between Democrats and Republicans. In contrast, both houses of the legislature have been almost consistently Republican since 1940. Political behaviour is characterized by generally effective party discipline in the legislature and strong leadership by the governor. The most bitter clashes have been between the two strongest political figures in the state, the governor and the mayor of New York City. Even when they have been of the same party, the conflicting necessities of the state and of the metropolis, usually financial, have brought the two into strident confrontation.

Education. New York spends more money per pupil for public elementary and secondary education than any other state. This public-school system, with compulsory schooling between the ages of seven and 16, had its beginnings in the Colonial period. Schools were established by churches with government support as early as 1638 in New Amsterdam. It was not until 1791, however, that the state's first public school was established. Some state support was granted in 1795 to elementary schools, and in 1812 a permanent system of public schools was established. Parent-paid fees provided a part of the support, however, until all elementary schools became free in 1867. Public secondary schools came even later. During the 1850s a few cities established such schools, and, during the second half of the 19th century, they spread across the state.

The Board of Regents

The University of the State of New York was established in 1784 and its governance placed under a Board of Regents. All private and public institutions of higher education were included in this general organization. In 1904 the legislature placed the entire educational system under the Board of Regents. This board governs all educational activities in the state. It selects the state commissioner of education, approves the establishment of new colleges, licenses entry into the professions, approves new degree programs, and advises the legislature on all educational issues. Standardized exams used in all secondary schools are called regents' exams. Scores on these exams provide a measure for determining school performance and form the basis for the awarding of a wide range of scholarships.

In 1948 the several public institutions of higher education, primarily teachers colleges and two-year agricultural and technical institutions, plus newly established ones, were incorporated into the State University of New York, an institution distinct from the University of the State of New York but a part of that larger entity. Until the creation of the State University, private institutions dominated higher education. Although private institutions still enroll a higher proportion of college students than in most other states, the state system has been the most rapidly growing public institution of higher education in the country since its founding.

The state-university system comprises four general types of institution. Major university centres are located at Stony Brook, Albany, Binghamton, and Buffalo. The teachers colleges and some new campuses have become general colleges concentrating on undergraduate education but providing some graduate training. Two-year state institutions and community colleges are supported in about equal parts by the state, the county, and student fees. Independent but supported by the state and by New York City, City University of New York provides a great variety of programs, ranging from two-year community colleges to graduate instruction.

Operating alongside this dual public system are over 120

Private colleges and universities

private colleges and universities ranging in size from a few hundred students to the 42,000 at New York University. Included in this group are some of the country's best known. Columbia University, founded in 1754 as King's College, is known for the high quality of its graduate instruction and for the national influence of its teachers' college. Cornell, the base for the agriculture, home-economics, veterinary-medicine, and industrial- and labour-relations units of the State University, is a member of the Ivy League, as is Columbia. Fordham is perhaps the best known of the state's many Catholic colleges and universities. The University of Rochester, known for its pioneering role in music and the natural sciences, and Syracuse University, home of the Maxwell Graduate School, the first university unit established for training students for public service, are also well-known private institutions. Other high-ranked institutions include Colgate, Hamilton, Union, St. Lawrence, Bard, Skidmore, Barnard, and Vassar.

Educational issues dominate much of the public debate in the state: public support of parochial schools, state aid to elementary and secondary schools, establishment of tuition at City University of New York, the relation between the state and city universities, and public support for private higher education.

CULTURAL LIFE AND INSTITUTIONS

The milieu of New York City. Much of the style and tone of life in the United States is set in New York City, which remains the artistic, cultural, and economic capital of the nation. The fashion industry is headquartered in its garment district; the chief live theatre in the country exists on and off Broadway; and many television programs originate in New York, where the three major networks have their home offices. The city's museums—particularly the Metropolitan Museum of Art, the Museum of Modern Art, and the American Museum of Natural History—set the pace for similar institutions across the land, and more and more motion pictures are being filmed on its streets.

Many major publishing houses, too, have their headquarters in New York, as do a large number of national magazines. Serving their needs and those of the central offices of many of the country's largest corporations are banks, public-relations and advertising firms, management consultants, and legal firms. This concentration of business and culture gives New York City its leading national position in so many aspects of U.S. life. These features are covered in greater detail in the article NEW YORK (CITY).

Regional museums and institutions

The arts elsewhere in the state. Cultural and related activities are not confined to New York City. Many art museums are located in the state's large and small cities. Among them, the Albright-Knox Art Gallery, in Buffalo, has outstanding collections of contemporary paintings and sculptures. In Rochester are the Memorial Art Gallery, the Rochester Museum of Arts and Sciences, and the George Eastman House of Photography, the last devoted to the history of photography. The Everson Museum of Art in Syracuse is considered an outstanding example of modern architecture, while the city's Canal Museum is the only museum in the U.S. devoted to canal history. Outstanding symphony orchestras include those of Buffalo and Rochester, while the Eastman School of Music at Rochester is internationally known. Fine architectural specimens are scattered across the state, and the performing arts are actively pursued by professional and amateur groups. The cultural and artistic life of the state's many college and university towns often is centred on these institutions, notably in departments of art, music, theatre, and the like.

Across the state, numerous artistic and cultural activities are presented throughout the year. The Saratoga Performing Arts Center in Saratoga Springs is the summer home of the Philadelphia Orchestra and the New York City Ballet. Theatrical performances also are held at this modern cultural centre. The Chautauqua Institution, located on Chautauqua Lake in southwestern New York, was founded in 1874 as a training school for Sunday-school teachers. The name Chautauqua has since been adopted to include a wide range of cultural and educational activities, including concerts, opera, drama, and lectures. Other music and art festivals are the Adirondack Chamber Music Festival at Schroon Lake, the Signal Hill Festival of Music and Dance at Lake Placid, and the Lake George Opera Festival at Glens Falls.

Cooperstown, founded by the father of James Fenimore Cooper (who used the central New York area as the locale for many of his novels) and known as the village of museums, has six, the best known of which is the National Baseball Hall of Fame and Museum. At Hill Cumorah near Palmyra, an annual pageant depicts the founding of the Mormon Church. Also located in this region are the Finger Lakes Wine Museum and the Glass Center in Corning. Dotting the state are historic homes, forts, and battlefields. Over one-third of all the battles of the American Revolution were fought in New York, including the decisive Battle of Saratoga.

Many of these activities have been encouraged in recent years, as New York became the first state in the Union to establish a program for continuing financial support of the arts. The Council on the Arts, which administers the program, had a 1970–71 budget of $18,000,000 for funding to organizations in the fields of the performing arts, visual arts, film and media, and special programs.

Recreation and tourism. The variety of New York's geography provides not only areas of great beauty but also vast opportunities for recreation, relaxation, and a study of the past across the entire state. The cool summers of the Adirondacks, the snowy slopes of the Catskills, the beaches of ocean and lakes, and an almost unlimited repertory of water sports give New York a recreational base certainly as broad as any state in the nation and as yet only partially exploited.

PROSPECTS

New York, now second to California in population, still leads the United States in many fields. The cultural centre of the nation, the headquarters for much of the nation's business community, and the national leader in the move from a manufacturing to service economy, the state has a generally bright future. Problems remain, however. Troubled by urban unrest and with a distribution of resources not matched to needs, the state soon must reorganize its system of local government. At the same time, it faces the prospect that its already high taxes, in the search for a more equitable balance of needs and resources, will probably continue to climb.

BIBLIOGRAPHY. Many state agencies publish annual reports in many areas, but the 16 volumes of the NEW YORK TEMPORARY STATE COMMISSION ON THE CONSTITUTIONAL CONVENTION, *Reports* (1967), are especially valuable. Other general works include the New York State, *Red Book* (annual); the FEDERAL WRITERS' PROJECT, *New York: A Guide to the Empire State* (1940); R.J. RAYBACK (ed.), *Richards Atlas of New York State* (1959); and JOHN H. THOMPSON (ed.), *Geography of New York State* (1966).

Historical works include D.M. ELLIS *et al.*, *A History of New York State*, rev. ed. (1967), containing a large annotated bibliography, and *New York: The Empire State*, 3rd ed. (1969). A host of books cover special aspects of the state's history, among them OSCAR HANDLIN, *Al Smith and His America* (1958); WILLIAM RITCHIE, *The Archaeology of New York State* (1965), which is lavishly illustrated; H.W. HERTZBERG, *The Great Tree and the Longhouse: The Culture of the Iroquois* (1966), one of many works on New York's Indians; LIONEL D. WYLD, *Low Bridge! Folklore and the Erie Canal* (1962); and CARL L. CARMER, *The Tavern Lamps Are Burning: Literary Journeys Through Six Regions and Four Centuries of New York State* (1964); and H.W. THOMPSON, *Body, Boots and Britches* (1940), among many works on folklore and related topics.

For state government, see L.K. CALDWELL, *The Government and Administration of New York* (1954); and ROBERT RIENOW, *Our State and Local Government*, rev. ed. (1965).

(A.K.Ca.)

New York (City)

The most populous metropolis of the Western Hemisphere, New York is, depending on one's point of view,

The four faces of the city

any one of four cities: to social scientists it is a laboratory in which to study the challenges of urban life, from ghastly slum to tycoon luxury; to tourists it is a city of jostling crowds, horn-honking traffic jams, dirty streets, smelly subways—all in dramatic contast to such international symbols as the skyscraper skyline, the United Nations buildings, Wall Street, the Statue of Liberty, the Metropolitan Museum of Art, Times Square, and Broadway theatres; to commuters it is an enervating beehive of world trade and finance, mass media, business administration, fashion, and assorted entrepreneurial activities and manufacture—a place to leave as soon as possible in the evening for the more serene atmosphere of greener suburbia.

But to the nearly 8,000,000 persons who live in this temperate, humid city, most of it raised up on the islands where the Hudson River empties into the Atlantic Ocean, New York is in reality a collection of many neighbourhoods scattered among the city's five boroughs—Manhattan, Brooklyn, the Bronx, Queens, and Richmond (Staten Island)—each ranging in size from a few thousand to more than 100,000 persons and exhibiting its own lifestyle. To move from one neighbourhood to another in the city's 320 square miles (830 square kilometres) may be like passing from one country to another. Such clichés as "New York is not the United States" or "It's a great place to visit, but I wouldn't want to live there" were probably coined by commentators unaware of the importance of this neighbourly aspect of what Walt Whitman called "the hurrying feverish, electric crowds."

This article is divided into the following sections:

For information on related topics, see the articles UNITED STATES OF AMERICA and NEW YORK (STATE).

I. Character and growth of the metropolis

New York has often been called ungovernable, and predictions of its approaching death date back into the 19th century. The prophecies of doom have become increasingly frequent since the late 1960s, as important businesses have left the Empire City for the suburbs; street crimes have multiplied in what the city's press agents have dubbed Fun City; and public services have deteriorated, jobs declined, and the fiscal plight become perilous in the city that displays a beaver, once a symbol of wealth, on its municipal seal.

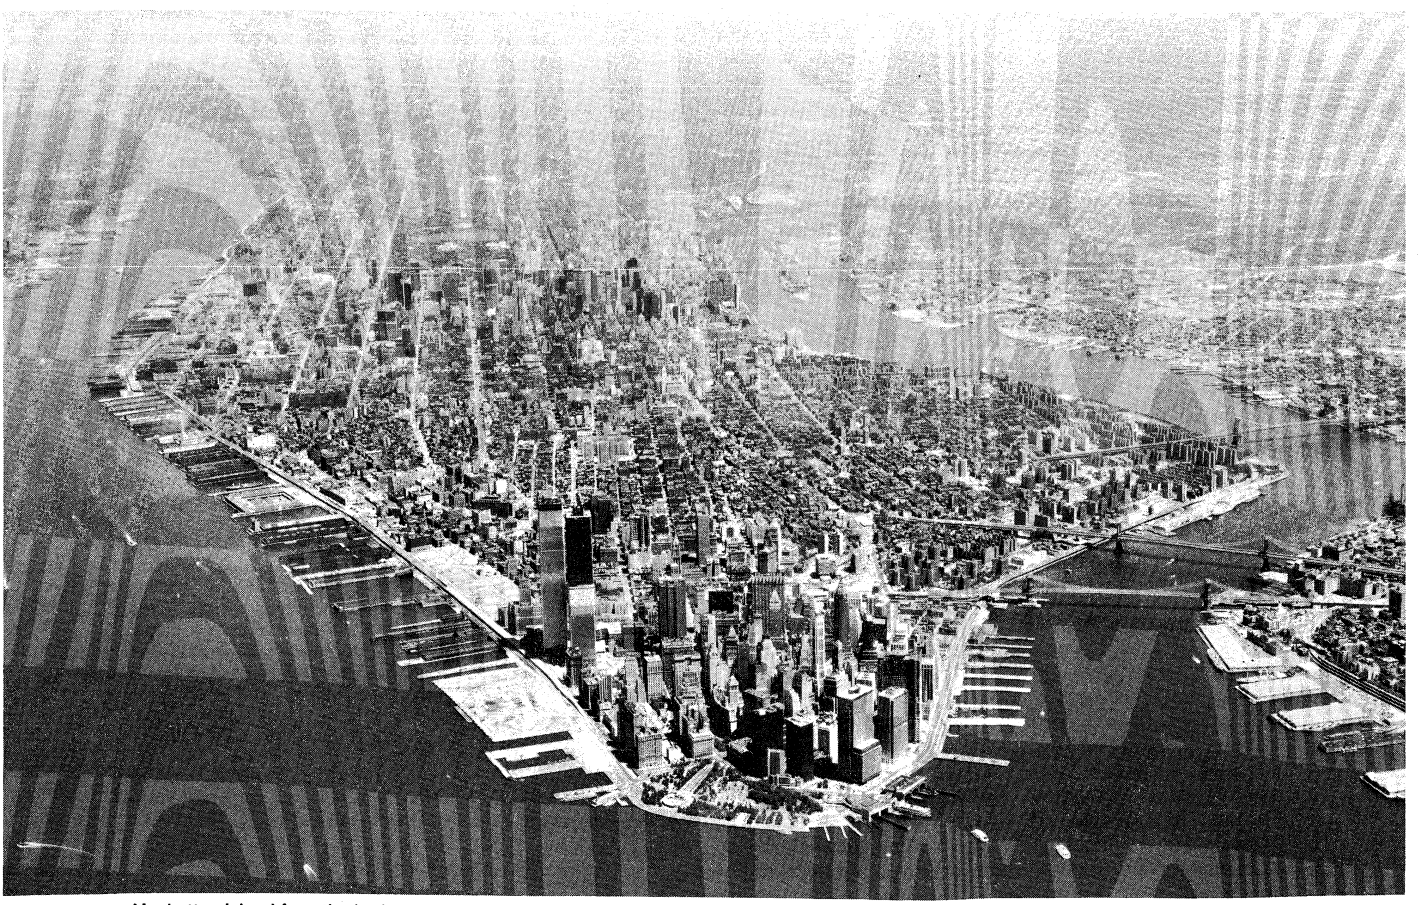
THE PROLIFERATION OF CRISIS

After spending about half of the 20th century reshaping New York with parks, highways, bridges, tunnels, and housing projects, one agency head reflected in his retirement on the difficulty of labelling the city.

> The best of the original Gotham recorders, the O. Henrys, Ring Lardners, Damon Runyons of bygone days, gave us sidelights, vignettes and what in painting is called genre, but it was only a quarter, a corner, phase or facet, certainly not the essence.

The novelist James Fenimore Cooper had sensed this a century earlier, when he wrote: "New York is essentially national in interest, position, pursuits. No one thinks of the place as belonging to a particular state, but to the United States." Periodically, thousands of New Yorkers and sometimes even their mayors, obsessed with the unique character of their fabulous city, have argued that

Thomas Airviews



Manhattan Island from the harbour; on the left is the Hudson River and on the right is the East River. New York's financial district and Battery Park are in the centre foreground. Central Park is at upper centre.

it ought to break away from New York state and set itself up as a separate state of the Union.

Centralization and decentralization. Since the 1960s, two basic thrusts in city government have been in conflict in New York City. Some say that at issue is the very survival of the city or of any huge city. Others contend that the city is going through another of its major transitions from which ultimately it will bring about a blend of the two approaches into a formula for a livable megalopolis. The argument, then, is between advocates of centralization and decentralization.

For more than three decades, beginning with the 1930s, reformers and other opponents of "machine politics" were generally successful in New York City in advancing centralization. The powers of the presidents of the five boroughs were greatly reduced and shifted to the mayor and his appointees. Such operations as education, health, sanitation, parks, recreation, sewers, and roads were directed almost entirely from ever larger central bureaus, almost always in Manhattan. Centralization, its supporters insisted, brought greater efficiency by eliminating replicated layers of bureaucracy in the boroughs and by dropping useless jobs created in those boroughs by district politicians.

During the administration of Mayor John Lindsay, beginning in 1966, the voices of decentralization became steadily stronger. The decentralists said that centralization had isolated the city government on pinnacles too far removed from the people and their problems.

The borough presidents called for the return of their powers so that they could start doing a better job of getting garbage collected, potholes in the streets filled, parks maintained. Sixty-two community-planning boards, their members appointed by the borough presidents, became more active and influential. This was as true in affluent Riverdale, in the Bronx, where beautiful homes and expensive apartment houses overlook the Hudson River, as in the slum of the Brownsville section of Brooklyn, in which burned-out tenements were falling down around newer low-income housing projects. Proposals advanced by the mayor and his City Planning Commission were delayed and sometimes blocked entirely by the pressure of the community-planning boards.

Resurgence of community self-determination

The communities assumed more power in all sorts of activities: picking principals of schools in Harlem, preventing construction of a department store in Manhattan's West Side, saving homes planned for demolition for a high school in the middle class Corona section of Queens, clearing welfare cases out of hotels in Greenwich Village or Brooklyn Heights. Community groups became the watchdogs of city operations on the basic level, pointing out where a police station was undermanned, a traffic light was essential, a hospital was in disrepair, fire equipment was antiquated. The neighbourhood newspaper, almost extinct, was reborn in many parts of the city.

Centralists claimed that the life of the city was being strangled by the whims of community leaders. Decentralists retorted that without healthy communities there could be no healthy city.

The community groups were cemented by fear—the fear of muggers and burglars. Like other large cities, New York was afflicted with many street crimes during the 1960s and 1970s, some of them sadistic. Since New York was the main point of entry and the major marketplace for smuggled narcotics, it became the nation's chief gathering place for drug addicts. Much of the street crime and burglaries were perpetrated by addicts.

Few areas were free of street crime. In the slums, iron fences were fixed inside windows that opened on fire escapes. Double and triple locks, often with bars that fitted from the door into the floor, were used in many apartments in middle class neighbourhoods. And the rich, despite round-the-clock doormen, often installed elaborate burglar systems in the luxury apartments that they owned and for which they paid $1,000 a month for maintenance alone. Purse snatching near supermarkets became so frequent that women stopped carrying handbags or bound the leather straps of the bags around their wrists. Parks and playgrounds became nocturnal hangouts for addicts and pushers. Dogs were bought more for protection than as pets. Skyscraper office buildings hired private police forces and iron gates were drawn across stores at night. Neighbourhoods organized their own volunteer auxiliary police details to patrol at night in cars equipped with two-way radios. Subways, the key arteries of the city, had their own police force.

Historic antecedents of contemporary crises. The growing strength of neighbourhood groups and the fears that bound them were manifestations of an older problem revived. At the core of nearly all of the city's crises—and of its triumphs—have been the masses of impoverished migrants who sailed into its beautiful harbour or spilled out upon its mammoth bus, train, and airplane terminals, their belongings in cardboard cartons, battered suitcases, knotted sheets and pillow cases. Writer and editor E.B. White described New Yorkers as "to a large extent strangers who have pulled up stakes somewhere and come to town, seeking sanctuary or fulfillment or some greater or lesser grail." The migrants, in search of security, prosperity, political power, set up the city's neighbourhoods—its Harlem, Little Italy, Chinatown, Greenwich Village, and scores of communities of tenements, apartment houses, and private homes. They gave the city a variety of flavours ranging from cuisine to speech.

Ethnic diversity and conflict

As far back as 1643, a Catholic missionary, walking the dirt streets of the fledgling Dutch community at the southern tip of Manhattan Island, was astonished to hear 18 languages. In 1870 the census of the turbulent city—it was still limited to Manhattan—showed that of nearly 1,000,000 residents, more than 400,000 were foreign born. In 1920, with the population above 5,600,000, the foreign born totalled just under 2,000,000 and the number of Negroes more than 150,000.

With the sharp curtailment of immigration by federal law in 1921 and 1924, the city entered a period of increasing stability, in spite of the violence of Prohibition, political scandals, the Depression, and World War II. Many of the immigrants and their children prospered and moved from the slums to middle or upper class neighbourhoods. The city was safe enough that New Yorkers during the 1920s, 1930s, and 1940s often slept in the parks or on the beaches on stifling summer nights. In the slums, residents kept their doors open for ventilation, and, in many sections of the city, residents did not lock their doors.

In the 1950s and 1960s, hundreds of thousands of new migrants arrived. The City Planning Commission has estimated that the combined population of blacks and Puerto Ricans in that period rose from 1,000,000 to about 2,300,000. The 1970 census, which counted over 7,900,000 residents and which was probably an undercount, revealed that during the 1960s the city's white population declined by 592,000 and its nonwhites increased by 705,000. Like the migrant waves before them—the Germans and Irish in the 19th century and the Italians and Jews from eastern Europe in the early 20th century—the arrival of these new minorities was followed by the usual disruptions.

Continuities in civic life. That the city has survived more than 130 years of slums, riots, epidemics, crime waves, and corruption, touched off by the many instabilities resulting from waves of immigration, plus vicious commercial competition is a tribute to its adaptability, basic democracy, and the priority given to the art of making a living—a mixture that has produced demagogues and knaves as easily as it has idealists and statesmen. In *Beyond the Melting Pot,* sociologists Nathan Glazer and Daniel Patrick Moynihan observed that "New York became the first great city in history to be ruled by men of the people, not as an isolated phenomenon of the Gracchi or Commune, but as a persisting, established pattern." But, looking upon the same municipal turmoil, the critic Lewis Mumford asserted that "purposeless materialism became the essential principle of the city's life."

THE HISTORY OF NEW YORK

Although the Italian explorer Giovanni da Verrazano spotted the site of New York City in 1524, it is the

English navigator Henry Hudson who is treated as the city's discoverer. On September 3, 1609, he sailed into its harbour and up the deep tidal river that now bears his name in a vain quest for a passage to India on behalf of the Dutch West India Company. Hudson's reports to his employers about the magnificent harbour, sheltered by green hills and limitless potential farmland at a seemingly semitropical degree of latitude, were responsible for the Dutch settlement that set the pattern for the city's drive and independence, a spirit that endured when only corrupted Dutch names remained to remind New Yorkers that it was the Dutch who had founded their city.

The colonizers. In 1614, six years before the Pilgrims landed on Plymouth Rock, a Dutch skipper and his crew were forced to spend a winter on Manhattan Island because their ship had burned; they built there a new seagoing vessel and, prophetically, named the 18-ton ship "Restless." In 1626, Peter Minuit, director general of the Dutch province of New Netherland, which included not only all of what has since become New York City but which also extended into what is now Connecticut, New Jersey, and Long Island, purchased Manhattan from the Indians for 60 guilders worth of gewgaws, the equivalent of $24. On February 2, 1653, New Amsterdam, capital of the province, became a city; its population was 800.

Extent of the Dutch colony

The Dutch West India Company refused to sell land in Manhattan until 1638, but early settlers found ample farmland. They also found out that much of the island was underlain by extremely hard rock and that in the southern portion were substantial stretches of marsh, as well as ponds and creeks. They learned to drain and fill swampy areas and to create land along the riverfronts by dumping refuse. Much of what was to become the borough of the Bronx was rocky ridge. The portion of Long Island that became Brooklyn and Queens was flatter and better suited to farming, though often stony and sandy in consistency. The section that became Staten Island was hilly, with a maximum altitude of 409 feet (125 metres), the highest point in the city.

The Dutch opened the city to foreign commerce, set up trade with the Indians, and laid out the roads that were to become major streets of downtown Manhattan. After a number of bloody clashes with the Indians between 1643 and 1655, interspersed with uncertain truces, the Dutch established the dominance of whites on the island and much of the nearby areas that became part of New York City.

The English city. Dutch supremacy ended on September 8, 1664, when a fleet sent by the Duke of York as part of the English–Dutch war in Europe seized the city easily, since the Dutch were not too fond of their stern ruler, Peter Stuyvesant. The English changed the name to New York. There was a short interruption of English rule in 1673, when a surprise invasion from the Netherlands was successful; the name was changed to New Orange, in honour of the Prince of Orange. But, the following year, in accordance with the Treaty of Westminster between England and the Netherlands, the city reverted to English rule and name. In 1686 New York became the first city in the colonies to receive a royal charter.

Since the Dutch and English got along well in Manhattan, the changes in political office did not interfere greatly with life and trade. English as well as Dutch settlers were agreed that representatives of the British crown were too autocratic. Between 1689 and 1691, Jacob Leisler, preaching rebellion in the city, tried to organize an expedition to attack Canada. He was hanged and beheaded in 1691, but resentment was so strong in the city that the British Parliament cleared his name.

Thus, long before the Revolution, the city had established a strong sense of independence, allied with a business acumen and raffishness that it never lost. Pirates made the city their hangout in the 17th century, and the notorious Capt. William Kidd was regarded as one of the city's leading citizens. He donated the block and tackle with which historic Trinity Church was first built. Merchants helped outfit pirates and shared in their booty.

It was in New York that the first great test of journalistic independence was won and the base of the nation's freedom of the press established in 1734, when John Peter Zenger, publisher and editor of the *New York Weekly-Journal,* charged with libel and jailed for making strong attacks on the government, fought the case and was acquitted in 1735. The first bloodshed in the struggle for independence is believed to have occurred in New York. On January 18, 1775, the Sons of Liberty, a patriotic group, clashed with British soldiers; one of the Sons was killed, and several were wounded.

Precursors of rebellion

Revolution and growth to world status. New York, which was occupied and almost destroyed during the Revolution, became the first capital of the nation (1789–90). George Washington was inaugurated as first president in the city on April 30, 1789. The first session of the state legislature was held there in 1784, and it remained the state capital until 1796. By 1790, with a population of 33,000, it had become the largest city in the nation; by the turn of the century, the population had passed 60,000.

The opening of the Erie Canal in 1825, connecting New York with Buffalo, the Great Lakes, and the opening West, guaranteed the city's pre-eminence as a seaport and world entrepreneur in commerce. When the immigrant waves swept ashore in the city in the 1840s, vast pools of cheap labour, skilled and unskilled, fuelled a new era of rapid growth and social turbulence.

One of the chief beneficiaries of this development was the local Democratic organization known as Tammany Hall. Incorporated in 1789, mainly for social and patriotic activities, Tammany developed political strength under Aaron Burr toward the end of the century and became an important political force after backing Andrew Jackson in his two victorious presidential campaigns (1828 and 1832). With success, Tammany, which had fought for wider suffrage, came under the domination of conservative elements for a time; but with the floods of immigrants in the 1840s, it directed strong appeals to them and built on their votes a massive power base that lasted for nearly a century, making it a national symbol of political bossism. Though Tammany became synonymous with corruption, it also served the vital function of opening up political opportunities to the immigrant poor.

During the Civil War, the city was shaken by its worst riots. For five days in July 1863, many thousands of rioters, mostly impoverished Irish immigrants, infuriated by the new draft law that permitted a draftee to buy his way out of service for $300, swept the city, looting, burning, and killing. Negroes were hanged from streetlights and trees. Warships trained guns on the city as they clashed repeatedly with the police, national guardsmen, and the army. At least 2,000 persons were killed and 8,000 wounded, and all business halted in the face of the armed conflict.

After the Civil War there was a steady clamour in the city for a merger with Brooklyn, Queens, the Bronx, and Staten Island. The strongest resistance was from Brooklyn, a city in its own right, which with good reason feared that the enormous corruption so evident in Tammany Hall under the political bosses William Marcy Tweed and Richard Croker would be extended to Brooklyn through any consolidation. With the opening of the Brooklyn Bridge connecting Brooklyn and Manhattan in 1883, the merger became inevitable. It took place on January 1, 1898, with Manhattan, the smallest of the five boroughs in size, becoming the most powerful. The birth of Greater New York represented a change from city to metropolis, from national to world stature.

Problems of consolidation

The transition to world metropolis in the first two decades of the 20th century was powered by the arrival of millions more immigrants from Italy and eastern Europe. This huge pool of cheap—and often skilled—labour tied together the sprawling city with networks of bridges, tunnels, elevated and subway systems; created its famous garment industry; boomed its printing trades and small manufacturing; drew entrepreneurs from around the world; and made the city a laboratory for unionism and radicalism. During the first decades of the century, the public education system turned out armies of

New York City Metropolitan Area.

extremely efficient white-collar and civil-service workers for the city's increasingly complex but booming economy.

II. The contemporary city

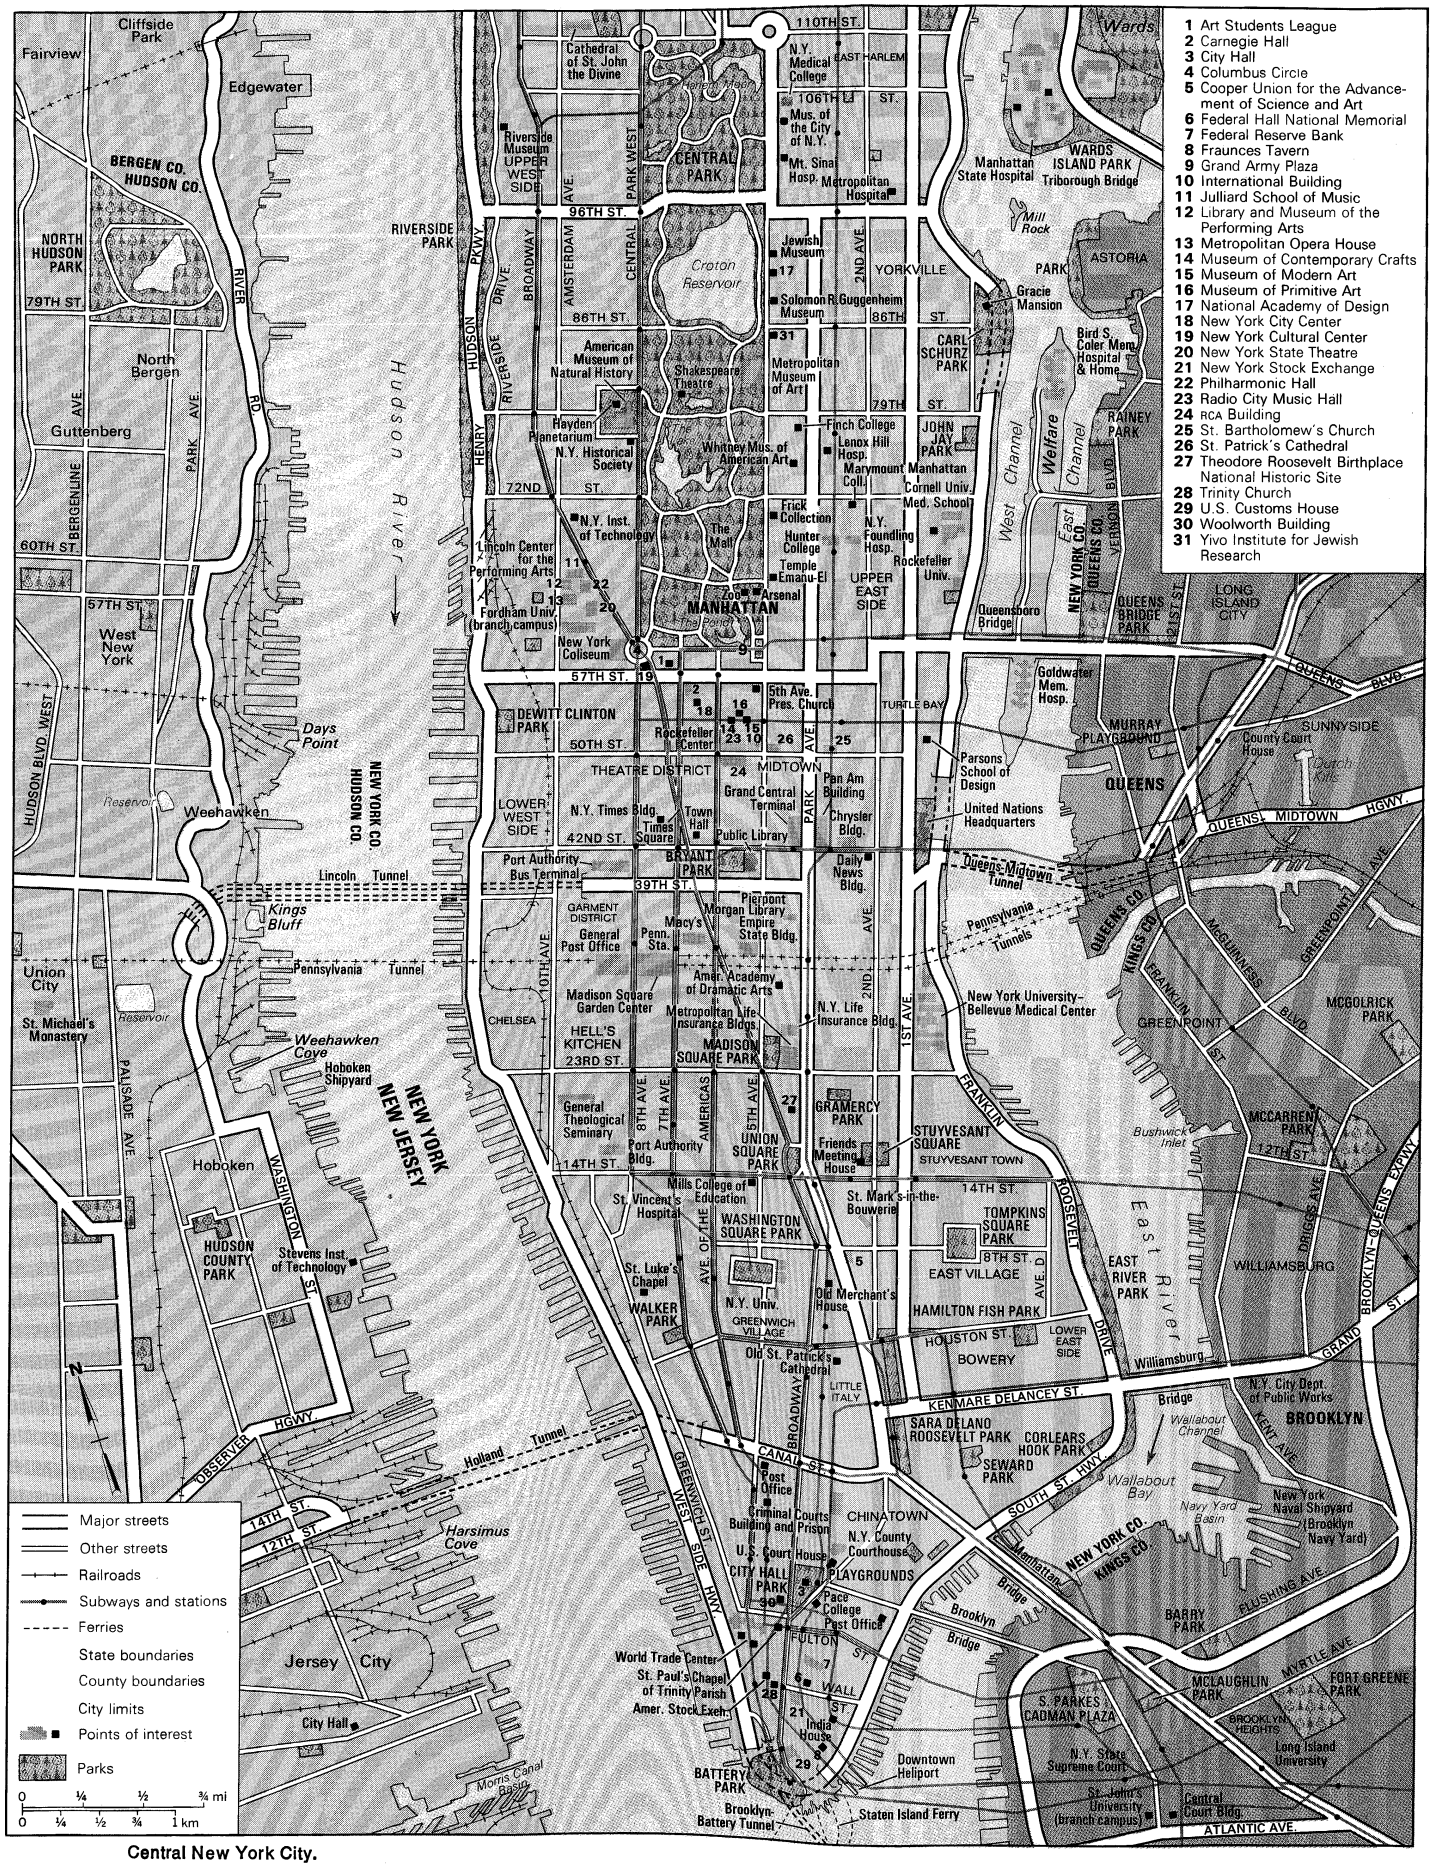
If eventually New York does prove to be ungovernable, its residential areas truly unlivable, and its commercial and cultural centres completely unvisitable, it will not be for want of effort on the part of its leaders or populace. The New York of the 1970s remains one of the most geographically and demographically complex of world cities, its economy one of the most diversified, its political structure among the most chaotic, and its cultural scene unquestionably the richest in the Western Hemisphere.

THE BOROUGHS AND THEIR PEOPLE

Many decades after the city's consolidation, tourists and even most New Yorkers, when they speak of "the city," still mean Manhattan. The boroughs of Brooklyn, Queens, the Bronx, and Richmond—each of them a separate county—remain the subject of jokes among New Yorkers as well as strangers. Brooklyn continues to be taunted with the title of the Thomas Wolfe story *Only the Dead Know Brooklyn*. Queens is known as "the borough of cemeteries." The Bronx is constantly reminded that its greatest claim to fame may be the derisive noise popularized in the bleachers of that borough's Yankee Stadium and known as "the Bronx cheer." And Richmond, closer to the smokestacks of New Jersey than to its political kin, is treated as outlying wilderness. Since most residents of these four boroughs work in Manhattan, the lingering feeling remains that Brooklyn, Queens, the Bronx, and Richmond are mere "bedrooms" of Manhattan.

Stereotypes and realities of the boroughs

Manhattan actually has been surpassed in population by all of the other boroughs except Richmond. Three of these boroughs—Brooklyn, Queens, and the Bronx—



Central New York City.

would rank among the nation's major cities if they were not a part of New York. Scores of thousands of residents of these other boroughs rarely visit Manhattan and know much less about the heart of their city than do the most casual of tourists. Legislators from these other boroughs complain endlessly that they are neglected by the city government in favour of Manhattan.

Only when seen in its entirety can the waterborne character of the city be fully appreciated. The Bronx, before 1895 a part of suburban Westchester County, is the only one of the boroughs that is part of the mainland of the United States, and even that borough is bounded on south, east, and west by water. The other boroughs are either islands or parts of an island. The city's only land boundaries are Westchester County on the north and Nassau County on Long Island to the east. Other than that, it is hemmed in by the Atlantic Ocean, Long Island Sound, the Hudson River, and assorted bays, straits, and rivulets that give the city a waterfront of 578 miles (930 kilometres) for shipping and recreation.

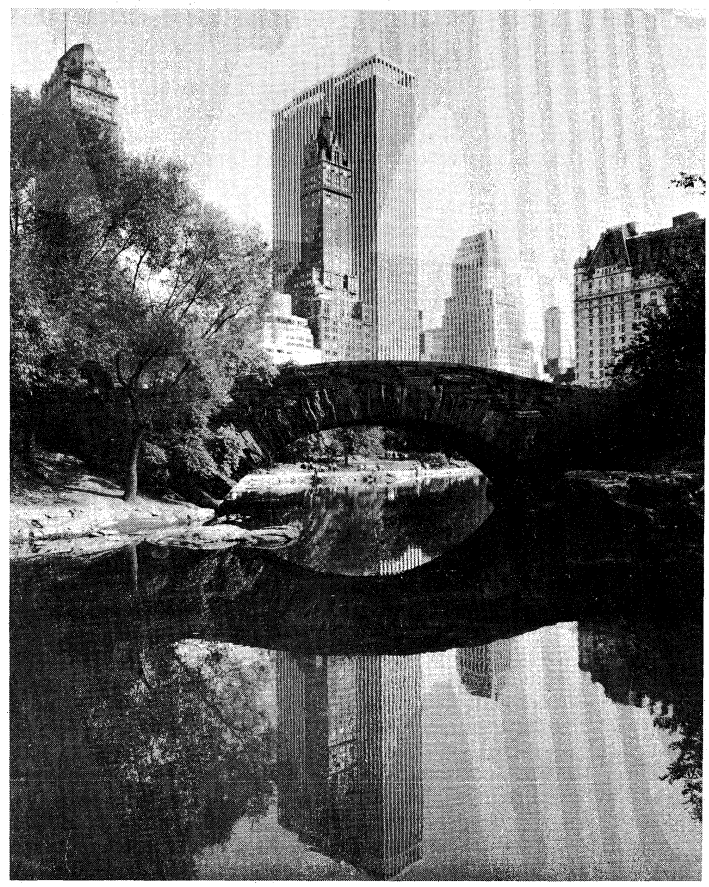
Manhattan. The magnet for tourists, the symbol of the city, Manhattan is probably the most deceptive of the boroughs to outsiders, who generally limit themselves to quick looks at the Times Square theatre district (moving gingerly past the seediness of 42nd Street west of Broadway), the shopping promenade of Fifth Avenue, the munificence of the temples of finance on and near Wall Street, the eccentricities of bohemian life in Greenwich Village, the exotica of Chinatown, or the special flavours of Little Italy and Harlem. At first glance, Manhattan is only the city of skyscrapers, glaring lights, frenzied pace, an island of the strange, the neurotic, the avant-garde. Crammed into its 22.36 square miles (57.91 square kilometres) were some 1,500,000 residents—according to the 1970 census, which undoubtedly missed many thousands because census takers feared to look too carefully in some slums. Its waterfront, formed by the Hudson, East, and Harlem rivers, is 43 miles in length, but only scattered groups of slum children swim in the pollution; and the few fishermen find only scanty catches.

To the residents of the island, each section is a hometown. Those who live in the West 70s, 80s, and 90s—the Upper West Side, though streets run above 200 at the northern tip—know their neighbourhoods as a cosmopolitan mixture of languages, occupations, and income levels. It is the cauldron in which much of the liberal experimentation in the Democratic Party is prepared, and some say it is the origin of much of the chaos of the party. On the Upper East Side, east of Central Park, is a different mixture, generally more affluent, with more unmarried men and women having a first fling in the big city.

The Manhattan that tourists do not see

The Chelsea area of the West 20s, with its tenements, renovated brownstones, and huge cooperatives built by labour unions, has a more sedate pace than the East Village, comprising much of the old Lower East Side in which generations of European immigrants festered. There, poverty, radicalism, crime, and drugs have created the most unstable area in the city. Harlem means more than just tenements, housing projects, and black politics. It means a vibrant street life ranging from sports to stoop seminars, and it is spiced with luxury apartment houses with doormen, inhabited almost entirely by blacks. Yorkville, in the East 80s, retains pockets of Czech, Hungarian, and German cultures in a clash of old tenements and towering luxury apartment houses. The neighbourhood taverns of the Irish proliferate through Inwood at the northernmost part of the island, where the borough of Manhattan spills over the Harlem River to encompass a few-square-block enclave within mainland Bronx. In Inwood lie Manhattan's few remaining forested acres, and on open recreation areas the Irish keep alive their national sports of hurling and Gaelic football—much as courts are maintained for bocciball games in Little Italy many miles to the south. On Morningside Heights around Columbia University, the civilities of the academic world overlook the bleak stretches of Harlem below and to the east and north.

Even fantastic Lower Manhattan, from the Battery, with its ferry slips at the island's tip, to City Hall, began taking on the atmosphere of a neighbourhood. Apartment houses went up in the vicinity of City Hall, and the overwhelming skyscraper jungle around Wall Street, which was home to some 2,900 financial and insurance institutions and six of the nation's 10 largest banks (with assets of $350,000,000,000), exerted international power. Indicative of the new era for Lower Manhattan were plans announced in 1972 to build a $1,200,000,000-development of apartments and office buildings on platforms in the East River bordering the financial district.



Luxury hotels and the General Motors Building surrounding the lower end of Manhattan's Central Park.
Peter Gridley—FPG

Brooklyn. The most populous of the city's boroughs and, next to Manhattan, the best known is Brooklyn, coterminous with Kings County. With adjacent Queens, it comprises the western end of Long Island. Bounded by the Atlantic Ocean, the East River, New York Bay, and Queens, it covers 80.95 square miles (209.7 square kilometres) and has a population of more than 2,600,000 at the start of this decade and 201 miles (323 kilometres) of waterfront, including that subway-Riviera amusement park known as Coney Island.

Brooklyn retains much of the identity that it developed as a separate city. Its downtown area has a bustling shopping district and office buildings. Many factories, some of them quite large, are scattered along its waterfront, and the discontinued Brooklyn Navy Yard, now the New York Naval Shipyard, where many of the nation's greatest warships were built and berthed, is being turned to industry in which the poor are being trained. Though Brooklyn has many private homes, the majority of Brooklynites live in apartment houses, tenements, or mammoth housing projects. The contrast of neighbourhoods in Brooklyn is, in its special way, as dramatic as those of Manhattan, ranging from the choice residential section of Brooklyn Heights, with its magnificent view of New York's harbour and the Manhattan skyline, to the dreadful slum of Brownsville, with many blocks of burned-out or abandoned buildings, dreary tenements, boarded-up stores, and low-income housing projects.

Contrasting life-styles of Brooklyn

The borough has one of the largest black communities in the world, Bedford-Stuyvesant, with some 400,000 persons cramped in a mixture of attractive brownstones, towering housing projects, and slums. There are, however, unmistakable signs that a stable neighbourhood is being built, and the area elected the first black U.S. congresswomen. Just as special in character are Borough Park, with an Orthodox Jewish community and storefront synagogues; Bensonhurst, with Italians who cling to their private homes with gardens to the rear; and Crown Heights, in which blacks and Jews are working to stem decline.

Queens. With its 118.63 square miles (307.3 square kilometres) and nearly 2,000,000 residents, Queens has become the bastion of the city's middle class, a catch basin for those who have fled deteriorating sections of Brooklyn, Manhattan, or the Bronx. Bounded by Long Island Sound, the East River, the Atlantic Ocean, Brooklyn, and Nassau County, it contains the beautiful beaches of the Rockaways and the boating facilities along the sound. Unlike Manhattan, which has suffered a population decline, Queens has boomed, with an increase of some 200,000 since 1960. It has drawn new department stores and shopping centres and is the site of Shea Stadium, home of the baseball Mets and the football Jets. Although the boom has brought with it many large apartment houses and tax-eating sewers, schools, and subways, the majority of its residents live in private homes. Thousands of these homes are owned by blacks, a situation uncommon in the rest of the city.

The borough of old neighbourhoods

In Queens, people usually think of themselves as belonging first to their neighbourhood, only then to the borough, and, finally, to the city. Continuity has become important in Queens. In the Irish area of Woodside, it is not uncommon for parent and children to have been married in the same church. Astoria has a public school in which the children were born in more than 20 countries, as well as the largest Greek community outside Greece. In Corona, couples with grandchildren are living in homes built by their Italian forebears. It is no accident that it is in Queens that the homeowners, white and black, have made the fiercest fight against low-income housing projects and high-rise apartment houses. The borough has some pockets of poverty but no slum in the usual big-city sense. "We don't want to be Manhattanized," is their slogan.

The Bronx. With 41.44 square miles (107.3 square kilometres) and about 1,470,000 residents, the Bronx is bounded by Long Island Sound, the East, Harlem, and Hudson rivers, and Westchester County. This borough, also known as Bronx County, has become the scene of one of the most dramatic urban struggles in the nation. The major effort has been to restrain the spread of slums, with their abandoned and burned-out buildings, closed down stores, and spreading crime. The areas known as South Bronx and Hunt's Point are infested with drug addicts and pushers who lurk in abandoned buildings the windows of which have been covered with metal and the doors of which are bricked up.

In these same areas and in Morrisania to the north, an exciting political battle has been under way between the blacks and the Puerto Ricans. As the population of the latter increased, they acquired greater political control, with disputes centring frequently in the antipoverty agencies funded with government money. The first Puerto Rican borough president in the city's history was elected in this borough and became a U.S. congressman. Puerto Ricans from this borough have also been elected to the state legislature. While slums spread steadily to the north in the borough, undermining even the once affluent Grand Concourse, a 15,000-apartment middle-income development has been built in an effort to halt the flight from run-down areas out of the city.

Richmond. Popularly known as Staten Island, a corruption of the original Dutch name Staaten Landt, Richmond is separated from the rest of the city by New York Bay and from New Jersey by narrow straits. Much of its shore lies along the Atlantic Ocean. It is the least densely populated of the city's boroughs, with some 295,000 persons in its 58 square miles (150 square kilometres). Much of its acreage remains open, almost rural country, with relatively few apartment houses. Richmond, however, may be facing the biggest boom of any of the city's boroughs, mainly because of the opening of the Verrazano-Narrows Bridge, which crosses the neck of the city's harbour to connect the borough with Brooklyn. In the 1960s, the population increased by more than 30 percent, by far the largest percentage increase of any of the city's boroughs.

The rural city: Staten Island

The major struggle on this island is between real-estate operators who want to realize the largest possible profit and civic groups who want to avoid the congestion that has accompanied growth in the other boroughs. Meanwhile, large tracts of woodland and meadow have vanished to become housing tracts for refugees from Brooklyn, Manhattan, and the Bronx. The growth of the borough has increased the strain on the famous ferry that runs between the island and Manhattan, which long has been a favourite ride of tourists and New Yorkers, since it passes the Statue of Liberty and affords a fine view of the Lower Manhattan skyline.

DEMOGRAPHIC CHANGE

There is strong evidence to support the view that, since the turn of the 20th century, demography more than geography has been the key to the many changes in New York. Except for land added by fill, the boundaries of the city and of its five boroughs in the early 1970s remained the same as they were in 1898; yet, over the intervening period the city was swept by political, social, and economic upheavals, demographic in origin, that in retrospect seem nothing short of revolutionary. New York City gave birth to much of the urban crossbreeding of capitalism and Socialism that, during the administrations of Pres. Franklin D. Roosevelt, came to be known as the New Deal. The impact of demography, more than the penal code or police activity, has determined the amount and kinds of crime in the city. Demography, more than educational theory or the quality of teachers, has been responsible for the serious dislocations in public education in New York—and for the many experiments in the field.

Demography has always been, in fact, a critical factor in shaping the city. First, New York was a Dutch city, then English, then Irish, then Irish–Italian–Jewish, then Jewish–Italian, then Jewish–Italian–Negro. Now—assuming that most Puerto Ricans classify themselves as white—it has become white–Negro. As each ethnic or religious group has attained power then moved away and lost power to the succeeding wave of immigrants and migrants, the life-style of the city has undergone transformation. But, no matter how often this has happened, New Yorkers, with short memories of their city's history, have behaved as though each demographic quake was unprecedented. Those who are threatened revile the newcomers and are, in turn, denounced as "the establishment." Physical force, political pressure, and economic muscle are all used by both sides in the periodic demographic struggles.

The past illustrates how attitudes change as demographic tides turn. Today, the city's Jews are, it appears, highly regarded for their ambition, industry, and cleanliness, and their contributions to the city's business and culture are enormous. The best estimate is that there are about 1,900,000 Jews in the city, but this figure could be high or low by more than 100,000. Many outsiders think of the city—mistakenly—as mainly Jewish. Yet, in 1895 an article in *The New York Times,* appraising the first large waves of Jewish immigration from eastern Europe to the Lower East Side of Manhattan, said, "Cleanliness is an unknown quality to these people. They cannot be lifted to a higher plane because they do not want to be." Attacks on the Irish a few decades earlier and on the Italians shortly after the turn of the century were just as savage. As late as the 1920s, opponents of private bathrooms in tenements argued that tenement dwellers would "only put coal in the bathtub." In recent years, descendants of these immigrants have made similar comments about blacks and Puerto Ricans, who have been stamped as uniformly

Historic animosity toward the immigrant

filthy, lazy, and criminal—a wholesale menace to society.

Today, as in earlier decades, there is an element of truth in these charges. The latest waves of immigrants and migrants do live in slums, amid prostitution and crime. They are aggressive in trying to move up. They become a threat as they reach for power. A major difference today, however, is that the tensions between white and black that exist in New York City are national, if not international, in scope as well. At the same time, journalistic standards have risen, and sharper distinctions are drawn between fact and prejudice.

The key unit in the city's demographic pattern is not the borough or other political district but its 2,159 census tracts. The 1970 census showed that, with the rise of blacks and Puerto Ricans and the departure of non-Puerto Rican whites, segregation became intensified at a time when the courts were handing down many decisions for desegregation. More than two-thirds of the census tracts are either 90 percent black or 90 percent white. Of the 5,100,000 non-Puerto Rican whites, some 4,400,000 live in tracts that are more than 90 percent non-Puerto Rican white. Dozens of these tracts, according to a study made by *The New York Times,* have no Puerto Ricans or blacks. This has meant, in effect, that, since 1960, ghetto areas have expanded to twice and three times their size in Brooklyn, the Bronx, and Queens.

A study of the city's Human Resources Administration revealed that over 80 percent of the city's black population lived in its 26 poverty areas in 1970 and that during the 1960s the population of these areas increased from 980,000 to over 1,300,000. During the same period, about 1,000,000 non-Puerto Rican whites left these areas, generally for other parts of the city, and some 750,000 non-Puerto Rican whites fled from the Bedford-Stuyvesant section of Brooklyn alone.

Shifting ethnic patterns

Overall city figures showed that during the 1960s nearly 1,000,000 non-Puerto Rican whites left the city entirely, while the black population grew by nearly 600,000, the Puerto Rican white by nearly 400,000, the Puerto Rican black by over 40,000, and the "other" group (mainly Chinese) by over 120,000 (more than tripling in size).

Apart from statistics, the movements of the ethnic groups within the city showed a strong hostility toward integration by whites, and any integration that did occur was short-term in areas into which blacks were moving and from which whites were fleeing. Whites did not move into black neighbourhoods, though there were some black neighbourhoods that were more prosperous than some white ones. Most whites living in black areas were elderly, poor, and unable to leave.

The demographic changes, however, were more than just colour. The median age of the black population in 1970 was about 10 years lower than that of whites, a difference that would have been even greater if the whites did not include Puerto Ricans, whose median age was believed to be even lower than that of the blacks.

The age figures are particularly significant, for crimes of violence in all ethnic groups are most prevalent among the young. So is social unrest. The lower age—combined with the larger families among blacks and Puerto Ricans—also placed an enormous strain on the public schools because the blacks and Puerto Ricans, for reasons that, it was alleged, ranged from fatherless homes to poverty, found it difficult to keep up with non-Puerto Rican whites. In 1971, tests taken by over 580,000 public-school pupils from the second to the ninth grades in Brooklyn and Queens showed a continued decline in reading achievement as compared to the rest of the nation. Two of every three pupils were from two to nine months below the national average. In poor areas the upper grades were frequently two to three years behind the national average, whereas in middle-income areas the students were as much as two years ahead of the average.

Though the enormity of these demographic shifts cannot be underestimated, they are not unprecedented in New York City. The census figures of 1870 show a situation not very different from those in 1970. The population of the city in 1870—it was then limited to Manhattan—was 940,000, of whom about 420,000 were foreign born. Considering the foreign born plus their New York-born children, the Anglo-Saxon elements that had dominated the city for the first half of the century were outnumbered. The Irish born, numbering over 200,000, were already the strongest political force in the city. Another 150,000 had moved from Germany, while England, the next highest supplier, sent only 24,432. Smaller amounts landed from dozens of other countries. The black population of the city at that time was just over 13,000.

Antagonisms between ethnic groups

The anti-Catholic feeling against the Irish in the city at that time was as bitter in other parts of the nation, often worse. Just as there is animosity in the city today between blacks and Puerto Ricans, so the antipathy between Germans and Irish was so strong that it erupted into bloody clashes. And the middle class was moving as fast as it could from the areas being settled by the Irish, the suburbs of that time being Brooklyn, Queens, the Bronx, and Staten Island—and a great deal of open land remained in Manhattan. A book of that period noted that "Strangers coming to New York are struck with the fact that there are but two classes in the city—the poor and the rich."

Yet, it would be a mistake to assume that all immigrant—or migrant—peoples in New York have faced equal difficulties. The Germans of the last century encountered much less trouble than the Irish. One reason was that most of them were Protestant, the religion of the group entrenched in power. The Italians, though of the same religion as the Irish, often built their own churches rather than go to those attended by Irish Catholics, partly because they wanted to be able to go to confession to a priest who knew their language. Difference of religion was an important reason for hostility toward Jewish immigrants.

There is a general assumption that the blacks and Puerto Ricans in New York are treated more harshly than earlier immigrants. There is undoubtedly a deep intensity to the anti-Negro feeling and, by many of the Negroes, to the anti-white feeling. Yet, in many respects, the blacks and Puerto Ricans are better treated than all earlier immigrants and migrants. None of their predecessors in the frightening city received welfare. During the first two decades of this century, immigrants often froze or starved, living in cellars or even in the streets. There was a time when tuberculosis became known as Jews' disease. As recently as the 1920s and 1930s, it was common in immigrant areas to see the possessions of these newcomers on the street for failure to pay one month's rent on time. Immigrants were expected to learn English or suffer. They were tormented and taunted for their different custom or their accent.

The city has learned—or been forced to learn—to handle immigrants and migrants with more consideration. For more than a decade, signs in such public buildings as police stations have often been in Spanish as well as English, and many policemen study Spanish. In one hospital near Chinatown, signs in the corridor are in Chinese as well as English, the latest indication of a new demographic trend in the city.

In trying to understand New York, the city he had written about for more than 40 years, Meyer Berger, in his book *New York,* wrote "The place wasn't always concrete and it wasn't always crowded. It just grew faster than any other city in history." The hordes of strangers were what made it grow so fast.

ECONOMIC LIFE

Contrary to the impression created by its soaring buildings, transportation crushes, and mass outpourings from office buildings, the economic life of New York City rests not on a few vast corporations but on a multitude of small businesses and manufacturing establishments. This diversity in the world's financial capital gives the city the flexibility and strength to withstand recession or depression with less suffering than Detroit, for instance, with its dependence on huge automobile plants, or Southern California, supported so heavily by government contracts in the aerospace and defense industries.

Components of the economy. Endless beehives of small factories populate the old loft buildings of Lower,

or downtown, Manhattan, lining the narrow cobblestoned streets built for horse and wagon in the long stretch of the island below glittering Midtown. In many glistening skyscrapers are thousands of small offices staffed by only a few persons. The world knows of the city's fabulous garment centre, but it is in little factories or storefronts of Brooklyn, Queens, and the Bronx or in ancient loft buildings of the Lower East Side that much of the subcontracting work is turned out for the kingpins in mid-Manhattan.

Patterns of industry and employment

According to studies by the New York City Economic Development Administration, the average manufacturer in the city in 1970 had only 29 employees, and the average business had 17. There are between 190,000 and 200,000 employers in New York, not counting the city itself, which is the largest employer, with a payroll ranging between 300,000 and 400,000. All told, about 4,000,000 persons worked in the city in the early 1970s including those on city, state, and federal payrolls.

White-collar workers made up the vast majority of the employment rolls, with slightly more than 800,000 in manufacturing and more than 3,000,000 in nonmanufacturing jobs. Of those in nonmanufacturing, nearly 800,000 were in service businesses; about 750,000 in wholesale or retail trade; more than 470,000 in finance, insurance, and real estate; about 330,000 in transport and public utilities; and more than 100,000 in contract construction. Governmental payrolls had more than 550,000.

Though small business and manufacturing make up the bulk of the city's employment, its biggest economic growth is in banking. The city's banking institutions handle some $80,000,000,000 a year. The glass-and-steel skyscraper headquarters of the mammoth banks are most conspicuous, but modest street-corner banks have sprung up all over the city.

The city's wholesale business runs also to some $80,000,000,000 a year; its retail trade, to about $13,000,000,000; department store sales, $660,000,000. With the headquarters of the nation's television and radio networks, the city is the heart of the mass media, and mid-Manhattan holds the main offices of most of the nation's major advertising agencies. Increasing computerization has made the city's white-collar workers more than ever the mainstay of employment.

New York's major industry is, as it has been for many years, apparel. In spite of the fact that many clothing manufacturers have moved to the South, this field employed more than 200,000 persons in the early 1970s. Printing and publishing, despite the death of newspapers in the city, continued to grow and employed more than 120,000. The headquarters of most of the nation's major publishing houses were clustered in the Midtown area.

Crisis in economic activity. Although the departure of a corporation headquarters for the suburbs of New Jersey, Connecticut, or Westchester County attracts a great deal of attention, losses have been greater in manufacturing. The decline in manufacturing was caused more by automation and mergers than by exodus from the city. City officials are particularly concerned about this drop, since it is in this sector of the economy that the relatively unskilled workers, especially the ethnic minorities, can get jobs or be trained for them.

One of the basic problems the city faces in struggling to keep manufacturing companies is how to find space in which they can expand without excessive cost increases. In manufacturing, city rents often account for 20 percent or more of the cost. Thus, some companies find it more expedient to leave the city entirely rather than pay the increased rent that expanded quarters in the city would add to the cost of operation.

To induce expanding manufacturing companies to remain, the city has been acquiring large areas of blighted or idle land for industrial parks in outlying parts of Brooklyn, the Bronx, Queens, and Staten Island. The city can offer this land to manufacturers at a rental that is better than they could obtain from private owners, often with an option to buy. The success of this program would keep more jobs in the city and bring into the treasury tax money that was lost in earlier exoduses of business.

Shipping, which for generations was one of the city's most flourishing industries, has been in steady decline in recent years. Considerable shipping has shifted to the New Jersey side of the harbour, where new facilities for containerization have made the loading and unloading of ships less costly. Wildcat strikes and waterfront crime have prompted other shippers to use ports a considerable distance from the city. Port facilities have become inefficient from disuse. In an effort to increase freight shipping to and from the city, plans have been worked out to resuscitate the huge terminals along the Brooklyn waterfront with a complex of warehouse and railroad facilities. Transoceanic luxury liners, once so common in the city's port, have decreased considerably, outdated by international air travel. It is conceded that nothing can save the once-famous docks along the Hudson known as Hell's Kitchen. The city plans to renovate this area by building "Convention City," with new housing and office buildings replacing the ancient tenements and marginal business operations.

Declining port activities

While jobs lost in shipping have been replaced, to a large extent, by gains in aviation, the city's survival rests on its ability to arrest and reverse the flight of business and industry for reasons other than technological change. One of the main reasons some corporations have left New York is the spread of crime. Those who feel threatened are not relieved to learn that crime is growing even faster in other cities and has spread to suburbia.

Street muggings in the early 1970s made a substantial number of New Yorkers fearful of walking along many streets at night. The hijacking of freight-carrying trucks, particularly those going to and coming from airports, became a matter of serious concern. Pilferage in offices forced enormous security expenses on corporations for

private guards and crime-prevention devices. And immigrant labour is no longer a guarantee of cheap workers, for the city is highly unionized. Finally, rising taxes to cope with soaring welfare costs—in 1971 about one in six New Yorkers was receiving public assistance—have become irksome to businessmen.

These rising costs have militated against such advantages as good transportation, enormous pools of skilled labour, a long tradition of organizational talents, and a city the people of which are geared to deal imaginatively with projects of almost any size or complexity. As the nuisances and even dangers of living in New York have mounted, the appeal of the city for the gifted has begun to wane. In some cases, young executives have declined promotion if it means living and working in New York City. At the same time, the huge exodus of middle class and upper middle class New Yorkers to the suburbs has increased substantially the excellent labour pool available outside the city.

Loss of civic appeal

Another development that some see as a threat to the city's economic health is the enormous advance in communications that may make highly centralized business unnecessary, perhaps inefficient. In recent years, the New York Stock Exchange, facing special taxes, has considered moving to New Jersey from Wall Street, where it was founded in 1792 when two dozen traders, gathered under a buttonwood tree, made a pact setting forth rules for trade in securities.

While statistics on economics and crime are used to argue that the city is or is not growing, there is no question that fear is contagious and breeds in businessmen and employees the thought that they ought to leave the city. To combat this psychology, in 1971, a group of business, industrial, financial, and civic leaders in the city formed the Association for a Better New York with the slogan "Where the corporate action is." Their campaign stressed that new skyscrapers were being built, that office rents in the city were competitive with those of the suburbs and other major cities, and that new businesses were moving into the city from points as far away as California. But, regardless of the future, there was no doubt that the city was struggling with one of the worst of its many crises.

POLITICS AND GOVERNMENT

"You can't fight city hall." This is said out of the side of the mouth by New Yorkers or with a fatalistic shrug or both, or else, "Go fight city hall," spoken with a mixture of resignation and anger. These clichés, trademarks of New York's political life for generations, are not entirely true, and probably they never have been—certainly not during the 20th century. What New Yorkers mean when they make these observations is that the gap between government and the people is greater than it should be or that government is not as responsive as it should be. What this boils down to is that New Yorkers have a strong feeling that they have a right at least to air their complaints before their local government, if not to get action in their favour.

Backgrounds of civic politics. There have been periods in the city's history—particularly in this century—when the avenues to power were clogged or changing so rapidly that a time lag developed during which the public felt particularly frustrated while it groped for openings. Many New Yorkers think this is the situation today, whereas others believe the government is more responsive than ever. The sense of frustration has happened in the past as much when reform groups established political organizations as when the traditional political "machines" tossed out the reformers. Thus, during the latter part of the 19th century, when the Tammany scandal under the political chief called Boss Croker became so outrageous that voters elected reformers, one term of high principled reform proved so irritating to the voters that in the very next campaign the old-line politicians, running their candidates on a slogan of "To hell with reform," regained control. On the other hand, Fiorello Henry La Guardia, during the 1930s, and, more recently, John Lindsay, although making repeated attacks on "clubhouse politics," were elected precisely because clubhouse politics had become lethargic. And once in office, they proceeded to win re-election by utilizing many of the methods that had made political machines successful in the first place. Their secret was to find ways to help the people "fight city hall"—or at least think they were fighting.

Machines and reformers in city hall

Charters of New York City government over the years have often been less important than the manner in which the government, which they established, actually functioned. This often depended on individuals. During many years, the organizational talent and style of a political "boss" have been dominant, for evil or good. The nefarious Boss Tweed used power to corrupt in the post-Civil War era, but Boss Charles Francis Murphy, during the early decades of the 20th century, had the vision to pick Alfred E. Smith from the midst of ward politics and back him for governor. By 1928, Smith had risen to become the Democratic presidential candidate.

Sometimes, it has been the personality and ability of the mayor that made democracy stumble or work in the highly complex and fluid society that is New York. Mayor James "Gentleman Jimmy" Walker, probably as popular as any mayor the city ever had, was forced to resign under fire in the early 1930s because he was too tolerant of the dishonesty of political cronies. La Guardia, in the later 1930s, was not only the mayor but the political ruler as well.

No matter whether it is a political boss or an elected mayor who rules, those New Yorkers who care make the necessary adjustment in learning how to fight or use city hall, for New Yorkers are never allowed to forget, in their politically turbulent city, that as long as they can vote, they have a voice in city hall—if they remember that in organization there is strength. On this fact, bosses and mayors never disagree. This was the essence of the only book written by Edward J. Flynn, who rose from district leader in the Bronx, to borough leader, and finally to close adviser to Pres. Franklin D. Roosevelt and Democratic national chairman. In explaining why he wrote *You're the Boss,* Flynn said,

> I am a practical politician. I know the facts of political life. I know that political machines, far from being anachronisms, are as modern as the combustion engine and as indispensable. . . . I know that wherever the majority of voters work actively inside a political machine, you have a machine that represents the voters. It is as simple as that.

Volunteers for Lindsay, operating out of storefront headquarters in 1965 and 1969, demonstrated this fact just as clearly as the Tammany block captains did during the 1920s.

Party organization and roles. Two facts are basic in the city's political life and its government: it is predominantly Democratic, and it is strongly independent. Registration in 1969 was over 3,000,000, two-thirds of it Democratic, one-fifth of it Republican. In the 1972 Presidential election, Richard Nixon was narrowly beaten by George McGovern, though Nixon swept the state.

The Liberal and Conservative parties

Many other voters are accounted for by the Liberal Party, founded in the 1930s; its leadership and adherents tend to represent an even stronger liberal position than does the Democratic Party. Although more often than not it lent support to Democratic candidates for city, state, or national office, it has backed liberal Republicans such as Lindsay in 1965 or, as in 1969, has fielded a candidate of its own. In this instance it was Lindsay again, who, having been repudiated by the city's Republican leadership, defeated both the Democratic and Republican candidates. Since the mid-1960s the statewide Conservative Party also has made inroads into registrations, tending to pick up support from normally Republican voters or from ethnic white communities concerned with rising crime, taxes, and welfare rolls. Both mayoralty elections demonstrated another New York City tradition: to win the city, a non-Democrat must split the vote of his opponents. Lindsay did not become a Democrat until 1971, when he opened his drive for the presidency.

The independent vote in New York City, with the ceaseless internal bickering that it generates in reform Demo-

cratic clubs, has had state and national repercussions. It has weakened the Democratic Party not only in the city but also in the state and nation. No longer do the Democrats, by piling up huge majorities in the city, guarantee the election of Democratic governors and United States senators. In the early 1970s, Republicans held the state governorship and split the Senate seats with the Conservatives, and all three men probably owed their election to the Democratic infighting in New York City. This weakness has been reflected on the national scene as each of the city groups has sought the support of national leaders or has fought them. The multiplicity of Democratic candidates for the presidency in 1972 was at least partly the result of the fragmentation that had its origins in New York City political arguments.

Infighting and outcries. Ironically, factionalism in New York City was fomented by the biggest Democratic vote getter in history, Franklin D. Roosevelt. When he sought the nomination for his first term, in 1932, Tammany Hall fought him bitterly, aiding the Democratic machines in the other boroughs, except Flynn's Bronx organization.

Once elected, Roosevelt decided to destroy Tammany's power. He supported the formation in the city of the American Labor Party, which drew largely upon unions. When it became apparent that it was being manipulated by Communist-oriented politicians, it was split, and the anti-Communist group that formed the Liberal Party significantly weakened Tammany. This condition stirred up other dissidents in the party, and the discipline was shattered. When Robert F. Kennedy was elected United States senator from New York in 1964, many Democrats believed he would unify the party in the city, but his assassination in 1968 was followed by even greater factionalism. Lindsay's switch to the Democratic Party raised hopes among some Democratic leaders that he might reconcile warring elements.

Political power of ethnic communities and the poor

Despite the splits in the party, the Democratic organization in the city has an enormous potentiality because, as always, it has a virtual monopoly on the poor. The organization that once built its strength on the Irish, then Italian, then Jewish immigrants now has almost exclusive power among the blacks and Puerto Ricans and has sponsored the only members of these groups to be elected to office.

One reason for this success in the slums is that the Democratic Party has always believed strongly in the "balanced" ticket—that is, a ticket on which racial or religious blocs are represented. It is understood, for example, that the Democratic candidate for borough president of Manhattan will be a black and that any citywide ticket will have a Catholic, a Jew, and a Protestant. This balance has been attacked by many as a form of demagoguery, whereas to others it is democracy at work, a way of showing that the Democratic Party believes in helping everyone have a foot in the door of City Hall—or of the governor's mansion in Albany.

Not since mobs of Irish immigrants were riled up in the 19th century to descend on City Hall have New Yorkers become so persistent and resourceful in forcing officials to listen to their complaints. In the early 1970s, the poor —this time the blacks and Puerto Ricans—were trying once more to push their way into office. They were developing their own leaders, some more opportunistic and ruthless than others, and they had the perfect medium of the poor—television, which does not require literacy. The poor and their leaders had learned that television likes demonstrations, the noisier the better. And, since New York City is not only the headquarters of the major television stations and a major outlet for public television, demonstrations can be fun. All subways lead to City Hall—and wooden barricades and mounted police are always waiting.

The rest of the city has learned that the way to win the attention of the mayor and other officials is to copy the television antics of the poor. They, too, picket, hold sitins, and shout in angry chorus at hearings on bills and appropriations. Unions, tenant groups, parent–teacher associations, civic organizations, civil-rights disputants —all come equipped with signs, bullhorns, public-relations panoply. They all know how to fight city hall.

Structure of city government. The structure of this city government under such constant pressure—the windows of the mayor's office are bulletproof—has three major components: the mayor, the Board of Estimate, and the City Council. Elected for four years, the mayor appoints his deputy mayor and agency heads and holds considerable additional patronage; he also prepares the budget. Thus, under the city charter, his power is considerable. Whether he is in fact powerful has varied with the individual mayor and the other political figures. In general, beginning with La Guardia, the mayors have been stronger than party leaders and usually led their own party.

Board of Estimate, City Council, and the mayor

The City Council is the main legislative body. It introduces and passes all laws and can override a mayoral veto by a two-thirds vote. It is made up of the president of the council, elected on a citywide basis, and 37 councilmen, elected for four years. Of these, 27 are elected from districts within the boroughs, two at large (and of different parties) from each borough.

The Board of Estimate, the main power of which is to act on the budget prepared by the mayor, is made up of the mayor, the council president, the comptroller, and the five borough presidents. Thus, the mayor, comptroller, and council president, through a system of unequal allocation of votes, can outvote the five borough presidents combined.

Friction between city and borough leadership

The real struggle for power by the borough presidents lies on the administrative side of the city's government. The Lindsay regime, which repeatedly voiced support for "community control," also set up an array of superagencies, the heads of which Lindsay appointed to run the city administratively. These superagencies operated in the fields of human resources, environmental protection, health and services, finance, housing and development, economic development, municipal services, and parks and recreation. In addition, a quasi-public organization called Health and Hospitals Corporation, with 10 of its 16 directors named by the mayor, was established. Plans were outlined by borough presidents and the governor to decentralize authority in the city by the establishment of neighbourhood councils and increased power for the borough presidents. And all of this stems from the old battle cry of New Yorkers, "Go fight city hall."

PUBLIC SERVICES

New York City, with a real estate assessed valuation of several tens of billions of dollars, spends more on its residents than any other city in the United States—more, in fact, than any state. And the more it spends, the larger its army of public employees becomes, and the louder is the clamour of New Yorkers about poor service or lack of service. From birth to death, New Yorkers are encased in billions of dollars worth of city services, taking them so much for granted that only when they falter are the people aware of them. One of the fascinating oddities of New York life is the strong strain of Socialism in the most capitalistic of cities. The city's services are burdened not only by size but also by the complexities of the metropolis. For example, in 1971 the city spent about $500,000 in the hopeless task of trying to remove the proliferating graffiti—often painted in letters a foot high —from subway stations and trains. In the parks, saplings are often chained to the ground immediately after they are planted to thwart tree thieves.

During the early 1970s, the city's annual budgets hovered close to $8,000,000,000, slightly lower than that for the entire state. Any one of the city's major functions—welfare, housing, sanitation, health, protection against crime or fire, recreation, water, roads, transportation—is in itself a mammoth operation. Even the air that is breathed involves an annual city expenditure of several million in pollution tests and prevention.

Despite endless complaints about municipal shortcomings, the city does far more for its residents—certainly spends vastly more money on them—than it used to. In the 1920s, for instance, snow removal was left mainly

Riverbend, new housing in Harlem.
Norman McGrath

to sun and rain. In the 1970s the failure to remove snow in most areas within a week—or to make a start in that direction—sparked demonstrations against the mayor.

The welfare rolls. But some services have suffered in the last few years, mainly because the soaring cost of welfare has forced the city to skimp on other services to which it gives lower priorities. Annual welfare costs passed $1,200,000,000, not including over $160,000,000 on staff and $410,000,000 on Medicaid. The number of welfare cases at the end of 1971 passed 1,200,000 and was rising at the rate of nearly 10,000 a month. The city estimated that soon one out of every six New Yorkers would be receiving some form of welfare assistance. Though the federal government paid about 40 percent of the welfare costs and the state assumed 30 percent, the remaining 30 percent was still a serious strain on the city treasury, particularly since the tax base was undermined by the departure of middle class wage earners for the suburbs. To cope with this the city imposed an income tax on commuters who work in the city.

Persons on welfare who are under 21 years of age comprise about 58 percent of the roll; those over 65, over 6 percent; adults caring for others, nearly 20 percent; disabled adults, over 10 percent. Only 2.8 percent of those on the rolls were considered employable. The enormous welfare costs created a widespread feeling among New Yorkers that there is considerable fraud in the area, caused by laxity in administration. The city's Human Resources Administration, which supervises welfare through its Department of Social Services, conceded that the system used to guard against the clients receiving duplicate checks was not effective. It estimated that fraud amounted to about $5,000,000 a year. The state, however, contended this was just a small fraction of the true total and that the number of employable persons on the welfare rolls was far greater. To some extent these disagreements reflected personal as well as traditional animosities between the city government and Albany.

When it was revealed in 1971 that several thousand welfare families had been placed in hotels, often at costs exceeding $1,000 a month, the condition illustrated more than laxity by city officials. It dramatized the dire shortage of apartments for the poor at a time when so many were on welfare. Lower middle class areas, when evacuated by the whites, soon became dreadful slums inhabited by blacks and Puerto Ricans. Apartments and often entire tenements were burned out, often by drug addicts.

Public housing

As a better solution than welfare hotels, the city had sought to increase construction of low-income housing. New York is already far ahead of other cities in these projects, which are now built almost entirely with federal funds. At the end of 1971, New York had 192 projects with some 157,000 apartments housing more than 500,000 persons. To run the buildings, the city's Housing Authority had 11,000 employees, including its own police force. Rents ranged from $18 to $22 a room. The apartments were mainly for the working poor, but the percentage of those on welfare in projects had been rising steadily for 10 years.

Education. The drama of school disorders and busing for racial balance have overshadowed the size and complexity of the city's educational system. At a cost of $1,500,000,000—with federal and state governments donating large shares—the system included almost 1,150,000 pupils, from pre-kindergarten through high school, some 70,000 teachers and 41,000 administrative personnel, and over 950 permanent buildings and 260 temporary buildings. More than 400,000 lunches are served daily to the students, of which about 75 percent are free.

Public education in New York is a vivid example of the desire for community power in the city. Under a state law of 1969, the city's school system was apportioned into 31 school districts, each with an elected board. The powers of these local boards include administrative duties in elementary and junior–intermediate schools, selection of the community superintendent, assignment of teachers, and some aspects of school construction and repair. The chancellor, the chief executive of the school system, is chosen by the citywide Board of Education, the members of which are appointed by the mayor.

The educational system includes schools for the handicapped and convalescent, trade schools, day schools for the socially maladjusted, and experimental programs with longer school days and individual instruction. Special programs reach back into the ninth grade to prepare underprivileged individuals for college. More than 120,000 pupils are learning English as a second language.

For high school students who want to specialize, there are the High School of Art and Design, the High School for Music and the Arts, the High School of Fashion Industries, the School for the Performing Arts, the New York School of Printing, and the Food and Maritime Trades School.

The city university system

New York is the only city in the United States with a large public-university system. Costs for public higher education in 1972-73, for example, were $441,100,000. The higher-education program has become increasingly important since the introduction of "open admission" in 1970, which allows any high school graduate into either a senior or a community college, depending on grades. Before open admission, the standards for entrance into senior colleges were very high. The new program was adopted to enable more blacks and Puerto Ricans to get into city colleges. More than 100,000 students are enrolled in the senior colleges, 51,000 in community colleges, and 15,000 in graduate programs.

The private universities offer, in addition to the usual courses, special areas of study. Columbia University, for instance, has its Russian studies and school of journalism; Fordham University its medieval studies; New York University its courses in art scholarship. Then there is Juilliard, with its world-famous music, and, more recently, theatre and dance; and the Rockefeller University of Biological Science.

Sanitation and water supply. For generations, New York City has been known as a dirty city. This is the result of ever present slums and of relative indifference of New Yorkers. In recent years, however, residents have become aroused by concern about environmental pollution and are more demanding. But it is still a dirty city in spite of the fact that some 17,000 men are assigned to sanitation work—street cleaning, refuse collection, and waste disposal. The city uses a wide variety of mechanical equipment and spends nearly $20,000,000 a year on automotive and plant maintenance. On an average day the city collects 26,000 tons of garbage. To some extent, the city is handicapped by lack of funds.

A prime example of the city's acceptance of a service until something goes wrong is its water system, which is piped in from many parts of the state, from as much as 300 miles away. On an average day the city uses 1,300,000,000 gallons. At times the various city agencies, each in its desire to perform an efficient service, clash. One agency, for example, decided to introduce electricity for heating in public housing as being cheaper and cleaner at the same time another agency was trying to hold down electric consumption because of the power shortage.

Police and fire protection. One of the most glaring examples of how service in the city is curtailed by the fiscal crisis is the police department. At a time when the most agonizing problem to most New Yorkers is street crime, the police department has been forced to allow its force to diminish by not replacing the men who retire or those who leave. At the end of 1971, the police force numbered 33,015, about 1,500 fewer than the year before. During that year, instances of homicide, rape, robbery, aggravated assault, and motor-vehicle theft rose, and 10 policemen were killed.

The statistic of most concern was that of crimes against the person. The city was third among the nation's top 10 most populous cities in major crimes. To cope with street crime, the department set up special units and task forces and decided virtually to ignore gambling offenses, an area in which police corruption has been the cause of many scandals over the years. New Yorkers are notoriously indifferent to laws against gambling, and strong pressure has begun to build for legalized gambling in the wake of legalized off-track betting. The police have been hampered further by their diversion to cope with all sorts of civic demonstrations.

The city's fire department, highly respected for its ability, has encountered two major difficulties in recent years. False alarms have risen to the point at which, for every three legitimate alarms turned in, there have been two false alarms. In addition, firemen have repeatedly found themselves under attack when trying to fight fires in ghetto areas. In New York, firemen have to know how to fight fires in skyscraper or subway, in ancient tenement or luxury apartment. In 1970, the department fought an average of 350 fires a day.

Subways and street jams

Transportation. The subways, though now part of a state-operated system, are still largely subsidized by the city, in addition to the revenue from the 4,400,000 passengers on an average day. The subways make up over 40 percent of all mass transit in the metropolitan area. About 90 percent of persons using the subways are residents of the city. The three subway divisions of the city have 237 miles of track. During rush hour, trains often run on a one-minute headway. In spite of the long lines of bumper-to-bumper traffic on highways into New York during rush hours, only about 5 percent of those who drive to Manhattan come from outside the island and only 2 percent from the suburbs.

Health and recreational services. Through its Health and Hospitals Corporation, the city operates 18 municipal hospitals. In addition, the city has over 80 voluntary hospitals (privately operated but nonprofit) and some 35 proprietary hospitals (private and for profit). Supplementing these medical institutions are six state hospitals and 22 health centres. The city, because of its connection with medical colleges and hospitals and its enormous variety of cases, long has been a magnificent training ground for doctors. Among the most famous training grounds for interns as well as experienced doctors are New York University–Bellevue Medical Center, New York Hospital–Cornell Medical Center, Columbia Presbyterian Medical Center, and Yeshiva–Albert Einstein, Mt. Sinai, and Roosevelt hospitals.

Some 37,000 acres of the city—more than twice the area of Manhattan—are devoted to parkland. Parks range in size from tiny triangular green patches amid heavy traffic to 526-acre Prospect Park in Brooklyn, 1,257-acre Flushing Meadows–Corona Park in Queens, 840-acre Central Park in Manhattan, 2,117-acre Pehlham Bay Park in The Bronx, and 1,454-acre Great Kills Park in Richmond. Included in the city's park areas are such intensively used public beaches as Coney Island in Brooklyn; the Rockaway beaches in Queens; Orchard Beach in The Bronx; and South Beach of Richmond. Erosion and official reports of pollution at some of these beaches have reduced usage.

CULTURAL LIFE AND INSTITUTIONS

The cultural milieu

Though many New Yorkers have come to think of the Fun City label pinned on their city as a bad joke, there may still be a great deal of truth in the nickname. For those who seek pleasure in almost any form, New York in the 1970s was, as it had been for more than a century, "the place to go." Whether it is theatre, music, ballet, painting, or literature or whether it is baseball, football, basketball, track, hockey, boxing, horse racing, soccer, cricket, or rugby or whether it is live, filmed, or printed erotica—whatever the taste of man or woman in culture, the arts, sports, or sex, New York has it in abundance. The city is the nation's greatest culture mart—and a major fleshpot.

Tied in with the culture and the arts are the middlemen —impresarios, agents, and assorted hucksters. Interlocked with and contributing to the talent pool required for these endeavours are great museums, a mammoth library system, and such world-famous schools as the Juilliard School of Music and the Art Students League. The overall result is an industry, ranging from genius to faker, that gives the city a flavour that attracts and churns up talent from all over the world.

There is no doubt that, as a purveyor of pleasure, the city has been hurt by the widely reported crime in its streets. Tourist business has declined, holding down attendance at theatres, sports arenas, and concert halls. The old New York tradition of staying up late after a show or musical event has been curtailed by fear. Restaurants close earlier. Taxis are scarce in the early morning hours. The city that was once wide awake around the clock now slinks home about 1 AM. New York still has dozens of

night spots, but the carefree atmosphere has been dampened. In some ways, however, New York is more exciting than ever as a cultural and artistic test tube.

The performing arts: drama, music, dance, and film. The most vivid paradox of simultaneous decline and growth is in the city's theatre. The decline of the Broadway theatre began in the late 1920s when the movies learned to talk. Since most plays of that period were mediocre or worse, they offered little competition to the "talkies." The Depression of the 1930s added to Broadway's woes, turning the theatres along 42nd Street into burlesque houses and then cinema palaces. World War II, with so much money to be spent, gave legitimate theatre a boost, but afterward it was hurt by television, rising production costs that could not be met by increased ticket prices, and the exodus of large chunks of the middle class audience to the suburbs. In the early 1970s, the 35 major theatres remaining in the Times Square area represented about one-half the number of the 1920s.

Perhaps more important, competition to the New York theatre was springing up in other parts of the country. What had once been fleeting summer theatres in the suburbs began to take root on a year-round basis. Regional theatres developed in Minneapolis, Los Angeles, Dallas, Washington, D.C., New Haven, and other cities. Theatres in universities grew in number, size, and professionalism.

Continuing vitality of theatrical activity

Yet, there are indications that the legitimate theatre in New York as a whole—not just the Times Square area—is very much alive. Off-Broadway and off-off-Broadway theatres by the scores have sprung up since the 1950s in lofts, cellars, garages, churches, and old restaurants—by the 1970s more than 150 of them. These new little theatres, having fewer than 300 seats, are a fertile field for experimental plays and a training ground for actors, directors, playwrights, and technicians who could no longer be absorbed by the Broadway theatre. They are particularly important for blacks and Puerto Ricans forming their own companies. A detailed study of the theatre in 1971 by scholars, professionals, and civic leaders established that the number of plays staged in the city almost certainly exceeded that in any city at any time. *Variety*, the show business weekly, reported that the 1970–71 season along Broadway had the fourth highest gross income in history, and road companies earned almost as much in spite of the nationwide economic recession.

Box-office statistics tell only a part of what the theatre means to New York City. It is impossible to convert into dollars the impact of curtain time in Times Square, with well-dressed crowds spilling out of taxis, thronging across sidewalks and into narrow lobbies, dashing back and forth from theatre to tavern during intermission, chattering excitedly at the final curtain, and chasing for cabs after the last echo of applause. There is a spontaneity, sophistication, and animation to legitimate theatre that movie premieres, even at their most elaborate in Hollywood, cannot capture with spotlights and velvet ropes.

Municipal subsidies for the arts

The city, aware that the theatre means more than money it brings in at the box office—or even at the hotels and restaurants—has taken several steps to bolster it. Four new theatres opened in Times Square skyscrapers in 1972 because of a change in building ordinances allowing builders a bonus in floor space if they include a theatre in the structure. Some experts in the field believe that in the future all Broadway theatres will be in skyscrapers instead of separate buildings. In addition, the city has given financial aid to theatrical work. It sponsors Shakespearean productions that for years have been shown in the parks without charge. It bought an old library that has been converted into five little theatres. The New York City Center, with its ballets and plays, has been able to maintain high standards at moderate ticket prices because the building is tax-exempt and, like the converted library, rented from the city for $1.00 a year. Despite the city's enormous financial difficulties, it spends over $1,000,000 a year on the performing arts, including theatrical productions in the streets of ghetto areas and operas and concerts in the parks by the Metropolitan Opera and the New York Philharmonic.

The most spectacular of the city's institutions of art and culture is the Lincoln Center for the Performing Arts, which has since been copied by Los Angeles and Washington, D.C. Its five buildings, built around a lagoon and fountain, are the home of the Metropolitan Opera, the New York City Opera, the New York Philharmonic, the New York City Ballet, a repertory theatre company, and a library for the arts. The performances at this centre, which has become one of the leading tourist attractions in the city, drew about 3,500,000 persons in 1971. It has been host to theatrical, musical, and dance groups from all over the world. Like most operatic and musical organizations, the Metropolitan Opera and the New York Philharmonic operate at deficits that are met by private contributions.

Concertgoers still think the best concert hall in the city is Carnegie Hall, which gets many of the major musical organizations of the world. Town Hall, the auditorium at Hunter College, and the Brooklyn Academy of Music are in constant use by major artists and chamber groups.

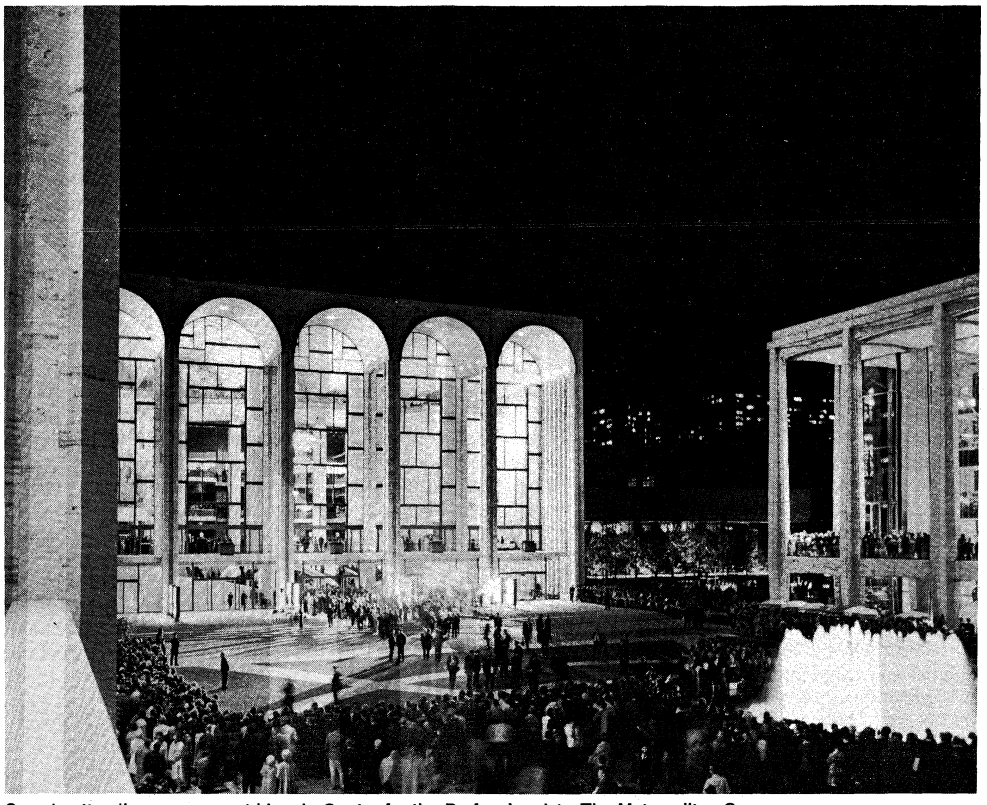
The selection of movies available in New York City is a major attraction. At any time, movie houses in Manhattan alone are showing hundreds of films—first runs, revivals, and anything in between. It is a treasury for those who seek old or new foreign films. The city is also growing as a film-making centre because directors and producers have learned that using the city as a setting gives any movie dramatic impact. This development is a reminder that, before movies went to Hollywood, they were made mainly in New York City.

Libraries, museums, and galleries. New York's library system, with nearly 200 branches, is one of the city's glories. As a result of the city's economy drive, the libraries are not open for as many hours as they once were, and book circulation has fallen. This decline may also reflect the impact of television on reading habits in the city. The circulation figures do not, however, represent the vast amount of research done in the main library, guarded at 42nd Street and Fifth Avenue by stone lions that are among the city's best known sights. Nor do the figures for the city's system reflect the value of special libraries such as the Pierpont Morgan Library, the Low Memorial Library at Columbia, or the collection of books and records at the Lincoln Center Library.

Museums are another important aspect of the city's cultural life. There the visitor can see paintings by old or modern masters, a replica of a whale diving from the ceiling, or a display of planetary mysteries. By the millions, New Yorkers and visitors troop through museum corridors, singly or in school groups, sometimes listening to explanations on earphones or to guides. Most famous are the Metropolitan Museum of Art and the American Museum of Natural History and the adjacent Hayden Planetarium, all situated on parkland. Other art museums are the Museum of Modern Art (with its major collections of photography and films as well), the Frick Collection, the Solomon R. Guggenheim Museum, the John Hay Whitney Collection, and the Brooklyn Museum.

Though the museums are private, the city pays about $18,000,000 a year to help some of them. The general pattern, however, is for museums to finance deficits by private contributions. In general, attendance at the city's museums has declined, and, in recent years, the Museum of Natural History and the Metropolitan have introduced a system of discretionary payment by visitors. Lesser-known institutions with special appeal for scholars as well as visitors are the Museum of the City of New York, the New York Historical Society, the Jewish Museum, the Museum of the American Indian, Heye Foundation, the Museum of Contemporary Crafts, the Studio Museum of Harlem, and the research centre for students of Jewish life known as Yivo. In addition, at least 70 private art galleries help keep the nation's artistic life centred in New York. Among recent developments in the arts are the special arrangements for artists to live and work in loft buildings in the vicinity that has come to be known as Soho—"south of Houston Street."

Outdoor attractions. Deep in the affections of city dwellers and visitors of all ages are the zoos and botanical



Crowds attending programs at Lincoln Center for the Performing Arts. The Metropolitan Opera House is at centre and Philharmonic Hall at right.

gardens. The city's major zoo is in the Bronx, but, because of its location, a much smaller zoo in Central Park has been photographed more often for movies. Other zoos are in Brooklyn, Queens, and Staten Island. The botanical gardens in the Bronx and Brooklyn are a meeting place for botanists as well as the less scholarly flower lovers. Attractive but not as well-known is the botanical garden in Queens.

The major-league sports events at Yankee Stadium, Shea Stadium, or Madison Square Garden Center may get the headlines and television coverage, but for New Yorkers the parks and beaches get much more recreational use. On an average summer weekend about 1,000,000 persons are at Brooklyn's Coney Island and another 750,000 swim at the Rockaway Beach in Queens, both on the southern shore of Long Island. Baseball can be seen at its most exciting among the Puerto Rican teams and the show-business teams in Central Park, in which rowboaters may while away the summer hours or skaters the gray winter days. At these events and among the countless thousands of picnickers in the city's parks is discernible a warmth and neighbourliness, an underlying dream of the human melting pot never realized but ever sought. It is perhaps fitting that New York City is the home of the United Nations.

PROBLEMS AND PROSPECTS

For all its troubles, New York remains the most exciting city in the nation, an endless drama that brings together the cultures and the peoples of the world. It is a metropolis of limitless paradox and surprise. When a 12-day subway strike hit New York in 1966, thousands of motorists gave lifts to strangers, and the city adjusted in dozens of ways to its paralysis. During an East Coast power blackout of 1965, the city of lawlessness had a drop in crime.

Still nothing compares with the subway crush, the ticker-tape parades for the nation's heroes, the glitter of an opening night on Broadway or at the Metropolitan Opera, the promenade of the young singles and couples along Second and Third avenues, the view from the Empire State Building, the sight of a luxury oceanliner gliding down the Hudson into New York Bay. If New York is dying, as many say, many others insisted that it is far more alive on its deathbed than the places to which so many New Yorkers have fled in the suburbs.

BIBLIOGRAPHY. The FEDERAL WRITERS' PROJECT, *New York City Guide* (1939), is a basic book about the city. The colour, history, and many of the social problems of New York have been caught in many works of fiction, notably CLAUDE BROWN, *Manchild in the Promised Land* (1965); and RALPH ELLISON, *Invisible Man* (1952), both concerned with the black experience of the city; STEPHEN CRANE, *Maggie and Other Stories* (1960); and HENRY ROTH, *Call It Sleep* (1935), recalling the life of the Jewish immigrant. WASHINGTON IRVING's classic *Knickerbocker's History of New York* (1809, many later editions), casts a facetious eye over the city's earlier centuries, especially the Dutch years. Works of nonfiction that offer a myriad of glimpses are MEYER BERGER, *New York* (1960), selections from his decades of chronicling for *The New York Times*; PHILIP HONE, *The Diary of Philip Hone, 1828–1851* (1889); and JAMES D. MCCABE, *Lights and Shadows of New York Life* (1872, reprinted 1970), both of which are impressions of 19th-century New York; ALEXANDER KLEIN (ed.), *The Empire City* (1955), a collection of essays and articles on the city; and LINCOLN STEFFENS, *The Autobiography of Lincoln Steffens*, 2 vol. (1931, reprinted 1968).

Problems of New York's political life are covered in WALLACE S. SAYRE and HERBERT KAUFMAN, *Governing New York City* (1960); and in EDWARD J. FLYNN, *You're the Boss* (1947, reprinted 1970). Tammany Hall is the subject of EDWARD N. COSTIKYAN, *Behind Closed Doors* (1966); GUSTAVUS MYERS, *The History of Tammany Hall*, 2nd ed. rev. (1917); and WILLIAM J. RIORDAN, *Plunkitt of Tammany Hall* (1948).

Aspects of New York's sociological and related problems may be found in HERBERT ASBURY, *Gangs of New York* (1937), a look at the structure of gangland; NATHAN GLAZER and DANIEL P. MOYNIHAN, *Beyond the Melting Pot: The Negroes, Puerto Ricans, Jews, Italians and Irish of New York City*, 2nd ed. (1970); JANE JACOBS, *The Life and Death of Great American Cities* (1961), a study of the nature and process of urban decay; OSCAR LEWIS, *La Vida* (1966), on the Puerto Rican community; and JACOB A. RIIS, *How the Other Half Lives* (1901, reprinted 1971), an early and classic study of poverty on the Lower East Side by a muckraking journalist. JOSEPH MITCHELL, *The Bottom of the Harbor* (1959), is an intimate look into the city's harbour and waterfront life; while ROBERT MOSES, *Public Works: A Dangerous*

Trade (1970), reviews the author's years as a builder of the city's physical plants.

Aspects of New York's cultural life appear throughout such books as BROOKS ATKINSON, *Broadway* (1970); IRA GLACKENS, *William Glackens and the Ashcan Group* (1957); MOSS HART, *Act One* (1959); and NORVAL WHITE and ELLIOT WILENSKY (eds.), *AIA Guide to New York City* (1967).

(Mu.S.)

New Zealand

New Zealand, an independent member of the Commonwealth, is situated in the South Pacific over 1,000 miles southeast of Australia, its nearest neighbour. Its population in the early 1970s was almost 2,900,000. The land area is just over 100,000 square miles (260,000 square kilometres)—about twice the size of England. About two-thirds of the land is economically useful, the remainder being mountainous. The country comprises two main islands—the North and South islands—and a number of little islands, some of them hundreds of miles from the main group. New Zealand administers the South Pacific islands of Niue and the Tokelaus, and a section of the Antarctic continent. The country's isolation has played an important part in the development of its social, cultural, and economic characteristics.

Originally a British colony, New Zealand has been technically sovereign only since 1947, although in practice it has been self-determining in many internal and external policy matters since 1901. Small, isolated, and of little political or strategic importance on the one hand, it enjoys a high standard of living on the other. Western-type society has been made to incorporate the original Maori inhabitants of the islands. It played a small, but significant, part in the United Nations immediately after World War II, but in the following two decades showed comparatively little interest in this area. Subsequently, however, New Zealand has become more conscious of its neighbours in the South Pacific, an underdeveloped region in which more developed countries such as Australia and New Zealand have an important contribution to make. This greater awareness of the existence of its smaller neighbours parallels greater interest in race relations and minority problems at home.

Economically, the country is very dependent on the export of its pastoral products, and therefore sensitive to conditions in Europe, the United States, and Japan, its main markets. The entry of Great Britain into the European Economic Community in 1973 will undoubtedly affect New Zealand adversely because much of its meat and dairy produce had been exported to Britain. Some success has attended efforts to expand markets in the developing countries and in Australia, Japan, and the United States, but this has been a slow process. Efforts are also being made to diversify the economy with tourism and greater industrial activity. High wages, a dearth of resources, and the small local market, however, are formidable barriers to efficient manufacturing. (For related information see NEW ZEALAND, HISTORY OF.)

THE LANDSCAPE

Relief. Although New Zealand is small, its geological history is as complex as that of a continent. There must have been land in the area from the oldest Paleozoic times (570,000,000 years ago) or earlier, although by the end of the Tertiary Period (2,500,000 years ago) little of the country remained above sea level. This was followed by periods of gentle warping and changing, alternating with great mountain-building activity during which the "backbone" of the North and South islands was created.

The role of volcanic activity

The Pleistocene Epoch (2,500,000 to 10,000 years ago) saw the beginning of volcanic activity which still continues in the North Island. The major North Island mountains are all volcanic in origin, and all but one are still active. Active volcanoes in a wide belt of thermal activity, including hot springs and geysers, indicate that earth-changing forces are still at work. New Zealand is part of the zone of structural weakness known as the circum-Pacific Mobile Belt; earthquakes are common, although less frequent and severe than in Japan or Chile.

Both the North and South islands are roughly bisected, by mountains in the South and ranges of hills in the North. Swift, snow-fed rivers drain from the hills, although only in the east of the South Island have extensive alluvial plains been built up. The alluvial Canterbury Plains contrast sharply with the precipitous slopes and narrow coastal strip on the west coast of the South Island. The Southern Alps are a 300-mile-long chain of fold mountains containing New Zealand's highest mountain —Mt. Cook (12,349 feet [3,764 metres])—and 16 other peaks over 10,000 feet, as well as an extensive glacier system with associated lakes.

In the north of the South Island, the Alps break up into steep upswelling ridges. On their western face there are mineral deposits, and to the east they continue into two parallel ranges, terminating in a series of sounds. To the south, the Alps break up into rugged, dissected country of difficult access and magnificent scenery, particularly toward the western tip of the island. On its eastern boundary, this wilderness borders a high central plateau with an almost continental climate.

The North Island is much less precipitous than the South and has a more benign climate and greater economic potential. The central region consists of a volcanic plateau rising abruptly from the southern shores of New Zealand's largest lake, Taupo, itself an ancient volcanic crater. To the east, ranges form a backdrop to rolling country in which pockets of great fertility are associated with the river systems. To the south more ranges run right to the sea. On the western and eastern slopes of these ranges the land is generally poor, although the western downland region is fertile enough until it fades into a coastal plain dominated by sand dunes. To the west of the central plateau, fairly mountainous country merges into the undulating farmlands of Taranaki, where the mild climate favours dairy farming even on the slopes of Mt. Egmont, an isolated, extinct volcano.

The northern shores of Lake Taupo bound a large area of high economic activity. Again, the soil, of volcanic origin, is poor, but very suitable for forestry. Even further north there are river terraces sufficiently fertile for widespread dairy and mixed farming. The hub of this area is Auckland, astride an isthmus with a deep harbour on the east and a shallow harbour to the west. The region north of Auckland becomes gradually subtropical in character, marked generally by poor, leached soil and numerous, deep-encroaching inlets of the sea bordered by mangrove swamps.

Hydrography

The mountainous country of both islands is cut by many rivers which are swift, dangerous, and a barrier to communication. The longest is the Waikato, in the North Island, and the swiftest, the Clutha, in the South. Many of the rivers arise from or drain into one or other of the numerous lakes associated with the mountain chains. Many of these lakes have been used as reservoirs for hydroelectric schemes, and artificial lakes of considerable magnitude have also been created for hydroelectric purposes.

The main rock formations of New Zealand are sedimentary and volcanic. The sedimentary rocks, found over three-quarters of the country, give some indication of the country's sojourns beneath the sea, when various strata were first laid down, then lifted up and tilted by mountain-building forces. The soils based upon these formations are mostly clays and generally poor, their continuing productivity depending upon expert farm management and the well-researched use of artificial fertilizers on a large scale. Pockets of fertile alluvial soil in river basins or along river terraces form the orchard and market-gardening regions of the country.

Climate. New Zealand's climate is determined by its latitude, its isolation, and its physical characteristics. Across such vast oceans as surround it, weather from elsewhere has little influence; there are no extremes of temperature.

Because of the high mountain chains which lie across the path of the prevailing westerly winds, the contrast in climate from west to east is sharper than that from north to south. Mountain ranges are also responsible for the

semicontinental climate of central Otago. New Zealand experiences strong equinoctial winds, partly modified on the coast by daytime sea breezes.

Rainfall is highest in areas dominated by mountains exposed to the prevailing winds. Although mean annual rainfall varies from 13 inches (330 millimetres) in central Otago to 300 inches (7,600 millimetres) in the Southern Alps, for the whole country it is typical of temperate zone countries (25–60 inches [635 to 1,525 millimetres]), usually spread reliably throughout the year.

Temperature and humidity

Mean temperatures at sea level decrease from 59° F (15° C) in the far north to 54° F (12° C) at Cook Strait, to 48° F (9° C) in the far south, and there are few extremes. Snow is common only in mountainous regions, but frost is frequent in inland valleys in winter. Humidity ranges from 70 to 80 percent on the coast, generally being 10 percent lower inland. In the lee of the Southern Alps, humidity can become very low. At such times northwesterly winds subject the Canterbury Plains to an unpleasant hot, dry spell. Humidity becomes really oppressive only in Northland, although the temperature there rarely reaches 84° F (29° C). New Zealand is a sunny country, with many areas receiving at least 2,000 hours of sunshine a year, much of it occurring in winter.

Vegetation, soils, and animals. The indigenous vegetation of New Zealand consisted of mixed evergreen forest covering perhaps two-thirds of the country. Prolonged isolation has encouraged the development of species unknown to the rest of the world. Today, dense "bush" remains only in areas unsuitable for settlement and in parks and reserves. On the west coast of the South Island this mixed forest still yields most of the native timber used by industry. Along the mountain chain running the length of the country, beech is the predominant forest tree.

European settlement made such inroads on the natural forest that erosion in high-country areas became a serious problem. The State Forest Service was established to repair the damage by forest-management techniques and reafforestation with exotic trees. Experimental areas on the volcanic plateau were planted with radiata pine, an introduction from California. This conifer has adapted to New Zealand conditions so well that it is now the staple plantation tree, growing to maturity in 25 years

and having a high rate of natural regeneration. Large areas of the central plateau, together with other marginal or subagricultural land in north Auckland and Nelson, are now planted with this species.

European broadleafs are widely used ornamentally, and willows and poplars are frequently planted to hold eroding hillsides. Gorse has acclimatized so readily that it is now a menace, spreading over good and bad land alike, its only virtue being as a nursery for regenerating bush.

Because of New Zealand's isolation there was no higher animal life in the country when the Maori arrived (at dates variously estimated from AD 970 to several centuries later). There were two species of lizards: the gecko, which is born directly instead of being hatched from an egg, and the tuatara, a "beak-headed" reptile extinct elsewhere for 100,000,000 years. There were also a few primitive frogs, and two species of bat. These are all extant, although confined to outlying islands and isolated parts of the country.

In addition to their domestic animals, Europeans also brought other species with them. The red deer, introduced for sport, and the Australian opossum (for skins) have both multiplied beyond imagination and do untold damage when browsing in the high-country bush. Attempts are being made to exterminate the opossum, although this will be a lengthy process and may be no more successful than the campaign against rabbits: the last rabbit has not been eliminated, but their numbers are rigidly controlled.

In the absence of predatory animals, New Zealand was a paradise for birds, the most interesting of which are flightless. The moa was a very large bird, easily exterminated by the Maori. The kiwi, another flightless species, is extant, though only in secluded bush areas. The weka and the notornis or takahe (barely rescued from extinction) probably became flightless after arrival. The pukeko, a swamphen relative of the weka, is even now in the act of losing the use of its wings.

Some birds, such as the huia, the saddleback, and the native thrush, are peculiar to New Zealand, but many others, such as the tui, the fantail, and the bellbird are closely related to Australian birds. New Zealand also has its share of migrants: the gannet from Australia, and the skua, penguin, shag, and royal albatross from the Antarctic.

Because New Zealand is the meeting place of warm and cool currents, a great variety of fish is found in its waters. Tropical species such as tuna, marlin, and some big-game sharks are attracted by the warm currents which are locally populated by snapper, trevally, and kahawai. The Antarctic cold currents, on the other hand, bring the blue and red cod and the hake, while some fish, tolerant to a considerable range of water temperature, are found off the entire coastline—tarakihi, groper, and bass. Flounder and sole abound on tidal mudflats, and crayfish are prolific in rocky areas off the coastline.

THE PEOPLE

Ethnic structure. New Zealand was first settled by the Maori, a Polynesian race, at a time and in a manner both of which are still disputed. Perhaps they arrived about AD 1300, in great migratory waves, the result of unknown pressures in Polynesia; but they may well have arrived haphazardly when their canoes, on regular interisland expeditions, were blown off course. Whenever and however they arrived, it is certain they remained isolated in New Zealand until the arrival of European explorers, the first of whom was the Dutchman Abel Tasman (1642).

Maori culture

Their culture, influenced by isolation and, perhaps, the temperate climate, became significantly different from that of their Polynesian relatives. They were sophisticated artists and shrewd politicians, skilled botanists, and ardent warriors. Because they were also intelligent, resourceful, and flexible, they fared better in the difficult encounter with white civilization than the original inhabitants of many other colonies.

The European settlers, who arrived in increasing numbers from 1840 onward, were mainly upper working class migrants determined to establish a society free from the bonds of privilege that had made life in Britain unendurable. They arrived to make a home which they were not unwilling to share with the original inhabitants, although as the rate of immigration increased, the European demand for Maori land led to an inevitable confrontation. With the loss, by enforced purchase, of Maori land there went a loss of psychological identity. The Maori birth rate declined and extinction appeared inevitable.

Fortunately for New Zealand, a Maori renascence occurred about the turn of the 20th century, great leaders were elected to Parliament, and the people took heart in the acknowledged worth of their contribution to the new society. The contemporary Maori is, nevertheless, still recovering from the psychological effects of European occupation. Despite legal equality with those of European origin, many Maori still feel unable to take full advantage of the opportunities of a European-type society without seriously compromising their traditional values.

New Zealand thus has two dominant ethnic groups: people of European origin, comprising some 91 percent of the population, and Maori, the indigenous inhabitants of the country, comprising 8 percent (in 1966). Pacific Islanders account for a further 1 percent. The Maori and Pacific Islander proportions are rising—for demographic reasons in the case of the former and through a combination of demography and migration in the latter.

Despite New Zealand's biracial structure, there is little of the racial tension common in other parts of the world. This is not to say that there is no discrimination (on both sides), but increasing efforts are now being made by both the Maori people and a growing body of white New Zealanders to make this a thing of the past.

New Zealand also has a rapidly growing community of Pacific Islanders, people from Samoa, the Cook Islands, Niue, and the Tokelaus, including a large number of young men and women, who are attracted by the benefits of a Western society. They generally congregate in low-cost housing areas where their different cultural habits often alienate their neighbours, whereas their children provide an acute educational problem. The Islanders present a growing problem, particularly as their rate of natural increase is much greater than that of the European or Maori populations.

Apart from that part of the population which is of British origin, there are throughout the country vestiges of settlement by immigrants of European extraction —Dalmations in North Auckland, Chinese market gardeners, Greek and Italian fishermen, Danish farmers, and a small group of Indians. There are also groups of central Europeans who arrived between World Wars I and II, and a large body of assisted Dutch immigrants from after World War II.

Language patterns

New Zealand is predominantly an English-speaking country. Children of European migrant families quickly lose their native tongue in favour of English, particularly when their parents are anxious to establish relationships with the existing community. Only Greeks, Chinese, and Indians make determined efforts to keep their children bilingual. Many Maori are bilingual, but often unsatisfactorily, speaking neither English nor Maori very well. Great efforts are being made to improve the English of Maori children, and Maori is offered in many secondary schools as an optional second language.

New Zealand is nominally Christian, four-fifths of the population adhering to the Anglican, Presbyterian, Roman Catholic, and Methodist denominations (in that order). At the last census only 10 percent either refused to state, or denied a religious affiliation. Minor Protestant sects, the Eastern Orthodox churches, Jewish congregations, and Maori adaptations of Christianity (the Ratana and Ringatu churches) account for the rest. Probably only about 20 percent of the population are active churchgoers. There is no established religion, but Anglican cathedrals are generally used for state occasions.

Patterns of settlement. Because New Zealand is small and homogeneous in population there are no sharply differentiated social or political regions, just as there are

no great differences in climate, terrain, or soil type. The North (roughly the northern half of the North Island), however, is popularly regarded as being more enterprising, while the South—either the whole of the South Island or its lower half—is traditionally regarded as being conservative and dour. While the west coast is romantically nostalgic for its rollicking gold-rush days, the east coast conjures up the not entirely ill-founded picture of sheep barons on their extensive stations. When Europeans first arrived there were practically no Maori in the South Island, and this is still the case today, they and their Pacific Islander cousins being predominantly in the North.

Trends in urban and rural settlement

The New Zealand countryside is thinly populated. There are, however, many small towns of up to 10,000 population and over 20 provincial cities of over 20,000. Very small towns or villages are becoming more and more deserted as people drift to the bigger towns and cities.

The main urban areas are Auckland (approximately 650,000), the centre of the North and the main industrial complex; Wellington, in the centre (approximately 150,000), the political and commercial capital; Christchurch (approximately 280,000), in the middle of the South Island and the second-largest industrial area; and finally, still farther south, Dunedin, with a population of over 100,000. Although New Zealand is notable for the strength and affluence of its rural sector, the great majority of people live in cities, and urban concentration is proceeding apace. There is also a marked difference in the rates of growth of the two main islands—the North now having over two-thirds of the total population, in sharp contrast to the earlier years of systematic settlement.

Demographic trends. In recent years births have been stable at around 22 per 1,000 population and deaths at nine, making the annual rate of natural increase about 1.3 percent. For the Maori, the rate of natural increase is over twice as great, because of a higher birth rate and a lower death rate, both largely a consequence of the more youthful structure of the Maori population. The Pacific Islander (immigrant) population exhibits this characteristic to an even greater extent.

Since World War II New Zealand has generally had an annual excess of arrivals over departures of 10,000 to 20,000, contributing about ½ percent to overall population growth. The majority of immigrants have come from Great Britain (or The Netherlands for a decade or so after World War II), but more recently Pacific Islanders have become a major element of the inflow.

Following an economic recession in 1967 there were three years of net outflow or zero inflow, but net immigration has since resumed, although not at as high a rate as formerly. It is clear that both immigration and emigration are sensitive to the rate of growth of the New Zealand economy and its employment opportunities, as well as to conditions overseas.

THE ECONOMY

New Zealand is exceptional in combining high living standards with continued reliance on primary production for a substantial proportion of national income and an overwhelming proportion of exports. In terms of national income per head, the country is among the first ten in the international tables, following immediately after Australia. Small population and great distance from the world's main industrial commercial centres, however, are considerable economic disadvantages.

Natural resources. Most minerals, metallic and nonmetallic, occur in New Zealand but few are found in commercial quantities. The exceptions are gold, which in the early years of organized settlement was a major export; coal, which is still mined to a considerable extent; iron sands, which are exploited both for export and to supply a local steel mill; and, most recently, natural gas, which shows promise of being ultimately the most significant of all. In addition to mining, construction materials, with which the country is well endowed, are quarried. Current interest in mineral exploration may well unearth other exploitable deposits.

Apart from gold's brief heyday, biological resources have always been more significant than minerals. Domestic animals introduced from the Old World have thrived in New Zealand, and the pastoral industry is still the country's mainstay. Forestry has always been important, but the emphasis has swung from felling the long-cycle original forest for timber, to reafforestation with pine trees for both timber and pulp—a flourishing paper industry being based on the latter. Wild animals are of little economic significance, and fish, despite their abundance, scarcely more.

Use of hydroelectric power

The country has great hydroelectric potential, which has been exploited to such an extent that hydro stations supply almost all its needs at low cost. Although costs are rising, further hydroelectric development in preference to fuel-, thermal-, or nuclear-power stations is likely. A notable feature of the New Zealand electricity grid is the direct current cable linking the two main islands, enabling the South's surplus energy to be used by the North's concentration of industry and people. The ready availability of energy sources, and of hydroelectricity in particular, has played a major part in New Zealand's development to date, supporting high standards of domestic comfort and latterly facilitating industrial expansion, including the construction of an aluminum smelter.

Economic activity. *Industry.* Primary industry accounts for roughly 18 percent of national income, agriculture contributing some 90 percent of this, and forestry and mining nearly all the rest in about equal proportions. Productivity is high, in agriculture especially, so that the sector accounts for a comparatively small proportion of total employment. Agricultural produce accounts for some 84 percent of total exports, and forest products for another 6 percent. Farming in New Zealand is highly capitalized, but still mainly an owner-occupier activity with corporate or cooperative marketing.

New Zealand has had relatively large-scale manufacturing units for a considerable period in the primary processing area. The country's long supply line (except from Australia), however, has encouraged the growth of a variety of industries producing for the local market. Even before World War II roughly a fifth of the work force was engaged in manufacturing, and its contribution to national product was of the same order. Manufacturing in the early 1970s accounted for over one-quarter of the national product.

Financial services and foreign trade. Banking was established early in New Zealand, and two British, two Australian, and one (the largest) state-owned bank cover the country with a branch network. All commercial bank branches are linked by a computerized check-clearing system which is being extended to embrace other means of transferring money. Traditionally, banks have played a large part in the financing of external trade.

Foreign trade has always been of great importance in New Zealand, and few countries have a higher ratio of exports to domestic production. Exports of dairy products are handled by a central cooperative agency, meat by individual processors (some cooperative), and wool by auction. Imports are increasingly obtained directly by manufacturers, but there are still major importing wholesalers.

In the last few decades, as industrialization has proceeded, there has been a steady trend toward less fabricated imports and a switch away from consumer goods to capital goods. This trend may be expected to continue, but there is now more emphasis on diversifying exports, a task difficult in a country heavily dependent on livestock production but essential because of British entry into the European Common Market.

Transportation. In spite of the rugged nature of the country, most of the inhabited areas of New Zealand are readily accessible; the road system is good even in rural districts, and modern freeways have been built around the main cities. Bus services link most centres. The difficult country makes for slow journeys, although the distances involved are seldom great.

A railway network, owned and operated by the state, comprises a main trunk line spanning both islands via roll-on ferries and branch lines linking most large towns and many smaller ones. Narrow tunnels limit the gauge of line, and until recently precluded the introduction of fast expresses. Rail travel is notoriously slow, in spite of the widespread use of diesel locomotives, and trains carry a decreasing number of passengers. The rail service is, however, efficient for large-scale movement of goods over considerable distances. Regulations generally forbid cartage of goods by road over routes that compete with the rail.

The difficult terrain has greatly encouraged air travel in New Zealand; most provincial towns have airports, and all major centres are linked by a good air service. The internal airline, New Zealand National Airways, is a public corporation, but smaller private operators run goods and tourist services. Air New Zealand and several foreign airlines provide New Zealand with international flights. There are international air terminals at Auckland, Christchurch, and a smaller terminal at Wellington.

Economic policy. State intervention in the economy has a long history in New Zealand. Many state trading enterprises thus had their origin long before the first Labour government was elected (in 1935), and the National Party has not tried to dismantle the social security system introduced by that government. State intervention is facilitated by the absence of provincial or state governments, and, since 1950, by the unicameral parliament. State influence has steadily increased through attempts—mostly unsuccessful—to stabilize the economy.

Encouragement of local manufactures and exports

In the 1930s deliberate efforts were made to encourage industry, and World War II, with its attendant disruption of imports, greatly boosted local manufacturing. Further impetus was lent by the government, which after the war continued import licensing. By the end of the 1960s the scope of import substitution was virtually exhausted, and policy switched to the encouragement of exports of manufactures other than primary produce and forest products. Stimulated by export incentives and devaluation, and spurred on by a short-term recession of local demand, the expansion of manufactured exports of a nontraditional sort was spectacular.

There is little variation in developed countries in the proportion of taxation to national income, and, despite common views to the contrary, New Zealanders are not heavily taxed by world standards. Direct taxation (taxation of personal income) is relied upon to an unusual extent, and is steeply progressive up to the relatively low maximum of 50 percent. Because indirect taxation (taxation of goods) is politically anathema, the cost of living has been less directly affected by taxation than in many countries. Strong wage inflation has, however, more than compensated for this.

The penchant for centralization, noticeable in New Zealand government circles, has its analogue in well-developed employer associations and a reasonably closely knit Federation of Labour.

Contemporary economic policy is directed mainly to constraining the growth of consumption sufficiently to enable diversification of production and exports in order best to meet the difficulties likely when access to the British market is substantially reduced.

New Zealand's essential economic problem is that no means have been discovered to raise productivity growth consistently above 2 percent a year without threatening external insolvency. Yet all sections of the community, in their demands on the national product, act as if real growth were much higher than this. With rising import prices, continuing weakness in export prices, and the possibility of acute difficulty in securing market access for some primary products in the mid-'70s, the economic picture is somewhat cloudy. Problems are compounded by the newly evident tendency for skills and initiative to emigrate when economic conditions at home deteriorate.

ADMINISTRATION AND SOCIAL CONDITIONS

Government. *Constitutional practice.* New Zealand's form of government reflects its historical association with Britain. Sovereign power is held by an elected single-chamber parliament (the House of Representatives), the decisions of which must command a majority of its members. A two-party system operates; the party holding a majority of the 80 European and four Maori seats is automatically the government. The leader of the governing party is the prime minister, who, with his ministers responsible for different aspects of government, forms a policy-making Cabinet within the government. Most of the legislation introduced to parliament is initiated by the government, and more particularly, by Cabinet. Parliament may veto legislation, but, since the majority party forms the government, this seldom happens.

The two-party system

Bills passed by parliament are sent to the governor general for the royal assent and become law whenever the bill specifies. The governor general—technically the Queen's representative in New Zealand—performs a variety of formal constitutional functions, historical relics from New Zealand's colonial days. In effect, apart from his social duties, he is the servant of the majority party in the House of Representatives, exercising real power only in the unlikely event of the House of Representatives having no party with a clear majority, or if the majority party has no accepted leader. The governor general is appointed by the Queen, in consultation with the New Zealand government, for a five-year period. A high commissioner represents the British government.

The party system. There is universal suffrage over the age of 20. Triennial elections are generally fought on a party affiliation basis, each electorate returning only one of the candidates presented, on a majority-vote basis. New Zealand's two-party system probably reflects the lack of deep ideological divisions in the country; conflict between groups and parties is usually economic, a field in which compromise is generally possible. The National Party bases its support upon a rural-urban coalition of interest and is primarily a conservative welfare party. The Labour Party is mainly supported by trade unions and urban working people; its policy on welfare is scarcely less conservative than that of its opponents.

The two-party system works well in New Zealand; it produces strong government because great power is given to Cabinet, which is ultimately responsible to the people, and which cannot escape responsibility for its decisions. The system also has the advantage of ensuring popular control of its political leaders. Retention of parliamentary power depends upon political competence, and a critical role of the opposition is to focus attention on controversial issues in an attempt to undermine the government's following. Strong political consciousness, however, is not a characteristic of New Zealanders, who are generally content with their triennial opportunity to unseat the governing party.

Departmental organization. The business of government is carried out by 40 government departments, each being responsible for one or more aspects of administra-

tion. Since New Zealand is a welfare state, the fields of government activity are wide and varied. Each department is ruled by a permanent head who is responsible to his minister for the administration of his department. Heads of departments and their officials do not change with a change of government, thus ensuring a continuity of administration.

Work of the parliamentary commissioner (ombudsman)

The work of government administration in New Zealand tends to be bureaucratic in the extreme, and as a check upon possible administrative injustices, the office of parliamentary commissioner (ombudsman) was set up in 1962. As an impartial authority, to whom complaints against decisions of government departments may be brought, he has wide powers of investigation and a final responsibility to the prime minister and parliament. The standard of the civil service is high, but the use of the ombudsman by the general public has confirmed the need for an appeal against bureaucratic authority.

In addition to government departments there are also many government corporations—commercial ventures of national importance in which the government is the sole or a major shareholder. These include the New Zealand Broadcasting Corporation, the New Zealand National Airways Corporation, and Air New Zealand.

Local government. Local government, which has very limited power in all but peculiarly local matters, is directly empowered by parliamentary statute. Local authorities are thus dependent upon the central government, but are at the same time legally independent bodies. The definition of their function and powers is under constant revision as adjustments are made to changing conditions.

Local bodies perform general purpose duties such as those of borough and town council, or else consist of ad hoc authorities with specialized functions such as harbour and hospital boards. Every local authority activity is controlled by an elected board of local members, whose work is generally honorary. The platform for election is sometimes based on party affiliation, although this does not noticeably affect the working of the boards.

Legal system. New Zealand derives from the common law of Britain certain statutes passed before 1947 by the British Parliament. New Zealand law usually follows the precedents of English law, and the British Privy Council acts as the final court of appeal for New Zealand. The law is administered by the Justice Department through its general courts and upheld by the police force, which is also maintained by the government. The hierarchy of courts dealing with civil and criminal cases includes magistrates' courts, the Supreme Court, and the Court of Appeal, in that order. The jury system operates, and legal aid is provided for those who lack financial means.

Lesser courts

In addition to the major courts, there are several specialized courts such as a Compensation Court which deals with claims for workers' compensation. Children's courts deal with most juvenile offenses. As far as possible these courts do not use a courtroom, their proceedings are not public, and convictions need not be recorded. The aim of the penal system is not so much to punish as to reform and rehabilitate. Attempts are made at many levels to use detention periods constructively, and include trade training, group therapy, and creative relaxation. Six prerelease hostels are in operation, and postrelease care is provided in many cases.

Education. Education in New Zealand is free and compulsory between the ages of six and 15, but almost all children start school at five. Many children attend preschool classes, which are financially assisted by the Education Department, after which they proceed to a state primary school. State secondary schools offer a broad general academic education with some emphasis on technical training. Students are prepared for an attainment examination (the school certificate), and for tertiary studies, which are provided free to students fulfilling certain academic prerequisites. There is also a small number of independent private schools taking fee-paying students; these schools receive considerable financial assistance from the state and are also inspected by the Education Department. There are six universities and one agricultural college, as well as several technical institutes. The New Zealand Technical Correspondence Institute provides courses for those who live outside a main city.

Since the 1960s, Maori education has received great attention, and in an effort to improve the attainment level of Maori students, extra financial assistance has been provided through the Maori Education Foundation. The difficulty is more social than academic, and its solution may well be within the Maori community itself.

Health, welfare, and housing. The control of public health is vested in the Health Department, which supervises preventive medicine and education as well as medical and hospital services. Doctors and chemists are usually private practitioners, but under the medical benefits scheme the state remits a large proportion of the cost to the individual. Hospitalization in general, maternity, and mental public hospitals is free, as is any specialist treatment required. The cost of many pharmaceuticals is also met by the state.

Many welfare services are provided by the state, but some are insufficient to meet the demand. Increased longevity has produced a geriatric problem with which the combined resources of church and state hardly begin to deal. An increase in illegitimate births has reopened children's homes and orphanages, while the problems of the unmarried mother have not yet been realistically faced.

The government's social security scheme embraces a system of noncontributory civil pensions, in addition to the medical benefits mentioned above. These include universal superannuation (a taxable grant payable to all citizens over 65) and, subject to a means test, benefits for the aged, widows, orphans, invalids, miners, sickness, unemployment, and emergencies. A family benefit is also paid, irrespective of income, to every mother for each dependent child.

Most New Zealanders attempt to own their own homes, usually bungalow-type (one-level) houses with three bedrooms, set in a garden. In the main cities, lack of space is modifying this concept; gardens are smaller and many elderly people are investing in apartments in high-rise buildings. Mortgage finance at a low interest rate is made available by the state to assist house purchase by those whose income is beneath a certain figure. Low-income rental housing is also provided by the state, and generally follows the traditional, land-consuming pattern. These houses are frequently concentrated in one area, producing a considerable sociological problem, in that there is little occupational range in the neighbourhood and no architectural diversification. The state also subsidizes a pensioners' accommodation built by local authorities, and gives financial assistance to Maori in buying and maintaining their homes. It has also built urban hostels for Maori boys and girls away from home for the first time.

CULTURAL LIFE

The cultural milieu in New Zealand is conditioned by a society which is egalitarian in the extreme. The introduction of a welfare state in the 1930s was a radical affirmation of the country's belief in the right of everyone to a good life, and showed a direct concern for social justice. The less attractive aspect of this thinking appears in a strong tendency toward conformity to an imaginary national norm. There is little tolerance for the eccentric in any field, and New Zealanders appear to be content with the dull uniformity to be found not only in thought and speech patterns, but also in the monotony of domestic architecture, the lack of individuality in status goods, and a ready acquiescence to authority. Contemporary New Zealanders appear hesitant to use the pragmatic initiative so obvious in the first century of European settlement, although since the stimulus was always economic rather than cultural, new signs of life may perhaps emerge with the difficulties that will attend British membership of the European Common Market.

Cultural conformity

A new element is being introduced to the social climate by the emergence of the Maori people, determined to make their contribution as a forceful, enlivening minority. Articulate Maori leaders are concerned to encourage their people, to improve the standard of Maori education,

and to increase Maori self-respect and confidence in their own culture. The activities of the Maori Council, the appointment of the first Maori bishop to a European see, and the introduction of the Maori language in schools are indications that the Maori, by insisting on making his contribution in his own way, is endeavouring to combine the best of both worlds. Perhaps, in some elements of the Maori way of life, New Zealand society may find a solution to the problems of materialism characteristic of Western countries.

The first century of artistic endeavour in New Zealand was one of experimentation and exploration in terms of the classical European tradition. From this, artists and writers struggled painfully toward an acceptance of the unique quality of the country, although this very acceptance embodied a homesickness for the cultural climate of the Northern Hemisphere, exemplified in the life and works of the writer Katherine Mansfield. The Depression of the 1930s, however, saw the appearance of a group of lively and competent poets concerned with themselves as New Zealanders, but the great promise and vitality of many of these writers has not been fulfilled. Contemporary New Zealand possesses a considerable number of writers and artists who, while very much of their society, are generally concerned with personal analysis and introspection.

Maori artistic expression, except for decorative design, was completely oral before the arrival of Europeans, and much has been lost. New songs and chants are being written in Maori, however, as well as some poetry and prose. An impressive number of Maori are now writing in English, a fact which may have considerable influence on the future of New Zealand literature.

Although most New Zealanders are generally suspicious of cultural activities, there is a lively amateur dramatic tradition throughout the country. There is also popular interest and support for highland pipe and brass bands. Pottery is a creative activity that has been consistently popular, and New Zealand's best potters are well able to compete with the world's masters of this art.

The small size of the population poses problems for cultural development. Scattered widely across two islands, it is capable of supporting only three small professional theatre companies and one opera and ballet company, and it is doubtful whether even these can survive without government support. The government subsidizes the activities of chamber music societies, individual writers, artists, and musicians, and assists art galleries and museums.

The national orchestra is completely supported by the government via the New Zealand Broadcasting Corporation, which controls broadcasting and a single-channel, black-and-white television system of a reasonably high standard; a second television channel is planned. The New Zealand Broadcasting Corporation also publishes *The New Zealand Listener*, New Zealand's only weekly magazine concerned with cultural discussion.

Newspapers in New Zealand provide a high standard of reporting with substantial coverage of world news, although this is largely dependent on foreign agencies. There is little cultural content in the daily paper, but there is also little sensationalism. The mildly conservative political colour of most papers suggests the moderate attitudes of their readers.

Sport is the main leisure time occupation of most of the population. There is widespread participation in most major sports, particularly rugby football, over which an almost religious and certainly patriotic fervour is aroused, and horse racing. The climate and the variety of terrain allow for year-round activity in sports of all types.

THE OUTLOOK

New Zealand is a small but affluent nation with a dominant European heritage, yet remote from its cultural forebears, and at the same time a multiracial society. Racial self-consciousness has always been an element in the relationship between Maori and European, but with urbanization and the consequent alienation from tribal roots, the contemporary Maori must solve his identity problem as well as make his proper contribution to the community. The Maori effort on both counts is constructive, forward-looking, and fundamentally practical; nevertheless, the social tensions endemic in such a situation are likely to become exacerbated in a world increasingly dominated by protectionist trade concepts, especially in the case of the agricultural products on which New Zealand depends. Despite some signs of the centrifugal tendencies in society which are afflicting other nations of the Western world, the New Zealand of the 1970s remains a strong society, although the initiative which characterized the early settlers seems to have been replaced by a certain complacency and lack of drive.

New Zealand, History of

European settlement in New Zealand began in the late 18th century; its Polynesian history goes back to the early Christian centuries. In the 19th century the country became predominantly British in the face of determined resistance from the indigenous Maori; subsequently the two races achieved considerable harmony. On land bought or wrested from the Maori, the settlers established a society dependent upon agrarian resources and overseas markets.

DISCOVERY

Little is known about the time or the manner of arrival of the first inhabitants except that they came over the sea from the north. Chronologies based upon Maori oral traditions are uncertain. Archaeology indicates a much longer Polynesian occupancy than had earlier been supposed; other studies point to accidental drift voyages as the means of settlement. No more is certain than that the Maori represent the southernmost point reached by Polynesian expansion in the Pacific.

The Polynesian period has been divided into an early "Archaic" and a later "Classic Maori" phase, but the transition from early to late is unexplored. In the South Island, if not elsewhere, the first Polynesians found moas (flightless birds) in immense numbers on tussock grasslands, and these became their major food supply. The "Classic Maori" encountered later by Europeans had only faint memories of the moa and was an agriculturalist. The 18th-century Maori population was most dense in the warmer northern parts of the country, where the Maori variant of Polynesian culture had reached its high point, particularly in the arts of war, canoe construction, building, weaving, and agriculture. Estimates of the extent of the Maori population vary widely; it was probably not more than a few hundred thousand. Numbers were to drop sharply in the first century of European influence, from the late 18th to the late 19th century.

The first European to arrive in New Zealand was a Dutch sailor, Abel Janszoon Tasman, who sighted the coast of Westland in December 1642. His sole attempt to land brought only a clash with a South Island tribe in which several of his men were killed. After his voyage the western coast of New Zealand became a line upon Euro-

pean charts and was thought of as the possible western edge of a great southern continent.

Captain Cook's explorations

In 1769–70 James Cook, the British naval officer and explorer, completed Tasman's work by circumnavigating the two major islands and charting them with a remarkable degree of accuracy. His first contact with the Maori was violent, but harmonious relations were established later. On this and on later voyages, Cook, with the explorer and naturalist Joseph Banks, made the first systematic observations of Maori life and culture. Cook's journal, published as *A Voyage Towards the South Pole and Round the World* (1777), brought the knowledge of a new land to Europeans. He stressed the intelligence of the natives, and the suitability of the country for colonization, and soon colonists, as well as other discoverers, followed Cook to the country he had made known.

EARLY EUROPEAN SETTLEMENT

Apart from convicts escaping from Australia and sailors seeking asylum with Maori tribes, the first European New Zealanders sought profits—from sealskins, timber, New Zealand flax, and whale oil. Early New Zealand was an offshoot of Australian enterprise in whaling and other activities; Sydney, New South Wales, founded as a convict settlement in 1788, became a base for South Pacific whaling; and Kororareka (now called Russell), in the far north of New Zealand, became a stopping place for American, British, and French deep-sea whalers. Around both islands Australian firms set up tiny settlements of land-based bay whalers. Traders supplying whalers drew Maori into their economic activity, buying provisions, supplying trade goods, implements, muskets, and rum. Initially the Maoris welcomed the newcomers; while the tribes were secure, the European was a useful dependent.

Maori went overseas, some as far as England. A northern chief, Hongi Hika, amassed presents in England, which he exchanged in Australia for muskets; back in New Zealand he waged devastating war on hereditary enemies. The musket travelled south; a series of tribal wars, spreading from north to south, displaced populations and disturbed landholdings, especially in the Waikato, Taranaki, and Cook Strait areas. Europeans were soon to found colonies in these unsettled regions. Missionaries quickly followed the traders. Between 1814 and 1838 Anglicans, Wesleyans, and Roman Catholics set up stations. Success was initially slow, but by the mid-19th century most Maori adhered, for varying reasons, to some form of Christianity.

European colonies

All of these newcomers had a profound effect upon Maori life. Warfare and disease reduced numbers; new values, pursuits, and beliefs modified tribal structure. Christianity cut across the sanctions and prohibitions that had supplied social cohesion. A capitalist economy, to which Maori were introduced both by traders offering new inducements (for instance, the brief demand for flax) and missionaries bringing new agricultural techniques, affected the whole material basis of life. At first in the north, and later over the whole country, a process of adjustment began, which has not yet been completed. By the late 1830s, chiefly through the Australian link, New Zealand had been joined to Europe. Settlers numbered at least some hundreds, and there were certain to be more. Colonization schemes were afoot in Great Britain, and Australian graziers were buying land from the Maori. These circumstances determined British policy.

ANNEXATION AND FURTHER SETTLEMENT

In 1838 the British government decided upon at least partial annexation. It commissioned William Hobson, naval officer, as lieutenant governor and consul to the Maori chiefs in July 1839; he became governor in 1841. Hobson, in the event, annexed the whole country, the North Island by the right of cession from the Maori chiefs and the South Island by the right of discovery. From June 1839 to May 1841 New Zealand was legally part of New South Wales. Before declaring the annexation of New Zealand, Hobson went through a process of discussion with the northern chiefs from which emerged the so-called Treaty of Waitangi (February 1840). Under this instrument, Maori ceded sovereignty to the crown in return for protection and guaranteed possession of their lands; they also agreed to sell land only to the crown. Hobson promised an investigation into past "sales" of land to private individuals to ensure fair dealing. This treaty imposed a strong moral obligation upon the British government to act as guardian to the Maori.

The Treaty of Waitangi

Even before annexation had been proclaimed, the first organized planting of an English colony was under way. The New Zealand Association, founded in 1837 to colonize on the principles laid down by Edward Gibbon Wakefield, sent a survey ship, the "Tory," in 1839. The agents on board were to buy land in both islands around Cook Strait. The company moved hastily because its founders were aware that British annexation was likely and would entail a crown monopoly of land sales and a consequent increase in price. "Purchases" were effected in great haste before Hobson could bring to an end such private transactions. Little effort was made to seek out the true Maori owners; this would have been difficult anyway, as Maori ownership was communal and titles had been disturbed by the musket warfare of the preceding quarter century. The company, combining skillful propaganda with outright trickery and brutality, enforced its claim to the land upon which New Plymouth, Wanganui, and Wellington in the North Island and Nelson in the South Island were founded in the 1840s. Later, through the crown, it secured other areas in the South Island where Otago (1848) and Canterbury (1850) were planted by separate associations. Meanwhile, Hobson moved the seat of government south from the Bay of Islands, bringing Auckland into existence (1841).

In the early 1840s settlement and government began to alarm the Maori. In the Cook Strait area a formidable chief, Te Rauparaha, obstructed settlement. Near the Bay of Islands there was open warfare, and Kororareka was repeatedly raided. Neither Hobson (died 1842) nor his successor, Robert Fitzroy, was able to overcome the Maori. George (afterward Sir George) Grey, who became governor in 1845, had money and troops and the will to use them. His victories brought a peace that lasted from 1847 until 1860. Hone Heke, the northern leader, was thoroughly defeated (1846), and in the south a likely uprising was prevented. Racial strife had been accompanied by economic distress. In the mid-1840s the nascent economy was depressed until the Australian gold rushes of the 1850s offered a market for foodstuffs to the New Zealand farmer, settler, and Maori alike.

War with the Maori

By the end of the 1840s racial and economic trouble gave way to political agitation. The leading settlements, apart from Auckland, began to campaign for representative government in place of Grey's personal rule. He, while refusing to give way, helped to draft the New Zealand Constitution Act (1852), which was designed to meet all the settler demands. He sought not to prevent the introduction of self-government but to delay it until he had determined both native and land policy. He wished to begin the rapid assimilation of the Maori (with whom his relations were excellent) to the British pattern. He also wished to bring in a land policy that would safeguard the small farmer against the great owner. He believed he had secured these goals by the time of his departure at the end of 1853.

Responsible government. When the Constitution Act came into operation, New Zealand was divided into six provinces—Auckland, New Plymouth (Taranaki), Wellington, Nelson, Canterbury, and Otago—each with a superintendent and a Provincial council. The central government (General Assembly) consisted of a governor, a Legislative Council nominated by the crown, and a House of Representatives elected upon a low property franchise for a five-year term. This General Assembly did not meet until 1854; it then embarked upon a quarrel with the acting governor, Colonel Robert Henry Wynyard, that was not ended until the achievement of full responsible government—*i.e.*, a system under which the governor could act in domestic matters only upon the advice of ministers enjoying the confidence of the elected chamber. Henry Sewell and James FitzGerald, of Canter-

bury, led the representatives in this struggle, against the opposition of E.G. Wakefield, who, having first moved the resolution for responsible government, then secretly opposed it while serving as extra-official adviser to the acting governor. The Colonial Office conceded responsible government in 1856. The next governor, Thomas Gore Browne, reserved Maori affairs to the competence of the governor alone.

Provincial institutions

For most purposes, during the 1850s New Zealand was administered not by central but by provincial institutions. These authorities (nine in number by the time of their abolition in 1876) directly affected the settler through their administration of land and control of immigration and public works. The native department, directly under the governor, bought land from the Maori; the provincial governments settled it, regulated immigration, and built roads and bridges. Until the wars of the 1860s the central legislature was less important, though its ultimate authority remained.

Each province disposed of a revenue arising from land sales, and upon this revenue depended its strength. Canterbury and Otago, with hardly any Maori, grew wealthy, spending their money upon communications, immigration, and education. Other provinces were either less fortunate or less wise and enjoyed smaller success. In the North Island, numerous and anxious Maori held on to desirable land. Here most of the land available for settlement had been taken up by the end of the 1850s, a good deal of it by speculators, and some of it was given away to attract immigrants. The island remained largely without roads until the 1870s, so impecunious were its governments. But by that time the major obstacle to settlement had been removed—the continuing power of the tribes. This was the result of a decade of war.

Racial conflict. In the 1850s race relations deteriorated. The settler population and the demand for land, especially pastoral land, increased. Many Maori, fearing for their future, became reluctant to sell more land. In the Taranaki Province, where the land shortage was acute, both settlers and those Maori willing to sell were opposed by Wiremu Kingi (Te Rangitake), chief of Te Atiawa. In the Waikato, where good land was coveted by settlers and speculators, an elderly chief, Te Wherowhero, was elected "king" in 1857, largely by the Waikato and Maniopoto tribes, and reigned as King Potatau I. This "king" movement and also the unrest in the Taranaki headed by Wiremu Kingi (the two movements remained distinct though related) were opposed to further land sales.

Land sales

The likelihood of conflict was not reduced by any particular wisdom in government policy. Gore Browne was guided in native policy by the head of the Native Land Purchase Department, Donald McLean, who, responsive to settler demands, increased pressure upon potential sellers. Grey's caution and his recognition that a chief could veto sales proposed by any section of his tribe were forgotten. McLean sowed a rich harvest of distrust. Christopher Richmond, the member of Cabinet in charge of native affairs, was also a Taranaki representative, fully responsive to the needs of his settler neighbours. The central ministry, theoretically unconcerned with native policy, could not, despite the promise of protection made to the Maori in the Treaty of Waitangi, neglect a matter so vital to the colony's future. In 1859 the representative of the crown unwittingly supplied the occasion for the outbreak of civil strife.

Gore Browne accepted an offer to sell from a Taranaki subchief, Te Teira, and ignored the veto imposed by the paramount chief, Wiremu Kingi. Early in 1860 troops were used to dislodge Kingi from the land in question, the Waitara block. A decade of fighting began. In 1861 Grey was sent back for a second term as governor in the hope that he would again prove to be a peacemaker. In fact he accelerated the extension of conflict. Fearing that Auckland was menaced by the followers of the Maori king, he took defensive measures which could easily be interpreted as acts of aggression, and the fighting subsequently spread from Taranaki to the Waikato. Imperial troops, colonial militia, Maori allies (for not all the tribes supported the Maori nationalist movement) had no easy task, but their victory could not be postponed for long. By the mid-1860s Maori resistance in the Taranaki and Waikato was ended. But the "king" tribes were by no means crushed, and the fear that they would embark upon war again haunted the colony for many years.

In the later 1860s the fighting was of a different character, in which religion acted as a last, desperate stiffener of Maori resistance. Pai Marire (Hauhauism), an amalgam of Christian and primitive beliefs, was the first of many cults in which the Maori, rejecting the religion of settler and missionary, put their own imprint upon Christianity. Toward the end of the decade, Te Kooti organized resistance on the east coast. He was the founder of another religious cult as well as a guerilla of some note; his adaptation of Christianity, Rin-gatu, still had thousands of followers in the mid-20th century. Te Kooti was never finally defeated, but by the early 1870s he was forced to retreat into the "king country" (the centre of the island), where he devoted the rest of his life to religious leadership.

An uneasy peace settled upon the colony in 1870. Casualties had not been high, but the loss of life was serious for the tribes concerned. Especially in those areas in which the Maori king retained some authority, defeat led to a period of withdrawal from settler society. Resentment was deepened by a punitive policy of land confiscation adopted by the victors, a policy improper in its nature and made worse in some places by undiscriminating application to "guilty" and "innocent" tribes alike. The Maori future looked black. By the 1862 Native Land Act private land transactions between settler and Maori had been legalized, and during the next 40 years the Maori lost most of their best land. Many years were to elapse before Maori numbers, morale, and confidence could revive over the whole country.

The Native Land Act

DEVELOPMENT OF THE COLONY

Economic growth in the North Island had been considerably retarded by the wars. Meanwhile, the South Island, especially Canterbury and Otago, had grown increasingly prosperous. Pastoral farming expanded steadily, and the discovery of gold, first in Otago and then on the west coast, led to a sudden boom in production and trade. Population rose as diggers poured in; economic life quickened as gold brought prosperity, less to the digger than to bankers, merchants, land sellers, and farmers supplying provisions. The South Island share of the European population jumped from about 40 percent to 60 percent during the 1860s. The North Island did not recover its previous lead until the 20th century.

Discovery of gold

Attempts by other provinces to emulate the development of Canterbury and Otago normally ended in embarrassment (in one case in bankruptcy) as money was recklessly borrowed and spent. To preserve the colony's reputation, the central government in 1867 banned further provincial overseas borrowing. About this time depression struck the greater part of the country, especially the South Island, where the first alluvial gold had by then been worked out. The South Island was thus looking for a stimulus, while the ending of the wars now made further development possible in the North Island. It was widely agreed that only the central government could adequately revitalize the economy.

In 1870 a development policy was provided by Julius Vogel, the colonial treasurer, who was convinced (not altogether accurately) that New Zealand was bursting with potential resources needing no more than the stimulus of capital and labour for their exploitation. He borrowed overseas capital for public works on an unprecedented scale and swelled the labour force with assisted immigrants.

Julius Vogel's development policy

Not all Vogel's schemes were wisely conceived; the prosperity of the mid-1870s was more an investment boom than a solid growth of productivity. But the colony ended the decade with a doubled population (about 500,000) and the beginnings of efficient internal and external communications. Roads, bridges, railways, and telegraph systems had been built, and overseas shipping services improved.

Private lending agencies contributed to the boom, and in a heady atmosphere land values and interest rates climbed alarmingly. The public debt greatly increased, and many of the men who had acquired land were in desperate financial straits. Falling overseas prices for farm products (chiefly wool and wheat), a declining gold output, a cautious note in government finance, and widespread unemployment marked the 1880s. Emigrant ships discharged their passengers at ports where unemployment was already rife. There had been growth in the 1870s, but it was succeeded by a depression that lasted until 1895.

Economic depression

Vogel abolished the provincial governments in 1876. They had earned his enmity by refusing to allow their lands to be used as security for public works and by blocking a forest conservation scheme. Essentially, they became outmoded when, in the early 1870s, the initiative in development passed to the central government. Provincial governments had been set up to colonize their districts; when the centre assumed this function they lost their raison d'être. Abolition came fairly painlessly; it was an affront more to local pride than to local prosperity. Only in Otago was there a strong attempt to resist change. Thereafter, provincial interests were long pursued by the respective delegates in the General Assembly, whose achievements were in no way diminished by the lack of particularist (provincial) institutions.

The governments of the 1880s, though led by men of some ability and imagination, such as Sir Robert Stout and Sir Harry Atkinson, did not deal effectively with the depression. The time-honoured remedy, spending loan money on development, was not fully given up until 1887. The basic problem was to find productive work for the country's labour force; closer land settlement was the remedy suggested in the 1880s and applied in the 1890s. Great areas, especially in the South Island, had fallen to large owners; these "monopolists" were attacked by the radicals, though probably the pastoral industry could not have been established under any other system. William Rolleston, minister of lands from 1882 to 1884, first proposed that the state should help men to become small farmers as state tenants; John McKenzie and the Liberal government applied this remedy with vigour in the 1890s. But closer settlement and intensive farming did not succeed until small farmers had a product to export and gained a good price for that product. Refrigeration and rising world prices provided the answer. It became possible in the 1880s to send to Great Britain refrigerated cargoes of butter, cheese, and meat; this encouraged the spread of small-scale intensive farming.

The Liberal era (1891–1912). The energetic Liberal government led by John Ballance, which took office in 1891, accelerated the process of change. It opened more land (much of it bought from the Maori), established farmers on perpetual state leaseholds, provided credit for land purchase and improvements, and built roads. So came into existence great dairying and meat producing areas, especially in the North Island. Dairy, meat, and also wool prices rose in about 1895 and stayed generally high until about 1920.

This economic stimulus was not limited to farmers. Urban distress had been serious in the 1880s, for many recent immigrants had been townsmen who had stayed in New Zealand towns on arrival. The ultimate cure for their distress was for the towns to share in the farmers' high prices. Urban New Zealand depended upon the prosperity of the country. But other remedies were considered, and some of them were applied. In the 1880s there was serious discussion of insurance against sickness, poverty, and old age; the Old Age Pensions Act of 1898 was the first measure of social security. Tariff protection to foster industrial employment was halfheartedly applied in the late 1880s. Revelations of oppression in industry led, in the 1890s, to a labour code to protect workers.

But the chief Liberal industrial policy, formulated by William Pember Reeves, minister of labour from 1892 to 1896, was to encourage trade unions and to introduce, in the Industrial Conciliation and Arbitration Act of 1894, a conciliation and compulsory arbitration system intended to end industrial unrest and give the unions the means of protecting their members. The growth of unions was stimulated by the fact that only through them could the workers use the system. Reeves's act, amended and occasionally suspended but still essentially his own handiwork, has never been repealed. It has enabled the worker in good times to resist wage cuts and to press for increases; but it has not managed to prevent cuts and unemployment when falling overseas prices have brought depression to New Zealand. It has not been strikingly radical in effect; employers and governments have used it to break strikes, such as that of miners at Waihi in 1912. It has built up the power of those majority elements in the unions that prefer coming to terms with capitalism to any effort to destroy it. Some occupations, such as transport, cargo handling, meat processing, and mining, have fostered unions keen to relinquish arbitration for direct action, but they have been in a minority and seldom, in the long run, successful. Farmers and governments have usually acted with severity in disputes affecting the movement of exports.

The growth of trade unions

The Liberal era, from 1891 to 1912, transformed political life. Previously politics had not been marked by neat party divisions. Local advantage had determined political behaviour in the development period during and after the 1870s; men had argued over the scope and details of policies and had advanced the claims of locality and province for a proper share of largess. Acute depression ended development and with it the politics of local advantage. In 1890 the Liberals began to act as a more or less unified party. Their 20 years in office, the success of their land and labour policies, and the formidable qualities of leadership discovered in Richard John Seddon, premier from 1893 to his death in 1906, welded the Liberals into a fairly coherent parliamentary and popular party.

R.J. Seddon as premier

Seddon was a portent of a new age. In 1893 this energetic goldfields trader-turned-politician provided a sharp contrast to the gentlemanly premiers who had preceded him. But his crudeness assisted rather than hindered the attainment of popularity none of them had known. He was devoted to political success and skilled in the manipulation of the means of success—parliamentary procedure, patronage, and party organization. By the time of his death he had established a kind of elective despotism over the country.

THE 20TH CENTURY

Seddon's successors, in his own and in other parties, were of the same stamp—men of the people devoted to a political career. Politics ceased to be a duty of the well-to-do amateur. The Liberal government, under Sir Joseph Ward, survived Seddon by six years. In 1912 it fell before a new party, Reform, led by a dairy farmer, William Ferguson Massey, prime minister until 1925. Based on prospering farmers and townsmen, especially of the North Island, and closely connected with their professional organizations, it was more narrowly sectional than the Liberals had been. Except for views borrowed from the Liberals, it had little positive policy. Reform made much of a promise to enable the state leaseholder to buy the freehold of his farm at original valuation; this promise was an emotional rallying cry for conservatives fearing land nationalization and complete socialism. Only a small minority of farmers were state tenants, and not all bought the freehold when the Reform government gave them the chance.

While the Liberals lost support in rural areas, they were further weakened by urban left-wing defections, which eventually led to a separate Labour Party. Four Labour members were returned in 1911. The initiative, on the right and on the left, was passing to other parties, and the Liberals were gradually eclipsed. The period before World War I was one of discontent and anxiety. Prosperity, though still considerable, had somewhat declined. The farmers were disturbed by what they took to be the threat of socialism, detected in the radicalism of a Liberal minority, but chiefly in the rebirth of direct action in some trade unions. This change in temper arose from labour dissatisfaction with wage levels achieved under arbitration and from the growth of syndicalist and socialist ideas. After 1906 the Arbitration Court refused to grant further

increases of real wages. Discontent flared up in the strikes of 1912–13, the biggest occurring on the waterfront when the farmers' government, headed by Massey, vigorously repressed a strike movement that had slight overtones of social revolution.

World War I and the interwar years. New Zealand supported Great Britain in World Wars I and II, chiefly by sending men overseas and producing food and wool. In World War II the Japanese brought danger close to New Zealand's shores; in the earlier conflict the peace of the Pacific was seldom disturbed.

New Zealanders served in the Dardanelles campaign at Gallipoli and subsequently in France. In these battles they began to learn that they were a distinctive branch of the British people. The infantry "digger" of 1914–18 came to symbolize those qualities that the country most respects —courage, endurance, and resourcefulness. New Zealand lost many of its young men, a serious loss for succeeding decades.

At home the war brought prosperity, as export markets were assured and prices good. Domestic unity was hardly shaken by the antiwar feeling of a handful of left-wingers. Massey remained prime minister, but in the wartime coalition government (1915–19) Ward and the Liberals carried great weight. Reform stayed in office until 1928, led after Massey's death in 1925 by Joseph Gordon Coates. The party survived the first postwar depression, but not that of the mid-1920s. Led by Ward, the Liberals, under the new name of United Party, were victorious in 1928; they thus had to face the deepening depression of 1929–30. After Ward's death (1930) and at the height of the depression, Reform and United formed a new coalition (1931) under the premiership of George Forbes, which lasted until the election of 1935 brought in a Labour government with a large majority.

Some postwar developments were of great importance. In external affairs, Massey led a delegation to the peace conference, signed the Treaty of Versailles, and so committed New Zealand to membership in the League of Nations. New Zealand thus began to acquire the status of a sovereign state, though Massey denied this consequence. The Liberals, especially Seddon, had already taken steps toward autonomy within the empire. At the series of colonial and imperial conferences from 1887 onward, New Zealand had followed Canada and Australia in asserting its right to a voice in certain foreign policy issues. Seddon argued vehemently against British reluctance to acquire more Pacific islands while permitting German influence to grow in Samoa. New Zealand legislation to restrict Asian immigration was sharply and obstinately at variance with British policy. Western Samoa, which New Zealand had captured from the Germans in 1914 and over which it was granted a mandate in 1920, also provided occasions for British and New Zealand differences.

Sovereign status

Reform leaders professed little love for the principle of autonomy, which, in the 1920s, came to dominate Commonwealth relations. New Zealand took part in the conferences leading to the Statute of Westminster in 1931 but did not adopt the statute until 1947. But the substance of autonomy had been enjoyed long before.

The major domestic achievement of the Reform administration was a system of export marketing agencies in which authority was shared by producer and state. These failed in their short-term objective—to sustain farmers' returns while prices fell—but they laid the foundations of a collectivist marketing structure that has continued to expand.

The leading domestic phenomenon was the rise of Labour. The New Zealand Labour Party was established in 1916; in the 1920s it came to dominate working class urban electorates. But complete success eluded it. It had little to attract the rural voter until 1928, when it offered easier credit, and then the revitalized Liberals (United) offered an attractive alternative quite free from the taint of extreme socialism that still clung to Labour. The United Party went back to the old remedy of massive expenditure of borrowed money. In fact, the prospect of electoral success had by this time caused the Labour Party to translate its socialism into a series of welfare and credit proposals. The formation of the coalition between Reform and United in 1931 made Labour the official opposition. Industrial labour, notably sections influenced by semi-syndicalist ideas, was a restive ally for the party. But unemployment, the suspension of the compulsory arbitration system in 1932, and a nationwide series of wage cuts drove the two wings of the Labour movement together. Trade unionists had now learned that their welfare depended upon political power. Politicians could abolish arbitration, their main defense against poverty, and other politicians would be necessary for its restoration. The new solidarity played a large part in the Labour victory of 1935.

Labour in power

J.G. Coates was the most energetic and least conservative coalition minister. His attempts to counter depression concentrated upon the rehabilitation of the farmer as a step toward the revival of the whole country. In order to increase export receipts, he devalued the New Zealand pound from £110 to £125 per £100 sterling; he protected the farmer against foreclosure, and he set up a credit agency, the Mortgage Corporation. He also established the Reserve Bank of New Zealand. When overseas prices began to recover in 1934, the country was financially strong.

But he had done little for the multitude of unemployed. Unenviable conditions in towns and relief camps led to outbreaks of rioting and violence, to widespread discontent, and to the Labour victory. Successful in the towns, Labour also won in many rural areas, especially in the dairying districts. Prices for dairy exports were slowest to recover, and the dairy farmer was drawn by Labour promises of a guaranteed price for dairy produce and of cheap and plentiful credit. The victory was particularly notable in terms of seats, for a right-wing third party (the Democrat Party) split the conservative vote to Labour's advantage. A contest in 1938 without the Democrat Party, however, had the same result, and the opposition (the successors of Reform and United, now renamed the National Party) was rendered temporarily ineffective.

The new ministers, among whom the most notable were Peter Fraser as minister of health and education, and Walter Nash as minister of finance, showed great energy; genially led by Michael Joseph Savage, they had good fortune to govern a country to which prosperity was fast returning. The farmer was enjoying increased earnings; the worker, increased wages and shorter hours. Jobs were multiplied by a massive public works and housing program; attempts were made to stimulate secondary industry and to diversify the economy to make it less vulnerable to overseas conditions. The education system was revitalized. In 1938 the Social Security Act provided a state medical service, extended the pension system, and increased benefits. The expansion of industry was accelerated after the outbreak of World War II in 1939.

World War II and after. The alacrity with which New Zealand went to war in 1939 showed that dominion autonomy had not weakened the country's ties to sentiment with Great Britain. At first the war resembled that of 1914; troops were sent to Egypt to train for the European conflict. There they were directly involved by the enemy advance in North Africa and the Balkans and saw action in Greece, Crete, North Africa, and Italy before the final Axis collapse. After 1941 New Zealand was directly threatened by Japan, and New Zealand forces also were engaged in the Pacific. They were not withdrawn from the European fighting, and well before the end of the war the double strain upon the country's manpower, together with the demands of home production, enforced a reduction of commitments in the Pacific.

The Pacific theatre was dominated by the U.S., whose forces, after the loss of Singapore (1942), provided New Zealand's sole defense. U.S. troops were stationed in New Zealand, and New Zealand forces fought under U.S. command. The fact that disaster was averted by U.S. and not by British troops imposed a certain strain on New Zealand's loyalties. For generations security had been guaranteed by British power; now it was conferred by a foreign, though friendly, power. External relations in the postwar period reflected this new situation, chiefly

through the ANZUS pact (1951), a defensive alliance between Australia, New Zealand and the United States.

At home the total economy was mobilized in the war effort. Controls, already considerable by 1939, were extended to cover every aspect of economic life. Conscription and direction sent manpower either into the armed forces or to essential occupations; heavy taxation, war loans, bulk purchase, and controlled marketing kept the economy in a firm grip. These devices also served to keep inflation in check; together with price control and wage restraint they amounted to a complete policy of economic stabilization. These controls were applied by a Labour government that remained in power until 1949. Savage died early in the war. Fraser, his successor as prime minister, inherited a large share of the tasks of war administration and peacetime reconstruction. In economic affairs, the leading minister was Nash. No full coalition was formed, but for a few months in 1942 a War Cabinet, on which some National M.P.'s had seats, among them Coates (died 1943) and Sidney (afterward Sir Sidney) Holland existed alongside the normal Cabinet.

Holland led the revival of the National Party, which was marked in the elections of 1943 and 1946 and culminated in victory in 1949. Discontent with controls and with the rising cost of living were among the factors that caused opinion to swing away from Labour. Subsequently, the two parties remained fairly evenly balanced. The National government benefitted from its vigorous handling of a serious waterfront dispute in 1951, but in later elections its majority narrowed until Labour returned to office in 1957. But in 1960 the National Party, led by Keith Holyoake, was returned to power, which it maintained into the 1970s. Holyoake resigned in 1972 and was replaced by Deputy Prime Minister John Marshall. By the time of the 1966 election the two parties agreed that the economy had to be controlled, secondary industry encouraged, and the welfare state maintained. But the nation's prosperity was precarious, and this led, especially in rural areas, to emergence of a Social Credit movement, which in 1966 won its first parliamentary seat, though it lost it in 1969.

International affairs

The most striking postwar development took place in international affairs. Not only did the U.S. come to supplant the U.K. in New Zealand's thinking about military security but also New Zealand began to play a relatively independent role in world politics. This latter development, in fact, began before World War II, when the Labour government's attitude to the League of Nations was coloured by an idealism that clashed with prewar British policy, especially over the Ethiopian issue. This independent spirit was carried by Fraser to the formation of the United Nations. During the war Fraser had insisted upon an independent voice in the councils of the Allied powers, especially where the fate of New Zealand troops was concerned. At the formation of the United Nations at San Francisco in 1945 he became a notable spokesman for the small powers and made a large impression upon the deliberations of the Trusteeship Council. None of these developments weakened New Zealand's close affinity with Great Britain or its loyalty to the Commonwealth of Nations. Independence and close identity were found to be compatible.

Geography and insecurity shaped New Zealand's postwar foreign policy. With Australia, New Zealand claimed a voice in the settlement of the South Pacific through the Canberra Agreement of 1944. This regional concern also appeared in its role in the South Pacific Commission and in the transfer of authority in Western Samoa, successfully completed when that country became independent in 1962. New Zealand also became deeply involved in Southeast Asia. From 1951, through the Colombo Plan, it provided assistance to many Southeast Asian countries. More militantly, New Zealanders fought in Malaya, Korea, and Vietnam; further, New Zealand became a member of the Southeast Asia Treaty Organization (SEATO) in 1954 and supported U.S. initiatives in that region. This reflected the fear felt at the growth of Communist power in Asia. Thus the independent spirit of the immediate postwar years was modified to a greater dependence on Western powers during the 1950s and 1960s. In the later 1960s the Vietnam war led to a vigorous and continuing public debate on foreign affairs.

Social problems

Two major social problems confronted New Zealand in the second half of the 20th century: to find a productive occupation for a growing population and to preserve harmonious relations between the two races. The country was still an exporter of primary products and an importer of manufactured goods and industrial raw materials. But farming absorbed a decreasing share of the labour force, and traditional farm exports and their markets proved less reliable. To maintain full employment and to strengthen exports, the country began to diversify at home, to explore new products, and to seek new markets. The threat of British entry into the European Economic Community (Common Market) was an incentive to economic reconstruction.

The rapid increase of the Maori population, and its steady urbanization, led governments, especially from the 1950s on, to attempt a "crash program" to raise educational and, eventually, socio-economic levels. These lagged considerably behind the New Zealand average, and this disparity provided ample ground for concern over the possibility of deepening racial tension, in spite of the full legal equality and frequent social harmony that continued to exist. Economic, racial, and foreign policy were the most vital issues in public affairs during the 1960s and early 1970s.

BIBLIOGRAPHY

General works: Of the many short histories, K. SINCLAIR, *A History of New Zealand*, 2nd ed. (1970); and W.H. OLIVER, *The Story of New Zealand*, 2nd ed. (1963), are the most useful.

Early history: Aspects of the culture of the pre-European Maori are explored in two works by PETER H. BUCK: *The Coming of the Maori*, 2nd ed. (1950), and *Vikings of the Sunrise* (1954). The 19th-century compilation of SIR GEORGE GREY, *Polynesian Mythology and Ancient Traditional History of the Maori* (1855; new ed., 1956 and 1970), remains invaluable. European discovery and exploration may be briefly studied in J.C. BEAGLEHOLE, *The Discovery of New Zealand*, 2nd ed. (1961); and W.G. MCCLYMONT, *The Exploration of New Zealand*, 2nd ed. (1959). Early contact between Maori and European is the subject of HARRISON M. WRIGHT, *New Zealand, 1769–1840* (1959). Annexation and early constitutional development are covered by I.M. WARDS in *The Shadow of the Land: A Study of British Policy and Racial Conflict in New Zealand, 1832–1852* (1968). Early settlement and the role of the New Zealand Company are vividly described by J.O. MILLER in *Early Victorian New Zealand: A Study of Racial Tension and Social Attitudes, 1839–1852* (1958).

Development since settlement: The interrelated themes of race relations, political development, and imperial relationships in the period from 1840 to 1870 are explored in J. RUTHERFORD, *Sir George Grey, K.C.B., 1812–1898* (1961); K. SINCLAIR, *The Origins of the Maori Wars* (1957); H.G. MILLER, *Race Conflict in New Zealand, 1814–1865* (1966); J.E. GORST, *The Maori King*, ed. by K. SINCLAIR (1959); B.J. DALTON, *War and Politics in New Zealand, 1855–1870* (1968); and W.P. MORRELL, *The Provincial System in New Zealand, 1852–76*, 2nd ed. (1964). A collection of documents covering this period is G.H. SCHOLEFIELD (ed.), *The Richmond-Atkinson Papers*, 2 vol. (1960). Subsequent political history may be examined through the following books: R.M. BURDON, *The Life and Times of Sir Julius Vogel* (1948) and *King Dick: A Biography of Richard John Seddon* (1955); K. SINCLAIR, *William Pember Reeves* (1965); P.J. O'FARRELL, *Henry Holland, Militant Socialist* (1964); B.M. BROWN, *The Rise of New Zealand Labour: A History of the New Zealand Labour Party from 1916–1940* (1962); R.M. CHAPMAN (ed.), *Ends and Means in New Zealand Politics* (1961); R.S. MILNE, *Political Parties in New Zealand* (1966); K.J. SCOTT, *The New Zealand Constitution* (1962); and R.M. CHAPMAN *et al.*, *New Zealand Politics and Action: The 1960 General Election* (1962). A general economic history with emphasis on the later period of development is M.F.L. PRICHARD, *An Economic History of New Zealand* (1970).

(W.H.O.)

Ney, Michel

Michel Ney was the most famous of Napoleon's marshals, a military hero of legendary courage. His death by

a firing squad in 1815 made him a popular symbol of resistance to the Bourbon restoration as well.

Ney was born January 10, 1769, at Sarrelouis (present-day Saarlouis) in eastern France, the son of a barrel cooper and blacksmith. Apprenticed to a local lawyer, he ran away in 1788 to join a hussar regiment. His opportunity came with the revolutionary wars, in which he fought from the early engagements at Valmy and Jemappes in 1792 to the final battle of the First Republic at Hohenlinden in 1800.

First military service

H. Roger-Viollet

Ney, lithograph by François Le Villain, early 19th century, after a portrait by Maurin.

The early campaigns revealed two contrasting features of Ney's character: his great courage under fire and his strong aversion to promotion. Willing to hurl himself into battle at critical moments to inspire his troops by his personal example, he was unwilling to accept higher rank, and when his name was put forward he protested to his military and political superiors. In every instance he was overruled: it was as general of a division that he fought in Moreau's Army of the Rhine at Hohenlinden.

A year before that battle, Napoleon, under whom Ney had never served, had emerged as master of France. In May 1801, Ney was summoned to be presented to the First Consul at the Tuileries, where Napoleon and Joséphine had surrounded themselves with the ceremony and splendour of a court. The Army of the Rhine had been disbanded, and Ney had bought a modest farm in Lorraine. His first encounter with Bonaparte was formal and unremarkable, for the First Consul, regarding Moreau as a military rival and political opponent, viewed the close associates of that general with suspicion. Joséphine, however, took him up and found him a wife, Aglaé Auguié, one of her maids of honour and daughter of a high civil servant. They were married in the chapel of the Auguié château near Versailles. Ney, with his influential new connections, became, at 33, part of the social and military world of the Consulate.

When peace with England broke down and Bonaparte was assembling armies along the Channel coast, Ney asked for employment and was given command of the VI Army Corps. Early in 1804, when police uncovered a plot by émigré Royalists to kidnap or murder Napoleon and restore the Bourbons to the throne, Ney's republican friend, General Moreau, was said to be involved, and with other alleged conspirators was put on public trial. Napoleon commuted Moreau's two-year sentence for banishment. On May 19, 1804, the day after Napoleon had had himself proclaimed hereditary emperor of the French, he revived the ancient military rank of marshal, and 14 generals, including Ney, were gazetted marshals of the empire.

When Napoleon led his armies in swift marches into the heart of the Continent, after a new European coalition of Russia, Austria, and England had been formed against France, the first victory was won by Ney at Elchingen in October 1805—for which he was created duke of Elchingen in 1808—and less than two months later Napoleon defeated the Russo-Austrian armies at Austerlitz. Ney was active in the defeat of Prussia at Jena in 1806, and of the Russians at Eylau and Friedland in 1807. When he was sent to Spain in 1808, his fame for personal bravery remained undimmed, but at the same time he was also known as a touchy and temperamental commander whom the general staff found difficult to fit into a tactical pattern. His impulsiveness sometimes verged on insubordination when his orders did not come from the Emperor himself. Since Napoleon directed the Spanish operations by remote control, Ney quarrelled with all those set above him, and, early in 1811, he was sent home in near-disgrace.

The Russian campaign of 1812 re-established his position. On the morning after the somewhat inconclusive battle at Borodino, Napoleon made him Prince de la Moskowa. On the retreat from Moscow, Ney was in command of the rear guard, a position in which he was exposed to Russian artillery fire and to numerous Cossack attacks. He rose to heights of courage, resourcefulness, and inspired improvisation that seemed miraculous to the men he led. "He is the bravest of the brave," said Napoleon when Ney, for weeks given up as lost, joined the main body of the frozen and shrunken Grand Army.

In the European campaigns of 1813, Ney had to fight against former friends. Moreau had returned from exile in America to serve as Tsar Alexander I's military adviser and was killed by a French cannonball outside Dresden. Ney had the mortification of being defeated at Dennewitz by the crown prince of Sweden, Charles XIV John, who as Jean Bernadotte had served as a sergeant in the revolutionary armies, as had Ney. At Leipzig, Ney was wounded and had to be sent home. The defeated army fought its way back across Germany into France, where, deaf to all appeals for peace, Napoleon launched a new campaign. Ney, commanding in eastern France, organized the kind of partisan warfare he had learned in the revolutionary wars. Napoleon concentrated his remaining forces at Fontainbleau to fight the allies in Paris, but Ney, speaking for himself and other marshals, told him that the army would not march. "The army will obey *me*," said Napoleon. "Sire," replied the Bravest of the Brave, "the army will obey its generals." Napoleon was forced to abdicate. Ney retained his rank and titles and took an oath of fidelity to the Bourbon dynasty.

Ney's political shift

On March 1, 1815, Napoleon reappeared in France. Ney, ordered to take command in the district of Besançon, told the king "that man deserves to be brought back to Paris in an iron cage." Ney, however, found that the population in his military district was intensely hostile to the Bourbons. Therefore, after receiving messages from Napoleon, he announced his decision to join the Emperor and was deliriously cheered by his soldiers and the populace. The king fled from Paris, and Napoleon re-entered the Tuileries. Ney spent the period mostly in disgruntled retirement at his country estate. He saw little of Napoleon until three days before Waterloo, when he was summoned and asked to serve. He was put in charge of the left wing against the English, Napoleon taking the right wing against the Prussians, whom he defeated at Ligny. Ney fought the English in the drawn battle of Quatre-Bras. His conduct at Waterloo has remained a matter of controversy. When at nightfall the French fled from the field, Ney, his face blackened by smoke and holding a broken sword in his hand, shouted to a colleague: "If they catch us now, they'll hang us," a remark of prophetic accuracy.

After the second return of the Bourbons, Ney made a halfhearted attempt to flee the country, but was recognized and arrested in a remote corner of southwestern France. First put before a court-martial, he refused to recognize its competence and insisted on his right as a peer to be tried by the upper chamber. As he had expect-

Trial and death

ed, he was sentenced to death in one of the most divisive trials in French history. On the morning of December 7, 1815, a firing squad in the Luxembourg Gardens ended what his soldiers had always regarded as a charmed life.

Ney was a soldier's soldier, wholly without political ambition or judgment. He was at his greatest in the campaigns for France's natural frontiers at the beginning and end of his career, but out of his depth in Napoleon's intricate strategy for the domination of Europe. He showed little interest in external distinctions or social success. The dignity with which he met his death effaced the memory of his political vagaries and made him, in an epic age, the most heroic figure of his time.

BIBLIOGRAPHY. ANDREW H. ATTERIDGE, *The Bravest of the Brave* (1912); JOHN B. MORTON, *Marshal Ney* (1958); and HAROLD KURTZ, *The Trial of Marshal Ney, His Last Years and Death* (1957), are the principal biographies, containing full-length bibliographies. Ney's second son published the *Mémoires du maréchal Ney* (1833; Eng. trans., 2 vol., 1833), but this work takes the story only up to 1805. The DUKE OF WELLINGTON'S attitude toward the captured and imprisoned Ney is amply documented in his *Supplementary Dispatches* . . . (1858–72), especially vol. 11; a vivid account of Ney's trial before the Upper Chamber in 1815 occurs in the *Personal Recollections of the Late Duc de Broglie, 1785–1820*, 2 vol. (1887). During his trial a number of English partisans were intent on liberating Ney in an action that misfired. Their exploits are described in GIOVANNI COSTIGAN, *Sir Robert Wilson* (1932); IAN BRUCE, *Lavalette Bruce* (1953); and HAROLD KURTZ (*op. cit.*).

(Ha.K.)

Niagara River and Falls

Flowing in a northerly direction from Lake Erie to Lake Ontario, a distance of about 35 miles (56 kilometres), the Niagara River constitutes part of the boundary between the United States and Canada, separating New York state from the province of Ontario. It is the drainage outlet for the four upper Great Lakes (Superior, Michigan, Huron, and Erie), the aggregate basin area of which is some 260,000 square miles (673,000 square kilometres). The relatively high flow and steep descent (about 326 feet [99 metres]) of the river combine to make it one of the best sources of hydroelectric power in North America.

About halfway along the river's course lies Niagara Falls, one of the major scenic spectacles of the continent. Although at 167 feet (51 metres) it is far from the highest waterfall in the world, its breadth and quantity of flow give the falls a grandeur and beauty attested to by over 4,000,000 visitors annually. United States and Canadian cities of the same name stand on either bank of the river. For many decades the falls were an attraction for honeymooners and for such stunts as walking over them on a tightrope or going over them in a barrel, but increasingly the appeal of the site has become its beauty and uniqueness as a physical phenomenon.

Course of the river. From its head at Lake Erie, the river flows through a single channel for about five miles. It is then divided into two channels by Strawberry and Grand islands, the eastern, or U.S., channel running for about 15 miles, the western, or Canadian, for about 12. At the foot of Grand Island the two merge again about three miles above the falls. From Lake Erie to the upper rapids the river descends about 10 feet, whereas in the short rapids it falls 50 feet before pouring over the falls.

Divisions of the falls

The falls are in two principal parts, separated by Goat Island. The larger division, adjoining the left or Canadian bank, is Horseshoe Falls; its height is 162 feet and the length of its curving crest line is about 2,600 feet. The American Falls, adjoining the right bank, is 167 feet high and 1,000 feet across.

Below the falls and extending for seven miles is the Niagara Gorge. The stretch of two and one-fourth miles from Horseshoe Falls is known as the Maid of the Mist Pool. It has a descent of only five feet and is navigable by excursion boats. Beyond this, the gorge descends another 93 feet, flowing northwestward first through the narrow Whirlpool Rapids for one mile to the Whirlpool. There the gorge makes a 90° bend to the northeast for two miles and turns north for another one and one-half miles to the foot of the Niagara Escarpment at Lewiston, New York. In its final seven miles, the river flows across a lake plain to Lake Ontario, falling less than one foot.

Geological history. The shaping of the gorge and the maintenance of the falls as a cataract depend upon peculiar geologic conditions. The rock strata from the Silurian Period (between 430,000,000 and 395,000,000 years ago) in the Niagara Gorge are nearly horizontal, dipping southward only about 20 feet to the mile. The uppermost layer of hard Niagaran dolomite is underlain by soft layers that are easily worn away. This disposition of the rock strata provides the conditions for keeping the water constantly falling vertically from an overhanging ledge during a long period of recession (movement upstream).

The river came into existence late in the Pleistocene, or Glacial, Epoch, more than 10,000 years ago, when the margin of a great continental ice sheet melted back and exposed the escarpment of Niagaran dolomite rock, allowing the discharge from the Lake Erie Basin to pour over it. Recession of the falls created the Niagara Gorge, the age of which, when calculated by dividing its length by the average rate of recession of the falls in recent time, is about 7,000 years. Other considerations led some geologists to estimate an age as great as 25,000 years. Determinations of the age of the last glacial ice advance in the area suggest, however, that the Niagara River is about 12,000 years old. The Whirlpool section differs from the rest of the gorge because there the river intersects an old channel that was formed before the last glacial ice advance and was later filled with glacial drift. Continued recession of the falls toward Lake Erie will ultimately cause the drainage of that lake, but such an event is not expected to occur within the next 25,000 years.

Age of the river and gorge

Human uses. *Navigation.* The river is navigable from Lake Erie to the upper rapids. Waterborne traffic along the Niagara passes through the upper single channel and the U.S. channel and enters the New York State Barge Canal at Tonawanda, New York. That canal, with minimum depth of 12 feet, connects with the Hudson River and has branches that connect with Lake Champlain and Lake Ontario. In winter Lake Erie ice floats into the Niagara River and tends to form a jam that restricts the flow. To prevent this, a floating timber boom is installed across the entrance, generally from early December to April. This obstruction may be bypassed by ships taking a route through the Black Rock Canal, from Buffalo Harbor to a point a few miles down the Niagara River, which extends the navigation period locally through a greater part of the winter. The principal shipping between Lakes Erie and Ontario, however, passes through the Welland Canal, an important link in the Great Lakes–St. Lawrence Seaway. Lying a few miles west of the Niagara River inside Ontario, it has a minimum depth of 27 feet. The ships that pass through it include vessels engaged in trade between the upper Great Lakes and Europe.

Generation of hydroelectricity. Canada and the U.S. agreed, in a treaty signed in 1950, to reserve sufficient amounts of water for flow over Niagara Falls to preserve their scenic value. The agreement provided for a minimum daytime flow during the tourist season of 100,000 cubic feet (3,000 cubic metres) per second and a minimum flow of 50,000 at all other times. All water in excess of these amounts, estimated to average about 130,000 cubic feet per second, was made available for diversion for power generation, to be divided equally between the U.S. and Canada. The total hydroelectric capacity of the river was fixed at about 4,000,000 kilowatts. This power is developed by public-authority power-plant installations on both sides of the gorge: the Robert Moses plant near Lewiston, New York, and the Sir Adam Beck plant at Queenston, Ontario, completed in the period 1960–63. The plants receive water diverted to them from the river above the falls and carried to them by tunnels and canals. The flow of the Niagara River averages 195,000 cubic feet per second but fluctuates from a minimum of 119,000 in winter to a maximum of 245,000 in summer. The amounts of water available for diversion range from about 110,000 cubic feet per second in winter to 120,000

on summer days and to 170,000 on summer nights. At night, when industrial power demand is low, turbine pumps deliver a part of the water to large storage basins about both plants; during daytime peak demand, the stored water is flowed back through the turbines to generate more electricity. Much of the energy is used in nearby electrochemical industries. The remainder of the energy is transmitted to various cities for miscellaneous uses. The maximum distance to which this power is transmitted is somewhat in excess of 350 miles.

The falls and other features. The water flowing over the falls is free of sediment, and its clearness contributes to the beauty of the cataract. In recognition of the importance of the waterfall as a great natural spectacle, the province of Ontario and the state of New York retained or acquired title to the adjacent lands and converted them into public parks.

In recent years the very large diversion of water above the falls for power purposes has lessened the rate of erosion. Elaborate control works upstream from the falls have maintained an even distribution of flow across both the U.S. and Canadian cataracts, and the curtains of the waterfalls have been maintained. Sightseers have found it difficult to believe that a large part of the great river above the falls is diverted and disappears into four great tunnels for use in the power plants downstream. Serious erosion of the American Falls has been occurring, however, and in 1969 the river was diverted from that area and some cementing of the bedrock was done, while at the same time an extensive boring and sampling program was carried out. River flow was returned to the American Falls in November 1969, and the effects of the work and results of the study continue to be evaluated.

Scenic sites

Excellent views of the falls are obtained from Queen Victoria Park on the Canadian side; from Prospect Point of the U.S. side at the edge of the American Falls; and from Rainbow Bridge, which spans the gorge about 1,000 feet downstream from Prospect Point. Visitors may cross from the U.S. shore to Goat Island by footbridge and may take an elevator to the foot of the falls and visit the Cave of the Winds behind the curtain of falling water. The Horseshoe Falls receded, or migrated upstream, at an average rate of nearly five feet per year in historic time, until control works and diversion of water decreased the erosion.

Another feature of the river is Ft. Niagara, a 504-acre (204-hectare) state park on the east bank at the mouth of the river. Located on the site of a blockhouse (Fort-Conti) built by the French in 1678–79, it includes old Ft. Niagara, which was built by the French in 1725–27 and is still standing. The fort was captured by the British in 1759 and was relinquished to the United States in 1796. Restoration of this and other structures in the park has provided an authentic historical flavour representing both the French and British periods of occupancy.

Nicaragua

The Republic of Nicaragua (República de Nicaragua) is located in the middle of Central America and is bounded by Honduras on the north, the Caribbean Sea on the east, Costa Rica on the south, and the Pacific Ocean on the west. Despite territorial losses to its neighbours, it is the largest of the Central American republics, with an area of 49,759 square miles (128,875 square kilometres). Its population of more than 1,900,000 represents a racial mixture that reflects the country's history. The national capital is at Managua.

Nicaragua can be characterized by its agricultural economy, its history of autocratic government, and its imbalance of regional development. Most of the population is engaged in subsistence farming, and the national economy is perhaps overdependent upon exports of cotton and coffee. Although several political parties are active, the government has been in the powerful hands of the family of former president Anastasio Somoza García since the 1930s. Almost all settlement and economic activities are concentrated in the west, and the rich tropical forests of the east remain unexploited. (For a related physical feature see NICARAGUA, LAKE. For a detailed discussion of history see CENTRAL AMERICAN STATES, HISTORY OF.)

The landscape. *Relief.* The western half of the country is occupied by a triangular region of mountains. One side of the triangle extends from northeast to southwest along the Honduras border, the second side runs from Honduras in the northwest to the Costa Rican border in the southeast, and the third side extends from north to south through the centre of Nicaragua. The short, steep, and rugged mountain ranges are separated by basins and contain fertile valleys. The intricately dissected region includes the Cordillera ("chain of mountains") Entre Ríos, on the Honduras border, the Cordilleras Isabella and Darién, in the north central area, and the serranías ("mountain range") Huapí, de Amerigue, and de Yolaina in the southeast. The mountains are highest in the north, where Pico Mogotón, in the Cordillera Entre Ríos, and Cerro Saslaya Peak, in the Cordillera Isabella, rise to 6,913 feet and 6,542 feet (2,107 metres and 1,994 metres), respectively.

The volcanic zone

To the west of the central mountains is a string of about 40 volcanoes that stretches from northwest to southeast along the Pacific coast. They are surrounded by low plains from the Golfo de Fonseca in the north to the Bahía (Bay) de Salinas in the south and are separated from the mountains by the great basin that contains Lakes Nicaragua, Managua, and Masaya. The volcanoes, some of which are active, are divided into two groups; in the north they are known as the Cordillera de los Marrabios and in the south as the Mesetas de los Pueblos. The highest volcanoes include San Cristóbal, which rises to 5,725 feet (1,745 metres); Concepción, which attains 5,282 feet (1,610 metres); and Momotombo, at 4,199 feet (1,280 metres).

The eastern half of Nicaragua is occupied by low, level plains. Among the widest Caribbean lowlands in Central America, they exceed 50 miles (80 kilometres) in width. The coast is broken by deltas and sandbars that enclose lagoons, and coralline reefs, islands, and banks that lie off shore.

Drainage and soils. The central mountains form the country's main watershed. The rivers that flow to the west empty into the Pacific Ocean or Lakes Managua and Nicaragua. They are short and carry a small volume of water; the most important are the Río Negro and Estero Real, which empty into the Golfo de Fonseca, and the Río el Tamarindo, which flows into the Pacific.

The eastern rivers are of greater length. The Río Coco (Río Segovia) flows for 295 miles along the Nicaragua–Honduras border with a total length of 425 miles and empties into the Laguna de Gracias a Diós on the extreme northern coast. The Río Grande de Matagalpa flows for more than 200 miles from the Cordillera Darién eastward across the lowlands to empty into the Caribbean north of Laguna de Perlas (Lagoon of Pearls) on the central coast. In the extreme south, the Río San Juan flows for 120 miles from Lake Nicaragua into the Caribbean in the northern corner of Costa Rica. Other rivers of the Caribbean watershed include the 120-mile-long Río Prinzapolca, the 60-mile-long Río Escondido, the 60-mile-long Río Indio, and the 37-mile-long Río Maíz.

Nicaragua's lakes

The west is a region of lakes. Lake Nicaragua, with an area of 3,191 square miles (8,264 square kilometres), is the largest lake in Central America. Located in the southern isthmus, the lake and its distributary, the Río San Juan, have long been discussed as a possible canal route between the Caribbean and the Pacific.

There are six freshwater lakes near the capital city of

Managua. They include the Lago de Managua, which covers an area of 405 square miles (1,049 square kilometres); Laguna de Asososca, which is 6,000 feet deep and acts as the city's reservoir of drinking water; and Laguna de Jiloá, which is slightly alkaline and is a favourite bathing resort. Laguna de Masaya is prized for its swimming and fishing facilities; the sulfurous waters of Laguna Nejapa have medicinal properties ascribed to them; and Laguna Tiscapa, which lies within the capital city, is the site of the Presidential Palace.

Other lakes in the Pacific watershed include Laguna de Apoyo, near Laguna de Masaya; Laguna Apoyeque, picturesquely located between two peaks on the Punta Chiltepe that juts into Lago de Managua; and the artificial Lago de Apanás on the Río Tuma, which generates much of the electricity consumed in the Pacific zone.

Soils on the east (Caribbean) coast are alluvial and are considered fertile. On the Pacific coast the soil is volcanic, and about 85 percent of its area is fertile.

Climate. The climate is slightly cooler and much wetter in the east than in the west. The Pacific side is characterized by a rainy season from May to November and a dry season from December to April. The annual average temperature is 81° F (27° C), and precipitation averages 75 inches (1,910 millimetres) yearly. On the Caribbean side of the country, the rainy season lasts for about nine months of the year, and there is no well-defined dry season. The annual average temperature is 79° F (26° C), and annual precipitation may total about 150 inches (3,810 millimetres). In the northern mountains temperatures are cooler and average about 64° F (18° C). Prevailing winds are from the northeast and are cool on the high plateau, warm and humid in the lowland.

Vegetation and animal life. Over 50 percent of the country is covered with a broad expanse of tropical forest. The numerous types of trees include the almond, walnut, broad-leaved male cedar, royal cedar, balsam, coast and okote pines, mahogany, and liquid amber. The quebracho, or axbreaker, yields hardwood; the guaiacum, or lignum vitae, yields one of the iron woods; the guapinal yields resin; and the medlar produces fruit similar to the crab apple. The western lowlands are comprised of savannas, the streams of which are lined with forests.

The hot and rainy regions are inhabited by various types of reptiles, including crocodiles, lizards, snakes, and turtles. Deer are common in the forested regions; wildlife also includes such cats as the puma and the jaguar, monkeys, and the peccary (a nocturnal mammal resembling the pig). There are many species of water and land birds, and the rivers, lakes, and lagoons are inhabited by freshwater and saltwater fishes and mollusks. Rodents and insects are abundant.

Traditional regions. The western volcanic mountains and surrounding lowlands and lakes contain more than 60 percent of the country's population, most of its cities, and most of its industry. The area also yields most of Nicaragua's agricultural produce and minerals. The valleys of the western central mountains contain about 30 percent of the population and yield about 25 percent of the national agricultural production. The highlands are also important for mineral extraction. Although they comprise about one-half of the country, the western lowlands are virtually uninhabited except along the coast and rivers. The region is important, however, as a vast resource of timber.

The four traditional regions

Patterns of settlement. In the early 1970s, about 52 percent of the population was rural. By far the largest city was Managua, on the southeastern shore of Lago de Managua. On December 23, 1972, the city was devastated by a series of earthquakes and subsequent fires that left approximately 7,000 dead, 15,000 injured, and half the city's enumerated population of 398,500 homeless. Other important urban centres included León (population, 55,600), Granada (35,000), Masaya (30,800), Chinandega (30,400), and Chichigalpa (15,000), all in the west. Matalgalpa, with a population of 21,000, and Estelí, with 20,200 inhabitants, were the largest cities of the central mountains. Bluefields, with 15,000 inhabitants, was the largest town on the Caribbean coast. All other urban centres had populations of fewer than 14,000.

People and population. *Population groups.* Most of Nicaragua's population of 1,911,543 is a product of racial admixture. Almost 70 percent of the people are mestizos (persons descended from mixed European and Amerindian ancestry), zambos (persons of mixed black and Amerindian descent), and mulattoes (persons of mixed European and black descent). About 20 percent are white and 10 percent are black. Of the original Amerindian population, only the Sumo, Miskito, and Ramaquie tribes remain; they occupy the basins of the northeastern rivers and other Atlantic areas.

Spanish is the official national language, and there is a widespread familiarity with English. The Amerindian languages have almost disappeared from use, but their influence remains in place names and in many nouns in Nicaraguan Spanish.

Roughly 85 percent of the population is Roman Catholic. The small Protestant and Jewish communities are concentrated in the larger cities. There is no official religion, and freedom of religious worship is guaranteed by law.

Demography. In the early 1970s the average population density was more than 41 persons per square mile. Because of the high birth rate of about 43 births per thousand of the population and the death rate of 8 per thousand, the population is young. In the early 1970s, 49 percent were under 15 years of age, and almost 47 percent were between the ages of 15 and 60. The natural rate of increase was about 35 per thousand of the population.

The national economy. Nicaragua is rich in natural resources, most of which have yet to be exploited on a large scale. The economy is basically agricultural, and industry is in an incipient stage of development.

Natural resources. Mineral resources include known deposits of gold, silver, copper, iron ore, bauxite, lead, marble, and gypsum. The forests are a vast resource of hardwoods and softwoods, and the inland and coastal waters contain abundant food fishes. Nicaragua's potential hydroelectric resources are considered immense.

Sources of national income. Agriculture, forestry, and fishing engage about 46 percent of the labour force and

produce about 30 percent of the total national income. The major cash crops are cotton and coffee, most of which are produced for export. Cotton alone represents almost 30 percent of total exports. Other crops include maize (corn), rice, beans, sugarcane, sesame, henequen (sisal; a plant that yields strong fibres), manioc (yucca and cassava), and wheat. A variety of fruits and vegetables are also produced for the local market. Soybeans and peanuts have been introduced, and in the early 1970s the possibilities of cultivating the sunflower were being studied. There is room for great expansion of agriculture, for only 30 percent of the arable land is exploited.

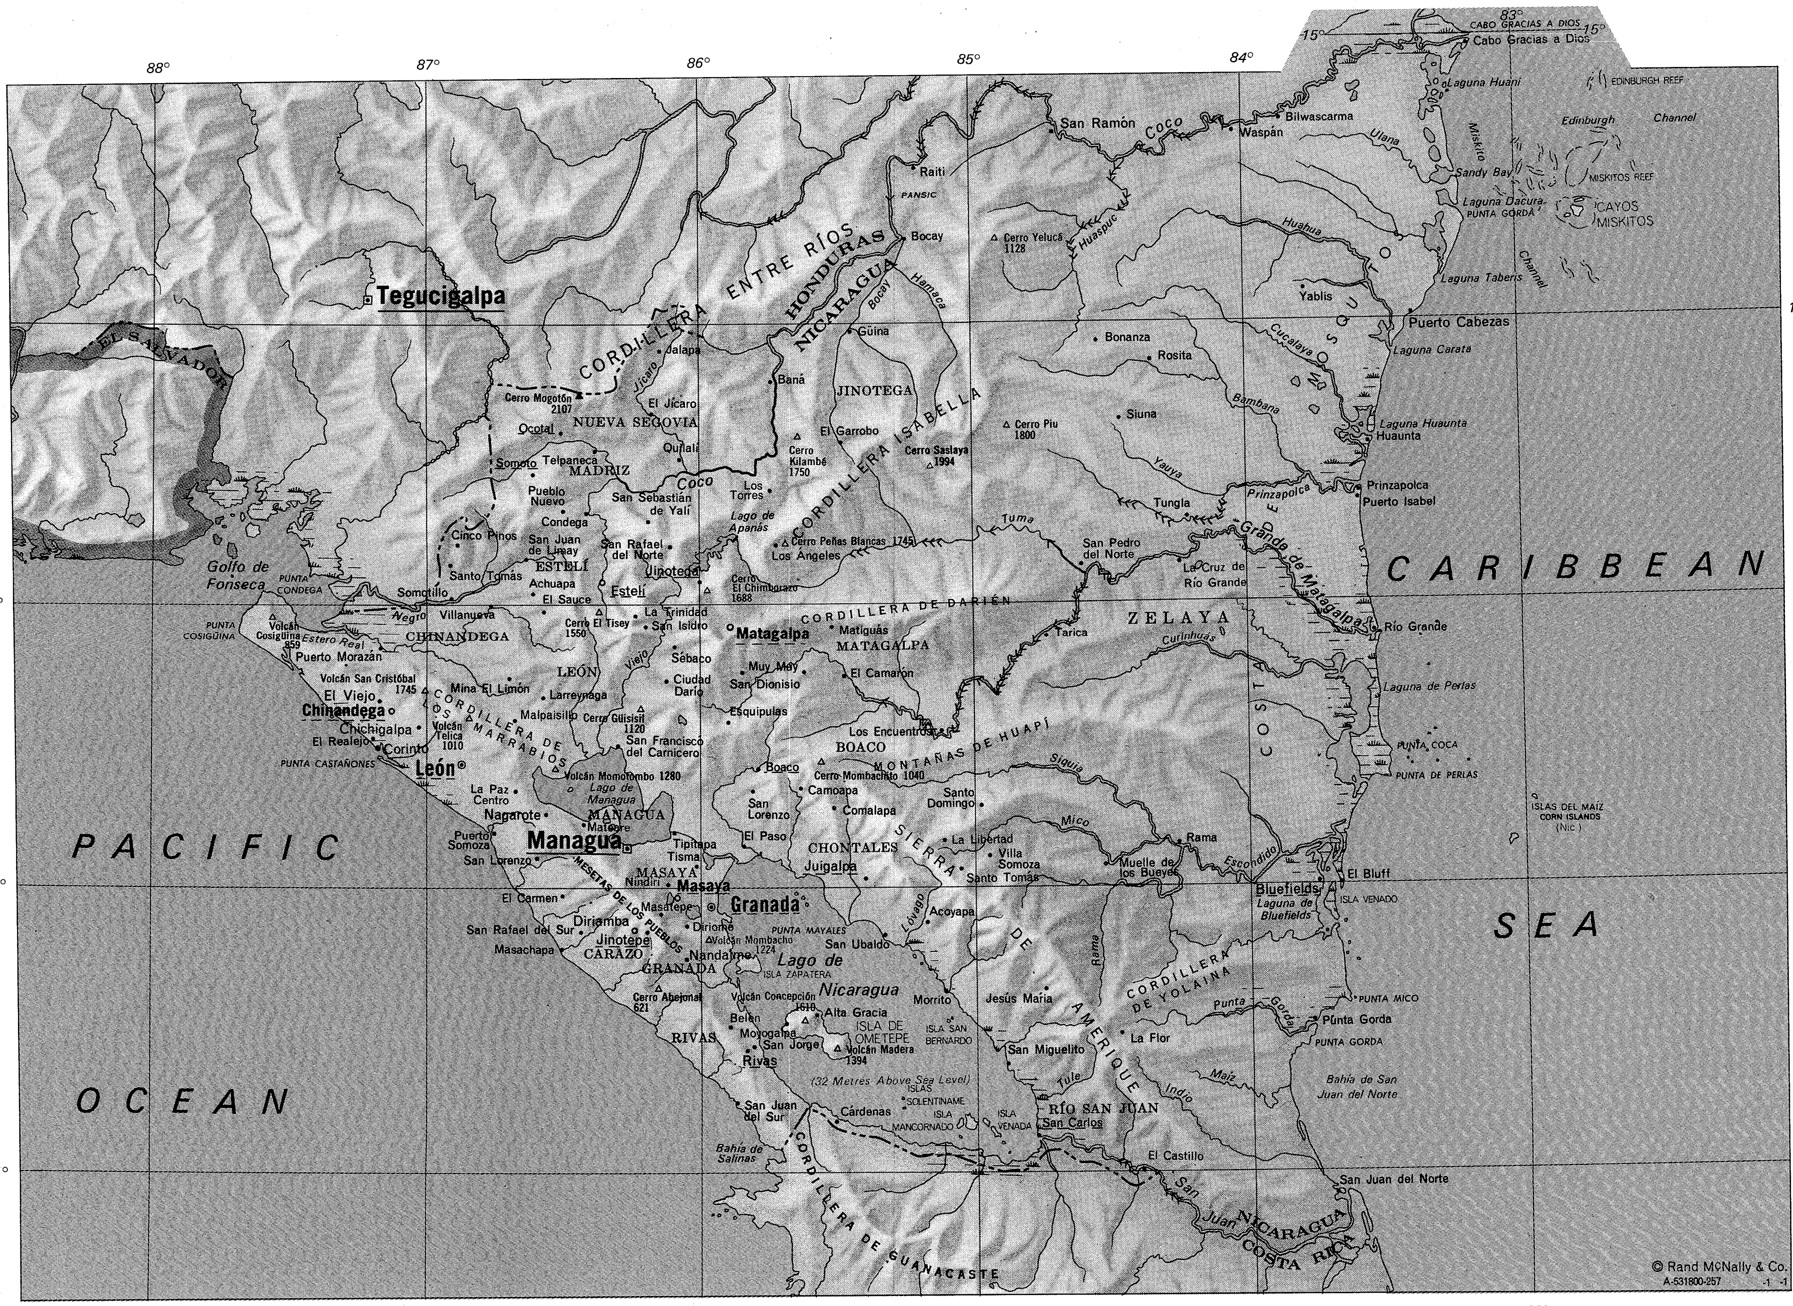
Cattle are significant as a source of dairy produce in the west and beef in the east. The cattle industry was increasing rapidly during the early 1970s, and exports of meat were reaching a competitive level with those of coffee. Other livestock includes goats, hogs, horses, and sheep.

Forestry is little developed because of the lack of adequate transportation facilities. Shrimping is the most important marine activity. About 95 percent of the shrimp, caught in both the Pacific and Caribbean, are exported; lobster is also exported in moderate quantities. Nicaragua's fish resources, however, are also little exploited because of lack of investment, and marine fishing remains largely a subsistence activity.

Of all the country's minerals, only its gold and copper are mined intensively. Both are mined for export; gold is extracted by Canadian and United States firms. Silver is also obtained on a smaller scale. Other reserves are as yet unexploited because of lack of financing.

The industrial sector

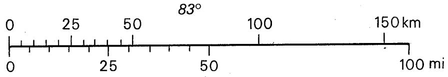
Nicaragua's infant industry is based on the production of consumer products, much of which require the importation of raw materials. In the early 1970s the government actively supported the diversification of production and the use of domestic raw materials. Products include refined petroleum, matches, footwear, soap and vegetable oils, cement, alcoholic beverages, and textiles. Upon the formation of the Central American Common Market in



NICARAGUA

Size of symbol indicates relative size of town • ○ ⊙ ⊡

Elevations in metres



1960, it was hoped there would be an increased demand for Nicaragua's processed foods, lumber, and fibres.

In the early 1970s the country had a total installed electrical capacity of more than 170,000 kilowatts at about 70 diesel and 11 hydroelectric stations. Construction continued on the Río Tuma scheme, which began to supply hydroelectric power to the western region in 1965. Research is being conducted on the applications of atomic power to engineering, medicine, and technology.

The Banco Central de Nicaragua, established in 1961, has the sole right of issue of the national currency, the cordoba. The financial system is dominated by the government-owned Banco Nacional de Nicaragua, which acts as a development bank and grants loans for agriculture and cattle raising. The Instituto de Fomento Nacional (Infonac; Institute for National Development) extends partial credit for industry, agriculture, and cattle raising. Long-term loans for housing construction are granted by the Banco de la Vivienda (Housing Bank), which covers less than 10 percent of the nation's needs. There is also an urgent need for financial institutions that can extend long-term credit for economic development.

Branches of U.S., British, and Canadian commercial banks operate in Nicaragua. There are also two private commercial banks and a savings and loan company.

Nicaragua's chief trading partners are the U.S., Japan, and West Germany. Imports are comprised largely of machinery, transport equipment, medicines, nonferrous metals, and petroleum. Exports include cotton, coffee, meat, oilseeds, copper, sugar, shrimp, and lobsters.

Management of the economy. Most government revenue is obtained through indirect taxes, such as import duties and surcharges, export taxes on coffee, and sales taxes on liquor, cigarettes, and other consumer goods. Direct taxes are levied only on property (land and houses).

Trade unions

Trade unions are small, and none of the larger organizations has more than 5,000 members. Organizations include the Confederación Nacional de Trabajadores de Nicaragua (National Confederation of Workers of Nicaragua), the Confederación General del Trabajo (General Confederation of Labour), the Federación de Transportadores Unidos Nicaragüense (United Transport Workers' Federation of Nicaragua), the Federación Sindical de Maestros de Nicaragua (Nicaraguan Teachers' Trade Union Federation), and the Movimiento Sindical Autónomo de Nicaragua (Autonomous Trade Union Movement). The independent union movement is growing, but most unions are still government controlled. Collective bargaining is used in settling some disputes.

Employers' associations include the Cámara Nacional de Comercio de Managua (National Chamber of Commerce of Managua). The Corporación Nicaragüense de Inversiones channels national and foreign financial resources into industrial development, and the Instituto Nacional de Comercio Exterior e Interior regulates trade balances and prices. The Comisión Nacional del Algodón is the official government agency for cotton development, and the Instituto Nicaragüense del Café is an autonomous government agency that controls the quality and export of coffee.

In the early 1970s the government was concerned with the unfavourable balance of trade and the nation's dependence upon cotton and coffee production. Imports were reduced, and the government continued modernizing and diversifying agriculture. Industries that used local raw materials continued to receive priority.

Transportation. Most of the country's transportation system is confined to the western zone. There is a network of highways estimated to be 8,740 miles (14,070 kilometres), of which more than half are impassable during the rainy season, 780 miles are paved, and about 750 miles are gravel covered. The system includes the 255-mile (410-kilometre) Nicaraguan section of the Pan-American Highway, which runs through the west from Honduras to Costa Rica. There is also an important road that runs from the Pan-American Highway, 24 miles from Managua, to Port Esperanza at Ciudad Rama, on the Río Escondido.

There are 235 miles (378 kilometres) of railways. The main line runs from Granada northwest to Corinto, on the Pacific Ocean. Branch lines lead north from Corinto to Puerto Morazán on the Golfo de Fonseca and north from León to the coffee area of Carazo.

The chief ocean ports of Puerto Morazán, Corinto, and San Juan del Sur serve the Pacific coastal area. The Caribbean ports include Puerto Cabezas, Port Isabel, and Bluefields, which is connected to the river port of Port Esperanza by regular small craft service. The short rivers in the west are navigable for canoes and small motorboats; the lower course of the Estero Real, however, can accommodate small commercial vessels. In the east, the Río Coco is navigable in its lower course for medium-size vessels. The Río Grande de Matagalpa is limited to small craft, as is the Río San Juan.

Air transport services

The international De Las Mercedes Airport, seven miles from Managua, offers daily jet service to North America and Latin America. The second largest airport at Puerto Cabezas can also accommodate jets; there are five other airports with scheduled domestic flights. Air services are offered by Lanica, a private airline, and by American and Central American airlines. Craft Airlines offers daily service between Managua and San José, Costa Rica.

Administration and social conditions. *Constitutional framework.* Nicaragua had nine constitutions between 1838 and 1972. Under the 1950 constitution, which remained in effect until 1972, the national government was headed by a strong president, who was elected to a one-time, five-year term. Given extensive executive powers, he could detain persons, suspend constitutional guarantees, and enact laws when the legislature was not in session. The president appointed his Cabinet of ministers, who could not be members of the legislature.

Nicaragua had the only bicameral legislature in Central America. It consisted of a 42-member Chamber of Deputies and a Senate of 16 elected members, all serving for six years, and all former presidents, who were appointed for life. The legislature acted as a rubber stamp of executive authority; it could amend the constitution with a majority vote.

Under an agreement reached in 1971 between Nicaragua's two major political parties, the president was succeeded on May 1, 1972, by a triumvirate of party leaders. The legislature was replaced with a 100-member Constituent Assembly that had been elected in 1971 and charged with the task of producing a new constitution by 1974. The triumvirate was to retain executive authority until a president was elected under the new constitution.

Local government. In 1971 the country was divided into 16 departments and the national district of Managua. Each was administered by a political head appointed by the president. The departments were subdivided into 123 *municipios*, each headed by a mayor, or alcalde. Except in Managua, mayors are elected for two years by a council; the council itself is elected for a four-year term. In Managua mayoral duties are performed by a presidential appointee.

The political process. The franchise extends to all persons over 21 years of age and all over 18 years who have earned an elementary school-leavers certificate, who are literate, or who are married. Voting is carried out by secret ballot.

Under the 1950 constitution, elections were controlled by the Supreme Electoral Tribunal, which ranked as the fourth branch of the government; it counted votes, verified the election, and determined the winners. Deputies were elected from a national list and senators from four electoral districts. Seats in the legislature were awarded by a system of proportional representation in which at least one-third were reserved for minority political parties. In 1971 seats in the Constituent Assembly were proportionately divided between the two major parties, as was the membership of the tribunal one year later.

Nicaragua's leading political organization is the Nationalist Liberal Party. The Nicaraguan Conservative Party is the second strongest party, although it is not con-

sidered by some to represent true political opposition to the government. The Traditionalist Conservatives and the Independent Liberals are clearly anti-government; they generally do not participate in elections, however, because of a lack of confidence in the electoral tribunal.

Justice and the armed forces. The judicial system is headed by the Supreme Court in Managua, which may initiate legislation. There are five courts of second instance in León, Granada, Masaya, Matagalpa, and Bluefields; more than 150 courts of first instance; and a labour court. Under the 1950 constitution, judges were appointed by the legislature. The supreme court magistrates are seven, of which four must belong to the majority party; all are appointed by Congress.

The National Guard

The National Guard serves as both the army and police force. Originally trained by the U.S. Marines, it is composed of about 5,400 active and 4,000 reserve personnel. Members enlist for a three-year period, but service can be made compulsory at any time. The Guard is politically important and has been the power behind the government since the 1930s. There is also a small coast guard and a well-equipped air force of about 1,500 men.

Education, health, and welfare. Primary education is free and compulsory for those between the ages of six and 13. The nation's facilities and teaching staff are inadequate, however, and can accommodate only about 50 percent of the school-age children. Of those who attend school, most leave before completing the secondary level, and over 40 percent of the population is illiterate.

The universities

Institutions of higher learning include the Nicaraguan branch of the Central American University at Managua, founded in 1961; and the National Autonomous University of Nicaragua at León, founded as the University of León in 1814. The Central American Institute of Business Administration offers post-graduate courses under the guidance of Harvard University.

Health and welfare services are inadequate. In the late 1960s there was one doctor for every 1,674 persons and one hospital bed for every 433. Welfare services are offered by the labour unions and the limited social security program is offered for inhabitants of Managua. The shortage of adequate housing in both urban and rural areas remains acute, despite the government's housing program that began in 1959.

Social conditions. In response to the nation's overall poverty, the government initiated minimum wages in 1963; agricultural workers receive food allowances and housing loans. These programs have had little effect, and the average annual income—including that of the multimillionaire families that dominate the economy—was US $380 in 1969.

Malaria, which was previously responsible for 30 percent of the nation's annual deaths, was eradicated by the early 1970s. Major causes of death are old age, infections of the digestive system, homicide, and war.

Cultural life. Nicaragua's literary tradition was consolidated in the late 19th and early 20th centuries with the poetry and prose of Rubén Darío, known as the "prince of Spanish-American literature." Later writers of importance include Santiago Argüello, Lino Argüello, Salomón de la Selva, and Salvador Buitrago Díaz.

José de la Cruz Mena is to Nicaraguan music what Darío is to its literature. Although he has not received international recognition, his waltzes are masterpieces of melody and harmony. The composers Edwin Krüger and José Ramirez excel in folkloric music. There are also many creative artists and sculptors.

The National Library at Managua maintains branches in most of the major cities. The National Museum is located in the capital city, and the Tenderi Museum of Indian artifacts is at Masaya. The Grand Theatre "Ruben Dario" in Managua rivals the best in Latin America.

The most important Nicaraguan daily newspapers are *La Prensa* and *Novedades* in Managua, *El Centroamericano* in León, and *El Diario* in Granada. There are also two popular weekly papers: *Semana* (owned by *La Prensa*) and *Extra.*

The government-owned National Radio operates 72 broadcasting stations throughout the country, and there is one radio receiver for every 18 persons. Three television stations broadcast from Managua.

Prospects for the future. Like many Latin American nations, Nicaragua faces problems of economic and social imbalance. The rising birth rate, combined with an uneven distribution of settlement on the land, and the concentration of economic control in the hands of relatively few, while the majority of the population lives at the subsistence level, all constitute direct or indirect obstacles to rapid development. A further factor is of particular importance—the country is dependent upon its agricultural exports, such as cotton, and national income is thereby subject to fluctuations in the world market. Tourism, however, has provided needed revenue, and prospects for its further expansion are bright. Hopes for the construction of a trans-Nicaraguan canal to supplement the Panama Canal have yet to materialize, although should they ever do so, the country's economic and strategic position would be transformed. A devastating earthquake hit Managua in December 1972; it compounded Nicaragua's economic difficulties and created serious problems of reconstruction and resettlement. It was planned to rebuild Managua's business district about six miles from its original site.

BIBLIOGRAPHY. Three good works on the geography of the country are PABLO LEVY, *Nicaragua* (1864); LOS HERMANOS CRISTIANOS, *Geografía de Nicaragua* (1930); and JAIME INCER BARQUERO, *Nueva Geografía de Nicaragua* (1970). In English, the accounts of the PAN-AMERICAN UNION, *Nicaragua* (1964) and *Visit Nicaragua* (1957), are also useful. For a description of the flora and fauna of the area, see THOMAS BELT, *The Naturalist in Nicaragua* (1874 and 1911).

(R.A.)

Nicaragua, Lake

Lake Nicaragua (Spanish, Lago de Nicaragua), the largest of several freshwater lakes in southwestern Nicaragua and the dominant physical feature of the country, is also the largest lake in Central America. Its aboriginal name was Cocibolca, meaning "sweet sea"; the Spanish called it Mar Dulce (freshwater sea); its present name is said to have been derived from that of Nicarao, an Indian chief whose people lived on the lake shores. Oval in shape, the lake has an area of 3,190 square miles, is 110 miles in length, and has an average width of 36 miles. About 60 feet deep in the centre, its waters reach a depth of 200 feet to the southeast of its largest island, Ometepe (Spanish, Isla de Ometepe). Its surface is 95 feet above sea level.

It is believed that Lake Nicaragua, together with Lake Managua (Lago de Managua) to the northwest, originally formed part of an ocean bay which, as a result of volcanic eruption, became an inland basin containing the two lakes, which are linked by the Tipitapa River (Río Tipitapa). The ocean fish thus trapped adapted themselves as the water gradually turned from saltwater to freshwater. Lake Nicaragua is the only freshwater lake containing oceanic animal life, including sharks, swordfish, and tarpon.

More than 40 rivers drain into the lake, the largest being the Tipitapa River. The San Juan River (Río San Juan) drains out of the lake, following a 112-mile (180-kilometre) course that runs from the southeastern shore of the lake through a densely forested region to empty into the Caribbean Sea. For part of its course, the San Juan forms the boundary between Nicaragua and Costa Rica. To the southwest, the lake is separated from the Pacific Ocean by a narrow land corridor—the Rivas Isthmus—which is 12 miles (19 kilometres) wide.

Contrary to popular belief, the lake is tideless, although there is a daily fluctuation in the water level caused by east winds blowing up the San Juan Valley. The water level also falls during the dry season, December to April, and rises during the rainy season, May to October. There are several currents in the lake; the principal one runs from southeast to northeast on the surface, while beneath it a deeper current flows in the opposite direction. Surface water temperature usually remains at 75° F (24° C), and

bottom temperature at 60° F (16° C). Due to the chemical composition of the volcanic rocks forming parts of the lake's bed and shores, the lake waters contain high proportions of dissolved magnesium and potassium salts.

There are over 400 islands in the lake, of which 300 are within five miles (eight kilometres) of the city of Granada on the northwest lake shore. Most of the islands are covered with a rich growth of vegetation, which includes tropical fruit trees. Some of the islands are inhabited. Ometepe, which, as mentioned, is the largest island, is 16 miles (26 kilometres) long and 8 miles (13 kilometres) wide. It is formed of what originally were two separate volcanoes—Concepción, which is 5,282 feet (1,610 metres) high and which last erupted in 1944, and Madera, which is 4,015 feet (1,224 metres) high. Lava from bygone eruptions forms a bridge between them, called the Tistian Isthmus. (A third volcano associated with the lake is Mombacho, 4,413 feet [1,345 metres] high, which stands on the western shore.) Ometepe Island is the pre-eminent site in Nicaragua for pre-Columbian examples of statuary, ceramics, and other archaeological remains, some of which, it is believed, represent vestiges of ancient South American, as well as North American, civilizations. Coffee, cocoa, corn, bananas, and fruit are grown on the island as well as a little cotton and tobacco.

The lake is a traditional means of communication between the cities of the west coast of Nicaragua and those in the south and east of the country. Steamships have operated on the lake since 1882. Lake steamers based at Granada visit small lakeside towns, such as San Jorge and La Virgen on the west shore; Cárdenas and San Carlos on the southern shore; San Ubaldo, Puerto Díaz, San Miguelito, and El Morrito on the eastern shore. Granada has a population of about 35,000; the next largest lakeside town is San Jorge, with a population of about 2,000.

In previous centuries, piratical raids from the Caribbean were sometimes made on the lakeside towns, until the building of fortifications in the 17th century on the San Juan River blocked the pirates' ingress. From the time of the ending of Spanish rule in the 1820s, the possibility of constructing a transoceanic canal from the Atlantic to the Pacific, which would run up the San Juan River, cross the lake, and be completed by a channel dug through the Rivas Isthmus, has been mooted. Surveys to this end were made in the 1830s. After the discovery of gold in California in 1848, Cornelius Vanderbilt, the New York millionaire, developed the Vanderbilt Road—a route over which gold prospectors from New York were transported up the river and over the lake, completing the final few miles to the Pacific by stage coach in order to take ship for San Francisco in California. The arrangement revived interest—which lasted for many years—in the possibilities of a transoceanic canal. After the completion of the Panama Canal in 1914, interest in the project once more subsided. Since 1916, however, by the provisions of the Bryan–Chamorro Treaty concluded between Nicaragua and the United States, the United States has had the exclusive right to build such a canal.

Lake Nicaragua remains, at present, largely undeveloped. Should a transoceanic waterway be constructed, however, its situation would be transformed. Meanwhile, because of its scenic beauty, and its archaeological interest, as well as its facilities for fishing, sailing, and swimming, it constitutes a focus for tourism. Commercial fishing also offers good prospects.

BIBLIOGRAPHY. There are no books exclusively on Lake Nicaragua. MILES P. DU VAL, *Cadiz to Cathay: The Story of the Long Diplomatic Struggle for the Panama Canal* (1968), has some material; the PAN-AMERICAN UNION, *Nicaragua* (1964) and *Visit Nicaragua* (1957), are also useful. For a description of the flora and fauna of the area, see THOMAS BELT, *The Naturalist in Nicaragua* (1874 and 1911).

Nicephorus II Phocas

Byzantine emperor from 963 to 969, Nicephorus II Phocas was a member of a great aristocratic landowning family that had distinguished itself under the Macedonian emperors in wars against the Arabs. He was the son and grandson of generals and before his accession he had commanded the Byzantine armies of the East (954–955) and had directed a victorious expedition against the Arabs in Crete in 960–961. In Byzantine history he is considered the military emperor *par excellence*, the artisan of Byzantine grandeur in the world of the 10th century, and the restorer of that imperial power in the East that had been fought for in battles against the infidel from the beginning of the 10th century.

Nicephorus II Phocas, coin, 10th century. In the British Museum.
Peter Clayton

Early life

Nicephorus Phocas was born in 912, the son of Bardas Phocas, an important Byzantine general in Anatolia, on the borders of the empire. He quickly embraced a military career of arms and as a young patrician distinguished himself at his father's side in a war against the Ḥamdānid Arabs in the East. In 954–955 the emperor Constantine VII Porphyrogenitus named him commander in chief of the armies of the East, to replace the aging Bardas. Nicephorus proceeded to restructure the army to reinforce discipline and improve recruiting. At this point he probably wrote the treatises on military tactics that are attributed to him, although proof is lacking.

The emperor Romanus II named him commander of a wartime expedition to liberate Crete (which had been controlled by the Arabs ever since 826), at great cost to Aegean populations and international commerce. This enterprise mobilized the entire Byzantine fleet and close to 24,000 men. Nicephorus gained the island with the capture of Chandax, now Iráklion, on March 7, 961. In a general massacre, the inhumanity of which revealed his fierce nature, he broke all Arab resistance. Aided by the monks, among whom was Athanasius, his spiritual director and founder of the Greek Orthodox monastery on Mt. Athos, Nicephorus achieved the reconsolidation of Christianity. He then returned to Constantinople with ʿAbd al-ʿAzīz, the last *amīr* of Crete, as his captive. This exploit, sung by the poet Theodosius the Deacon, realized the Byzantine dream (after dozens had failed to liberate Crete) of imperial mastery of the eastern Mediterranean. Later, as emperor, Nicephorus could state proudly that he controlled the seas. By that time, however, he had recovered Cilicia and the island of Cyprus and had captured other Muslim naval bases.

At the beginning of 962, Nicephorus attacked the Arabs of Cilicia and Syria, capturing more than 60 fortresses. After the death of Romanus II on March 15, 963, the situation in the capital changed. The Emperor's will had left a eunuch, Joseph Bringas, in charge of the affairs of state and the 20-year-old empress, Theophano, as acting regent for the legitimate emperors, Basil and Constantine, aged six and three, respectively. These circumstances do not seem to have tempted Nicephorus.

Rise to power

In spite of his great popularity, there was no indication that Nicephorus—whose physical appearance was report-

edly not very agreeable and who seemed destined under the influence of Athanasius the Athonite to embrace the monastic life—would end up seducing and being seduced by the young and beautiful empress. If such a plan existed at the time (and there is reason to believe it did) it was probably the brainchild of the ambitious Theophano, who was unhappy with Bringas' government. The people of Constantinople, aroused by Basil the chamberlain, revolted against Bringas; and the imperial army, through the intermediation of John Tzimisces, Nicephorus' faithful lieutenant, "obliged" the soldier to accept the crown at Caesarea on July 3, 963, and to march against Constantinople. On August 16, 963, Nicephorus was crowned in the Hagia Sophia by the patriarch Polyeuctus, and on September 20 he celebrated his marriage to Theophano.

Smitten with the young woman and influenced by his brother Leo Phocas, whose self-interested machinations (he was accused of speculating on the price of wheat) stirred up the discontent of the people of Constantinople, Nicephorus gradually became taciturn and suspicious even of his best advisers, who, one after another, were removed from office. As emperor, Nicephorus continued his exploits against the Arabs until finally, abandoned by all, he retired to the fortified palace of Boukoleion, which he had built for his personal safety. During the night of December 10, 969, he was killed there by former friends, guided by Tzimisces and advised by Theophano.

The contradictions in Nicephorus' life and character also marked his domestic politics. His government evoked unanimous discontent: the hostility of the people to the new fiscal charges and coinage debasement required by military needs; the exasperation of ecclesiastical authorities over decisions against enrichment of the monasteries; the remonstrances of his spiritual director, Athanasius, against his private life; and the apprehensions of Theophano that her children would be ousted through the machinations of Leo Phocas. These all created a climate of intrigue, which resulted in Nicephorus' assassination and brought John Tzimisces to the throne.

Military achievements

The failure of Nicephorus' domestic policies did not cast a shadow on his military achievement, which made his reign one of the Byzantine Empire's most glorious. In the words of C. Schlumberger, his most exhaustive biographer, he inaugurated the Byzantine era in the East. In fact, though known primarily for his exploits against the infidel, Nicephorus also carried the imperial frontier beyond the Euphrates to Syria. Nor did he neglect the other imperial frontiers in the conception of Byzantine grandeur. To counteract the Bulgar menace he spurred Russian intervention in the Danubian area, a policy that was not without danger for Byzantium, especially after his death. Also, to stop expansionist plans of the Germanic sovereign Otto I, who was re-creating the Carolingian heritage, Nicephorus opposed Otto's title of emperor, while trying with more or less success to consolidate the Byzantine presence in Italy. Nicephorus II's policies, seen in their entirety, indicate that his purpose was to assure Byzantium of its place as international arbiter, which he accomplished through the use of arms.

Phocas was indeed a Nicephorus (Bringer of Victory) for the empire. The Byzantines surnamed him Kallinikos, artisan of good victories; the Arabs called him Nikfour, the Saracen hammer. His death caused joy in the Muslim world and shook Christianity. His legend was quickly nourished with stories of his exploits and tragic death. Byzantine and even Bulgar poets were inspired by his exploits, and posterity has kept his memory alive: he is celebrated in the epic poetry of the frontier; the church beatified him (an *acolouthie* was composed in his honour); and the monks of Mt. Athos still venerate as their benefactor and founder Nicephorus, emperor and martyr. His life was summed up in the phrase inscribed on his sarcophagus: "You conquered all but a woman."

BIBLIOGRAPHY. C. SCHLUMBERGER, *Un Empereur byzantin au X^e siècle: Nicéphore Phocas* (1890), is a comprehensive biography. The same author's *L'Épopée byzantine à la fin du X^e siècle*, 3 vol. (1896–1905); and A.A. VASILIEV, *Byzance et les Arabes*, vol. 2, *La dynastie macédonienne* (1968), are useful for Nicephorus Phocas' career in the East. Also of interest is H. GREGOIRE, "The Amorians and the Macedonians, 842–1025," in *The Cambridge Medieval History*, new ed., vol. 4, pt. 1, pp. 147–156 (1966).

Nichiren

Nichiren, a Buddhist monk of the Kamakura period (1192–1333), is one of the most significant figures in Japanese Buddhism. Together with the other Buddhist founders of that period (see HONEN and SHINRAN), he greatly contributed to the complete adaptation of Buddhism to the Japanese religious mentality. Because of his uncompromising commitment, militant personality, and concern with national regeneration through true religion, he has been called "the Japanese prophet."

Nichiren was born in 1222, the son of a fisherman, in the village of Kominato, on the Pacific coast of the present Bōsō-hantō in eastern Japan. When he was 11 years old, he entered the Buddhist monastery of Kiyosumi, near Kominato, and after four years of noviceship received the Buddhist orders. Buddhism in Japan had become more and more doctrinally confused, and the identity of the various sects was based more on institutional aspects than on doctrinal tenets. Though the monastery of Kiyosumi officially belonged to the Tendai sect, centred on the *Lotus Sūtra* text and realization of the universal Buddha-nature, the doctrine practiced there was a mixture of different Buddhist schools with a strong emphasis on Shingon, an esoteric school that emphasized an elaborate symbolic ritual.

Quest for true Buddhist teaching

The young monk was too intense and too sincere in his quest for the true doctrine of the Buddha to be satisfied with such prevailing confusion of doctrine. Soon his central spiritual problem was to find, through the maze of scriptures and doctrines, the authentic teaching the historical Buddha, Gautama (Śākyamuni), had preached for the salvation of mankind. So he undertook a thorough study of all the major Buddhist schools existing in Japan. In 1233 he went to Kamakura, where he studied Amidism—a pietistic school that stressed salvation through the invocation of Amida, the Buddha of infinite compassion—under the guidance of a renowned master. After having persuaded himself that Amidism was not the true Buddhist doctrine, he passed to the study of Zen, which had become popular in Kamakura and Kyōto. He then went to Hiei-zan, the cradle of Japanese Tendai Buddhism, where he found the original purity of the Tendai doctrine corrupted by the introduction and acceptance of other doctrines, especially Amidism and esoteric Buddhism (see BUDDHISM, *Shingon*). To eliminate any possible doubts, Nichiren decided to spend some time at Kōyasan, the centre of esoteric Buddhism, and also in Nara, Japan's ancient capital, where he studied the Ritsu sect, which emphasized strict monastic discipline and ordination.

By 1253 Nichiren had reached his final conclusion: the true Buddhism was to be found in the *Lotus Sūtra*, and all other Buddhist doctrines were only temporary and provisional steps used by the historical Buddha as a pedagogical method to lead men to the full and final doctrine contained in the *Lotus Sūtra*. Moreover, the Buddha himself had decreed that this doctrine was to be preached to men during the age of the Latter Law (Mappo)—the last, degenerate period after his death, the present age—and that a teacher would then appear to preach this true and final doctrine.

In the spring of 1253, Nichiren returned to Kiyosumi where he proclaimed his faith before his old master and his fellow monks, adding that all other forms of Buddhism were to be banished, for they were false and were misleading the people. Neither the monks of Kiyosumi nor the feudal lord of the region accepted his doctrine, and their angry reaction was such that he had to escape to save his life.

Expelled from his monastery, Nichiren lived in a little hut in Kamakura and spent his days preaching his doctrine at the busiest crossroads of the city. His constant attacks against all other sects of Buddhism attracted an ever-increasing hostility and finally open persecution

from Buddhist institutions and from the authorities. The country was at the time afflicted by epidemics, earthquakes, and internal strife. Reflecting on this sad situation, Nichiren is said to have read once again all the Buddhist scriptures and in 1260 published a short tract, *Risshō ankoku-ron* ("The Establishment of Righteousness and the Pacification of the Country"), in which he stated that the deplorable state of the country was due to the fact that the authorities and the people refused to follow true Buddhism and were supporting false sects. The only salvation was for the authorities and the people of Japan to accept Nichiren's doctrine as the national faith and banish all the other sects. If this was not done, the state of the country would become even worse, and Japan would be invaded by a foreign power. The military government in Kamakura reacted to this prophetic admonition by exiling the monk to a deserted place in the Izu-hantō (Izu Peninsula), in the present Shizuoka Prefecture, in June 1261. He was pardoned in 1263, but upon his return to Kamakura he renewed his attacks.

Nichiren's message to Japan

In 1268 an embassy from the Mongols—who had conquered China—arrived in Japan demanding that the Japanese become a tributary nation to the new Mongol dynasty. Nichiren saw in this the fulfillment of his prophecy of 1260. Once again he sent copies of his *Risshō ankoku-ron* to the authorities and the heads of the major Buddhist institutions, insisting again that if his doctrine was not accepted and the other sects were not banished, Japan would be visited with all sorts of calamities.

Again the authorities and the older Buddhist sects were enraged by the extraordinary audacity of this troublesome monk, and in 1271 Nichiren was arrested and condemned to death. The penalty was commuted at the last moment, and instead he was exiled to the island of Sado, in the Sea of Japan, where in 1272 he wrote his systematic work *Kaimokushō* ("The Opening of the Eyes"). According to Nichiren's account and the belief of his adherents, he was saved from execution by a miraculous intervention that struck the sword from the executioner's hand. While the fiery monk was in exile, a second and a third Mongol embassy arrived, threatening an invasion if Japan persisted in her refusal to become a vassal nation. Nichiren's prophecy and the pressure of his influential friends in Kamakura moved the government, and an edict of pardon was issued in the spring of 1274. In May, Nichiren arrived in Kamakura, where he met with high government officials and reiterated his stern requests. Though this time the authorities treated him with deference and respect, they still refused to comply with his demands.

Full of indignation, Nichiren left Kamakura in June and with a small number of disciples retired to a solitary place on Minobu-san, in the present Yamanashi Prefecture. There he spent his last years instructing his followers and writing. Among the main works of this period are the "Selection of the Time," a synthetic exposition of his philosophy of history, and "In Recompense of Indebtedness," in which a good life is seen as one of practical gratitude toward one's parents, all creatures, one's sovereign, and the Buddha.

The hardships and persecutions endured for so many years began to take their toll, and Nichiren's state of health grew worse and worse. His final illness was probably a cancer of the intestinal tract. In the fall of 1282 he left his hermitage at Minobu and took residence in the mansion of one of his disciples in the district of Ikegami (in what is now Tokyo), where he died on November 4, 1282.

Contribution to Japanese Buddhism

Nichiren is perhaps the most controversial figure in the history of Japanese Buddhism. Incapable of accepting any compromise, he described himself as a most intractable character. Yet letters he wrote to his disciples and friends reveal how loving, understanding, and even delicate he could be. He dearly loved Japan and wanted her to fulfill her mission of being the chosen country of Buddhism, from which Buddha's salvation was to spread to the entire world. His Buddhism was typically Japanese in the sense that it could not be confined to mere speculation or even to individual salvation but had to be concerned with the salvation of society and temporal institutions; hence, the importance he gave to the right understanding of history and human affairs. The continuing vitality of the religious system he founded in the 13th century is attested by the fact that many of the modern Buddhist sects now flourishing in Japan are, in various degrees, based on Nichiren's doctrines.

BIBLIOGRAPHY. MASAHARU ANESAKI, *Nichiren, the Buddhist Prophet* (1916, reprinted 1966), a highly readable work that gives a good exposition of Nichiren's life and doctrine—the only available biography in English; GEORGE B. SANSOM, "Nichiren," in SIR CHARLES ELIOT, *Japanese Buddhism* (1935, reprinted 1969), a brief but adequate exposition of Nichiren's doctrine.

Nicholas V, Pope

As pope from 1447 to 1455, Nicholas V (Tommaso Parentucelli), perhaps the most influential of the Renaissance popes, is notable for his sponsorship of the new Humanist learning and thus for the attempted conciliation of religion with secular culture. He was the founder of the world-famous Vatican Library.

Alinari

Nicholas V, effigy on his tomb in St. Peter's Basilica, Vatican City, 15th century.

Parentucelli was born November 15, 1397. His father died when he was nine. Later he studied at Bologna, but for lack of funds had to interrupt his studies there. Then, to earn money, he acted as tutor for two years in two wealthy, cultured Florentine families, and this contact with the early Renaissance coloured all his life. After returning to the university and completing his studies, at the age of 22 he entered the household of Niccolò Albergati, the cardinal-archbishop of Bologna, whom he served devotedly for 20 years, accompanying him on his many diplomatic missions throughout Europe. Pope Eugenius IV recognized Parentucelli's merit and experience and, on Albergati's death, made him bishop of Bologna (1444), but he was prevented from entering the city by its rebellious inhabitants, who sought independence from papal rule. At the Council of Ferrara–Florence (1438–45), he led the discussions with the Armenians, Copts, and Jacobites that attempted to end their doctrinal differences with the Latin Church, and he later journeyed on missions for the Pope. After his diplomatic success in pacifying the German Electors at the Diet of Frankfurt in 1446, he was created cardinal and only three months later, on March 6, 1447, was elected pope. Thenceforward, his chief aims were, in his words, "without using arms other than those which Christ has given me for my defence, that is to say, His Cross," to work for ecclesiastical and political peace, to reform the church, and to make Rome architecturally and artistically the worthy centre of Christianity.

Achievements in diplomacy and church reform

When Nicholas became pope, the remnant of the rebellious Council of Basel (1431–37)—which advocated control of the church through councils rather than through the pope—and its antipope Felix V still challenged Rome. Nicholas, by demanding little and yielding much, brought the schism to an end. He restored peace in

the papal states, not by mercenary armies, which he disbanded, but by strategically situated castles entrusted to carefully chosen governors. In Rome he was conciliatory with the nobility and granted concessions to the restive citizens. He allowed the town of Palestrina, destroyed by his predecessor, to be rebuilt; pacified Bologna by granting it virtual independence; won the allegiance of Poland by concessions; and, by promising coronation as Holy Roman emperor to Frederick III, gained the support of Austria. In order to give peace to Italy by preserving the status quo and to organize a crusade against the Turks, he initiated the Peace of Lodi among Venice, Milan, Florence, and Naples and solemnly ratified it on February 25, 1455.

Nicholas helped the church by furthering legislation against the old abuses of simony (buying and selling of church offices) and clerical concubinage and by encouraging bishops to govern their dioceses wisely. In Germany Cardinal Nicholas of Cusa (1401–64), a notable scholar and thinker, and the Franciscan theologian and preacher, Saint John of Capistrano (1386–1456), laboured hard at reform with much success. A wider measure to stimulate piety and restore the papal reputation was the proclamation of the 1450 Jubilee Year. Vast numbers of pilgrims visited Rome, and the project did much good, though it was marred by an outbreak of the plague and a tragedy when 172 people died in a panic-crush on the St. Angelo Bridge.

Pope Nicholas is best remembered for his influence on the Renaissance in Rome. "Of all Renaissance popes," says Eugène Müntz, a famous curator and art historian, "Nicholas is the one who ventilated the greatest number of architectural ideas: his successors only executed one or another element of his programme." He had plans for building a new St. Peter's Church but was able only to rebuild what was crumbling, to reconstruct the Vatican Palace, and to surround the whole with a wall. The restoration and embellishment of many Roman architectural treasures, such as the senatorial palace on the Capitoline Hill, are credited to him, but he pillaged ancient monuments to quarry materials for his new constructions. At his initiative, Rome became a centre for goldsmiths and silversmiths; he employed French, Belgian, and German tapestry makers; he commissioned artists of note, among them the great Florentine painter Fra Angelico (1387–1455) to beautify his constructions.

Architectural and Humanistic achievement

He had the Humanist's passion for books. On his diplomatic missions he sought them out, and as pope he spent vast sums on buying them. His court became a centre for Humanists, some of them more pagan in outlook than Christian; they were employed in copying and translating ancient texts, among them the works of Homer, Herodotus, Thucydides, and many Greek Church Fathers.

His last years were saddened by a plot against his life. Twice he dealt mercifully with the ringleader; the third time, in 1453, he had him and his accomplices executed. Also in 1453, Constantinople, the seat of Eastern Christianity, was captured by the Turkish sultan. Nicholas had ordered a fleet to aid the beleaguered city, but it arrived too late. This was a military reverse of great religious and cultural significance.

Nicholas was a man of gentle character who achieved more by wise concession than others did by force. Of him Vespasiano da Bisticca (1421–98), the biographer of 15th-century luminaries, wrote: "He did not know what avarice was: indeed, if he retained anything of his own, it was simply because no one had asked him for it." His diplomatic efforts on behalf of peace in Italy and elsewhere and his patronage of the arts, especially of literature, restored to the church much of the ancient prestige it had lately lost. His failure to promote sufficiently religious reform, however, was destined to result in the Reformation in the 16th century.

(J.Gi.)

Nicholas I of Russia

Nicholas I, emperor of Russia from 1825 to 1855, was by circumstance and choice a military man, whose uncompromising bearing, personality, and deeds made him the personification of the classic autocrat. A reactionary, he has been called the emperor who froze Russia for 30 years. He may have summarized his philosophy of life in the following passage:

> Here [in the army] there is order, there is a strict unconditional legality, no impertinent claims to know all the answers, no contradiction, all things flow logically one from the other; no one commands before he has himself learned to obey; no one steps in front of anyone else without lawful reason; everything is subordinated to one definite goal, everything has its purpose. That is why I feel so well among these people, and why I shall always hold in honour the calling of a soldier. I consider the entire human life to be merely service, because everybody serves.

By courtesy of Mrs. Merriweather Post, Hillwood, Washington, D.C.

Nicholas I, watercolour by Christina Robertson, 1840. In the collection of Mrs. Merriweather Post, Hillwood, Washington, D.C.

Early life. Nicholas (Nikolay Pavlovich) was born on July 6 (June 25, old style), 1796. His parents were Grand Duke Paul and Grand Duchess Maria. Some three and a half months later, following the death of Catherine II the Great, Nicholas' father became Emperor Paul I of Russia. Nicholas had three brothers, two of whom, the future emperor Alexander I and Constantine, were 19 and 17 years older than he. It was the third, Michael, his junior by two years, and a sister, Anne, who became his childhood companions and intimate lifelong friends.

Family relations

Paul was extremely neurotic, overbearing, and despotic. Yet it is believed that he showed kindness and consideration to his younger children and that, in fact, he loved and cherished them tenderly. He was killed in a palace revolution of 1801, which made Alexander emperor when Nicholas was not quite five years old. Maria, on the contrary, remained formal and cold in her relationship to the children, very much in keeping with her general character. She belonged, apparently, among those human beings who combine numerous conventional virtues

with a certain rigidity and lack of warmth. In the words of a competent observer: "The only failing of this extraordinary woman was her being excessively, one may say, exacting of her children and of the people dependent on her."

Education. The future emperor's first guardian and instructress was a Scottish nurse, Miss Jane Lyon, who was appointed by Catherine II to care for the infant and who stayed with Nicholas constantly during the first seven years of his life. From Miss Lyon the young grand duke learned even such things as the Russian alphabet, his first Russian prayers, and his hatred of the Poles (at least he liked later to trace the origin of his bitter antipathy toward that people to the stories told by his nurse about her painful experience in Warsaw in the turbulent year of 1794). In 1802–03 men replaced women in Nicholas' entourage, and his regular education began. As directed by Gen. Matthew Lamsdorff, it emphasized severe discipline and formalism. The growing grand duke studied French and German as well as Russian, world history, and general geography in French, together with the history and geography of Russia. Religion, drawing, arithmetic, geometry, algebra, and physics were added to the curriculum. Nicholas received instruction also in dancing, music, singing, and horseback riding and was introduced at an early age to the theatre, costume balls, and other court entertainment. In 1809 a more advanced curriculum went into effect, with courses ranging from political economy, logic, moral philosophy, and natural law to strategy. English, Latin, and Greek were added to the language program. Though, on the whole, a belief that Nicholas had not been trained for his role of Russian sovereign is wrong, he did profit little from the instruction, which he found rigid and tedious. He loved only military science, becoming a fine army engineer and expert in several other areas of military knowledge. Moreover, he always remained in his heart a dedicated junior officer.

Love for military science

Circumstances also favoured militarism. Nicholas' education, as well as that of his younger brother, was interrupted and largely terminated by the great struggles against Napoleon in 1812–15. The grand dukes were allowed to join the army in 1814; and, although they saw no actual fighting, they lived through the heady emotions of those momentous years and also enjoyed the opportunities to stay in Paris and other places in western and central Europe. On November 4, 1815, at a state dinner in Berlin, Alexander I and King Frederick William III rose to announce the engagement of Nicholas and Princess Charlotte of Prussia (Alexandra, after she became Orthodox). The solemn wedding followed some 20 months later, on July 13, 1817. The match represented a dynastic and political arrangement sought by both reigning houses, which had stood together in the decisive years against Napoleon and after that at the Congress of Vienna—the peace settlement following the Napoleonic Wars—and it proved singularly successful. Not only was Nicholas in love with his wife, but he became very closely attached to his father-in-law as well as to his royal brothers, one of whom was later to be his fellow ruler as King Frederick William IV. Beyond that, Nicholas was powerfully attracted by the Prussian court and even more so by the Prussian Army. He felt remarkably happy and at home in his adopted family and country, which for many years he tried to visit as often as he could.

To complete his training, Grand Duke Nicholas was sent on two educational voyages—an extensive tour of Russia that lasted from May to September in 1816 and a journey to England, where the future emperor spent four months late that same year and early in 1817. The Russian trip covered much ground at great speed and was quite superficial, but it has interest for the historian because of the notes that Nicholas, following the instructions of his mother, took on everything seen and heard. The grand duke's observations deal, typically, with appearances rather than with causes and reflect a number of his prejudices, including his bitter dislike of Poles and Jews. Such quick inspection tours later became almost an obsession of the Emperor. In England, Nicholas stayed mostly in London, although he travelled to a score of other places. While he did attend the opening of the houses of Parliament and in general obtained some knowledge of English politics, his only recorded comments on that score were unfavourable. The future emperor found it much more congenial to examine military and naval centres. His favourite English companion was the Duke of Wellington. Less than a year after his return to Russia and a few months after his marriage, Nicholas was appointed inspector general of the army corps of engineers. In subsequent years he held several other military positions but of secondary significance.

Ascension to the throne. Alexander I's unexpected death in southern Russia on December 1, 1825, led to a dynastic crisis. Because Alexander I had no direct male successor, Constantine was next in line for the throne. But the heir presumptive had married a Polish woman not of royal blood in 1820 and renounced his rights to the crown. Nicholas was thus to become the next ruler of Russia, the entire matter being stated, in 1822, in a manifesto confirmed with Alexander I's signature. But the manifesto remained unpublished, and Nicholas questioned the legal handling of the whole issue and the reaction in the country, which expected Constantine to succeed Alexander. In any case, Constantine and the Polish kingdom of which he was commander in chief swore allegiance to Nicholas; but Nicholas, the Russian capital, and the Russian Army swore allegiance to Constantine. It was only after Constantine's uncompromising reaffirmation of his position and the resulting lapse of time that Nicholas decided to publish Alexander's manifesto and become emperor of Russia. On December 26, 1825 (December 14, O.S.), when the guard regiments in St. Petersburg were to swear allegiance for the second time in rapid succession, this time to Nicholas, liberal conspirators staged what came to be known as the Decembrist Rebellion. Utilizing their influence in the army, in which many of them were officers, they started a mutiny in several units, which they entreated to defend the rightful interests of Constantine against his usurping brother. Altogether some 3,000 misled rebels marched in military formation to the Senate Square—now the Decembrist Square—in the heart of the capital. Although the rebellion had failed by nightfall, it meant that Nicholas I ascended the throne over the bodies of some of his subjects and in actual combat with the dreaded revolution.

Dynastic crises

Personality. Nicholas I has come down in history as the classic autocrat, in appearance and manner as much as in behaviour and policy. To quote Andrew Dickson White, a United States diplomat:

Appearance and manner

> With his height of more than six feet, his head always held high, a slightly aquiline nose, a firm and well-formed mouth under a light moustache, a square chin, an imposing, domineering, set face, noble rather than tender, monumental rather than human, he had something of Apollo and of Jupiter . . . Nicholas was unquestionably the most handsome man in Europe.

Or to refer to Adolphe, marquis de Custine, whose lasting literary fame rests on his denunciation of the Russia of Nicholas I: "Virgil's Neptune . . . one could not be more emperor than he." In short, Nicholas I came to represent autocracy personified: infinitely majestic, determined and powerful, hard as stone, and relentless as fate. Yet, on closer acquaintance, the other side of the Emperor emerged. The detachment and the superior calm of an autocrat, which Nicholas I tried so often and so hard to display, were essentially a false front. The sovereign's insistence on firmness and stern action was based on fear, not on confidence; his determination concealed a state approaching panic, and his courage fed on something akin to despair. Nicholas' violent hatred could concentrate apparently with equal ease on an individual, such as the French king Louis-Philippe; a group, such as the Decembrists; a people, such as the Poles; or a concept, such as revolution. His impulse was always to strike and keep striking until the object of his wrath was destroyed.

Aggressiveness, however, was not the Emperor's only method of coping with the problems of life. He also used regimentation, orderliness, neatness, and precision, an

enormous effort to have everything at all times in its proper place. Nicholas I was by nature a drill master and an inspector general; the army remained his love, almost an obsession, from childhood to the end of his life. But, in every other sphere of activity and existence too, the Emperor insisted on minute and precise regulation, with nothing to be left to chance. Position, circumstances, and his own character placed an almost intolerable burden on his shoulders. Still, he managed to carry it for three decades, sustained by his overwhelming sense of duty and devotion to hard work, by his sincere religious convictions, and by his family. His outlook, however, became ever more pessimistic and fatalistic, until in the disaster of the Crimean War the autocrat declared simply: "I shall carry my cross until all my strength is gone. Thy will be done."

Ideology. Nicholas' views fitted his personality to perfection. In contrast to Alexander I, he had been brought up at the time of wars against Napoleon and of reaction, which he accepted wholeheartedly as his own cause. Eventually the Russian wing of European reaction, represented by Nicholas I and his government, found its ideological expression in the doctrine of so-called Official Nationality. Formally proclaimed in 1833 by Count Sergey Uvarov, the Emperor's minister of education, Official Nationality rested on three principles: Orthodoxy, autocracy, and nationality. Autocracy meant the affirmation and maintenance of the absolute power of the sovereign, which was considered the indispensable foundation of the Russian state; in foreign relations it was transformed into legitimism and a defense of the Vienna settlement. Orthodoxy referred to the official church and its important role in Russia and also to the ultimate source of ethics and ideals that gave meaning to human life and society. Nationality (*narodnost*) described the particular nature of the Russian people, considered as a mighty and dedicated supporter of its dynasty and government. Whereas Alexander I had never quite abandoned dreams of change, Nicholas I was determined to defend the existing order in his motherland, especially autocracy.

Doctrine of Official Nationality

Reign. Nicholas I's rule reflected in a striking manner both his character and his principles. The new regime became pre-eminently one of militarism and bureaucracy. The Emperor surrounded himself with military men, to the extent that late in his reign there were almost no civilians among his immediate assistants. Also, he relied heavily on special emissaries, most of them generals of his suite, who were sent all over Russia on particular assignments to execute immediately the will of the sovereign. Operating outside the regular administrative system, they represented an extension, so to speak, of the monarch's own person. In fact, the entire machinery of government came to be permeated by the military spirit of direct orders, absolute obedience, and precision, at least as far as official reports and appearances were concerned. Corruption and confusion, however, lay immediately behind this facade of discipline and smooth functioning.

In his conduct of state affairs, Nicholas I often bypassed regular channels and generally resented formal deliberation, consultation, or other procedural delay. The importance of the Committee of Ministers, the State Council, and the Senate decreased in the course of his reign. Instead of making full use of them, the Emperor depended more and more on special bureaucratic devices meant to carry out his intentions promptly while remaining under his immediate and complete control. As one favourite method, Nicholas I made extensive use of ad hoc committees that stood outside the usual state machinery. The committees were typically composed of a handful of the most trusted assistants of the Emperor; because these were few in number, the same men in different combinations formed these committees throughout Nicholas' reign. As a rule, the committees carried on their work in secret, adding further complication and confusion to the already cumbersome administration of the empire. The failure of one committee to perform its task merely led to the formation of another. For example, some nine committees tried to deal with the issue of serfdom during Nicholas' reign.

Administration of the empire

The propensities of the autocrat found expression also in the development and the new role of His Majesty's Own Chancery. Organized originally as a bureau to deal with matters that demanded the sovereign's personal participation and to supervise the execution of the Emperor's orders, it acquired five new departments: in 1826 the Second and the Third, to deal with the codification of law and the newly created corps of gendarmes, respectively; in 1828 the Fourth, to manage the charitable and educational institutions under the jurisdiction of the empress dowager Maria; in 1836 the Fifth, to reform the condition of the state peasants (soon replaced by the new Ministry of State Domains); in 1843 the Sixth, to draw an administrative plan for Transcaucasia. The departments of the Chancery served Nicholas I as a major means of conducting a personal policy that bypassed the regular state channels. Its Third Department, the political police, acted as the autocrat's main weapon against subversion and revolution and as his principal agency for controlling the behaviour of his subjects and for distributing punishments and rewards among them. Its assigned fields of activity ranged from "all orders and all reports in every case belonging to the higher police" to "reports about all occurrences without exception!" The two successive heads of the Third Department—Count Aleksandr Benckendorff and Prince Aleksey Orlov—probably spent more time with Nicholas than did any of his other assistants; they accompanied him, for instance, on his repeated trips of inspection throughout Russia. During his entire reign the Emperor strove to follow the principle of autocracy—to be a true father of his people concerned with their daily lives, hopes, and fears.

Yet Nicholas I could do little for them beyond the minutiae. Determined to preserve autocracy, afraid to abolish serfdom, and suspicious of all independent initiative and popular participation, the Emperor and his government could not introduce in their country the much-needed basic reforms. In practice as well as in theory they looked backward. Important developments took place only in a few areas in which change would not threaten the fundamental structure of the Russian Empire. Thus Count Mikhail Speransky codified law, and Count Pavel Kiselev changed and improved the lot of the state peasants; but even limited reforms became impossible after 1848. Frightened by European revolutions, Nicholas I became completely reactionary. During the last years of the reign the Emperor's once successful foreign policy collapsed, leading to isolation and to the tragedy of the Crimean War. A dauntless champion of legitimism and a virtual hegemon of eastern and central Europe following the revolutions of 1848–49, Nicholas—in part because of his own miscalculations, rigidity, and bluntness—found himself alone fighting the Crescent (the Ottoman Empire), supported by such countries of the Cross as France, Great Britain, and Sardinia.

Isolation and tragedy

Although it is unlikely that Nicholas committed suicide, as several historians have claimed, death did come as liberation to the weary and harassed Russian emperor. An ordinary cold picked up in late February 1855 turned into pneumonia, which the once mighty, but now apparently exhausted, organism refused to fight. To the end the autocrat retained lucidity and dignity.

Nicholas died in St. Petersburg on March 2 (February 18, O.S.), 1855. His last words to his heir and his family were: "Now I shall ascend to pray for Russia and for you. After Russia, I loved you above everything else in the world. Serve Russia." Nicholas I was survived by his wife, Empress Alexandra, and their six children: Emperor Alexander II, grand dukes Constantine, Nicholas, and Michael, and grand duchesses Maria and Olga. Another daughter, Grand Duchess Alexandra, had died in 1844.

BIBLIOGRAPHY. The leading full account of Nicholas I and his reign, especially valuable on foreign relations and with numerous documentary appendixes, is THEODOR SCHIEMANN, *Geschichte Russlands unter Kaiser Nikolaus I*, 4 vol. (1904–19). An emperor- and court-centred history, incomplete but very rich in primary sources, is НИКОЛАЙ ШИЛДЕР, *Император Николай Первый, его жизнь и царствование*, 2 vol.

(1903). A readable popular study is CONSTANTIN DE GRUNWALD, *La Vie de Nicolas Ier* (1946; Eng. trans., *Tsar Nicholas I*, 1954). See also NICHOLAS V. RIASANOVSKY, *Nicholas I and Official Nationality in Russia, 1825–1855* (1959).

Nicholas II of Russia

The forced abdication of Tsar Nicholas II in 1917 marked the end of centuries of imperial government in Russia; and the execution by the Bolsheviks of him and his family during the ensuing civil war effectively extinguished the chances of a restoration of the monarchy. By nature timid and vacillating, Nicholas had early embraced the God-given role of autocrat of all Russia. His reactionary attitude, coupled with his generally inept handling of domestic and foreign affairs, contributed much to the popular discontent that led to his downfall and to four years of revolution and civil war.

Nicholas II, watercolour by an unknown artist. In the collection of Mrs. Merriweather Post, Hillwood, Washington, D.C.

He was born at Tsarskoye Selo, one of the tsar's summer palaces near St. Petersburg, on May 18 (May 6, old style), 1868, the eldest son of the tsarevich Aleksandr Aleksandrovich (emperor as Alexander III from 1881) and his consort Maria Fyodorovna (Dagmar of Denmark). Succeeding his father on November 1, 1894, he was crowned in Moscow on May 26, 1895.

Neither by upbringing nor by temperament was Nicholas fitted for the complex tasks that awaited him as autocratic ruler of a vast empire. He had received a military education from his tutor, and his tastes and interests were those of the average young Russian guards officer of his day. He had few intellectual pretensions but delighted in physical exercise and the minutiae of army life: uniforms, insignia, parades. Yet on formal occasions he felt ill at ease. Though he possessed great personal charm, he was by nature timid; he shunned close contact with his subjects, preferring the privacy of his family circle. His domestic life was serene. To his wife, Alexandra, whom he had married on November 26, 1894, Nicholas was passionately devoted. She had the strength of character that he lacked, and he fell completely under her sway. Under her influence he sought the advice of spiritualists and faith healers, most notably Rasputin, who eventually acquired great power over the imperial couple. Nicholas also had other irresponsible favourites, often men of dubious probity who provided him with a distorted picture of Russian life, but one that he found more comforting than that contained in official reports. He distrusted his ministers, mainly because he felt them to be intellectually superior to himself and feared that they sought to usurp his sovereign prerogatives. His view of his role as autocrat was childishly simple: he derived his authority from God, to whom alone he was responsible, and it was his sacred duty to preserve his absolute power intact. He lacked, however, the strength of will necessary in one who had such an exalted conception of his task. In pursuing the path of duty, Nicholas had to wage a continual struggle against himself, suppressing his natural indecisiveness and assuming a mask of self-confident resolution. His dedication to the dogma of autocracy was an inadequate substitute for a constructive policy, which alone could have prolonged the imperial regime.

Influence of Alexandra

Soon after his accession Nicholas proclaimed his uncompromising views in an address to liberal deputies from the *Zemstva*, the self-governing local assemblies, in which he dismissed as "senseless dreams" their aspirations to share in the work of government. He met the rising ground swell of popular unrest with intensified police repression. In foreign policy, his naïveté and lighthearted attitude toward international obligations sometimes embarrassed his professional diplomats; for example, he concluded an alliance with the German emperor William II during their meeting at Björkö in July 1905, although Russia was already allied with France, Germany's traditional enemy.

He was the first Russian sovereign to show personal interest in Asia, visiting in 1891, while still tsarevich, India, China, and Japan; and later he nominally supervised the construction of the Trans-Siberian Railway. His attempt to maintain and strengthen Russian influence in Korea, where Japan also had a foothold, was partly responsible for the Russo-Japanese War (1904–05). Russia's defeat not only frustrated Nicholas' grandiose dreams of making Russia a great Eurasian power, with China, Tibet, and Persia under its control, but also presented him with serious problems at home, where discontent grew into the revolutionary movement of 1905.

Nicholas considered all who opposed him, regardless of their views, as malicious conspirators. Disregarding the advice of his prime minister, Sergey Yulyevich Witte, he refused to make concessions to the constitutionalists and workers until events forced him to yield more than might have been necessary had he been more flexible. On March 3, 1905, he reluctantly agreed to create a national representative assembly, or Duma, with consultative powers; and by the manifesto of October 30 he promised a constitutional regime under which no law was to take effect without the Duma's consent, as well as a democratic franchise and civil liberties. Nicholas, however, cared little for keeping promises extracted from him under duress. He strove to regain his former powers and ensured that in the new "fundamental laws" (May 1906) he was still designated an autocrat. He furthermore patronized an extremist right-wing organization, the Union of the Russian People, which sanctioned terrorist methods and disseminated anti-Semitic propaganda. Witte, whom he blamed for the October manifesto, was soon dismissed, and the first two Dumas were prematurely dissolved as "insubordinate." Pyotr Arkadyevich Stolypin, who replaced Witte and carried out the coup of June 16, 1907, dissolving the second Duma, was loyal to the dynasty and a capable statesman. But the Emperor distrusted him and allowed his position to be undermined by intrigue. Stolypin was one of those who dared to speak out about Rasputin's influence and thereby incurred the displeasure of the Empress. In such cases Nicholas generally hesitated but ultimately yielded to Alexandra's pressure. To prevent exposure of the scandalous hold Rasputin had on the imperial family, Nicholas interfered arbitrarily in matters properly within the competence of the Holy Synod, backing reactionary elements against those concerned about the Orthodox Church's prestige.

Foreign affairs

After its ambitions in the Far East were checked by Japan, Russia turned its attention to the Balkans. Nicholas sympathized with the national aspirations of the Slavs and was anxious to win control of the Turkish straits but tempered his expansionist inclinations with a sincere desire to preserve peace among the great powers. After the assassination of the Austrian archduke Francis Ferdinand at Sarajevo, he tried hard to avert the impending war by diplomatic action and resisted, until July 30, 1914, the pressure of the military for general, rather than par-

tial, mobilization. The outbreak of World War I temporarily strengthened the monarchy, but Nicholas did little to maintain his people's confidence. The Duma was slighted, and voluntary patriotic organizations were hampered in their efforts; the gulf between the ruling group and public opinion grew steadily wider. Alexandra turned Nicholas' mind against the popular commander in chief, his father's cousin the grand duke Nicholas; and on September 5, 1915, he dismissed him, assuming supreme command himself. Since the Emperor had no experience of war, almost all his ministers protested against this step as likely to impair the army's morale. They were overruled, however, and soon dismissed.

Nicholas II did not, in fact, interfere unduly in operational decisions, but his departure for headquarters had serious political consequences. In his absence, supreme power in effect passed, with his approval and encouragement, to the Empress. A grotesque situation resulted: in the midst of a desperate struggle for national survival, competent ministers and officials were dismissed and replaced by worthless nominees of Rasputin. The court was widely suspected of treachery, and antidynastic feeling grew apace. Conservatives plotted Nicholas' deposition in the hope of saving the monarchy. Even the murder of Rasputin failed to dispel Nicholas' illusions: he blindly disregarded this ominous warning, as he did those by other highly placed personages, including members of his own family. His isolation was virtually complete.

Abdication and death

When riots broke out in Petrograd on March 8, 1917, Nicholas instructed the city commandant to take firm measures and sent troops to help restore order. It was too late. The government resigned, and the Duma, supported by the army, called on the Emperor to abdicate. At Pskov, on March 15, with fatalistic composure, Nicholas renounced the throne—not, as he had originally intended, in favour of his son Alexis but in favour of his brother Michael, who, however, refused the crown.

Nicholas was detained at Tsarskoye Selo by Prince Lvov's provisional government. It was planned to send him and his family to England; but instead, mainly because of the opposition of the Petrograd Soviet, the Revolutionary Workers' and Soldiers' Council, they were removed to Tobolsk, in western Siberia. This step sealed their doom. In April 1918 they were taken to Yekaterinburg (now Sverdlovsk) in the Urals. When the anti-Bolshevik "White" Russian forces approached the area, the local authorities were ordered to prevent a rescue; and in the night of July 16/17 the prisoners were all slaughtered in the cellar of the house where they had been confined. The bodies were burned and cast into an abandoned mine shaft, but the facts were established by investigation after Yekaterinburg had been taken by the "White" forces.

BIBLIOGRAPHY. R.K. MASSIE, *Nicholas and Alexandra* (1967), is a popular study of life at the imperial court. A reliable general survey of Nicholas' reign is given by RICHARD CHARQUES in *The Twilight of Imperial Russia* (1958); on the last years, compare SIR BERNARD PARES, *The Fall of the Russian Monarchy* (1939 and 1961); and GEORG KATKOV, *Russia 1917: The February Revolution* (1967), the latter is more favourable to Nicholas. СЕРГЕЙ ПЕТРОВИЧ МЕЛЬГУНОВ, *Судьба Императора Николая II после отречения; историко-критические очерки* (1951), gives a thorough account of the Emperor's fate after his abdication. For a selection from his correspondence with Alexandra, see *The Letters of the Tsar to the Tsaritsa, 1914-1917*, ed. by C.E. VULLIAMY (1929; reprinted, with Alexandra's letters, in 2 vol., 1970).

Nickel Products and Production

Nickel was used industrially as an alloying metal almost 2,000 years before it was isolated and recognized as a new element. Although it is best known for its use in coinage, nickel has become much more important for its many industrial uses, particularly as a constituent in alloy steels.

History. As early as 200 BC, the Chinese made substantial amounts of a white alloy from a copper–nickel ore found in Yunnan province and zinc. The alloy, known as *pai-t'ung*, was exported to the Middle East and even to Europe.

Later, miners in Saxony encountered what appeared to be a copper ore but found that processing it yielded only a useless slaglike material. They considered it bewitched and ascribed it to "Old Nick." Thus, it became known as kupfernickel (Old Nick's copper). It was from this ore, studied by A.F. Cronstedt, that nickel was isolated and recognized as a new element in 1751. In 1776 it was established that *pai-t'ung*, now called nickel-silver, was composed of copper, nickel, and zinc.

Demand for nickel-silver was stimulated in England around 1844 by the development of silver electroplating, for which it was found to be the most desirable base. The use of pure nickel as a corrosion-resistant electroplated coating developed a little later; both these uses continue, with nickel plating much the more important.

Ores and mining. Small amounts of nickel were produced in Germany in the mid-19th century. More substantial amounts came from Norway, and a little from a mine at Gap, Pennsylvania. A new source, New Caledonia in the South Pacific, came into production about 1877 and dominated until the development of the copper-nickel ores of the Copper Cliff-Sudbury, Ontario, region in Canada, which since 1905 has been the world's largest source of nickel. Several producers are active in Canada.

Canadian ores are sulfides containing nickel, copper, and iron. The most important nickel mineral is pentlandite $(Ni,Fe)_9S_8$, followed by pyrrhotite, usually ranging from FeS to Fe_7S_8, in which some of the iron may be replaced by nickel. Chalcopyrite, $CuFeS_2$, is the dominant copper mineral in these ores, with small amounts of another copper mineral, cubanite, $CuFe_2S_3$. Some gold, silver, and the six platinum-group metals also are present, and their recovery is important. Cobalt, selenium, tellurium, and sulfur also may be recovered from the ores.

Table 1: World Production of Nickel (1969)

	metric tons
Canada	192,700
U.S.S.R.	105,000
New Caledonia	90,474
Cuba	35,200
U.S.	14,167
Europe	11,294
Australia	10,796
Rhodesia	8,000
Indonesia	7,025
South Africa	5,500
Brazil	1,089

Other important classes of ore are the laterites, which are the result of long weathering of peridotite initially containing a small percentage of nickel. Weathering in subtropical climates removes a major portion of the host rock, but the contained nickel dissolves and percolates downward and may reach a concentration sufficiently high to make mining economical. The nickel magnesium silicate, garnierite, is the richest in nickel. The New Caledonian deposits are of this type, and numerous other laterite deposits are scattered around the world, presenting a wide range of mining, transport, and recovery problems. The nickel content of laterites varies widely: at Le Nickel in New Caledonia, for example, the ore delivered to the smelter in 1900 contained 9 percent nickel; currently it contains around 3 percent, but production from this source is increasing substantially.

Laterite deposits

The search for new ore bodies is an essential part of a mining enterprise. Though prospectors using visual surface indications found the earliest ore bodies, many sulfides, particularly in Canada, are covered with clay and give no surface clues. Geophysical methods are thus required, and magnetic and electrical methods have been employed. Nickel ore bodies may contain magnetic components that are reasonably good conductors of electricity. Much of the surface, however, is wooded, rough, or boggy, so efforts have been made to devise airborne prospecting devices. An air magnetometer developed dur-

ing World War II as an antisubmarine device was thus employed after the war by International Nickel Company. A second method, developed by the same company, is the airborne conductor sensor or electromagnetic device that detects changes in the conductivity of the earth by inductive methods. It opened a new era in prospecting, not only for the nickel–copper sulfides but also for other sulfide ores and is now used throughout the world.

Refining. The Sudbury sulfide deposits were originally identified as copper deposits, and the Canadian Copper Company was organized in 1885 to develop the mines. But the new ore, which contained 2 percent of nickel, along with copper and iron, baffled copper refiners. The owner of a copper smelter at Bayonne, New Jersey, who contracted to buy 100,000 tons of the new ore, found that it could not be handled by normal copper smelting. After extensive experimentation, it was discovered that by adding sodium sulfide and allowing the molten mixture to cool slowly, two layers, which could be broken apart, formed. The top layer contained most of the sodium sulfide and copper sulfide; the bottom was largely nickel sulfide. If the bottom was again melted with more sodium sulfide and slowly cooled, the separation was improved. After several repetitions, a nickel sulfide of good purity resulted. This could be roasted to remove the sulfur, then reduced to yield nickel of adequate purity for use. The process, known as "Orford tops and bottoms," was used until 1948, when it was supplanted by a scheme first proposed in 1932, when it was determined that the low-temperature mutual solubility of copper sulfide (Cu_2S) and nickel sub-sulfide (Ni_3S_2), which constituted the mixture of sulfides (the matte), was very small and could be selectively floated as mechanical mixtures of the two sulfides. Though first efforts in selectively floating solidified matte containing these two components were not successful, good separation was achieved after much finer grinding of the solidified matte was employed.

In the present practice, the ore is crushed and ground with water to liberate the sulfides from the less dense gangue (the waste part of the ore). Density differences as well as magnetic properties are utilized in this step. The sulfide minerals can then be separated from the other minerals by selective flotation, in which chosen minerals attach themselves to air bubbles and form a froth. This process has been refined to achieve good separation of the copper-containing chalcopyrite from the nickel-containing fractions. The nickel-containing fraction of pyrrhotite-pentlandide from the flotation process, plus material recovered by magnetic concentration, is roasted to remove a portion of the sulfur, and the material is then smelted to remove much of the iron and silica. The resulting matte consisting of nickel, copper, and iron sulfides is further oxidized in a Bessemer converter to yield essential copper and nickel sulfides. These are separated by slowly cooling the matte, grinding it, and selectively floating it to yield essentially nickel sulfide and copper sulfide. In subsequent operations, the two sulfides are reduced to metal and converted into anodes for electrolytic refining to yield high-purity nickel and copper. Special methods have been devised to recover nickel from pyrrhotite and to produce a marketable iron ore.

Selective flotation

At another Canadian mine, impure nickel sulfide is cast into anodes that are heat-treated to render them less brittle and are then decomposed electrolytically in a sulfate solution, a process that yields nickel cathodes of good purity. The sulfur, precious metals, and copper are also recovered.

A unique method for recovering high-purity nickel from matte is employed at a nickel plant at Clydach, Wales, where the impure sulfide is roasted to remove all of the sulfur and then processed to form finely divided metal, which is treated with carbon monoxide gas at about 55° C that reacts to produce volatile nickel carbonyl, $Ni(CO)_4$. This in turn is decomposed at about 230° C to yield pure nickel in the form of small pellets.

Another version of the carbonyl nickel process is used at Clydach to produce very fine nickel powder for many powder-metallurgy applications. In this process, the reduced nickel reacts with carbon monoxide at about 120° C at a pressure of 300 pounds per square inch. The resulting $Ni(CO)_4$ is condensed, fractionated to remove iron carbonyl, and decomposed at high temperature to yield high-purity nickel powder of sizes and shapes required for various end uses, including the nickel–cadmium storage battery.

Refining laterite ores is difficult because of the impossibility of concentrating the nickel fraction by gravity or flotation. In processing laterites by pyrometallurgy, all the diluent material must be removed by means of a flux, a process requiring large amounts of fuel or electrical energy. In some cases, sulfur is added in the form of gypsum to produce a matte that can be further processed in the manner employed for sulfide ores. The copper content usually is low, however, so processing is somewhat simpler. When sulfur is not added, the nickel plus considerable iron may be reduced with carbon or silicon to yield a ferronickel alloy.

An alternative to pyrometallurgy is chemical extraction of the nickel. With one type of laterite, the extraction of nickel, plus some iron and cobalt, can be accomplished by treatment with a sulfuric solution under high temperature and pressure. Alternatively, extraction can be effected by treatment with an aqueous solution containing ammonia or ammonia plus carbon dioxide.

Chemical extraction

It is difficult to generalize about the worldwide methods used to refine nickel since the methods depend upon the ore, the cost of electric power, and the market for the various end products that are possible. In the U.S.S.R., most of the production comes from the north, Norilsk in western Siberia and the Pechenga area of the Kola Peninsula. The ores involved are the copper-nickel-iron-sulfide type similar to those of Canada. The methods employed for processing them are similar to those used in Canada, including selective flotation of the matte. The remainder of Russian production comes from the southern Urals. The various oxide ores of this area are smelted with gypsum to provide enough sulfur to produce a matte, the same method long used at New Caledonia.

Production. Tables 1 and 2 give the world production of nickel and the distribution of uses in the U.S.

Characteristics and uses of nickel and its alloys. Pure nickel possesses a useful combination of properties including corrosion resistance, good strength, and high ductility, even at extremely low temperatures. It also possesses useful electronic properties and special magnetic properties. Nickel is a particularly good catalyst for reactions involving hydrogen, and substantial quantities of it are used in hydrogenating natural oils. Nickel catalyzes the addition of hydrogen to unsaturated compounds in vegetable, animal, and fish oils, converting them from liquids to solids. Natural oils treated in this way are used in such products as shortening, oleomargarine, and soap.

Table 2: Distribution of Nickel Use in U.S. (1969)

use	percent of total production
Stainless steel	30.0
High nickel alloys	21.6
Alloy steels	10.7
Ferrous castings	11.0
Iron–nickel alloys	2.0
Nonferrous alloys	6.5
Plating and chemicals	17.4
Coinage and powder	0.8

The white colour of nickel is attractive, and most of its alloys with copper are substantially white. Its ability to form strong, ductile alloys with many metals, including iron, chromium, cobalt, copper, and gold, is utilized in industry.

Nickel is resistant to corrosion by fluorine, alkalies, and a variety of organic materials. It remains bright on indoor exposure but tarnishes outdoors, although its corrosion rate is very low. Its low corrosion rate, coupled with its resistance to corrosion by sodium chloride and other chlorides used on roads during the winter, makes it essential as an undercoat on chromium-plated automotive trim (see ELECTROPLATING). About one-half of the nickel used

for electroplating in the United States is used in this way. Nickel containing some phosphorus can be deposited by chemical reduction; this "electroless nickel" is finding new uses.

Heavy nickel plating is employed as a lining for tank cars and as a coating for the inner walls of large pipes and similar equipment in the chemical industry.

Nickel is essential as the base for oxide-coated cathodes used in all television tubes and all but the largest radio power tubes. Alloyed with about 2 percent tungsten plus a trace of magnesium, nickel is used as the cathode base in amplifiers for submarine cables that are expected to function for 20 years without attention.

Nickel also is an essential component of white-gold alloys widely used for jewelry. These alloys also contain nickel, copper, and zinc, all of high purity.

Monel

The addition of copper to nickel provides a series of useful alloys. Monel metal, 67 percent nickel and the balance essentially copper, is stronger than nickel and has broad corrosion-resisting applications. Extremely resistant to rapidly flowing seawater, it has many marine uses. The addition of a small percentage of aluminum and titanium renders it precipitation hardenable; this high-strength version is widely used for propeller shafts. Increasing copper to 55 percent produces an electrical resistance alloy known as Constantan, which is used as a thermocouple in conjunction with pure copper.

The 30 percent and 10 percent nickel–copper alloys, usually containing 0.5 percent and 1.5 percent iron, are widely used in the form of tubes for heat interchangers and condensers. Their resistance to seawater corrosion makes them important in desalination plants. Copper-base alloys containing a small percentage of nickel become precipitation hardenable if 5–8 percent of tin or a smaller amount of silicon or phosphorus is added. These have special uses.

The ancient Chinese alloy *pai-t'ung*, now known as nickel-silver, contains 10–30 percent nickel with the balance copper plus zinc. This alloy continues as a favoured base for silver-plated ware. It is also used as a spring material for relays and has numerous other applications.

An alloy of 25 percent nickel and 75 percent copper is essentially white in colour and was adopted for coinage by Belgium in 1860 and by the U.S. five years later. More recently it has been employed in the U.S. as the outer layer of copper-centred 10- and 25-cent coins. Pure nickel was adopted by the Swiss for coinage in 1881; this use has spread to many other countries.

The fact that nickel changes in length as it is magnetized makes it useful as an ultrasonic transducer in various underwater defense devices. Alloying nickel with about 21 percent of iron has a spectacular effect in producing alloys with extraordinarily high magnetic permeability in weak fields. This type of alloy, known as Permalloy, discovered at Bell Telephone Laboratories in 1916, has had a great value in long-distance telephone transmission, including undersea cables. Other alloys of about 45–50 percent nickel, and the balance iron, have been developed for magnetic uses at higher field strengths.

Invar, an alloy containing 36 percent nickel, with the balance iron, is notable for its extremely small thermal expansion. Discovered in 1898, it has, along with later developed nickel alloys, many applications ranging from thermostats to balance wheels for watches, metal-to-glass seals essential to electric lights, and radio tubes.

A remarkable group of nickel-containing permanent-magnet alloys was developed, beginning in Japan in the early 1930s. An early example contained 25 percent nickel, 12 percent aluminum, and the balance iron. More powerful versions, such as Alnico V (containing 8 percent aluminum, 14 percent nickel, 24 percent cobalt, 3 percent copper, balance iron), developed in The Netherlands, were heat-treated in a magnetic field. These materials had a profound effect on the design of many electrical devices, including magnetic separators, dc motors, and automobile generators.

The first major market for nickel was in the production of nickel and nickel–chromium steels for armour plate, an application based on the work of James Riley of Glasgow in 1889 and tests by the U.S. Navy in 1891 on armour plate from a French steel producer. Military demands supported the industry for many years, but with the development of steam-turbine power plants, the automobile, agricultural machines, and aircraft, a whole new group of high-strength steels containing from 0.5 to about 5 percent nickel along with chromium, molybdenum, etc., were developed. More recently, with a demand for steels for ultra-low-temperature use with liquefied gases, steel of 9 percent nickel and alloys of higher nickel content have come into demand. These steels rely on carbon for hardening by heat treatment. The nickel toughens the steel and slows the hardening process so that larger sections can be heat-treated. A carbon-free iron alloy known as maraging steel has been developed. It contains 18 percent nickel, plus cobalt, titanium, and molybdenum. This alloy can be heat-treated to provide a tensile strength of some 300,000 pounds per square inch, coupled with an elongation of 5 percent to 10 percent.

High-strength steels

Nickel is resistant to oxidation at high temperatures and to electrical erosion. For these reasons, alloys that are high in nickel, such as the 4 percent manganese alloy, are used for spark plug electrodes in automobiles and for other types of ignitors. The addition of 15–20 percent of chromium to nickel vastly improves oxidation resistance so that such alloys are used for electric resistance heaters. Alloys containing 15–20 percent chromium, plus various amounts of iron, and an alloy containing 35 percent chromium, 20 percent nickel, with the balance iron, find extensive industrial use where high strength and corrosion resistance over a wide range of temperatures are essential. The addition of small amounts of aluminum and titanium permits the alloy that is high in nickel and chromium to be further strengthened by precipitation treatment. Alloys of this general type made the jet-aircraft engine possible. Gas turbines require the same alloys and are growing in importance for industrial power uses.

A large group of alloy steels ranging from 18 percent chromium, 8 percent nickel, and 25 percent chromium, 20 percent nickel, to 20 percent chromium, 35–40 percent nickel are employed where corrosion resistance is a major requirement. The stainless steels, of which the 18 percent chromium–8 percent nickel variety is the best known, are widely used where stain and corrosion resistance must be coupled with high strength. The largest single use of nickel is in the production of stainless steel.

Important compounds. Nickel sulfate hexahydrate, $NiSO_4 \cdot 6H_2O$, is employed in the electrolytic refining of nickel as well as in most nickel electroplating baths. Nickel chloride hexahydrate, $NiCl_2 \cdot 6H_2O$, is often used in conjunction with the sulfate in plating baths; while the nickel sulfamate, $Ni(SO_3NH_2) \cdot 4H_2O$, and the nickel fluoborate, $Ni(BF_4)_2$, are employed in some of the newer types of electroplating baths.

Nickel dimethylglyoxime is an insoluble salt useful in analytical chemistry in precipitating nickel. Nickel carbonyl, $Ni(CO)_4$, a liquid at room temperature, is employed in a carbonyl nickel refining process. Like all other carbonyls, it is poisonous. Nickel sub-sulfide, Ni_3S_2, is the nickel component of matte involved in pyrometallurgy. Nickel oxide, NiO, is involved in refining processes and also may be an end product.

Pentlandite, $(Ni,Fe)_9S_8$, is the most important sulfide mineral; but pyrrhotite (FeS to Fe_7S_8) with some nickel replacing iron also is important in nickel and iron-recovery processes. Millerite, NiS, is a rare mineral. In the laterites, garnierite, $(NiMg)_6Si_4O_{10}(OH)_8$, is the richest in nickel; but nickeliferous limonite, $(Fe,Ni)O(OH) \cdot nH_2O$, constitutes a major portion of the laterites.

BIBLIOGRAPHY. The development of the world nickel industry is described by J.F. THOMPSON and N. BEASLEY in *For the Years to Come* (1960). A summary of present world sources and a description of the processes employed for recovery may be found in J.R. BOLDT, JR., and P. QUENEAU, *The Winning of Nickel* (1967). See also E.J. PRYOR, *Mineral Processing* (1965), for an excellent discussion. The properties of nickel and many of its alloys are discussed in the *Metals Handbook*, 8th ed., vol. 1 (1961); and in *Monograph 106* of the NATIONAL BUREAU OF STANDARDS (1968). The corrosion resistance of nickel and its alloys is summarized by H.H. UHLIG,

Corrosion Handbook (1948). The development of nickel steels from the earliest time to the present is covered by R.B.G. YEO and O.O. MILLER in *The Sorby Centennial Symposium on the History of Metallurgy* (1965). Nickel plating was an early use of nickel that has grown substantially over the years. Much practical information on this aspect may be found in a publication of the INTERNATIONAL NICKEL CO., *Nickel Plating Processes and Properties* (1967). A summary of the use of nickel in various industrial fields is given in *Applications of Nickel*, MAB 248, Metallurgical Advisory Board, National Academy of Sciences (1968). World production statistics plus other information on developments may be found in the *Annual Reports of the U.S. Bureau of Mines.*

(E.M.W.)

Niebuhr, Reinhold

Reinhold Niebuhr was one of the most influential American theologians of the 20th century. His special contribution was his stress on the issues on the borderline between theology and social ethics. His criticism of the prevailing theological liberalism of the 1920s significantly changed the intellectual climate within the Protestant churches in the United States, and his enormous influence on political thought, both inside and outside the church, caused Hans J. Morgenthau, an eminent political scientist, to say that Niebuhr was "the greatest living political philosopher of America." He was probably the most popular preacher in university chapels from the early 1920s to the early 1950s. Many sophisticated Christians today trace their conviction that Christianity makes sense to the influence of his preaching. He was not a specialized scholar in the technical sense in any field, including theology, but his broad learning and his original and incisive thought made him the subject of many theses and other scholarly writings, and he exercised a seminal influence on scholarship and thought in a variety of fields.

By courtesy of the Rare Book Department, Union Theological Seminary Library, New York

Niebuhr, 1963.

Niebuhr was born in Wright City, Missouri, on June 21, 1892. He was the son of Gustav and Lydia Niebuhr, who had emigrated to the United States at an early age from Germany. Gustav Niebuhr was a minister of the Evangelical Synod of North America, a denomination with a Lutheran and Reformed German background that merged into the Evangelical and Reformed Church in 1934 and is now a part of the United Church of Christ. At an early age Reinhold Niebuhr decided to emulate his father and become a minister. He graduated from his denomination's Elmhurst College, Illinois (1910), and Eden Theological Seminary, St. Louis, Missouri (1913), and completed his theological education at Yale, receiving a bachelor of divinity degree (1914) and a master of arts (1915). He was ordained to the ministry of the Evangelical Synod in 1915.

Niebuhr served as pastor of Bethel Evangelical Church in Detroit from 1915 to 1928. This experience—and especially his exposure to American industrialism, specifically, the automobile industry, before labour was protected by unions and by social legislation—caused him to become a radical critic of capitalism and an advocate of Socialism. His *Leaves from the Notebook of a Tamed Cynic* (1929), an account of his years in Detroit, reveals his spirit and bent of mind, which continued to characterize him throughout his life. He never lost the pastoral concern for individuals that is so well expressed in this book. Though he was formidable as a polemicist in his writings and in his public life, his personal relations were warm and friendly. This was especially true of his relations with his students. Even people who were targets of his polemics on issues of theology or of ultimate philosophical outlook were often his coworkers in many a social or political issue.

Years as a pastor

He left the pastoral ministry in 1928 to teach at Union Theological Seminary in New York City, where he was a great intellectual and personal force until his retirement in 1960. As a theologian he is best known for his "Christian Realism," which emphasized the persistent roots of evil in human life. In his *Moral Man and Immoral Society* (1932) he stressed the egoism, the pride and hypocrisy of nations and classes. Later he saw these as ultimately the fruit of the insecurity and anxious overdefensiveness of man in his finiteness; here he located "original sin." He emphasized the tendency for sin—in the form of destructive pride—to appear on every level of human achievement, especially where claims to perfection were made, either in religious or political terms. His powerful polemics against liberal beliefs in assured progress and radical utopian hopes have caused a neglect of his more hopeful teaching concerning the image of God in all men that is never completely destroyed by sin and concerning "common grace" that is not dependent on recognized Christian redemption in personal or collective life. Also, he was himself a hopeful political activist and emphasized the good that could be achieved if pretentions were overcome. His outlook is well expressed in his statement that "the saints are tempted to continue to see that grace may abound, while sinners toil and sweat to make human relations a little more tolerable and slightly more just." He always had faith in what he called "indeterminate possibilities" for humanity in history as long as men did not deceive themselves into thinking that absolute solutions of historical problems were in their control. Though he did much to encourage the revival of the theology of the Reformation, with its emphasis on sin and grace—so-called Neo-orthodoxy—his salient theological work, *The Nature and Destiny of Man*, was planned by him as a synthesis both of the insights of the Reformation and of the Renaissance, with its hopefulness about cultural achievements.

His distance from the strongly Christocentric forms of Protestant Neo-orthodoxy can be seen in his unusual attitude toward the Jewish community. He was perhaps the first Christian theologian with ecumenical influence who developed a view of the relations between Christianity and Judaism that made it inappropriate for Christians to seek to convert Jews to their faith.

Political activities

His early political activities were influenced by his Socialist convictions (he was a founder of the Fellowship of Socialist Christians) and he ran for office several times on the Socialist ticket. In the 1930s he broke with the Socialist Party over its pacifist or noninterventionist attitude in foreign policy, and in the 1940s he became a left-wing, anti-Communist Democrat. He was a founder and for a time chairman of the Americans for Democratic Action and he was vice chairman of the Liberal Party in the state of New York. In the 1930s he was much influenced by Marxist theory, but he rejected Marxist absolutism and both the tactics of Communists in the United States and Stalinism in the Soviet Union.

He did much to persuade Christians influenced by pacifism to support the war against Hitler. He himself had been a pacifist as a result of his revulsion against World War I, but during the 1930s he became the strongest theological opponent of any form of pacifism that claimed to have universally applicable nonviolent solu-

tions of political problems. Identifying himself with the resistance to Hitler within Germany, he opposed a vindictive peace. After World War II, he had considerable influence with the policy planners in the State Department. He was a strong supporter of the Cold War resistance to Russian political expansion in Europe. His political activity ended during the early stage of the Cold War, but his later thought showed his capacity to transcend the outlook of that period. His book *The Irony of American History* (1952), while justifying American anti-Communist policies, gave much attention to criticism of American messianism and the American tendency to engage in self-righteous crusades. He always attacked American claims to special virtue. Early he favoured the recognition by the United States of mainland China, and he was an early opponent of the Vietnam War. He regarded as an error attempts to impose U.S. solutions on the new countries that emerged after World War II.

Niebuhr was an editor of *The World Tomorrow*, a religious pacifist and Socialist journal; *Christianity and Crisis*, a biweekly with wide-ranging social and religious concerns; and a quarterly, now discontinued, first named *Radical Religion* and later *Christianity and Society*.

He married Ursula M. Keppel-Compton in 1931. His wife was herself a teacher of religion at Barnard College in New York City, and they worked closely together.

After 1952 his public activities were seriously limited as the result of a stroke, but he was able to continue much of his teaching and writing. He died on June 1, 1971, at Stockbridge, Massachusetts.

BIBLIOGRAPHY. CHARLES W. KEGLEY and ROBERT W. BRETALL (eds.), *Reinhold Niebuhr: His Religious, Social, and Political Thought* (1956), includes an intellectual autobiography, interpretive essays with Niebuhr's response, and a comprehensive bibliography. More recent is RONALD H. and JOANN M. STONE (comps.), "Writings of Reinhold Niebuhr, 1953–1971," *Union Seminary Quarterly Review*, 27:9–29 (1971). JUNE BINGHAM, *Courage to Change: An Introduction to the Life and Thought of Reinhold Niebuhr* (1961), is an Impressionistic biography based on careful research. GORDON HARLAND, *The Thought of Reinhold Niebuhr* (1960), is one of the best overall expositions with theological emphasis.

Writings of Niebuhr (in addition to works mentioned above) include: *Faith and History: A Comparison of Christian and Modern Views of History* (1949), theological orientation; *The Self and the Dramas of History* (1955), probably his profoundest philosophical work; and *The Structure of Nations and Empires* (1959), his chief systematic discussion of international relations. Four volumes of essays, some of which are essential for understanding Niebuhr's thought and his influence on events, are *Christianity and Power Politics* (1940); *Christian Realism and Political Problems* (1953); *Pious and Secular America* (1958); and *Faith and Politics: A Commentary on Religious, Social, and Political Thought in a Technological Age*, ed. by RONALD H. STONE (1968). *Love and Justice*, ed. by D.B. ROBERTSON (1957), is a collection of shorter writings showing Niebuhr's response to events; *Children of Light and Children of Darkness: A Vindication of Democracy and a Critique of Its Traditional Defence* (1944), a brief but comprehensive discussion of social ethics.

(J.C.Be.)

Niedersachsen

Niedersachsen, or Lower Saxony, is one of the more important of the *Länder*, or states, of the Federal Republic of Germany. The second largest in size, with an area of 18,304 square miles (47,408 square kilometres), it occupies an important band of territory across the northern part of the nation, stretching from The Netherlands border and the coast of the North Sea to the frontier, with the German Democratic Republic in the east. The neck of land occupied by Schleswig-Holstein, Hamburg, and, farther north, Denmark borders it on the north, while its neighbours to the south are the *Länder* of Nordrhein-Westfalen, containing the industrial zone of the Ruhr, and Hessen. By the early 1970s, its population exceeded 7,000,000, making the *Land*, with about 12 percent of the total population of West Germany, fourth in rank. There was, by contrast, a low population density of some 386 persons per square mile, due mainly to the low level of industrial development. At the end of the 1960s, the gross national product per capita was below the average for West Germany. This economic retardation was to be the key to Niedersachsen's situation in the 1970s.

The landscape. With the exception of a small highland area to the south, the landscapes of the state are dominated by the great north German plain. In the northwest, the Ostfriesische Inseln—12 islands in the North Sea—and about 325 square miles of coastal land are actually below sea level, protected from inundation by dikes similar to those in the nearby Netherlands. The highland area, which lies south of the important Mittelland Kanal (Midland Canal) running across the state, contains the Weser, Deister, and the rugged Harz Mountains. More than half of Niedersachsen is drained by the Weser and its tributaries, the Fulda and the Werra, although the major settlement of Bremerhaven (at the mouth of the Weser) and Bremen itself (40 miles up the river) form a separate political entity, the Freie Hansestadt Bremen, smallest of the West German *Länder*. The territory also contains two large lakes: Steinhuder Meer (12 square miles) and Dümmer (6 square miles). At the mouths of the rivers flowing into the North Sea fertile marshes are found, mostly supporting a pasture economy. In the northeastern region there is a less fertile area of land partly covered with forests. This contains Lüneburger Heide (heath), noted for its old-fashioned red farmhouses and the ancient megalithic structures known as "graves of giants." It is now a celebrated nature preserve.

Regional divisions

The troughlike valleys of the forested southern uplands provide good-quality land, as do their foothills farther north. The latter form part of the treeless belt of rich, often windblown, soils known as the Börde, which runs in a narrow east–west zone across the state. In addition to supporting an arable farming population this area, situated on the boundary between plain and upland, became a historical nucleus for the growth of a string of small towns. Niedersachsen's climate offers mild winters, moderately warm summers, and a steady year-round rainfall ranging from 24 to 35 inches (600 to 900 millimetres).

Niedersachsen was established on November 1, 1946, by the British military government, which merged the former Prussian province of Hanover with the states of Braunschweig, Oldenburg, and Schaumburg-Lippe. A quarter of a century later, nearly one-fifth of its population was living in large cities (defined as those with more than 100,000 inhabitants), more than a quarter in places with 10,000 to 100,000 inhabitants, and more than half in communes of fewer than 10,000 inhabitants.

Ethnic origins

The people. The population of Niedersachsen regards itself as lower German, linked by a common ancient Saxon origin and use of the lower German language known as Plattdeutsch. The latter, a dialect closely related to Dutch, Frisian, and English, is quite distinct from the official High German. Some regional literature is still produced in this form, and it remains the language of the home in much of the state. This feeling of cultural unity helps to bind together such diverse areas as the parts of ancient Hanover east of the Weser, the younger regions of Braunschweig, Emsland, Osnabrück, and South Oldenburg (which were formerly under Westphalian influence), and the Frisian portions of northern Oldenburg and Ostfriesland. The northern European character of social life is further illustrated by the adherence of about 77 percent of the population to Protestantism and 19 percent to Roman Catholicism.

In 1939 the population of Niedersachsen as presently defined amounted to 4,500,000. By 1946 the influx of refugees from other areas of war-torn Europe had caused an increase to 6,200,000, and this in spite of war losses. By 1950 the population had reached 6,744,000. During the 1950s over 340,000 refugees were transferred to other states of the Federal Republic of Germany that were able to offer better living conditions. By the middle of 1968 the population passed the 7,000,000 mark. This growth was mainly caused by natural increase and, to a certain degree, by immigration. By the early 1970s, the average birthrate was about 18 per 1,000, the average death rate 12 per 1,000, the rate of increase about 6 per 1,000. Niedersachsen entered the 1970s with seven cities of over 100,000

population: Hannover, 518,000; Braunschweig, 225,000; Osnabrück, 141,000; Oldenburg, 131,000; Salzgitter, 118,000; Göttingen, 114,000; and Wilhelmshaven, 103,000.

The economy. Agriculture, the traditional mainstay of the local economy, is still important. By the 1970s about 61.5 percent of the area of the state was used for agriculture (grain land, 24.1 percent; other arable land, 8.2 percent; permanent grassland, 27.1 percent; other agriculturally utilized land, 2.1 percent). Some 20 percent of the land was covered by forests, 2.5 percent consisted of uncultivated moors, almost 4 percent was wasteland, 2 percent water surface, and about 10 percent used for roads and buildings. Industrial turnover in 1968 exceeded 46,000,000,000 Deutsche Marks ($11,500,000,000).

Industrial Employment in Niedersachsen
(1968)

industry	percent of total workers
Vehicles	15.9
Machines	11.0
Electrical goods	9.5
Investment goods (other than those mentioned above)	9.3
Raw materials, industrial intermediates*	20.5
Consumer goods†	20.7
Food, beverages, tobacco	9.5
Mining‡	3.6
Total	100.0

*Chemicals, rubber and asbestos manufactures, steel. †Textiles, clothing, furniture, etc. ‡Iron ore (4,200,000 tons), potash (1,100,000 tons), petroleum (6,400,000 tons), natural gas, and peat.

Hannover Industrial Fair

Once a year Hannover, the state capital, becomes the meeting point of the industrial world, when the German Industries Fair, the largest of its kind all over the world, is held there. In the 1970s it was attracting more than 600,000 visitors a year from over 100 countries and 5,500 exhibitors, among whom were 1,100 from 33 foreign countries, including eastern Europe and the German Democratic Republic.

Transportation. Niedersachsen is well provided with transport facilities. By 1970, 1,750,000 road vehicles in the state could travel on a network made up of autobahns, federal highways, state highways, and numerous district and commune roads. In addition, the railway network transported over 3,000,000 tons of goods annually. The state's importance in the regional economy of West Germany was enhanced by such inland waterways as the Mittelland Kanal, the Dortmund–Ems Kanal, and a host of others, facilitated by the flat landscapes. In addition, the major rivers, notably the Weser and the Elbe, were navigable for considerable distances.

More than 40,000,000 tons of goods pass through the ports of Wilhelmshaven, Emden, Nordenham, and Brake each year, an indication of Niedersachsen's importance in regional and world trade.

The state's main airport of Hannover-Langenhagen handles some 2,000,000 passengers annually, together with 15,750 tons of freight and mail. The scenic beauties of Lüneburger Heide and the southern uplands, and also the seaside resorts of the northwest, attract a considerable tourist traffic, amounting by the 1970s to almost 20,000,000 overnight stays, all but 5 percent of which were by German citizens. The nearly 6,000 hotels included 7.6 percent in large towns, 32.5 percent in watering places and climatic health resorts, and 33.2 percent in seaside resorts. The latter proved attractive to inhabitants of the great industrial regions bordering the state to the south.

Administration and social conditions. The governmental structure is comprised of a prime minister, state chancellory, and eight ministries. Regional governmental divisions include the six *Regierungsbezirke* (Hannover, Hildesheim, Lüneburg, Stade, Osnabrück, and Aurich) and two *Verwaltungsbezirke* (Oldenburg and Braunschweig). According to an administrative and regional reform initiated in 1965, it was anticipated that the 4,000 or so small communes would shrink to about a quarter of that number of larger, more functional units. Niedersachsen entered the 1970s with its two main political parties evenly balanced: results of Landtag elections held in June 1970 showed the Social Democrats (left-wing) had 46.2 percent of the vote, the Christian Democrats (centre right) 45.7 percent, and the Free Democrats (partner of the Social Democrats in the federal government) and the National Democrats each with less than the 5 percent necessary to enter the state parliament. Justice is administered by means of a constitutional court, three courts of appeal, 11 regional courts, and 132 local courts. The armed forces in this strategically important state, together with British, Dutch, and Belgian forces, participate in national defense through the framework of NATO. By the 1970s, there were some 700,000 pupils at primary schools, 100,000 pupils at middle schools (*Mittelschulen*), and 120,000 pupils at secondary schools, with a further 25,000 pupils being educated in special schools.

Educational facilities

University education was offered by the University of Göttingen, with an enrollment of 10,000 students; the seven institutes of the Max-Planck-Gesellschaft (Society for the Advancement of Science); the technical universities of Hannover and Braunschweig (5,000 enrollment each); and a number of smaller institutes. The forested landscapes of the state have given rise to no fewer than 12 research institutes for forestry attached to the University of Göttingen. The second oldest German Academy of Science (founded in 1751) is located in Göttingen, where it flourishes with 22 separate committees.

Cultural life and institutions. In common with other West German *Länder* and indeed with many other parts of Europe, Niedersachsen has a thriving and well-subsidized cultural life. There are state theatres at Hannover, Oldenburg, and Braunschweig. Hannover, the cultural as well as the state capital, can boast of three other theatres, among them the Landesbühne, which gives performances in more than 40 towns in the region. Other notable theatres are, in Wilhelmshaven, the Landesbühne Niedersachsen-Nord; in Göttingen, the Deutsches Theater; in Hildesheim, the Stadttheater; and in Celle, the Schlosstheater, whose plays are performed in a fine baroque building dating from 1674. In addition, nearly 500 cinemas (with 16,000,000 patrons annually) cater to a more popular audience. The *Hannoversche Allgemeine Zeitung* and *Hannoversche Presse* are the leading state newspapers, each with a circulation of more than 150,000. Hannover is also the centre of the agricultural and forestry press. A famous cultural periodical, the *Westermanns Monatshefte*, is edited from Braunschweig. Radio and television are broadcast by Norddeutscher Rundfunk (NDR), based in Hamburg but with studios at Hannover and Oldenburg. There are many facilities for sports, both indoor and outdoor, and there are nearly 1,000,000 members of sports clubs—one in seven of the entire population.

Problems and prospects. In the years to come the industrial basis of Niedersachsen will be considerably expanded, bringing a fresh flow of capital investment and, it is hoped, a more diversified and prosperous regional economy. Plans were underway in the early 1970s for an aluminum plant at Stade and another chemical complex at Wilhelmshaven. Nuclear power plants were planned or under construction at nearby Würgassen (upper Weser), at Stade (lower Elbe), and at Esenshamm (lower Weser), and the once backward state appeared in the forefront of a national economic development.

BIBLIOGRAPHY. For current information on this subject, see *Statistisches Jahrbuch für Niedersachsen*, a statistical handbook published annually.

(W.G./G.Dn.)

Nietzsche, Friedrich

Friedrich Nietzsche, a 19th-century German philosopher, was one of the most influential thinkers of modern times. He was an impassioned critic of the culture and ethos of his time, and particularly of Christianity, conformism, nationalism, and resentment. Almost all 20th-century German philosophers, as well as the greatest German poets, novelists, and psychologists, are profoundly in-

debted to him. In other countries, too, and most especially in France, he ranks among the most influential philosophers since Kant and Hegel.

Louis Held—Deutsche Fotothek, Dresden.

Nietzsche, 1888.

Early life and studies. Nietzsche was born October 15, 1844, at Röcken, in the Prussian province of Saxony, the son and grandson of Lutheran ministers. His father christened him Friedrich Wilhelm, after the reigning king of Prussia. (Nietzsche later dropped the Wilhelm.) The King became mad a few years later, as did Nietzsche's father; and in January 1889 Nietzsche himself became insane. The father's illness was diagnosed as "softening of the brain," and after his death in 1849 his skull was opened and the diagnosis confirmed. But there is some question about the meaning of softening of the brain; most experts agree that the philosopher's eventual insanity was not inherited.

In January 1850 Nietzsche's mother moved her family to Naumburg (on the Saale). The household there included Nietzsche's younger sister Elizabeth, his maternal grandmother, and two maiden aunts. This may help to account for some of Nietzsche's snide remarks about women. In 1858 Nietzsche was admitted to one of the most distinguished boarding schools in Germany, Pforta, near Naumburg. He was frequently at the head of his class, received a superb classical education, and graduated in the year 1864.

Student of classical philology

He went to the University of Bonn to study theology and classical philology but gave up theology the following year and followed Friedrich Ritschl, a professor of classics, to Leipzig. Ritschl, founder of a famous school of classical scholarship, who had never before included the work of a graduate student in his scholarly journal, published some of Nietzsche's papers there. One paper won a prize, but Nietzsche wrote his friend Erwin Rohde, later an eminent classicist too, that he himself found the paper "repulsive." By now he was more interested in philology than in philology.

He may have contracted syphilis while he was a student, which might account for his later madness. It seems certain that during his adult life he was, sexually, an ascetic. The most that has been claimed is that as a student he may have visited a brothel twice. In October 1867 he commenced his military service, but in March he hurt himself seriously when his chest hit the pommel of the saddle as he jumped on his horse. He rode on as if nothing had happened but then was hospitalized and suffered for a long time.

Back at Leipzig, he wrote Rohde on November 20, 1868, about his disgust with philology—"the whole molish business, the full cheek pouches and blind eyes, the delight at having caught a worm, and indifference toward the true and urgent problems of life." He still published some reviews of scholarly books, but at one point thought of writing his dissertation on Immanual Kant's philosophy; and early in 1869 he considered switching to chemistry, "throwing philology where it belongs, with the household rubbish of our ancient ancestors."

At that point the University of Basel (Switzerland) was looking for a professor of classical philology. Nietzsche had not yet written his doctor's thesis, much less the additional dissertation that a German Ph.D. must have accepted before lecturing at a university (after which he generally writes a book before obtaining a professorship). But Ritschl wrote Basel that in almost 40 years of teaching he had never seen a student like Nietzsche. When Nietzsche was offered the chair, Ritschl assured Basel that, although most of Nietzsche's work had been in Greek literature and philosophy, "with his high gifts he will work in other fields with great success. He will simply be able to do anything he wants to do." Without any dissertation or examination, he got his doctorate, and in April 1869 he went to Basel and became a Swiss subject.

When the Franco-Prussian War broke out in 1870, Nietzsche obtained a leave to serve as a medical orderly with the Prussian army. After a month, he returned to Germany with dysentery and diphtheria. Although his health was shattered, he returned to Basel in October to resume a very heavy teaching load. Whenever possible, he visited Richard Wagner, the great operatic composer, in Tribschen, near Lucerne, Switzerland. Wagner was then in voluntary exile from Germany, where his work was not yet widely accepted; he shared Nietzsche's admiration for the philosophy of Schopenhauer, and he appreciated Nietzsche as a professorial apostle of his music. For Nietzsche this was his first encounter with a major artist; and he could do, if only briefly, with a father figure (Wagner was the same age as his father). The basic conflict between the two was to emerge later.

First works. His first book, *Die Geburt der Tragödie* (1872; *The Birth of Tragedy*, 1968), eschewed all the customary trappings of the classical scholar. He dispensed with footnotes and Greek quotations and made no show whatever of his learning. Nietzsche acknowledged the Greeks' genius of measure, restraint, and harmony, which he called "the Apollinian"; but he argued that one must not ignore "the Dionysian"—the irrational passions that had to be harnessed to make possible Greek literature and art. His thesis was that tragedy was born out of the fusion of the two, and was killed by rationalism. He proposed his own ideas about the birth and death of Greek tragedy in a mere 85 pages and ended with a considerable addition on the "rebirth of tragedy" from the spirit of Wagner's music. A young philologist, Ulrich von Wilamowitz-Möllendorff, who was later to become a distinguished classicist, seized this opportunity to demonstrate his erudition by publishing a pamphlet in which he tried to demolish the book and the reputation of its author. It occasioned a heated controversy with Nietzsche's friend Rohde. By 1912 F.M. Cornford, a leading British classicist, was to call *The Birth of Tragedy* "a work of profound imaginative insight, which left the scholarship of a generation toiling in the rear." Until World War II, it was Nietzsche's ideas about the birth of tragedy that were most influential; since then his ideas about the death of tragedy have been widely echoed. Despite trenchant criticisms of the work's thesis by present-day scholars, however, Nietzsche's first book retains considerable importance. It brought to an end the era in which Greek culture could be summed up as "sweetness and light."

Thesis of *The Birth of Tragedy*

In his later work Nietzsche extols Dionysus, by then not in contrast with Apollo but as standing for the synthesis of the Apollinian and the Dionysian, the sublimation of passion, and the creative affirmation of this world and this life. In the later writings, Dionysus is opposed to Christ, to otherworldliness, and to the extirpation (not sublimation) of the passions.

In *The Birth of Tragedy* Nietzsche emancipated himself from Arthur Schopenhauer's "Buddhistic negation of the will," as he called it. He had admired Schopenhauer, an influential 19th-century German philosopher, for his frank recognition of the suffering in this world, but in Greek tragedy Nietzsche found that it was possible to face up to

the horrors of existence and to affirm life, nevertheless, as beautiful in spite of everything. He argued that tragedy had died of the spirit of rationalism and optimism that was embodied in Socrates, but near the end of the book he envisaged the possibility of "an artistic Socrates": a philosopher with a passion for poetry and music as well as an intellectual conscience. This was clearly his conception of his own mission, and it remains a splendid image of his spirit. Nietzsche followed up his first book with four *Unzeitgemässe Betrachtungen* (1873–76; *Thoughts Out of Season*, 1909) published one at a time. They are fine essays, but Nietzsche's fame rests squarely on his later works. In 1878 he published the first of five collections of aphorisms. He called it *Menschliches, Allzumenschliches* (1878; *Human All-too-Human*, 2 vol., 1909–11) and dedicated it to the memory of Voltaire on the 100th anniversary of his death. Nietzsche's emerging break with Wagner was sealed shortly thereafter when Wagner received this deeply antiromantic book of aphorisms. In August Wagner attacked Nietzsche in the *Bayreuther Blätter*. The breach had been inevitable. As long as Wagner was a lonely genius in exile, his hatred of the French and the Jews did not matter that much to Nietzsche, who admired these peoples; but by 1878 Wagner had moved to Bayreuth, made his peace with the new German empire, and become a major influence. That Nietzsche also considered Wagner's *Parsifal*, of which he received an inscribed copy, an insincere obeisance to Christianity was a relatively minor matter.

The break with Wagner

The great creative decade (1879–89). In 1879 Nietzsche resigned from the university, pleading his poor health, and was granted a modest pension. His doctors advised him to do as little reading and writing as possible to save his poor eyes. But during the next ten years he devoted himself entirely to his writing, living very frugally and driving himself relentlessly. He published a book every year, and each of them represented a triumph over his half-blind eyes, terrible migraine headaches, and manifold physical agonies. His major works were written in utter solitude in Sils Maria (Switzerland), in Nice and Mentone on the Riviera, and in Rome and Turin in Italy. Until 1888 they received virtually no attention either in the press or from scholars. Without any response, Nietzsche kept writing.

Of his former colleagues at Basel, only Franz Overbeck, a church historian but an unbeliever, remained utterly loyal to him until the end. An unsuccessful young composer, Heinrich Köselitz—Nietzsche called him Peter Gast—worshipped Nietzsche and helped him occasionally with proofreading and other chores. Nietzsche's relationship with two other friends was much more troubled. He first met Paul Rée in 1873. Two years later Rée received his doctorate in philosophy and published *Psychologische Beobachtungen* ("Psychological Observations"), a work that Nietzsche liked. They exchanged letters, and a genuine friendship developed. Rée had a light touch and worked on some of the same problems that concerned Nietzsche. He inscribed a copy of his *Der Ursprung der moralischen Empfindungen* (1877; "The Origin of Moral Feelings") to Nietzsche: "To the father of this essay, most gratefully from its mother."

Friendship with Lou Andreas-Salomé

In 1882 he wrote Nietzsche about a young woman, Lou Salomé (1861–1937). Nietzsche met her, was greatly impressed, and the friendship became three-cornered. Gradually and subtly, Rée's feelings for Lou undermined his relationship to Nietzsche. But the jealousy of Nietzsche's sister, Elizabeth, was uncompromising. She led Nietzsche to believe that his friends had betrayed him, speaking evil about him behind his back; and by the end of that year Nietzsche felt lonelier and more forsaken than ever. After Rée's death (1901), Lou, by then a well-known writer, claimed that both men had proposed marriage to her and that Nietzsche asked Rée to transmit his proposal. Others embellished the story by adding that, unknown to Nietzsche, she was Rée's mistress at that time. But Rudolph Binion has argued in his biography *Frau Lou* (1968) that she remained a virgin until ten years later and that Nietzsche never proposed marriage to her, although she was apparently waiting for him to do so. After her marriage Lou became known as Lou Andreas-Salomé.

Once, Nietzsche actually had asked a woman (Mathilde Trampedach) to marry him. He did not know her well at all and evidently felt relieved when she turned him down. But the break with Lou and with Rée hurt him deeply. It was in despair and utter solitude that he began writing *Also sprach Zarathustra* (Eng. trans., *Thus Spoke Zarathustra,* 1954), a rhapsodic and aphoristic attempt to present his thought as a whole. The first three parts appeared separately (1883–84) and met with no response at all. Of the fourth part Nietzsche had only 40 copies printed privately and then distributed seven among friends. The first public edition appeared in 1892. After that, *Zarathustra* became Nietzsche's most popular book, widely read but rarely understood. It is now generally considered one of the masterpieces of world literature, daring in form and full of ideas—especially, but by no means only, about morals and psychology.

In *Jenseits von Gut und Böse* (1886; *Beyond Good and Evil*, 1968) and *Zur Genealogie der Moral* (1887; On *the Genealogy of Morals*, 1968) Nietzsche tried to explain his ideas in more explicit prose. In form and manner these books come closer to British and American philosophy than Nietzsche's other works, which are aphoristic or lyrical. But no English-speaking philosopher has ever subjected the faith and morals of Western man to such merciless questioning.

In 1888 Nietzsche published *Der Fall Wagner* (1888; *The Case of Wagner*, 1968), an often very funny book of roughly 50 pages that says some very serious things about culture and decadence. That year Georg Brandes, a Danish Jew who was a literary critic and scholar, began to lecture on Nietzsche at the University of Copenhagen; this was the first significant public notice of Nietzsche's works and thought. Nietzsche completed four more books in 1888. In *Götzen-Dämmerung* (1889; *Twilight of the Idols*, 1954) he tried to summarize his philosophy in a mere 100 pages. In *Der Antichrist* (1895; *The Antichrist*, 1954) he presented a single-minded attack on Christianity. In *Ecce Homo* (1908; Eng. trans. 1968) he reflected on his own significance and, one by one, on his books. In *Nietzsche contra Wagner* (1895; Eng. trans. 1954), finally, he brought together passages on Wagner from his earlier works, making a few slight stylistic changes. This little book is perhaps his most beautifully written work.

Period of collapse. Early in January 1889, Nietzsche collapsed in the street in Turin. Carried back to his room, he sent out some mad but meaningful letters and post cards. Overbeck came to take him back to Basel. He spent the last 11½ years of his life first in an asylum, then in his mother's care in Naumburg, and finally in Weimar, where his sister took him after his mother's death (1897). He died in Weimar on August 25, 1900.

During this last period he wrote nothing and was incapable of conversation. Informed opinion favours the diagnosis of an atypical general paralysis, which would indicate tertiary syphilis. If so, the disease was dormant in him during his creative years. But his works cannot be written off as the products of a madman, as some opponents of his thought claim. The insanity that comes of syphilis hardly ever lasts 11 years or more. The breakdown in January 1889 is very clear. The books—all written before the collapse—must be judged and can afford to be judged on their merits.

Nietzsche's sister's distortion of his thought

His sister had married a prominent German anti-Semite, Bernhard Förster, in 1885, and they were in Paraguay when Nietzsche collapsed. Before her marriage she had been very attached to her brother without understanding his philosophy; and she found little to admire in it after his break with Wagner. In 1889 she was absorbed in her husband's attempt to found a Teutonic colony in South America. But the settlers felt swindled by the Försters; her husband committed suicide; and her attempts to make a national hero of him came to nothing. Meanwhile, Nietzsche's fame was spreading. Then his sister transferred all her energies to his cause and changed her name to Förster-Nietzsche. The irony of her new name was

lost on her: Nietzsche had loathed the anti-Semitic nationalism of her husband; but, as the chief apostle of her brother's philosophy, she always remained Förster first and misrepresented Nietzsche. She even stooped to forgery and published as addressed to her some drafts of letters to others. She also published a selection of some of his most interesting notes as if it were his systematic main work: *Der Wille zur Macht* (1901; *The Will to Power*, 1967). These notes merit serious study, but it is important to distinguish them from the books that Nietzsche himself polished for publication. As he remarked repeatedly about himself, few writers require to be read with so much regard for context.

Evaluations. At one time Nietzsche was widely associated by interpreters of his thought with Darwin and evolution, then with the Nazis, and more recently with the Protestant theologians who liked to cite his dictum that "God is dead." Still others see him as an Existentialist. All such perspectives are partial and misleading. It is no less legitimate to stress his relationship to Sigmund Freud and psychoanalysis or to such writers as Thomas Mann, Hermann Hesse, Rainer Maria Rilke, and André Gide.

As a writer of German prose, he remains unexcelled. His poetry has also had considerable influence. Freud paid lavish tribute to his psychology and often remarked that Nietzsche had a more thorough self-knowledge than any other man had had or ever would have. But his greatest importance was as a philosopher. In 1950 Gottfried Benn, a leading German poet, said:

> Virtually everything my generation discussed, tried to think through—one might say, suffered; one might also say, spun out—had long been expressed and exhausted by Nietzsche, who had found definitive formulations; the rest was exegesis.

MAJOR WORKS

PHILOSOPHY: *Die Geburt der Tragödie* (1872; *The Birth of Tragedy* in *Basic Writings of Nietzsche*, 1968); *Unzeitgemässe Betrachtungen*, 4 vol. (1873–76; *Thoughts Out of Season*, 2 vol., 1909) comprising: *David Strauss der Bekenner und der Schriftsteller*, *Vom Nutzen und Nachtheil der Historie für das Leben*, *Schopenhauer als Erzieher*, and *Richard Wagner in Bayreuth*; *Menschliches, Allzumenschliches* (1878; *Human All-too-Human*, 1909–11); *Vermischte Meinungen und Sprüche* (1879); *Der Wanderer und sein Schatten* (1880: the last two included in later editions of *Menschliches, Allzumenschliches* as part 2); *Morgenröte* (1881; *The Dawn of Day*, 1911); *Die fröhliche Wissenschaft* (1882); new ed. augmented by book 5 and *Lieder des Prinzen Vogelfrei* (1887; *The Joyful Wisdom*, 1910; *The Gay Science*, 1974); *Also sprach Zarathustra* pt. 1–3 (1883–84) and pt. 4 (1891; *Thus Spoke Zarathustra* in *The Portable Nietzsche*, ed. by Walter Kaufmann, 1954); *Jenseits von Gut und Böse* (1886; *Beyond Good and Evil* in *Basic Writings of Nietzsche*); *Zur Genealogie der Moral* (1887; *On the Genealogy of Morals* in *Basic Writings of Nietzsche*); *Der Fall Wagner* (1888; *The Case of Wagner* in *Basic Writings of Nietzsche*); *Götzen-Dämmerung* (1889; *Twilight of the Idols* in *The Portable Nietzsche*); *Der Antichrist* (1895; *The Antichrist* in *The Portable Nietzsche*); *Nietzsche contra Wagner* (1895; Eng. trans. in *The Portable Nietzsche*); *Der Wille zur Macht*, selections from Nietzsche's notebooks (1901; rev. and enlarged ed., 1910–11; *The Will to Power*, 1967); *Ecce Homo* (1908; Eng. trans. in *Basic Writings of Nietzsche*, trans. and ed. by Walter Kaufmann, 1968).

VERSE AND MUSIC: Nietzsche's poems—first collected in *Gedichte und Sprüche* (1898)—are included in the first two collected editions, listed below. Not so his musical compositions, which are of minor interest: *Hymnus an das Leben* (for chorus and orchestra, text by Lou Andreas-Salomé, 1887) and 16 songs with piano accompaniment, collected in the incomplete edition of his *Musikalische Werke*, vol. 1 (1924).

COLLECTED EDITIONS OF THE WRITINGS: Of the various collected editions the most satisfactory is the *Musarion-Ausgabe*, 23 vol. including 2½ vol. of indexes (1920–29). *Kröners Taschenausgabe*, 12 vol. (including index volume) that can be bought separately, is the handiest edition, but contains fewer notes and fragments. *Werke in drei Bänden*, 3 vol. (1954–56) contains fewer poems, far fewer notes and fragments, but a selection of letters. Vol. 4 contains an index. *Kritische Gesamtausgabe* of works (projected: about 30 volumes) and letters (projected: about 15 volumes), ed. by Giorgio Colli and Mazzino Montinari, began to appear in 1967. There are also various collections of Nietzsche's letters, notably including *Gesammelte Briefe*, 5 vol. (1900–09), supplemented by *Nietzsches Briefwechsel mit Franz Overbeck* (1916). The English collected edition by Oscar Levy, 18 vol. including index (1909–13), comprises unreliable translations by various hands. Translations of the major works are provided by Walter Kaufmann (ed.), *The Portable Nietzsche* (1954) and *The Basic Writings of Nietzsche* (1968).

BIBLIOGRAPHY. The *International Nietzsche Bibliography*, ed. by HERBERT W. REICHERT and KARL SCHLECTA, 2nd enlarged ed. (1968), lists over 4,500 studies in 27 languages. Some studies by otherwise reputable scholars are unreliable and have been refuted on crucial points; *e.g.*, CRANE BRINTON, *Nietzsche* (1941); and ARTHUR C. DANTO, *Nietzsche As Philosopher* (1965). GEORGE A. MORGAN, JR., *What Nietzsche Means* (1941), is scholarly but ignores Nietzsche's development. R.J. HOLLINGDALE, *Nietzsche: The Man and His Philosophy* (1965), is an intellectual biography (partially dated by more recent scholarship), but the author is not a philosopher. The two leading German Existential philosophers have written a great deal about Nietzsche: KARL JASPERS, *Nietzsche* (1936; Eng. trans., 1965) and *Nietzsche und das Christentum* (1938; Eng. trans., *Nietzsche and Christianity*, 1961); MARTIN HEIDEGGER, *Nietzsche*, 2 vol. (1961), in German. The present article is based on WALTER KAUFMANN, *Nietzsche: Philosopher, Psychologist, Antichrist*, 3rd rev. and enlarged ed. (1968), which contains a 26-page bibliography. Kaufmann's *From Shakespeare to Existentialism*, rev. ed. (1960), contains five chapters on Nietzsche, and his translations of eleven of Nietzsche's works feature commentaries.

(W.Ka.)

Niger

The Republic of the Niger, a landlocked West African country, takes its name from the river Niger, which flows through the southwest part of its territory. The name Niger derives in turn from the phrase *gher n-gheren*, meaning "river among rivers," in the Tamashek language. The republic has an area of 458,075 square miles (1,186,408 square kilometres) and a population of more than 4,200,000. It is bounded on the northwest by Algeria, on the northeast by Libya, on the east by Chad, on the south by Nigeria and Dahomey, and on the west by Upper Volta and Mali. The capital is Niamey, on the Niger River.

Physically the tenth largest country in Africa, Niger is only sparsely populated. The Sahara covers the northern part of its territory. Peanuts (groundnuts) and cattle are its principal products. The majority of its peoples are Muslim. Though the country obtained its independence on August 3, 1960, after 50 years of French rule, economically, it still relies heavily on France, and French is its official language. Hamani Diori has been president of the republic since independence.

The lack of transport has always constituted an obstacle to Niger's economic development. The recent discovery of large deposits of uranium at Arlit (Arhli) near Agadez, which are to be mined by a Franco-Niger company, has, however, opened new prospects of economic development. This circumstance offers new hope to a country that had previously been among the most remote and underdeveloped of African nations. (For coverage of related physical features, see CHAD, LAKE; NIGER RIVER; and SAHARA. For coverage of historical aspects, see WEST AFRICA, HISTORY OF.)

The landscape. *Relief.* Niger extends for about 750 miles from north to south, and about 930 miles from east to west. It tends to monotony in its features, is intersected by numerous depressions, and is dominated by arid highlands in the north. Rainfall increases as one proceeds southward so that the country divides naturally into three distinct zones—a desert zone in the north; an intermediate zone, where nomadic pastoralists raise cattle in the centre; and a cultivated zone in the south, where the greater part of the population, both nomadic and settled, is concentrated.

Three geographic zones

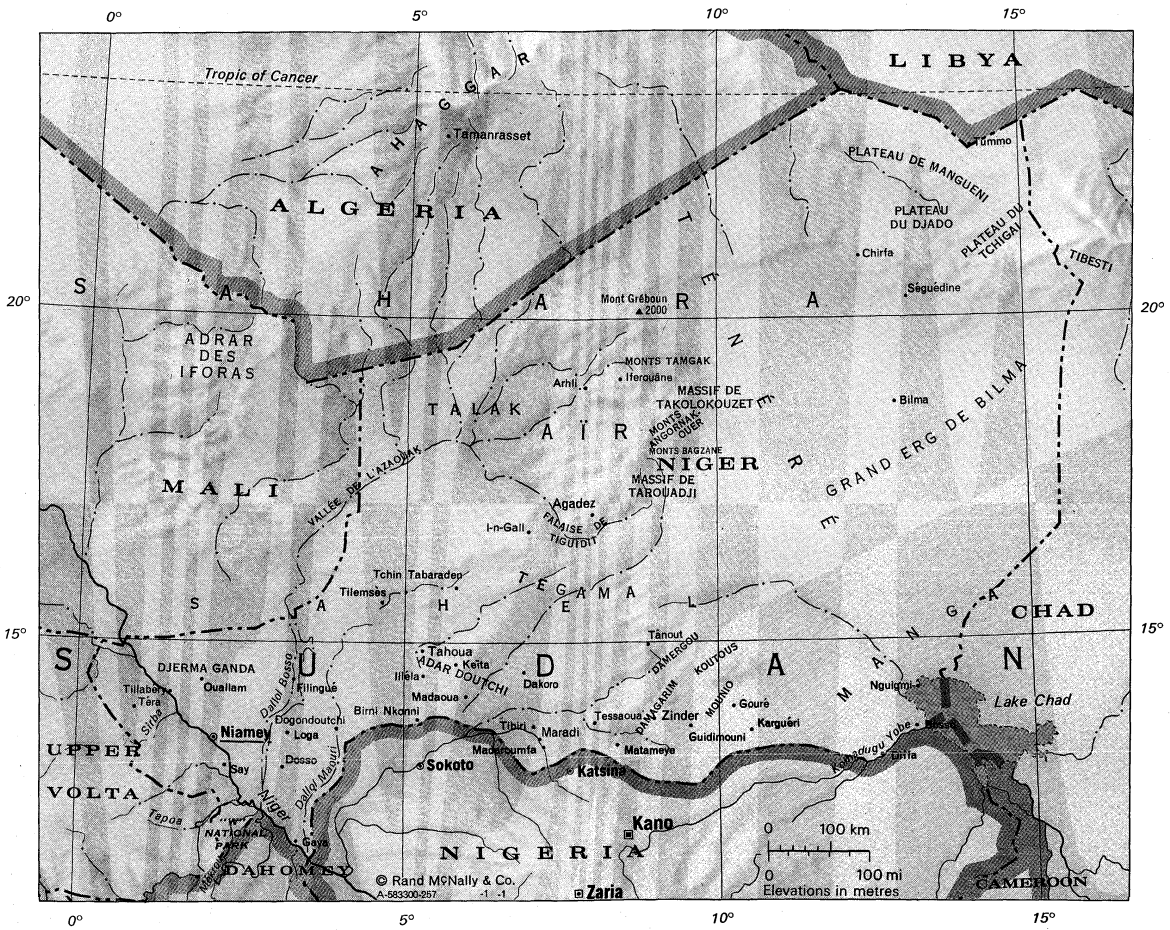
The highlands of the north are cut by valleys (*kori*) of the Massif de l'Aïr, which are an extension of the Ahaggar (Hoggar) Mountains of Algeria, and consist of a range running north to south in the centre of Niger, with individual mountain masses forming separate "islands": from north to south these are firstly Tazerzaït, where the highest point in the country is Mont Gréboun, which

reaches an altitude of 6,562 feet; Tamgak; Takolokouzet; Angornakouer; Bagzane; and Tarouadji. To the northeast are a series of high plateaus, which form a bridge between the Ahaggar Mountains of Algeria and the Tibesti mountains of Chad. From west to east, these are the plateaus of Djado, Mangueni, and Tchigaï.

The sandy regions of the Nigerian Sahara extend to either side of the Massif de l'Aïr. To the west, the Talak region includes the Tamesna area in the north (where fossil valleys are filled with moving sand dunes) and the Azaoua area in the south. East of the Massif de l'Aïr is the Ténéré region, covered partly by an expanse of sand called an erg, partly by stony plain called a reg.

The plateaus of the south, which form a belt about 900 miles long, may be divided into three regions. To the west is the Djerma Ganda region. Its large valleys are filled with sand, while *dallol* (fossilized valleys of rivers that formed tributaries of the Niger in ancient times) descend from the Massif de l'Aïr and the Adrar des Iforas massif (mountainous mass) of neighbouring Mali. The central region consists of the rocky Adar Doutchi and Majia areas; it is the region of the *gulbi* (dried-up valleys of former tributaries of the Sokoto River) and the Tegama —a tableland of sandstone, ending, towards the Massif de l'Aïr, at the Tiguidit scarp. To the east the underlying rock reappears in the Damagarim, Mounio, and Koutous regions, to the north of which is the region of Damergou, consisting of clays. In the Manga region, in the east, traces of ancient watercourses appear on the sandy plain.

Hydrography and soils. It is convenient to make a distinction between the ancient hydrographic system, which allowed agriculturalists, fishermen, and pastoralists to live in the Aïr region about 5,000 or 6,000 years ago, and the present simple system, which forms the basis



NIGER

MAP INDEX

of the marked difference between the northern and southern parts of the country. The present system includes to the west the Niger River Basin, and to the east the basin of Lake Chad; between the two occur vestiges of the older system, such as the *dallol* and the *gulbi*.

To the west, the Niger River crosses about 370 miles of Niger's territory. Because of the change in river flow, which occurs because of the dispersal of its waters in its interior "delta" region in Mali, it is only in January and February that it flows past Niamey in flood. At other times the river is fed by certain temporary watercourses that flow in from the right bank. These are the Gorouol, the Dargol, the Sirba, the Goroubi, the Djamangou, the Tapoa, and the Mékrou; the last two flow through the "W" National Park (so called because the Niger flows through the area in the form of a W). On the left bank, proceeding eastward, appear the *dallol*, the vestiges of the older watercourses. Generally running from north to south, they constitute zones of dampness, although a few still contain waters that flow towards the Niger. The best known are the Dallol Bosso, the Dallol Foga, and the Dallol Maouri. Other vestiges consist of the *kori*, which runs down from the Massif de l'Aïr and from former tributaries that had their sources in the massif of the Adrar des Iforas, and which flowed to a confluence at what is now the wadi (channel of a watercourse that is dry except during periods of rainfall) of Ti-m-merhsoï. No waters flow through the *kori* now, but water is still to be found beneath their sands. Other remnants of the old system are formed by the *gulbi*, through which water still flows annually, occasionally causing damage.

Ancient watercourses

To the east is situated the basin of Lake Chad, a large, shallow lake, which at its highest level has an area of approximately 9,650 square miles; of this, Niger possesses about 1,100 square miles. Its extent is considerably reduced during the dry season. The Komadougou Yobé River, which flows into Lake Chad from the west, forms part of the frontier between Niger and Nigeria. Its water level, which begins to rise in August, from January to May consists only of some stagnant pools.

In addition to the drainage system described, it may be noted that rainwater collects in several basins, so that some permanent lakes or pools also exist; these are found at Keïta and Adouna in the Adar Doutchi region, at Madaroumfa in the Maradi *gulbi*, and at Guidimouni to the east of Zinder. The water table underground can be tapped by means of artesian wells.

The soils fall into three natural regions. In the Saharan region in the north, which extends over an area of about 308,000 square miles, the soil remains infertile, except in a few oases where water is found. In the region known as the Sahel, which forms a transitional zone between the Sahara and the cultivated region to the south, the soils are thin and white, being covered with salty deposits that form an infertile crust. The third region (in the south) is cultivated. In this area the soils are associated with extensive dunes or uplands or with basins or depressions. Some of the soils in the latter, such as those in the Niger Basin and in the *gulbi* are rich. Black soils occur in the Kolo Basin. Throughout the region, however, and above all on the plateaus, layers of laterite (leached iron-bearing soil) occur.

Climate. Niger extends southward from the Tropic of Cancer, so that the greatest part of its territory lies in the dry tropical zone. In the southern part of the territory the climate is usually of the type known as Sahelian, which is characterized by a single rainy season. In January and February the continental equivalent of the northeast trade winds blow, dry and fresh, from the Sahara toward the Equator, meeting the harmattan, a dry wind which blows from east to west between the Tropic of Cancer and the Equator, hindering normal living conditions on the southern fringe of the desert. From April to May the southern trade winds blowing from the Atlantic reach the Equator and are diverted toward the Sahara where they meet with the harmattan—an encounter that results in tornadoes. A long dry season occurs between October and June, while the winter rains occur between June and October. The winter season begins with the June tornadoes, and lasts from between one to four months, according to the latitude; August is everywhere the rainy month.

Temperature and rainfall

Niger lies in one of the hottest regions of the world. Temperatures rise to the maximum from February to May, and drop during the winter rainy season, rising again somewhat before reaching the annual minimum in January or February. Annual minimum temperatures vary between 29° F (−2° C) at Bilma and 61° F (16° C) at Tillabéry. Tillabéry, which is on the Niger River, is also the hottest place, recording an annual average maximum of 106° F (41° C). The daily range is greater in the north than in the south, and is also more extreme during the dry season. The severity of the temperature increases from south to north: at Niamey the absolute extremes of temperature are 47° F (8° C) and 114° F (46° C); in the Massif de l'Aïr temperatures of −23° F (−31° C) have been recorded, while the absolute maximums are in the region of 122° F (50° C) in the shade.

Rainfall varies according to location as well as season. In general, it diminishes from south to north; the limit of assured annual rainfall is reached to the north of Agadez, where, furthermore, temperatures are excessive. The ten-inch isohyet (line on a map connecting points having equal rainfall) follows a line from Tahoua to Gouré, in effect marking the northern limit of nomadic pastoral life, for the rainfall permits a sparse vegetation to grow. To the south the 30-inch isohyet marks the southern limit of this zone, after which the southern agricultural zone begins. The extreme southwest receives the most abundant rainfall; the Gaya region is the first and the last to receive rainfall each year. Seasonal variations in rainfall are striking. In the course of the same winter rainy season a most irregular pattern of rainfall may occur, while from one year to another the amount of rainfall may double; in addition, the rainy season itself may arrive early or late, thus jeopardizing the crops.

Vegetation and animal life. The vegetation of the desert zone clusters around the oases; it includes the date palm and corn; its animal life, which must be able to endure hunger and thirst, includes the dromedary.

In the Sahel zone, where the doum palm and the cram cram (a prickly grass) appear, the vegetation has a short life cycle, and is principally used for grazing. Animal life includes the ostrich and the gazelle.

In the cultivated zone the vegetation includes acacia trees, doum palms, and rônier palms, as well as baobabs. Wild life, which has partially disappeared, includes antelope, elephants, and warthogs; giraffe are found in the Zarmaganda and Damergou regions, and hippopotamuses and crocodiles on the banks of the Niger. The extreme southwest is a savanna (grassy parkland) region where baobabs, kapok trees, and tamarind trees occur. Animal life is preserved in the "W" National Park, where antelope, lions, buffalo, hippopotamuses, and elephants may be seen.

Traditional regions. The southern part of Niger's territory is situated in the vast region of Africa known as the Sudan, in which, in former times, large political states arose, such as Ghana, Mali, and Songhai, as well as the Hausa states, the empire of Sokoto, and Bornu. The northern part of Niger remains the domain of the Tuareg. As a result of this geographic and historical heritage, Niger contains a multitude of traditional regions the names of which remain despite the establishment of contemporary administrative divisions.

Tuareg predominate in northern Niger's Aïr (Azbine) and Azaouak regions and have also constituted two further regions further to the south known as Imanan and Tagazart. In the northeast is the Tibesti region, which is the land of the nomadic Teda (or Toubou).

People of the south

In the south, from east to west, three groups of peoples are found. The first consists of the Kanuri, who occupy the Manga region, as well as parts of the regions known as the Damergou and the Damagarim, which are traditionally associated with Bornu in Nigeria. The second group is formed by the Hausa who occupy the traditional regions of Daura, Katsina, Gober Toudou, Adar Doutchi, Aréoua, and Kourfey. The third group consists of the

Zerma (Djerma) and Songhai peoples of southwestern Niger. The Zerma occupy the Zidji (or Zarmatarey), Boboye, Zarmaganda, and Fakara regions, while the Songhay are to be found in the Anzourou region to the north, and the Dendi region to the south, as well as on the right bank of the Niger. The Fulani, or Peul, people are found scattered in all these regions, and are found in compact groups only in the Boboye and Manga areas.

All these regions have a fluctuating political, economic, and geographic significance: the Hausa regions, for example, have been cut in two and divided between Niger and Nigeria. Most regions, moreover, have been and remain zones where contact takes place between different peoples—between the Hausa and the Tuareg in the Adar Doutchi region, for example; between the Tuareg and the Kanuri in the Damergou region; and between Hausa and Zerma in the Aréoua area.

The landscape under human settlement. Only about 8 percent of the population are town dwellers. The rural population is divided into nomads and sedentary peoples. There are about 8,000 villages, out of which 5,000 have fewer than 200 inhabitants; there are practically no villages in the desert zone. The Fulani herdsmen, who breed horned cattle and oxen, and the Tuareg, who raise goats, sheep, and dromedaries, tend to travel over the northern region during the winter. They meet together for the salt cure (*i.e.*, to permit the cattle to lick the salty soil of the area) in the In Gall region during August and September but move southward during the dry season. Both Fulani and Tuareg live in tribal groups and gain their subsistence from their livestock. The Fulani subsist above all on milk in various forms; while travelling they live in shelters that are often of a temporary nature. The Tuareg live on meat and dates and shelter themselves in tents.

The Fulani and the Tuareg

Sedentary peoples, such as the Hausa, the Songhai-Zerma, and the Kanuri, who inhabit the Niger and Chad Basins, live largely by agriculture. They raise millet, rice, corn, peanuts, and cotton. They also work as blacksmiths and shoemakers, while on the banks of Lake Chad and of the Niger the Buduma and Sokoro (Sorko) peoples are fishermen. Sedentary peoples live in dwellings that vary from those made of straw to those made of banco (hardened mud), although the Woko (Wogo) people live in tents of delicate matting.

There is a tendency among the nomads to settle down and the already sedentary peoples are expanding the lands under cultivation toward the north. Rural life, above all in its sedentary form, tends to slow its pace during the long dry season; it is at this time of year that migration to the towns or other countries occurs.

It was approximately in the 15th century that a few towns, such as Agadez or Zinder, were first established as halting places, or depots, on the trans-Saharan caravan routes. As commercial routes gradually developed on the coasts, however, these northern towns lost their former economic importance, while other centres, such as Birni Nkonni, and Tessaoua, declined in the course of the 19th century as a result of the colonial era.

At the present time there are four principal towns in Niger. Niamey, the political capital, has experienced rapid growth. A town of about 100,000 people, it has a cosmopolitan character; its transient population may rise to as many as 10,000. Its characteristic life varies between the European and African rural styles, including various intermediate steps, of which the style of life of the *évolués* (educated Africans) is the most distinctive. Zinder, for which the African name is Damagaram, is an older town than Niamey; a Hausa town, it was the capital of Niger until 1926 and has a number of skilled craftsmen, especially leatherworkers and dyers. The town is experiencing some industrial growth and has close links with Nigeria. Its population amounts to about 40,000 people. Maradi has a population of about 35,000 and has developed rapidly. The town is situated in the heart of the peanut-growing region near the Nigerian frontier. Many European companies have established branches there; the town is particularly renowned for its red goats, the skins of which are exported to Europe and the Americas. Tahoua has grown up on the edge of the desert. There, with its 31,000 inhabitants, it forms a large livestock market, where nomad pastoralists and sedentary farmers meet. But all of the towns remain little more than modest administrative and commercial centres. Because of the discovery of uranium ore it is expected that Agadez will experience a spectacular growth. Maradi, Zinder, and Tahoua all have buildings in the striking Sudanese architectural style.

Population centres

People and population. *Linguistic groups.* The largest linguistic group is formed by the Hausa, whose language, also spoken in Nigeria, is one of the most important in West Africa; 85 percent of the inhabitants of Niger understand Hausa, which possesses an abundant literature that has been printed in Latin characters in neighbouring Nigeria. Songhai is the second most important language; also called Songhoi, it is also spoken in Mali, in northern Upper Volta, and in northern Dahomey. In Niger itself it is divided into various dialects, such as Songhai proper, Zerma, and Dendi. The language of the Fulani is Fulfulde; in Niger it has two dialects, eastern and western, the demarcation line between them running through the Boboye district. Tamashek is the language of the Tuareg, who often call themselves the Kel Tamagheq, or Tamashek-speakers. The language is also spoken in Algeria and Mali and possesses its own writing, called *tifinagh*, which is in widespread use. Kanuri is spoken not only in Niger but also in Cameroon and Nigeria; the tongue is called *beriberi* by the Hausa. While these five languages are the principal ones spoken in Niger, there is also an important Teda, or Toubou, linguistic group in the Tibesti region. In addition, many of the peoples of Niger speak Arabic, and a still larger number read and write in that language; Agadez possesses one of the oldest Arabic schools in Africa. The use of the Arabic alphabet resulted in Fulfulde and Hausa becoming written languages; the resulting script is called *ajami*; a search for more old manuscripts in *ajami* is currently being conducted.

By using Hausa and Songhai, one may make oneself understood from one end of the country to the other. French, however, remains the official language, as well as the language of instruction, although it remains understood only by a small minority. English is taught as the principal foreign language in secondary schools.

Ethnic groups. Ethnic groups correspond to the five linguistic groups already mentioned. The Hausa are the most important, constituting more than half of the present population of Niger, even though the majority of the Hausa people live in Nigeria. The Hausas occupy the centre of southern Niger as far as Dogondoutchi. The Songhai-Zerma are found in the southwest; the Songhai proper live along the Niger, where they are assimilating the Kurtey and Woko peoples. The majority of the Songhai people as a whole, however, live in Mali. The Zerma live on the left bank of the Niger, remaining in close contact with the Maouri and Aréoua peoples. The Fulani, who are dispersed throughout the country, are 80 percent nomadic; they are also found dispersed throughout West Africa. The Tuareg, also nomadic, are divided into three subgroups—the Aulliminden of the Azaouak region in the west, the Asben (Kel Aïr) in the Aïr region, and the Itesan (Kel Geres) to the south and east of Aïr. The Tuareg people are also found in Algeria and in Mali. The Kanuri, who live to the east of Zinder, are divided into a number of subgroups—the Manga, the Dogara (Dagara), the Mober, the Buduma, and the Kanembu; they are also found living in Chad, Cameroon, and Nigeria. Apart from the Teda (Toubou), who constitute an important minority, the remainder of the population consists of Arabs, black Africans from other countries, and Europeans, of whom the greater part are French. In statistical terms it has been estimated that the Hausa form 54 percent of the population, the Songhai-Zerma 24 percent, the Fulani 11 percent, the Beriberi-Manga 9 percent, and the Tuareg and others 1 percent each.

Religious groups. Christianity (Catholicism and Protestantism) remains above all a religion of the towns, particularly of Niamey. There are several Christian missions in the Songhai and Aréoua areas. Christianity remains primarily a European religion, although it is also

practiced by some black Africans from other countries. The traditional animist religions of the black Africans continue to manifest themselves in strength. Though the Annaawaa group of Hausa have always refused to accept Islām, as have a group of Fulani, the Wodaabe—who distinguish themselves from other Fulani for this reason—Islām remains the religion of the majority of the peoples of Niger. It is practiced by at least 90 percent of them, is increasing its number of adherents, and constitutes a unifying force within the country. The various religious groups coexist harmoniously.

Demography. In 1972 the population numbered an estimated 4,243,000 inhabitants, representing a density of about nine persons per square mile. According to estimates made in 1970, the birthrate was 5.2 percent and the death rate 2.3 percent a year, giving a rate of population increase of 2.9 percent. The Kanuri people, however, have a much reduced rate of increase apparently due to the lower fecundity of Kanuri women; in general, the nomads have a lower rate of population increase than the sedentary peoples.

Rate of population increase

Immigration is insignificant; in 1960, for example, about 20,000 black Africans, Arabs, and Europeans entered the country, the Africans coming from Dahomey, Upper Volta, Mali, and Nigeria. Emigration or migration, on the other hand, is more important—whether to the towns of Niger itself or to other countries. In 1960, out of an estimated 130,000 persons who had migrated, 80,000 had travelled to the towns, and 50,000 abroad. An estimated 500,000 nationals of Niger are living abroad. The migrants usually leave the country after the harvest, passing the dry season in another country and returning before the opening of the rainy season. Many spend years abroad—the Songhai-Zerma people in Ghana and Togo, and the Hausa in the Cameroon, Nigeria, and Chad.

The distribution of population shows a great imbalance. Except for a few oases, the desert is virtually empty of human life. The majority of the population lives in the south, occupying about a quarter of the national territory.

Niger, Area and Population

	area		population	
	sq mi	sq km	1959-60 census	1972 estimate
Départements				
Agadez	244,869	634,209	55,000	82,000
Diffa	54,138	140,216	46,000	142,000
Dosso	11,970	31,002	332,000	560,000
Maradi	14,896	38,581	494,000	740,000
Niamey	34,862	90,293	727,000	919,000
Tahoua	41,188	106,677	608,000	871,000
Zinder	56,151	145,430	600,000	929,000
Total Niger	458,075*	1,186,408	2,864,000*	4,243,000

*Figures do not add to total because of rounding.
Source: Official government figures.

The national economy. Niger's only exports are peanuts and cattle. Previously one of the poorest of the French West African colonies, it has remained, after independence, one of the least endowed of the developing countries, with an average per capita income of about $70. Agriculture and livestock account for about 86 percent of the gross domestic product. In the production of both peanuts and livestock, Niger is third among West African countries.

Natural resources. Salt is traditionally exploited in the Kaouar and Aïr regions, as well as in the *dallol*, and in the Manga district. Annual production, which is insufficient, is estimated at 3,000 tons. Natron (hydrated sodium carbonate) is extracted locally. Cassiterite (the most important ore of tin) is mined at open workings in the Massif de l'Aïr, about 120 tons being produced in 1969. Gold is obtained by panning in the Sirba River; production amounted to about 11,000 pounds. About 30,000,000 tons of limestone and an important deposit of gypsum have been located at Malbaza and in the Ader Doutchi and Majia region. Cement production at Malbaza amounted to about 22,000 tons in 1967. The exploitation of uranium ore was due to begin in the Aïr region in 1971; known reserves in the Arlit region, amounting to about 20,000 tons, rank among the most important in the world. Annual production is expected to amount to 1,500 tons in 1973. Apart from tungsten, of which a little has been worked in the Aïr region, traces of copper, lignite (a brownish-black coal), molybdenum (a silver-white metal used as an alloy with iron in making high-speed cutting tools), zinc, oil, phosphates, and titanium (a metallic element used in making steel) have been found and are the subject of further prospection. In addition, a reserve of 250,000,000 tons of iron ore, with an iron content of 55 percent, has been located in the Say region, but is not considered commercially exploitable at this time.

Uranium ore

The exploitation of plant resources has long been practiced but on a small scale. The doum palm and the palmyra (rônier) palm provide wood for construction, while the 120,000 date palms of the Manga oasis produce 3,500 tons of dates a year. Small amounts of kapok (a silky down from the kapok tree, used for insulation, in making life jackets, and so forth) and of gum from the acacia gum tree are exported. Skins of ostriches, crocodiles, and snakes are used for making handicrafts that are exported to Europe. Fish from the Niger River and Lake Chad are exported southward to the coastal countries.

Energy. Hydrocarbon fuels, brought up from the port of Cotonou in Dahomey, first by rail and then by truck, constitute virtually the only source of industrial power; they are used either directly, or to drive diesel engines to generate electricity. In 1969 electricity production amounted to 30,000,000 kilowatt-hours; total installed capacity in 1970 amounted to 12,600 kilowatts. The Office of Solar Energy has been pursuing research, and has already produced solar batteries, which are used by the educational television program. Peanut shells have been experimentally used to supplement hydrocarbon fuels since 1968. Wood is the traditional domestic fuel. The possibility of establishing hydroelectric projects on the Mékrou and Niger rivers is being studied. It is anticipated that the production of uranium at Arlit may eventually result in a new source of energy for Niger.

Manufacturing. Some manufacturing industries have been established, mostly at Niamey. They produce chemicals, food products, textiles, transport equipment, and metal furniture. There are many small craft industries in the principal towns.

Management of the economy. The economic system is based upon planning but accords an important role to private enterprise. The three main policy objectives are the maintenance of national unity, the elevation of the living standards of the population, and the attainment of economic independence. The current four-year plan, establishing economic priorities, covers the period from 1970 to 1973. The private sector of the economy consists partly of a multitude of small enterprises, and partly of enterprises belonging to large French or international companies, such as the banks of Paris and Unilever Ltd. The government, through the agency of the Banque de Développement de la République du Niger, which is funded partly by aid from abroad, has promoted the establishment of about 30 companies, including real estate, road transport, air transport, and agricultural processing enterprises. In 1969, 16 companies were financed partly by the government and partly by private enterprise. There is a Chamber of Commerce, Agriculture, and Industry that promotes both private and public enterprise.

The private sector of the economy

Trade unions. In 1970 Niger had fewer than 15,000 wage earners, all of whom were members of the Union Nationale des Travailleurs du Niger, the only national trade union; its members are engaged in such activities as agriculture, education, and health services.

Economic perspectives. The economy has suffered from the fall in the prices of agricultural commodities, which, in addition to the drought that occurred in 1968, caused substantial losses. Industrialization and an increase in mining production are therefore envisaged as means of strengthening the economy. Problems associated with energy generation, communications, and of outlets to the sea will, however, have to be solved. Mean-

while, Niger is encouraging the strengthening of economic links between African countries. Apart from its membership in the Organization of African Unity, Niger is a member—together with the Ivory Coast, Dahomey, Upper Volta, and Togo—of the Conseil de l'Entente, a regional cooperative grouping, as well as of Organisation Commune Africaine, Malgache et Mauricienne, a larger grouping of French-speaking African states.

Transportation. While the economically active zone of the country consists of a belt running from east to west across the southern part of the country, the principal lines of communication run southwards towards the coast. The two ports used by Niger—Cotonou in Dahomey and Lagos in Nigeria—are each more than 600 miles away, and Niger possesses no railroad. Traditional systems of transport and communication are still largely relied upon. These include camel caravans in the northern Sahel region, canoes on Lake Chad and the Niger, and individual travel on horseback or on foot. Only a small tonnage of goods is transported. Out of about 11,000 vehicles, some 2,500 trucks maintain transport communications between Maradi and Zinder in Niger and Kano in Nigeria, and between Niamey, the capital, and Parakou in Dahomey; between them they transport virtually all imports and exports. Only a small amount of goods are transported by air.

Roads

The principal road axis enters the country from Gao in Mali, runs on the banks of the Niger as far as Niamey, and then continues eastwards to Zinder. It is currently being tarred, and is to be extended to Nguigmi on the shores of Lake Chad. From this central route roads branch off southwards. Toward the north, routes running via Tahoua and Tânout converge near Agadez, linking Niger to Algeria via Tamanrasset. The Air Niger Company is responsible for domestic air services linking the airports of Tahoua, Maradi, Zinder, Agadez, and Arlit. An International Airport at Niamey links Niger with the West African capitals of Abidjan, Libreville, and Bamako, and with Porto Novo in Dahomey, as well as with European capitals.

A bridge over the Niger near Niamey was completed in 1970. When the exploitation of uranium begins at Arlit, the development of a trans-Sahara route is to be considered, as well as the possibility of extending the railroads from Parakou in Dahomey and from Ouagadougou in Upper Volta to Niger's frontiers.

Administration and social conditions. The present administrative system combines the principles of western-style democracy with the traditional political system of the Niger region.

The structure of government. A constitution promulgated in November 1960 established a presidential type of regime, in which the president wields executive power, nominates cabinet ministers, and stands at the head of the army and of the administration. It is mandatory, however, that certain matters be considered by the cabinet. Legislative authority is exercised by the National Assembly, which is composed of 50 deputies. Judicial power is held by the Supreme Court, which also constitutes a final court of appeal. A state secretariat, a general commissariat for information, and a general commissariat for development are also attached to the presidency.

Niger is divided into seven *départements* (provinces)—Agadez, Diffa, Dosso, Maradi, Niamey, Tahoua, and Zinder—each of which is administered by a prefect assisted by a commission of specialists concerned with development. Each *département* is divided into *arrondissements* (administrative subdivisions), 33 in all, each of which is administered by a subprefect.

Political organization. According to the constitution, suffrage is "universal, equal, and direct." The president is elected for five years by direct universal suffrage; he may be re-elected. The deputies of the national assembly are elected in the same way from a national roll. Niger is one of the few African states of French expression that has not decreed the constitutionality of a single party system. Niger, nevertheless, has a single party, the Parti Progressiste Nigérien-Rassemblement Démocratique Africain. The president of the Republic, Diori Hamani, heads the secretariat-general of the party, and the president of the National Assembly, Boubou Hama, heads the Parti Progressiste Nigérien. The participation of the population in national life is maintained by rural political campaigns; radio programs on political themes are also broadcast.

Education. Out of a school-age population that in 1970 numbered about 750,000, about 90,000 children are in school; most of these are boys rather than girls. Of the total, about 84,000 are in primary school, and 6,000 in secondary school. In addition, there are facilities for teacher training. Primary and secondary schools and teacher-training colleges are the responsibility of the Ministry of National Education. Other ministries are responsible for technical education. Educational television so far reaches only an estimated 800 children. Literacy programs are conducted in the five principal African languages. In October 1971 a centre for advanced scientific studies is due to open, and will constitute the first institution for higher learning in the country. Niger devotes about 10 percent of its budget to education.

Health and welfare. Health services are organized on a mass basis and concentrate on the eradication of certain diseases in rural areas, as well as on health education. Campaigns have been successfully waged against sleeping sickness and meningitis, while vaccinations against smallpox and measles are also conducted. Other diseases, however, such as tuberculosis, malaria, and leprosy remain endemic. There are about 2,500 hospital beds available in Niger's hospitals. Anti-tuberculosis centres are established at Niamey, Zinder, and Tahoua. Lack of finances and shortage of trained personnel remain the principal obstacles to the improvement of health conditions.

Cultural life and institutions. Niger forms part of the vast Sahelian cultural region of West Africa. Although the influence of Islām is predominant, pre-Islāmic cultural traditions are also strong and omnipresent. Paradoxically, the numerous ethnic strains to be found in Niger have resulted in a strengthening of the fabric of national life. Since independence, greater interest has been shown in the country's cultural heritage, particularly with respect to traditional architecture, handicrafts, dances, and music. With the assistance of the United Nations Educational, Scientific, and Cultural Organization a regional centre for the collection of oral traditions has been established at Niamey.

An institution predominant in cultural life is the National Museum at Niamey, and a cultural celebration is National Youth Week, held annually in December. Among youth the most popular sports are football, basketball, boxing, and cycling.

The press includes official publications, such as the *Journal Officiel de la République du Niger, Le Temps du Niger* (a daily), and *Le Niger* (a weekly), and specialized publications put out by the Chamber of Commerce and the Centre Régional de Recherche et de Documentation pour la Tradition Orale. There are eight newspapers published in the national languages—five in Hausa, one in Songhai, one in Tamashek, and a bilingual publication in Hausa and Songhai. There are several radio transmitters which between them cover the entire country. Television is so far uniquely educational. Broadcasts are in French and in the five principal languages.

Prospects for the future. Niger can lay claim to a share in a proud historic heritage—that of the region known as the West African Sudan. But, because of its geographical situation, it has remained in the shadow for much of the time that has elapsed since its creation as a separate political unit—that is to say, since the beginning of the colonial era. Endowed with unfavourable natural conditions, including a severe climate and a reputed paucity of resources, Niger has suffered above all from the circumstance that distance makes it difficult of access, and from the fact that its transportation system has been insufficiently developed. It is hardly to be wondered at, therefore, that people of other continents frequently confuse it with its larger southern neighbour, Nigeria.

The need for improved communications

Several favourable factors may, nevertheless, be distinguished. It does not suffer from a demographic pressure on the land, or from a rate of population increase that

robs it of the benefits of economic progress. Exports, few as they are, are sufficiently diversified not to make the economy dependent upon, or vulnerable to, price fluctuations or market speculations. There is, moreover, reason to hope that the projected exploitation of mineral resources, particularly uranium, will substantially increase national revenues and permit the construction of roads and other facilities—social no less than logistic—that will later open the way to further economic development.

Niger may thus be said to hold a privileged place among the developing countries. Having for long had to learn to moderate its ambitions and to rely upon its own efforts, having experienced a poverty, which is not to be confused with misery, and having neither made, nor had to resist, any territorial claim, Niger has remained apart from ideological and other conflicts, and has thus found itself able to play a moderating role in international relations. For these reasons, as well as others already mentioned, the future prospects opening before Niger would appear relatively bright.

(Di.L.)

Nigeria

Nigeria—in full, Federal Republic of Nigeria—is the largest of the West African coastal states. Its population of 55,074,000 (1970) is the largest of any country in Africa. With an area of 356,699 square miles (923,773 square kilometres), it is the 13th largest state on the continent. Located approximately between 4° and 14° N, and 3° and 14° E, its territory extends about 650 miles (1,050 kilometres) from north to south, and 700 miles east to west. It is bordered on the south by the Gulf of Guinea, on the west by the Republic of Dahomey, on the north by the Republic of the Niger, and on the east by the republics of Chad and Cameroon. Part of the eastern boundary runs along the crest of the Adamawa Plateau.

Modern Nigeria dates from 1914, when the two British protectorates of Northern and Southern Nigeria were joined. The country became independent on October 1, 1960, and three years later adopted a republican constitution but elected to remain a member of the Commonwealth of Nations. Relics of British rule are still to be seen in various aspects of Nigerian life. The official language, English, is likely to remain unchanged, since there are more than 200 different languages spoken by the many national groups living in the country. Trade and cultural contacts with the more distant English-speaking countries of Ghana and Sierra Leone remain stronger than those with the adjacent French-speaking Dahomey, Niger, and Cameroon. (For associated physical features, see CHAD, LAKE; GUINEA, GULF OF; and NIGER RIVER; for details of cities, see IBADAN; LAGOS; for historical aspects, see WEST AFRICA, HISTORY OF.)

THE LANDSCAPE

Relief features. Nigeria is on the lower part of the great African continental plateau, which slopes slowly downward from south and east to north and west. Nigeria itself consists of several eroded surfaces, occurring as plateaus, at elevations of 2,000 feet (610 metres), 3,000 feet, and 4,000 feet above sea level. The coastal areas, including the Niger Delta, are covered with young soft rocks, commonly found in the Lake Chad Basin, and the western parts of the Sokoto region. Gently undulating plains, which become waterlogged during the rainy season, are found in these areas. In most parts of the Western State, and in the central part of the six northern states, the underlying rocks are old and hard, and the characteristic landforms consist of high plains with broad shallow valleys, dotted with numerous hills or inselbergs (steep-sided residual masses of rock, left after erosion).

The Udi Hills

The Udi Hills, with their scarp faces turned to the east, are perhaps the country's most prominent relief feature. Other prominent relief forms include the Jos Plateau and the Biu Plateau, both of which are dotted with many extinct volcanic cones. The craters of these volcanic hills are well preserved; several of them contain crater lakes.

Drainage. There are three major drainage areas—the Niger–Benue Basin; the Lake Chad Basin; and the coastal, or Gulf of Guinea, basin. The Niger River (*q.v.*), after which the country is named, and the Benue, its largest tributary, are the principal rivers. Both have their sources outside the country. The Niger has numerous rapids and waterfalls, but the Benue (whose valley, in its Nigerian course, is cut through young sedimentary rocks) is not interrupted by waterfalls and is navigable throughout its length whenever the water level is high enough. All the rivers draining the area north of the Niger–Benue trough rise on the Jos Plateau. These include the Sokoto, the Kaduna, and the Gongola as well as the rivers draining into Lake Chad. The coastal areas are drained by short rivers, which flow from north to south into the Gulf of Guinea.

Navigation is restricted to river stretches unhampered by rapids or falls. During the months of the dry season, the low water level renders navigation impossible, even along the Benue, which is free of rapids. At this season the smaller streams may dry up completely.

Only a small part of Lake Chad lies within Nigerian territory.

Climate. Nigeria has a tropical climate with wet and dry seasons. It is hot and wet throughout the year in the southeast but markedly dry in the southwest and further inland. The duration of the seasons depends on the relation of the area to the sea or to the Sahara. Three climatic patterns are distinguished: (1) a tropical wet climate in the southeast with uniformly high temperatures and heavy rainfall distributed throughout the year; (2) a tropical wet and dry, or savanna, climate in the north and west; and (3) the dry, or steppe, climate in the far north.

Two air masses, the equatorial maritime and the tropical continental, dominate the climate. The former is associated with the rain-bearing southwest monsoon, which blows from the ocean; the latter is associated with the harmattan, a dry and dusty wind from the Sahara. In general, the length of the rainy and dry seasons decreases from south to north. In the south, the rainy season lasts from March to November. In the far north, however, it lasts only from mid-May to September. This pattern is interrupted in the south, where rainfall reaches a peak twice a year and where there is a break in the rains in August. There are thus four seasons in the south: the long rainy season (March to early August), the short dry season (August), the short rainy season (September to early November), and the long dry season (mid-November to February).

Rainfall is heavier and more reliable in the south, particularly in the southeast, which has more than 120 inches (3,050 millimetres) a year, as compared with 70 inches in the southwest. The annual rainfall decreases as one moves farther from the coast; in the far north it is not more than 20 inches. The rainy season is preceded by intense heat, after which the drought is broken by sharp thunderstorms accompanied by lightning, during which as much as one and a half inches of rain may fall in less than an hour.

Temperature and humidity remain relatively constant throughout the year in the south. In the north, however, considerable seasonal changes occur, and the daily temperature range is wide during the dry season. On the coast, the mean monthly maximum temperatures are steady throughout the year, remaining, for example, constant at 95° F (35° C) at Lagos and at about 85° F (29° C) at Port Harcourt; the mean monthly minimum temperatures remain approximately at 70° F (21° C) for Lagos, and at 73° F (23° C) for Port Harcourt. In the northeastern city of Maiduguri, on the other hand, the mean monthly maximum temperature may exceed 100° F (38° C) during the hot months of April and May, while in the same season frosts can also occur at night.

southeast—the original forest vegetation has consequently been completely replaced by open palm bush. In the Western and Mid-Western states, large areas of forest have also been replaced by cocoa and rubber farms.

Tree-studded savanna (tropical grassland) occupies more than half the area north of the forest belt. Trees characteristic of this area are the baobab, the tamarind, and the locust bean. The savanna landscape becomes more open in the far north and is characterized by scattered stunted trees and short grass. Semidesert conditions appear in the Lake Chad region, where common trees include various species of acacia (of which one is the source of gum arabic) and the doum species of palm. Gallery forests (narrow forest zones occurring along rivers) are also characteristic of the open type of savanna landscape encountered in the north.

Animal life. Camels, several species of antelope, hyenas, lions, and giraffes are found in the grassland to the north, while the red riverhog, the forest elephant, the chimpanzee, and some varieties of birds and snakes are confined to the rain forest belt. Animals found all over the country include leopards, the golden cats, monkeys, gorillas, and wild pigs. Rodents, or gnawing animals, constitute the largest family of mammals and are also ubiquitous. Among common rodents are various squirrels, the porcupine, and the cane rat, known locally as "Cutting-Grass." The northern grasslands also abound in Guinea fowl. Other common birds include quails, vultures, kites, bustards, and gray parrots. The rivers contain a great variety of fish, crocodiles, and hippopotamuses. There are many butterflies, moths, and insects. Large scorpions are to be found, as also are goliath beetles.

Soils. The four main soil groups correspond closely with the main climatic and vegetation zones, which comprise the coastal swamp and alluvial soils, the rainforest soils, the lateritic soils (red soils, leached of silica and containing iron and aluminum hydroxides), and the sandy soils of the north.

Along the coast, the soils are either sandy or swampy and, like the soils of the forest belt, are heavily leached. In the rain forest belt, soils derived from old hard rocks, complex in structure, which pre-date the sedimentary rocks found elsewhere, support cocoa trees, while those derived from sandstones do not. Under cultivation, forest soils soon lose their fertility, which is concentrated in a thin top layer. Lateritic soils, which form along gentle slopes in areas with a markedly dry season, are widespread. Rich in iron compounds, and sometimes so hard as to appear to be rocks, they are difficult to cultivate.

Soil erosion

Soil erosion is most obvious in those densely populated areas of northern and eastern Nigeria in which overcultivation and overgrazing have exposed the soil to erosion by wind and running water. The areas most affected include the scarplands of Iboland in the east, where the threat posed by advancing gullies has resulted in the abandonment of some villages; the Jos Plateau in the centre; and the Kano–Katsina region and parts of Sokoto region, in the north. In the extreme north, wind erosion is particularly noticeable toward the end of the dry season, when the storms preceding the onset of the rains blow away much soil.

The landscape under human settlement. Marked differences exist between north and south not only in physical landscape, climate, and vegetation but also with respect to social organization, religion, literacy, and agricultural practices. These differences, due in part to the fact that the north is landlocked and the south is not, and in part to historical antecedents, form the basis of the division of Nigeria under human settlement into three main regions—the south, or Guinea coastlands; the middle belt; and the north, or Nigerian Sudan ("Sudan," as a historic region and as distinct from the state of that name, here signifies the open savanna belt which runs east to west from the Nile to the Atlantic).

The south is the most developed part of Nigeria. Its forest resources are intensively exploited, and its tree crops harvested on peasant farms as well as in commercial plantations. All the major industrial centres and oil fields, as well as the seaports, are concentrated in this

In general, as one proceeds northward, mean maximum temperatures increase, while mean minimum temperatures decrease. Owing to the blanketing effect of clouds during the rainy season, and of dust haze during the harmattan, the heat of the sun is not as fierce as might be expected. The climate of Nigeria is rendered trying not so much by high temperatures as by the high relative humidity, which, for example, at 6 AM averages 95 percent at Port Harcourt, and 85 percent at Lagos.

The harmattan season

The relative humidity falls considerably during the harmattan, which blows for over three months in the north but rarely for more than two weeks along the coast. During the harmattan period, the climate is invigorating, dust is pervasive, and the climate is excessively dry, causing lips to split and furniture to crack.

Vegetation. Vegetation in Nigeria is governed by the south to north decrease in rainfall, and the main vegetation belts run, therefore, in broad east to west belts, parallel to the Equator. Mangrove and freshwater swamps occur along the coast and in the Niger Delta. A few miles inland, swamps give way to dense tropical rain forests, in which the most important economic species of tree include such hardwoods as mahogany, iroko (a tree with mottled wood), and obeche, which has whitish wood. The oil palm tree, which is economically valuable, grows wild in the forest and is usually preserved when the forest is cleared for cultivation. In the more densely populated parts of Iboland and Ibibioland—areas in the

region. The south itself also consists of several cultural regions, of which the most important are the Yoruba areas in the west, the Benin area in the central part, and the Ibo–Ibibio area in the east.

The middle belt, stretching across the centre of the country, is the most sparsely settled and least developed part of Nigeria. The peoples inhabiting it are divided into more than 180 linguistic groups. Although a few highly capitalized schemes, such as the Kainji Dam and the Bacita sugar project, have been developed there, its future depends primarily upon its ability to increase its food production.

Historically and culturally, the Nigerian Sudan is a region of great interest. Until the beginning of the 20th century, when a new economic pattern was created by the construction of the railroad to the coastal ports, the region maintained regular trans-Saharan contacts with the Mediterranean and the Middle East. Islām is the predominant religion. It is a cattle zone, inhabited by the nomadic cattle-owning Fulani people and by the Hausas, who are settled cultivators. Except in the Lake Chad Basin, where the Kanuri people established the state of Bornu, the Nigerian Sudan is dominated by a blend of Hausa–Fulani culture.

Rural settlement. About 90 percent of the people live in rural settlements consisting mainly of small hamlets and villages. In parts of Iboland and the Anang region in the southeast and of Tivland in the central region, rural settlements consist of dispersed homesteads, called compounds. Each compound houses a man, his immediate family, and some relations. The compound is enclosed by a fence of matting and sticks or by a wall of mud or concrete. It is usually surrounded by a small garden area, called compoundland, which is cropped every year with corn, vegetables, and yams. A number of compounds make up the hamlet or village, which is usually inhabited by people claiming a common ancestor—often the founder of the village, after whom the settlement may be named.

Composition of compounds

Rural Nigerians do not use stone for building but depend on whatever materials are at hand. House types therefore change as one travels inland. Along the coastlands, where the soil is too sandy for making daub, the walls of houses consist of bamboos tied together with ropes, with the roofs being made of bamboo leaf mats. Bamboos, ropes, and mats are all made from the raffia palm, which abounds in the region. Rectangular mud houses with mat roofs are also found in the forest belt; the houses of the more prosperous are roofed with corrugated iron sheets. In the extensive savanna areas of the middle belt, and in parts of the north, houses consist of round mud buildings roofed with grass thatch; in the drier areas of the extreme north, flat roofs of mud replace the sloping grass thatch.

Each village has a chief, or headman, who usually is one of the oldest men in the community, and who usually rules by consent of the people. This is particularly true in the eastern states. In Yorubaland, and in most parts of the northern states, the chief is usually more powerful and is held in high esteem. A characteristic feature of village life is the existence of an age-grade system of social organization, which groups together people of the same age group. Communal jobs, such as road building or the raising of funds for a social purpose, such as building a school, are usually organized on the basis of the age-grade system.

Urban settlement. With the exception of the Yorubas, the Hausas, and the Kanuris, Nigerians were not town dwellers before the 20th century. The Yorubas, of whom perhaps half live in towns of over 5,000 persons, are the most urbanized people in tropical Africa. Their towns, most of which are several hundred years old, were originally administrative and trading centres, and most of them still are. The more important Yoruba towns, with their approximate populations, are Ibadan (*q.v.*), with about 758,000 people living in the municipality alone; Ogbomosho (387,000); Abeokuta (226,000); Ife (157,000); and Oyo (136,000).

The northern towns of the Nigerian Sudan, including Kano (with almost 357,000 inhabitants), Zaria (201,000), Sokoto (109,000), and Katsina (109,000), are much older than the Yoruba towns. Owing their growth to the trans-Saharan trade, as well as to the agricultural wealth of the Sudan, these ancient towns, like other pre-industrial cities, were unplanned, and they consist of an amorphous assemblage of mud buildings. Their inhabitants include traders, farmers, and administrators as well as craftsmen, musicians, and drummers.

During the period of British rule, many new towns grew up, and the older ones grew larger. Many towns originally were primarily administrative centres but—like the southern towns of Port Harcourt, Lagos, and Ibadan, as well as the Sudanese towns of Kano and Kaduna—have since become industrialized. Outside the walls of the ancient cities, the British established two customarily segregated towns or quarters—one, for white administrative officers and commercial agents, known as the Reservation and the other, for Nigerians from other regions, known as Sabon Gari (strangers' town). Such quarters exist in most cities in Yorubaland and Hausaland. Along the coast there are a few important pre-British trading towns, such as Calabar and Bonny. Other port towns, such as Port Harcourt and Sapele, were established during the colonial period.

Ancient and modern towns

Lagos (*q.v.*), the federal capital, is the only conurbation in Nigeria. Primarily a Yoruba town, it is built on an island. It is also the most industrialized city in the country and is one of the largest towns in tropical Africa.

PEOPLE AND POPULATION

The great diversity of peoples and cultures in Nigeria is largely a result of the location of the country at the meeting point of transcontinental migration routes from north to south, west to east and southeast to northwest. There are over 200 ethnic groups in the country, each of which has its own customs, traditions, and language. The larger groups include the Hausas (perhaps 6,000,000), the Fulanis (perhaps 5,000,000), the Yorubas (perhaps 10,000,000), and the Ibos (perhaps 7,000,000). Other prominent but less numerous groups include the Edos, of Benin City, as well as the Ibibios, in the forest belt; the Tivs and Nupes, in the middle belt; and the Kanuris, in the Chad Basin. The greatest concentration of smaller ethnic groups occurs—as already mentioned—in the middle belt, where there are over 180 linguistic groups. In the Niger Delta, the home of the Ijaws, social organization was altered radically during the period of the slave trade, in part because of the forced migration of peoples from the interior into the area and in part because of contact with European traders. The distinct cultural group which emerged stressed its cultural separation from other groups rather than its common descent. Jaja of Opobo, a 19th-century chief renowned for defying the British, was an Ibo who grew up among the Ijaw people of the Niger delta.

Racial and religious groups. Nigeria is a country of black-skinned peoples. The peoples of the savanna zone in the north tend to be taller than those of the forest belt of the south. Arab penetration into the Chad Basin has resulted in much racial mingling; the Shuwa Arabs and the Kanuris of this region are of mixed Negro and Arab origin. The cattle-owning Fulanis still maintain non-Negro features, but the town Fulanis have intermingled with Negroes. (The origin of the Fulani people—also known as Fulbes, Fulas, Fellatas, or Peuls—remains undetermined. Earlier migrations resulted in their establishing states throughout the Sudan region, from Fouta Toro in Senegal, to Macina in the Sudan itself. Speculation has attributed to them a West African, an East African, and a Middle Eastern origin.) Much intermingling has also occurred in the south, particularly in the coastal port towns of Calabar, Abonnema, and Warri, where many Syrians and European traders settled in the course of the last 70 years. Much of the country was originally animist in its beliefs, worshipping idols. At the time of the 1963 census, about 47 percent of the people were Muslims, and 35 percent professed Christianity. Though these figures might suggest that few people now worship idols, the fact is that many professing Muslims and Christians remain

idol worshippers. Religious freedom is entrenched in the constitution, and to some extent in all parts of the country; but especially in the Lagos and Western states, Muslims and Christians live and work together. The greatest concentration of Muslims is in the northern states, where 72 percent of the people profess Islām. In the Yoruba west, Christians are slightly more numerous, and in the eastern states they make up 77 percent of the population.

The main Christian groups are Roman Catholic, British Methodist, Anglican, and American Baptist. All of these church groups, as well as some Muslim sects, own and run schools and hospitals throughout the country. The development of education in the country has always primarily been the responsibility of religious groups, and about 90 percent of literate Nigerians have attended missionary institutions. This pattern is now being modified, however, because, since the civil war of the late 1960s, some states have taken over the control of schools from missionary groups.

Hausa as the lingua franca

Ethnic and linguistic groups. Hausa is the most widely spoken African language in Nigeria. It is spoken by the Hausas and the Fulanis but is also the lingua franca in the northern states. As a result of the Fulani conquest of Hausaland in the early 19th century, and the subsequent imposition of Fulani rule, the two groups live together in the same towns and villages. The religion of both groups is Islām. The town Fulanis, who are less orthodox in their religion, remain a distinctive aristocratic group. While they intermarry freely with Hausas and other groups, they nevertheless continue to control the administration of the Hausa towns. The cattle-owning Fulani, on the other hand, are not only more orthodox but also more disinclined to intermarry. Pure Fulani blood is therefore found more often amongst these nomadic herdsmen, than it is in the towns. The pastoral Fulani, while more ardent Muslims than those of the towns, are also, paradoxically, less subject to Islāmic influences. They also speak the Fulani language—Fulfulde—rather than Hausa. Unlike the Fulanis, the numerically dominant Hausas are settled cultivators as well as renowned traders. Cattle, however, including those owned by the settled Hausa farmers, are cared for by the Fulanis. At the time of the British conquest, the Fulani had established a rather unwieldy empire that extended beyond Hausaland to include vast areas occupied by the small groups of the middle belt, but before the Fulani conquest, which occurred in the early 19th century, the Hausas were organized into large states, of which the most prominent were Zaria, Kano, and Gobir.

Another important linguistic group consists of the 10,000,000 Yoruba-speaking peoples who, like the Hausas and the Fulanis, have ancient connections with the Middle East. The Yorubas, although they are farmers, often live in large pre-industrial cities. Each Yoruba subgroup is ruled by an influential paramount chief, or *oba,* who is usually supported by a council composed of chiefs of various ranks. The *oni* of Ife, who is the accepted spiritual leader of the Yorubas, and the *alafin* of Oyo, who is their traditional political leader, are the two most powerful rulers; their influence is acknowledged throughout Yorubaland. The various Yoruba subgroups also share a traditional religious system. It features the worship, through cults and secret societies, of gods such as Ogun, the god of war and iron; Shango, the god of thunder and lightning; and Orisha Oko, the goddess of farmland.

The Ibo-speaking peoples, whose leaders unsuccessfully attempted between 1967 and 1970 to establish the independent state of Biafra, are one of the largest linguistic groups in Nigeria. They live in small dispersed settlements and have never organized into large political units. Traditional Ibo society has rather been ultrademocratic; the largest political unit has been the village group, ruled by a council of elders rather than by a chief. The Ibos have a reputation throughout West Africa for energy and individualism. The relatively rapid progress of Iboland owes much to community efforts made at the village level, or through the extended family system.

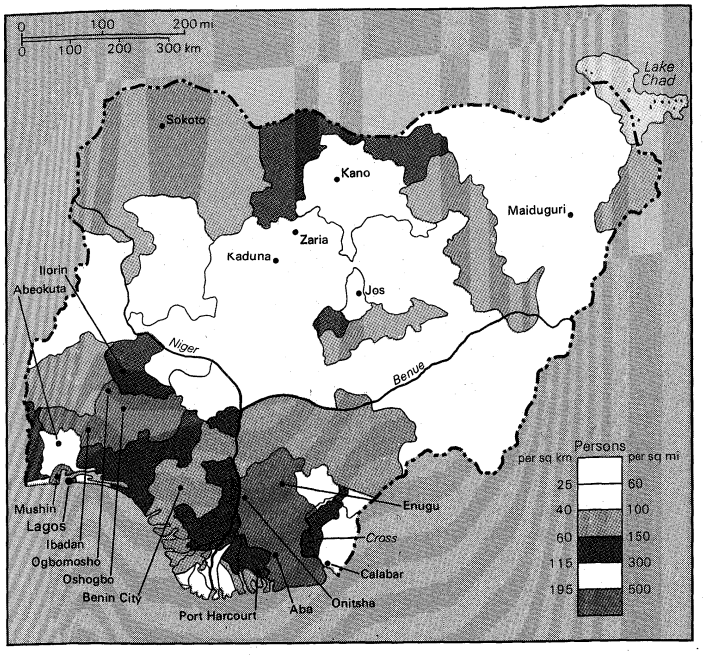
Other large linguistic groups include the Ibibios (who live near to the Ibos and share many common characteristics with them), and the Edo people of Benin City, whose culture has largely been influenced by their Yoruba neighbours. In the middle belt, the Tivs and the Nupes form the largest groups. Both are settled cultivators, but while Nupe society is hierarchical, that of the Tivs tends to be decentralized.

Densely settled areas

The distribution of population. The main concentrations of people are in the forest belt west of the Cross River and in the western half of the extreme north. In parts of Iboland and Ibibioland, the population density exceeds 800 persons per square mile (compared with the average national density of 154 persons per square mile). With the exception of Rwanda and Burundi, southeast Nigeria therefore constitutes the most densely settled area in Africa south of the Sahara. This concentration of agricultural people nevertheless occurs in a region which has heavily leached and impoverished soils, and a food-deficit consequently exists. Many migrants therefore leave the region to seek employment in the cities or in other rural parts of the country. The second region of dense population in the forest belt occurs in the cocoa-growing area of Yorubaland, which attracts many migrants from the congested districts of Iboland and Ibibioland. In the extreme north, there are also two areas of dense population—the Sokoto area and the Kano–Katsina area. The Kano concentration is based on intensive agriculture in an area of relatively fertile soils, but the densely settled areas around Sokoto and Katsina have somewhat impoverished soils and do not produce enough food for the local population. The average density in these northern areas is about 500 persons per square mile.

Smaller pockets of dense concentrations of people, averaging about 400 persons per square mile, occur in the tin fields of the Jos Plateau, in southern Tivland, and in the Okene district. The remaining, and by far the greater, part of the country is somewhat sparsely settled; vast areas of the middle belt, the Lake Chad Basin, and the Cross River district are virtually uninhabited. While most of these sparsely peopled areas suffered from extensive slave raids during the 19th century, there are some areas, such as the Niger Delta, the Cross River area, and parts of the middle Benue Valley, which, because of their difficult environment, have never been densely populated. The dense concentrations around Kano, Sokoto, and in parts of the cocoa belt occur, on the other hand, in areas that were protected by powerful chiefs and were therefore relatively peaceful during the period of the slave trade.

Demographic trends and migrations. Although the census figures are unreliable, there is sufficient evidence to show that demographic trends in Nigeria are similar to those in other developing nations. High birth and mortality rates are characteristic, although, during the last 30 years, there has been a decline in the rate of infant mortality and an increase in life expectation. There has consequently been a rapid growth in the population, which, reported as about 55,700,000 in 1963, was expected to increase to 70,000,000 in 1972. Except for the influx of a



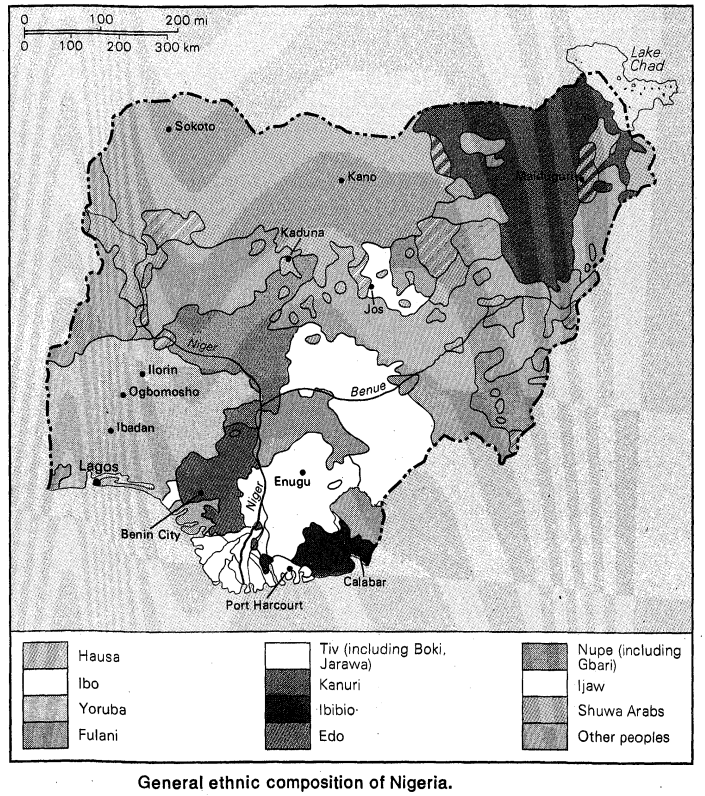
Population density of Nigeria.

small number of skilled workers from Europe or of traders from the Middle East, the growth in population has been by natural increase. A considerable movement of population nevertheless does take place within the country.

Internal migrations

Past census figures indicated that internal migrations took the form of a south to north movement of migrants who settled in the cities of the north as well as a north to south movement of seasonal migrants, from the Sokoto and Kano areas, who travelled to work in the cocoa-growing areas of Yorubaland. A larger number of people migrate westward from Iboland and Ibibioland as well as out of the Niger Delta. Most of these migrants work as labourers in the cocoa- or rubber-producing districts or as self-employed tenant farmers, cultivating food crops for sale to the neighbouring towns.

Many Nigerians also migrate to work in the neighbouring West African countries, such as Dahomey, Ghana, Equatorial Guinea, Cameroon, and even Sierra Leone. Before the deportation of many aliens from Ghana which began in 1969, about 1,000,000 Nigerians were living there. On the island of Fernando Po, however, which is part of Equatorial Guinea, Nigerians work on four-year contracts, at the expiration of which they normally return home. (R.K.U.)



General ethnic composition of Nigeria.

THE NATIONAL ECONOMY

From the economic point of view, Nigeria's most important characteristic is its size. Its population is the largest, and its gross domestic product the third largest (after that of South Africa and that of Egypt) in Africa. From 1967 until January 1970, the economy was disrupted by civil war. Until then, the 1960s had been a period of fairly rapid economic growth, with an annual average rate of increase in real gross domestic product of 4.5 percent in 1960–66—slightly faster than the average rate of increase for less developed countries as a whole. The growth of industrial production, from a small initial base, was particularly fast—an 8.5 percent annual average rate of increase, compared with about 6.5 percent for all less developed countries combined. Agricultural production, however, rose at a much slower rate—2 percent per year, or about the same as in other less developed countries. The rapid increase in exports, at about 9 percent a year, as against under 5 percent for less developed countries as a whole, was partly due to the expansion of production of crude oil, of which Nigeria was the world's 12th largest producer, being responsible for about 1 percent of the total output. Other world markets in which Nigerian exports are important are those for palm oil and palm kernels (of which Nigeria accounts for over a third of the total), cocoa, and groundnuts.

Despite a rate of growth that is rapid by the standards of other less developed countries, Nigeria still has one of the poorest economies in the world. Of the countries for which estimates were available in the mid-60s, only five —Ethiopia, Malawi, Tanzania, Upper Volta, and Burma —had a gross national product per capita that was lower than the $150 estimated for Nigeria.

Oil resources

Mineral resources. Oil, natural gas, coal, tin, and columbite are Nigeria's most important minerals. Proved reserves of crude oil are over 400,000,000 tons, with estimated reserves amounting to at least another 400,000,000 tons. The discovery of oil and its production in commercial quantities dates only from the late 1950s, although prospecting had been going on for many years before that. All of the reserves are in the southern part of the country (south of a line through Benin, Owerri and Calabar), with most of the output at the beginning of the 1970s coming from onshore fields in the Niger Delta area. Natural-gas reserves, both associated and unassociated with oil, are large, but most of the gas produced has to be flared for lack of a market. Coal reserves are estimated at over 350,000,000 tons, 110,000,000 of which are in the East-Central State around Enugu, the remainder being in the northern states. As a fuel, Nigerian coal is unlikely to be competitive with local oil in the long run. Extensive deposits of lignite (an imperfectly formed coal) also exist in the south, but technical exploitation difficulties exclude their economic use. In the northern and eastern states there are deposits, as yet unexploited, of tin as well as of columbite (a black crystalline mineral used to make niobium, which is used to make alloy steels).

Biological resources. Approximately a quarter of Nigeria's total area of over 357,000 square miles (924,000 square kilometres) is in use as arable land and under permanent crops, about 24 percent consists of permanent meadows and pastures, and about 34 percent is forested. Thus, in relation to the size of the population, there can hardly be said to be a shortage of land, although the prevalence of the shifting cultivation system means that such a shortage is emerging in some areas. This system has the merit, however, of protecting the soil against both erosion and loss of fertility. Most of the commercially exploited timber resources are in the Benin lowlands immediately to the northwest of the Niger Delta, the

main types being obeche (a whitish hardwood, used for furniture making), abura (a pinkish-brown wood, used for veneers), and mahogany.

Hydroelectric resources. There is a widespread network of rivers, many of which are potential sources of hydroelectric energy. At the end of 1966, total installed generating capacity was 417 megawatts, of which only 21 megawatts was hydroelectric, from stations in the Jos plateau. Since 1968, however, the Kainji power station has been in operation, with an initial capacity of 320 megawatts, eventually to be raised to 960 megawatts. With additional stations planned at Jebba and in the Shiroro Gorge, total hydroelectric capacity could exceed 1,800 megawatts during the 1970s.

Agriculture, forestry, and fishing. Agricultural production, including forestry and fishing, although still accounting for over half of the gross domestic product, has nevertheless represented a declining proportion of it in recent years. Since over 70 percent of the active population is still engaged in agricultural occupations, it is evident that output per man in agriculture is well below that in other sectors of the economy. Produce grown mainly for domestic consumption (most of it not marketed) is worth about five times that grown for export. The main food crops grown in the southern states are yam, cassava, and cocoyam, and in the northern states maize, guinea corn, rice, millet, cowpeas and cattle. The range of export crops is wide. The eastern states concentrate on producing palm oil and kernels, the midwest on rubber, the west on cocoa, and the north on groundnuts, cotton, and hides and skins. In the past, a marketing board in each of the regions has handled the main export commodity and guaranteed prices to producers, while a central marketing board has been responsible for exports—selling on behalf of the regional boards. With the creation of new states or of new state boundaries the marketing system had not been fully readjusted by the beginning of the 1970s. Interim arrangements, however, preserved the essentials of the old system. Output of all crops has tended to be variable, but, in general, output of export crops appears to have been growing faster than that of local food.

Crops for export

The output of cocoa, groundnuts, and rubber has expanded particularly fast in recent years. In 1966—the year preceding the civil war—the following quantities in short tons were exported: cocoa, 190,000; palm kernels, 394,000; palm oil, 143,000; groundnuts, 573,000; groundnut oil, 104,000; groundnut cake, 133,000; rubber, 70,000; and cotton (mostly for the local textile industry), 15,000. Of these, palm kernels, palm oil, and rubber were the only crops to be significantly affected by the civil war, and by the early 1970s output of these commodities was again substantial. The timber industry also suffered from the war, but even before that output had been falling away from the high level of production of the early 1960s, because of destruction of forests for the purpose of temporary cultivation. Forest products amount to about 4 percent of gross domestic product; another 3 percent is accounted for by fisheries. Lake Chad is the main source of fish, yielding about 25,000 tons per year. Over 80 percent of the domestic demand for fish is met by imports, mostly from Iceland and the United States.

Mining and quarrying. Mining represents the fastest growing sector of the Nigerian economy, accounting for over 5 percent of the gross domestic product, compared with less than 1 percent in the late 1950s. The most spectacular increase has been in oil, the output of which amounts to over 20,000,000 tons. The oil industry was seriously affected by the civil war, but recovery has been fast, with output exceeding 1,000,000 barrels a day early in 1970. The oil refinery near Port Harcourt, which has a capacity of 45,000 barrels per day and which was supplying nearly all the domestic demand before the civil war, came back into operation in 1970, after war damage had been repaired. Even before the civil war, the output of coal, used mainly by the railway and a cement company, and for electricity generation, had been declining. The tin industry, which was less affected by the war, produces ore, practically all of which is smelted locally and exported as metal. Production is about 13,000 tons. Columbite output, on the other hand, which reached a peak of 2,500 tons in 1965, has been declining because of a fall in world prices; production is about 1,000 tons a year. The mining industry is virtually entirely foreign owned.

Manufacturing. While the manufacturing sector has grown rapidly in recent years, it still accounts for only about 5 percent of Nigeria's gross domestic product. The largest production is of consumer goods for the home market; unlike the rest of the economy, manufacturing was stimulated by the civil war and by its restrictions on imports. Major industries in terms of value of output are textiles, beer, food, tobacco, and vegetable oils. Companies engaged in manufacturing are of all sizes; categories range from rural cottage industry to small-scale urban industry to large modern industrial plants. Over two-thirds of the last category is foreign owned. Most of the remainder is owned by public authorities; only a small proportion is privately owned by Nigerians.

Energy. With its oil, natural gas, and coal deposits, and hydroelectric resources, Nigeria has a wide range of potential sources of energy. Output of electricity in 1970 was 1,549,200,000 kilowatt-hours. The discovery and exploitation of the oil and gas reserves is still to be fully reflected in the pattern of energy consumption, which —before the war—was: coal, 21 percent; petroleum products, 69 percent; natural gas, 8 percent; and hydroelectricity, 1 percent.

Financial services. The Central Bank of Nigeria, founded in 1959, performs central banking functions. There are 11 commercial banks. The Nigerian Industrial Development Bank provides medium- and long-term finance to private firms. Since the war, during which the financial sector tended to be dominated by government borrowing requirements, prospects for normal operations have improved.

Foreign trade. The value of Nigeria's domestic exports more than doubled in the ten years before the war, reaching a total of more than $780,000,000 in 1966. In the same period the ratio of exports to gross domestic product rose from 15 percent to 17 percent, due to foreign exchange earnings from the growing oil industry. By 1966 this commodity, which earned nothing a decade earlier, had become the most important single export, contributing 33 percent of total export earnings. Next in importance were groundnuts (15 percent), followed by cocoa (10 percent), palm kernels (8 percent), rubber (4 percent), palm oil (4 percent), and groundnut oil (4 percent). This pattern of exports, disturbed by the war, was re-establishing itself in the early 1970s.

Imports grew more slowly in the ten years before the war, rising by about 67 percent to a total of $717,000,000. Nigeria thus moved in this period from a position of chronic trade deficit at the outset to one of a potentially regular surplus. The war destroyed this favourable position, but only temporarily. The war also changed—perhaps more permanently—the pattern of imports, with chemicals (over 10 percent of the total) and machinery (about 9 percent) displacing food and cotton piece goods at the top of the import list. The United Kingdom, still Nigeria's main trading partner, in 1970 bought 30 percent of Nigeria's exports, and supplied 29 percent of its imports.

Management of the economy. *The private sector.* The Nigerian private sector is numerically dominated by cash-crop farmers and small-scale local businessmen, operating in both urban and rural areas. So far, however, few Nigerian businessmen have been successful in building up large industrial firms, most of which are owned by foreign private investors or public authorities.

The public sector. Government accounts for about 5 percent of the gross domestic product, even when its directly economic activities, such as manufacturing, are excluded. Apart from manufacturing projects (which represent a total investment of over $98,000,000), the government owns a shipping line, an airline, sporting facilities, broadcasting stations, and hotels. Of these only the shipping line has operated at a profit. The public authorities also provide incentives to private firms, including tariff protection, import duty relief on materials,

The role of government

accelerated depreciation allowances, and some relief from income tax as well as assisting the growth of private industry by providing credit, industrial estates, and technical assistance.

Taxation. Taxation arrangements are complicated by the federal constitution, according to which part of the revenue collected by the federal government has to be redistributed to the states. The allocation of revenue between the states and the federal government, and between the states themselves, is a constant bone of contention; at the beginning of the 1970s a satisfactory accommodation still had not been arrived at. The most important source of all governmental revenue is import duties, which account for about a third of the total, followed by excise duties (under 20 percent) and mining royalties and rents (about 15 percent). Personal income tax accounts for less than 10 percent, and company tax for about 5 percent, of total revenue. Fiscal policy has been orthodox, with budgets being balanced in the early 1970s. Public finances were, however, severely strained during the civil war.

Trade unions and employer associations. The Nigerian trade-union movement is weak, in spite of having a membership equivalent to about 65 percent of all those employed in establishments with ten or more employees. Membership is spread throughout hundreds of small unions, and there is no single effective central organization. The largest employers of wage labour are the government and public corporations, which fix wage rates unilaterally. The larger private employers have formed the Nigerian Employers Consultative Association, in the hope of encouraging the growth of a collective-bargaining system.

Contemporary economic policies. Before the civil war, there were virtually no restrictions on imports or foreign exchange remittances, and generous incentives were offered to foreign investors. With the onset of the war, this situation inevitably changed. Import restrictions and exchange controls were imposed, severe legislation against strikes was enacted, and efforts were made to raise extra tax revenue from private companies as well as by imposing indirect tax increases. At the same time a new Companies Act required all foreign companies to place their local operations under subsidiaries incorporated in Nigeria, and a new petroleum decree gave the government wide discretionary powers in the oil industry. The change of emphasis in general economic policy engendered by the war is likely to be permanent.

Problems and prospects. Among Nigeria's current economic problems are a high rate of population growth, a growing problem of unemployment (particularly among students leaving school), a potential shortage of local food, and an accelerating rate of price inflation. Other problems stem directly from the three-year war that ended at the beginning of 1970. Among these, the relief and rehabilitation of the areas affected by the war are the most pressing. The huge internal debt built up during the war will also constitute a drain on public finances for several years. That the prospects for the Nigerian economy in the 1970s are nevertheless good is due partly to the large market it offers to potential investors, partly to the stimulation of economic development resulting from restrictions on imports during the war, and, most of all, to the expansion in the oil industry. Earnings from oil could end the foreign exchange shortage at a crucial stage in Nigerian development. This hopeful prospect assumes continuing political stability in a country in which many potential sources of tension remain. (E.I.U.)

TRANSPORTATION

The north–south traffic flows

Patterns of transport flow. The general pattern of transport flow is in a north–south direction, running from the interior to the southern seaports. Construction of main railroad lines started from the ports of Lagos (1898) and Port Harcourt (1916) and continued inland to the Sudanese commodity collection centres—reaching Kano in 1912, Nguru in 1930, Kaura Namoda in 1929, and Maiduguri in 1964. The major roads also run north–south. In the resulting competition between rail and road traffic, road traffic is gaining the advantage. The north–south pattern of flow is characteristic of the colonial type of economy, in which raw materials are produced in the interior and are then shipped out through the nearest port to the metropolitan country, which in turn supplies manufactured goods. The flow pattern also results from the fact that different agricultural products are grown in zones, or belts, running east to west, so that the general direction of internal exchange trade is from north to south. This pattern is modified in the south, however, where local staples flow from the eastern states and the Midwestern State to Ibadan and Lagos in the southwest. Feeder roads, running in an east–west direction, also link up districts to the main north–south railways and roads.

On several occasions the country's single-track railroads have proved incapable of transporting large quantities of groundnuts and cotton from the north, a circumstance which has stressed the growing importance of huge haulage, even over such long distances as from Kano to Lagos. The greater flexibility of road transport also appeals to importers, most of whom ship their goods by road. The proportion of imports moved from Lagos by road has, for example, increased from one-fifth to over a half in recent years, while the proportion of imports moved by rail has declined sharply.

The average daily traffic flow on the roads is greatest in the cocoa belt of southwestern Nigeria, after which it is greatest in the groundnut and cotton belt of the Kano–Katsina region, in the Jos Plateau tin fields, and in the palm belt of southeastern Nigeria. These are the four main areas of economic development and of population concentration in the country, and each is consequently served by a dense network of all-weather roads. By contrast, the relatively unproductive and sparsely settled areas of the middle belt, of the Cross River region, and of the Chad Basin have tenuous road links that carry only a few trucks a day.

Component systems of transportation. Although the development of the railway and of roads have overshadowed inland waterways, the creeks and rivers were the first means of communication in 20th-century Nigeria. The most important waterways are the Niger and Benue rivers, which still carry substantial quantities of goods, including transit cargo to and from Garoua in the Federal Republic of Cameroon. The Cross River is used to ship exports to Calabar, but, like other rivers in the country, it is not navigable during the dry season when the water level falls. Passenger and cargo boats also operate on the lagoons and on the numerous creeks that occur along the Nigerian coast from Lagos to the Cross River estuary.

The railroad system

Although the road is now the most important means of transportation, it was the railroad that formerly was most relied upon. The railroad system consists of two single-track main lines—the eastern line from Port Harcourt to Maiduguri and the western line from Lagos to Kano. Branch lines connect the western main line to Kaura Namoda, to Nguru, and to Baro on the Niger. The total route mileage amounts to about 2,680 miles (4,313 kilometres) of three-foot six-inch (1.067-metre) track. Since 1960, tracks have been relaid with heavier rail to permit heavier axle loads and higher speeds, rail movements have been speeded by improvements in signalling, and steam engines have been replaced by diesel locomotives, which can haul heavier loads. Diesels also require less maintenance and servicing and, since they do not need to pick up water, save running time; they are particularly useful in the drier north where services were often disrupted by water shortages during the dry season.

Nigerian roads fall into three categories; these are trunk A roads, which are maintained by the federal government and which link Lagos with the state capitals; trunk B roads, which are maintained by state governments and which connect provincial capitals and other large towns with the trunk A system; and other roads, which are maintained by local government, which carry local traffic, and which act as feeders to the trunk-road systems. All trunk A and most trunk B roads are surfaced; almost all other roads are earth roads.

The southern terminals of both the two main-line railways, as well as of the north–south trunk roads, are the

port towns of Lagos and Port Harcourt. These are Nigeria's main international seaports, the less important ones being Warri, Sapele, Koko, and Calabar. Lagos and Port Harcourt both have modern equipment for handling cargo. Both are administered by the Nigerian Ports Authority, which was established in 1954 and which has recently (1970) taken over responsibility for the port installations and for the administration of the other seaports. Shore labour in Nigerian ports is, however, supplied by private contractors.

All the 12 state capitals are served by air transport that is supplied by the Nigeria Airways Corporation. A few minor airfields also exist in some provincial cities, but only two international airports—those at Lagos and at Kano—handle transcontinental traffic. The creation of more states in 1967 resulted in an increase in air services beween Lagos and the state capitals. While air fares are relatively high, Nigerian Airways has nevertheless maintained flights from Lagos to cities such as Kano and Kaduna at fares that are less than the corresponding first class rail fare.

ADMINISTRATION AND SOCIAL CONDITIONS

The structure of government. *The constitutional framework.* Although the two British protectorates of Northern and Southern Nigeria were amalgamated in 1914, the government of the two territories remained essentially different until 1946, when the first legislative council for the entire country was established. This situation arose largely as a result of cultural differences as well as of wide variations in the degree of development of political institutions among the many ethnic groups in the country. Thus, the north, much of which had a Hausa—Fulani administration in pre-British days, was administered by indirect rule—a system whereby the British governed through established feudal overlords. The south was directly administered by the British. The 1946 constitution provided for a central legislature for the whole country as well as for three Regional Houses of Assembly —one for each group of provinces. This was in accordance with the thinking of Nigerian politicians, who became prominent after World War II, demanding independence and a federal form of government with strong powers vested in the states.

The 1951 federal constitution, however, gave only limited powers to the states, until, three years after its adoption and as a result of mounting pressures from the states, residual powers were transferred from the federal government to the states. By the modified federal constitution of 1954, the states became responsible for direct taxes (including income tax), school education, health, and most aspects of economic development. The weakened federal government retained responsibility for defense, external affairs, aviation, railways and some key roads, postal services, higher education, customs and excise, and banking. The federal government was, however, permitted to assume more powers in time of war or whenever any state threatened the continued existence of the federation.

When the army assumed power in January 1966, the legislative sections of the constitution were suspended, and the political structure of the country transformed by the creation in 1967 of twelve states, instead of four. With the end of the 30-month civil war in January 1970, a return to civilian rule is eventually expected. It is anticipated that a federal constitution will be maintained.

State and local governments. When, in 1960, the United Kingdom granted independence to Nigeria, Nigerian politicians inherited an unwieldy federation in which one state—the Northern Region—had a much greater size and population than the other two states combined. Before independence there was, therefore, a sustained demand by minority groups within the federation for more states. Although, however, the 1954 constitution provided for the creation of more states, none of the state governments was willing to "dismember" its territory. The creation of the Mid-Western State out of Western Nigerian territory in 1963 followed a major political crisis in that part of the country, during which the federal government invoked its emergency powers. It was not until May 1967, on the eve of the Biafran secession, that the federal military government created 12 states in place of the previous four.

Under the civilian regime that ended in 1966, the federal government consisted of a Council of Ministers presided over by the prime minister, a Senate, and a House of Representatives. Legislative powers were vested in the Senate and the House, while executive powers were vested in the Council of Ministers. The head of state was the president, who was elected for a five-year term, after which he could be re-elected. Each region, or state, had a similar constitution, in which there was a governor; an Upper House, or House of Chiefs; and a regional House of Assembly. At the local government level, there was considerable variation from one state to another. In the feudal Northern Region, the state was divided into emirates, in each of which the emir, a traditional ruler, presided over the local council. In the Western Region, where the Yoruba people had established centralized administrations in precolonial days, each local government unit was ruled by an *oba* and his chiefs. Administration in the Eastern Region was, however, of a totally different kind. As the sphere of influence of a chief rarely extended beyond the territory of a village, the region was constituted in provinces, each of which had an elected Provincial Assembly, presided over by a provincial commissioner appointed by the state government.

Since the assumption of power by the army in 1966, the country has been ruled by the Supreme Military Council, consisting of the commander in chief of the armed forces as head of state and chairman, 12 military governors, and the heads of the army, navy, police, and air force. There is also a Federal Executive Council, presided over by the commander-in-chief General Gowon and made up of civilian representatives, one from each of the 12 states. The representatives, who are designated commissioners, are appointed by the commander in chief. Each state is governed by an Executive Council, which also consists of civilian commissioners appointed by the state governor, who is also chairman of the council. Local council areas are each administered by a single administrator, appointed by the state governor.

The political process. *Elections.* Political activity at all levels was banned when the army came to power, but during the previous civilian regime, election to the federal and state legislatures, as well as to local councils, was on the basis of one man one vote. The franchise was extended to all adults, except in the Northern Region, where women were not allowed to vote. No government party ever lost in any election. To maintain itself in power many governing parties, both at the federal and at the state level, resorted to fraudulent practices and to the victimization of political opponents, many of whom were imprisoned. The life of the federal and state legislatures was five years.

Parties. At the time of independence in 1960, and until the end of civilian rule in 1966, there were three main political parties in the country. These were the National Convention of Nigerian Citizens (NCNC), founded by Nnamdi Azikiwe; the Action Group (AG), a Yoruba party founded by Chief Awolowo, a former lawyer and trade unionist; and the Northern Peoples Congress (NPC), founded by the late Sir Ahmadu Bello, the *sardauna* of Sokoto. Of all the parties, only the NCNC had some semblance of being a national party. In 1965 it controlled the governments of Eastern and Mid-Western Nigeria as well as the Lagos City Council in the federal capital. It had a strong following in the Yoruba west, but, like other Nigerian parties, was identified with an ethnic group—in this instance the Ibos of Eastern Nigeria. The most conservative party was the NPC, which, as the name implies, was a Northern Nigerian party. Thus, when in 1954 and 1959 the NCNC and the AG contested all seats in the federal legislature, the NPC restricted itself to Northern Nigeria, and—because of the large size of the north as well as because of fraudulent election practices—was able to control not only the north but also the federal legislature.

The former political parties

In each state there were a number of small parties, which were usually in opposition to the state government. Thus, in the Northern Region there were the Northern Elements Progressive Union (NEPU)—led by *mallam* (a title signifying "Muslim legal clerk") Aminu Kano, a Fulani teacher—and the United Middle Belt Congress; in the Western Region there was the Nigerian National Democratic Party, led by the late Chief Samuel Akintola, a lawyer and former Action Group leader; and in the Eastern Region there were the United Independence Party (UNIP) and the Dynamic Party.

Participation of citizens. Except in the north, where the influence of tradition was greater and education less widespread, Nigerians showed much interest in postindependence politics. Political consciousness was particularly marked in the towns and cities of the southern states. The large-scale involvement of citizens in politics resulted primarily from the fact that, since Nigeria is a developing country, people looked to the government for jobs as well as for basic services such as roads, water, schools, and hospitals.

Justice. The Nigerian legal and judicial system is subject to regional variations, particularly between the largely Muslim north and the Christian-influenced south. Three codes of law may be recognized in the country; customary law, Nigerian statute law, and English law. Customary laws are administered by native, or customary, courts. Such courts are usually presided over by persons with no formal legal education excepting in the case of the Alkali, or Muslim, Courts where the judges (*alkalis*) have to undergo formal training in Muslim law. Customary courts are of different grades, with Grade A courts serving as courts of appeal for cases from Grades B, C, and D courts. During the postindependence period of civilian rule, these courts fell into disrepute through their use as instruments of political coercion.

Three codes of law

Nigerian statute laws include much of the legislation enacted by the British colonial administration, most of which has since been revised. State legislatures may pass laws on certain matters not included in the Exclusive Legislative List, which is composed of such subjects as defense, external affairs, and mining—all of which can only be legislated upon by the federal government. It is also the practice that, whenever federal legislation on any matter is in conflict with state legislation, federal law prevails in the courts. In addition to Nigerian statutes, English law is used in the high courts and in magistrate's courts. There is a high court for each state, but one Supreme Court for the federation.

The armed forces. The armed forces of Nigeria consist of the army, the navy, and the air force. Before the civil war, Nigeria had a ceremonial army of about 7,000, most of whose officers were killed during the military coups that occurred in January and July 1966 respectively. The war to end the Biafran seccession led to the enlistment of thousands of people and to heavy expenditure on military equipment for all sections of the armed forces. When the war ended in January 1970, an estimated 200,000 persons were bearing arms. Since the government does not intend to demobilize the army, it appears that Nigeria will maintain the largest army in tropical Africa. Both the navy and the air force also grew considerably during the war, but further expansion is not envisaged.

Administration. *Educational services.* Education is largely the responsibility of the state governments although there are two federal universities at Lagos and Ibadan. The University of Nigeria at Nsukka and Enugu, the Ahmadu Bello University at Zaria and Kano, and the University of Ife are owned by state governments. Each of these universities has a medical school attached to it. Another state university was opened at Benin City in 1970. In the 1969–70 academic year there were about 10,000 students attending university institutions. About 20,000 Nigerian students are attending United States or European universities.

Primary education is free in some states, including the Western State and Lagos State as well as North-Western State. In the northern states, where the literacy rate is lowest, secondary education is also virtually free. In general, formal education is less sought after in the north. Teachers are trained not only in the universities but also in several advanced teachers colleges (maintaining higher standards) and in numerous other training colleges.

Until 1950, most schools were controlled by religious bodies, such as the American Baptist Mission, the Wesleyan Methodist Mission, the Church of Scotland Mission, and the Anglican Church's Church Missionary Society. A few government schools were also maintained, although government policy was to give grants to mission schools rather than to expand its own. After independence, many more secondary schools were established by local council authorities or by the legislatures. There is a shortage of teachers of all kinds, which the federal government is attempting to remedy by training teachers in the universities.

Health services. Medical and health services are the responsibility of the state governments, each of which maintains a hospital in the larger cities or towns. Specialized hospitals are located in Lagos, Ibadan, Jos, Port Harcourt, and Kano. Many maternity hospitals are run by religious organizations. Medical services are generally inadequate; many hospitals do not have enough medical personnel. Drugs are always scarce. Rural areas are the most deprived of services, with most communities being served only by dispensaries and maternity homes, staffed by junior personnel.

There are about 2,180 practicing doctors in Nigeria, an average of about one for every 29,000 people. It is hoped that when the five medical schools in the country are in full service, they will, from 1975 onward, produce a total of 400 doctors a year, as compared to about 120 in 1970.

Housing. Housing is inadequate in the cities, where overcrowding has led to the spread of slums. Since there are only a few housing corporations, most houses are built by individuals, who acquire plots to build houses either by direct or by contract labour. Each city has three types of residential districts; the local Nigerian town, with congested and poor quality housing; the Nigerian strangers' town (usually called the Sabon Gari), equally congested and occupied by Nigerians from other states or regions; and a district of modern and expensive housing, occupied by the Nigerian professional elite. In the villages, most people live in huts, but, especially in the cocoa belt, modern houses are now being built.

Police services. The Nigeria Police Force, established by the federal constitution, is headed by the inspector general, who is represented in each state by a police commissioner. On the eve of independence the organization of the police was a controversial issue between some politicians who wanted each state to control its police force and others who advocated federal control. The matter was settled by a compromise, whereby the police force remained united under the inspector general but with the state governments being allowed to appoint their police commissioner. Each commissioner is responsible to the inspector general but has to comply with the directions of the state government.

During the period of civilian rule, the Native Authority Police, in Northern Nigeria, and the Local Government Police, in Western Nigeria, were sometimes open to criticism because they were far below the national police force in training and standards. The Federal Military Government followed a policy of gradually absorbing local police forces into the Nigeria Police Force.

Social conditions. *Wages and cost of living.* The gap between the rich and the poor is far greater than in industrialized countries. Most wage earners in the country earn less than $700 a year, while lawyers, university teachers, engineers, and doctors earn over $3,000. There is a general sentiment that the wages of the poor are too low; in consequence, the federal government has established a wage review board. A price control board was also established to deal with the problem of sharp price increases that occurred during and after the war. Since the last general salary review in 1959, the cost of living has increased so much that many families find it difficult to eat adequately, particularly during the hungry-season

months from March to July before the first harvests are gathered, when local staple food prices are very high.

Health conditions. The concentration of people in the large pre-industrial cities such as Ibadan, Oshogbo, Zaria, and Kano has created enormous sanitary problems concerning sewage disposal, water shortages, and poor drainage. Medical science has brought about improvements in health conditions, but many people still die from malaria, cerebro-spinal meningitis, and other preventable diseases.

Rural communities in particular suffer greatly from inadequate or impure water supplies. Some villagers have to walk distances of up to six miles to the nearest water point—usually a stream. Since people wash clothes, bathe, and fish in the same stream, the water drawn by anyone living in villages further downstream is often polluted. During the dry season, wayside pits containing rain water are used until they dry up. Cattle are also often watered in such pools, a circumstance that contributes to the high incidence of intestinal diseases and guinea worm in many rural areas.

CULTURAL LIFE AND INSTITUTIONS

Nigeria has a rich and varied cultural heritage, deriving partly from the varied racial elements in the population and partly from the influence of Middle Eastern and western European cultures. The oldest works of art so far discovered consist of late Stone Age terra-cotta heads associated with the Nok culture, which flourished in the region of the Jos tin fields from about 500 BC to about AD 200. The heads are considered to be of a technical standard indicating an advanced agricultural culture connected with iron and tin. Nok culture is thought to have influenced the celebrated bronze and terra-cotta heads of Ife and of ancient Benin. Ancient art works of wood and bronze have also been excavated at Awka, near Onitsha, as well as in the coastal areas of Oron. During the last two centuries, the cultural life of the south has been influenced by Europe, while Arabic influence has been manifest in the north.

The Nok culture

Nigerian arts and traditions have revived since independence partly because of the realization of the desirability of preserving Nigerian culture and partly because of the patronage that Nigerian arts have received from abroad. Carved calabashes from Oyo, masks and ebony heads from Benin City, Awka, or Ikot Ekpene, or thorn carving from Shagamu are used to decorate the houses of the well-to-do, who also wear locally woven and locally dyed cloths, instead of, as in the past, using imported materials. Oil paintings of Nigerian subjects are also common.

The Institutes of African Studies at the Universities of Ibadan and Ife have done much to publicize and re-awaken interest in traditional folk dancing and in poetry, as also have the School of Fine Arts and the School of Drama at Zaria and Ibadan respectively. Vernacular radio and TV programs in at least ten languages include traditional music and dancing, folk operas, and story telling. Since, except in the Muslim north, writing became common only during the last 60 years, and since until recently few Nigerians showed any interest in folk traditions and local culture, it is believed that much of the country's culture has perished during the last two generations. Today, many ancient folk songs have been revived by popular singers who use modern musical instruments to produce sounds that villagers can hardly identify with the songs they inherited from their ancestors.

Cultural institutions. In Nigeria, where superstition still waxes strong, many cultural institutions touch upon various aspects of life. Secret societies, such as Ekpo and Ekpe among the peoples of the South-Eastern State, were formerly used as instruments of government, while other institutions were associated with matrimony. According to the Fulani custom of *sharo* (test of young manhood), rival suitors underwent the ordeal of caning as a means of eliminating the less persistent grooms-to-be, while in Ibibio territory, girls were confined for several years in bride-fattening rooms before they were handed over to their husbands. These and other customs were discouraged by colonial administrators and missionaries, who disapproved of them. Some of the more adaptable cultural institutions have, however, been revived since independence; these include, for example, the EKPO and EKONG societies for young boys in parts of the South-Eastern State.

Press and broadcasting. In addition to the radio networks of the Nigerian Broadcasting Corporation (NBC), owned by the federal government, there are several state-owned broadcasting stations, of which the most prominent is the Western Nigeria Broadcasting Service. The Lagos NBC studios broadcast news in English and in nine Nigerian languages, as well as music, while local NBC stations concentrate on local culture and languages. Television broadcast is from Lagos, Ibadan, Enugu, Port Harcourt, Aba, and Kaduna. Most programs are composed of films from the United States and western Europe, although local drama groups also feature prominently.

There are several national papers, all of which are published in English. The most widely read daily papers are the *Daily Times*, the *Nigerian Morning Post*, and the *New Nigerian*. Regional papers include the *Midwest Echo*, the *Daily Sketch*, and the *Daily Standard*.

CONCLUSION

The 30-month civil war over the attempted Biafran secession proved a serious, although temporary, setback to the development of tropical Africa's most populous country. It has encouraged Nigerian self-reliance and has stimulated the establishment and expansion of Nigerian manufacturing industries, as well as of raw-material processing. In the aftermath of the war, much still remains to be done to reconstruct war-damaged areas, as well as to rehabilitate millions of people. The greatest task, however, appears to be that of reconciling Ibos and other ethnic groups inhabiting the former secessionist territory. These other groups, now constituted into the Rivers and South-Eastern states, were subjected to pressures from the Ibos, who wished them to support the Biafran cause.

Economically, the outlook is bright. The war ended with little national debt, thanks to Nigeria's production of crude oil, which financed the prosecution of the war. Soon after the end of the war, oil production exceeded prewar figures.

(R.K.U.)

Niger River

The Niger, with a length of nearly 2,600 miles (4,200 kilometres), is the principal river of West Africa, and the third longest in Africa. It is believed to have been named by the Greeks. Along its course it is known by several names. These include the Joliba (a Malinke [Mandingo] word meaning "great river") in its upper course; the Mayo Balleo and the Isa Eghirren in its central reach; and the Kwarra, Kworra, or Quorra, in its lower stretch.

Courses of the Niger and its tributaries

Physiography. The Niger rises in Guinea at 9°05′ N and 10°47′ W on the landward side of the Fouta Djallon highlands, only 150 miles from the Atlantic Ocean. Issuing as the Tembi from a deep ravine 2,800 feet above sea level, it flows due north over the first 100 miles. It then takes a northeast course, during which it receives its upper tributaries, the Mafou, the Niandan, the Milo, and the Sankarani on the right bank and the Tinkisso on the left bank. Seven or eight miles below Bamako, in Mali, the Sotuba rocks mark the end of what may be considered the upper river. Over the next 40 miles the Niger drops more than 1,000 feet into a valley formed by a tectonic subsidence. The Sotuba and Kénié Rapids both occur in the course of this descent.

A little lower down is Koulikoro, from which point the river takes a more east-northeasterly direction and its bed becomes fairly free from impediments for the next 1,000 miles. At Mopti it is joined by the Bani, its largest tributary on the right bank, after which it enters a region of lakes, creeks, and backwaters. These lakes are chiefly on the left bank and are connected to the river by channels that experience seasonal changes in the direction of flow. At high water most of the lakes become part of a general inundation. The largest of the lakes is Lac Faguibine, which is nearly 75 miles long and 15 miles wide, and more than 160 feet deep in places.

The labyrinth of lakes, creeks, and backwaters comes to an end at Kabara, port of Timbuktu (Tombouctou). Here, the river turns almost due east, passing its most northern point at latitude 17°5′ N, where it is bordered by the Sahara on its left bank. Near Taoussa, 250 miles downstream from Timbuktu, a rocky ridge that obstructs the course of the river is pierced by a defile (narrow gorge) more than a mile long, with an average width of about 800 feet, and a depth of over 100 feet in places. At low water the strong current here endangers navigation. Further downstream the river widens considerably, flowing down to Gao in a southeasterly direction across a floodplain three to six miles wide.

Except for the stretch from Bamako to Koulikoro, which is an area of rapids and steep descents, the middle course of the Niger River is navigable to small craft during high water as far as Ansongo—1,057 miles in all. Below Ansongo, 430 miles downstream from Timbuktu, navigability is interrupted by a series of defiles and rapids. The river becomes navigable to small vessels again at Labbezenga, Republic of the Niger, and continues navigable to the Atlantic Ocean. Navigation is seasonal, due to water level fluctuation in the rainy and dry seasons.

Downstream from Jebba, the Niger enters its lower course, flowing east–southeast through a broad and shallow valley five to ten miles wide. About 70 miles from Jebba it is joined by the Kaduna River, an important tributary that contributes about 25 percent to the annual discharge of the river below the Niger–Kaduna confluence. At Lokoja, in Kwara state, Nigeria, the river receives the water of its greatest tributary, the Benue, thereby approximately doubling the volume of its annual discharge. At their confluence the Niger is about three-quarters of a mile wide, and the Benue over a mile. Together they form a lake-like stretch of water about two miles wide and dotted with islands and sandbanks. From Lokoja downstream to the town of Idah, the Niger runs between hills, and the channel is narrow and rocky. Between Idah and Onitsha the banks are lower, and the country flatter. At Onitsha, the largest town on the Niger's banks, the valley narrows as the river flows south through what is probably a fault in the area's sandstone. It emerges at Aboh, separating into many branches before reaching the ocean via Africa's largest delta.

The Niger Delta

The Niger Delta, which stretches for nearly 150 miles from north to south and spreads along the coast for about 200 miles, extends over an area of 14,000 square miles. Within the delta the river breaks up into an intricate network of channels called rivers. The Nun River is regarded as the direct continuation of the river, but some of the other important channels include the Forcados, the Brass, the Sombreiro, and the Bonny. The mouths of these channels are almost all obstructed by sandbars. The Forcados, for instance, which supplanted the Nun as the most travelled channel in the early 20th century, was in turn displaced by the Escravos River in 1964.

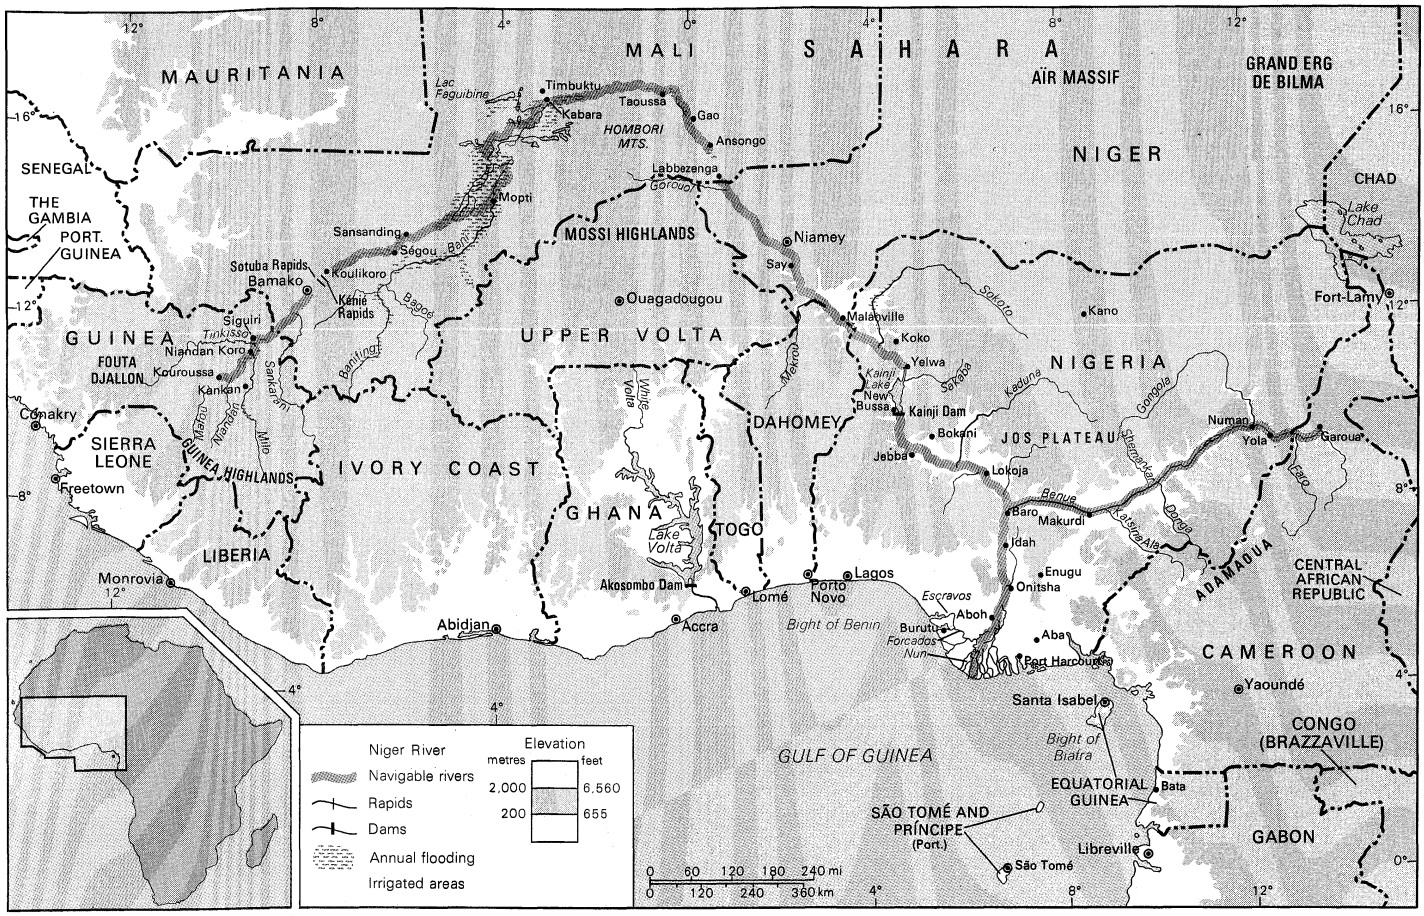
The Benue, (signifying "Mother of Water" in the Batta tongue), rises at 4,400 feet above sea level on the Adamawa (Adamaoua) Plateau in northern Cameroon at about 7°40′ N and 13°15′ E. In its upper course, which extends north–northwest to its confluence with the Mayo Kebi, close to the town of Garoua, it is a mountain torrent, falling more than 2,000 feet over a distance of 110 miles. The river then turns westward and, for the greater part of its course, flows over a broad and fertile floodplain. At Yola (Jimeta), a town in northeastern Nigeria 600 feet above sea level, some 850 miles inland, the width of the river in flood is from 1,000 to 1,500 yards. Near Numan, some 40 miles downstream from Yola, the Benue is joined on its north bank by its most important tributary, the Gongola. Other important tributaries include the Shemankar, the Faro, the Donga, and the Katsina Ala.

Together with its tributaries, the Niger drains a total area of more than 730,000 square miles. The Niger drainage system is bounded in the south by such highlands as the Fouta Djallon, the Kong Mountains, the Yoruba Hills, and the Cameroon Highlands. This southern rampart forms a watershed separating the rivers of the Niger system from others that flow directly southward to the Atlantic Ocean. With the exception of such highlands as the Jos Plateau, and the Adrar des Iforas, the Aïr, and the Haggar Mountains to the northeast, the northern edge of the Niger Basin is, however, less clearly defined than the southern edge.

Climate and hydrology. Within the Niger Basin, climate shows great variability. Mean annual rainfall decreases northward from over 160 inches in the delta area to under 10 inches in Timbuktu. Both the upper and the lower stretches of the river, however, drain areas with more than 50 inches of rain per annum. The middle Niger is an area where rainfall decreases and is also the sector where the greatest amount of evaporation takes place. It is estimated that in the lake region the Niger loses nearly 65 percent of the annual volume of discharge that flows past Mopti.

Because of climatic variations, the annual river flood does not occur at the same time in different parts of the basin. In the upper Niger the high-water discharge occurs in June, and the low-water season is in December. In the middle Niger, a first high-water discharge—the white flood (so-called because of the light sediment content of the water)—occurs soon after the rainy season between July and October; a second rise—the black flood (so-called because of the greater sediment content)—begins in December with the arrival of floodwaters from upstream. May and June are the low-water months in the middle stretch. On the Benue, there is only one high-water season. Due to the more southerly location, this normally occurs from May to October—earlier than on the middle Niger. The lower Niger below its confluence with the Benue consequently has a high-water period that begins in May or June—about a month earlier than on the middle Niger—and a low-water period at least a month shorter, as rains in the south start earlier. In January there also occurs a slight rise of water due to the arrival of floodwaters from the upper Niger. The difference between high and low water often measures as much as 35 feet.

Vegetation and fauna. Along its course, the Niger traverses virtually all the vegetational zones in West Africa. The Fouta Djallon plateau, where the Niger rises, is covered by a sedge type of vegetation consisting of fine, wire-like tufts interspersed with bare rock surfaces. From the



Niger and Benue rivers.

Fouta Djallon to well below the Niger's confluence with the Benue, the river flows mainly through savannah grassland country. In the north of the grassland region, tall, tussocky grass is interspersed with fairly dense wooded vegetation. In the south, the grass becomes short and discontinuous, and thorny shrub and acacia wood occur. About the latitude of Onitsha, the river enters the high rain-forest belt, which merges below Aboh with the mangrove swamp vegetation of the Delta.

River fauna

Many fish are found in the Niger and its tributaries; the chief food species are catfish, carp, and Nile perch.

Other Niger fauna include the hippopotamus, at least three different types of crocodile (including the much-feared Nile crocodile), and a variety of lizards. There is a rich variety of bird life. Geese are found in the lake region; and heron, egrets, and storks are found both on the river and the lakes. The striking crown bird is found wherever there is open ground in the grassland zone, and pelicans and flamingos are particularly associated with the upper Benue area. Smaller riverain species include white-headed plover, crocodile bird, sandpiper, curlew, and green-red shank.

Human ecology. The Niger Valley is sparsely settled, although there are population concentrations in the lake region and in the Nupe area of Nigeria. In medieval times, the valley was the heartland of the Mali and Songhai empires, and some of the river towns date from this period. The ethnic pattern along the course of the river shows larger groups, such as the Bambara, the Malinke, the Songhai, and the Zerma, occupying both sides of the river until the Nigerian boundary is reached, after which many small ethnic groups are encountered. Fishing is an important activity along the length of the river system, especially during the dry season when the deep-sea and coastal fish catch is smallest. River fishing is a specialized occupation for certain ethnic groups such as the Bozo and Somono in the lake region, the Sorkawa on the middle Niger, the Kede and the Kakanda between Jebba and Lokoja, and the Wurbo and the Jukun on the Benue.

History of the mapping of the Niger. It was not until the late 18th century that systematic European attempts to find the source, direction, and outlet of the Niger were made. In 1795 Mungo Park, a Scottish explorer sent out by the African Association of London, travelled overland from the Gambia region and reached the Niger near Ségou where, on July 20, 1796, he established that the river flowed eastward. In 1805 he sailed over 1,500 miles down the river, seeking to reach its mouth, but lost his life at Bussa. In 1822 another Scottish explorer, Major Alexander G. Laing located but did not visit the source of the river. In 1830 two English explorers, Richard and John Lander, established the lower course of the Niger by canoeing down the river from Yauri, 60 miles above Bussa, to the Atlantic Ocean, via the Nun River passage. In the second half of the 19th century, two German explorers—Heinrich Barth, and Edward R. Flegel—in separate travels established the course of the Benue from its source to its confluence with the Niger.

Mungo Park's expedition

Irrigation and navigation. The irrigation of the Niger Valley—for the purpose of transforming it into a densely populated, agricultural corridor running through the interior of West Africa—has long been a goal of planners. The French colonial administration, for example, set up the Office du Niger in 1932 to study and develop the Niger Valley, and to plan the irrigation of large areas in the lake region. A barrage to raise the level of the Niger by some 14 feet was completed at Sansanding in 1947. Feeder canals were constructed, and by 1969 some 500,000 hectares had been irrigated for rice, cotton, sugarcane, and vegetable production. The British colonial administration, for its part, also encouraged irrigated rice cultivation in the Bida region. In 1964 a large irrigated sugar plantation was started at Bacita, below Jebba.

Hydroelectric development

The Niger is also a source of hydroelectricity. The largest project is the Kainji Dam in Nigeria, completed in 1969. A new lake 500 square miles in extent has been created upstream, offering opportunities for fishing and irrigation. It is proposed that another dam should be built

at Jebba in 1982 to add a further 500 megawatts to the installed capacity.

Most of the Niger River—more than 75 percent of its total length—is used by commercial shipping. From the Atlantic Ocean to Onitsha—232 miles—the river is navigable to oceangoing vessels the year around. From Onitsha to Lokojo, at the confluence of the Benue and the Niger, oceangoing vessels can move for ten months of the year, from June to March. Navigation in this stretch is made possible by the influx of water from the Benue River, which is at high level in June. From Lokojo to Jebba the Niger is navigable to all craft only from October to mid-November. Thus, Jebba is in effect the head of navigation of the Niger waterway, although extreme fluctuation in water level at times constitutes a major handicap to vessels plying beyond Lokojo. Above Jebba the Niger is navigable only to smaller craft. The Bussa Rapids, formerly an obstacle to navigation between Jebba and Yelwa, may have been effectively eliminated by the construction of the Kainji Dam and Reservoir.

Seasonal limits to navigation

Rail and road routes cross the river at many points. Two railway bridges span the river at Kouroussa and Jebba, and a third crosses the Benue at Makurdi. Road bridges have been built at Ségou, Malanville, Kainji, and Onitsha. Ferries carry traffic across the Niger at Bamako, Gao, Niamey, Yelwa, Lokoja, and Idah; and across the Benue at Garoua, Yola and Numan. Among ports used for riverboat traffic are Koulikoro, Timbuktu, Baro, Onitsha, Burutu, and Koko.

The coordination of multinational efforts to develop the Niger and its tributaries is the responsibility of the Niger River Commission, formed in 1963 by Nigeria, Niger, Mali, Guinea, Chad, Cameroon, the Ivory Coast, Dahomey, and Upper Volta. The Commission has sponsored a study of the navigational possibilities of the middle Niger from Gao (Mali) to Yelwa (Nigeria). There are also plans to develop more irrigation and fishing projects, especially in the Kainji Lake area in Nigeria.

Nightingale, Florence

Florence Nightingale, for her pioneering development of military and civilian nursing and of hospital care, is universally regarded as the founder of trained nursing as a profession for women. Her work made her a legend in her own time. She also made important contributions to the welfare of the soldier in peace and war, to military and civil hygiene, and to the foundation of British district nursing and the training of midwives.

Florence Nightingale, *c.* 1885.
By courtesy of the Gernsheim Collection, the University of Texas at Austin

The second daughter of William Edward Nightingale and Frances (Fanny) Smith, Florence Nightingale was born on May 12, 1820, at Florence, Italy, where her well-to-do parents were temporarily resident. She grew up in Derbyshire, Hampshire, and London, where her family maintained comfortable homes. She was educated largely by her father, who taught her Greek, Latin, French, German, Italian, history, philosophy, and mathematics. Throughout her life she read widely in many languages. Social life was generally unsatisfying for Miss Nightingale. On February 7, 1837, she believed that she had heard the voice of God informing her that she had a mission, but it was not until nine years later that she realized what that mission was. Meanwhile, she strove to escape to a life of her own. Her proposal to study nursing at a hospital was scotched. She was then persuaded to study Parliamentary reports, and in three years she was regarded by influential friends as an expert on public health and hospitals. In 1846 a friend sent Miss Nightingale the Year Book of the Institution of Protestant Deaconesses at Kaiserswerth, Germany, which trained country girls of good character to nurse the sick. Four years later she entered the institution and went through the full course of training as a nurse. In 1853 she was appointed superintendent of the Institution for the Care of Sick Gentlewomen, in London. The changes that she made and her administration were very successful. But she yearned for a wider field; by January 1854 she was referring to the institution as "this little molehill."

The beginning of her nursing career

The Crimean War broke out in March 1854, and the allied British and French armies landed on the Crimea in September. Almost at once the British conscience was dismayed by published graphic reports of the disgraceful conditions suffered by sick and wounded British soldiers. Women were urged to serve as nurses like the French Sisters of Charity. Miss Nightingale volunteered at once to leave in three days for Constantinople, taking three nurses with her. Meanwhile, she was officially approached by her old friend, the then secretary of state at war, Sidney Herbert (later Lord Herbert of Lea), to take out a much larger party of nurses. She was to have complete charge of the nursing in the military hospitals in Turkey (*i.e.*, at Scutari). The party left England on October 21, 1854, and entered the Barrack Hospital at Scutari on November 5.

On her party's arrival she found that they had no decent facilities whatever. Their quarters were flea and rat infested, and the water allowance was one pint per head per day for all purposes. She had to use the provisions brought with her. The doctors were hostile, and at first the nurses were not allowed in the wards. After the Battle of Inkerman (fought on the very day of her arrival) the hospital was soon grossly overcrowded with sick and wounded. Furniture, clothing, and bedding were deficient, and in the corridors men lay on straw palliasses amidst filth caused by inadequate sanitation. Miss Nightingale was then asked to help, and one of her first requisitions was for 200 scrubbing brushes. She next arranged for the patients' filthy clothes to be washed outside the hospital.

All supplies had completely broken down, but Miss Nightingale had authority to purchase outside the hospital; she had brought £30,000 with her. By the end of the year she was purveying the hospital. She was harrassed by the cares of administration, a vast correspondence, the writing of numerous official and private reports, as well as by the insubordination of her nurses, some of whom had to be sent home because of drunkenness or immorality. She spent many hours a day in the wards, and there was scarcely a man whom she had not personally attended. After 8:00 PM she would allow no woman in the wards except herself. The night nursing—such as it was—was done by convalescent orderlies. Each night, however, she made her rounds, giving comfort and advice and establishing the wounded soldiers' conception of "The Lady with the Lamp."

By May 1855 nursing the sick had become her secondary interest, and her prime concern now was the welfare of the British Army. She now transferred herself and some of her nurses to the Crimea, and on landing at Balaklava she was very ill with Crimean fever. Then her opponent, the inspector general of hospitals, contended that she had authority only at Scutari and none in the Crimea. It was not until March 16, 1856, that her position as general superintendent of the Female Nursing Establishment of the Military Hospitals of the Army was confirmed in general orders.

Shortly after the last patient left the Barrack Hospital, Miss Nightingale sailed for England, where she had long been a national hero. But she refused official transport home and every kind of public reception. Miss Nightingale returned home determined to destroy her popular image and to inaugurate official action to improve the health, living conditions, and food of the British soldier. In the first she succeeded extraordinarily well. In the second she encountered difficulties, as the important men regarded her scheme tolerantly but without enthusiasm. In October 1856, however, she had a long interview with Queen Victoria, the Prince Consort, and Lord Panmure, Herbert's successor. She later had a private interview with the Queen, and Panmure promised a royal commission.

Soldiers' welfare and training of nurses

The Royal Commission on the Health of the Army was appointed in May 1857. Miss Nightingale gave extensive evidence and compiled an immense confidential report, covering the whole field of army medical and hospital administration, which was later privately printed as her *Notes on Matters Affecting the Health, Efficiency and Hospital Administration of the British Army* (1858). One consequence of the commission's activities was the foundation of the Army Medical School in 1857. The Indian Mutiny in the same year turned Miss Nightingale's interest to the health of the Army in India, and for that purpose another royal commission was appointed in 1859. This resulted in 1868 in the establishment of a Sanitary Department in the India Office with supreme authority in India.

Meanwhile, Miss Nightingale had been engaged in other pioneering activities. In 1860 she used the Nightingale Fund of £45,000, subscribed by the public to commemorate her Crimean work, to establish at St. Thomas's Hospital the Nightingale School for Nurses—the first of its kind in the world. Within a few years she was largely instrumental in inaugurating training for midwives and for nurses in workhouse infirmaries, and she played a part in the reform of workhouses. All these works were accomplished by a woman generally supposed to have died. From 1857 Miss Nightingale had lived, mainly in London, as an invalid. Her correspondence was enormous. Lying on her couch year after year, she received innumerable visitors, from the highest to the humblest, and few came who did not give information or receive it. Although she had never been to India, she was an acknowledged master of most things Indian, and successive viceroys consulted her before assuming their offices. She drove her influential friends to obtain for her those things that she felt her cause needed. When Sidney Herbert, a dying man, was forced to discontinue his active cooperation in their work, she sent him a very cruel letter.

It has never been shown that Florence Nightingale had any organic illness; her invalidism may have been partly neurotic and partly intentional. By this apparent stratagem she was able to devote herself night and day to the task at hand. Her sight gradually failed, until in 1901 she became completely blind. In 1907 the king conferred on her the Order of Merit—the first woman ever to receive it. Florence Nightingale died on August 13, 1910. The offer of a national funeral and burial in Westminster Abbey was, by her wish, declined. Her coffin was borne to the family grave in the country churchyard of East Wellow, Hampshire, by six sergeants of the British Army.

BIBLIOGRAPHY. SIR EDWARD COOK, *The Life of Florence Nightingale*, 2 vol. (1913), still the most comprehensive and completely documented biography; CECIL WOODHAM-SMITH, *Florence Nightingale, 1820–1910* (1950, reprinted 1964), a full and well-written modern biography; SIR ZACHARY COPE, *Florence Nightingale and the Doctors* (1958), very valuable in its field; LYTTON STRACHEY, essay in *Eminent Victorians* (1918, reprinted 1969), a brilliant sketch, but must be read with attention to subtle bias.

Nijinsky, Vaslav

The leading dancer of the Mariinsky Theatre of St. Petersburg (now Leningrad) and of Sergey Diaghilev's great Ballets Russes, Vaslav Nijinsky created a new epoch in the dance and won almost legendary fame in doing so. His choreographies are noted for their rejection of the conventional forms of classical ballet and of the even then old patterns and structure of both the Classical and Romantic styles of dancing. Nijinsky was in search of pure line in movement and free form of expression.

The second son of Thomas Laurentiyevich Nijinsky and Eleonora Bereda, Vaslav was born in Kiev, Ukraine, on March 12 (February 28, old style), 1890. Both his parents were celebrated dancers, and his father in particular was famous for his virtuosity and enormous leaps. The Nijinskys had their own dance company and performed throughout the Russian Empire. Nijinsky's childhood was mostly spent in the Caucasus, where he danced as a small child with his brother Stanislav and his little sister Bronisława. His father, noticing the child's great disposition for

Nijinsky in *Spectre de la rose*.

dancing, gave him his first lessons, and at the age of nine, at the end of August 1898, Nijinsky entered the Imperial School of Dancing in St. Petersburg, where his teachers, the foremost of the time, soon discovered his extraordinary talent. When he was 16 years old, they urged him to graduate and enter the Mariinsky Theatre. Nijinsky declined, preferring to fulfill the customary period of study. At the time he already had been heralded as the "eighth wonder of the world" and the "Vestris of the North" (in reference to Auguste Vestris, a famous French dancer of the 18th century). During his school years he appeared at the Mariinsky Theatre, first as a member of the *corps de ballet*, later in small parts. He danced in St. Petersburg before the Tsar at the Chinese Theatre of Tsarskoe Selo and the Hermitage Theatre of the Winter Palace.

Association with the Mariinsky Theatre

Nijinsky graduated in the spring of 1907 and on July 14, 1907, joined the Mariinsky Theatre as a soloist. His first appearance was in the ballet *La Source* with the Russian ballerina Julia Sedova as his partner; the public and the ballet critics burst out immediately in wild enthusiasm. Among his Mariinsky partners were three great ballerinas, Mathilde Kschessinskaya, Anna Pavlovna Pavlova, and Tamara Platonovna Karsavina. As *danseur noble*, he danced the leading parts in many ballets, including *Ivanotschka, Giselle, Swan Lake, The Sleeping Beauty*, and *Chopiniana*. From 1907 to 1911 Nijinsky danced all of the leading parts at the Mariinsky Theatre and at the Bolshoi Theatre in Moscow, where he was a guest performer. His success was phenomenal.

In 1909 Sergey Diaghilev, former assistant to the administrator of the Imperial Theatres, was commissioned by the grand duke Vladimir to organize a ballet company of the members of the Mariinsky and Bolshoi theatres. Diaghilev decided to take the company to Paris in the spring and asked Nijinsky to join as principal dancer. Its first performance was on May 17, 1909, at the Théâtre du Châtelet. Nijinsky took Paris by storm. The expression and beauty of his body, his featherweight lightness and steellike strength, his great elevation and incredible gift of rising and seeming to remain in the air, and his extraordinary virtuosity and dramatic acting made him a genius of the ballet. From 1907 to 1912 he worked with the company's choreographer, Michel Fokine. With his phenomenal talent for characterization, he created some of his most renowned roles in Fokine's *Le Carnaval, Les Sylphides* (a revision of *Chopiniana*), *Le Spectre de la rose, Shéhérazade, Petrushka, Le Dieu bleu, Daphnis et Chloé*, and *Narcisse*. His later ballets were *Mephisto Valse, Variations on the Music of Johann Sebastian Bach, Les Papillons de nuit*, and *The Minstrel*. Until 1917 Nijinsky appeared all over Europe, in the United States, and in South America. He was called *le dieu de la danse*.

Principal dancer with Diaghilev's Ballets Russes

In 1912 he began his career as a choreographer. He created for Diaghilev's Ballets Russes the ballets *L'Après-midi d'un faune, Jeux*, and *Le Sacre du printemps. Tyl Eulenspiegel* was produced in the United States without Diaghilev's personal supervision. His work in the field of choreography was generally considered daringly original.

Nijinsky married Romola, countess de Pulszky-Lubocy-Cselfalva, in Buenos Aires on September 10, 1913. During part of World War I and again in World War II, he was interned in Hungary as a Russian subject. In 1919, at the age of 29, he retired from the stage, owing to a nervous breakdown, which was diagnosed as schizophrenia. He lived from 1919 until 1950 in Switzerland, France, and England, and died in London on April 8, 1950. Nijinsky is buried next to Auguste Vestris in the cemetery of Montmartre in Paris.

BIBLIOGRAPHY. The standard biographies, both by his wife, ROMOLA NIJINSKY, are *Nijinsky* (1933), and *The Last Years of Nijinsky* (1952). Other important studies are GEOFFREY WITHWORTH, *Nijinsky* (1911); CYRIL W. BEAUMONT, *Nijinsky* (1932); and COLIN WILSON, *The Outsider* (1956). Nijinsky's diary was published as *The Diary of Vaslav Nijinsky* (1936). *Nijinsky As We Knew Him* (1972), is a collection of reminiscences of the dancer by such prominent writers, artists, musicians, and dancers as Paul Claudel, Jean Cocteau, Auguste Rodin, Marcel Proust, Sergei Prokofiev, and Tamara Karsavina.

(R.Ni.)

Nikon

Russian patriarch and the leader of a reform movement that caused a schism in the Russian Orthodox Church, Nikon (Nikita) was born in 1605 in the village of Veldemanovo, near Nizhny Novgorod (now Gorky), the son of a peasant of Finnic stock. After acquiring the rudiments of an education in a nearby monastery, Nikon married, entered the clergy, and settled in Moscow, until the death of all three of his children moved him to seek repentance and solitude. For the next 12 years, from 1634 to 1646, he lived as a monk, as a hermit, and finally as an abbot in several northern localities. In 1646 he went on monastic business to Moscow, where he made so favourable an impression on the young tsar Alexis and on Patriarch Joseph that they appointed him abbot of the Novospassky monastery in Moscow, the burial place of the Romanov family. During his stay there, Nikon became closely associated with the circle led by the Tsar's confessor, Stefan Vonifatyev, and the priests Ivan Neronov and Avvakum Petrovich (all, like him, natives of the Nizhny Novgorod region), which strove to revitalize the church by bringing about closer contact with the mass of the faithful and to purify religious books and rituals from accidental errors and Roman Catholic influences. With their backing, Nikon became first metropolitan of Novgorod (1648) and then patriarch of Moscow and all Russia (1652).

Tass—Sovfoto

Nikon, portrait by an unknown artist, 1687.

Nikon accepted the highest post in the Russian Church only on condition that he be given full authority in matters of dogma and ritual. In 1654, when the Tsar departed for the campaign against Poland, he asked Nikon to supervise the country's administration as well as watch over the safety of the Tsar's family; and in 1657, with the outbreak of the new war with Poland, he invested him with full sovereign powers. Enjoying the friendship of the Tsar, the backing of the reformers, and the sympathy of the population of Moscow, Nikon stood at the pinnacle of his career.

It was not long, however, before Nikon alienated his friends and infuriated his opponents by his brutal treatment of all those who disagreed with him. On assuming the patriarchate, he consulted Greek scholars employed in Moscow as well as the books in the patriarchal library and concluded not only that many Russian books and practices were badly corrupted but also that the revisions of the circle of vonifatyev had introduced new corruptions. He

Nikon's reforms

then undertook a thorough revision of Russian books and rituals in accord with their Greek models to bring them in line with the rest of the Orthodox Church. When his onetime friends questioned his reforms, Nikon had them exiled. Assisted by Greek and Kievan monks and supported by the Greek hierarchy, he next carried out several reforms of his own: he altered the form of bowing in the church, replaced a two-fingered manner of crossing oneself with a three-fingered one, and ordered that three alleluias be sung where Moscow tradition called for two. A council of the Russian clergy that he convened in 1654 authorized him to proceed with the revision of liturgical books. He next began to remove from churches and homes icons that he considered incorrectly rendered. To quell mounting opposition to these moves, he called in 1656 another council, which excommunicated those who failed to adopt the reforms.

Though all the changes introduced by Nikon affected only the outward forms of religion, some of which were not even very old, the population and much of the clergy resisted him from the beginning. The uneducated Muscovite clergy refused to relearn prayers and rituals, while the mass of the faithful was deeply troubled by Nikon's contempt for practices regarded as holy and essential to Russia's salvation. This was the origin of the Raskol, or great schism within the Russian Orthodox Church. Yet what really brought about Nikon's downfall was the hostility of the Tsar's family and the powerful boyar (aristocratic) families, who resented the high handed manner in which he exercised authority in the Tsar's absence. They also objected to his claims that the church could interfere in affairs of state but was itself immune to state interference.

When Alexis returned to Moscow in 1658, relations between Tsar and Patriarch were no longer what they had been. Grown in self-confidence and incited by relatives and courtiers, Alexis ceased to consult the Patriarch, though he avoided an open break with him. Nikon finally struck back after several boyars had insulted him with impunity and the Tsar failed to appear at two consecutive services at which Nikon officiated. On July 20 (July 10, old style), 1658, in characteristically impetuous fashion he announced his resignation to the congregation in the Church of the Assumption in the Kremlin, and shortly afterward he retired to the Voskresensky monastery.

Nikon had apparently hoped by this act to compel the Tsar, whose piety was well known, to recall him and to restore his previous influence. This did not happen. After several months in self-imposed exile, Nikon began to regret his decision and attempted a reconciliation, but the Tsar either refused to answer his letters or urged him to formalize his resignation. Nikon refused to do so on the ground that he had resigned merely from the Moscow see, not from the patriarchate as such. For eight years, during which Russia was effectively without a patriarch, Nikon stubbornly held on to his post, while Alexis, troubled by lack of clear precedent and by the fear of damnation, could not decide on a formal deposition. Finally, in November 1666, Alexis convened a council attended by the patriarchs of Antioch and Alexandria to settle the dispute. The charges against Nikon were presented by the Tsar himself. They concerned largely his behaviour in the period of the Tsar's absence from Moscow, including his alleged arrogation of the title of "grand sovereign." Many of the charges were entirely without foundation. The Greek hierarchy now turned against Nikon and decided in favour of the monarchy whose favours it needed. A Greek adventurer, Paisios Ligaridis (now known to have been in collusion with Rome), was particularly active in bringing about Nikon's downfall. The council deprived Nikon of all his sacerdotal functions and on December 23 exiled him as a monk to Beloozero, about 350 miles directly north of Moscow. It retained, however, the reforms he had introduced and anathemized those who opposed them and who were henceforth known as Old Ritualists (or Old Believers). In his last years, Nikon's relations with Alexis improved. The succeeding tsar, Fyodor III, recalled Nikon from exile; but he died on August 27, 1681, en route to Moscow.

Exile

Nikon was one of the outstanding leaders of the Russian Orthodox Church, an able administrator, and a man of principle. His ultimate failure was due to two main factors: (1) his insistence on the hegemony of church over state had no precedent in Byzantine or Russian traditions and could not be enforced in any event; and (2) his uncontrollable temper and autocratic disposition alienated all who came in contact with him and enabled his opponents first to disgrace and then to defeat him.

Nile River

The Nile, the father of African rivers and the longest river in the world, rises south of the Equator and flows northward through northeastern Africa to drain into the Mediterranean Sea. It has a length of about 4,132 miles (6,648 kilometres) and drains an area estimated at 1,293,000 square miles (3,349,000 square kilometres). Its basin includes parts of Tanzania, Burundi, Rwanda, Zaire, Kenya, Uganda, most of The Sudan, Ethiopia, and the cultivated part of Egypt. It supports a population estimated at about 50,000,000 people in the mid-1960s. Its most distant source is the Kagera River in Burundi.

The Nile is formed by three principal streams, the Blue Nile and the Atbara, which flow from the Highlands of Ethiopia, and the White Nile, the headstreams of which flow into lakes Victoria and Albert.

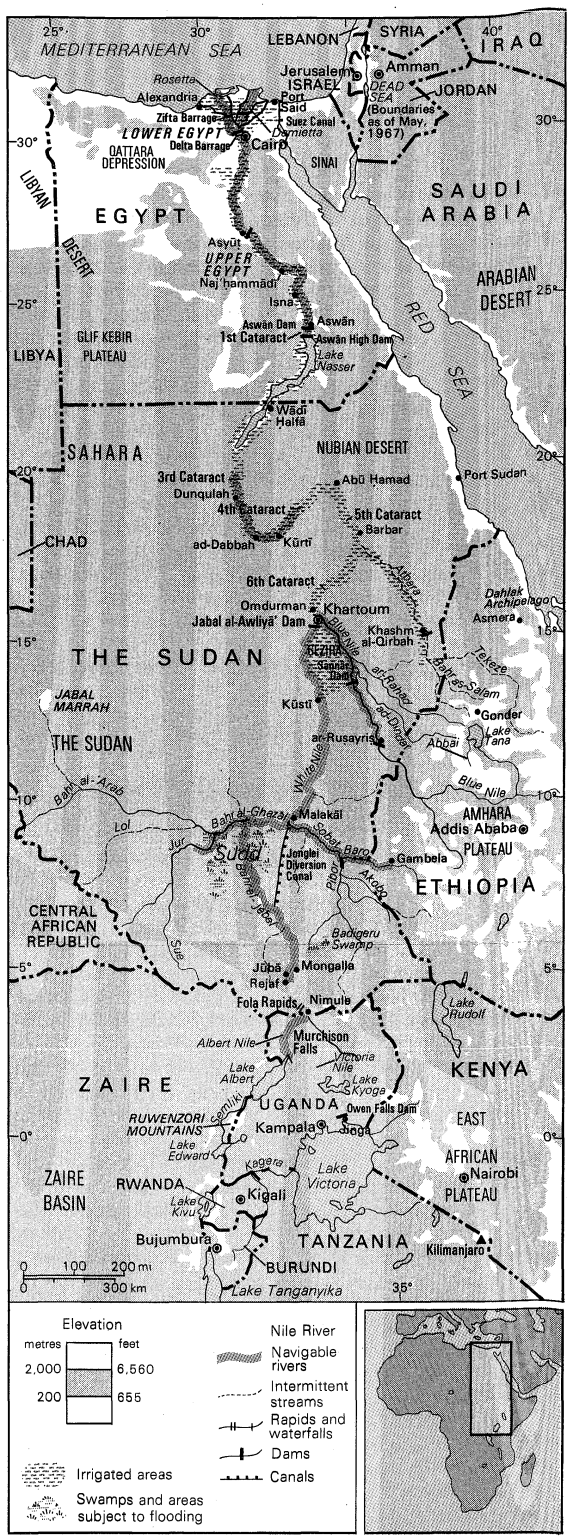
Origin of the name

The name Nile comes from the Greek Neilos (Latin Nilus), which is probably derived from the Semitic root *naḥal*, meaning a valley or river valley, and hence, by an extension of the meaning, a river. The fact that the Nile, unlike other great rivers known to them, flowed from the south northward, was an unsolved mystery to the ancient Egyptians and Greeks. The ancient Egyptians called the river Ar or Aur (Coptic Iaro), or "black," in allusion to the colour of the sediments carried by the river when it is in flood. Nile mud is black enough to have given the land itself its oldest name, Kem or Kemi, which also means "black" and signifies darkness. In *The Odyssey*, the epic poem written by the Greek poet Homer (7th century BC), Aigyptos is the name of the Nile (masculine) as well as the country of Egypt (feminine) through which it flows. The Nile in Egypt and northern Sudan is now called an-Nīl, al-Baḥr (the sea), and Baḥr an-Nīl or Nahr an-Nīl (the River Nile). (For physical features, see EAST AFRICAN LAKES; EAST AFRICAN MOUNTAINS; SAHARA.)

THE NATURAL ENVIRONMENT

The Nile Basin. The Nile River Basin, which covers about one-tenth of the area of the continent, served as the stage for the evolution and decay of advanced civilizations in the ancient world. On the banks of the river dwelled men who were the first to cultivate the arts of agriculture and the first to use the plow. The basin is bordered on the east by the Red Sea and the Ethiopian Highlands; on the west by the less well-defined watershed between the Nile, Chad, and Congo basins, extending northwest to include the Jabal Marrah (Marra Mountains) of The Sudan, the Glif Kebir Plateau, and the Libyan Desert (part of the Sahara); on the south, by the East African Highlands north of Lake Victoria, a Nile source; and on the north, by the Mediterranean.

The availability of water from the Nile throughout the year, combined with the area's unusually high temperature, makes possible intensive cultivation along its banks. Even in some of the regions in which the average rainfall is sufficient for cultivation, such as The Sudan, marked year to year variations in precipitation often make cultivation without irrigation hazardous. The Nile is also a vital waterway for transport, especially when motor transport is not feasible; *e.g.*, during the flood season. Recent improvements in air, rail, and highway facilities, however, have reduced dependency on the waterway.



The Nile River Basin and its drainage network.

Physiography of the Nile. *Origin and sources.* It is thought that in the mid-Tertiary Period (approximately 30,000,000 years ago), the early Nile, then a much shorter stream, had its sources about latitude 18° to 20° N. Its main headstream may then have been the present Atbara River. To the south lay the vast enclosed drainage system containing the large Lake Sudd. In a later stage (about 20,000 to 25,000 years ago), the East African drainage system—that of Lake Victoria—developed a new outlet, which sent its water northward into Lake Sudd. With the accumulation of sediments over a long period, the water level of this lake rose gradually; as a result of the overflow, the Sudd was drained, spilling over to the north. The overflow waters of Lake Sudd, rapidly forming a riverbed, linked the two major parts of the Nile system, thus unifying the drainage from Lake Victoria to the Mediterranean Sea.

The basin of the present-day Nile falls naturally into seven major regions.

The Lake Plateau of East Africa. The Lake Plateau region produces a number of headstreams and lakes that feed the White Nile. It is generally agreed that the Nile has several sources rather than one. The furthest headstream may be regarded as the Kagera River, which rises in the highlands of Burundi near the northern tip of Lake Tanganyika and then flows into Lake Victoria. The Nile proper, however, rises from Lake Victoria, the third largest lake in the world, which has an area over 26,800 square miles and forms a huge but shallow lake. The Nile begins near Jinja, Uganda, on the north shore of the lake, flowing northward over Ripon Falls, which has been submerged since the construction of the Owen Falls Dam in 1954. The northward stretch of the river, known as the Victoria Nile, enters the shallow Lake Kyoga (Kioga) and, passing through its swamp vegetation, flows out in a westerly direction, descending into the East African Rift Valley over Murchison Falls before entering the northern end of Lake Albert. Unlike Lake Victoria, Lake Albert is a deep, narrow lake with mountainous sides. Here the waters of the Victoria Nile unite with the lake waters, passing northward as the Albert Nile, a portion of the river, somewhat wider and slower, that is fringed with swamps and navigable for steamers.

Sources of the Nile

Bahr el-Jebel. At Nimule the Nile enters The Sudan rapidly over steep slopes and gorges and is called the Bahr el-Jebel (the River of Mountain). About four miles below Nimule lie the Fola Rapids, where the river is confined between rocky walls. It is not until Rejaf, about 100 miles downstream, that the river flows smoothly onto the huge and extremely flat clay plain, which extends through a narrow valley with hill country on either side, lying some 1,200 to 1,500 feet above sea level, and through the centre of which flows the mainstream. As the gradient of the Nile is here only 1:13,000, the great volume of additional water that arrives during the rainy season cannot be accommodated by the river, with the result that almost the entire plain becomes inundated. This circumstance promotes the growth of enormous quantities of swamp vegetation, including tall grasses and a tall reedlike papyrus known as sudd, literally meaning "barrier." The general term sudd is applied to the area because the great masses of vegetation, the growth of which is helped by the gentle flow of the water, break off and float downstream, choking the mainstream and locking the navigable channels. Channels have become further choked since 1957 by the rapid spread of the South American water hyacinth.

This basin receives drainage from numerous other streams. The Baḥr el-Ghazāl (River of Gazelles) flows in from the southwestern Sudan, joining the Bahr el-Jebel at Lake No, a large lagoon where the mainstream takes an easterly direction. The Baḥr el-Ghazāl looks impressive on a map, but its waters undergo such extensive loss through evaporation that only a small proportion of them ever reach the Nile. From the Ethiopian mountains to the southeast, the mainstream is joined by the Sobat—which from that point is called the White Nile—a short distance above Malakāl. The Sobat, the regime of which is quite different from that of Bahr el-Jebel, is an important source of water that compensates for the water lost through evaporation in the marshes.

The White Nile (al-Baḥr al-Abyaḍ). The White Nile, about 500 miles in length, is the longest branch of the Nile and supplies two-sevenths of its volume. It begins at Malakāl and joins the Blue Nile at Khartoum, receiving no tributaries of importance. Throughout this stretch it is a wide, placid stream with a very small slope (the gradient is no more than 1:19,000), often having a narrow fringe of swamps; the swamps have an average width of about 400 yards, but they are much wider in some places. The valley is wide and shallow, thus causing a considerable loss of water both by evaporation and seepage.

The Blue Nile (al-Baḥr al-Azraq). The Blue Nile drains from the lofty Ethiopian mountains north-northwestward, where it descends from a height of 6,000 feet above sea level. Its reputed source is a small spring, considered holy by the Orthodox Church of Ethiopia, from which a small stream, the Abbai, flows down to Lake Tana, a fairly shallow lake (with an area of about 1,400 square miles) that lies 6,000 feet above sea level. The river leaves Lake Tana in a southeasterly direction, flowing through a series of rapids and plunging through a deep gorge. It is estimated that the lake supplies the river with only one-fourteenth of its total flow, but this is important since it is silt-free. The river then flows west and northwest through The Sudan to join the White Nile at Khartoum. In the greater part of its course from Lake Tana down to The Sudan plains, it runs in a canyon that in places is 4,000 feet below the general level of the plateau. All its tributaries also run in deep ravines. While the White Nile at Khartoum is a river of almost constant volume, it is the Blue Nile that contributes to the Nile floods, which occur in Egypt in September as a result of the seasonal rains the river receives from its torrential tributary streams.

Source of the Blue Nile

The Atbara. The Atbara, the last tributary of the Nile, flows into the mainstream nearly 200 miles north of Khartoum. It rises in Ethiopia at heights of 6,000 to 10,000 feet above sea level, not far from Gonder, to the north of Lake Tana. The two principal tributaries that feed the Atbara are the Baḥr as-Salam and the Satīt, or Tekeze (the Terrible). The Satīt is the most important of these, having a basin more than double the area of the Atbara itself. It rises among the high peaks of Amhara and flows north through a spectacular gorge to join the Atbara in The Sudan. For most of its course in The Sudan, the Atbara is well below the general level of the plains. Between the plains and the river, the ground is eroded and cut into by gullies formed by water running off the plains after rainfall. The Atbara rises and falls rapidly, like the Blue Nile. In flood it becomes a large muddy river, and in the dry season it is a string of pools.

The Nile north of Khartoum. Along this stretch, which is sometimes called the United Nile, two parts can be distinguished. The first part, which stretches from Khartoum to Wādī Ḥalfā', is about 930 miles in length; the river is never far from the desert, and the desert often forms the riverbank. The second part consists of the stretch from Wādī Ḥalfā' (where the river enters Egypt) to Cairo, where the Nile Delta begins—a stretch along which cultivation is feasible.

Below Khartoum, the Nile flows 50 miles northward until it reaches Sablūkah (Sababka), the site of the sixth and highest cataract. Here the river cuts through hills for a distance of eight miles. Flowing northward at Barbar, the river takes an S-bend, in the middle of which, from Abū Ḥamad to Kūrtī and ad-Dabbah (Debba), the river flows southwestward for about 170 miles. At the end of this bend, at Dunqulah, it starts taking a northeasterly direction, crossing the second cataract below Wādī Ḥalfā'.

The cataracts

For the 1,200 miles from the sixth cataract to Aswān, the riverbed alternates between gentle stretches and series of rapids. Outcropping crystalline rocks that cross the course of the Nile cause the five famous cataracts. Because of these cataracts, the river is not completely navigable, although sections between the cataracts are navigable by sailing vessels and by river steamers. Since the land on both sides of the river in this stretch is not suitable for cultivation, the desert course of the Nile serves mainly to transport the water to Egypt. The Nile is navigable throughout Egypt from as far south as Aswān.

From the Sudanese border to Cairo, the Nile flows in a relatively narrow, flat-bottomed groove, sinuous in outline and generally incised into underlying sandstone and limestone rock surface; the gradient is approximately 1:14,000 over a distance of about 700 miles. For the first 250 miles it flows over sandstone in a narrow valley that is, on the average, less than two miles wide (although narrowing in some parts to a width of only 220 yards), except at Aswān, where resistant igneous and metamorphic rocks (*i.e.*, rocks formed by heat and pressure) appear in the rapids of the first cataract. The river then flows northward for about 500 miles through a valley that consists of a level-floored groove in a limestone plateau, averaging ten to 14 miles in width and enclosed by scarps that rise in places to heights of 1,500 feet above the river level. For the last 200 miles of its course before reaching Cairo, the Nile shows a strong tendency to hug the eastern edge of the valley floor, so that the greater part of the cultivated land is found on the left bank.

The Nile Delta. North of Cairo, the head of the alluvial plain of Lower Egypt, the walls of the plateau that form the Nile Valley become ill defined and diverge from each other, leaving between them the triangular lowland that forms the Nile Delta. In the 1st century AD, the Greek geographer Strabo recorded the Nile as having seven delta distributaries. The flow has since been controlled, so that the river now flows across the delta to the sea through two main distributaries, the Rosetta and the Damietta branches.

The Nile Delta, the prototype of all deltas, comprises a gulf of the prehistoric Mediterranean Sea that has been filled in; it is composed of silt brought mainly from the Ethiopian Highlands. The silt varies in its thickness from 50 to 75 feet and comprises the most fertile soil in Africa. It forms a monotonous plain that extends 100 miles from north to south, its greatest width being 155 miles between Alexandria and Port Said; altogether it covers an area twice that of the Nile Valley in Upper Egypt. The land surface slopes gently to the sea, falling some 52 feet from Cairo in a gentle gradient of 1:10,000. In the north, on the seaward border, are a number of shallow brackish lagoons and salt marshes: Buḥayrat Maryūṭ (Lake Marout), Buḥayrat Idkū (Edku), Buḥayrat al-Burullus (Burullus), and Buḥayrat al-Manzilah (Menzalah).

Climate. There is hardly an area within the Nile Basin that experiences a true Equatorial or a true Mediterranean type of climate. While almost the whole of the basin is rainless during the northern winter, its southern parts and the Highlands of Ethiopia experience heavy rain, amounting to over 60 inches, during the northern summer. The greater part of the region falls under the influence of the trade winds, which flow from the northeast in the Northern Hemisphere and from the southeast in the Southern Hemisphere, and account for the prevailing aridity of most of the basin.

Rainfall

Tropical climate with well-distributed rainfall is found in parts of the Lake Plateau and southwest Ethiopia. On the Lake Plateau there is little variation throughout the year in the mean temperature, which ranges from 60° F to 80° F (16° C to 27° C) depending on locality and height. Relative humidity, which varies similarly, is about 80 percent on the average. Similar climatic conditions prevail over the extreme southern parts of The Sudan, which receive as much as 50 inches of rain spread over a nine-month period (March–November), with the maximum occurring in August. At the beginning and end of the rainy season, strong and sudden windstorms may occur. The humidity reaches its highest at the peak of the rainy season and reaches its low level between January and March. Maximum temperatures are recorded during the dry season (December to February) with the minimum occurring in July and August.

Northward, the rainy season gets shorter, and the amount of rainfall decreases. The rainy season, which occurs in the south from April to October, is confined to July and August in the northern part of central Sudan, where three seasons may be distinguished. The first of these is the pleasant, cool, dry winter, which occurs in December and January; this is followed by hot and very dry weather from March to June; this is followed, in turn, by a hot rainy period from July to October. The minimum temperature occurs in January and the maximum in May or June, when it rises to 94° F (34° C) in Khartoum. Only about ten inches of rainfall occur in the Gezira area, as compared with over 21 inches at Dakar, in Senegal, which is in the same latitude, 15° N. North of Khartoum less than five inches of rain falls annually, an amount insufficient for permanent settlement. In June and July the central parts of The Sudan are frequently visited by storms during which strong winds carry large

quantities of sand and dust. These storms, which are of three to four hours duration, are called haboobs.

A desert-type climate exists over most of the remainder of the area north to the Mediterranean. The principal characteristics of the northern Sudan and the desert of Egypt are aridity, a dry atmosphere, and a considerable seasonal, as well as diurnal, temperature range in Upper Egypt. Temperatures can surpass 100° F (38° C); in Aswān, for example, the mean daily maximum in June is 107° F (42° C). While no low temperatures are recorded anywhere in The Sudan or Egypt, winter temperatures decrease to the north. Thus, only Egypt has what could be called a winter season, which occurs from November to April, when the average temperature in Cairo is 52° F (11° C). In the hot summer season from May to October, temperatures average about 81° F (27° C). The rainfall in Egypt is of Mediterranean origin and falls mostly in the winter, with the amount decreasing toward the south. From eight inches on the coast, it falls gradually to a little over an inch in Cairo and to less than an inch in Upper Egypt. During the spring, from March to June, depressions from the Sahara or along the coast travel east, causing dry southerly winds, which sometimes results in a condition called khamsin. These are sandstorms or dust storms during which the atmosphere becomes hazy; on occasion they may persist for three or four days, at the end of which the phenomenon of a "blue" sun may be observed.

Plant and animal life *Vegetation.* In the areas where no irrigation is practiced, different zones of plant life may be roughly divided according to the amount of rainfall.

The tropical forest zone

Tropical rain forest is found along the Nile–Congo divide, in parts of the Lake Plateau, and in southwest Ethiopia. Heat and copious rainfall produce thick forests with a great variety of tropical trees and plants, including ebony, banana, rubber, bamboo, and coffee shrub. Savanna (grassland) forest, characterized by a sparse growth of thinly foliaged trees of medium height and a ground covering of grass and perennial herbs, occurs in large parts of the Lake Plateau, in parts of the Ethiopian plateau, in the area that fringes the Blue Nile near ar-Ruṣayris and in the southern Baḥr el-Ghazāl region.

On The Sudan plains, a mixture of thin bush, thorny trees, and open grassland, or true savanna, prevails. This area is swampy during the rainy season. This is particularly true of the Sudd region of the south central Sudan, an area of nearly 100,000 square miles. Here the vegetation includes papyrus; tall bamboo-like grasses; reed mace; ambatch, or turor; water lettuce; a species of convolvulus; and the South American water hyacinth.

North of latitude 10° there occurs a belt of thorny savanna or orchard shrub country characterized by small scattered tree stands, thornbush, and—after rain—grass and herbs. North of this, however, rainfall decreases and the vegetation thins out, so that the countryside is dotted with small thorny shrubs, mostly acacias; this area is known as shrub steppe. From Khartoum northward there is true desert, with scanty and irregular rainfall and no permanent vegetation at all except for a few stunted shrubs. Grasses and small herbs may be scattered along drainage lines after rainfall, but these die away in a few weeks. In Egypt, the vegetation near the Nile is almost entirely the result of irrigation and cultivation.

Animal life. Many varieties of fish are found in the Nile system. Notable among those found in the Lower Nile system are the Nile perch (which may weigh over 200 pounds), the bolti (tilapia), the barbel, several species of catfish, the elephant-snout fish, and the tiger fish, or water leopard. Most of these species and the sardine-like *Haplochromis*, the lungfish, and mudfish are found as far upstream as Lake Victoria. The common eel penetrates as far south as Khartoum, and the spiny eel is found in Lake Victoria.

The Nile crocodile, found in most parts of the river, has not yet penetrated the lakes of the Upper Nile Basin. Other reptiles found in the Nile Basin include the soft-shelled turtle, three species of monitor lizard, and some 30 species of snakes, of which more than half are venomous. The hippopotamus, once common throughout the Nile system, is now found only in the Sudd region of Sudan and to the south.

Fish

Many schools of fish that come to feed on the reddish-gray waters of the Nile, in Egypt, during the flood season may be reduced or disappear after the floodwaters are controlled by the High Dam at Aswān. Most of the species of the Nile fish are migrants; the dam may prevent such species from migrating to Lake Nasser. The diminution in the number of anchovies in the eastern Mediterranean has also been attributed to the reduction in the outflow of waterborne nutrients due to the construction of the dam.

MAN AND THE NILE

Human ecology. Nilote is the general term used to describe the people of the Upper Nile Basin. Much of southern Sudan is populated by Nilotic and Negro people consisting of such tribes as the Shilluk, the Dinka, and the Nuer, who are a mixture of Negro and Hamitic stock. The Hamites are lean, slender, brown people with aquiline features and frizzy hair; they include Nubians, Bejas, Gallas, and Somali, who also live on the banks of the Nile. The Dinka, a typical group living in the Sudd region, are a pastoral people who live a seminomadic life, grazing their cattle on the grasslands between rivers in the dry season and moving to the uplands when the lower land is flooded. There are also the Nilo-Hamites, who include the Bari, a people who resemble the Dinka in appearance and live in the country of Bahr el-Jebel south of Mongalla. The Azande, a Nigritic people who are of median height and copper coloured, live in the southern Baḥr al-Ghazāl and in Zaire (formerly Congo [Kinshasa]). The central zone of Sudan (between latitudes 10° and 15° N) is inhabited by pastoral Semitic people, but Muslim Arabs and Nubians, as well as Hamitic people, such as the Beja, predominate in the northern parts. While many different people are found in Ethiopia, most are classified as Hamitic. The ruling peoples of the country, the Amhara and the Galla, though both of Hamitic stock, have been subjected to strong Semitic influence. The remainder of the population is made up of many tribes of Negro people known as Shangalla. The modern Egyptian is still primarily of Hamitic stock intermixed with Semitic and Caucasian elements to the north and Nubian–Negro elements to the south. The Egyptian peasant is stocky; his facial features show some resemblance to those of the Arabs. The people of the purest Arab descent are the Bedouins of the desert.

The average population density in the cultivated parts of the Nile floodplain is more than 1,000 per square mile. This great population, composed mostly of peasant farmers (fellahin), can survive only by making the most careful use of the available land and water.

The large quantities of silt washed down from the rich Highlands of Ethiopia are deposited by the floodwaters in Egypt, where the fertility of the riverine lands has continued over the centuries, despite intensive cultivation. A vital feature in the life of the Egyptian people is the river's behaviour, since a good harvest follows a good flood, and a poor flood may mean a later food shortage.

Exploration and mapping of the Nile. The ancient Egyptians were probably familiar with the Nile as far as Khartoum and with the Blue Nile as far as its source in Lake Tana, but they showed little or no interest in exploring the White Nile. The source of the Nile was unknown to them, but the river was associated with the worship of the god Apis (Hapi), the bull of Memphis, since it provided them with water to irrigate their crops. The Greek historian Herodotus, who visited Egypt in 457 BC, travelled down the Nile as far as the first cataract (Aswān). About the second century BC, the Greek scientific writer Eratosthenes sketched a nearly correct route of the Nile to Khartoum, showing the two Ethiopian affluents, and suggested lakes as the source of the river.

Early exploration

About 30 BC the Greek explorers Bion, Dalion, and Simonides and the merchant Diogenes, explored the Nile above the first cataract and perhaps south of Khartoum. In 25 BC the Greek geographer Strabo and a Roman governor of Egypt, Aelius Gallas, also explored the Nile as far as the first cataract. A Roman expedition to find the

source of the Nile in AD 66, during the reign of the emperor Nero, was impeded by the Sudd, and the attempt was abandoned. Claudius Ptolemy, the Greek astronomer and geographer who lived in Alexandria, wrote in AD 150 that the White Nile originated in the high snow-covered Mountains of the Moon (since identified with the Ruwenzori Mountain Range).

From the 17th century onward, several attempts were made to explore the Nile. In 1613, Pedro Páez, a Spanish Jesuit priest, located the source of the Blue Nile. In 1786, the Scottish explorer James Bruce visited Lake Tana as well as the source of the Blue Nile. He was followed by a number of other 19th-century explorers of various nationalities. After Mohammed Ali, the Ottoman viceroy of Egypt, conquered the Sudan in 1821, he sent expeditions (between 1839 and 1842) to attempt to find the source of the Nile.

After the English explorers Richard Burton and John Speke made an expedition, during which Speke reached the southern end of Lake Victoria in 1858, Speke returned in 1860 with another Englishman, James Grant, and after more than a year reached the western end of Lake Victoria, discovered the Kagera, and reached the Ripon Falls in 1862. The last unexplored stretch of the Nile was identified when yet another English explorer, Sir Samuel White Baker, discovered Lake Albert in 1864. Although Speke and Baker between them had solved the mystery of the Nile's headstreams, doubts persisted and were only laid to rest when the Scottish soldier General Charles George Gordon and his officers followed the river and mapped part of it and Lake Albert. Later, further features of the region were identified when the Welsh explorer Sir Henry Morton Stanley and the German traveller Mehmed Emin Paşa travelled through the Semliki Valley and by Lake Edward in 1889, and Stanley discovered the Ruwenzori Mountain Range. Exploration and mapping has continued over the years: it was not until the 1960s, for example, that a detailed study of the upper gorges of the Blue Nile was completed.

WATER RESOURCES AND THEIR USE

Hydrology. The periodic rise of the Nile, which occurred as regularly as the revolution of heavenly bodies, remained an unsolved mystery until the discovery of the role of the tropical regions in its regime. In effect, there was little detailed knowledge about the hydrology of the Nile before the 20th century except for early records of the river level that the ancient Egyptians made with the aid of nilometers (gauges formed by graduated scales cut in natural rocks or in stone walls), some of which still remain. Today, however, no other river of comparable size has a regime that is so well known. The discharge of the mainstream, as well as the tributaries, is regularly measured at all points critical for irrigation.

The Nile flood

The Nile swells in the summer, the floods rising as a result of the heavy tropical rains of the Upper Nile Basin, both in Ethiopia and on the East African Plateau. In southern Sudan the flood begins in April, but the effect is not felt at Aswān, in Egypt, until July. The water then starts to rise and continues to do so throughout August and September, with the maximum occurring in mid-September. At Cairo, the maximum is delayed until October. The level of the river then falls rapidly through November and December and more rapidly through the succeeding months. From March to May the level of the river is at its lowest. Although the flood is a fairly regular phenomenon, it occasionally varies in volume and date.

Following the river from its sources, an estimate can be made of the contribution of the various lakes and tributaries in the Nile flood.

Lake Victoria, in effect, forms a plateau reservoir. Most of its water (86 percent) is from rainfall, while the rest is contributed by its main tributary, the Kagera, as well as other much smaller ones. Much of the water is lost by evaporation. Only 18 percent of the lake's water flows into the Victoria Nile to feed Lake Albert, which forms a natural reservoir with a total annual inflow of about 1,000,000,000 cubic feet. The Victoria Nile contributes about two-thirds of the total inflow in Lake Albert, the rest coming from tributaries (of which the Semliki is the most important) as well as from rainfall. The loss by evaporation is not as high as it is in Lake Victoria, thus permitting a large annual outflow down the Bahr el-Jebel of 780,000,000,000 cubic feet. In addition to the water it receives from the great lakes, the torrential tributaries of the Bahr el-Jebel supply it with about 17 percent of its water. The discharge of Bahr el-Jebel varies little throughout the year because of the regulatory effect of the large swamps and lagoons of the Sudd region. About half of its water is lost in this stage by seepage and evaporation. The average flow of water is estimated at 950,000,000,000 cubic feet per annum as it enters the Sudd region at Mongalla, but only an average of 600,000,000,000 cubic feet per annum leaves at Malakāl. In order to reduce water loss, it has been proposed that a canal be cut through the basin and maintained as an open waterway.

The White Nile provides a regular supply of water throughout the year. During April and May, when the mainstream is at its lowest level, 83 percent of its water comes from the White Nile. The White Nile obtains its water in roughly equal amounts from two main sources. The first source is the rainfall on the East African Plateau of the previous summer. This long delay in reaching the lower parts of the Nile is caused partly by the retention of water in Lake Victoria and partly by the slow flow in the flat Sudd region. The second source is the drainage of southwestern Ethiopia through the Sobat (contributed mainly by its two tributaries, the Baro and the Pibor) that enters the mainstream below the Sudd. The annual flood of the Sobat, a consequence of the Ethiopian summer rains, is to a great extent responsible for the variations in the level of the White Nile. The rains that swell its upper valley begin in April and cause widespread inundation over the 200 miles of plains through which the river passes, thus delaying the arrival of the rainwater in its lower reaches until November–December. Relatively small amounts of the mud carried by the Sobat's flood reach the White Nile.

The regime of the Blue Nile

The Blue Nile, the most important of the three great Ethiopian affluents, plays an overwhelming part in bringing the Nile flood to Egypt. It receives two tributaries in The Sudan—the Rahad and the Dindar—both of which also originate in Ethiopia. The regime of the Blue Nile is distinguished from that of the White Nile by the more rapid passage of its floodwater into the mainstream. The river level begins to rise in June, reaching a maximum level at Khartoum in about the first week in September.

The Atbara River draws its floodwater from the rains on the northern part of the Ethiopian Plateau, as does the Blue Nile. While the floods of the two streams occur at the same time, the Blue Nile is a perennial stream, while the Atbara, as mentioned, shrinks to a series of pools in the dry season.

The swelling of the Blue Nile causes the first floodwaters to reach the central Sudan in May. The maximum is reached in August, after which the level falls again. The rise at Khartoum averages more than 20 feet. When the Blue Nile is in flood it holds back the White Nile water, turning it into an extensive lake and delaying its flow. The Jabal al-Awliyā', about 45 miles south of Khartoum, increases this ponding effect.

The effect of the flood is not felt at Wādī Ḥalfā' (on the Egyptian border) until mid-June. At Aswān the maximum is delayed until September, when the total discharge amounts to a little over 24,700,000,000 cubic feet per day. Out of this amount the Blue Nile accounts for 68 percent, the Atbara 22 percent, and the White Nile 10 percent. In early May, the Nile discharge at Aswān drops to its minimum. At this time the total discharge of 1,600,000,000 cubic feet comes mainly from the White Nile, which contributes 83 percent, while the Blue Nile contributes 17 percent. On the average, 84 percent of the Nile water at Aswān comes from the Ethiopian Highlands, while 16 percent is contributed by the East African Lake Plateau system.

Irrigation. As an aid to cultivation, irrigation almost certainly originated in Egypt. A particular phenomenon

that makes irrigation from the Nile feasible is the slope of the land from south to north—which amounts to about five inches to the mile—as well as the slightly greater slope downward from the riverbanks to the desert on either side.

Basin irrigation

The first use of the Nile for irrigation in Egypt began when seeds were sown in the mud left after the annual floodwater had subsided. With the passing of time, these practices were refined until a traditional method emerged, which is known as basin irrigation, and is still practiced on less than 10 percent of the agricultural land, mainly in Upper Egypt. The fields on the flat floodplain are divided by earth banks into a series of large basins, which vary in size but may be as large as 50,000 acres. At the time of the flood, the Nile waters, rich in reddish-gray silt, are drained off through carefully constructed flood canals. As the flood rises, the water spills into the various basins, where it is allowed to stand from six to eight weeks before it is permitted to drain away, leaving the rich silt behind it. Autumn and winter crops are then sown. The disadvantage of this method is that it allows only one crop per year—a crop, moreover, that is always at the mercy of annual fluctuations in the size of the flood.

In the basins situated above the flood level, water is elevated by such means as the shadoof (a counterbalanced lever device that uses a long pole); the sakieh, or Persian waterwheel; and the Archimedean screw. It should be noted that water thus lifted is largely free from sediments and thus does not fertilize the fields. Modern mechanical pumps are also in wide use today.

Because of the limitations of the basin method of irrigation, perennial irrigation, which controls the water so that it can be run into the land at regular intervals throughout the year, has been introduced. Perennial irrigation was made possible by the completion of several barrages and waterworks before the end of the 19th century. By the beginning of the 20th century, the canal system had been remodelled and the first Aswān Dam completed (see below, *Dams and reservoirs*). Over four-fifths of Egyptian cultivated land now benefits from perennial irrigation; after the completion of the Aswān High Dam it is likely that cultivation in Egypt will be almost entirely perennial.

While the people of The Sudan make use of the Nile for irrigation, reliance on the river is not absolute, as a fair amount of rainfall occurs in the southern parts. Basin irrigation from the Nile floods is used to a small extent, but it is less satisfactory because the surface is more uneven, with less deposition of silt; the area inundated also varies from year to year. Since about 1950, these traditional methods of irrigation have been largely displaced by diesel-engined pumps, which are used on about 2,500,000 acres on the banks of either the main Nile or the White Nile.

Perennial irrigation in The Sudan began with the completion of the combined dam and barrage near Sannār on the Blue Nile in 1925. This made possible the irrigation of the area of the clay plain called Gezira between the two Niles south of Khartoum. The success of this attempt encouraged the construction of more dams and barrages for large-scale irrigation schemes.

Dams and reservoirs. In 1843 it was decided to build a series of diversion dams (barrages or weirs) across the Nile at the head of the Delta about 12 miles north of Cairo, so as to raise the level of water upstream to supply the irrigation canals and to regulate navigation. This Delta barrage scheme was not fully completed until 1861, after which it was extended and improved; it may be regarded as marking the beginning of modern irrigation in the Nile Valley. The Zifta Barrage, nearly half way along the Damietta branch of the deltaic Nile, was added to this system in 1901. In 1902 the Asyūṭ Dam, more than 200 miles upstream from Cairo, was completed. This was followed in 1909 by the barrage at Isnā (Esna), about 159 miles above Asyūṭ, and in 1930 by the dam at Naj' Hammādī, 150 miles above Asyūṭ.

The Aswān High Dam

The first Aswān Dam was constructed between 1899 and 1902; it has a series of four locks to allow navigation. It has twice been enlarged—first between 1908 and 1911 and again between 1929 and 1934—thus raising the water level 120 feet and increasing the dam's capacity to 4,000,000 acre feet. It is equipped with a hydroelectric plant with an installed power of over 345,000 kilowatts.

The Aswān High Dam (as-Sadd al-'Ālī) is located about 600 miles upstream from Cairo and four miles upstream from the first Aswān Dam. It is built at a place where the river is 1,800 feet wide and has steep banks of granite. The dam is designed to control the Nile water for the expansion of cultivation and for the generation of hydroelectric power and to provide protection against unusually high floods. The work began in 1959 and was completed in 1971.

The High Dam has a storage capacity of 133,000,000,000 acre feet. It is 12,565 feet long at crest level and 3,280 feet wide at the base, with a height of 364 feet above the river bed. A hydroelectric plant was installed, which in 1966 generated 5,895,000,000 kilowatt hours of electricity. This will double when the plant's 12 turbine power stations are in full operation. Lake Nasser, the reservoir formed upstream as a result of the construction of the dam, will be over 300 miles long and will form the largest man-made lake in the world. The Aswān Reservoir will stretch 311 miles upstream from the dam site, thus extending 125 miles into The Sudan, where it will inundate an area inhabited by 50,000 Sudanese who will have to be resettled. The reservoir will have a storage capacity of 5,790,000,000,000 cubic feet, of which 2,500,000,000,000 is to store water for perennial irrigation, 1,000,000,000,000 for the disposition of silt and 1,000,000,000,000 for flood protection and for the regulation of flood flows for downstream use. By 1970 there were indications that the reduction in the flow of the Nile resulting from the construction of the dam was permitting the inundation of the lower reaches of the river by saltwater from the Mediterranean Sea with resulting deposition of salt in the delta soils.

In The Sudan the Sannār Dam on the Blue Nile, which was completed in 1925, provides water for the Gezira Plain at the time of year when the water level of the Blue Nile is low. It has a storage capacity of 33,000,000,000 cubic feet and also produces hydroelectric power. Another dam, at Jabal al-Awliyā' on the White Nile, was completed in 1937; it has a storage capacity of 88,000,000,000 cubic feet. In 1964, a dam was built on the Atbara at Khashm al-Qirbah with a storage capacity of 46,000,000,000 cubic feet; it also produces hydrolectric power. The ar-Ruṣayriṣ Dam on the Blue Nile was completed in 1966; it has a storage capacity of 102,000,000,000 cubic feet.

In Uganda, Lake Victoria was made into a reservoir by the completion in 1954 of the Owen Falls Dam; the dam is situated on the Victoria Nile just below the point where the lake waters flow into the river. This permits the storage of surplus water in high-flood years to meet the deficit in years when the waters are low. The fall from the lake is harnessed by a hydroelectric plant that provides power for industries in Uganda.

Navigation. As already mentioned, the Nile River is still a vital waterway for the transportation of people and goods, especially in the flood season when motor transport is not feasible; river steamers still provide the only means of transport facilities in most of the area, especially in The Sudan south of latitude 15° N, where motor transport is not usually possible from May to November. Most of the towns in Egypt and The Sudan are situated on or near riverbanks.

In The Sudan, steamer service on the Nile and its tributaries extends for about 2,400 miles. Until 1962 the only link between the northern and southern parts of The Sudan was by stern-wheel river steamers of shallow draft. The main service is from Kūstī to Jūbā. There are also seasonal and subsidiary services on the Dunqulah reaches of the main Nile, on the Blue Nile, up the Sobat to Gambela in Ethiopia, and up the Baḥr al-Ghazāl in the high-water season. The Blue Nile is navigable only during the high-water season and then only as far as ar-Ruṣayriṣ.

Navigable stretches

Because of the presence of the cataracts north of Khartoum, the river is navigable only in three stretches. The

first of these is from Wādī Ḥalfā' down to the first cataract south of Aswān. The second is the stretch between the third and the fourth cataract. The third and most important stretch extends from Khartoum southward to Jūbā.

In Egypt, the Nile is navigable by sailing vessels and shallow-draft river steamers as far south as Aswān; thousands of small boats ply the Nile and Delta waterways.

Prospects for the future. The Nile is a geographical unit. Despite the great diversity in the religious, ethnic, and political backgrounds of the people who live within its basin, all depend on the Nile. Much has been accomplished in the control and use of the Nile water by means of such projects as the Owen Falls Dam, the Sannār Dam, the Aswān High Dam, and many others. These projects not only provide water for irrigation and land reclamation but also affect every aspect of the livelihood of the people who dwell on the Nile's banks. The completion of the High Dam, for example, doubled the per capita consumption of electricity in Egypt, providing power for many basic industries. Plans are already completed to exploit the fish resources from Lake Nasser, which was formed as a result of the construction of the dam.

Further conservation projects on the Upper Nile are possible, and the tasks of accomplishing them become less difficult as understanding and cooperation increase among the Nile countries. In 1970 Egypt was planning to include in its development budget the financing of a project located in The Sudan—the Jonglei Diversion Canal (to run from Jonglei to the junction of the White Nile and Sobat near Malakāl), which would hasten the flow of water northward and prevent excessive losses in the Sudd region.

Present indications are that future developments may eventually lead to an integrated plan for the entire Nile Basin.

BIBLIOGRAPHY. S.W. BAKER, *Exploration of the Nile Tributaries of Abyssinia* (1868), is a description of the author's exploration of the Ethiopian tributaries of the Nile; a later edition is entitled *The Nile Tributaries of Abyssinia.* Geographical and other aspects of the Nile in The Sudan are covered in K.M. BARBOUR, *The Republic of Sudan: A Regional Geography* (1961); P.M. HOLT, *A Modern History of Sudan* (1961); J.H.G. LEBON, "Land Use Mapping in Sudan," *Econ. Geogr.*, 35:60–70 (1959); and J.D. TOTHILL (ed.), *Agriculture in the Sudan* (1948). F.V.M. BEKER, *Le Général Desaix, étude historique* (1852), is an account of the French expedition up the Nile, a member of which, D.V. DENON, wrote *Travels in Upper and Lower Egypt During the Campaigns of General Bonaparte,* 2 vol. (1802). J. BRUCE, *Travels to Discover the Source of the Nile,* abridged ed. (1964), was first published in 1790. Criticized as fiction because of exaggeration and the absence of witness, it is a work of major originality and importance; it contains descriptions of Bruce's travels in 1769, 1770, 1771, 1772, and 1773. R.F. BURTON, *The Nile Basin,* was first published in 1864; the 1967 edition contains a reprint of Burton's paper that introduced his theory of the Nile arising from Lake Tanganyika. A second essay by JAMES MACQUEEN is a critical review of *Captain Speke's Journal of the Discovery of the Source of the Nile* (1864, reprinted 1969), which gives a full account of his discovery of the sources of the Nile. A general study of the river from its source and a discussion of the utilization of its water is contained in H.E. HURST, *The Nile* (1952), and "Progress in the Study of the Hydrology of the Nile in the Last Twenty Years," *Geogrl J.*, 70:440–463 (1927). Experimental studies on the methods of long-term storage in the Nile are H.E. HURST, R.P. BLACK, and Y.M. SIMAIKA, *Long-Term Storage* (1965); and E. LOMBARDINI, *Essai sur l'hydrologie du Nil* (1865). Other important works in this area are J. LOZACH, *Le Delta du Nile* (1935); E. LUDWIG, *Der Nil* (1935; Eng. trans., 1939); H.G. LYONS, *The Physiography of the River Nile and Its Basin* (1906); and M. MACDONALD, *Nile Control,* 2 vol. (1920). H.H. JOHNSTON, *The Nile Quest* (1903), is a good introduction to the river's history. P. JOLLOIS, *Journal d'un ingénieur attaché à l'expédition d'Egypte, 1798–1802* (1904), presents an account of the difficulties encountered by the French scientists in their explorations up the Nile. A. MOORHEAD wrote two interesting books: *The White Nile* (1960) and *The Blue Nile* (1962), which provide a comprehensive study of the exploration and political history of the Nile. S. RAPPOPORT, *History of Egypt,* 3 vol. (1904), gives a historical account of the early expeditions of discovery with a detailed description of the land and people at the time.

Nilotic Sudan, History of the

The Sudan generally is a zone that extends across the African continent south of the Sahara and north of the equatorial rain forest. The Nilotic Sudan, in this article, is understood to be the area along the Nile River south of Egypt, roughly equivalent to ancient Nubia and to the northern and central parts of the present Democratic Republic of The Sudan. Historically, this region has been one of the main points of contact between sub-Saharan Africa and the areas to the north.

This article is divided into the following sections:

I. The Nilotic Sudan to 1821

ANCIENT NUBIA TO THE 4TH CENTURY AD

The origins of Nubian culture. The earliest inhabitants of the Nilotic Sudan can be traced to Negroid peoples who lived in the vicinity of Khartoum, the Sudan, in Mesolithic (Middle Stone Age) times (30,000–20,000 BC). They were hunters and gatherers who made pottery and (later) objects of ground sandstone. Toward the end of the Neolithic (Late Stone Age; 10,000–3,000 BC) they had domesticated animals. These Negroid peoples were clearly in contact with predynastic civilizations (before *c.* 3100 BC) to the north in Egypt, but the arid uplands separating them from Nubia appear to have discouraged the Egyptians from settling there. At the end of the 4th millennium BC, kings of Egypt's 1st dynasty conquered upper Nubia beyond Aswān, introducing Egyptian cultural influence to a non-Negroid people who were scattered along the riverbank. In subsequent centuries, Nubia was subjected to successive military expeditions from Egypt in search of slaves or building materials for royal tombs, which destroyed much of the Egyptian-Nubian culture that had sprung from the initial conquests of the 1st dynasty. Throughout these five centuries (2800–2300 BC), the descendants of the Nubians continued to eke out an existence on the Nile, an easy prey to Egyptian military expeditions.

Migrations from Libya

Sometime after *c.* 2181, in the period known to Egyptologists as the First Intermediate Period (*c.* 2160–*c.* 2040), a new wave of immigrants entered Nubia from Libya, in the west, where the increasing desiccation of the Sahara drove them to settle along the Nile as cattle farmers. Other branches of these people seem to have gone beyond the Nile to the Red Sea Hills, while still others pushed south and west to Wadai and Darfur. These newcomers were able to settle on the Nile and assimilate the existing Nubians without opposition from Egypt. After the fall of the 6th dynasty (*c.* 2181), Egypt experienced a century and a half of weakness and internal strife, giving the immigrants in Nubia time to develop their own distinct civilization with unique crafts, architecture, and social structure, virtually unhindered by the potentially more dynamic civilization to the north. With the advent of the 11th dynasty (2133), however, Egypt recovered its strength and pressed southward into Nubia, at first sending only sporadic expeditions to exact tribute, but by the 12th dynasty (1991–1786) effectively occupying Nubia

as far south as Semna. The Nubians resisted the Egyptian occupation which was only maintained by a chain of forts erected along the Nile. Egyptian military and trading expeditions, of course, penetrated beyond Semna, and Egyptian fortified trading posts were actually established to the south at Karmah against frequent attacks upon Egyptian trading vessels by Nubian tribesmen beyond the southern frontier.

Egyptianization and the Kingdom of Kush. Despite the Egyptian presence in upper Nubia, the indigenous culture of the region continued to flourish, little changed by the proximity of Egyptian garrisons or the imports of luxury articles by Egyptian traders. Indeed, the Egyptianization of Nubia appears to have been enhanced during the decline in Egypt's political control over Nubia in the Second Intermediate Period (*c.* 1786–1567 BC), when Nubians were employed in large numbers as mercenaries against the Asian Hyksos invaders of Egypt. This experience did more to introduce Egyptian culture, which the mercenaries absorbed while fighting in Egyptian armies, than did the preceding centuries of Egyptian military occupation. The defeat of the Hyksos was the result of a national rising of the Egyptians who, once they had expelled the Hyksos from the Nile Valley, turned their energies southward to re-establish the military occupation of Nubia that the Hyksos invasion had disrupted. Under Thutmose I (1525–*c.* 1512 BC) the Egyptian conquest of the Northern Sudan was completed as far as Kurqus, 50 miles south of Abū Ḥamad, and subsequent Egyptian military expeditions penetrated even farther up the Nile. This third Egyptian occupation was the most complete and the most enduring, for despite sporadic rebellions against Egyptian control Nubia was deeply influenced by Egyptian culture. Nubia was divided into two administrative units: Wawat in the north, with its provincial capital at Aswān, and Kush (Cush) in the south, with its headquarters at Napata (Marawī). It was governed by a viceroy, usually a member of the royal entourage, who was responsible to the Egyptian king. Under him were two deputies, one for Wawat and one for Kush, and a hierarchy of lesser officials. The bureaucracy was staffed chiefly by Egyptians, but Egyptianized Nubians were not uncommon. Colonies of Egyptian officials, traders, and priests surrounded the administrative centres, but beyond these outposts the Nubians continued to preserve their own distinct traditions, customs, and crafts. To the Egyptians, Nubia remained a foreign land.

From J. Fage, *An Atlas of African History*; Edward Arnold (Publishers) Ltd.

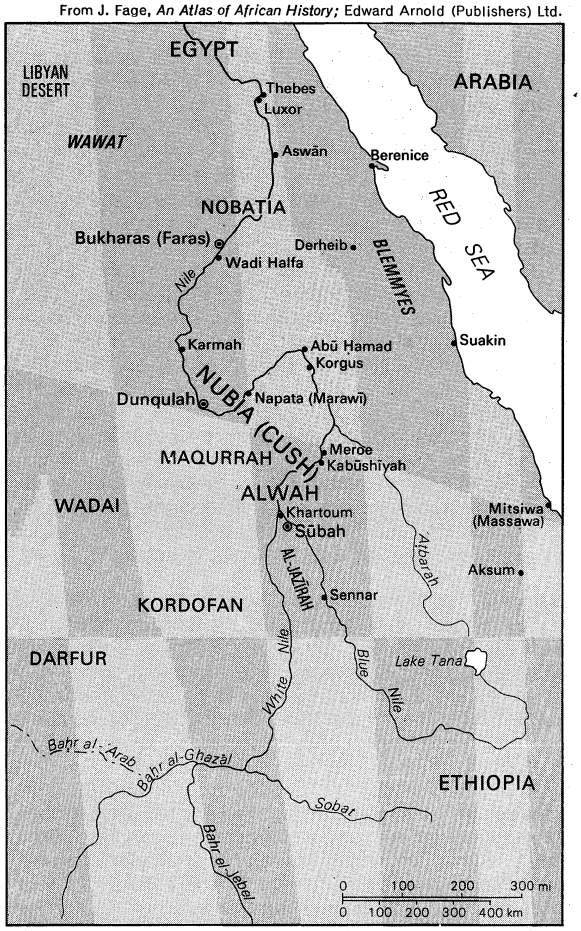

Figure 1: The Nilotic Sudan in ancient and medieval times.

But if it were a foreign land, it was also a rich one. Its position athwart the trade routes from Egypt to the Red Sea, and from the Nile to the south and west, brought great wealth from far-off places. Moreover, its cultivations along the Nile were rich, and in the hills the gold and emerald mines produced bullion and jewels for Egypt. The Nubians were also highly valued as soldiers. Nubia's wealth

As Egypt slipped once again into decline at the close of the New Kingdom (11th century BC), the viceroys of Kush, supported by their Nubian armies, became virtually independent kings, free of Egyptian control. By the 8th century BC, the kings of Kush came from hereditary ruling families of Egyptianized Nubian chiefs who possessed neither political nor family ties with Egypt. Under one such king, Kashta, Kush acquired control of Upper Egypt, and under his son Piankhi (*c.* 751–716 BC), the whole of Egypt to the shores of the Mediterranean was brought under the administration of Kush. As a world power, however, Kush was not to last. Just when the kings of Kush had established their rule from Abū Ḥamad to the Delta, the Assyrians invaded Egypt (671 BC) and with their superior iron-forged weapons defeated the armies of Kush under the redoubtable Taharqa; by 654 the Kushites had been driven back to Nubia and the safety of their capital, Napata.

Although reduced from a great power to an isolated kingdom behind the barren hills that blocked the southward advance from Aswān, Kush continued to rule over the Middle Nile for another thousand years, its unique Egyptian-Nubian culture preserved, while that of Egypt came under Persian, Greek, and Roman influences. Although Egyptianized in many ways, the culture of Kush was not simply Egyptian civilization in a Nubian environment. The Kushites developed their own language, expressed first by Egyptian hieroglyphs, then their own, and finally by a cursive script. They worshipped Egyptian gods but did not abandon their own. They buried their kings in pyramids but not in the Egyptian fashion. Their wealth continued to flow from the mines and to grow with their control of the trade routes. Soon after the retreat from Egypt the capital was moved from Napata southward to Meroe near Shandī, where the kingdom was increasingly exposed to the Negroid, African cultures farther south at the very time when its ties with Egypt were rapidly disappearing. The subsequent history of Kush is one of gradual decay, ending with inglorious extinction in AD 350 by the king of Aksum, who marched down from the Ethiopian highlands, destroyed Meroe, and sacked the decrepit towns along the river.

CHRISTIAN AND ISLAMIC INFLUENCE

Medieval Christian kingdoms. The two hundred years from the fall of Kush to the middle of the 6th century is an unknown age in the Sudan. Nubia was inhabited by a people called the Nobatae by the ancient geographers and the X-Group by modern archaeologists, who are still at a loss to explain their origins. The X-Group were clearly, however, the heirs of Kush, for their whole cultural life was dominated by Meroitic crafts and customs, and occasionally they even felt themselves sufficiently strong, in alliance with the nomadic Blemmyes (the Beja of the Eastern Sudan), to attack the Romans in Upper Egypt. When this happened, the Romans retaliated, defeating the Nobatae and Blemmyes and driving them into obscurity once again. When the Sudan was once more brought into the orbit of the Mediterranean world by the arrival of Christian missionaries in the 6th century, the Middle Nile was divided into three kingdoms: Nobatia, with its capital at Bukharas (modern Faras); Maqurrah, with its capital at Old Dunqulah; and the kingdom of ʿAlwah in the Nobatia, Maqurrah, and ʿAlwah

south, with its capital at Sūbah near Khartoum. Between 543 and 575 these three kingdoms were converted to Christianity by the work of Julian, a missionary who proselytized among the Nobatia (543–45), and his successor Longinus, who between 569 and 575 consolidated the work of Julian in Nobatia and even carried Christianity to ʿAlwah in the south. The new religion appears to have been adopted with enthusiasm. Christian churches sprang up along the Nile, and ancient temples were refurbished to accommodate Christian worshippers. After the retirement of Longinus, however, the Sudan once again receded into a period about which little is known, and it did not re-emerge into the stream of recorded history until the coming of the Arabs in the middle of the 7th century.

After the death of the Prophet Muḥammad in AD 632, the Arabs erupted from the desert steppes of Arabia and overran the lands to the east and to the west. Egypt was invaded in 639, and small groups of Arab raiders penetrated up the Nile and pillaged along the frontier of the Kingdom of Maqurrah, which by the 7th century had absorbed the state of Nobatia. Raid and counter-raid between the Arabs and the Nubians followed until a well-equipped Arab expedition under ʿAbd Allāh ibn Saʿd ibn Abī Sarḥ was sent south to punish the Nubians. The Arabs marched as far as Dunqulah, laid siege to the town, and destroyed the Christian cathedral. They suffered heavy casualties, however, so that when the King of Maqurrah sought an armistice, ʿAbd Allāh ibn Saʿd agreed to peace, happy to extricate his battered forces from a precarious position. Arab-Nubian relations were subsequently regularized by an annual exchange of gifts, trade relations, and the mutual understanding that no Muslims were to settle in Nubia and no Nubians were to take up residence in Egypt. With but few interruptions this peaceful, commercial relationship lasted for nearly six centuries, its very success undoubtedly the result of the mutual advantage that both the Arabs and the Nubians derived from it. The Arabs had a stable frontier; they appear to have had no designs to occupy the Sudan and were probably discouraged from doing so by the arid plains south of Aswān. Peace on the frontier was their object, and this the treaty guaranteed. In return, the Kingdom of Maqurrah gained another six hundred years of life.

Islāmic encroachments. When non-Arab Muslims acquired control of the Delta, friction arose in Upper Egypt. In the 9th century the Turkish Ṭūlūnid rulers of Egypt, wishing to rid themselves of the unruly nomadic Arab tribes in their domain, encouraged them to migrate southward. Lured by the prospects of gold in the Nubian Desert, the nomads pressed into Nubia, raiding and pillaging along borders, but the heartland of Maqurrah remained free from direct hostilities until the Mamlūks established their control over Egypt (1250). In the late 13th and early 14th centuries, the Mamlūk sultans sent regular military expeditions against Maqurrah, as much to rid Egypt of uncontrollable Arab Bedouins as to capture Nubia. The Mamlūks never succeeded in actually occupying Maqurrah, but they devastated the country, draining its political and economic vitality and plunging it into chaos and depression. By the 15th century Dunqulah was no longer strong enough to withstand Arab encroachment, and the country was open to Arab immigration. Once the Arab nomads, particularly the Juhaynah people, learned that the land beyond the Aswān reach could support their herds and that no political authority had the power to turn them back, they began to migrate southward, intermarrying with the Nubians and introducing Arabic, Muslim culture to the Christian inhabitants. The Arabs, who inherited through the male line, soon acquired control from the Nubians, who inherited through the female line, intermarriage resulting in Nubian inheritances passing from Nubian women to their half-Arab sons, but the Arabs replaced political authority in Maqurrah only with their own nomadic institutions. From Dunqulah the Juhaynah and others wandered east and west of the Nile with their herds; in the south, the Kingdom of ʿAlwah stood as the last indigenous Christian barrier to Arab occupation of the Sudan.

The Ṭūlūnids and Mamlūks

ʿAlwah extended from Kabūshīyah as far south as Sennar. Beyond, from the Ethiopian escarpment to the White Nile, lived Nilotic peoples about which little is known. ʿAlwah appears to have been much more prosperous and stronger than Maqurrah. It preserved the ironworking techniques of Kush, and its capital at Sūbah possessed many impressive buildings, churches, and gardens. Christianity remained the state religion, but its long isolation from the Christian world had probably resulted in bizarre and syncretistic accretions to liturgy and ritual. ʿAlwah was able to maintain its integrity so long as the Arabs failed to combine against it, but the continuous and corrosive raids of the Bedouins throughout the 15th century clearly weakened its power to resist. Thus, when an Arab confederation led by ʿAbd Allāh Jammāʿ was at last brought together to assault the Christian kingdom, ʿAlwah collapsed (*c.* 1500). Sūbah and the Blue Nile region were abandoned, left to the Funj, who suddenly appeared, seemingly from nowhere, to establish their authority from Sennar to the main Nile.

The fall of ʿAlwah

The Funj. The Funj were a strange and mysterious people. They were neither Arabs nor Muslims, and their homeland was probably on the upper Blue Nile in the borderlands between Ethiopia and The Sudan. Under their leader, ʿAmārah Dunqas, the Funj founded their capital at Sennar and throughout the 16th century struggled for control of the al-Jazīrah region against the Arab tribes who had settled around the confluence of the Blue and the White Niles. The Funj appear to have firmly established their supremacy by 1607–08. By the mid-17th century the Funj dynasty had reached its golden age under one of its greatest kings, Bādī II Abū Daqn (reigned 1644/45–80), who extended Funj authority across the White Nile into Kordofan and reduced the tribal chieftaincies scattered northward along the main Nile to tribute-paying feudatories. But as Bādī expanded Funj power, he also planted the seeds of its decline. During his conquests, slaves were captured and taken to Sennar, where, as they grew in numbers and influence, they formed a military caste. Loyal to the monarch alone, the slaves soon came to compete with the Funj aristocracy for control of the offices of state. Intrigue and hostility between these two rival groups soon led to open rebellion that undermined the position of the traditional ruling class. Under Bādī IV Abū Shulūkh (reigned 1724–62), the ruling aristocracy was finally broken, and the king assumed arbitrary power, supported by his slave troops. So long as Bādī IV could command the loyalty of his army, his position was secure and the kingdom enjoyed respite from internal strife, but at the end of his long reign he could no longer control the army. Under the leadership of his viceroy in Kordofan, Abū Likaylik, the military turned against the king and exiled him to Sūbah. Abū Likaylik probably represented a resurgence of older indigenous elements who had been Arabized and Islāmized but were neither Arab nor Funj. Henceforward, the Funj kings were but puppets of their viziers (chief ministers), whose struggles to win and to keep control precipitated the kingdom into steady decline, interrupted only by infrequent periods of peace and stability established by a strong vizier who was able to overcome his rivals. During its last half century the Funj kingdom was a spent state, kept intact only through want of a rival, but gradually disintegrating through wars, intrigue, and conspiracy, until the Egyptians advanced on Sennar in 1821 and pushed the Funj empire into oblivion.

Islāmization. The Funj were originally pagans, but the aristocracy soon adopted Islām and, although they retained many pagan customs, remained nominal Muslims. The conversion was largely the work of a handful of Islāmic missionaries who came to the Sudan from the larger Muslim world. The great success of these missionaries, however, was not among the Funj themselves but among the Arabized Nubian population settled along the Nile. Among these villagers the missionaries instilled a deep devotion to Islām that appears to have been conspicuously absent among the nomadic Arabs who first reached the Sudan after the collapse of the Kingdom of Maqurrah. One early missionary was Ghulām Allāh ibn

Early missionaries

ʿĀʾid from the Yemen, who settled at Dunqulah in the 14th century. He was followed in the 15th century by Ḥamad Abū Danana, who appears to have emphasized the way to God through mystical exercises rather than through the more orthodox interpretations of the Qur'ān taught by Ghulām Allāh.

The spread of Islām was advanced in the 16th century, when the hegemony of the Funj enhanced security. In the 16th and 17th centuries, numerous schools of religious learning were founded along the White Nile and the Shāyqīyah were converted. Many of the more famous Sudanese missionaries who followed them were Ṣūfī holy men, members of influential religious brotherhoods who sought the way to God through mystical contemplation. Although the fervour of Sudanese Islām waned after 1700, the great reform movements that shook the Muslim world in the late 18th and early 19th centuries produced a revivalist spirit among the Ṣūfī brotherhoods, giving rise to a new order, the Mirghanīyah or Khatmīyah, later one of the strongest in the modern Sudan.

These men, called *fakīs*, attracted a following by their teachings and piety, and laid the foundations for a long line of indigenous Sudanese holy men who passed on the way to God taught them by their masters, or who founded their own religious schools, or who, if extraordinarily successful, gathered their own following into a religious order. The *fakīs* held a religious monopoly until the introduction, under Egyptian-Ottoman rule (see below), of an official hierarchy of jurists and scholars, the *ʿulamāʾ*, whose orthodox legalistic conception of Islām was as alien to the Sudanese as were their origins. This disparity between the mystical, traditional *fakīs*, close to the Sudanese, if not of them, and the orthodox, Islāmic jurists, aloof, if not actually part of the government bureaucracy, created a rivalry that in the past produced open hostility in times of trouble and sullen suspicion in times of peace. Recently, this schism has diminished; the *fakī* continues his customary practices unmolested, while the Sudanese have acknowledged the position of the *ʿulamāʾ* in society.

II. The Sudan since 1821

EGYPTIAN-OTTOMAN RULE

The administration of Muhammad ʿAli and his successors. In July 1820, Muḥammad ʿAlī, viceroy of Egypt under the Ottoman Turks, sent an army under his son Ismāʿīl to conquer the Sudan. Muḥammad ʿAli was interested in the gold and slaves that the Sudan could provide and wished to control the vast hinterland south of Egypt. By 1821 the Funj and the Sultan of Darfur had surrendered to his forces, and the Nilotic Sudan from Nubia to the Ethiopian foothills and from the ʿAṭbarah River to Darfur became part of his expanding empire.

Resistance to Egyptian rule

Collection of taxes under Muḥammad ʿAlī's regime amounted to virtual confiscation of gold, livestock, and slaves, and opposition to his rule became intense, eventually erupting into rebellion and the murder of Ismāʿīl and his bodyguard. But the rebels lacked leadership and coordination, and their revolt was brutally suppressed. A sullen hostility in the Sudanese was met by continued repression until the appointment of ʿAlī Khūrshīd Agha as governor general in 1826. His administration marked a new era in Egyptian-Sudanese relations. He reduced taxes and consulted the Sudanese through the respected Sudanese leader ʿAbd al-Qādir wad az-Zayn. Letters of amnesty were granted to fugitives. A more equitable system of taxation was implemented, and the support of the powerful class of holy men and *shaykhs* (tribal chiefs) for the administration was obtained by exempting them from taxation. But ʿAlī Khūrshīd was not content merely to restore the Sudan to its previous condition. Under his initiative trade routes were protected and expanded, Khartoum was developed as the administrative capital, and a host of agricultural and technical improvements were undertaken. When he retired to Cairo in 1838, Khūrshīd left a prosperous and contented country behind him.

His successor, Aḥmad Pasha abū Widān, with but few exceptions continued his policies, and made it his primary concern to root out official corruption. Abū Widān dealt ruthlessly with offenders or those who sought to thwart his schemes to reorganize taxation. He was particularly fond of the army, which reaped the benefits of regular pay and tolerable conditions in return for the brunt of the expansion and consolidation of Egyptian administration in Kassala and among the Baqqārah of southern Kordofan. Muḥammad ʿAlī, suspecting Abū Widān of disloyalty, recalled him to Cairo in the autumn of 1843, but he died mysteriously of poisoning before he left the Sudan.

During the next two decades the country stagnated because of ineffective government at Khartoum and vacillation by the viceroys at Cairo. If the successors of Abū Widān possessed administrative talent, they were seldom able to demonstrate it. Alarmed by the independent attitude of Abū Widān, Muḥammad ʿAlī first abolished the office of governor general and then, just as suddenly, revived it but sought to control its incumbents by limiting their tenure. Thus, no governor general held office long enough to introduce his own plans, let alone carry on those of his predecessor. New schemes were never begun, and old projects were allowed to languish. Without direction the army and the bureaucracy became demoralized and indifferent, while the Sudanese became disgruntled with the government. This state of affairs persisted until the more dynamic viceroy Ismāʿīl took over the guidance of Egyptian and Sudanese affairs in 1862.

Attempts to end the slave trade

During these quiescent decades, however, two ominous developments began that presaged future problems. Reacting to pressure from the Western powers, particularly Great Britain, the governor general of the Sudan was ordered to halt the slave trade. But not even the viceroy himself could overcome established custom with the stroke of a pen and the erection of a few police posts. If the restriction of the slave trade precipitated resistance among the Sudanese, the appointment of Christian officials to the administration and the expansion of the European Christian community caused open resentment. European merchants, mostly of Mediterranean origin, were either ignored or tolerated by the Sudanese and confined their contacts to compatriots within their own community and to the Turko-Egyptian officials whose manners and dress they frequently adopted. They became a powerful and influential group, whose lasting contribution to the Sudan was their lead taken in opening the

Southern Sudan to navigation and commerce, thereby bringing the vast Negroid, equatorial regions of the Upper Nile into the orbit of Sudanese history.

Ismaʿīl Pasha and the growth of European influence. In 1863, Ismāʿīl Pasha became viceroy of Egypt. Educated in Egypt, Vienna, and Paris, Ismāʿīl had absorbed the European interest in overseas adventures as well as Muḥammad ʿAlī's desire for imperial expansion, and had imaginative schemes for transforming Egypt and the Sudan into a modern state by employing Western technology. First he hoped to acquire the rest of the Nile Basin, including the Southern Sudan and the Bantu states by the great lakes of Central Africa. To finance this vast undertaking, and his projects for the modernization of Egypt itself, Ismāʿīl turned to those capital surplus nations of Europe, where investors were willing to risk their savings at high rates of interest in the cause of Egyptian and African development. But such funds would be attracted only as long as Ismāʿīl demonstrated his interest in reform by intensifying the campaign against the slave trade in the Sudan. Ismāʿīl needed no encouragement. He was genuinely opposed to the slave trade and made sincere efforts to suppress it and to cooperate with the European powers toward that end. Thus, these two major themes of Ismāʿīl's rule of the Nilotic Sudan—imperial expansion and the suppression of the slave trade—became intertwined, culminating in a third major development, the introduction of an ever-increasing number of European Christians to carry out the task of modernization.

Samuel Baker's expedition

In 1869 Ismāʿīl commissioned the Englishman Samuel Baker to lead an expedition up the White Nile to establish Egyptian hegemony over the equatorial regions of Central Africa and to curtail the slave trade on the Upper Nile. Baker remained in Equatorial Africa until 1873, where he established the Equatoria Province as part of Egyptian Sudan. He had extended Egyptian power and curbed the slave traders on the Nile, but he had also alienated certain African tribes, and being a rather tactless Christian, Ismāʿīl's Muslim administrators as well. Moreover, Baker had struck only at the Nilotic slave trade. To the west, on the vast plains of the Baḥr al-Ghazāl (now a province of the Democratic Republic of The Sudan), slave merchants had established enormous empires with stations garrisoned by slave soldiers. From these stations the long lines of human chattels were sent overland through Darfur and Kordofan to the slave markets of the Northern Sudan, Egypt, and Arabia. Not only did the firearms of the Khartoumers (as the traders were called) establish their supremacy over the peoples of the interior but those merchants with the strongest resources gradually swallowed up lesser traders until virtually the whole of the Baḥr al-Ghazāl was controlled by the greatest slaver of them all, az-Zubayr Raḥma Manṣūr, more commonly known as Zobeir Pasha. So powerful had he become that in 1873, the year Baker retired from the Sudan, the viceroy (now called the khedive) appointed az-Zubayr governor of the Baḥr al-Ghazāl. Ismāʿīl's officials had failed to destroy az-Zubayr as Baker had crushed the slavers on the Victoria Nile, and to elevate az-Zubayr to the governorship was the only way to establish at least the nominal sovereignty of Cairo over that enormous province. Thus, the agents of az-Zubayr continued to pillage the Baḥr al-Ghazāl under the Egyptian flag, while officially Egypt extended its dominion to the tropical rain forests of the Congo.

Gordon's administration

Ismāʿīl next offered the governorship of the Equatoria Province to another Englishman, Charles George Gordon, who in China had won fame and the sobriquet Chinese Gordon. Gordon arrived in Equatoria in 1874. His object was the same as Baker's—to consolidate Egyptian authority in Equatoria and to establish Egyptian sovereignty over the kingdoms of the great lakes—but his means were considerably more pacific. He reasserted government control over the stations that had been reoccupied by the slave traders since Baker's departure and stopped the slavers' raids against the local tribes. But Gordon's goal was the lakes, not the river, and he also sought to make the kingdoms of Bunyoro and Buganda (in present Uganda) recognize Egyptian sovereignty. Like Baker, he failed. Although he established stations beyond the Victoria Nile in Bunyoro proper at Foweira and Mruli, his resources were never sufficient to accomplish by force what he could not achieve by peaceful negotiation. When Gordon retired from Equatoria, the lake kingdoms remained stubbornly independent.

In 1877 Ismāʿīl appointed Gordon governor general of the Sudan. Gordon was the first European, Christian governor general of the Sudan. He returned there intending to lead a crusade against the slave trade, and to assist him in this humanitarian enterprise, he surrounded himself with a cadre of European and American Christian officials. In 1877 Ismāʿīl had signed the Anglo-Egyptian Slave Trade Convention, which provided for the termination of the sale and purchase of slaves in the Sudan by 1880. Gordon set out to fulfill the terms of this treaty and in whirlwind tours through the country broke up the markets and imprisoned the traders. His European subordinates did the same in the provinces.

The effects of the anti-slavery campaign

Gordon's crusading zeal blinded him to his invidious position as a Christian in a Muslim land and obscured from him the social and economic effects of arbitrary repression. Not only did his campaign create a crisis in the Sudan's economy but the Sudanese soon came to believe that the crusade, led by European Christians, violated the principles and traditions of Islām. By 1879 a strong current of reaction against Gordon's reforms was running through the country. The powerful slave-trading interests had, of course, turned against the administration, while the ordinary villagers and nomads, who habitually blamed the government for any difficulties, were quick to associate economic depression with Gordon's Christianity. And then suddenly, in the middle of rising discontent in the Sudan, Ismāʿīl's financial position collapsed. In difficulties for years, he could now no longer pay the interest on the Egyptian debt, and an international commission was appointed by the European powers to oversee Egyptian finances. After sixteen years of glorious spending, Ismāʿīl sailed away into exile. Gordon resigned.

Gordon left a perilous situation in the Sudan. The Sudanese were confused and dissatisfied. Many of the ablest senior officials, both European and Egyptian, had been dismissed by Gordon, departed with him, or died in his service. Castigated and ignored by Gordon, the bureaucracy had lapsed into apathy. Moreover, the office of governor general, on which the administration was so dependent, devolved upon Muḥammad Raʾūf Pasha, a mild man, ill-suited to stem the current of discontent or to shore up the structure of Egyptian rule, particularly when he could no longer count on Egyptian resources. Such then was the Sudan in June of 1881 when Muḥammad Aḥmad declared himself to be the Mahdī ("the divinely guided one").

THE MAHDIYAH

Muḥammad Aḥmad ibn ʿAbd Allāh was the son of a Dunqulah boatbuilder who claimed descent from the Prophet Muḥammad. Deeply religious from his youth, he was educated in one of the Ṣūfī orders, the Sammānīyah, but he became disgusted with the worldly ways of his teacher and secluded himself on Ābā Island in the White Nile to practice religious asceticism. In 1880 he toured Kordofan, where he learned of the discontent of the people and observed those actions of the government that he could not reconcile with his own religious beliefs. Upon his return to Ābā Island he clearly viewed himself as a *mujaddid*, a renewer of the Muslim faith, his mission to reform Islām and return it to the pristine form practiced by the Prophet. To Muḥammad Aḥmad the orthodox *ʿulamāʾ* who supported the administration were no less infidels than Christians, and when he later lashed out against misgovernment, he was referring as much to the theological heresy as to secular maladministration. Once he had proclaimed himself *mahdī* (a title traditionally used by Islāmic religious reformers) Muḥammad Aḥmad was regarded by the Sudanese as an eschatological figure, one who foreshadows the end of an age of darkness (which happened to coincide with the end of the 13th Muslim century) and heralds the beginnings of a new era

of light and righteousness. Thus, as a divinely guided reformer and symbol, Muḥammad Aḥmad fulfilled the requirements of Mahdiship in the eyes of his supporters.

The Mahdī's followers

Surrounding the Mahdī were his followers, the *anṣār*, and foremost among them was ʿAbd Allāh ibn Muḥammad, the *khalīfah* ("deputy"), who came from the Taʿāishah tribe of the Baqqārah Arabs and who assumed the leadership of the Mahdist state upon the death of Muḥammad Aḥmad. The holy men, the *fakis*, who for long had lamented the sorry state of religion in the Sudan brought on by the legalistic and unappealing orthodoxy of the Egyptians, looked to the Mahdī to purge the Sudan of the faithless ones. Also in his following, more numerous and powerful than the holy men, were the merchants formerly connected with the slave trade. All had suffered from Gordon's campaign against the trade, and all now hoped to reassert their economic position under the banner of religious war. Neither of these groups, however, could have carried out a revolution by themselves. The third and vital participants were the Baqqārah Arabs, the cattle nomads of Kordofan and Darfur who hated taxes and despised government. They formed the shock troops of the Mahdist revolutionary army, whose enthusiasm and numbers more than made up for its primitive technology. Moreover, the government itself only managed to enhance the prestige of the Mahdī by its fumbling attempts to arrest him and proscribe his movement. By September 1882, the Mahdists controlled all of Kordofan and at Shaykān on November 5, 1883, destroyed an Egyptian army of 10,000 men under the command of a British colonel. After Shaykān, the Sudan was lost, and not even the heroic leadership of Gordon, who was hastily sent to Khartoum, could save the Sudan for Egypt. On January 26, 1885, the Mahdists captured Khartoum and massacred Gordon and the defenders.

The reign of the Khalīfah. Five months after the fall of Khartoum, the Mahdī suddenly died on June 22, 1885. He was succeeded by the Khalīfah ʿAbd Allāh. The Khalīfah's first task was to secure his own precarious position among the competing factions in the Mahdist state. He frustrated a conspiracy by the Mahdī's relatives, and disarmed the personal retinues of his leading rivals in Omdurman, the Mahdist capital of the Sudan. Having curtailed the threats to his rule, the Khalīfah sought to accomplish the Mahdī's dream of a universal *jihād* (holy war) to reform Islām throughout the Muslim world. With a zeal compounded from a genuine wish to carry out religious reform, a desire for military victory and personal power, and an appalling ignorance of the world beyond the Sudan, the forces of the Khalīfah marched to the four points of the compass to spread Mahdism and extend the domains of the Mahdist state. By 1889 this expansionist drive was spent. In the west the Mahdist armies had achieved only an unstable occupation of Darfur. In the east they had defeated the Ethiopians, but the victory produced no permanent gain. In the Southern Sudan the Mahdists had scored some initial successes but were driven from the Upper Nile in 1897 by the forces of the Congo Free State of Leopold II of Belgium. On the Egyptian frontier in the north the *jihād* met its worst defeat at Tūshkī in August 1889, when an Anglo-Egyptian army under General Francis W. Grenfell destroyed a Mahdist army led by ʿAbd ar-Raḥmān an-Nujūmī. The Mahdist state, having squandered its resources on the *jihād*, a period of consolidation and contraction followed, necessitated by a sequence of bad harvests resulting in famine, epidemic, and death. Between 1889 and 1892 the Sudan suffered its most devastating and terrible years, as the Sudanese sought to survive on their shrivelled crops and emaciated herds. After 1892 the harvests improved and food was no longer in short supply. Moreover, the autocracy of the Khalīfah had become increasingly acceptable to most Sudanese, and having tempered his own despotism and eliminated the gross defects of his administration he too received the widespread acceptance, if not devotion, that the Sudanese had accorded the Mahdī.

In spite of its many defects, the Khalīfah's administration served the Sudan better than its many detractors would admit. Certainly the Khalīfah's government was autocratic, but while autocracy may be repugnant to European democrats, it was not only understandable to the Sudanese but appealed to their deepest feelings and attitudes formed by tribe, religion, and past experience with the centralized authoritarianism of the Turks. For them, the Khalīfah was equal to the task of governing bequeathed him by the Mahdī. Only when confronted by new forces from the outside world, of which he was ignorant, did ʿAbd Allāh's abilities fail him. His belief in Mahdism, his reliance on the superb courage and military skill of the *anṣār*, and his own ability to rally them against an alien invader were simply insufficient to preserve his independent Islāmic state against the overwhelming technological superiority of Great Britain. And as the 19th century drew to a close, the rival imperialisms of the European powers brought the full force of this technological supremacy against the Mahdist state.

The British conquest. British forces invaded and occupied Egypt in 1882 to put down a nationalist revolution hostile to foreign interests, and remained there to prevent any further threat to the khedive's government or the possible intervention of another European power. The consequences of this were far-reaching. A permanent British occupation of Egypt required the inviolability of the Nile waters without which Egypt could not survive, not from any African state, who did not possess the technical resources to interfere with them, but from rival European powers who could. Consequently, the British government, by diplomacy and military manoeuvres, negotiated agreements with the Italians and the Germans to keep them out of the Nile Valley. They were less successful with the French, who wanted them to withdraw from Egypt. Once it became apparent that the British were determined to remain, the French cast about for means to force the British from the Nile Valley; in 1893 an elaborate plan was concocted by which a French expedition would march across Africa from the west coast to Fashoda (Kodok) on the Upper Nile, where it was believed a dam could be constructed to obstruct the flow of the Nile waters. After inordinate delays, the French Nile expedition set out for Africa in June 1896, under the command of Capt. Jean-Baptiste Marchand.

British interest in the Nile Valley

As reports reached London during 1896 and 1897 of Marchand's march to Fashoda, Britain's inability to insulate the Nile Valley became embarrassingly exposed. British officials desperately tried one scheme after another to beat the French to Fashoda. They all failed, and by the autumn of 1897 British authorities had come to the reluctant conclusion that the conquest of the Sudan was necessary to protect the Nile waters from French encroachment. In October an Anglo-Egyptian army under the command of General Sir Horatio Herbert Kitchener was ordered to invade the Sudan. Kitchener pushed steadily but cautiously up the Nile. His Anglo-Egyptian forces defeated a large Mahdist army at the ʿAṭbarah River on April 8, 1898. Then, after spending four months preparing for the final advance to Omdurman, Kitchener's army of about 25,000 troops met the massed 60,000-man army of the Khalīfah outside the city on September 2, 1898. By midday the battle was over. The Mahdists were decisively defeated with heavy losses, and the Khalīfah fled, to be killed nearly a year later. Kitchener did not long remain at Omdurman but pressed up the Nile to Fashoda with a small flotilla. Here on September 18, 1898, he met Captain Marchand, who declined to withdraw—the long expected Fashoda crisis had begun. Both the French and British governments prepared for war. Neither the French army nor the navy was in any condition to fight, however, and the French were forced to give way. An Anglo-French agreement of March 1899 stipulated that French expansion eastward in Africa would stop at the Nile watershed.

THE ANGLO-EGYPTIAN CONDOMINIUM

The early years of British rule. Having conquered the Sudan, the British now had to govern it. But the administration of this vast land was complicated by the legal and diplomatic problems that had accompanied the conquest.

The Sudan campaigns had been undertaken by the British to protect their imperial position as well as the Nile waters, yet the Egyptian treasury had borne the greater part of the expense, and Egyptian troops had far outnumbered those of Britain in the Anglo-Egyptian Army. The British, however, did not simply want to hand the Sudan over to Egyptian rule; most Englishmen were convinced that the Mahdīyah was the result of sixty years of Egyptian oppression. To resolve this dilemma the Anglo-Egyptian condominium was declared in 1899 whereby the Sudan was given separate political status in which sovereignty was jointly shared by the khedive and the British crown, and the Egyptian and the British flags were flown side by side. The military and civil government of the Sudan was invested in a governor general appointed by the khedive of Egypt but nominated by the British government. In reality, there was no equal partnership between Britain and Egypt in the Sudan. From the first the British dominated the condominium and set about pacifying the countryside and suppressing local religious uprisings, which created insecurity among British officials but never posed a major threat to their rule. The north was quickly pacified and modern improvements were introduced under the aegis of civilian administrators, who began to replace the military as early as 1900. In the south, resistance to British rule was more prolonged; administration there was confined to keeping the peace rather than making any serious attempts at modernization.

Wingate's administration

The first governor general was Lord Kitchener himself, but in 1899 his former aide, Sir Reginald Wingate, was appointed to succeed him. Wingate knew the Sudan well, and during his long tenure as governor general (1899–1916) became devoted to its people and their prosperity. His tolerance and trust in the Sudanese resulted in policies that did much to establish confidence in Christian British rule by a devoutly Muslim, Arab-oriented people.

Modernization was slow at first. Taxes were purposely kept light, and the government consequently had few funds available for development. In fact, the Sudan remained dependent on Egyptian subsidies for many years. Nevertheless, railways, telegraph, and steamer services were expanded, particularly in al-Jazīrah, in order to launch the great cotton-growing scheme that remains today the backbone of the Sudan's economy. In addition, technical and primary schools were established, including the Gordon Memorial College, which opened in 1902 and soon began to graduate a Western educated elite that was gradually drawn away from the traditional political and social framework. Scorned by the British officials, who preferred the illiterate but contented fathers to the ill-educated, rebellious sons, and adrift from their own customary tribal and religious affiliations, these Sudanese turned for encouragement to Egyptian nationalists; from that association Sudanese nationalism in this century was born.

Its first manifestations occurred in 1921, when ʿAlī ʿAbd al-Laṭīf founded the United Tribes Society, and was arrested for nationalist agitation. In 1924 he formed the White Flag League, dedicated to driving the British from the Sudan. Demonstrations followed in Khartoum in June and August and were suppressed. When the governor general, Sir Lee Stack, was assassinated in Cairo on November 19, 1924, the British forced the Egyptians to withdraw from the Sudan, and annihilated a Sudanese battalion that mutinied in support of the Egyptians. The Sudanese revolt was ended, and British rule remained unchallenged until after World War II.

The growth of national consciousness. In 1936 Britain and Egypt had reached a partial accord in the Anglo-Egyptian treaty that enabled Egyptian officials to return to the Sudan. Although the traditional Sudanese *shaykhs* and chiefs remained indifferent to the fact that they had not been consulted in the negotiations over this treaty, the educated Sudanese elite were resentful that neither Britain nor Egypt had bothered to solicit their opinions.

The Graduates' General Congress

Thus, they began to express their grievances through the Graduates' General Congress, which had been established as an alumni association of Gordon Memorial College and soon embraced all educated Sudanese. At first the Graduates' General Congress confined its interests to social and educational activities, but with Egyptian support the organization demanded recognition by the British to act as the spokesman for Sudanese nationalism. The Sudan government refused, and the Congress split into two groups: a moderate majority prepared to accept the good faith of the government, and a radical minority, led by Ismāʿīl al-Azharī, turned to Egypt. By 1943 Azharī and his supporters had won control of the Congress and organized the Ashiqqā' ("Brothers"), the first genuine political party in the Sudan. Seeing the initiative pass to the militants, the moderates formed the Ummah ("Nation") Party under the patronage of Sayyid ʿAbd ar-Raḥmān al-Mahdī, the posthumous son of the Mahdī, with the intention of cooperating with the British toward independence. Sayyid ʿAbd ar-Raḥmān had inherited the allegiance of the thousands of Sudanese who had followed his father. He now sought to combine to his own advantage this power and influence with the ideology of the Ummah. His principal rival was Sayyid ʿAlī al-Mirghanī, the leader of the Khatmīyah brotherhood. Although he personally remained aloof from politics, Sayyid ʿAlī threw his support to Azharī. The competition between the Azharī-Khatmīyah faction—remodelled in 1951 as the National Unionist Party (NUP)—and the Ummah-Mahdist group quickly rekindled old suspicions and deep-seated hatreds that soured Sudanese politics for years and eventually strangled parliamentary government.

Although the Sudan government had crushed the initial hopes of the congress, the British officials were well aware of the pervasive power of nationalism among the elite and sought to introduce new institutions to associate the Sudanese more closely with the task of governing. An Advisory Council was established for the Northern Sudan consisting of the governor general and 28 Sudanese, but Sudanese nationalists soon began to agitate to transform the Advisory Council into a legislative one in which the Southern Sudanese would be included. The British had facilitated their control of the Sudan by segregating the pagan or Christian Africans of the south from the Muslim Arab northerners. The decision to establish a legislative council forced them to abandon this policy; in 1947 they permitted southern participation in a legislative council to represent the Sudan as a whole.

The creation of this council produced a strong reaction on the part of the Egyptian government, which in October 1951 unilaterally abrogated the Anglo-Egyptian agreement of 1936 and proclaimed Egyptian rule over the Sudan. These hasty and ill-considered actions only managed to alienate the Sudanese from Egypt until the Nasser-Naguib revolution in July 1952 placed men with more understanding of Sudanese aspirations in power in Cairo. Not only did they seek to regain Egyptian influence in the Sudan but on February 12, 1953, signed an agreement with Great Britain granting self-government for the Sudan and self-determination within three years for the Sudanese. Elections for a representative Parliament to rule the Sudan followed in November and December 1953. The Egyptians threw their support behind Ismāʿīl al-Azharī, the leader of the National Unionist Party, who campaigned on the slogan "Unity of the Nile Valley." This position was opposed by the Ummah Party, which had the less vocal but pervasive support of British officials. To the shock of many British officials and to the chagrin of the Ummah, which had enjoyed power in the Legislative Council for nearly six years, Ismāʿīl al-Azharī's NUP won an overwhelming victory. Although Azharī had campaigned to unite the Sudan with Egypt, the realities of disturbances in the Southern Sudan and the responsibilities of political power and authority ultimately led him to disown his own campaign promises and to declare The Sudan an independent republic with an elected representative Parliament on January 1, 1956.

The end of the condominium

THE REPUBLIC OF THE SUDAN

The triumph of liberal democracy in The Sudan was short-lived. Compared to the strength of tradition, which still shaped the life of the Sudanese, the liberalism imported from the West, disseminated through British edu-

cation and adopted by the Sudanese intelligentsia, was a weak force. At first parliamentary government had been held in high esteem; it was the symbol of nationalism and independence, signifying the nation's coming of age and freedom from alien rule. But at best Parliament was a superficial instrument. It had been introduced into The Sudan at precisely the time when parliamentary forms were rapidly disappearing from other countries in the Middle East. Parties, the machinery by which parliamentary government functions, were not well-organized groups with distinct objectives, but loose alliances attached opportunistically to personal interests and sectarian loyalties. Such groups were difficult to manage, almost impossible to direct. When the tactics of party management were exhausted, Parliament became debased, benefitting only those politicians who reaped the rewards of power and patronage. Disillusioned with their experiment in liberal democracy, the Sudanese turned once again to the authoritarianism to which their traditions had accustomed them.

The Abboud government. On the night of November 16, 1958, the commander in chief of the Sudan army, Gen. Ibrahim Abboud, carried out a bloodless coup d'etat and took charge of the government. The following day Abboud himself broadcast to the nation, blaming the "state of degeneration" on the political strife between rival factions. He dissolved all political parties, prohibited assemblies, and temporarily suspended newspapers. The country was henceforth governed by a Supreme Council of the Armed Forces, consisting of 12 senior officers. Parliament was abolished, the transitional constitution suspended, and a state of emergency proclaimed. Only the Communists opposed the military regime, but they were powerless against the army, and despite several attempts by dissident officers to seize control of the Supreme Council, at the end of its first year in power the Abboud government was securely in control.

Economic improvements

Despite these internal struggles, army rule brought rapid improvements in The Sudan's deteriorating economic position. The Abboud government at once abolished the fixed price on cotton and within six months had sold all the Sudanese cotton. Although disposed of at lower rates, the ultimate effect of the cotton sale was to give The Sudan a surplus revenue and dramatically rebuild the nation's foreign reserves. The other achievement of the military government was the conclusion of a Nile waters agreement with the United Arab Republic on November 8, 1959. Although both the monetary compensation and the share of the Nile waters that The Sudan received have proven insufficient, the Nile waters agreement was more significant than the inadequate technical division implies, for the United Arab Republic not only recognized but appeared to be reconciled to an independent Sudan on its southern frontier astride the water upon which Egypt depends.

The problem of the south. In the Southern Sudan Abboud's policies were less successful. Partly in fear of another rebellion and partly restricted by the moderation imposed upon them under a parliamentary system, the politicians had left the south to follow its own ways. The army officers of the military government were under no such restraints. In the name of national unity they introduced numerous measures designed to facilitate the spread of Islām and of the Arabic language. Important positions in the administration and police were staffed by northerners. The Southern Liberal Party, which represented the views of the core of southern intellectuals, was proscribed. Education was shifted from the English curriculum of the Christian missionaries, who had long been solely responsible for education in the south, to an Arabic, Islāmic orientation. Mosques and Islāmic schools were established under the direction of the department of religious affairs. Foreign Christian missionaries were increasingly restricted and finally expelled in February and March 1964.

In the Southern Sudan itself, the measures of the central government were greeted by ever-increasing resistance. In October 1962 a widespread strike in southern schools resulted in antigovernment demonstrations followed by a general flight of students and others over the border. During the spring and summer of 1963 feelings relaxed and affairs appeared to improve, most of the discontented having fled, and The Sudan government reinforced its army and police units in the southern provinces. Suddenly, however, in September 1963, rebellion again erupted in eastern Equatoria and in the Upper Nile Province led by the Anya Nya, a Southern Sudanese guerrilla organization. Bitterly opposed to the policies of the government and disenchanted with the ineffectual attempts by the more moderate southern leaders to reach a settlement, the Anya Nya declared open hostility against the Northern Sudanese in the belief that only violent resistance would make the government of General Abboud seek a solution acceptable to the southerners. Taking refuge in the illimitable bush, the guerrillas continued their sporadic attacks on isolated posts of the Sudan army, while the Southern Sudanese carried on their way of life much as before, wandering off when the pressure of government became too great, returning when the weight of administration relaxed. Without confidence, however, there was little growth or progress in any field. Thus, while economic and educational developments transformed the north, the south remained a stagnant backwater. Blind to the aspirations of the Southern Sudanese and devoid of imagination in their dealings with them, the generals in Khartoum sought to establish their authority by repression, which increased in proportion to southern discontent.

The Anya Nya revolt

Resistance in the north. Although the Northern Sudanese had little sympathy for their countrymen in the south, the intelligentsia was able to use the government's failure there to assail authoritarian rule in the north and to revive demands for democratic government that the military coup d'etat had brought to an end. By 1962 numerous urban elements, including the intelligentsia, the trade unions, and the civil servants, as well as the powerful religious brotherhoods, had become alienated from the military regime. The intelligentsia resented its exclusion from the councils of government, the trade unions chafed at the restrictions placed upon their activities, and the civil servants sulked at orders from their military ministers. Even the more conservative religious brotherhoods grew restless when they were unable to carry on their former political activities. Moreover, the tribal masses and growing proletariat had become increasingly apathetic toward the government. Military reviews, parades, and heroic pronouncements were no substitute for the enthusiasm of party politics and the passions stirred by political action. Even if they considered the problem, the military rulers never provided an outlet for the political frustrations of the Sudanese, and in the end the regime was overwhelmed by boredom and overthrown by the reaction to its lassitude. The means of its overthrow was the southern problem.

In October 1964 students at the University of Khartoum held a meeting in defiance of a government prohibition in order to condemn publicly government action in the Southern Sudan and to denounce the regime. In the ensuing clash with police one student was killed. Larger demonstrations followed, and with most of its forces committed in the Southern Sudan, the military regime was unable to maintain control. The disorders soon spread and General Abboud, unwilling to crush the disturbances with massive repression, resigned as head of state, and a transitional government was appointed to govern under the provisional constitution of 1956.

The Sudan since 1964. Under the leadership of Sirr al-Khātim al-Khalīfah, the transitional government held elections in April and May 1965 to determine an elected, representative government. A coalition government led by a leading Ummah politician, Muḥammad Aḥmad Maḥjūb, was formed in June 1965. As before, parliamentary government was characterized by factional disputes. On the one hand, Maḥjūb enjoyed the support of the traditionalists within the Ummah Party represented by the imam al-Hādī, the spiritual successor to Sayyid ʿAbd ar-Raḥmān al-Mahdī, while he was challenged by the Sayyid Ṣādiq al-Mahdī, the young great grandson of the Mahdī, who led the more progressive forces within the

Ummah. Unable to find common objectives to unite their differences, the Parliament failed to deal with the economic, social, and constitutional problems in The Sudan. Moreover, the earlier hopes expressed by the transitional government of cooperation with the southerners soon vanished before northern intransigence and southern indecision, disunity, and paucity of leadership. Conflict continued in the south, and with little hope of resolution dragged on tragically from one year to the next. Having no workable constitution, a stagnant economy, a political system torn by secretarian interests, and a continuing civil conflict in the Southern Sudan, a group of young officers led by Col. Gaafar an-Nimeiry seized the government on May 25, 1969. For the second time the army had seized control of The Sudan in an effort to resolve the formidable problems that had defied resolution by the politicians.

Resumption of military control

BIBLIOGRAPHY. The early history of the Sudan is best presented by P.L. SHINNIE in *Meroe: A Civilization of the Sudan* (1967); and YUSUF FADL HASAN, *The Arabs and the Sudan* (1967). The age of the Funj is most comprehensively covered by O.G.S. CRAWFORD in *The Fung Kingdom of Sennar* (1951), supported by ANDREW PAUL, *A History of the Beja Tribes of the Sudan* (1954). The best recent history of the Sudan from the Funj sultanate to the present is P.M. HOLT, *A Modern History of the Sudan* (1961), which is admirably suited to the general reader. Holt's account may be supplemented by more specialized studies, particularly R.L. HILL, *Egypt in the Sudan, 1820–1881* (1959); and Holt's own study of the Mahdist period, *The Mahdist State in the Sudan, 1881–1898* (1958). The reconquest of the Sudan resulted in a great outpouring of historical literature. The campaigns themselves are brilliantly narrated by WINSTON S. CHURCHILL in *The River War: An Account of the Reconquest of the Soudan*, 2 vol. (1899). The formulation of British policy that led to the Anglo-Egyptian reconquest is adequately analyzed by MÉKKI SHIBEIKA in *British Policy in the Sudan, 1882–1902* (1952); G.N. SANDERSON, *England, Europe, and the Upper Nile, 1882–1899* (1965); and in the decade immediately following the Fashoda crisis by ROBERT O. COLLINS, *King Leopold, England, and the Upper Nile, 1899–1909* (1968). There is no adequate single history of the Anglo-Egyptian condominium, although SIR HAROLD A. MACMICHAEL, *The Sudan* (1954); and J.S.R. DUNCAN, *The Sudan* (1952) and *The Sudan's Path to Independence* (1957), present a general survey. Thus the student must seek the story of Anglo-Egyptian rule in a host of biographies, memoirs, and personal reminiscences. The transitional period of self-government and the vicissitudes of independence have been narrated by K.D.D. HENDERSON, *Sudan Republic* (1965). The Southern Sudan has its own historical literature, the most useful being RICHARD GRAY, *A History of the Southern Sudan, 1839–1889* (1961); ROBERT O. COLLINS, *The Southern Sudan, 1883–1898* (1962) and *Land Beyond the Rivers: The Southern Sudan, 1898–1918* (1971); and J. ODUHO and W. DENG, *The Problem of the Southern Sudan* (1963).

(R.O.C.)

Nineveh

Nineveh, the most populous and the oldest city in Assyria, lay on the east bank of the Tigris opposite modern Mosul (in Iraq). From time immemorial, roads from the foothills of Kurdistan debouched there, and a tributary of the Tigris, the Khawṣar River, added to the value of the fertile agricultural and pastoral lands in the district. The first to survey and map Nineveh was the archaeologist Claudius J. Rich in 1820, a work later completed by Felix Jones and published by him in 1854. Excavations have been undertaken intermittently since that period by many persons. A.H. (later Sir Henry) Layard during 1845–51 discovered the palace of Sennacherib and took back to England an unrivalled collection of stone basreliefs together with thousands of tablets inscribed in cuneiform from the great library of Ashurbanipal. Hormuzd Rassam continued the work in 1852. During 1929–32 R. Campbell Thompson excavated the temple of Nabu (Nebo) on behalf of the British Museum and discovered the site of the palace of Ashurnasirpal II. In 1931–32, together with M.E.L. (later Sir Max) Mallowan, Thompson for the first time dug a shaft from the top of the Quyunjik (Acropolis), 90 feet (30 metres) above the level of the plain down through strata of accumulated debris of earlier cultures to virgin soil. It was then proved that over four-fifths of this great accumulation is prehistoric.

Early settlements in Neolithic times

The first settlement, a small Neolithic hamlet, was probably founded not later than the 7th millennium BC. An obsidian-blade industry suggests that there was contact from the beginning with Van in eastern Armenia. Hassuna-Sāmarrā' and Tall Halaf painted pottery of the subsequent Early Chalcolithic phases, characteristic of the north, was succeeded by gray wares such as occur westward in the Jabal Sinjār. Farmers during the 4th millennium used clay sickles of a type found in the Ubaid period, and these imply contact with the south.

One of the most remarkable discoveries that Mallowan and Thompson made within the mound of Quyunjik in the prehistoric strata consisted of many hundreds of roughly made, bevelled bowls, overturned in the soil and filled with vegetable matter. On the analogy of much later medieval deposits they may have been intended as magical offerings to expel evil spirits from houses. Their typology conforms exactly with that of Uruk (Erech) pottery, which was widespread throughout the Tigris-Euphrates Valley in the late 4th millennium. In these levels also large metal vases occur, again characteristic of southern Babylonia, and there can be no doubt that technologically this district of the Tigris had much in common with the cities of the lower Euphrates Valley at this period. This similarity is of particular interest because it indicates that some time before 3000 BC, a period of economic prosperity had united the commercial interests of north and south in an altogether exceptional manner, for later these two civilizations diverged widely.

A little before and after 3000 BC, unpainted Ninevite pottery was similar to that used at Sumerian sites such as Ur and Uruk (biblical Erech); to approximately the same period belongs a series of attractively painted and artistically incised ware known as Ninevite V, which is a home product distinct from that of the south. Hoards of beads found in these strata may be dated *c.* 2900 BC.

Metal sculpture from the 3rd millennium

The most remarkable object of the 3rd millennium BC is a realistic bronze head—life-size, cast, and chased—of a bearded monarch. This, the finest piece of metal sculpture ever recovered from Mesopotamia, may represent the famous King Sargon of Akkad (*c.* 2334–*c.* 2279 BC). This bronze head, however (now in the Iraq Museum, Baghdad), because of its brilliant technique and elaborately modelled features, is thought by some authorities to belong to a rather later stage of the Akkadian Period (*c.* 2334–*c.* 2154 BC); if so, the head might represent King Naram-Sin (*c.* 2254–*c.* 2218 BC). The hypothesis for the earlier period seems preferable, for metal work advanced more rapidly in style in Mesopotamia at that period than did stone sculpture, and it is known from inscriptions that Sargon's second son, Manishtusu, had built the temple of E-Mashmash at Nineveh by virtue of being the "son of Sargon"; thus a model of the founder of the dynasty would have been appropriately placed there.

Surprisingly, there is no large body of evidence to show that Assyrian monarchs built at all extensively in Nineveh during the 2nd millennium BC: certainly not during the four centuries that succeeded Shamshi-Adad I (*c.* 1813–*c.* 1781 BC), when Assyria was of little account because of the power of the superior Hittite, Kassite, and Mittanian dynasties. An interesting historical document, however, describes a victorious campaign of Ashur-uballit I (ruled *c.* 1365–*c.* 1330 BC) against a Kassite usurper, during a period of Assyrian renascence. The fame of Ishtar of Nineveh had indeed reached the ears of the Pharaoh before that, for her statue was sent to Egypt by Tushratta, king of Mitanni, to restore the Pharaoh's health. Later monarchs whose inscriptions have appeared on the Acropolis include Shalmaneser I and Tiglath-pileser I, both of whom were active builders in Ashur; the former had founded Calah (Nimrūd).

But Nineveh had to wait for the neo-Assyrians, particularly from the time of Ashurnasirpal II (ruled 883–859 BC) onward, for a considerable architectural expansion. Thereafter successive monarchs kept in repair and founded new palaces, temples to Sin, Nergal, Nanna, Shamash, Ishtar, and Nabu (Nebo). Unfortunately, severe depredations have left few remains of these edifices.

It was Sennacherib who made Nineveh a truly magnificent city (*c.* 700 BC). He laid out fresh streets and squares and built within it the famous "palace without a rival," the plan of which has been mostly recovered and has overall dimensions of about 600 by 630 feet (180 by 190 metres). It comprised at least 80 rooms, of which many were lined with sculpture. A large part of the famous "K" collection of tablets was found there (see below); some of the principal doorways were flanked by human-headed bulls. At this time the total area of Nineveh comprised about 1,800 acres (700 hectares), and 15 great gates penetrated its walls. An elaborate system of 18 canals brought water from the hills to Nineveh, and several sections of a magnificently constructed aqueduct erected by the same monarch were discovered at Jerwan about 25 miles (40 kilometres) distant.

His successor Esarhaddon built an arsenal in the Nabī Yūnus mound, south of Quyunjik, and either he or his successor set up statues of the pharaoh Taharqa (Tarku) at its entrance as trophies to celebrate the conquest of Egypt. These were discovered by Fuad Safar and Muḥammad ʿAlī Muṣṭafā on behalf of the Iraqi Department of Antiquities in 1954.

Ashurbanipal's library and the "K" collection

Ashurbanipal later in the 7th century BC constructed a new palace at the northwest end of the Acropolis. He also founded the great library and ordered his scribes to collect and copy ancient texts throughout the country. The "K" collection included more than 20,000 tablets or fragments of tablets and incorporated the ancient lore of Mesopotamia. The subjects are literary, religious, and administrative, and a great many tablets are in the form of letters. Branches of learning represented include mathematics, botany, chemistry, and lexicology. The library contains a mass of information about the ancient world and will exercise scholars for generations to come.

Fourteen years after the death of Ashurbanipal, however, Nineveh suffered a defeat from which it never recovered. Extensive traces of ash, representing the sack of the city by Babylonians, Scythians, and Medes in 612 BC, have been found in many parts of the Acropolis. From the ruins it has been established that the perimeter of the great Assyrian city wall was about 7.5 miles (12 kilometres) long and in places up to 148 feet (45 metres) wide; there was also a great unfinished outer rampart, protected by a moat, and the Khawṣar River flowed through the centre of the city to join the Tigris on the western side of it.

The 15 great gates that intersected the Acropolis walls were built partly of mud-brick and partly of stone. The long eastern sector, about three miles (five kilometres), contained six gates; the southern sector, 2,624 feet (800 metres), contained only one, the Ashur Gate; the western sector, about 2.5 miles (four kilometres), had five gates; the northern sector, about 1.2 miles (two kilometres), three gates, Adad, Nergal, and Sin. Several of these entrances are known to have been faced with stone colossi (lamassu). In the Nergal Gate two winged stone bulls, attributable to Sennacherib, have been reinstalled: a site museum has been erected adjacent to it by the Iraqi Department of Antiquities. The Adad Gate contained many inscribed tiles, and what may prove to be the Sin Gate contained a corridor that led through an arched doorway into a ramp or stairwell giving access to the battlements.

Most impressive was the Shamash Gate, which has been thoroughly excavated by Tariq Madhloum on behalf of the Iraqi Department of Antiquities. It was found to have been approached across two moats and a water course by a series of bridges in which the arches were cut out of the natural conglomerate. The wall was faced with limestone and surmounted by a crenellated parapet, behind which ran a defense causeway. The structure was built with mud as well as burnt bricks, which bore the stamp of Sennacherib. There was an entrance 14.8 feet (4.5 metres) wide in the centre of a long, projecting bastion, which was further strengthened by six towers. Crudely incised stone slabs on the inner side of the gateway depicted the burning of a tower; it is possible that these carvings represented the fall of Nineveh and are post-Assyrian. The internal plan of the gate includes six great chambers lined with uncarved orthostats (upright slabs), which were discovered by Layard and Rassam.

Archaeologists also have been active within the Quyunjik (Acropolis). Since 1966 Madhloum has been restoring the throne room of Sennacherib's palace and some of the adjoining chambers. He found that all the entrances to the two main chambers were flanked by winged bull colossi, and he recovered a series of orthostats not recorded by any of the 19th-century excavators. One such slab illustrates a foreign city, heavily defended by towers, surrendering to the Assyrian army. He discovered a stone paved bathroom adjoining the throne room and, in the great antehall, no fewer than 40 carved orthostats. The subjects represented include Sennacherib's campaigns against mountain-dwelling peoples, besieged cities, and units of the Assyrian army.

Decline of Nineveh

After 612 BC the city ceased to be important, although there are some Seleucid and Greek remains. Xenophon in the *Anabasis* recorded the name of the city as Mespila. In the 13th century AD the city seems to have enjoyed some prosperity under the *atabegs* of Mosul. Subsequently, houses continued to be inhabited at least as late as the 16th century AD. In these later levels imitations of Chinese wares have been found.

(M.Mn.)

Ningsia Hui

Ningsia Hui (Ning-xia Hui in Pin-yin romanization), an autonomous region of the People's Republic of China, is bounded on the east in part by Shensi and on the east, south, and west by Kansu, and on the north by the Inner Mongolian Autonomous Region. About one-third of its population of 2,200,000 in 1970 was Hui (Chinese Muslim). Most of the region is desert, but the vast plain of the Huang Ho (Yellow River) in the north has been irrigated for agriculture for centuries. The total area of the autonomous region is 65,600 square miles (170,000 square kilometres). Its capital is Yin-ch'uan.

Ningsia Hui is nearly coextensive with the ancient kingdom of the Tangut people, known in China as the Hsi Hsia; after its conquest by Genghis Khan, it was named Ningsia (Peaceful Hsia).

History. Irrigation canals on the Ningsia plains of the Huang Ho dating from the time of the Ch'in, Han, and T'ang dynasties (*i.e.*, from about 220 BC) provide evidence that the area has long been inhabited.

In the 11th century AD the area became part of the kingdom of Tangut (Hsi Hsia) in western China. Yin-ch'uan, its chief city and now the capital, was captured by Genghis Khan early in the 13th century and remained tributary to China. In 1914 the area became a part of the province of Kansu, and in 1928 it was constituted as the province of Ningsia. In 1954, under the People's Republic of China, the province was again merged with Kansu; in 1956 that part of Ningsia largely occupied by Mongolians became a part of the Inner Mongolian Autonomous Region; and in 1958 the rest of the former province became the Ningsia Hui Autonomous Region.

Physical geography. Physiographically, the Ningsia Hui region can be divided into two parts. Southern Ning-

sia Hui is part of the Loess Plateau, with the Liu-p'an Shan (Liu-p'an Mountains) as the main ridge. The region is covered with a thick layer of loess, in some places over 300 feet deep, and the topography is generally fairly flat. Northern Ningsia Hui is made up for the most part of the Ningsia plain of the Huang Ho, which enters Ningsia Hui from the Tsinghai plateau in Kansu and flows east, then north into Inner Mongolia. On an elevation of 3,600–3,900 feet (1,100–1,200 metres), the plain slopes gradually from south to north. West of the plain are the Ho-lan Shan. These mountains serve as a shelter against the sandstorms from the Ala Shan, a desert to the west. In the piedmont belt, a few coal mines have been opened.

With an annual precipitation of only eight inches (200 millimetres), the Ningsia plain is an arid area, but the Huang Ho provides irrigation. Many canals have been built over the centuries. The network of willow-lined canals and paddy fields gives the landscape a look resembling that of southern China. The climate is continental. Temperatures range from an annual average maximum of 80° F (27° C) to an annual average minimum of 7° F (−14° C).

Ethnic composition of the people

Population. The ethnic composition of Ningsia Hui includes the Han (Chinese-speaking Chinese), Hui (Chinese Muslims), Mongolians, and Manchus. Out of the total population of about 2,200,000 (1970), about 700,000, or one-third, were Hui and 1,000,000 were Han. The Mongolians and Manchus, combined, numbered about 500,000. The people speak Mandarin Chinese, Tibetan, and Mongolian, and the predominant religions are Islām or Buddhism. Islām is well developed and has the most believers, including the Hui. In the late 1940s, before the Communists came into power, it was estimated that Muslims comprised 60 percent of the total population.

The region is predominantly rural, with most of the population engaged in pasturing and farming the land. One of China's more sparsely settled areas, Ningsia Hui has a population density of about 34 persons per square mile (13 per square kilometre). In the widely scattered cities, residents have traditionally been devoted to handicrafts. In recent years, however, more workers have begun to be employed in mining and manufacturing.

Administration. Until 1958 the Hui minority of the region was organized into two autonomous districts (*tzu-chih-chou*) and one autonomous county (*tzu-chih-hsien*). Wu-chung Hui Autonomous District had a population of 230,000, about 62 percent of whom were Hui. Its capital was at Wu-chung. Ku-yüan Hui Autonomous District had a population of 220,000. Its capital was at Ku-yüan. Finally, there was the Ching-yüan Hui Autonomous County, on the southern border of the Ku-yüan District, with its seat in the former county town of Hwa-pingling (now known as Ching-yüan).

In 1958 the two autonomous districts and the Ching-yüan County became part of the Ningsia Hui Autonomous Region. In 1969 the region acquired a Mongol banner (district)—A-la-shan East. The banner had its headquarters at A-la-shan-tso-ch'i; its annexation increased the total area from 25,000 to about 65,000 square miles. Local government is organized in accord with the Chinese Communist Party plan.

Social conditions. Ningsia Hui was formerly a backward area in education. In 1935 there was not a single college in the province. There were only two high schools; two normal schools, with about 425 students; and about 200 elementary schools, with 12,600 students.

Advances in education

About 85 percent of the children did not attend schools. Since the Communist government was organized in 1949, much improvement has been reported. It was estimated that by 1958 illiteracy had been reduced by more than 60 percent. In 1965 the region was reported to have 3,000 elementary schools, 185 high schools, and three colleges and special technical colleges, with a total enrollment of 289,000 students.

In the area of public health, there are reported to be about 860 hospitals.

Economy. The Ningsia plain produces abundant wheat and good-quality rice. Cash crops include sesame and sugar beet. In the mixed agricultural and pastoral areas, a good breed of sheep, a domesticated form of the argali of eastern Mongolia, is being raised. Its wool is soft, white, and lustrous. The Manchus especially have long been known for breeding and raising pigs. The principal crops are rice, wheat, millet, cotton, and sugar beets. Melons and apricots are also grown in quantity.

Mineral resources of Ningsia Hui are limited to coking-coal reserves in the P'ing-lo area, near the Inner Mongolian border. Coal was mined on a small scale in the past but has been expanded since the construction of the Pao-t'ou–Lan-chou railroad in 1958. Well-known in ancient times as a border city on the western frontier of China, the capital, Yin-ch'uan, used to be a trading centre for farm and animal products. Now medium-sized and small factories have been built there, including a farm-tool plant and a woolen-textile mill.

Transportation. Yin-ch'uan, the capital of the autonomous region, lies in the centre of the Ningsia plain. The Huang Ho, to the east, provides irrigation and water transportation facilities.

The Pao-t'ou–Lan-chou railway, an extension of the main Peking–Pao-t'ou railway completed in 1958, now links Yin-ch'uan to the two new industrial bases of Pao-t'ou (in Inner Mongolia, to the north) and Lan-chou (in Kansu, to the south) and helps the development of industry and agriculture in Ningsia Hui.

Cultural life. Hui cultural life is intimately interrelated with the Hui religion, Islām. Muslims, for example, never eat pork, and this religious practice has caused much trouble between the Hui and the Han, who, like the Manchus, are fond of pork. The Hui woman traditionally keeps house; her role is domestic, and she cannot have contact with outside work. When they go out, Hui women must wear the veil to conceal their faces, and they are forbidden to talk to males. Under the Communist regime, however, Hui women have had to do farm work in the communes and production work in the factories. The traditional culture is undergoing change.

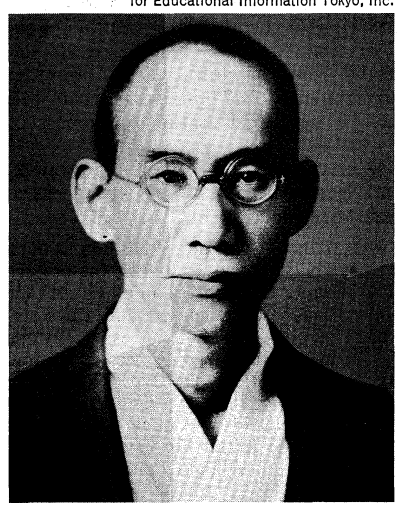
(C.–M.H.)

Nishida Kitarō

Nishida Kitarō was the outstanding Japanese philosopher of the last 100 years, during which period the Japanese endeavoured to assimilate Western philosophy and to produce original works based on the Oriental spiritual tradition. Nishida was both an outstanding example of and influence upon this cultural development.

Nishida's life. He was born on April 19, 1870, in a little village near Kanazawa in Ishikawa Prefecture. His father, Nishida Yasunori, was for a time a teacher of the elementary school in the village, among whose few pupils was Kitarō. His mother, Tosa, was a pious devotee of the Jōdo, or "True Pure Land," school of Buddhism. He respected his mother very highly and cherished her memory. Although Nishida's family was descended from a former village landowner, Yasunori ruined his fortune when Kitarō was young, and all of the Nishidas had to move to Kanazawa in 1883. Kitarō entered primary course at Kanazawa Normal School in that year but had to leave on account of sickness in the following year. He was admitted in 1886 into the second

class of the high school, and in 1888 he became a student of the Fourth Higher School (junior college). In his boyhood, Nishida took traditional lessons in Chinese from an excellent Confucian teacher, and in his higher school days he was taught by another good scholar erudite in Chinese. Another important teacher of Nishida's was Hōjō Takiyoshi, a professor of mathematics of the Fourth Higher School, under whom Nishida had studied mathematics even before he entered high school. Such a training and refinement of his personality through Chinese culture enriched his life with a lasting Confucian quality and worldview. Later, when Western philosophy and Buddhism (especially Zen Buddhism) were merged in his mature mind, there remained deep within him an undercurrent of Confucian conviction with regard to "the ideal man," "the Way" to good and truth, sincerity, self-negation, and detachment. He and his contemporaries belonged to the last Japanese generation whose education in the Chinese Classics molded their personal character. From his boyhood days, he made several good friends in Kanazawa, among whom was D.T. Suzuki, later an eminent Buddhologist and the main interpreter of Zen Buddhism to the West. Nishida and Suzuki became classmates at higher school, and from that time their mutual spiritual influence continued till Nishida's death.



Nishida Kitarō.

In his memoirs, entitled "A Certain Professor's Statement upon Retirement (from Kyōto University, December 1928)," he writes:

> My student days at the Fourth Higher School were the happiest of my life. I was filled with youthful zest. I did anything I wished, heedless of the consequences. As a result I had to leave school before my graduation. At the time I thought it was not necessarily true that one could not achieve anything by studying alone. In fact I thought it would be better to rid myself of the fetters of school and to read freely. But within one year I was prohibited to read any more by my doctor, since I was afflicted with an eye disease. I had to abandon my principle, and went to Tokyo to be a non-regular student of philosophy, in Tokyo University (1891–1894).

At that time in the Faculty of Letters and Law, there were several promising students who later became famous, some as men of letters and others as university professors. Together with them, Nishida appeared at the same lectures but could not form close friendships, as he had done in higher school. After graduation he became a teacher in a middle school near his home (1895). In the following year, he was appointed a lecturer in the Fourth Higher School at Kanazawa; and after two years as a lecturer and later as a professor at the Yamaguchi Higher School in Yamaguchi, he was again appointed as a professor of the Fourth Higher School, teaching psychology, logic, ethics, and German (1899–1909). During his Yamaguchi and Kanazawa teaching periods, he was much engaged in the practice of Zen meditation. Remarks about Zen practice are overwhelmingly conspicuous in his diary of this period. From this effort and through his lectures at the higher school came Nishida's maiden work, *Zen-no-Kenkyū*, (1911; Eng. trans., *A Study of Good*, 1960). At about this time parts of the book were published in Japanese philosophical journals, and his name as an original philosopher attracted attention in the Japanese philosophical world.

After one year as professor at Gakushūin University (Tokyo) in 1909, he was appointed associate professor of ethics at Kyōto University. In 1913 he was appointed professor of philosophy of religion and in 1914 professor of philosophy, a post he held until his retirement in 1928. About the end of his professorship in Kyōto University, Nishida's philosophy attained its maturity, which can be defined as "the philosophy of the *topos* [place] of Nothingness." In his latter years he delved most deeply into philosophical problems and endeavoured to explain more concrete facts by his logic. Thus his idea of the true reality that overcomes the dichotomy of subjectivity and objectivity (the mind and its objects) in the *topos* of Nothingness became significant, he emphasized, for "historical reality in the historical world." Nishida developed this implication of absolute Nothingness in his *Tetsugakulon-Bunshū* ("Philosophical Essays"; 7 vols.), which he wrote after his retirement. In his last days, as World War II was coming to an end, looking at the fires of the burning cities in the darkness of night, Nishida was much inspired by the words of the prophets of Israel in the Old Testament. He said that the result of this war might be something that neither the victors nor the vanquished could at that time foresee. He died on June 7, 1945, at Kamakura.

Philosophy of Nothingness

Nishida's philosophy was attacked by the nationalists and militarists during World War II because of the Western way of his philosophical thinking. Since then he has been criticized for his loyalty to his nation and for his alleged metaphysical obscurantism by Marxist philosophers and antimetaphysical Rationalist philosophers, but such criticism is decreasing for lack of solid grounds. More philosophically important are the criticisms by Takahashi Satomi and Tanabe Hajime. Takahashi was the first scholar to appreciate and evaluate the distinctively Japanese philosophy in Nishida's *Zen-no-Kenkyū*, and later he contributed his critical investigation of Nishida's philosophy in its mature form. Tanabe, Nishida's disciple, who succeeded him in the chair of professor of philosophy at Kyōto University (1927–45), contributed valuable criticism from his own philosophical point of view.

The three stages of Nishida's thought. Nishida says in his memoirs that he thought of his life in terms of a change of position with the blackboard as an axis; in the first half of his life he sat at a desk facing the blackboard, while in the latter half he sat with the blackboard behind him. Continuing this metaphor, it may be said that in the third stage (see below), represented by his philosophy of the *topos* of Nothingness, he wished to relinquish both positions, whether in front of or behind the blackboard, so that he and his logic became chalk on the blackboard of the historical world. In Nishida's philosophy, each stage has its independent value. Like a series of vortexes floating on the stream when two (*i.e.*, Western and Eastern) rivers converge, each closes its own circle. The preceding system should not be replaced by the later, even if they flow successively.

In the first stage of his philosophy, Nishida derived his basic insights from his long, concentrated practice of Zen. He was also much inspired by William James's philosophy and psychology, and tried to interpret his own basic insights philosophically with the use of psychological concepts borrowed from James. The opening page of Nishida's *Zen-no-Kenkyū* indicates the general direction of his thought:

> To experience means to know events precisely as they are. It means to cast away completely one's attitude of discriminative reflection, and to know in accordance with the events. Since people include some reflection even when speaking of experience, the word "pure" is here used to

His notion of pure experience

signify a condition of true experience itself without the addition of the least thought or reflection. For example, it refers to that moment of seeing a color or hearing a sound which occurs not only before one has added the judgment that this seeing or hearing relates to something external or that one is feeling this sensation, but even before one has judged what color or what sound it is. Thus, *pure experience* is synonymous with *direct experience*. When one experiences directly one's conscious state there is as yet neither subject nor object, and knowledge and its object are completely united. This is the purest form of experience.

The concept of pure experience expounded here is the Western philosophical mold into which Nishida poured his own religious experience cultivated by his Zen training. As it is beyond the dichotomy of subject and object, so it is far removed from the difference of whole and part. The whole universe is, as it were, crystallized into one's own being. In the total activity of one's own pure and alert life, one's entire being becomes transparent, so that it reflects, as in a mirror, all things as they become and also participates in them. This is "to know in accordance with the events." The profoundness of reality, the directness of one's experience of reality, a dynamic system developing itself in the creative stream of consciousness —these are the characteristic motifs of Nishida's philosophy, all suggesting where his thinking was ultimately rooted. According to Nishida, judgment is formed by analysis of the intuitive whole. For instance, the judgment that a horse runs is derived from the direct experience of a running horse. The truth of a judgment is grounded on the truth of the original intuitive whole from which the judgment is formed through the dichotomy of subject and predicate or that of subject and object. For the establishment of its truth a judgment is, through its dichotomy itself, referred back to intuition as its source, because intuition is here considered a self-developing whole, similar to Hegel's Notion (*Begriff*). As Hegel says, "All is Notion," or "All is judgment," so could Nishida say, "All (reality) is intuition," or "All reality is immediate consciousness." For this is practically the import of his dictum, "Consciousness is the Unique Reality."

In the second stage of his philosophy, Nishida was under the influence of the philosophy of Henri Bergson, a French philosopher, which he tried to synthesize with a Neo-Kantian type of German thought that was then prevalent in Japanese philosophical circles. He thus entered the second stage of his thinking, the result of which was incorporated into a book entitled *Jikaku-ni okeru chokkan to hansei* (1917, "Intuition and Reflection in Self-consciousness"). His basic notion did not undergo any change, but he tried to express what he once called pure experience in a different way. Neo-Kantian influence led him to eliminate from his thought all psychological terms and to follow strictly the path of logical thinking to the end. Actually, however, he found himself standing at the end of a blind alley, where he came up against something that was impenetrable to his logic. "After a long struggle with the Unknowable my logic itself bade me surrender to the camp of mysticism," so he himself says in the preface. Thus the self as the unity of thought and intuition acquires a mystical background. It is pure activity but ultimately finds itself in the abyss of darkness, enveloping every light of self-consciousness. This darkness, however, is "dazzling obscurity" giving the self the unfathomable depth of meaning and being. The self is thus haloed with a luminous darkness.

The "Non-self" and individuality

The third stage of Nishida's philosophy was marked by a reversal of his whole procedure, as is shown in his *Hataraku-mono kara miru-mono e* (1927, "From the Acting to the Seeing Self"). Whereas he had always made the self the starting point for his philosophical thinking, he now parted definitely with Transcendental Idealism (see IDEALISM) or, rather, broke through it to find behind it a realm of reality corresponding to his own mystical experience. This may be called the realm of Non-self, or Nothingness, which should not be confused with the non-self of Idealism as the realm of the objective over against that of the subjective, or with annihilating nothingness of Sartre's Existentialism. The "Non-self" of Nishida is the ultimate reality where all subject–object cleavage is overcome. In accordance with Buddhist tradition he called it "Nothingness" and sought to derive the individual reality of everything in the world, whether it be a thing or a self, from the supreme identity of Nothingness. The Idealist "pure self," as the universal consciousness or consciousness in general, is still abstract, while the "Non-self" of Nishida establishes itself as true individuality in the absolute Nothingness, which includes, not excludes, the individual reality of the thing-in-itself (the ultimate reality of things). Indeed, the problem of the individual now became Nishida's chief concern. In his quest for its solution he made an intensive study of Greek philosophy, especially Plato and Aristotle. He found the thinking of these philosophers to be relatively free from the cleavage of subject and object, in comparison with modern Western philosophy, which always presupposes, consciously or unconsciously, the *cogito* (the thinking subject) as the starting point of thought. The ontology of Plato and Aristotle rather makes a logic of reality reveal itself, a logic that explains the world of reality as seen from within. Whether "explaining" or "seeing," such a logic is to be understood as an act taking place in the world of reality itself. Nishida seeks thus to clarify the significance of the individual and the universal from the viewpoint of the Absolute Nothingness. Thus he propounds that Nothingness or *mu* is the universal that is to be sought behind the predicate as the universal concept and, at the same time, is the abyss of Nothingness in which the self as the individual is crystalized. He developed the idea of the "*topos* of Nothingness," adopting the concept of *topos* from Plato's *Timaeus* and from this time on Nothingness is explained as the uniqueness of the *topos*.

In the fourth stage of the development of his thought, Nishida applied the idea of the *topos* of Nothingness to the explanation of his "historical world."

BIBLIOGRAPHY. SHIMOMURA TORATARO, "Nishida Kitaro and Some Aspects of His Philosophical Thought," the preface to Nishida's *A Study of Good* (1960), gives an excellent view of the history of modern Japanese philosophy and a description of the development of Nishida's thought, especially the early period, when Japan was undergoing westernization. VALDO H. VIGLIELMO, "Nishida Kitaro, The Early Years," in *Tradition and Modernization in Japanese Culture*, ch. 13 (1971), goes into details of Nishida's younger days (until 1903). DAVID A. DILWORTH, "The Initial Formations of 'Pure Experience' in Nishida Kitaro and William James," in *Monumenta Nipponica*, 24:93–111 (1969), treats the influence of William James on Nishida's thought, and compares the two philosophies. See also the same author's "The Range of Nishida's Early Religious Thought: Zen no Kenkyū," *Philosophy East and West*, 19:409–421 (1969); and "Nishida's Final Essay: The Logic of Place and Religious World-View," *ibid.*, 20:355–367 (1970); and NODA MATAO, "East-West Syntheses in Kitarō Nishida," *ibid.*, 4:345–359 (1955), which stresses the significance of Nishida's later thought as compared with the philosophical ideas of Whitehead. The following works of Nishida are available in English translation. *A Study of Good*, trans. by VALDO H. VIGLIELMO (1960), is Nishida's maiden work which gives a well-balanced treatment of philosophical problems. *Intelligibility and the Philosophy of Nothingness*, trans. by ROBERT SCHINZINGER (1958), and *Fundamental Problems of Philosophy*, trans. by DAVID A. DILWORTH (1970), include introductory remarks on Nishida's life and work. See also "Nishida Kitarō: The Problem of Japanese Culture," trans. by ABE MASAO in *Sources of the Japanese Tradition*, pp. 857–872 (1958); and GINO K. PIOVESANA, *Recent Japanese Philosophical Thought, 1862–1962* (1963).

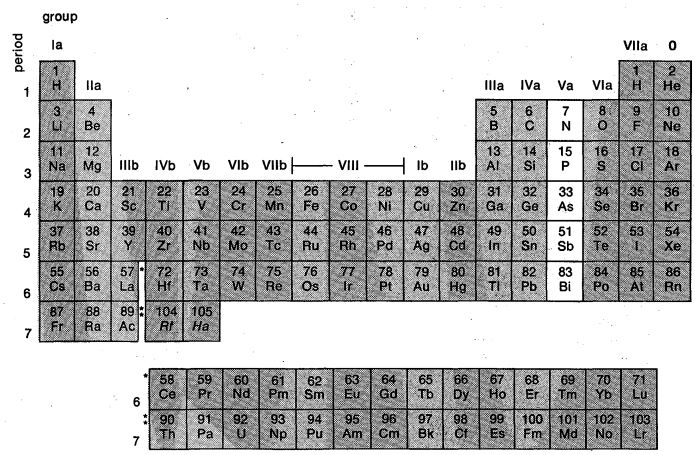
Nitrogen Group Elements and Their Compounds

In the formal classification of the chemical elements known as the periodic table, the nitrogen group elements, consisting of nitrogen (N), phosphorus (P), arsenic (As), antimony (Sb), and bismuth (Bi), form a vertical file commonly designated group Va (see figure). These elements share certain general similarities in chemical behaviour, though they are clearly differentiated from one another

chemically, and these similarities reflect common features of the electronic structures of their atoms. For this reason, they are conveniently discussed together.



Nitrogen group elements in the periodic table of elements.

Probably no other group of the elements is more familiar to the layman than this group. Although the five elements together make up less than 0.2 percent by weight of the earth's crust, they assume an importance far out of proportion to their abundance. This is especially true of the elements nitrogen and phosphorus, which comprise 2.4 and 0.9 percent, respectively, of the total weight of the human body.

The nitrogen elements have, perhaps, the widest range in physical state of any group in the periodic table. Nitrogen, for example, is a gas that liquefies at about −200° C, whereas bismuth is a solid melting at 271° C and boiling at about 1,560° C. Chemically, too, the range in properties is wide, nitrogen and phosphorus being typical nonmetals; arsenic and antimony, metalloids; and bismuth, a metal. Even in appearance these elements exhibit great variety. Nitrogen is colourless both as a gas and as a liquid. Phosphorus exists in a variety of physical modifications, or allotropic forms, including the familiar white, highly reactive form that must be stored under water to prevent it from igniting in the air; a much less reactive red or violet form; and a black modification that, although least known, appears to be the most stable of all. Arsenic exists mainly as a dull gray metallic solid, but a more reactive yellow, solid form is also known, and there are indications that other forms exist under certain conditions. Antimony is a silver, metallic appearing, but somewhat brittle solid; and bismuth is a silver-white metal with a trace of pink in its lustre.

Physical appearance

Together with carbon, hydrogen, oxygen, and sulfur, the first two members of this group, nitrogen and phosphorus, are the principal chemical elements incorporated into living systems. Nitrogen and phosphorus are readily removed from the soil by plant growth, and therefore they are immensely important components of plant foods. Such designations as "5–10–5" on commercial fertilizers represent the respective weight percentage composition of the material in terms of nitrogen, phosphoric oxide, and potassium oxide (potassium being the third principal element needed for healthy plant growth). Nitrogen in fertilizers may be in the form of sodium or potassium nitrates, ammonia, ammonium salts, or various organic combinations. Phosphorus is supplied chiefly as inorganic phosphate.

Ironically enough, these same elements, nitrogen and phosphorus, can also be used in ways less helpful to man. The explosives in conventional warfare are heavily dependent on their content of nitrogen compounds, and the deadly nerve gases are composed of organic compounds of phosphorus.

On the other hand, arsenic, which is notorious for its toxicity, is most useful in agriculture, where its compounds are an aid in controlling harmful insect pests. Antimony and bismuth are used chiefly in metal alloys, because they impart unique and desirable properties to these alloys.

Beginning with a brief historical review, this article first studies carefully the fundamental nature of this group to see how its members are related to one another, and to reveal how this group fits into the periodic system as a whole. This study is then followed by a detailed survey of the individual elements and some of their most important compounds.

DISCOVERIES OF THE NITROGEN GROUP ELEMENTS

Nitrogen. Since four-fifths of the earth's atmosphere is nitrogen, the recognition of nitrogen as a specific substance came about during early investigations of oxygen. Carl Wilhelm Scheele, a Swedish druggist, showed in 1772 that air is a mixture of two gases, one of which he called "fire air," because it supported combustion, and the other "foul air," because it was left after the "fire air" had been used up. The "fire air" was, of course, oxygen, and the "foul air" nitrogen. At about the same time nitrogen also was recognized by a Scottish botanist, Daniel Rutherford, and by the controversial British clergyman, Joseph Priestley, who, with Scheele, is given credit for the discovery of oxygen. Later work showed the new gas to be a constituent of nitre, a common name for potassium nitrate (KNO_3); and, accordingly, it was named nitrogen by the French chemist Jean-Antoine-Claude Chaptal in 1790. Nitrogen also was considered a chemical element by Antoine-Laurent Lavoisier, whose explanation of the role of oxygen in combustion eventually overthrew the phlogiston theory, an erroneous view of combustion that became popular in the early 18th century. The inability of nitrogen to support life led Lavoisier to name it *azote*, still the French equivalent of nitrogen.

Early theories of air

Phosphorus. Arabian alchemists of the 12th century may have isolated elemental phosphorus by accident, but the records are unclear. Phosphorus appears to have been discovered in 1669 by Hennig Brand, a German merchant whose hobby was alchemy. Brand allowed 50 buckets of urine to stand until they putrified and "bred worms." He then boiled the urine down to a paste and heated it with sand, thereby distilling elemental phosphorus from the mixture. Brand reported his discovery in a letter to Gottfried Wilhelm Leibniz, and, thereafter, demonstrations of this element and its ability to glow in the dark, or "phosphoresce," excited public interest. Phosphorus, however, remained a chemical curiosity until about a century later when it proved to be a component of bones. Digestion of bones with nitric or sulfuric acid formed phosphoric acid, from which phosphorus could be distilled by heating with charcoal. In the late 1800's, James Burgess Readman of Edinburgh developed an electric furnace method for producing the element from phosphate rock, which is essentially the method employed today.

Arsenic. Arsenic was known in the form of certain of its compounds long before it was clearly recognized as a chemical element. In the 4th century BC Aristotle wrote of a substance called *sandarachē*, now believed to have been the mineral realgar, a sulfide of arsenic. Then, in the 1st century AD, the writers Pliny the Elder and Pedanius Dioscorides both described *auripigmentum*, a substance now thought to have been the dyestuff orpiment, As_2S_3. By the 11th century AD three species of "arsenic" were recognized: white (As_4O_6), yellow (As_2S_3), and red (As_4S_4). The element itself possibly was first observed in the 13th century by Albertus Magnus, who noted the appearance of a metallike substance when *arsenicum*, another name for As_2S_3, was heated with soap. It is not certain, however, that this natural scientist and scholar actually observed the free element. The first clearly authentic report of the free substance was made in 1649 by Johann Schroeder, a German pharmacist, who prepared arsenic by heating its oxide with charcoal. Later, Nicolas Lémery, a French physician and chemist, observed the formation of arsenic when heating a mixture of the oxide, soap, and potash. By the 18th century, arsenic was well known as a unique semimetal.

Antimony. The ancients were familiar with antimony both as a metal and in its sulfide form. Fragments of a

Some Properties of Nitrogen Group Elements

Chaldean vase made of antimony have been estimated to date from about 4000 BC. The Old Testament tells of Queen Jezebel using the naturally occurring sulfide of antimony to beautify her eyes. Pliny, during the 1st century AD, wrote of seven different medicinal remedies using *stibium* or antimony sulfide. Early writings of Dioscorides, dating from about the same time, mention metallic antimony. Records of the 15th century show the use of the substance in alloys for type, bells, and mirrors. In 1615 Andreas Libavius, a German physician, described the preparation of metallic antimony by the direct reduction of the sulfide with iron; and a later chemistry textbook by Lémery, published in 1675, also describes methods of preparation of the element. In the same century, a book summarizing available knowledge of antimony and its compounds was purportedly written by a Basil Valentine, allegedly a Benedictine monk of the 15th century, whose name appears on chemical writings over a span of two centuries. The name antimony appears to be derived from the Latin *antimonium*, in a translation of a work by the alchemist Geber, but its real origin is uncertain.

Bismuth. Bismuth evidently was known in very early times, since it occurs in the native state as well as in compounds. For a long period, however, it was not clearly recognized as a separate metal, being confused with such metals as lead, antimony, and tin. Miners during the Middle Ages apparently believed bismuth to be a stage in the development of silver from baser metals and were dismayed when they uncovered a vein of the metal thinking they had interrupted the process. In the 15th-century writings of Basil Valentine this element is referred to as *wismut*. The name may have been derived from the German words *wis mat*, meaning white mass. In any case it was latinized to *bisemutum* by the mineralogist Georgius Agricola, who recognized its distinctive qualities and described how to obtain it from its ores. Bismuth was accepted as a specific metal by the middle of the 18th century, and works on its chemistry were published in 1739 by the German chemist Johann Heinrich Pott and in 1753 by the Frenchman Claude-François Geoffroy.

Comparative chemistry of the nitrogen group elements

ELECTRONIC CONFIGURATIONS

Similarities in orbital arrangement. In the periodic table, each of the nitrogen group elements occupies the fifth position among the main group elements of its period, a position designated Va. In terms of the electronic configuration of its atoms, each nitrogen group element possesses an outermost shell of five electrons. In each case, these occupy an outer *s* orbital completely (with two electrons) and contribute one electron to each of the three outer *p* orbitals (the orbitals being electron regions within the atom and the letter designations, *s*, *p*, *d*, and *f*, being used to designate different classes of orbital). The arrangement of outer electrons in the atoms of the nitrogen elements thus provides three half-filled outer orbitals that, by interaction with half-filled orbitals of the atoms of other elements, can form three covalent bonds. The other atoms may attract the shared electrons either more or less strongly than do the nitrogen group atoms; therefore the latter may acquire either positive or negative charges and exist in oxidation states of +3 or −3 in their compounds. In this respect, the nitrogen elements are alike.

Another similarity among the nitrogen elements is the existence of an unshared, or lone, pair of electrons, which remains after the three covalent bonds, or their equivalent, have been formed. This lone pair permits the molecule to act as an electron pair donor in the formation of molecular addition compounds and complexes. The availability of the lone pair depends upon various factors, such as the relative size of the atom, its partial charge in the molecule, the spatial characteristics of other groups in the molecule, and the as-yet poorly understood phenomenon called the "inert pair effect." This effect consists of a tendency for the paired *s* electrons in the outermost shell of the heavier atoms of a major group to remain chemically unreactive. Because of it, the electron pair-donating ability of the nitrogen group elements is not uniform throughout the group; it is probably greatest with nitrogen, less with the intermediate elements, and nonexistent with bismuth.

Lone pairs

Variations in bonding capacity. Significant differences in electronic configurations also occur among the elements of the nitrogen group with respect both to the underlying shell and to the outer *d* orbitals. Since the latter first appear with the third period of the table, they are present in all elements of the group but nitrogen. The possibility of utilizing these outer *d* orbitals for bonding thus exists for phosphorus, arsenic, antimony, and bismuth, but not for nitrogen.

There are three principal ways in which the outer *d* orbitals can be used to increase the number of bonds or expand the valence octet. One is by providing a space to which one of the *s* electrons can be promoted. This creates two additional half-filled orbitals (one *d* and one *s* orbit-

Utilization of *d* orbitals

al), and it therefore generates the capacity to form two additional covalent bonds. This is exemplified by the production of phosphorus pentafluoride, PF_5, by further fluorination of the trifluoride, PF_3. Such promotion appears to be greatly assisted by the increase in outer *d*-orbital stability that results from the withdrawal of part of the screening electron and the attendant increase of the effective nuclear charge of the central atom. In PF_5, for example, the fluorine atoms, being much more electronegative than the phosphorus atom, draw away a portion of the phosphorus electrons, leaving the outer *d* orbitals more exposed to the phosphorus nucleus and therefore more stable.

A second way in which the outer *d* orbitals can become involved in the bonding is by their becoming sufficiently stable to attract a lone pair of electrons from a donor. For example, PF_5 can serve as an electron pair acceptor through an outer *d* orbital to coordinate a fluoride ion donor and form the complex ion PF_6^-.

A third way of involving *d* orbitals in bonding is for them to become partially occupied in accommodating lone-pair electrons from another atom, which is already attached by a single bond, thereby strengthening the bond. The phosphorus oxyhalides, of general formula POX_3, appear to be examples of this; their phosphorus–oxygen bonds are observed to be shorter and stronger than expected for ordinary single bonds.

The +5 oxidation state. It thus is possible for an atom of phosphorus, arsenic, antimony, or bismuth to expand its valence octet to form five covalent bonds and one additional coordinate covalent bond. This is not possible for nitrogen, which exhibits a maximum coordination number of four: three single covalent bonds and a coordinate covalent bond with nitrogen acting as donor (through its lone pair). Nevertheless, the +5 oxidation state is formally applicable to nitrogen, so that all five elements can be found in this state. When compounds in the +5 oxidation state are studied, however, it is observed that their properties do not exhibit a uniform trend within the group. Rather, a certain degree of alternation is observed, the +5 states of nitrogen, arsenic, and bismuth appearing less stable and more strongly oxidizing than the corresponding states of phosphorus and antimony. In part this alternation may find explanation in the electronic differences among the atoms with respect to their underlying shells. The number of electrons in the shell just below the outermost level, is two for nitrogen, eight for phosphorus, and 18 for arsenic, antimony, and bismuth.

Alternation of properties

Increasing the nuclear charge by 18 from phosphorus to arsenic may be accompanied by incomplete shielding of this extra charge by the ten 3*d* electrons also added. This would imply smaller size and a greater electronegativity for arsenic than for phosphorus and thus a greater similarity between the phosphorus and antimony atoms. This subject, however, is still controversial, and the widely used scale of electronegativities devised by Linus Pauling fails to make this distinction.

An interesting anomaly is presented by the fact that nitrogen as a free element is in the form of gaseous diatomic molecules, while the elements immediately preceding it in its period of the table are solids, as are the other elements in its group. In surveying the elements of the second period, the most obvious difference in atomic structure found on reaching nitrogen is the appearance for the first time in compounds of the element of a lone pair of electrons not used in bonding with other atoms. Calculations suggest that the presence of this lone pair of electrons is associated with a considerable weakening of nitrogen to nitrogen single bonds in compounds where these bonds occur. In the diatomic nitrogen molecule, however, the bonding is of a different variety—triple bonds being found between the atoms. It is thought that the triple bond is unaffected (unweakened) by the lone pairs of electrons on the nitrogen atoms, and this is assumed to be the reason why nitrogen "prefers" to exist as triply bonded gaseous diatomic molecules rather than as a condensed singly bonded solid polymer.

Bond weakening by lone pairs

The same effect might be expected to be operable with the other elements of the nitrogen group, all of which also contain lone electron pairs in their outermost shells. Further calculations disclose, however, that the bond-weakening effect of the lone pair is far less pronounced with these elements than it is with nitrogen. As a result, with these elements, single bonds are favoured over multiple bonds, and the diatomic state of the molecules is not the preferred form.

Relative electronegativities. It might also be expected that the weakening effect of the lone pair would be observed in compounds of the nitrogen group elements. The picture is more complicated here because the bonds under discussion are formed between different types of atoms. Since different elements differ in electronegativity, bonds between the atoms of different elements are inevitably polar. For purposes of discussion it can be assumed that polar bonds consist of blends of nonpolar covalent bonds and completely polar, ionic bonds. It can then be shown that a relatively small amount of ionic character will contribute a disproportionate share to the overall bond strength. Since the weakening effect of the lone pair is felt only on the covalent portion of the polar bond, rather than on the ionic portion, the less polar bonds will exhibit the greater lone-pair weakening effects.

Comparison of compounds of nitrogen group. These considerations become important in comparing the chemical behaviour of the nitrogen group elements. The electronegativity of nitrogen itself, although lower than that of oxygen, is substantially higher than that of any of the other elements of this group. Bonds between nitrogen and oxygen, therefore, will be considerably less polar than those between oxygen and phosphorus, or oxygen and arsenic, antimony, or bismuth. Consequently, for this reason alone, the covalent contribution to the nitrogen–oxygen bond energy will be relatively more important than is the case with the bonds between oxygen and the heavier elements of the group. Thus, single-bond weakening by the lone pair—and a corresponding tendency toward bond multiplicity—is likely to be much greater with oxides of nitrogen than with oxides of the heavier nitrogen group elements.

FORMATION OF CHEMICAL COMPOUNDS

Oxides. The nitrogen oxides are all very volatile compounds, and all but one are gaseous and show no polymerization; those of the heavier elements, on the other hand, are all solids and demonstrate considerable polymerization. Only two of the six oxides of nitrogen have molecular formulas formally similar to those of the oxides of the other elements in the group. Specifically, the nitrogen oxides are formulated as follows: N_2O, NO, N_2O_3, NO_2, N_2O_4, and N_2O_5, all but the last being gaseous at ordinary temperatures and the last very volatile. The principal oxides of the other elements, however, are relatively nonvolatile solids having the formulas P_4O_6, P_4O_{10}, As_4O_6, As_2O_5, Sb_2O_3, Sb_2O_5, Bi_2O_3, Bi_2O_5. The most important contributing factor to the explanation of these differences is the fact that multiplicity is energetically favoured over single bonds between nitrogen and oxygen, while single bonds are favoured over multiple bonds between oxygen and the other elements of the group.

Multiple and single bonding

Acids. Similar differences, attributable to the same basic cause, are observed among the oxygen acids derived from these oxides. For example, two of the nitrogen oxides are anhydrides of acids: dinitrogen trioxide, N_2O_3, which is the anhydride of the unstable nitrous acid, HNO_2, and dinitrogen pentoxide, N_2O_5, which is the anhydride of the strong acid, nitric acid, HNO_3. The analogous phosphorus acid, HPO_3, is a highly polymeric solid, and the fully hydrated form, phosphoric acid, H_3PO_4, has no parallel in nitrogen chemistry. In part, the existence of the multiply bonded HNO_3, rather than H_3NO_4, with its single bonds, represents the great advantage of multiplicity in nitrogen to oxygen bonding. Such multiplicity of bonding is less advantageous in phophorus–oxygen bonding, as evidenced by the fact that HPO_3 exists as the singly bonded polymer.

Because the ionic species in solution are not necessarily

analogous, it is difficult to make a meaningful comparison among acid strengths in this group. The strongest of the acids is, of course, nitric acid. Phosphoric and arsenic acids are roughly comparable to one another in strength, but the latter is a fairly strong oxidizing agent, whereas the former is relatively nonoxidizing. In the +3 state, phosphorous acid is a moderately strong acid, but arsenious acid is very weak and shows some properties similar to those of bases. Antimonous acid also has both acidic and basic properties, but it is somewhat weaker as an acid and stronger as a base. Finally, bismuth(V) oxide is very unstable; it is a strong oxidizing agent but of uncertain acidity. Bismuth(III) oxide is almost exclusively basic. The trend, therefore, although it is confused in interpretation by dissimilarities from element to element, is from strongly acidic to weakly basic oxides as one proceeds down the group.

Hydrides. Somewhat greater similarities are shown by the hydrogen compounds of the nitrogen group elements, ammonia, NH_3; phosphine, PH_3; arsine, AsH_3; stibine, SbH_3; and bismuthine, BiH_3. All are gaseous and, with the exception of ammonia, extremely toxic. All can be formed by hydrolysis of a binary compound with a metal, and all can be oxidized easily. The smaller size and higher electronegativity of nitrogen make ammonia atypical, in that its bonds are more polar and more stable; and, unlike the other hydrides of the group, ammonia tends to associate through protonic bridging. A lone pair of electrons resides on the central atom of each of these hydrogen compounds, but it is much more available for electron-pair donation on the more negatively charged nitrogen atom of ammonia. Ammonium salts, for example, are much more stable and better known than phosphonium salts, which exist, but dissociate readily.

Halides. Numerous halides of the nitrogen group elements are known. These include all the possible trihalides except NBr_3 (NI_3 occurs as $NI_3 \cdot NH_3$), and some pentahalides. The known pentahalides are PF_5, PCl_5, PBr_5, AsF_5, SbF_5, $SbCl_5$, and BiF_5. The possibility of preparing $AsCl_5$ has been explored thoroughly, without success. This failure is probably related to a higher electronegativity for arsenic than for either phosphorus or antimony, although this is controversial. The failure is, however, consistent with the relative instability of the higher oxidation states of arsenic, selenium, and bromine, a fact that must somehow be associated with these substances being the first of the 18-shell elements in their respective groups. In general, the Va group electronegativities are too high to permit highly polar bonds to halogen, and, as a result, the halogen remains potentially a halogenating agent in these compounds. They are all molecular substances of relatively high volatility, with little opportunity for association, except as $PCl_4^+PCl_6^-$, in the case of PCl_5, and as $PBr_4^+Br^-$, in the case of PBr_5. Since the hydroxides of nitrogen and phosphorus are exclusively acidic, their halides are, as expected, susceptible to complete hydrolysis; the other halides of the group also hydrolyze extensively. Nitrogen halides are again exceptional in that they are extremely unstable, tending to explode violently (an exception to this generalization is the fairly stable fluoride, which possesses moderately polar bonds between atoms of a size favourable for strong bonding). This explosive tendency is aided by the low polarity, and therefore low bond energy, of bonds between nitrogen and the halogens, plus the large amount of energy released when two nitrogen atoms join to form the very stable N_2 molecule.

Instability and electronegative differences

Sulfides. The nitrogen elements form a variety of compounds with sulfur. Although these compounds are not always comparable, there is a general similarity between the nitrogen and arsenic compounds and thus an alternation in properties observed upon proceeding down the group. This is shown by the existence of the compounds S_4N_4 and As_4S_4, while no analogous compounds of phosphorus or antimony have been prepared. Major sulfides known are P_4S_7, P_4S_{10}, P_4S_3, As_2S_5, As_4S_6, Sb_2S_5, Sb_2S_3, and Bi_2S_3.

Organic derivatives. Organic derivatives of all the nitrogen elements exist. Some of these also show alternations in properties. Trimethylamine, trimethylphosphine, trimethylarsine, trimethylstibine, and trimethylbismuthine are all volatile compounds; and all but the bismuth compound show an ability to utilize the lone pair on the central atom as a donor to a positive alkyl group, forming salts of the general formula, $R_4E^+X^-$, in which R is an alkyl group, E the group Va element, and X a halogen atom. The alternation in properties of the trimethyl compounds is most conspicuous with respect to oxidizability, for the phosphorus, antimony, and bismuth compounds are spontaneously inflammable in air, whereas those of nitrogen and arsenic are not. Another evidence of alternation in properties is given by the existence of stable tetramethylhydrazine $(CH_3)_2N–N(CH_3)_2$ and cacodyl $(CH_3)_2As–As(CH_3)_2$, whereas the phosphorus analogue is unknown and the antimony analogue very unstable. Surprisingly, pentamethylarsenic and pentamethylantimony have been made, as have pentaphenyl compounds of phosphorus, arsenic, antimony, and bismuth.

That each element is a chemical individual, regardless of how it might be placed within the periodic table, is well substantiated by a close examination of the individuals of the nitrogen group. Further evidences of the uniqueness of the individual elements will be recognized in the more detailed discussion of their chemistry in the following section. General atomic and physical properties are presented in the table.

Individual nitrogen group elements and their compounds

NITROGEN AND ITS COMPOUNDS

Occurrence and distribution. The atmosphere consists of 78.03 weight percent of nitrogen; this is the principal source of nitrogen for commerce and industry. The atmosphere also contains varying small amounts of ammonia and ammonium salts, as well as nitrogen oxides and nitric acid (the latter substances being formed in electrical storms and in the internal combustion engine). Nitrogen occurs also in mineral deposits of nitre or saltpetre (potassium nitrate, KNO_3) and Chile saltpetre (sodium nitrate, $NaNO_3$), but in quantities far inadequate for man's needs. Another material rich in nitrogen is guano, found in bat caves and in dry places frequented by birds. Nitrogen constitutes on the average about 16 percent by weight of the complex organic compounds known as proteins, present in all living organisms. The natural abundance of nitrogen in the earth's crust is 0.3 parts per 1,000. The cosmic abundance—the estimated total abundance in the universe—is between three and seven atoms per atom of silicon, which is taken as the standard.

Commercial production and uses. *Nitrogen.* Commercial production of nitrogen is largely by fractional distillation of liquefied air. The boiling temperature of nitrogen is −195.8° C, about 13° below that of oxygen, which is therefore left behind. Nitrogen can also be produced on a large scale by burning carbon or hydrocarbons in air and separating the resulting carbon dioxide and water from the residual nitrogen. Various laboratory reactions that yield nitrogen include heating ammonium nitrite (NH_4NO_2) solutions, oxidation of ammonia by bromine water, and oxidation of ammonia by hot cupric oxide.

$$NH_4^+ + NO_2^- \rightarrow N_2 + 2\ H_2O$$
$$8\ NH_3 + 3\ Br_2 \rightarrow N_2 + 6\ NH_4^+ + 6\ Br^-$$
$$2\ NH_3 + 3\ CuO \rightarrow N_2 + 3\ H_2O + 3\ Cu$$

Uses of molecular nitrogen

Elemental nitrogen can be used as an inert atmosphere for reactions requiring the exclusion of oxygen. In the liquid state, nitrogen has valuable cryogenic applications; except for the gases hydrogen, methane, carbon monoxide, fluorine, and oxygen, practically all chemical substances have negligible vapour tensions at the boiling point of nitrogen and exist, therefore, as crystalline solids at that temperature.

In the chemical industry, nitrogen is used as a preventive of oxidation or other deterioration of a product, as an inert diluent of a reactive gas, as a carrier to remove heat or chemicals and as an inhibitor of fire or explosions. In the food industry nitrogen gas is employed to prevent

spoilage through oxidation, mold, or insects, and liquid nitrogen is used for freeze drying and for refrigeration systems. In the electrical industry nitrogen is used to prevent oxidation and other chemical reactions, to pressurize cable jackets, and to shield motors. Nitrogen finds application in the metals industry in welding, soldering, and brazing, where it helps prevent oxidation, carburization, and decarburization. As a nonreactive gas, nitrogen is employed to make foamed—or expanded—rubber, plastics, and elastomers, to serve as a propellant gas for aerosol cans, and to pressurize liquid propellants for reaction jets. In medicine rapid freezing with liquid nitrogen may be used to preserve blood, bone marrow, tissue, bacteria, and semen.

Nitrogen fixation

Although the other applications are important, by far the greatest bulk of elemental nitrogen is consumed in the manufacture of nitrogen compounds. The bond between atoms in the nitrogen molecules is so strong (226 kilocalories per mole; more than twice that of molecular hydrogen) that it is difficult to cause molecular nitrogen to enter into other combinations. Most living organisms cannot utilize nitrogen directly and must have access to its compounds. Therefore the fixation of nitrogen, the incorporation of elemental nitrogen into compounds, is vitally important. In nature, two principal processes of nitrogen fixation are known. One is the action of electrical energy on the atmosphere, which dissociates nitrogen and oxygen molecules, allowing the free atoms to form nitric oxide, NO, and nitrogen dioxide, NO_2. Nitrogen dioxide then reacts with water as follows:

$$3\ NO_2 + H_2O \rightarrow 2\ HNO_3 + NO.$$

The nitric acid, HNO_3, dissolves and comes to earth with rain as a very dilute solution. In time it becomes part of the combined nitrogen of the soil. The other principal process of natural nitrogen fixation is that of certain plants and vegetables called legumes. Through a cooperative action with bacteria, legumes are able to convert atmospheric nitrogen directly into nitrogen compounds. Certain bacteria alone, such as *Azotobacter chroococcum* and *Clostridium pasteurianum,* are also capable of fixing nitrogen.

The Haber process

Ammonia. The chief commercial method of fixing nitrogen is the Haber process for synthesizing ammonia. This process was developed during World War I to lessen the dependence of Germany on Chilean nitrate. It involves the direct synthesis of ammonia from its elements. The synthesis is favoured thermodynamically (the standard free energy of formation of ammonia at 25° C being –3.94 kilocalories per mole). The equation of the reaction however,

$$N_2 + 3\ H_2 \rightarrow 2\ NH_3,$$

shows that four moles of gases (one of nitrogen and three of hydrogen) are used to produce two moles of ammonia. As a result there is a substantial decrease in entropy, or unavailable energy in the system during the reaction, and poorer yields of ammonia would be expected at higher temperatures. The ideal of carrying out the process at low temperature has not yet been realized, however, because of the high energy of activation required to cause the very stable nitrogen and hydrogen molecules to react. The Haber process succeeds in satisfying these conflicting requirements by means of a catalyst. The catalyst, based on iron, enables reaction to occur at a useful rate at temperatures around 500°C if the pressure is about 1,000 atmospheres.

Uses of ammonia

In the early 1970s, tens of millions of tons of ammonia were synthesized by the Haber process each year. Large amounts of this ammonia are used directly in agriculture, being applied directly to the soil from tanks containing the liquefied gas. Further amounts are converted to ammonium nitrate, ammonium phosphates, and other salts that also are used principally in commercial fertilizers. Ammonia from the Haber process is supplemented by ammonia obtained as a by-product of coke ovens, about six pounds being released per ton of coal.

In the textile industry, ammonia is used in the production of synthetic fibres, such as nylon and rayon. It is also employed in the dyeing and scouring of cotton, wool, rayon, and silk. Ammonia serves as a catalyst in the production of Bakelite and certain other synthetic resins. It is used in the synthesis of sulfa and many other drugs and vitamins. It neutralizes acidic by-products of petroleum refining, and, in the rubber industry, it prevents a coagulation of raw latex during transportation from plantation to factory. Because of its high heat of vaporization, low density, high stability, and low corrosiveness, ammonia is a valuable refrigerant for air conditioning, ice making, and cold storage.

In the paper industry, ammonia can be used in place of calcium salts in the bisulfite process for making wood pulp, and it is also used to dissolve casein for coating paper. Large quantities of ammonia find application in a widely used method for producing soda ash (Na_2CO_3), called, after its inventor, the Solvay process. Ammonia is used in various metallurgical processes, including the nitriding of alloy sheets to harden their surfaces. Since ammonia can be decomposed easily to give hydrogen, it is a convenient portable source of atomic hydrogen for welding. Together with chlorine, ammonia is used to purify water supplies, the active intermediates being chloramines. Finally, among its minor uses is inclusion in certain household cleansing agents.

Nitric acid. Perhaps the largest part of commercially synthesized ammonia is converted to nitric acid and nitrates. The process depends on the catalyzed oxidation of ammonia to nitric oxide:

$$5\ O_2 + 4\ NH_3 \rightarrow 4\ NO + 6\ H_2O.$$

At lower temperatures, the nitric oxide reacts readily with atmospheric oxygen to form nitrogen dioxide, NO_2. As indicated above, this substance reacts with water to form nitric acid and nitric oxide. The latter is reoxidized and recycled. It is possible also to distill nitric acid from a mixture of a nitrate and concentrated sulfuric acid.

Uses of nitric acid

Nitric acid is used in very large quantities to make explosives, such as TNT (trinitrotoluene), nitroglycerine, and gunpowder. It is also used to carry out other nitrations, which produce valuable synthetic organic chemicals. Commonly it is mixed with concentrated sulfuric acid for this purpose; the principal active component is NO_2^+, and the by-product water is effectively absorbed by the sulfuric acid. Nitrocellulose, prepared by nitration of cellulose, forms the base for pyroxylin lacquers and plastics, as well as certain synthetic fibres.

Other compounds. Ammonia and nitric acid are the principal nitrogen compounds of commerce, from which most other nitrogen compounds are derived. Also of some importance are certain nitrides, solids formed by direct combination of metals with nitrogen, usually at elevated temperatures. Some of these are extremely hard and refractory, as well as chemically unreactive. The nitrides of boron, titanium, zirconium, and tantalum have useful special applications. For example, a diamond-structured modification of boron nitride (borazon) is nearly as hard as diamond and less easily oxidized, thus having advantages for abrasive, grinding, and polishing uses.

Another nitrogen compound of industrial importance is hydrazine, N_2H_4. Hydrazine is a colourless liquid made by careful oxidation of ammonia with sodium hypochlorite. Hydrazine is used chiefly as a rocket fuel, but is also applied in pharmaceuticals, manufacturing, agriculture, polymer preparation, petroleum refining, chemical processing, detergent synthesis, and the metals industry.

Cyanides

Hydrogen cyanide, HCN, is a gaseous compound that condenses easily to a colourless liquid. It can be prepared by the action of strong acids on its salts, but it is usually produced by a catalytic high-temperature reaction of methane, ammonia, and oxygen. It is employed industrially chiefly to form acrylonitrile by reaction with acetylene. (Acrylonitrile is a starting material for the production of synthetic fibres.) Sodium cyanide can be made by heating sodium metal with ammonia to form sodium amide (or sodamide, $NaNH_2$), which is then heated with carbon:

$$2\ Na + 2\ NH_3 \rightarrow 2\ NaNH_2 + H_2$$
$$NaNH_2 + C \rightarrow NaCN + H_2.$$

Sodium cyanide has uses in electroplating and various chemical processes.

When lime, CaO, is heated with coke, calcium carbide, CaC_2, is formed. Heating this substance and nitrogen together in an electric furnace at a high temperature causes release of carbon and formation of calcium cyanamide, $CaCN_2$. This process is a large-scale industrial method for fixing nitrogen. The crude product can be used directly in fertilizers, since slow hydrolysis liberates ammonia in the soil. It also can be the basis of synthesis of other nitrogen compounds.

Properties and reaction. *Nitrogen.* Nitrogen is a colourless, odourless gas, which condenses at −195.8° C to a colourless, mobile liquid. The element exists as N_2 molecules, represented as :N:::N:, for which the bond energy of 226 kilocalories per mole is exceeded only by that of carbon monoxide, 256 kilocalories per mole. Because of this high bond energy the activation energy for reaction of molecular nitrogen is usually very high, causing nitrogen to be relatively inert to most reagents under ordinary conditions. Furthermore, the high stability of the nitrogen molecule contributes significantly to the thermodynamic instability of many nitrogen compounds, in which the bonds, although reasonably strong, are far less so than those in molecular nitrogen. For these reasons, elemental nitrogen appears to conceal quite effectively the truly reactive nature of its individual atoms.

A relatively recent and unexpected discovery is that nitrogen molecules are able to serve as ligands in complex coordination compounds. The observation that certain solutions of ruthenium complexes can absorb atmospheric nitrogen has led to hope that one day a simpler and better method of nitrogen fixation may be found.

Atomic nitrogen

An active form of nitrogen, presumably containing free nitrogen atoms, can be created by passage of nitrogen gas at low pressure through a high-tension electrical discharge. The product glows with a yellow light and is much more reactive than ordinary molecular nitrogen, combining with atomic hydrogen and with sulfur, phosphorus, and various metals, and capable of decomposing nitric oxide, NO, to N_2 and O_2.

A nitrogen atom has the electronic structure represented by $1s^2$, $2s^2$, $2p^3$, or alternatively, 2–5. The five outer shell electrons screen the nuclear charge quite poorly, with the result that the effective nuclear charge felt at the covalent radius distance is relatively high. Thus nitrogen atoms are relatively small in size and high in electronegativity, being intermediate between carbon and oxygen in both of these properties. The electronic configuration includes three half-filled outer orbitals, which give the atom the capacity to form three covalent bonds. The nitrogen atom should therefore be a very reactive species, combining with most other elements to form stable binary compounds, especially when the other element is sufficiently different in electronegativity to impart substantial polarity to the bonds. When the other element is lower in electronegativity than nitrogen, the polarity gives partial negative charge to the nitrogen atom, making its lone pair electrons available for coordination. When the other element is more electronegative, however, the resulting partial positive charge on nitrogen greatly limits the donor properties of the molecule. When the bond polarity is low (due to the electronegativity of the other element being similar to that of nitrogen), multiple bonding is greatly favoured over single bonding. If disparity of atomic size prevents such multiple bonding, then the single bond that forms is likely to be relatively weak, and the compound is likely to be unstable with respect to the free elements. All of these bonding characteristics of nitrogen are observable in its general chemistry, but with kinetic restrictions imposed by the high stability of the N_2 molecule.

Nitrides. The simplest nitride is that of hydrogen, H_3N, which is customarily called ammonia (formulated

Ammonia

NH_3) and not usually thought of as a nitride at all. The synthesis of ammonia by the Haber process represents a successful technological overcoming of the problems caused by the stability of molecular nitrogen. The ammonia molecule has a pyramidal structure, as would be predicted from a knowledge of the presence of the lone-pair electrons on nitrogen, which force the three nitrogen–hydrogen bonds out of planarity to create bond angles of about 107°. Because hydrogen has a lower electronegativity than nitrogen, the N–H bonds are somewhat polar, with calculated partial charges of 0.06 on hydrogen and −0.17 on nitrogen. The combination of polarity of bonds with geometrical dissymmetry gives the ammonia molecule an appreciable dipole moment 1.49 Debye units. The partial positive charge on the hydrogen atoms, together with the lone pair of electrons on the relatively small, negatively charged nitrogen atom, permits the formation of protonic bridges (hydrogen bonds). Although ammonia is unassociated in the gaseous state, it is much more readily condensed than any of its congeners within the group, none of which appear to associate through protonic bridging. Ammonia can be liquefied under a pressure of about ten atmospheres at ordinary temperatures, and the boiling point of the liquid at one atmosphere pressure is −33.4° C.

Liquid ammonia as solvent

As a liquid, ammonia is an interesting and useful solvent, analogous to water but uniquely different. One of the differences is that ammonia is fundamentally a weaker oxidizing agent than water; another is that it is more basic. A third is that the extent of auto-ionization of liquid ammonia is much less than that of water. A very interesting consequence of these differences is that solvated electrons can exist for a considerable length of time in liquid ammonia, whereas they reduce water and lose their identity in that solvent very quickly. Thus, if sodium metal comes in contact with water, the evolution of hydrogen is immediate, leaving behind sodium ions and hydroxide ions. In pure liquid ammonia, however, sodium dissolves as sodium ions and "free" solvated electrons. Other reactive metals behave similarly, all giving highly coloured solutions that demonstrate conduction of electricity comparable to that of metals. Such solutions are blue when diluted and bronze when highly concentrated. Both colour and electrical conductivity are ascribed to the solvated electrons, which are highly mobile but which are believed to lie in cavities surrounded by the hydrogen portions of four ammonia molecules. Since the action of a reducing agent is to supply electrons, solutions of metals in liquid ammonia—with their large solvated-electron content—are extremely effective in that regard.

The relative solubilities of salts in liquid ammonia are different from the corresponding solubilities in water. Liquid ammonia can be used as the solvent medium for a variety of useful inorganic and organic syntheses and reactions. Acid-base reactions in liquid ammonia are related to the autoionization product species:

$$2\ NH_3 \rightarrow NH_4^+ + NH_2^-;\ \text{ionization constant, } K \sim 10^{-33}.$$

In this ionization, ammonium ion, NH_4^+, is analogous to the hydronium ion, H_3O^+ in water, and amide ion, NH_2^-, is analogous to the hydroxide ion, OH^-. According to the solvent theory of acids and bases, any substance, such as an ammonium salt, that increases the concentration of the anion associated with the solvent (in this case, the amide ion) is thereby basic. A typical neutralization reaction in liquid ammonia thus would be:

$$NH_4Br + KNH_2 \rightarrow KBr + 2\ NH_3.$$

Largely because of the formation of protonic bridges, ammonia is very soluble in water; a small amount of ionization occurs as follows:

$$NH_3 + H_2O \rightarrow NH_4^+ + OH^-.$$

Aqueous ammonia, often called ammonium hydroxide although no molecular species NH_4OH has ever been isolated or identified, is therefore a weak base ($K = 1.8 \times 10^{-5}$), comparable in strength to acetic acid as an acid. By virtue of the lone pair of electrons and the partial negative charge on nitrogen, ammonia is also a good Lewis base (electron-pair donor), donating its electron pair—both in and out of water solution—to thousands of Lewis acids (electron-pair acceptors) with the formation of complex compounds called ammines and ammino-complexes. The simplest Lewis acid is the proton, or H^+,

to which ammonia readily coordinates to form the moderately stable ammonium ion, NH_4^+. Ammonium salts, of course, are well-known. They are readily formed by the neutralization of acids by ammonia, both in aqueous solution and in the gaseous phase. These salts appear to sublime when heated, but evidently they are dissociated completely in the gas phase; cooling reforms the ammonium salt as a white smoke, ammonium chloride being a familiar contaminant of any laboratory, wherein hydrochloric acid and aqueous ammonia are commonly used reagents.

Although basicity resulting from the lone-pair electrons is the most familiar property of ammonia, the compound also can exhibit acidity as the result of its partially positive hydrogen atoms. Thus metal–ammonia solutions slowly evolve hydrogen, and the same metals react with ammonia gas on heating to displace part of the hydrogen, forming amides and imides.

Other nitrides

Molecular nitrogen, despite its relative inertness, reacts directly with certain metals at ordinary temperatures, and even more rapidly when heated. Such metals include lithium (but none of the other alkali metals), magnesium, calcium, strontium, barium, and several others. Beryllium unites with nitrogen above 900° C, but the product is unstable above its melting point of about 220° C in the absence of nitrogen. Boron and aluminum form stable polymeric nitrides when heated with nitrogen gas. Other nitrides can be prepared by heating the metal with ammonia or by other indirect methods.

Nitrides of the major group elements have the expected composition and are fairly typical binary compounds. Nitrides of the transitional elements, on the other hand, tend to have indefinite compositions, being of an "interstitial" or "alloy" nature. These transitional metal nitrides are commonly metallic in appearance, highly conducting, hard, high melting, and resistant to chemical reaction. In contrast, the major group nitrides hydrolyze readily to form ammonia and the corresponding hydroxides. The question of whether a metal nitride actually contains a nitride ion, N^{3-}, probably must be answered in the negative, for it is extremely doubtful whether the often asserted existence of anions of higher than unit charge in a crystalline solid is reasonable. Calculations of partial charge according to the principle of electronegativity equalization show that nitrogen retains only a small fraction of the postulated −3 charge in such compounds. Even for Cs_3N the charge on nitrogen should be only about −0.9.

Lithium nitride, Li_3N, is a red solid, in which each nitrogen is equidistant from two lithium atoms, situated at distances of 1.94 Å from the nitrogen, and six more, situated at 2.11 Å. Because oxygen is more electronegative than nitrogen, it can displace nitrogen from its binary compounds; and lithium nitride, therefore, is oxidized readily on warming in air. Sodium nitride, Na_3N, can be made only by indirect methods, since it is much less stable and more reactive than Li_3N. Presumably the crystal energy of the nitrides of these larger atoms (including also the heavier alkali metals) is insufficient to compensate for stability to be gained by conversion to molecular nitrogen.

Boron nitride

Of especial interest is boron nitride, BN, which forms normally as a graphite-like layer structure when boron is heated with nitrogen. This substance is extremely unreactive, being almost inert to air and alkalies; it is hydrolyzed only slowly, but it can be decomposed by acids. The similarity of boron nitride to graphite is an interesting example of how two elements horizontally separated in the periodic table by one element can form a compound whose properties resemble that intermediate element. The resemblance of boron nitride to the graphite form of carbon led to successful attempts to convert graphitic boron nitride to a diamond structure, following the technology of converting real graphite to diamond. This diamond form, called borazon, is second only to diamond itself in hardness. Borazon has greater resistance than diamond to oxidation at the high temperatures caused by friction, and this gives it significant advantages over diamond as an industrial abrasive and polishing agent.

Oxides and acids. The direct combination of nitrogen with oxygen occurs only under the influence of electrical energy. Several oxides are known, of which the most familiar are nitrous oxide, or nitrogen(I) oxide, N_2O; nitric oxide, or nitrogen(II) oxide, NO; nitrogen sesquioxide, or nitrogen(III) oxide, N_2O_3; nitrogen dioxide, or nitrogen(IV) oxide, NO_2; and dinitrogen pentoxide or nitrogen(V) oxide, N_2O_5. The last is a volatile solid; the others are gases under ordinary conditions. The electronegativity of nitrogen is sufficiently close to that of oxygen to prevent oxygen from becoming very negative in these compounds. Thus they are all at least potentially acidic and oxidizing, and although their multiple bonds are quite strong, they tend to be thermodynamically unstable with respect to the free elements.

Cautious heating of ammonium nitrate, NH_4NO_3, produces smooth decomposition:

$$NH_4NO_3 \rightarrow N_2O + 2\,H_2O.$$

Incautious heating may be disastrously explosive. In 1947 a freighter load of ammonium nitrate inexplicably detonated in Texas City, Texas.

Laughing gas

Nitrous oxide, also known as "laughing gas" because it induces mild hysteria when used as an anesthetic, is one of the few gases other than oxygen capable of supporting combustion. This is not surprising, since the structure favours loss of oxygen and the formation of molecular nitrogen; the two nitrogen atoms are already joined together and the oxygen atom is attached to one of them at the end of the linear molecule. The principal characteristic of nitrous oxide is its oxidizing action.

Nitric oxide is the principal product of the catalyzed oxidation of ammonia, nitrous oxide, being unstable at the high temperature of the reaction. Nitric oxide is commonly formed from nitric acid when the latter is used as an oxidant. In addition, nitric oxide is produced in the internal-combustion engine by oxidation of atmospheric nitrogen. After it is emitted in the exhaust from the engine, nitric oxide reacts with oxygen of the air to form the dioxide, NO_2, which in turn reacts with organic air impurities to form highly irritating components of smog.

Nitrogen sesquioxide, N_2O_3, is the least stable of the familiar nitrogen oxides; at ordinary temperatures it is about 90 percent dissociated into NO and NO_2 molecules. An equimolar mixture of these gases, in fact, acts as though it were N_2O_3, which is the anhydride of nitrous acid, HNO_2. For example, an equimolar mixture of NO and NO_2 is absorbed by sodium hydroxide solution, forming a solution of sodium nitrite, $NaNO_2$.

Nitrous acid

Nitrous acid is a weak and unstable acid, known only in solution. Its salts, however, usually are much more stable, those of the alkali metals being resistant toward decomposition at very high temperatures. Ammonium nitrite is an exception, being quite unstable, and its solutions serve as a laboratory source of nitrogen:

$$NH_4NO_2 \rightarrow N_2 + 2\,H_2O.$$

Nitrogen dioxide, NO_2, is not itself an anhydride of a stable nitrogen acid but it reacts with water in the following way:

$$3\,NO_2 + H_2O \rightarrow 2\,HNO_3 + NO.$$

This reaction is used for the commercial production of nitric acid, the nitric oxide formed being oxidized to nitrogen dioxide and recycled. Nitrogen dioxide is a reddish-brown gas, which boils at 22.4° C; it is quite familiar as a reduction product of concentrated nitric acid. The gas is conveniently prepared by thermal decomposition of lead nitrate. Like all molecules having an odd number of electrons, NO_2 is paramagnetic (as is NO), but it loses both its paramagnetism and its colour when cooled, for it dimerizes to dinitrogen tetroxide, N_2O_4. The latter is a colourless liquid, which freezes to a colourless solid at −10.2° C. As would be expected, NO_2 is a powerful oxidant. Dissolved in concentrated nitric acid, it forms a reddish-brown acid called fuming nitric acid, which is also a powerful oxidizing agent, causing easily combustible materials like wood to burst into flame.

The pentoxide, N_2O_5, which in the crystalline form appears to exist as nitronium nitrate, $NO_2^+NO_3^-$, is the anhydride of nitric acid:

$$N_2O_5 + 2\,H_2O \rightarrow 2\,HNO_3.$$

The chief method of preparation of N_2O_5 is by dehydration of nitric acid with phosphoric anhydride. Nitrogen pentoxide is unstable; it loses oxygen easily and is a strong oxidizing agent.

Nitric acid

Nitric acid, HNO_3, which—with hydrochloric and sulfuric acid—is one of the most common laboratory reagent acids, is a colourless liquid boiling at 84° C. It is miscible with water in all proportions and is slowly decomposed by light even at 25° C according to the following equation:

$$4\,HNO_3 \rightarrow 4\,NO_2 + 2\,H_2O + O_2.$$

This decomposition occurs even in the usual 69 percent aqueous solution, commonly called concentrated nitric acid, so that the initially colourless material slowly becomes yellowish brown. Nitric acid is a powerful oxidizing agent and attacks all metals, with the exception of gold and some of the platinum group. It is a strong acid in aqueous solution, and in dilute form it is used as a source of hydrogen ions.

The principal use of nitric acid is as a nitrating agent for the manufacture of nitro compounds employed as explosives and for other purposes. For this use nitric acid is usually mixed with concentrated sulfuric acid, which, being a stronger acid, causes the nitric acid to act essentially as a base:

$$HNO_3 + 2\,H_2SO_4 \rightarrow NO_2^+ + H_3O^+ + 2\,HSO_4^-.$$

In this circumstance, the nitronium ion, NO_2^+, is evidently the active nitrating species, and the overall result is that the sulfuric acid absorbs the by-product water from the nitration reaction.

Nitrate salts

Practically all metal nitrates are soluble in water, and many readily form crystalline hydrates. The alkali metal nitrates have the greatest thermal stability but lose oxygen at high temperatures to form nitrites. Other metal nitrates decompose more easily, forming metal oxides and various oxides of nitrogen.

Halides. The only stable halide of nitrogen is nitrogen trifluoride, NF_3. It is a colourless gas, which boils at −129° C; it can be prepared by electrolysis of fused anhydrous ammonium bifluoride, NH_4HF_2. Explosive by-products appear to be dinitrogen difluoride, N_2F_2, and the tetrafluoride, N_2F_4. Fluorine is sufficiently more electronegative than nitrogen to give appreciable polarity to the N–F bond and leave the nitrogen atom in NF_3 with a partial positive charge. This renders the nitrogen lone-pair electrons almost completely unavailable for the kind of Lewis-base coordination typical of ammonia. The compound is almost insoluble in water and in bases. When mixed with hydrogen and ignited, nitrogen trifluoride reacts explosively to form hydrogen fluoride and liberate nitrogen.

Action of free chlorine or hypochlorite salts on ammonium chloride, or on aqueous ammonia, leads to stepwise substitution of chlorine atoms for hydrogen atoms, forming first chloramine, NH_2Cl; then dichloramine, $NHCl_2$; and finally nitrogen trichloride, NCl_3. The last compound separates as a dark yellow oil, which has a boiling point of 71° C but is so unstable that it is likely to explode violently below 71° C. When dissolved in an inert solvent and stored in the dark, it is more stable. It is hydrolyzed slowly by a reaction that is the reverse of its formation:

$$NCl_3 + 3\,H_2O \rightleftharpoons NH_3 + 3\,HOCl.$$

Attempts to prepare nitrogen bromide have been unsuccessful, free nitrogen being evolved too readily even at lower temperatures. Nitrogen triiodide, on the other hand, appears to form readily from the action of aqueous ammonia on iodine, but the product includes a molecule of ammonia, $NI_3 \cdot NH_3$. This copper-coloured solid is so unstable that it detonates even when touched.

Other compounds. As mentioned earlier, hydrogen cyanide, HCN, is formed, along with acetylene, when a mixture of nitrogen and methane is exposed to an electric arc. Because it is a very weak acid, hydrogen cyanide also is liberated readily by acidification of any of its salts. The molecule is linear, as would be predicted for a molecule in which the outer-shell electrons of the central atom, a carbon atom, are utilized in only two locations, one as a single bond to hydrogen and the other as a triple bond to nitrogen. The nitrogen in the molecule possesses a partial negative charge and a lone pair of electrons, the hydrogen a partial positive charge. These are the two requisites for protonic bridging; hydrogen cyanide is therefore highly associated, melting at −13.4° C and boiling at 25.6° C. Correspondingly, it has a very high dielectric constant, 194.4, more than twice that of water. Nevertheless, its properties as a solvent are disappointingly poor.

Cyanogen and sulfur nitride

Cyanogen, $(CN)_2$, is called a "pseudohalogen" because of its resemblance to the diatomic halogens. It can be prepared by oxidation of a cyanide, much as a halogen can be prepared by oxidation of a halide. Like several of the halogens, it is a gas at normal temperature and pressure; its melting point is −27.8° C, and its boiling point is −21.1° C. The compound is extremely stable toward heat, dissociating only above 1,000° C. It will burn in air, and water slowly hydrolyzes it, principally to ammonium oxalate. (Cyanogen, in fact, may be regarded as the dinitrile of oxalic acid.)

Sulfur tetranitride, S_4N_4, can be formed by the action of ammonia on sulfur:

$$10\,S + 4\,NH_3 \rightarrow S_4N_4 + 6\,H_2S.$$

It is a golden-yellow solid that melts at 178° C; it can sometimes be distilled, but it is apt to explode. Hydrolysis occurs slowly in water; more rapidly in alkaline solution, according to the following equation:

$$S_4N_4 + 6\,NaOH + 3\,H_2O \rightarrow Na_2S_2O_3 + 2\,Na_2SO_3 + 4\,NH_3.$$

Most of the thousands of known organic nitrogen compounds may be regarded as derived from ammonia, hydrogen cyanide, cyanogen, or nitrous or nitric acid.

Analytical chemistry. Often the percentage of nitrogen in gas mixtures can be determined by measuring the volume after all other components have been absorbed by chemical reagents. Decomposition of nitrates by sulfuric acid in the presence of mercury liberates nitric oxide, which can be measured as a gas. Nitrogen is released from organic compounds when they are burned over copper oxide, and the free nitrogen can be measured as a gas after other combustion products have been absorbed. The well-known Kjeldahl method for determining the nitrogen content of organic compounds involves digestion of the compound with concentrated sulfuric acid (optionally containing mercury, or its oxide, and various salts, depending on the nature of the nitrogen compound). In this way, the nitrogen present is converted to ammonium sulfate. Addition of an excess of sodium hydroxide releases free ammonia, which is collected in standard acid; the amount of residual acid, which has not reacted with ammonia, is then determined by titration.

The Kjeldahl method

Biological and physiological significance. As might be expected in view of the importance of the presence of nitrogen in living matter, most—if not all—organic nitrogen compounds are physiologically active. Of the inorganic compounds, ammonia is relatively harmless in very small concentrations; but in higher concentrations it strongly irritates the eyes and upper respiratory tract and, in fact, inhibits respiration. Nitrous oxide finds considerable use as an anesthetic, especially in dentistry; prolonged breathing of higher concentrations, however, can be fatal. The higher oxides of nitrogen are all extremely toxic. They are severe lung irritants that can cause pleural edema and subsequent death. These compounds are especially insidious because they may be formed in fires involving nitrogenous materials and inhaled with smoke without causing awareness of their presence until several hours after exposure. Hydrazine also is an extremely toxic substance, as are hydrogen cyanide (prussic acid) and cyanogen. Nitric acid, especially in concentrated form, inflicts severe burns, which are painful and slow healing. Mild contact produces a typical yellow-brown stain (resulting from the formation of xanthoproteic acids in the skin).

Nitrogen itself, being inert, is innocuous except when breathed under pressure, in which case it dissolves in the blood and other body fluids in higher than normal con-

The bends

centration. This in itself does no harm, but if the pressure is reduced too rapidly, the excess nitrogen evolves as bubbles of gas in various locations in the body. These can cause muscle and joint pain, fainting, partial paralysis, and even death. These symptoms are referred to as "the bends." Divers, and others forced to breathe air under pressure, must therefore be extremely careful that the pressure is reduced to normal very slowly following exposure. This enables the excess nitrogen to be released harmlessly through the lungs without forming bubbles. A better alternative is to substitute mixtures of oxygen and helium for air. Helium is much less soluble in body fluids, and the dangers are thus diminished.

Isotopes of nitrogen. Nitrogen exists as two stable isotopes, ^{14}N and ^{15}N. These can be separated by chemical exchange or by thermal diffusion. Artificial radioactive isotopes have masses of 12, 13, 16, and 17. The most stable has a half-life of only about ten minutes.

PHOSPHORUS AND ITS COMPOUNDS

Occurrence and distribution. Phosphorus is a very widely distributed element—12th most abundant in the earth's crust, to which it contributes about 0.10 weight percent. Its cosmic abundance is estimated to be about one atom per 100 atoms of silicon, the standard. Its high chemical reactivity assures that it does not occur in the free state. The principal combined forms in nature are the phosphate salts. Nearly 190 different minerals have been found to contain phosphorus, but, of these, the principal source of phosphorus is the apatite series in which calcium ions exist along with phosphate ions and variable amounts of fluoride, chloride, or hydroxide ions, according to the formula $[Ca_{10}(PO_4)_6(F, Cl, \text{or } OH)_2]$. Commonly such metal atoms as magnesium, manganese, strontium, and lead substitute for calcium in the mineral; and silicate, sulfate, vanadate, and similar anions substitute for phosphate ions. Very large sedimentary deposits of fluoroapatite are found in many parts of the earth. The phosphate of bone and tooth enamel is hydroxyapatite. (The principle of lessening tooth decay by fluoridation depends upon the conversion of hydroxyapatite to the harder, more decay resistant, fluorapatite.)

Estimates of the total phosphate rock in the earth's crust average about 50,000,000,000 tons, of which north Africa contains two-thirds, and the U.S.S.R. and the United States most of the remaining third. This estimate includes only ore that is sufficiently rich in phosphate for conversion to useful products by present methods. Vast quantities of material lower in phosphorus content also exist.

Acidulation and reduction

Commercial production and uses. Two principal techniques for converting phosphate rock to usable materials are practiced. One involves acidulation of the crushed rock—with either sulfuric or phosphoric acids—to form crude calcium hydrogen phosphates that, being water soluble, are valuable additions to fertilizer. The other method is the reduction of the phosphate with carbon in an electric furnace to give elemental phosphorus. The latter reaction is extremely complex, and its precise details depend upon the composition of the mineral phosphate. A charge of sand, coke, and phosphate rock is melted at about 1,500° C in an electric furnace. The calcium and impurities are left in the form of a complex fluorosilicate slag, and elemental phosphorus vapour, at about 300° C, distills out and is collected, condensed, and stored underwater as the white allotropic form of the element. More than half a million tons of phosphorus are made annually in the United States in this way. Most of the output is burned to phosphoric anhydride and subsequently treated with water to form phosphoric acid, H_3PO_4.

Only about 5 percent of the 2,000,000 tons of phosphorus consumed per year in the United States is used in the elemental form. Pyrotechnic applications of the element include tracers, incendiaries, fireworks, and matches. Some is used as an alloying agent, some to kill rodents, and the rest is employed in chemical synthesis. A large amount is converted to sulfides used in matches and in the manufacture of insecticides and oil additives. Most of the remainder is converted to halides or oxides for subsequent use in synthesizing organic phosphorus compounds.

Most of the elemental phosphorus produced is converted to high purity phosphoric acid. This is used in industrial processes where impurities present in the acidulated phosphate products would be unacceptable. Much of the pure product is used in soft drinks, metal cleaners, and special liquid fertilizers.

Phosphates in fertilizers

Over 70 percent of the total phosphate rock consumed is used to prepare fertilizers for crops and lawns. If the phosphate is treated with sulfuric acid, the mixture of inert calcium sulfate and calcium hydrogen phosphates is used directly as "superphosphate." When the acid used is phosphoric acid, no inert portion exists, and the product is called "triple superphosphate." Nitric acid also may be used as the acidulant, and this produces a mixture of calcium nitrate and calcium hydrogen phosphates, called "nitrophosphates." These three materials make up about two-thirds of the total phosphate fertilizer produced. Most of the remaining fertilizer phosphate is ammonium phosphate made by neutralizing phosphoric acid with ammonia.

The next most important application of phosphate salts is in synthetic detergents. Nearly 60 percent of the elemental phosphorus produced is converted to detergent components, chiefly sodium tripolyphosphate, $Na_5P_3O_{10}$. Other salts used in detergents, water softeners, and metal cleaners are tetrasodium pyrophosphate, $Na_4P_2O_7$, tetrapotassium pyrophosphate, $K_4P_2O_7$; sodium metaphosphate, $(NaPO_3)_x$; trisodium phosphate (TSP), Na_3PO_4; and sodium dihydrogen phosphate, NaH_2PO_4. In the early 1970s, however, increasing awareness of the heavy pollution of natural waters by phosphates from detergents brought about a search for nonpolluting substitutes.

Phosphate salts also are used as leavening agents for baking and as abrasives in toothpastes. About 5 percent of the total phosphate consumption is in the form of feed supplements for poultry and animals.

Properties and reactions. *Phosphorus.* The electronic configuration of the phosphorus atom can be represented by $1s^2$, $2s^2$, $2p^6$, $3s^2$, $3p^3$, or 2–8–5. The outer shell arrangement therefore resembles that of nitrogen, with three half-filled orbitals each capable of forming a single covalent bond and an additional one pair of electrons. Depending on the electronegativity of the elements with which it combines, phosphorus can therefore exhibit oxidation states of +3 or −3, just as does nitrogen. The principal differences between nitrogen and phosphorus are that the latter is of considerably lower electronegativity and has larger atoms, with outer *d* orbitals available. For these reasons, the similarities between nitrogen and phosphorus chemistry are largely formal ones, tending to conceal the actual, wide differences. The outer *d* orbitals in phosphorus permit an expansion of the octet, which leads to the +5 state, with five actual covalent bonds being formed in compounds, a condition impossible for nitrogen to achieve.

Allotropic forms

The first striking difference in chemistry of the two elements is that elemental phosphorus exists under ordinary conditions in any of several modifications, or allotropic forms, all of which are solid. Phosphorus molecules of formula P_2, structurally analogous to N_2 molecules and evidently also triply bonded, exist only at very high temperatures. These P_2 molecules do not persist at lower temperatures—below about 800°—because of the fact that three single bonds in phosphorus, in contrast to the situation with nitrogen, are favoured over one triple bond. On cooling, the triply bonded P_2 molecules condense to form tetrahedral P_4 molecules, in which each atom is joined to three others by single bonds. These molecules further condense to form either hexagonal- or cubic-structured molecular solids, both called "white phosphorus." Because of the relatively weak intermolecular attractions (van der Waals forces) between the separate P_4 molecules, the solid melts easily at 44.1° C and boils at about 280° C. Formation of tetrahedra requires bond angles of 60° instead of the preferred 90°–109° angles, so that white phosphorus is a relatively unstable, or metastable, form. It changes spontaneously, but slowly, at temperatures around 200° or higher, to a polymeric form called "red phosphorus." This substance is amorphous

when formed at lower temperatures, but it can become crystalline, with a melting point of about 590° C. At higher temperatures and pressures, or with the aid of a catalyst, at ordinary pressures and a temperature of about 200° C, phosphorus is converted to a black crystalline form, which somewhat resembles graphite. This may prove to be the most stable form of phosphorus, despite the relative difficulty in its preparation. In both the red and the black forms, each phosphorus atom forms three single bonds, which are spread apart sufficiently to be relatively strain free.

Consistent with the metastable condition of the white modification, and the crowding of its covalent bonds, this form is far more reactive chemically than the others. It is highly toxic, reacts vigorously with most reagents, and inflames in air at only 35° C, so that it must be stored under water or other inert liquid. White phosphorus dissolves readily in solvents such as carbon disulfide, in which it maintains the composition P_4. In contrast, red phosphorus is insoluble and relatively inert, although large quantities of the usual commercial form can ignite spontaneously in air and react with water to form phosphine and phosphorus oxyacids. Black phosphorus is more inert and is capable of conducting electricity. Both these polymeric forms are insoluble and are very much less volatile than white phosphorus.

Phosphine. Elemental phosphorus does not appear to react with hydrogen directly. Action of strong base, or even hot water, on white phosphorus, however, produces the gaseous compound called phosphine, PH_3. This compound is also produced by hydrolysis of metal phosphides. It melts at −133.8° C and boils at −87.7° C, thus showing far less association than ammonia, which boils more than 50° higher. The molecule is structurally similar to that of ammonia, being pyramidal, as expected, with the lone pair of electrons occupying one corner of a tetrahedron formed by it and three P–H bonds. Although hydrogen is less electronegative than nitrogen, it is slightly more so than phosphorus. The bonds in phosphine are, therefore, only very slightly polar, with the hydrogen partially negative and the phosphorus partially positive (thereby reversing the situation found in the ammonia molecule). In addition, the phosphorus atom is substantially larger than the nitrogen atom, so that its lone-pair electrons are more spread out and thereby less available for attracting a positive hydrogen. Thus, phosphine shows no tendency toward protonic bridging and, correspondingly, liquid phosphine is a much poorer solvent than liquid ammonia. Furthermore, phosphine is much less soluble in water than is ammonia. Similarly, although phosphine does act as an electron-pair donor toward certain Lewis acids, it does not come close to rivalling ammonia in the number and variety of the complexes it forms. Phosphonium salts can be produced by interaction of particularly protonic substances with phosphine, but they are easily dissociated and, in general, much less stable than the corresponding ammonium salts. Of the reaction products with the various hydrogen halides, for example, only phosphonium iodide, PH_4I, is moderately stable at ordinary temperatures.

Phosphonium salts

Phosphine is a good reducing agent and thus is easily oxidized. When it is prepared by the usual method—hydrolysis of calcium phosphide, Ca_3P_2—phosphine contains a small amount of diphosphine, P_2H_4, which is spontaneously inflammable and imparts this property to the mixture. Carefully purified phosphine does not ignite spontaneously, but it is very inflammable. The instability of phosphine is further illustrated by the reaction with atomic nitrogen, which produces the polymeric phosphorous nitride, PN, and liberates hydrogen. Diphosphine is even more unstable; it readily decomposes to elemental phosphorus and phosphine. Diphosphine melts at −99° and boils at 51.7° C.

Oxides and acids. The oxidation of white phosphorus in moist air is often accompanied by a glowing in the dark or phosphorescence. Phosphorus combines very readily with oxygen, the best known products being the so-called phosphorus trioxide, or more properly, phosphorus(III) oxide, P_4O_6, and phosphorus pentoxide, or phosphorus(V) oxide, P_4O_{10}. These bear only a slight, formal resemblance to the oxides of nitrogen with the formulas N_2O_3 and N_2O_5. The structure and bonding of the two pairs of compounds are altogether different, because of the lower electronegativity and larger size of the phosphorus atom and its available outer *d* orbitals.

It may be considered that P_4O_6 is formed by the attachment of single oxygen atoms along each of the six edges of the P_4 tetrahedron, spreading apart the phosphorus atoms by substituting oxygen bridges for the original P–P bonds. This molecule can then easily be oxidized further by joining one oxygen atom to each of the phosphorus atoms at the corners of the P_4O_6 tetrahedron. The last four oxygen atoms, in fact, are found to be bound much more closely and tightly to the phosphorus atoms than the bridging oxygens are, thus indicating a degree of multiple bonding, which probably involves interaction of the outer *d* orbitals of the phosphorus atoms with the lone pairs of electrons on the more tightly bound oxygen atoms.

Phosphorus trioxide is a white solid, which melts at 23.8° C and boils at 173° C. Above 210° C it decomposes yielding, among other products, an intermediate oxide of the empirical formula PO_2, which may correspond to the vapour at high temperatures of formula P_7O_{14}. Phosphorus trioxide slowly takes up oxygen in air to become the pentoxide, P_4O_{10}. The former also dissolves in cold water to form phosphorous acid, H_3PO_3, of which it is thus the anhydride. In hot water, however, the oxide disproportionates, forming phosphine and a mixture of phosphorus acids.

Phosphorous acid is a good reducing agent, being readily oxidized to phosphoric acid, H_3PO_4. It is a weak, diprotonic acid, having only two replaceable hydrogens. Investigation shows that this behaviour corresponds to a tetrahedral structure in which one of the hydrogen atoms is directly attached to a phosphorus atom instead of to oxygen. This is evidently the unreplaceable, nonacidic hydrogen.

Phosphorous and phosphoric acids

Phosphorus pentoxide is a very effective dehydrating agent, being itself hydrated in the process. The first step of its hydration occurs very rapidly to form a polymeric metaphosphoric acid, $(HPO_3)_x$. More slowly, additional water is acquired and orthophosphoric acid, H_3PO_4 commonly called simply phosphoric acid, is formed. It is interesting to note that, again, the similarity to nitrogen chemistry is formal only, in that metaphosphoric acid, a polymeric solid, in almost no way resembles nitric acid, HNO_3, which shows no tendency to polymerize, and that there is no orthonitric acid, H_3NO_4. Phosphoric acid usually is available in the laboratory as a syrupy solution of about 85 percent concentration in water. The high viscosity of this material reflects the extensive protonic bridging that occurs within it. Phosphoric acid is a triprotonic acid; the first ionization constant is that of a moderately strong acid, but the successive ionizations are progressively weaker. A striking difference between nitric and phosphoric acids is that the former is a powerful oxidizing agent, whereas the latter has almost no oxidizing properties at all.

The monohydrogen and dihydrogen phosphates, as well as the neutral phosphates, comprise the salts of phosphoric acid. As is more generally true, the presence of unneutralized hydrogen in these salts makes them much more soluble in water. This effect is the basis for using the calcium hydrogen salts in fertilizers.

Phosphorus–oxygen compounds exist in polymeric form in great variety. There are many families of polyphosphoric acids and their corresponding salts. In a sense these resemble the silicates, in that the phosphorus atoms are surrounded by oxygen atoms in tetrahedral array, some of which are shared with other tetrahedra. The "heteropoly acids" consist of phosphate tetrahedra surrounded by varying numbers of metal-oxide tetrahedra, usually tungstate or molybdate.

Polymeric phosphorus–oxygen compounds

The final important phosphorus acid is hypophosphorous, H_3PO_2. This compound can be formed as the barium salt by treatment of phosphorus with barium hydroxide. The barium salt is converted to the free acid by reaction with sulfuric acid. Hypophosphorous acid is in-

teresting in that only one of its hydrogens is acidic, the other two occupying positions of direct attachment to the phosphorus atom. The acid is a strong reducing agent, as are its salts.

Halides. Phosphorus readily forms a series of halogen-containing compounds: PF_3, PF_5, PCl_3, PCl_5, PBr_3, PBr_5, and PI_3, and many mixed halides as well. These are all volatile, molecular substances, easily susceptible to irreversible hydrolysis, liberating the respective hydrogen halides. They can be made by direct combination of the elements.

Pentahalides

The pentahalides may be thought of as resulting from the promotion of one of the phosphorus lone-pair electrons to an outer *d* orbital, which becomes more available through electron withdrawal from phosphorus by the halogen atoms. As free molecules, or in solution, these substances have trigonal, bipyramidal structures, each comprised of a planar triangle of halogen atoms surrounding the phosphorus atom, with a fourth and fifth halogen above and below the triangle. In the pentafluoride, which is a gas boiling at −84.5° C, it is uncertain whether the apical bonds are greatly different from the equatorial bonds; but in the pentachloride, a volatile solid that sublimes at 159° C, the bonds to the apical chlorine atoms are appreciably longer and only about half as strong as those to the equatorial chlorine atoms. It is possible that the two apical bonds in the chloride are different in nature from those in the fluoride, and perhaps they could be described more accurately as half-bonds.

In the solid state, phosphorus pentachloride has a structure that can be represented as $PCl_4^+PCl_6^-$. The solid state of the corresponding bromide, an orange solid that decomposes above its melting point of about 100° C, can be represented as $PBr_4^+Br^-$. This difference suggests that six bromine atoms cannot be fitted around one phosphorus atom. On the other hand, six fluorine atoms fit very well, for the pentafluoride readily coordinates a fluoride ion to form PF_6^-, of which many salts are known, in addition to the free acid. The failure to detect phosphorus pentaiodide suggests that five iodine atoms cannot be positioned around one phosphorus atom. Also, one would not expect iodine—the least electronegative of the common halogen elements—to activate the *d* orbitals of phosphorus as readily as the other halogens do.

Since the halogen atoms in the pentahalides cannot individually acquire large partial negative charges, these compounds are potentially good halogenating agents. Phosphorus pentachloride is commonly used for this purpose, and, in the process, it becomes converted to phosphorus oxychloride, $POCl_3$. Other, similar, oxyhalides are also known. In these compounds, the oxygen atom is attached by a short, strong bond to the phosphorus atom, a fact that suggests interaction between the oxygen lone pairs and the phosphorus *d* orbitals.

Trihalides

The trihalides of phosphorus range in character from the gaseous fluoride, which boils at −101.2° C, through the liquid chloride and bromide, boiling respectively at 76° C and 176° C, to the red, solid iodide, which melts at 61° C. Ordinarily one would expect the lone-pair electrons on the phosphorus atom in these molecules to be relatively unavailable for coordination because of the partial positive charge induced on the phosphorus atom by the halogen atoms. Although this is generally reflected in the behaviour of these compounds, the trifluoride serves as a ligand (that is, group coordinated with a central atom) in a number of complex compounds. Its behaviour in these compounds is much like that of carbon monoxide in the metal carbonyls—that is, the bonding is substantially reinforced by the use of a vacant orbital (in this case, a phosphorus *d* orbital) to accommodate an electron pair from the metal atom. An interesting reaction of phosphorus trifluoride is its bromination to form the mixed halide PF_3Br_2, which then easily disproportionates to form the simple pentahalides, PF_5 and PBr_5. This is an effective synthesis of PF_5.

Other compounds. The chemical behaviour of phosphorus with sulfur is complex and in some respects surprisingly unlike phosphorus–oxygen chemistry, as well as unlike nitrogen–sulfur chemistry. The principal compounds formed by heating together the appropriate proportions of phosphorus and sulfur are P_2S_5, P_4S_3, P_4S_5, and P_4S_7 (but apparently not P_4S_6). These compounds burn very readily but hydrolyze only slowly, liberating hydrogen sulfide and forming phosphorus acids. Numerous metal phosphides are known, which somewhat resemble the corresponding nitrides.

Analytical chemistry. Elemental phosphorus can be detected by its phosphorescence. It can also be converted to phosphine with boiling sodium hydroxide solution or with zinc and sulfuric acid; the phosphine is identified by means of test paper containing either silver nitrate or mercuric chloride, both of which are reduced to the free metal by phosphine, thereby darkening the paper. Phosphorus vapour also readily darkens silver nitrate test paper. Phosphorus is determined quantitatively by oxidation to phosphate, followed by any of several standard procedures. Phosphate, for example, may be precipitated as the magnesium ammonium salt, $MgNH_4PO_4$, converted by ignition to magnesium pyrophosphate, $Mg_2P_2O_7$, and weighed. Alternatively, phosphate may be precipitated as ammonium phosphomolybdate; this can be weighed as such, converted to magnesium pyrophosphate and weighed, or titrated directly with sodium hydroxide solution.

Biological and physiological significance. Phosphorus is an important constituent of bones and teeth, and it is essential to the growth of living organisms. In organisms the element usually appears as phosphate. In its other forms phosphorus is likely to prove very toxic. White phosphorus attacks the skin and, when ingested, causes a necrosis of the jawbone, called "phossy jaw." Certain organic esters of phosphoric acid, used as lubricating-oil additives, have been found to cause permanent paralysis when accidentally ingested. Phosphine is extremely toxic, as are its organic derivatives. Some of the most toxic substances known to man, collectively termed nerve gas, are organic derivatives of phosphorus.

Nerve gas

Isotopes of phosphorus. The only naturally occurring isotope of phosphorus is that of mass 31. The other isotopes from mass 29 to mass 34 have been synthesized by appropriate nuclear reactions. All of these are radioactive with relatively short half-lives. The isotope of mass 32 has a half-life of about 14 days and has proven extremely useful in tracer studies involving the absorption and movement of phosphorus in living organisms.

ARSENIC AND ITS COMPOUNDS

Occurrence and distribution. The abundance of arsenic in the earth's crust is about five grams per ton; the cosmic abundance is estimated as about four atoms per million atoms of silicon. The element is widely distributed. A small amount exists in the native state, in 90–98 percent purity. Most, however, is combined in more than 150 different minerals, as sulfides, arsenides, sulfoarsenides, and arsenites. Mispickel, or arsenopyrite, FeAsS, is among the most common of arsenic-bearing minerals; others are realgar, As_4S_4; orpiment, As_2S_3; loellingite, $FeAs_2$; and enargite, Cu_3AsS_4. Most commercial arsenic is recovered as a by-product of the smelting of copper, lead, cobalt, and gold ores.

Commercial production and uses. Metallic arsenic forms when arsenopyrite is heated at 650°–700° C in the absence of air. The arsenic in arsenopyrite and the arsenic impurities in other metal ores unite readily with oxygen when heated in air, forming the easily sublimed oxide, As_4O_6, also known as "white arsenic." The vapour of the oxide is collected and condensed in a series of brick chambers and later purified by resublimation. Most arsenic is prepared by carbon reduction of the arsenious oxide dust thus collected.

World consumption of metallic arsenic is relatively small, only a few hundred tons per year. Most of what is consumed comes from Sweden. It is used in metallurgical applications because of its metalloid properties. About one percent arsenic content is desirable in the manufacture of lead shot, for example, because it improves the roundness of the molten drops. Bearing alloys based on lead are improved in both thermal and mechanical properties when they contain about 3 percent arsenic. A small

amount of arsenic in lead alloys hardens them for use in batteries and cable sheathing. Small concentrations of arsenic improve the corrosion resistance and thermal properties of copper and brass. Very highly purified arsenic finds applications in semiconductor technology, where it is used with silicon and germanium, as well as in the form of gallium arsenide, GaAs, for diodes, lasers, and transistors.

Uses of arsenic compounds

In contrast to the small use of metallic arsenic, tens of thousands of tons of the element are consumed annually in the form of its compounds. These are used primarily in agriculture. Calcium arsenate, $Ca_3(AsO_4)_2$, enhances cotton production by controlling boll weevils; it is also used to kill crabgrass. Lead arsenate, $PbHAsO_4$, controls fruit pests, especially the codling moth, whose larvae are very destructive of apples. Sodium arsenite, Na_2AsO_3, helps prevent potato leaf rot. It also debarks trees and kills aquatic weeds in ponds and streams. As an ingredient of sheep and cattle dip, it helps control ticks and other pests. The harvesting of cotton is facilitated by use of arsenic acid, H_3AsO_4, and cacodylic acid, $(CH_3)_2As(O)OH$, as desiccants. These compounds also serve to sterilize soils. Other arsenic compounds are used as selective herbicides and as additives in the feed of swine and poultry. The pentasulfide is an ingredient of fireworks, and it is used in the making of infrared lenses. In glass manufacture pure arsenious oxide is an effective decolorizing agent.

Properties and reactions. *Arsenic.* In its most stable free state, arsenic is a steel-gray, brittle solid with low thermal and electrical conductivity. Other forms have been reported but are not well characterized, including especially a yellow, metastable form, which may consist of As_4 molecules analogous to white phosphorus, P_4. Arsenic sublimes at 613° C, and in the vapour it exists as As_4 molecules, which do not begin to dissociate until about 800° C; dissociation to As_2 molecules becomes complete at about 1,700° C.

Electronic structure

The electronic structure of the arsenic atom, 2–8–18–5, resembles those of nitrogen and phosphorus in that there are five electrons in the outermost shell, but it differs from them in having 18 electrons in the penultimate shell instead of two or eight. The addition of ten positive charges to the nucleus during the filling of the five 3*d* orbitals frequently causes a general contraction of the electronic cloud and a concomitant increase in electronegativity of the elements. In other groups of the periodic table this is clearly shown. Thus, it seems generally accepted that zinc is more electronegative than magnesium and, similarly, that gallium is more electronegative than aluminum. The difference diminishes, however, in the next groups, and many authorities do not agree that germanium is more electronegative than silicon, although an abundance of chemical evidence appears to indicate that this is so. The similar transition from penultimate 8-shell to 18-shell element in passing from phosphorus to arsenic might also produce an increase in the electronegativity of arsenic over phosphorus, but this remains controversial.

Bonding properties

The outer-shell similarity of the two elements suggests that arsenic, like phosphorus, can form three covalent bonds per atom, with an additional lone pair of electrons left unbonded. The oxidation state of arsenic should, therefore, be either +3 or −3 depending on the electronegativity of arsenic and that of the elements with which it is combined. The possibility should also exist of utilizing the outer *d* orbitals to expand the octet, thereby allowing arsenic to form five bonds. This possibility is realized only in compounds with fluorine. The availability of the lone pair for complex formation (through electron donation) appears much less in the arsenic atom than in phosphorus and nitrogen, as evidenced by the chemistry of the element.

Arsenic itself is stable in dry air, but in moist air it tends to become coated with a black oxide. Sublimed arsenic vapour readily burns in air to form arsenious oxide. The free element is essentially unaffected by water, bases, or nonoxidizing acids, but it can be oxidized by nitric acid to the +5 state. Halogens attack arsenic, as does sulfur, and the element will combine directly with many metals forming arsenides.

Arsine. The compound arsine, AsH_3, is evidently too unstable to be formed from the elements by direct combination, but it is readily produced by the hydrolysis of metal arsenides and by the reduction by metals of arsenic compounds in acidic solutions. Since arsine is an extremely toxic gas, it presents a potential hazard whenever metal and acid—either of which may contain arsenic impurities—are brought into contact. Arsine is not very soluble in water. It boils at −62.5° C. Its molecules are pyramidal, with bond angles of 97.5°. The instability of the substance is evidenced by the formation of a "mirror" of arsenic metal and the liberation of hydrogen at about 300° C. Arsine is a strong reducing agent and burns readily to water and oxides. In a limited oxygen supply, only the hydrogen burns, and free arsenic remains behind.

Oxides and acids. The principal oxides of arsenic are arsenious oxide, or arsenic(III) oxide, As_4O_6, formed by burning arsenic, and arsenic pentoxide, or arsenic(V) oxide, As_2O_5. The latter compound cannot be formed by direct oxidation with oxygen of either the free element or arsenious oxide. Like nitrogen pentoxide, it must be prepared by dehydration of the corresponding acid, and it is unstable toward heat, being decomposed completely above 400° C to oxygen and arsenious oxide. In this respect, as in many others, the chemistry of arsenic appears to resemble that of nitrogen somewhat more than it does that of phosphorus; like nitrogen and unlike phosphorus, arsenic in the +5 state is strongly oxidizing.

Arsenious oxide, or white arsenic, is very stable thermally. It is easily reduced to free arsenic, in contrast to phosphorus trioxide, which tends rather to be itself a reducing agent. The arsenic compound is moderately soluble in water forming solutions called arsenious acid, which are very weakly acidic and possibly slightly basic as well. The exact species present in solution are not well established, and no free arsenious acid as such has been isolated—again, unlike phosphorus chemistry, where the corresponding phosphorous acid is a crystalline solid.

The arsenic acids

Arsenic acid, whose molecular formula is usually written as H_3AsO_4, is formed by the action of various strong oxidizing agents on arsenious oxide. The compound isolated from solution has the formula $As_2O_5 \cdot 4H_2O$. It is a fairly strong oxidizing agent, capable of oxidizing chloride ions to free chlorine and sulfurous acid to sulfuric. It is a triprotonic acid, the first dissociation constant of which is about half that of phosphoric acid, but the second and third of which are much larger. When heated to 200° C, arsenic acid is converted to the so-called meta acid, $HAsO_3$. This substance gives no evidence of being highly polymeric like the phosphorus analogue, and, in fact, it is very quickly hydrated when water is added. In general, arsenic–oxygen compounds tend to polymerize much less than do phosphorus–oxygen compounds.

Halides. As expected, arsenic readily forms all four of the possible trihalides by direct combination of the elements. The trifluoride, AsF_3, a liquid boiling at 58° C, can also be formed by heating together solid arsenious oxide and calcium fluoride. The trichloride is also a liquid, boiling at 130° C. Arsenic tribromide is a white solid melting at 31.2° C and boiling at 221° C. The triiodide is a red solid, which melts at about 145° C and boils somewhere in the vicinity of 400° C. All four halides hydrolyze, but slowly. This is especially true of the fluoride and the iodide, which is not very soluble in water.

Instability of pentahalides

Arsenic pentafluoride, AsF_5, is a colourless gas that condenses to a yellow liquid boiling at −52.6° C. It is not very stable and loses fluorine at moderate temperatures. It acts, therefore, as a powerful fluorinating agent. The compound is much less stable than either phosphorus or antimony pentafluoride. Consistent with this fact is the complete failure to prepare arsenic pentachloride, although both the phosphorus and antimony compounds are well known. These examples of the relative instability of arsenic in the +5 state, as compared to both phosphorus and antimony, are in line with the supposition that the electronegativity of arsenic is higher than that of either phosphorus or antimony and that its bonds to halogen are, therefore, less polar and less stable. The pentabromide and pentaiodide of arsenic are also nonexistent.

Other compounds. Arsenic combines directly with many metals forming arsenides, which have a general resemblance to the nitrides and phosphides. Arsenic also forms thousands of organic compounds, which have been investigated since early times because of great interest in their possible medicinal properties. Among the better known organic arsenic compounds is tetramethyldiarsine, or cacodyl, $(CH_3)_2As–As(CH_3)_2$, used in preparing the herbicide cacodylic acid. This was first discovered as a component of "Cadet's liquid"—chiefly cacodyl oxide, $(CH_3)_2As–O–As(CH_3)_2$—which is obtained by dry distillation of arsenious acid and potassium acetate. In the absence of air, cacodyl is stable up to 400° C, but it is spontaneously inflammable, giving as its primary oxidation product cacodyl oxide.

Analytical chemistry. Qualitatively, arsenic may be detected by precipitation as the yellow arsenious sulfide from hydrochloric acid of 25 percent or greater concentration. Trace amounts of arsenic are usually determined by conversion to arsine. The later can be detected by the so-called Marsh test, in which arsine is thermally decomposed, forming a black arsenic mirror inside a narrow tube, or by the Gutzeit method, in which a test paper impregnated with mercuric chloride darkens when exposed to arsine because of the formation of free mercury.

Tests for arsine

Biological and physiological significance. The toxicity of arsenic and its compounds varies widely, ranging from the exceedingly poisonous arsine—and its organic derivatives—to elemental arsenic itself, which is relatively inert. Arsenical compounds in general are skin irritants, which easily cause dermatitis. Protection against inhalation of arsenic-containing dusts is recommended, but most poisoning appears to come from ingestion. The maximum tolerable concentration of arsenic in dusts during an eight-hour day is 0.5 milligrams per cubic metre. For arsine, exposure of similar duration requires that the concentration be less than 0.05 parts per million in the air. In addition to the many uses of arsenic compounds as herbicides and pesticides, they have in several instances been employed as pharmacological agents. The first successful antisyphillitic agent, for example, was an arsenic compound, "Salvarsan," or "606," or 3,3′-diamino-4,4′-dihydroxyarsenobenzene dihydrochloride.

Isotopes of arsenic. Only one stable isotope of arsenic, that of mass 75, occurs in nature. Among the artificial radioactive isotopes is one of mass 76, which has a half-life of 26.4 hours.

ANTIMONY

Occurrence and distribution. Antimony is about one-fifth as abundant as arsenic, contributing on the average about one gram to every ton of the earth's crust. Its cosmic abundance is estimated as about one atom to every 5,000,000 atoms of silicon. Small deposits of native metal have been found, but most of the antimony occurs in the form of more than 100 different minerals. The most important of these is stibnite, Sb_2S_3. Small stibnite deposits are found in Algeria, Bolivia, China, Yugoslavia, Mexico, Peru, and South Africa. Some economic value also attaches to kermesite ($2Sb_2S_3 \cdot Sb_2O_3$), argentiferous tetrahedrite [$(Cu,Fe)_{12}Sb_4S_{13}$], livingstonite ($HgSb_4S_7$), and jamesonite ($Pb_4FeSb_6S_{14}$). Small amounts are also recoverable from the production of copper and lead. About half of all the antimony produced is reclaimed from scrap lead alloy from old batteries, to which antimony had been added to provide hardness.

Stibnite

Commercial production and uses. High-grade or enriched stibnite reacts directly with scrap iron in the molten state, liberating antimony metal. The metal can also be obtained by conversion of stibnite to the oxide, followed by reduction with carbon. Sodium sulfide solutions are effective leaching agents for the concentration of stibnite from ores. Electrolysis of these solutions produces antimony. After further purification of the crude antimony, the metal, called regulus, is cast into cakes.

About half of this antimony is used metallurgically, principally in alloys. It improves the hardness and corrosion resistance of lead. Most of the metal is used for lead alloys, largely for storage batteries, but also for chemical equipment such as tanks, pipes, and pumps. With tin, antimony forms such alloys as britannia metal and pewter, used for utensils and Babbitt metal for bearings. Other applications of antimony alloys are in solder, type metal, and other special materials. Highly purified antimony is used in semiconductor technology to prepare the intermetallic compounds indium, aluminum, and gallium antimonide for diodes and infrared detectors.

The principal commercial compound of antimony is its oxide, Sb_2O_3. This substance is used to prepare opaque enamels for ceramics and metalware, and it is employed as a white pigment for paints. It also aids in flameproofing fabrics and plastics and in decolorizing glass. It finds some use in medicine, in dyeing, and in staining iron and copper. Antimony sulfide, Sb_2S_5, is used as a vulcanizing agent and Sb_2S_3 as a vermilion pigment, and as a component of fireworks, ammunition primers, and tracer bullets.

Properties and reactions. *Antimony.* The most stable form of antimony is a brittle, silvery solid of high metallic lustre. Electrolytic deposition of antimony under certain conditions produces an unstable, amorphous form called "explosive antimony," because, when bent or scratched, it will change in a mildly explosive manner to the more stable, metallic form. There is also an amorphous black form of antimony that results from sudden quenching of the vapour, and a yellow form produced by low temperature oxidation of stibine, SbH_3, with air or chlorine. Metallic antimony is not affected by air or moisture under ordinary conditions, but it can be oxidized easily by oxygen, sulfur, and the halogens, especially when heated.

The electronic structure of antimony closely resembles that of arsenic. It is represented as 2–8–18–18–5, with three half-filled orbitals in the outermost shell. Thus it can form three covalent bonds and exhibit +3 and −3 oxidation states. The electronegativity of antimony, like that of arsenic, remains somewhat controversial. It is generally agreed to be lower than that of arsenic, but whether it is lower also than that of phosphorus is undecided. It can act as an oxidizing agent and reacts with many metals to form antimonides that, in general, resemble nitrides, phosphides, and arsenides, but are somewhat more metallic. The promotion of one of the lone-pair electrons to an outer *d* orbital apparently occurs more easily with antimony than with arsenic, since antimony exhibits the +5 oxidation state in forming both the pentafluoride and the pentachloride.

Electronic structure

Stibine. The formation and properties of stibine, SbH_3, closely resemble those of arsine. Direct combination of antimony with hydrogen does not occur, but reduction of antimony compounds, or hydrolysis of metal antimonides, produces the gaseous stibine, which boils at −17° C. This compound is even less stable than arsine, separating into its elements slowly at 25° C and very rapidly at 200° C. It is a good reducing agent but inactive as an electron donor. It is very toxic.

Oxides and acids. Antimony burns in oxygen, forming principally the so-called trioxide and tetroxide, Sb_4O_6 and Sb_4O_8, respectively. The element is converted to the pentoxide, Sb_2O_5, by concentrated nitric acid. Since the pentoxide is somewhat unstable, its hydrated form loses small amounts of oxygen when dehydrated by gentle heating.

The molecules of the trioxide, which are stable even above 1,500° C in the gas phase, do not form definite hydroxides. Even in the presence of liquid water, the hydrous oxide tends to revert to the oxide by losing water slowly. The species in solution are not well identified, but the solution displays both acidic and basic properties, the supposed "antimonous acid" being somewhat more basic and less acidic than arsenious acid. The salts formed appear to be mainly the salts of the meta acid, $HSbO_2$.

Antimony tetroxide appears to be a stable oxide, especially between 300° and 900° C. It is formed by heating either the pentoxide or the trioxide in air. The pentoxide loses oxygen to form the tetroxide above 300° C, and the trioxide combines with additional oxygen to form the tetroxide up to about 900° C, above which temperature the additional oxygen is lost again. The tetroxide, like the other oxides, is a white solid. It is slightly soluble in water,

Antimony tetroxide

giving a weakly acidic solution, and it dissolves readily in alkaline but not in acid solutions. These solutions contain both antimonites and antimonates, but no Sb(IV) compounds, suggesting that the tetroxide is either a double oxide of Sb_4O_6 and Sb_2O_5 or an antimony(III) antimonate, $SbSbO_4$.

Antimonic acid, a poorly characterized colloidal material, is amphoteric but much weaker in acidity than arsenic acid. There is some evidence that antimonic acid should be represented by the formula $H[Sb(OH)_6]$.

Halides. Antimony pentafluoride, SbF_5, resembles the corresponding phosphorus and arsenic compounds except that, instead of being gaseous, it is a liquid boiling at 149° C. It can be formed by reaction of hydrofluoric acid with antimony pentachloride, which in turn is formed by direct chlorination of antimony trichloride. Like the phosphorus compound, but unlike the arsenic compound, antimony pentafluoride can coordinate fluoride ions, and a number of salts of the resulting SbF_6^- ion are known. Antimony pentachloride is a liquid that freezes at 2.8° C and loses chlorine at about 140° C. In the solid state it appears to consist of $SbCl_4^+Cl^-$. Many metal hexachloroantimonates are known. Antimony forms no pentabromide or pentaiodide.

The antimony trihalides are easily formed by direct halogenation. The trifluoride is a white solid melting at 290° C, and boiling more than 300° higher than the corresponding arsenic compound. Antimony trichloride, called "butter of antimony," is a soft, colourless solid, which melts at 73.2° C and boils at 221° C. It is much more saltlike than is arsenic trichloride. In dilute solution antimony trichloride hydrolyzes to give basic chlorides, such as antimony oxychloride, SbOCl. The trichloride forms many complex compounds with the general formula M_3SbCl_6. Antimony tribromide, which melts at 96.6° C, is very similar to the chloride. The triiodide is a yellow or red solid melting at 171° C.

Other compounds. Antimony forms many other types of compounds, including sulfides, which have industrial importance in the manufacture of rubber. Large numbers of organic compounds have been investigated, some for possible medicinal applications, but, in general, these—like arsenic compounds—tend to be too toxic for wide use.

Analytical chemistry. Antimony may be separated and weighed for analysis as the sulfide, Sb_2S_3. Alternatively, the sulfide may be converted to the oxide and, after careful ignition, weighed as Sb_4O_6. Numerous volumetric methods are also available, including several methods of oxidizing Sb(III) with potassium permanganate, potassium bromate, or iodine. In the absence of arsenic, small amounts of antimony may be determined by a modified Gutzeit method.

Biological and physiological significance. Antimony and a number of its compounds are highly toxic. In fact, the use of antimony compounds for medicinal purposes was temporarily outlawed several centuries ago because of the number of fatalities they had caused. A hydrated potassium antimonyl tartrate called "tartar emetic" is currently used in medicine as an expectorant, diaphoretic, and emetic. The maximum tolerable concentration of antimony dust in air is about the same as for arsenic, 0.5 milligrams per cubic metre.

Tartar emetic

Isotopes of antimony. Two stable isotopes, nearly equal in abundance, occur in nature. One has mass 121 and the other mass 123. Radioactive isotopes of masses 120, 122, 124, 125, 126, 127, 129, and 132 have been prepared.

BISMUTH AND ITS COMPOUNDS

Occurrence and distribution. Bismuth is about as abundant as silver, contributing about 2×10^{-5} weight percent of the earth's crust. Its cosmic abundance is estimated as about one atom to every 7,000,000 atoms of silicon. It occurs both native and in compounds. In the native state, it is found in veins associated with lead, zinc, tin, and silver ores in Bolivia, Canada, England, and Germany. Its naturally occurring compounds are chiefly the oxide (bismite or bismuth ochre), the sulfide (bismuthinite or bismuth glance), and two carbonates (bismutite and bismutosphaerite). Commercial bismuth, however, is produced largely as a by-product in the smelting and refining of lead, tin, copper, silver, and gold ores. Thus, it comes—for example—from tungsten ores in South Korea, lead ores in Mexico, copper ores in Bolivia, and both lead and copper ores in Japan.

Commercial production and uses. Bismuth is volatile at high temperature, but it usually remains with the other metals after smelting operations. Electrolytic refining of copper leaves bismuth behind as one component of the anode sludge. Separation of bismuth from lead by the Betterton–Kroll process involves the formation of high-melting calcium or magnesium bismuthide (Ca_3Bi_2 or Mg_3Bi_2), which separates and can be skimmed off as dross. The dross may be chlorinated to remove the magnesium or calcium, and finally the entrained lead. Caustic soda treatment then produces highly pure bismuth. An alternative separation, the Betts process, involves electrolytic refining of lead bullion (containing bismuth and other impurities) in a solution of lead fluosilicate and free fluosilicic acid, bismuth being recovered from the anode sludge. Separation of bismuth from its oxide or carbonate ores can be effected by leaching with concentrated hydrochloric acid. Dilution then precipitates the oxychloride, BiOCl. This—heated with lime and charcoal—produces metallic bismuth.

Alloys of bismuth

Metallic bismuth is used principally in alloys, to many of which it imparts its own special properties of low melting point and expansion on solidification. Bismuth is thus a useful component of type-metal alloys, which make neat, clean castings; and it is an important ingredient of low-melting alloys, called fusible alloys, which have a large variety of applications, especially in fire-detection equipment. A bismuth–manganese alloy has been found effective as a permanent magnet. Small concentrations of bismuth improve the machinability of aluminum, steel, stainless steels, and other alloys and suppress the separation of graphite from malleable cast iron. Thermoelectric devices for refrigeration make use of bismuth telluride, Bi_2Te_3, and bismuth selenide, Bi_2Se_3. Liquid bismuth has been used as a fuel carrier and coolant in the generation of nuclear energy.

The principal chemical application of bismuth is in the form of bismuth phosphomolybdate, which is an effective catalyst for the air oxidation of propylene and ammonia to acrylonitrile. The latter is used to make acrylic fibres, paints, and plastics. Pharmaceutical uses of bismuth have been practiced for centuries. It is effective in indigestion remedies and antisyphilitic drugs. Slightly soluble or insoluble salts are utilized in the treatment of wounds and gastric disorders, and bismuth is sometimes injected in the form of finely divided metal, or as suspensions of its insoluble salts. Substantial quantities of the oxychloride, BiOCl, have been used to impart a pearlescent quality to lipstick, nail polish, and eye shadow.

Properties and reactions. Bismuth is a rather brittle metal with a somewhat pinkish, silvery metallic lustre. It undergoes a 3.3 percent expansion when it solidifies from the molten state. Its electrical conductivity is very poor, but somewhat better in the liquid state than in the solid. With respect to thermal conductivity, it is the poorest of all metals except mercury. Bismuth is quite resistant to corrosion by air and moisture, but it is oxidized rapidly at its boiling point of 1,560° C. It is oxidized and dissolved by concentrated nitric acid.

Bismuth atoms have the same electronic structure in their outermost shell as do the other elements of the nitrogen group. They can, therefore, form three single covalent bonds, exhibiting either a $+3$ or -3 oxidation state. The element has a somewhat lower electronegativity than the others, and its lone pair of electrons is evidently quite inert, causing the $+5$ state of bismuth to be rare and unstable.

Bismuth compounds

Bismuth forms a very unstable compound with hydrogen, bismuthine, BiH_3, which boils at about 22° C and slowly decomposes above that temperature. Ignition of the basic nitrate produces bismuth trioxide, Bi_2O_3, a yellow solid that is stable even above 1,750° C. The oxide is

nonacidic but only very weakly basic; it forms no definite hydroxide. Powerful oxidants in alkaline solution oxidize bismuth to the +5 state, and acidification then precipitates a red-brown solid (approximating Bi_2O_5 in composition), which is quite unstable, losing some oxygen even on drying at 100° C. This product appears to be acidic. Fluorine is the only halogen capable of oxidizing bismuth to the +5 state; it produces a fairly stable, white, solid pentafluoride, BiF_5, which sublimes at 550° C and appears to decompose at still higher temperatures. The other halides of bismuth are all solid trihalides. They hydrolyze readily to form oxyhalides, which are generally insoluble. Bismuth also forms sulfides and various other salts, including the sulfate. It can form bismuthides with active metals.

Analytical and physiological chemistry. Bismuth is usually determined gravimetrically, being precipitated and weighed as the phosphate or the oxychloride, BiOCl. To produce the latter, a suitable amount of hydrochloric acid is added to a nitric acid solution containing the bismuth, and the resulting solution is poured into a large volume of water, causing the oxychloride to precipitate. Volumetric and colorimetric methods of determination are also available.

Bismuth is relatively nontoxic, the least so of the heavy metals. It is generally not an industrial hazard. Although bismuth and certain of its compounds find considerable therapeutic use, some authorities recommend that other remedies be substituted. Soluble inorganic bismuth compounds are toxic.

Isotopes of bismuth. Bismuth forms only one stable isotope, that of mass 209. A large number of radioactive isotopes are known, as shown in the table, most of them being very unstable.

BIBLIOGRAPHY. A short concise summary of nitrogen chemistry is contained in W.L. JOLLY, *The Inorganic Chemistry of Nitrogen* (1964). More detailed is the comprehensive compendium edited by C.A. STREULI and P.R. AVERELL, *Analytical Chemistry of Nitrogen and Its Compounds*, 2 vol. (1970), which includes especially useful tables. For a popularized, readable, introductory account, see ISAAC ASIMOV, *The World of Nitrogen*, rev. ed. (1962). Information about nitrogen and its compounds, as well as about the other elements of the nitrogen group and their compounds, is found in standard textbooks and treatises of inorganic chemistry. Among these are: R.T. SANDERSON, *Inorganic Chemistry* (1967), a modern textbook emphasizing the periodicity of the chemical elements by surveying their binary compounds with each of principal nonmetals; and *Chemical Bonds and Bond Energy* (1970), a brief book giving new insights into the nature of chemical bonds; HEINRICH REMY, *Grundriss der anorganischen Chemie*, 5th ed. (1955; Eng. trans., *Treatise on Inorganic Chemistry*, 2 vol., 1956), a thorough exposition; E.G. ROCHOW, *The Metalloids* (1966), a brief, very readable survey of the elements that border between metallic and nonmetallic; and N.V. SIDGWICK, *The Chemical Elements and Their Compounds* (1950), a classic, thoroughly documented treatise on inorganic chemistry, largely descriptive in nature.

(R.T.S.)

Nizām al-Mulk

Nizām al-Mulk (Regulator of the Kingdom; personal name Abū ʿAlī Ḥasan ibn ʿAlī), the Iranian vizier of the Seljuq sultans Alp-Arslan (1063–72/73) and Malik-Shāh (1072/73–92), was an outstanding statesman and administrator.

Born in 1018 or 1019 near Ṭūs, in the province of Khorāsān, of a father who was a revenue official for the Ghaznavid dynasty that, before the invasion of the Seljuqs, ruled over Khorāsān from their centre at Ghazna (present-day Ghaznī, Afghanistan), he may have studied with one of the outstanding Shāfiʿī teachers of Nīshāpūr, the imam Muwaffaq. Through his father's position and his family's connections with the sayyids of Bayhaq, he was born into the literate, cultured milieu of the Persian administrative class, a background that molded his attitudes and determined his career. In the years of confusion following the initial Seljuq expansion, his father fled, eventually to Ghazna, where Nizām al-Mulk, too, in due course entered Ghaznavid service. He soon returned to Khorāsān, however, and joined the service of Alp-Arslan, then governing Khorāsān. When Alp-Arslan's vizier died, Nizām al-Mulk was appointed to succeed him, and, when Alp-Arslan himself succeeded his father in 1059, Nizām al-Mulk had the entire administration of Khorāsān in his hands. His abilities so pleased his master that, when Alp-Arslan became the supreme overlord of the Seljuq rulers in 1063, Nizām al-Mulk was made vizier.

For the next 30 years, under two remarkable rulers, he held this position in an empire that stretched from the Oxus in the east, to Khwārezm and the southern Caucasus, and westward into central Anatolia. During these decades, the Seljuq Empire was at its zenith; Nizām al-Mulk's influence guided the Sultan's decisions, sometimes even military ones, and his firm control of the central and provincial administration, through his many dependents and relatives, implemented those decisions. His influence was especially felt in the rule of Malik-Shāh, who succeeded to the throne when he was only 18. Indeed, Nizām al-Mulk's boast shortly before his assassination (1092) was substantially true: "Tell the Sultan, 'If you have not already realized that I am your co-equal in the work of ruling, then know that you have only attained to this power through my statesmanship and judgment'." Such was his reputation among contemporaries that he was compared to the Barmakids, viziers to the 8th-century caliph Hārūn al-Rashīd.

Influence in Seljuq policy

His aim, like that of other great Persian viziers, was to impress on his less sophisticated Turkmen rulers, brought up in the rude tradition of the steppe, the superiority of Persian civilization and its political wisdom. Nizām al-Mulk's conception of society was based partly on the ideals that he had inherited from his background, a Persian tradition of order and hierarchy in the state that reached back beyond the Arab conquest of Persia in the 7th century to the traditions of Sāsānian society. The ruler, chosen by God, had as his main task the preservation of stability in the kingdom and the traditional forms of society. His power was absolute, requiring no authorization, and the administration was centralized in his person.

Yet, despite his immense power and prestige, Nizām al-Mulk was only in some measure able to mold his sultans in this ideal of kingship. Shortly before his death, at Malik-Shāh's request, he wrote down his views on government in the *Seyāsat-nāmeh* (Eng. trans., *The Book of Government; or, Rules for Kings*, 1960). In this remarkable work, Nizām al-Mulk barely refers to the organization of the dewan (administration) because he had been able, with the help of his well-chosen servants, to control and model it on traditional lines. But he never had the same power in the *dargāh* (court) and found much to criticize in the Sultan's careless disregard for protocol, the lack of magnificence in his court, the decline in prestige of important officials, and the neglect of the intelligence service.

The *Seyāsat-nāmeh*

The most severe criticisms in the *Seyāsat-nāmeh*, however, are of those with heterodox religious views, the Shīʿī in general and the Ismāʿīlīs in particular, to whom he devotes his last 11 chapters. His support of "right religion," Sunnī Islām, was not only for reasons of state but also a matter of passionate conviction, providing the other major influence that shaped his view of society. His relations with the ʿAbbāsid caliphate show him interested only in extending the Sultan's and his own influence, until 1086 when the Caliph's gracious reception made him his fervent champion in the later disputes between the Caliph and the Sultan. He expressed his religious devotion in other ways, however, that more effectively contributed to the Sunnī revival. He founded Nizāmīyah *madrasah*s (colleges of higher learning) in many major towns throughout the empire to combat Shīʿī propaganda, as well as to provide reliable, competent administrators, schooled in his own branch of Islāmic law. Less orthodox religious communities among the Ṣūfī orders also benefitted from his generosity; hospices, pensions for the poor, and extensive public works related to the pilgrimage to Mecca and Medina were created or sustained by his patronage. Particularly in his last years, when the Ismāʿīlī threat grew stronger and found a

Opposition to the Assassins

refuge in Alamūt, the castle of the Assassins, he set himself the task of combatting their influence by every means possible. In the closing sections of the *Seyāsat-nāmeh*, when he himself was surrounded by court intrigues, had lost the Sultan's confidence, and felt too acutely the dangers threatening the empire and orthodoxy, he reminded Malik-Shāh of the validity of his warnings:

> My words will be remembered when they [the Ismā'īlīs] begin to throw into the pit the distinguished and the great, when the ears echo with the sound of their drums, and when their evil practices and intrigues are laid bare. At the time of this misfortune he [the Sultan] will realize that I was right in all that I said and never refused to offer any possible advice or goodwill.

His words were prophetic. Niẓām al-Mulk was assassinated on October 14, 1092, on the road from Isfahan to Baghdad, near Nehāvand. The murder was probably committed by an Ismā'īlī from Alamūt, possibly with the complicity of Niẓām al-Mulk's court rival, Tāj al-Mulk, and of the queen, Terkhen-Khatun, if not that of Malik-Shāh himself. Within a month, however, the Sultan, too, was dead, and the disintegration of the great empire had begun.

Despite his accumulation of personal wealth, his nepotism and the arrogance of some of his relatives, and his occasional acts of ruthlessness, Niẓām al-Mulk was, for contemporaries, as he has remained for successive generations who read his *Seyāsat-nāmeh*, the quintessential vizier—wise, prudent, resourceful and successful, and a devout Muslim. By his life and work, he brought the Persian and the Islāmic cultures toward a closer integration at a time when medieval Islām reached its zenith.

BIBLIOGRAPHY. The only complete English translation of Niẓām al-Mulk's *Seyāsat-nāmeh* is by HUBERT DARKE, *The Book of Government; or, Rules for Kings* (1960). There is an older French translation using a different text by CHARLES SCHEFER, *Siasset Namèh, traité du gouvernement*, 2 pt. (1891–93); and a more recent German translation by K.E. SCHABINGER VON SCHOWINGEN, *Siyāsatnāma* (1960), with a useful introduction. There is no biography; HAROLD BOWEN'S article in the *Enclyclopaedia of Islam*, 1st ed., vol. 3 (1936), gives a clear outline of his life; and E.G. BROWNE in *A Literary History of Persia*, vol. 2 (1906), assesses the value of his work.

Nkrumah, Kwame

A political organizer of outstanding ability, the African statesman Kwame Nkrumah achieved the liberation of the Gold Coast from British colonial rule. As first prime minister of independent Ghana—as the former colony came to be called—and subsequently president of the republic, Nkrumah's policies made him a figure of acute controversy: inflexible dictator, according to his opponents; redeemer of Africa, according to his followers. As theoretician of the anti-imperialist cause, his writings achieved a major impact and remain among the more cogent expressions of the black liberation movement.

Early years

Kwame Nkrumah was born in September 1909, at Nkroful, a coastal village. His father was a goldsmith and his mother a retail trader. Baptized a Roman Catholic, Nkrumah spent nine years at the Roman Catholic elementary school in nearby Half Assini. After graduation from Achimota College in 1930, he started his career as teacher at Catholic junior schools in Elmina and Axim and at a seminary, where he became seriously attracted to the priesthood. In 1934, however, he came under the influence of Nnamdi Azikwe and other exponents of the new African nationalism. Increasingly drawn to politics, Nkrumah decided to pursue further studies in the United States. He entered Lincoln University, Pennsylvania, in 1935 and, after graduating in 1939, obtained masters degrees from Lincoln and from the University of Pennsylvania. He began to clarify his ideological position after intensive study of the literature of Socialism, notably Marx and Lenin, and of nationalism, especially Marcus Garvey, the American leader who in the 1920s sought to promote unity among the Negroes of the world and to establish a black-governed Negro nation in Africa. Eventually, he came to describe himself as a "nondenominational Christian and a Marxist socialist." He also immersed himself in political work, reorganizing and becoming president of the African Students' Association. He left the United States in May 1945, intending to study law in Britain, but instead he enrolled at the London School of Economics and Political Science. He became vice president of the West African Students Union; an official of other African organizations; and leader of "The Circle," an experiment in the creation of revolutionary activist cells. In 1947, in his first major publication, *Towards Colonial Freedom*, he outlined an ideological blueprint for the anticolonial struggle.

Nkrumah, 1962.
Marc and Evelyne Bernheim—Rapho Guillumette

Meanwhile, in the Gold Coast, J.B. Danquah had formed the United Gold Coast Convention (UGCC) to work for self-government by constitutional means. Invited to serve as its general secretary, Nkrumah returned home in late 1947. Appealing particularly to the youth and former servicemen, he addressed meetings throughout the country and began to create a mass base for the new movement. When extensive riots occurred in February 1948, the British ordered the detention of Nkrumah and other leaders of the UGCC, but he was released in April to testify before a commission of inquiry. As a split developed between the middle class leaders of the UGCC and the more radical supporters of Nkrumah, he launched, in September 1948, the *Accra Evening News* as a vehicle for his views and in June 1949 announced the creation of the new Convention Peoples' Party (CPP), which was committed to a program of immediate self-government. In January 1950, he initiated the campaign of Positive Action: "Non-violence and non-cooperation—the adoption of all legitimate and consitutional means by which we can cripple the forces of imperialism in the country." In the ensuing crisis, services throughout the country were disrupted, and Nkrumah was again arrested and sentenced to one-year's imprisonment with hard labour. But the first general election (February 8, 1951) demonstrated the support the CPP had already won. Elected to Parliament, Nkrumah was released from prison to become leader of government business and, in 1952, prime minister. During a short visit to the U.S. in 1951, he received the LL.D. degree from Lincoln University.

Release from prison and entry into government

When the Gold Coast and the British Togoland trust territory became an independent state within the British Commonwealth—as Ghana—in March 1957, the CPP held 72 of the 104 seats in Parliament. Such opposition as had emerged was regionally based. Maintaining such a situation was inherently dangerous; in December 1957, Nkrumah forced the regional parties to merge into a national opposition. The Preventive Detention Act of the following year legalized imprisonment without trial of those regarded as security risks. It soon became ap-

parent that Nkrumah's style of government was to be authoritarian—in the tradition not only of the preceding colonial administration but also of the powerful 19th-century kingdoms, such as Ashanti, out of which, historically, Ghana had evolved. Nkrumah's popularity in the country rose, however, as new roads, schools, and health facilities were built and as the policy of Africanization created better career opportunities for Ghanaians.

By a plebiscite of 1960 Ghana became a republic and Nkrumah became its president, with wide legislative and executive powers under a new constitution. Nevertheless, whole sectors of the economy remained essentially controlled by foreign interests, including cocoa marketing, insurance, and banking. The Second Development Plan, announced in 1959, had to be abandoned in 1961 when the deficit in the balance of payments rose to more than $125,000,000. Contraction of the economy led to widespread labour unrest and to a general strike in September 1961. From that time on Nkrumah began to evolve a much more rigorous apparatus of political control and to turn increasingly to the Communist countries for support. The attempted assassination of Nkrumah at Kulugungu in August 1962—the first of several—led to his increasing seclusion from public life and to the growth of a personality cult, as well as to a massive build-up of the country's internal security forces. Early in 1964 Ghana was officially designated a one-party state, with Nkrumah as life president of both nation and party. While the administration of the country passed increasingly into the hands of party officials, many of whose standards of public service were unfortunately low, Nkrumah, although introducing into the government a number of talented and dedicated intellectuals, seems to have interested himself more in the ideological education of a new generation of political activists. It was in this period that he published some of his best known works: *Africa Must Unite*, a general analysis of the problems facing the new African nations; *Consciencism*, a highly theoretical analysis of the ideology of decolonization worked out by his followers; and *Neo-Colonialism; The Last Stage of Imperialism*, an indictment of European and American economic activity in Africa.

Life president of Ghana

As the economic crisis worsened and shortages of foodstuffs and other goods became chronic, Nkrumah explored ways of linking the party with the masses—"Democratic Centralism"—and of representing all major interest groups in the nation within Parliament, thus exemplifying to the end the maxim he had long propounded, "Seek ye first the political kingdom." His considerable international reputation as leading spokesman in the cause of African unity seemed enhanced further when he was invited to Hanoi by President Ho Chi Minh to present proposals for ending the Vietnam War. While he was in Peking, however, the army in Ghana seized power on February 24, 1966. Returning to West Africa, Nkrumah found asylum in Guinea, whose president, Sékou Touré, as a gesture of solidarity declared him a co-head of state. There he immersed himself once more in the cause of black nationalism. His *Handbook of Revolutionary Warfare* (1968) was addressed to the oppressed peoples of Africa, and he also involved himself in the problems of "Black Power" in the United States and the Caribbean. In his last work, *Class Struggle in Africa* (1970), Nkrumah reaffirmed his basic Marxist approach and argued that the African revolutionary struggle "forms part of the world socialist revolution, but must be seen in the context of the Black Revolution as a whole." However posterity may judge Nkrumah's stewardship of Ghanaian affairs between 1957 and 1966, his leadership of the independence movement undoubtedly provided a model of nonviolent political action that changed the course of development of a continent. Nkrumah continued to articulate an ideology of contemporary significance until his death, from cancer, in Bucharest, on April 27, 1972.

Noble Gases and Their Compounds

The so-called noble gases consist of a group of six chemical elements that exist under ordinary conditions as colourless, odourless, tasteless, nonflammable gases: helium (symbol He, atomic number 2), neon (symbol Ne, atomic number 10), argon (symbol Ar, atomic number 18), krypton (symbol Kr, atomic number 36), xenon (symbol Xe, atomic number 54), and radon (symbol Rn, atomic number 86). They traditionally have been labelled Group 0 in the periodic table (see figure) because for decades after their discovery it was believed that they had a valence of zero; that is, that their atoms could not combine with those of other elements to form chemical compounds. Their electronic structures and the finding that some of them do indeed form compounds suggest that a more appropriate designation would be Group VIIIa.

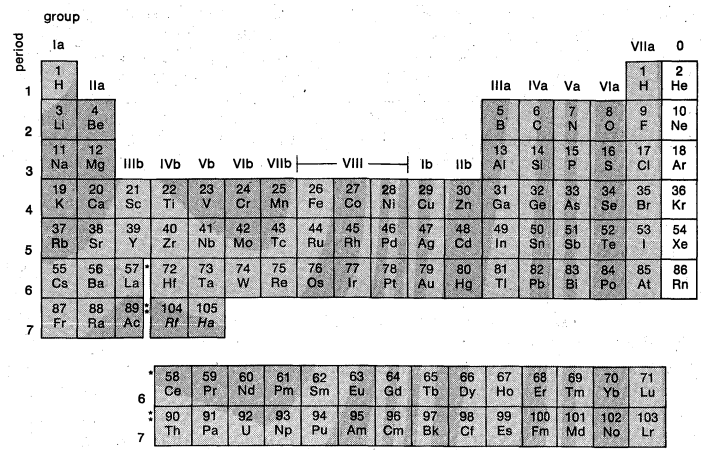
When the members of the group were discovered and identified they were thought to be exceedingly rare, as well as chemically inactive, and therefore were called the rare gases or the inert gases. It is now known, however, that several of these elements are quite abundant on Earth and in the rest of the universe, so the designation rare is misleading. Similarly, use of the term inert has the drawback that it often is applied to gases such as nitrogen and carbon dioxide to connote their nonflammability. In chemistry and alchemy, the word noble long has signified the passivity toward oxygen of a group of metals, such as gold and platinum; it applies in the same sense to the group of gases covered in this article.

THE NOBLE GASES AS A GROUP

Occurrence. The abundances of the noble gases decrease as their atomic numbers increase; helium is, in fact, the most plentiful element in the universe except hydrogen. All the noble gases are present in the Earth's atmosphere and, except for helium and radon, their major commercial source is the air, from which they are obtained by liquefaction and fractional distillation. Most helium is produced commercially from certain natural gas wells. Radon usually is isolated as a product of the radioactive decomposition of dissolved radium compounds (the nuclei of radium atoms spontaneously decay by emitting energy and particles; the particles are the nuclei of helium and radon atoms).

Uses. Several important uses of the noble gases rest on their marked lack of chemical reactivity. Their indifference toward oxygen, for example, confers utter nonflammability upon all six noble gases. Although helium is not quite as buoyant as hydrogen, its incombustibility makes it a safer lifting gas for lighter-than-air aircraft. The noble gases—most often helium and argon, the least expensive—are used to provide chemically unreactive environments for such operations as cutting, welding, and refining of metals (atmospheric oxygen and, in some cases, nitrogen or carbon dioxide would react with the hot metal) and in the handling of other easily attacked materials.

The noble gases absorb and emit electromagnetic radiation in a much less complex way than do other substances. The absorption and emission behaviour is utilized in the employment of these gases in discharge lamps and fluorescent lighting devices: if any of them is confined at low pressure in a glass tube and an electrical discharge is passed through it, the gas glows. Neon produces the familiar orange-red colour of advertising signs; xenon emits a beautiful blue.



Periodic table of elements showing the noble gases.

The very low boiling points and melting points of the noble gases make them useful as refrigerants in the study of matter at extremely low temperatures. The low solubility of helium in fluids leads to its use in admixture with oxygen for breathing by deep-sea divers: because helium does not dissolve in the blood, it does not form bubbles upon decompression (as nitrogen does, leading to the condition known as bends; see COMPRESSION AND DECOMPRESSION INJURIES). Xenon has been used as an anesthetic; although it is costly, it is nonflammable and readily eliminated from the body. Radon is highly radioactive; its only uses have been those that exploit this property, as, for example, in radiotherapy.

The compounds of the noble gases are powerful oxidizing agents (substances that tend to remove electrons from others) and have potential value as reagents in the synthesis of chemical compounds.

History. In 1785 Henry Cavendish, an English chemist and physicist, found that air contains a small proportion (slightly less than 1 percent) of a substance that is chemically less active than nitrogen. A century later Lord Rayleigh, an English physicist, isolated from the air a gas that he thought was pure nitrogen but found that it was denser than nitrogen prepared chemically by liberating it from its compounds. He reasoned that his aerial nitrogen must contain a small amount of a denser gas. Sir William Ramsay, a British chemist, collaborated with Rayleigh in isolating (1894) this gas, which proved to be a new element, argon.

Discovery of argon

After the discovery of argon, and at the instigation of other scientists, Ramsay undertook to investigate the gas evolved upon heating the mineral clevite, which was thought to be a source of argon. The gas proved (1895) instead to be helium, which in 1868 had been detected spectroscopically in the sun but had not been found on Earth. Ramsay and his co-workers searched for related gases and by fractional distillation of liquid air discovered krypton, neon, and xenon, all in 1898. Radon, first identified in 1900, was established as a member of the noble-gas group in 1904.

In 1895 Henri Moissan, a French chemist, failed in an attempt to bring about a reaction between fluorine and argon. In fact, all late-19th- and early-20th-century efforts to prepare chemical compounds of argon failed. The lack of chemical reactivity implied by these failures was of significance in the development of theories of atomic structure. In 1913 a Danish physicist, Niels Bohr, proposed that the electrons in atoms are arranged in successive shells having characteristic energies and capacities and that the capacities of the shells determine the numbers of elements in the periods of the periodic table. On the basis of experimental evidence relating chemical properties to electron distributions, it was suggested that in the atoms of each noble gas beyond helium the electrons are arranged in these shells in such a way that the outermost shell always contains eight electrons, no matter how many others (in the case of radon, 78 others) were arranged inside those of eight. (Further details are discussed in the article ATOMIC STRUCTURE.)

In a theory of chemical bonding advanced by others in 1916, this octet (as it came to be called) of electrons was taken to be the most stable arrangement for the outermost shell of any atom. Although only the noble-gas atoms possessed this arrangement, it was the condition toward which the atoms of all other elements tended in their chemical bonding. Certain elements satisfied this tendency by either gaining or losing electrons outright, becoming electrically charged particles (ions); other elements shared electrons, forming stable combinations linked together by covalent bonds. The valences of elements—that is, the proportions in which their atoms combined to form ionic or covalent compounds—were thus controlled by the behaviour of their outermost electrons, which for this reason were called the valence electrons. This theory rationalized the chemical bonding of the reactive elements as well as the relative inactivity of the noble gases, which is their chief characteristic. (Additional information appears in the article CHEMICAL BONDING.)

Octet theory

The outer electrons of the atoms of the heavier noble gases, screened from the nucleus by intervening electrons, are held less firmly and can be removed more easily from the atoms than can the electrons of the lighter noble gases. This fact had been known for a long time from experiments using electrical and magnetic fields; the energy required for removal of one electron is called the first ionization potential. In 1962 it was discovered that platinum hexafluoride would oxidize molecular oxygen to form a salt. Knowledge that the first ionization potential of xenon is very close to that of oxygen led to the suggestion that a salt of xenon might be formed similarly. In the same year it was established that it is indeed possible to remove electrons from xenon by chemical means—that is, to oxidize xenon—when two teams of chemists independently prepared fluorides of that element. This achievement was followed by the preparation of other xenon compounds and of the fluorides of radon (1962) and krypton (1963).

Properties of the gases. Each noble-gas element is situated in the periodic table between an element of the most electronegative group, the halogens (Group VIIa, the atoms of which add electrons to achieve the octet and thereby become negative ions), and an element of the most electropositive group, the alkali metals (Group Ia, the atoms of which lose electrons to become positive ions). The noble gases thus form a dramatic transition group in the periodic table of the elements and are neither electropositive nor electronegative but, relatively speaking, neutral, neither gaining nor losing electrons easily.

The sizes of the atoms of noble gases increase smoothly with the increase in atomic number, partially because repulsion between the electrons prevents them from occupying the same region of space and forces each successive shell to extend into a larger concentric spherical volume. In the largest atoms, the weaker attraction of the

nucleus for the electrons in the most distant shell explains the greater ease with which the outer electron clouds of these atoms are distorted by other charged bodies, or polarized. A polarized atom as a whole remains electrically neutral but the distribution of charge within it becomes unsymmetrical, the centre of gravity, so to speak, of the negative charge being displaced from that of the positive charge. The polarizability of the noble gases increases markedly through the group from helium to radon as the ionization potential decreases.

Generally speaking, a polarizable substance is attracted more strongly to surfaces and dissolves in fluids more extensively than a nonpolarizable one. Because the polarizability of helium is minimal, it shows little or no tendency to adsorb upon surfaces and it is not very soluble in fluids. These properties may account for the fact that helium does not induce narcosis when it is breathed by divers at high pressures and that it does not form clathrates. (Clathrates—from a Latin word meaning "enclosed by a lattice"—are substances in which the molecules of one compound, called the host, form a cagelike crystalline lattice within which there are open spaces that may be occupied by molecules of a second compound or element, called the guest, although no chemical bonds are formed between the host and the guest. The stability of a clathrate is influenced by the closeness with which the guest particles fit into the holes as well as by the polarizability of the guest.) The properties of small size and low polarizability make helium a highly mobile gas; *i.e.*, one that is not trapped by various structures of other atoms. The greater polarizability of argon and the heavier noble gases accounts for their formation of clathrates, including those in which water is the host—hydrates—and also accounts for the ready adsorption of these gases on surfaces. The narcotic activity of the noble gases also parallels their polarizability. The noble gases reduce the sensitivity of living cells to attack by oxygen under the influence of radiation; the heavier gases are more effective than the lighter ones in this action, perhaps simply as a result of their greater solubility in fluids, but possibly also as a consequence of their greater ability to absorb neutrons.

Clathrates

THE INDIVIDUAL NOBLE GASES

Helium. Because the first evidence of the existence of helium was the presence of certain wavelengths in the yellow region of the spectrum of the light emitted from the sun, the name of the element was derived from the Greek word *hēlios*, "sun." Helium constitutes about 23 percent of the mass of the universe, but only about eight parts per 1,000,000,000 of the Earth's crust; ordinary air contains about five parts per 1,000,000 of helium.

The nucleus of every helium atom contains two protons (that is, the atomic number of helium is two) but, as is the case with all elements, isotopes of helium exist. (Isotopes are different forms of the same element that vary in the number of neutrons present in the nuclei of their atoms.) The known isotopes of helium contain from one to six neutrons, so their mass numbers (the sums of the numbers of protons and neutrons) range from three to eight. Of these six isotopes, only the two having mass numbers of three (helium-3, symbolized ^{3}He) and four (helium-4, ^{4}He) are stable; all the others are radioactive, decaying very rapidly into other substances. Helium-4 is by far the more plentiful of the stable isotopes: helium-4 atoms outnumber those of helium-3 about 700,000 to one in atmospheric helium and about 7,000,000 to one in certain helium-bearing minerals.

Most of the helium of commerce is derived from natural gas produced in the southwestern United States. The helium, which comprises between 1.5 and 7 percent of the gas, is separated by continuous processes involving several steps. A portion of the helium market is supplied from plants that liquefy air on a large scale; the

amount of helium obtainable from 1,000 tons of air is about 1.3 pounds (about 112 cubic feet, measured at room temperature and atmospheric pressure).

Liquid and solid helium

The boiling and freezing points of helium are lower than those of any other known substance. Helium is the only element that cannot be solidified by sufficient cooling at normal atmospheric pressure; it is necessary to apply pressure of 25 atmospheres at a temperature of 1° K (−272.15° C, −457.9° F) to convert it to its solid form.

The isotope helium-4 is unique in having two liquid forms. The form designated I exists at temperatures from its boiling point of 4.21° K down to 2.18° K (−270.97° C, −455.75° F); form II exists at still lower temperatures. Liquid helium II exhibits the property called superfluidity: its viscosity, or resistance to flow, is so low that it has not been measured. This liquid spreads in a thin film over the surface of any substance it touches, and this film flows without friction even against the force of gravity.

A liquid mixture of the two isotopes helium-3 and helium-4 separates at temperatures below about 0.8° K into two layers. One layer is practically pure helium-3; the other is mostly helium-4, but retains about 6 percent helium-3 even at the lowest temperatures achieved. Dissolving helium-3 in helium-4 is accompanied by a cooling effect that has been utilized in the construction of cryostats (devices for production of very low temperatures) that can attain—and maintain for periods of days—temperatures as low as 0.01° K.

Neon. Neon, the name of which is derived from the Greek word *neos*, "new," is present in some minerals, but its only commercial source is the atmosphere, of which it comprises 18 parts per 1,000,000 by volume. Because its boiling point is −246° C (−411° F), neon remains, along with helium and hydrogen, in the small fraction of air that resists liquefaction upon cooling to −196° C (−321° F). Neon is isolated from this cold, gaseous mixture by bringing it into contact with activated charcoal, which adsorbs the neon and hydrogen; removal of hydrogen is effected by adding enough oxygen to convert it all to water, which, along with any surplus oxygen, condenses upon cooling.

Neon was the first element shown to consist of more than one stable isotope. In 1913 application of the technique of mass spectrometry (*q.v.*) revealed the existence of neon-20 and neon-22, which comprise 90.92 and 8.82 percent, respectively, of the naturally occurring mixture. The third stable isotope, neon-21, which makes up 0.26 percent of natural neon, was detected later. Five radioactive isotopes of neon also have been identified.

Argon. The first of the noble gases to be discovered, argon was named from the Greek word *argos*, "lazy," because of its chemical inertness. In cosmic abundance, argon ranks approximately 12th among the 100-odd chemical elements; although the stable isotopes argon-36 and argon-38 make up all but a trace of this element in the universe, the third stable isotope, argon-40, comprises 99.60 percent of the argon found on Earth. The terrestrial preponderance of argon-40 presumably arose from the formation of this isotope by the radioactive decay of potassium-40.

Argon is the most plentiful of the noble gases on Earth, comprising 0.934 percent by volume, or 1.288 percent by weight, of the atmosphere. The element is obtained from air by liquefaction and fractional distillation; although the boiling points of argon, oxygen, and nitrogen all lie within a few degrees of each other, efficient processing provides each gas in a purity of more than 99.9 percent.

Krypton. Krypton is named from the Greek word *kryptos*, "hidden." Traces of krypton are present in minerals and meteorites, but the usual commercial source is the atmosphere, which contains 1.14 parts per 10^6 by volume. Krypton also is formed by the nuclear fission of uranium triggered by slow neutrons: this source may be expected to become increasingly important because of the growing number of fission-power plants. Krypton has isotopes of every mass number from 74 through 95; six, with mass numbers 78, 80, 82, 83, 84, and 86, are stable. After it has been stored a few days, krypton obtained by nuclear fission contains only one radioactive isotope, krypton-85, which has a half-life of about 10 years, because all the other radioactive isotopes have half-lives of three hours or less. (The half-life is the length of time during which one-half of any original amount of an unstable substance decays.)

Because its boiling point is about 30° C higher than those of the major constituents of air, krypton is readily separated from liquid air by fractional distillation; it accumulates along with xenon in the least volatile portion. These two gases are further purified by adsorption onto silica gel, redistillation, and passage over hot titanium metal, which removes all impurities except other noble gases.

Krypton is the lightest of the noble gases that has been converted into chemical compounds (see below *Compounds of the individual noble gases: Krypton*).

Xenon. The name xenon is derived from the Greek word *xenos*, "strange" or "foreign." Like several other noble gases, xenon is present in meteorites and certain minerals, but its only useful source has been the atmosphere, of which it composes 86 parts per 10^9 by volume. Nuclear reactors may become an important source of xenon, because the fission of uranium produces several isotopes of xenon.

The mass numbers of the known isotopes of xenon range from 118 to 144; nine of these numbers correspond to stable isotopes. The xenon isotopes produced in the greatest amount by nuclear fission are xenon-131, -132, -134, and -136, which are stable, and xenon-133, which is radioactive, having a half-life of 9.2 hours.

Xenon is the least volatile of the noble gases obtainable from the air. Its purification has been mentioned above (see *Krypton*). Numerous compounds of xenon have been prepared since the discovery of the noble-gas compounds in 1962 (see below *Compounds of the individual noble gases: Xenon*). Although xenon itself is an unusually safe anesthetic, its compounds appear to be toxic.

Radon. Radon was originally called radium emanation: it is the radioactive gas formed, along with helium, as radium decays. The term radon sometimes has been restricted to the isotope of mass 222, other isotopes being referred to as thoron (symbolized Tn, now called radon-220), formed from thorium; and actinon (An, now radon-219), formed from actinium. The name emanation, symbolized Em, has been used to denote the entire family now recognized as radon isotopes. Radon has no stable isotope; radioactive isotopes having masses ranging from 204 through 224 have been identified, the longest-lived of these being radon-222, which has a half-life of 3.82 days. All the radon isotopes undergo radioactive decay, the stable end-products being helium and isotopes of heavy metals, in most cases lead.

COMPOUNDS OF THE NOBLE GASES

General considerations. In the combination of atoms to form chemical compounds, the atoms become bound together by forces arising from changes in the arrangements of their outermost electrons. In simplified terms, the outright transfer of electrons from one atom to another creates oppositely charged particles (ions) that attract one another to form ionic, or electrovalent, compounds. If, instead, the electrons are shared by the atoms, the bond is called covalent, one covalent bond involving a pair of electrons. In actuality, there exists a practically continuous gradation between these two extreme types, because even in compounds called ionic, certain aspects of their behaviour suggest a small degree of electron sharing, and in covalent compounds, inequality in the electron affinities of the bonded atoms causes the electron distribution to be more or less unsymmetrical, giving the effect of partial electrical charges on the bonded atoms.

Ionic and covalent compounds

The first known compounds of the noble gases were discovered in 1962 and, although none of them yet has found commercial application, they have attracted much

attention as representatives of a class of substances previously thought incapable of existence. In much of their chemical behaviour the noble gases closely resemble their neighbours in the periodic table, the halogens, but because the gain or loss of electrons would disrupt the stable configuration of the outermost shell of a noble-gas atom, these elements conform most closely to covalent, rather than ionic, bonding patterns.

By the early 1970s only the heavier noble-gas elements krypton, xenon, and radon were known to form any compounds at all. Even in these compounds, only the most electronegative atoms or groups of atoms are capable of bonding to the noble-gas atoms. These binding units, often called ligands, include fluorine, oxygen, and combinations of oxygen with sulfur, fluorine, tellurium, or chlorine. In their compounds, the noble-gas atoms display a variety of bonding arrangements depending on the number of valence electrons that become involved in the bond-forming process. These numbers of electrons often are referred to as oxidation numbers and are specified by roman numerals in the names of the compounds; thus, in xenon(VI) fluoride (xenon hexafluoride) six electrons of the xenon atom participate in bond formation. The established oxidation states of the noble-gas elements harmonize with the pattern shown by other nontransition elements; *i.e.*, those in the a-groups (see figure, Groups Ia, IIa, etc.). According to this pattern, any element prefers those oxidation states that are numerically equal to the number of its periodic group or that number less two, four, or six. Assignment of VIIIa as the group number of the noble gases is amply justified by the existence of compounds in which xenon exhibits oxidation states of +8 (*e.g.*, xenon tetroxide), +6 (xenon hexafluoride), +4 (xenon tetrafluoride), and +2 (xenon difluoride).

Oxidation numbers

Each of the five elements preceding xenon in the fifth period of the table forms a fluoride in which the element has its maximum number: indium binds three fluorine atoms; tin, four; antimony, five; tellurium, six; and iodine, seven. It might be anticipated, therefore, that xenon octafluoride could exist; actually, this compound has not been prepared, but the failure is thought to be due to the difficulty of arranging eight fluorine atoms within the necessary distance of the xenon atom, rather than to an incapability of engaging eight electrons in chemical bonding. In the fourth period of the table, ending with krypton, the fluorides of gallium, germanium, arsenic, selenium, and bromine create a pattern that indicates, correctly, that the compounds of krypton are likely to be less stable than those of xenon.

Stability of noble-gas compounds. The stabilities of the noble-gas compounds are best expressed in terms of the energies required to break the bonds present, forming either ions or neutral atoms. Generally, across each period of the periodic table, the mean bond energy (the amount of energy needed to break all the bonds divided by the number of bonds) of fluorides decreases from Group IVa to Group VIIIa; *i.e.*, the fluorides of the noble gases are the least stable. Thus, for the xenon period, the bond energies per ligand decrease from tin to iodine, indicating a relatively low value for the bond energies in xenon octafluoride, a compound that has resisted all attempts to prepare it. A similar extrapolation in the same series for the +6 oxidation state, however, predicts that xenon hexafluoride should be a stable compound, as it is. In the krypton period, the figures correctly predict low bond energies for all the krypton fluorides. Similarly, it is evident that the bond energies of argon fluorides will be less than those of krypton fluorides. It seems unlikely, therefore, that argon compounds can be prepared.

The noble-gas fluorides are oxidizing agents of extraordinary power. This property is consistent with the value of the enthalpy of atomization (a measure of the energy change in a chemical reaction that breaks up a molecule into its component atoms) of the krypton difluoride molecule, which is only two-thirds that of the diatomic fluorine molecule itself (fluorine being the strongest oxidizing agent of all the elements).

The noble-gas compounds (those of xenon, in particular) may eventually prove to be useful reagents, because the by-product of their reactions is always a noble gas, a relatively inert substance. The noble-gas fluorides are, therefore, much less likely to yield unwanted products than are the halogen fluorides long employed in the preparation of metal fluorides and in the fluorination of aromatic compounds, because the halogens liberated in the use of the halogen fluorides are themselves very active and therefore apt to bring about undesired reactions. Xenon difluoride already has proved to be useful in fluorinating aromatic hydrocarbons, and it is a powerful oxidizer in aqueous alkali.

Noble-gas compounds as reagents

Bond structures in noble-gas compounds. The close relationship of noble-gas compounds to compounds of the elements of Groups VIIa and VIa, as indicated by the bond-energy data, also is shown by the structural similarities of the molecules.

Because each of the noble-gas cations has the name electron arrangement as its neighbouring halogen atom, it is to be expected that the cations consisting of single atoms of fluorine and noble gas—for example, the xenon monofluoride cation (formula XeF^+) and the krypton monofluoride cation (KrF^+)—would each show a close relationship to the corresponding halogen monofluoride molecule. This is so for iodine monofluoride (IF) and the xenon monofluoride ion, as shown by various measurements made of the structures.

The chemical bonding should be similar in these related species, and it is appropriate to represent the bonding in terms of a classical electron-pair bond, each element achieving an octet configuration. The bonding of two fluorine atoms to a neutral noble-gas atom, as in the generation of compounds of xenon and krypton, should be very similar to the bonding of two fluorine atoms to a halogen monofluoride.

Theories of bonding in noble-gas compounds. Since 1913, when Bohr proposed the existence in atoms of shells occupied by particular numbers of electrons, considerable advances have been made in understanding how energy states of atoms are related to the distribution of electrons in these shells and how the electronic structures of atoms account for the patterns expressed by the periodic table of the chemical elements. It has been impossible to provide exact mathematical descriptions of these energy states—because there is no way to evaluate all the interactions among the electrons and between them and the nucleus—but methods have been developed that make it possible to estimate, with a fair degree of accuracy, many of the observable properties of atoms, such as their absorption of light.

The union of two or more atoms to form a stable molecule is possible only because the energy of the combination is less than the sum of the energies of the separated atoms. Calculation of energies of molecules poses an even more formidable problem than does the calculation of atomic energies; comparison of estimates with observed properties also is more difficult, because the behaviour of molecules—for example, their absorption of light—is much more complex. Two widely used methods of estimating molecular energies, called the molecular-orbital theory and the valence-bond theory, may be regarded as attempts to relate the electronic energy levels of molecules to those of the atoms making them up. The two techniques differ in detail, and although they yield similar results when applied to certain molecules, they lead to divergent predictions in other cases.

Calculation of molecular energies

One of the theories embodies the viewpoint that covalent bond formation represents the presence of electrons in new energy states common to both bonded atoms. Bonding of atoms that do not have electrons in such energy levels in their ground states requires excitation, or promotion, of valence electrons into suitable states. For the molecule to be stable, the energy decrease resulting from bonding must more than offset the excitation energy; in the case of noble-gas compounds, a controversy has arisen over the validity of this approach because the excitation energies appear to be too large to be balanced by bonding.

Compounds of the individual noble gases. *Helium.* The great difficulty of removing an electron from an atom of helium to form a helium ion is a clear indication of the chemical inertness of the element. In the gaseous state, however, ions represented by the formula HeR^+ (*R* being another atom or group) are well known. The helium atom has an affinity for the hydrogen ion, or proton (H^+), and the chemical bonding in the positive ion formed (HeH^+) is presumably similar to that between hydrogen atoms in molecular hydrogen (H_2). It is unlikely, however, that this ion or its relatives can be stabilized enough to exist in the solid state.

Neon. As would be expected from the high ionization potential of neon, compounds of the element are unknown. Ions, such as Ne_2^+ and NeH^+, may be generated in electrical discharges, but salts incorporating these ions have not been prepared.

Argon. The outer (valence) electrons of argon are tightly bound, and it has not been possible to prepare chemical compounds of this element. The argon fluoride ion (ArF^+) has the same electron arrangement as the compound chlorine fluoride (ClF); its electron affinity, however, may be so high that it will be hard to find a suitable ion partner for salt formation. Numerous gaseous positive ions of argon have been observed by mass spectroscopy.

A number of clathrates of argon are known. One, a hydrate, is composed of eight argon atoms and 46 water molecules; clathrates with organic compounds include several formulated $Or{\cdot}2Ar{\cdot}17H_2O$, in which the symbol *Or* represents acetone, methylene chloride, chloroform, or carbon tetrachloride.

Krypton. In its known chemical behaviour, krypton exhibits only the oxidation state +2, which appears in the compound krypton difluoride (KrF_2) and its derivatives. Because of the ease with which it gives up fluorine atoms, krypton difluoride is the most powerful oxidative fluorinator known. It is a colourless solid, decomposing at room temperature; the compound interacts with water to produce krypton gas, oxygen, and hydrogen fluoride. Krypton clathrates include a hydrate consisting of eight krypton atoms and 46 water molecules.

Xenon. Compounds have been prepared in which xenon has the oxidation states +2, +4, +6, and +8; these substances represent the greatest range of oxidation states and the largest variety of compounds known for any of the noble gases.

The xenon atoms with oxidation state +2 forms the stable difluoride and its derivatives, as well as an unstable dichloride. Xenon monoxide has not yet been prepared.

The only compound of xenon with oxidation state +4 that is available in appreciable quantities is xenon tetrafluoride; xenon tetrachloride is stable only at extremely low temperatures. The fluorine ligands of the tetrafluoride may be successively replaced by other highly electronegative ligands, leading to a series of compounds with the general formula $XeF_{4-n}L_n$, in which *L* represents the ligand and *n* is an integer from one to four. The ready spontaneous conversion of xenon(IV) compounds, in part to xenon(VI) compounds and in part to the free element, a reaction known as disproportionation, parallels the more familiar example of the iodine-containing ion, hypoiodite.

The xenon atom with an oxidation state of +6 is present in xenon hexafluoride, xenon trioxide, and several derivatives of these compounds. Interaction of xenon hexafluoride with oxides produces, initially, xenon oxide tetrafluoride. Xenon dioxide difluoride may be prepared from the interaction of xenon trioxide and xenon hexafluoride. Xenon oxide tetrafluoride and xenon dioxide difluoride are colourless, somewhat volatile solids. Xenon trioxide, also colourless, is readily soluble in water and is a powerful explosive. Successive replacement of the fluorine atoms in xenon hexafluoride by other ligands leads to a series of compounds formulated $XeF_{6-n}L_n$. The pair of nonbonding valence electrons in these Xe(VI) compounds evidently occupies an appreciable volume of space, because the shape of the molecule of xenon hexafluoride is not that of a regular octahedron, as it would be expected to be if the six fluorine atoms were packed as closely as possible around the xenon atom. The molecular arrangements of other Xe(VI) compounds also indicate the spatial requirements of the nonbonding electron pair.

Xenon octafluoride is unknown, as mentioned previously (see above *Compounds of the individual noble gases: General considerations*). In strongly alkaline solutions, xenon hexafluoride disproportionates into gaseous xenon and xenon in the +8 oxidation state in the form of the perxenate, or xenate (VIII) ion XeO_6^{4-}. In this ion, the six oxygen atoms are located at the vertexes of a regular octahedron with the xenon atom at the centre, in contrast to the distorted arrangement of the atoms of xenon hexafluoride. The perxenate ion is present in several solid compounds, combined with metal ions such as sodium or barium; these compounds are salts of perxenic acid, H_4XeO_6, which is a relatively weak acid. The perxenate ion oxidizes water to oxygen, itself undergoing reduction to the xenate(VI) ion, $HXeO_4^-$; this process occurs slowly in alkaline solutions but almost instantaneously in acids. Despite this instability in solution, the crystalline perxenates possess considerable thermal stability, the anhydrous sodium salt being unaffected by heating to temperatures up to 360° C.

Perxenate ion

Xenon tetroxide may be prepared from anhydrous perxenates; great care must be taken in the preparation because the tetroxide is even more unstable than the explosive trioxide.

Radon. Radon interacts spontaneously with fluorine and with any of the interhalogen fluorides except iodine pentafluoride to form a colourless fluoride that is considered to be (by analogy with the similar behaviour of xenon difluoride) radon difluoride. Radon fluoride may be an ionic compound; it decomposes without vaporizing at temperatures above 250° C. No complex compounds, oxides, or chlorides of radon have yet been reported, probably because the high radioactivity and short life of radon make research upon it very difficult. Several clathrates of radon, including a hydrate, have been described.

Nordrhein-Westfalen

Nordrhein-Westfalen (North Rhine-Westphalia) is a state, or *Land,* of the Federal Republic of Germany and plays a leading role in the national economy. The Rhine–Ruhr area—the nation's most important industrial area—runs through the centre of the state and dominates it economically and culturally. It is one of the most heavily populated areas of the world, and its rich natural resources support a wide variety of burgeoning industries. Outside of this complex, the state exhibits a contrasting character of rural charm grounded in the German past. It covers an area of 13,144 square miles (34,044 square kilometres) and is located in the west central section of the country. The state is bordered by The Netherlands and Belgium on the west and the states of Niedersachsen (Lower Saxony) on the north, Hessen on the east, and Rheinland-Pfalz on the south. The state capital is at Düsseldorf, and Bonn is the national capital. With a population of nearly 17,000,000 inhabitants, it is the most populous state of West Germany, containing almost 30 percent of the national total.

The landscape. *Relief.* The state includes the upland regions of North Eifel in the south and the mountains of

the Sauerland in the southeast. Their plateaus—cut sharply by valleys—cover layers of schist, graywacke (dark gray rock composed of fine particles), and sandstone. The areas composed of limestone are pocked with caves and crevices, and volcanic rock occurs in the region of the Siebengebirge (the Seven Hills) on the eastern bank of the Rhine River. In the east, the Weserbergland—the mountainous region bordering the Weser River—is composed of layers of limestone, clay, and sandstone and is characterized by several escarpments and by the narrow, elongated ridges of the Wiehengebirge (Wiehen Mountains), the Teutoburger Wald, and the Eggegebirge (Egge Mountains).

Mountains and lowlands

The northwest is composed of lowlands that gradually merge with the upland regions. The region of the lower Rhine consists of terraced surfaces of gravel, sand, and loam and some hills formed by glacial activity. In the south, the lowlands extend in a baylike formation covered with loess (a brownish mixture of fine particles deposited by the wind) to the vicinity of Bonn, and, in the east, the Westphalian extension, or bay, with bowl-shaped layers of limestone, marl, and sand, partly covered by glacial formations, pushes forward between the Weserbergland and the Sauerland. Fertile areas of loess are also found along the southern border of the Westphalian bay around the Hellweg.

Drainage. The Rhine River drains the largest physical region of the state. Areas bordering on the west are drained by the Maas River, on the north by the Ems, and on the northeast by the Weser. Ultimately, the drainage system leads to the North Sea.

Climate. The climate of the area is influenced by the proximity of the North Sea to the Gulf Stream. The lowland zones are mild in the winter, with mean January temperatures of about 34° F (1° C), while July temperatures average about 63° F (17° C). Precipitation is often less than 30 inches in the Rhine Valley. The mountainous regions, however, are cool and receive high precipitation. On Kahler Asten Berg, in the Sauerland, the average winter temperature does not rise above 32° F (0° C), and the average temperature in July barely reaches 55° F (13° C). The annual precipitation exceeds 55 inches, and for more than 110 days of the year Kahler Asten Berg is covered with snow.

Vegetation and animal life. Forests predominate in the higher mountain regions, where the ancient beechwoods have been replaced by pines. In the lowlands, large forests are generally found only in barren, sandy areas. In parts of the Westphalian bay extensive moorlands are maintained as small nature reserves or protected areas. Red deer and wild boars are found in the larger forested regions, and roe deer are widespread. Wild horses still live in the Westphalian bay. The largest bodies of water —Altwässer Reservoir and Staubecken (a pond)— are renowned for their numerous types of birds, including thousands of migratory or hibernating ducks and geese.

Settlement patterns. The settlement pattern of the state reflects the influence of both physical features and historical development. The principalities that existed until about 1800 and played an important role in commercial development are recalled by the regional names of Bergisches Land (the Duchy of Berg), Märkisches and Kurkölnisches Sauerland (the Mark and the Cologne Archbishopric-Electorate of Sauerland), and Münsterland (the princely bishopric of Münster). In the former religious territories—especially in the Kurkölnisches Sauerland and in the princely bishoprics of Münster and Paderborn—economic development was slow and quiet, and large areas still possess a predominantly rural character. In Westphalia, many of the great farmhouses have been preserved, with their large gates at the gabled front and the stables along both sides of the long halls. In the Münsterland, the widely scattered or loosely grouped farms are surrounded by oak groves, forest plots, and hedges, giving the impression of a landscaped park. Along the lower Rhine, the architectural form known as the T-house is found, the barn area is opened from the gable front, and the dwelling area is erected across like a crossbar. The Frankish farm—with buildings grouped at right angles around a courtyard—predominates in the southern section of the Rhine lowlands.

Historic development

Industrial development, particularly in the case of the iron and metal industries, centred in the mountains, as it was dependent upon the existence of ore, the production of charcoal, and the supply of water power from rivers and brooks. The large, industrially concentrated region of the Rhine–Ruhr between Bonn and Hamm contains many large cities and metropolitan areas. It is one of the most densely populated regions of the world, with a population exceeding 11,000,000 inhabitants by the early 1970s. In addition, there are smaller urban areas around Aachen, Münster, Bielefeld, and Siegen.

The people. *Cultural identities.* The Rhineland–Westfalen boundary—running through the state from northwest to southeast—corresponds to the old border between the Saxons and the Franks and is reflected in certain dialectical variations. The language differences involve the conjugation of verbs and the shifting of sounds in many words.

During the Reformation, the principalities in the Nordrhein-Westfalen area were divided between Roman Catholicism and Protestantism. These differences still exist, and the regional predominance of one religion over the other still exists in many areas. More than half of the total state population is Roman Catholic, but local dominance of either religion often claims more than 75 percent of a region's inhabitants.

These cultural differences are strongest in the rural areas. In the urban centres, social displacement and the mixture of peoples has dissipated the strength of original cultural identifications. Since 1870 the heavy immigration of East Germans and Poles—as well as Italians, Turks, Greeks, Yugoslavs, and the Dutch—has created a more cosmopolitan atmosphere in the cities. Most of the cultural mingling has occurred in the Rhine–Ruhr area where almost two dozen major cities are located (*e.g.*, Cologne, Essen, Düsseldorf, Dortmund, and Duisburg).

Demography. The average population density of the state is about 1,300 persons per square mile. Densities are highest in the urban Ruhr region, where they reach over 9,000 inhabitants per square mile. In the agrarian areas, however, densities range between 400 and 650 persons per square mile, while the heavily forested mountains support only 200 to 250 persons per square mile. Immediately after World War II, population increase was largely the result of immigration, but this trend decreased after 1960. The excess of births of less than one percent during the 1960s has also decreased.

The economy. *Agriculture and forestry.* Almost two-thirds of the state's total land area are utilized for commerical farms, gardens, or orchards. The most important fertile regions are located in the southern lowlands, where wheat and sugar beets are grown. In the vicinity of the Rhine near Bonn, Cologne, and Düsseldorf, fruits and vegetables are cultivated, while in Münsterland and in the regions of the lower Rhine cattle raising and pig breeding play considerable roles. The most important regions engaged in forestry are the montane spruce-forest and the lowland pine-forest areas.

The total forested area of 3,100 square miles represents 24 percent of the state's total land area. Agriculture and forestry together earn about 3 percent of the gross domestic product.

Mining and industry. The state is the most significant mining and energy-producing area of West Germany. Bituminous coal deposits are located in the regions of the Ruhr and Aachen, and lignite is mined west of Cologne. In the late 1960s, 100,000,000 tons of bituminous coal and about 90,000,000 tons of lignite were mined annually, representing almost 90 percent of national production. Petroleum refineries—connected with the North Sea ports of Wilhelmshaven and Rotterdam by a system of pipelines—are concentrated in the region of the Ruhr and on the Rhine. The water supply necessary to heavy industry and urban concentration is maintained by almost 60 dams, located mainly in the mountains of the Sauerland, the Bergisches Land, and in the north Eifel region.

Coal, oil, and water

Industrial, mining, and energy production comprise

over half of the state's gross domestic product. On the basis of coke production, blast furnaces, steel mills, and rolling mills have developed in the Ruhr region, mainly in Duisburg and Dortmund. Raw steel production exceeds 30,000,000 tons annually, amounting to more than 70 percent of national production. In the territories of the Berg-Mark bordering on the south, the iron and metalware industries and textiles play a leading role. The textile industry is also extensive around Krefeld, Mönchengladbach, and in northwestern Münsterland. Leverkusen, Marl, and a few locations along the Rhine are noted for their chemical industry, and the area of Lippe is well-known for its wood and furniture industries. The areas around Düsseldorf, Cologne, Aachen, and Bielefeld have a highly diversified industrial structure.

Services. The service industry produces about 45 percent of the state's gross domestic product. There are many commercial enterprises, trading houses, loan societies, and banking houses. The system of municipal savings banks is extended throughout the state.

Transportation. The close-meshed transportation network meets the heavy demands of urban concentration and industrialization. In the densely settled areas of the Rhine and Ruhr rivers, a streetcar system is maintained for passenger traffic, and the most important lines of the 4,700 miles of railway track have been electrified.

There are 660 miles of federal superhighways, as well as nearly 17,700 miles of federal, provincial, and county roads. The Rhine is one of the world's most heavily travelled water routes. Together with the state's important canals, it serves primarily as a means of transport for mass-produced goods. Duisburg-Ruhrort, at the mouth of Ruhr River, is the largest inland harbour in Europe. The two largest airports of the region are located at Düsseldorf-Lohausen and Cologne-Wahn.

Administration and social conditions. *Government.* According to the state constitution of 1950, representatives to the state parliament, or Landtag, are elected by direct, secret ballot. Political activity operates within a multiparty system, and state government is formed by coalition. The *Land* is presided over by the minister-president, who appoints his cabinet. The state is divided into the six major administrative districts of Düsseldorf, Cologne, Aachen, Münster, Detmold, and Arnsberg; these are further divided into local administrative units, municipalities, and unincorporated cities. In the local districts and municipalities, the chief administrator shares responsibility with the head of the council or the mayor.

Administrative divisions

The regional leagues of the Rhineland and Westphalia-Lippe have their seats in Cologne and Münster, respectively. Specific duties—including welfare, traffic, and cultural affairs—have been transferred to them from the local administrative districts and unincorporated cities. A nonmunicipal association for the coal-mining territory of the Ruhr has its seat at Essen.

Justice. There are three superior courts of appeal, in Düsseldorf, Hamm, and Cologne; 19 provincial courts; and 160 magistrates' courts with approximately 2,700 judges. In addition to the regular courts, there are administrative courts and courts of finance, labour, and social relations.

The police. The police are under the authority of the national Ministry of the Interior. The areas of state police jurisdiction coincide with the governmental districts, while the areas of local police jurisdiction agree generally with the local administrative districts and the unincorporated cities.

Education. Free public schools for general education are divided into primary schools, or *Grundschulen;* upper primary schools, or *Hauptschulen;* advanced training schools, or *Fachoberschulen;* secondary schools, or *Realschulen;* and grammar schools, or *Gymnasien.* In addition, there are special schools for those with learning disabilities. Evening classes are available for professional people desiring to obtain a diploma for completion of grammar or secondary school studies.

The system of colleges has been greatly expanded to include universities in Bonn, Münster, Aachen, Cologne, Bochum, Düsseldorf, Dortmund, and Bielefeld. There are also several education colleges. The total college enrollment—including theological and denominational colleges—numbered about 100,000 in the early 1970s.

Health and welfare. In the late 1960s many hospitals were newly constructed or enlarged. There were about 750 hospitals, with 110 beds and six staff doctors for every 10,000 persons. Public welfare services include sickness, accident, revenue, and unemployment insurance, the funds for which are raised through premiums paid by the insured and their employers.

The standard of living index has been steadily rising since the early 1960s, and gross weekly earnings of those employed in industry had risen about 58 percent by 1969. Durable consumer goods, such as television receivers, refrigerators, and automobiles are common, but less than one-third of the population owns telephones. Multiple housing units, as opposed to single-family dwellings, are prevalent in the cities.

The common economic interests of employers in the industrial sector are represented by some 20 industrial federations and chambers of commerce. There are also eight trade associations that operate on the principle of self-administration in the same manner as the two agricultural associations.

Industrial associations

Over 2,000,000 employees are represented through labour unions that are affiliated with the German Federation of Trade Unions (Deutscher Gewerkschaftsbund); the German Federation of Office-workers (Deutsche Angestellten-Gewerkschaft) and the German Federation of Officials (Deutscher Beamtenbund) also have considerable memberships.

Cultural life and institutions. Cultural institutions, such as the theatre, orchestras, museums, and libraries are to be found in considerable numbers. An attempt was being made in the 1970s to organize them into a unified and coordinated system. There are 21 cities with municipal and state theatres, 13 private indoor theatres and studios, and from 15 to 20 summer, open-air theatres. Symphony orchestras and choirs are cultivated at the state and municipal levels, and further cultural development is promoted by the Folkwang School (Folkwangschule) in Essen and the state music conservatories in Cologne and Detmold.

Many cities possess museums noted for their excellent exhibits of the history of art and culture. There are also a number of small local museums and the national gallery for the state collection of works of art in Düsseldorf. In 1963 the Prize for Art of the State of Nordrhein-Westfalen was established as a distinction for excellence in artistic endeavours. There are state archives in Düsseldorf, Münster, Detmold, and Brühl, and the state's 75 libraries possess a total of 9,000,000 volumes.

Closer attention is being given to the maintenance and care of architectural and cultural monuments as a result of destruction during World War II. The older industrial buildings, some of them of considerable interest to industrial archaeologists, are also maintained as monuments.

There are about 100 daily newspapers with almost 250 local editions and a total circulation of approximately 4,000,000. The West German Radio in Cologne broadcasts three daily musical programs and is involved in 25 percent of the community programming on German television. It also broadcasts a regional program.

Future prospects. As a result of its highly developed industrial economy, Nordrhein-Westfalen is faced with the problems of balanced economic advance. Growing industry places a high demand on the area's natural resources, and the extraction industries must face the problems of reserve depletion. Improvement of the environment is of particular importance. Measures against air and water pollution have been enacted, and recreational facilities are being expanded. In the Ruhr region, new parks have been opened, and entertainment centres are under construction or planned. In the east, the health baths have been promoted and 13 nature parks have been established, especially in the richly forested mountains. These facilities are close to the industrial cities and are planned to promote an aesthetic as well as physical relief from urban problems. (W.v.K.)

North Africa, History of

North Africa as here used means the area of present-day Morocco, Algeria, Tunisia, and Libya. In ancient times the Greeks used the word Libya, derived from a tribal name on the Gulf of Sidra, to describe the land north of the Sahara, the territory whose native peoples were subjects of Carthage; and also the whole continent. The Romans applied the name Africa (of Phoenician origin) to their first province in the northern part of Tunisia, to the whole area north of the Sahara, and to the whole continent. The Arabic term Jazīrat al-Maghrib, meaning island of the west, applied first of all to land west of Egypt but more particularly to present-day Tunisia, Algeria, and Morocco. French scholars regularly use Maghrib in this sense, and it is so used here. The Arabs used the word Barbar (Berber), perhaps derived from the Latin *barbari*, to describe the non-Latin-speaking peoples of the Maghrib at the time of the Arab conquest, and it has been used in modern times of the non-Arabic-speaking population (French Berbères, Berbers). A frequent usage refers to the non-Phoenician and non-Roman inhabitants of classical times, and their language, as Berber. It should be stressed that the theory of a continuity of language and race between ancient inhabitants and the modern Berbers is not proved; consequently the word Libyan is used in this article of these peoples in ancient times. This article is outlined as follows:

I. Ancient North Africa

GEOGRAPHY AND PREHISTORY

The description of the area as an island refers to its isolation, bounded by the sea to the north and west, by the Sahara to the south and east. The desert has been the dominant factor in the North African environment, though it has not always been as dry as it is today. At various times during the last million years there have been periods of abundant rainfall, the last occurring about the 6th millennium BC at the beginning of the Neolithic Period (see below). A major trade route connecting the Mediterranean with the African world existed along the Hoggar-Tibesti ridge in the central Sahara, and it is probable that communications existed across the western Sahara also. Nevertheless, the Sahara always constituted a formidable barrier to the movement of techniques and peoples. In ancient historical times, much of North Africa was evergreen forest or scrub of Mediterranean type, and the fauna included animals such as the elephant, zebra, and ostrich, now extinct in the area.

The mountains were of the utmost importance in the historical development of the area. They run generally from east to west, parallel to the coast, with their highest elevations in the Atlas range. They are not continuous but constitute separate blocks, especially in the coastal areas. Although it was in the mountains that the rainfall was highest, the forest was intractable, and early settlements tended to opt for the plains and valleys between or south of the mountains. The Mediterranean coast, for much of its length, is extremely inhospitable, offering few natural harbours and still fewer natural lines of communication into the interior. Even the major rivers, such as the Majardah and Cheliff, are unnavigable. Only in northeastern Tunisia is the coastline more favourable, and it is not surprising that the main movement of culture and conquest have moved from there westward.

The coastal strip in the area of Tripoli (Ṭarābulus) in western Libya is an extension of that of Tunisia. To the east, some 800 miles of the Sirtic Desert separates it from Barqah (Cyrenaica) at the eastern end of modern Libya, which thus has had a very different history from the Maghrib. Settlement there was effectively confined to the elevated plateau of al-Jabal al-Akhḍar and did not extend more than about 70 miles south of the coast. Barqah's contact with Egypt was limited by an intervening 600 miles of semidesert.

The Maghrib provided the paradox of an area in which various cultures have imposed some measure of uniformity, while political unity has been rare; for this geography is largely responsible. The area of settlement is of vast length but little breadth and has no natural centre from which political uniformity could be imposed; its natural communications have never been easy, and the mountain blocks have been large enough to maintain populations to a greater or lesser degree independent of and hostile to those that controlled the plains.

Earliest inhabitants

Although there is uncertainty about some factors, Ain Hanech (in Algeria) is the site of one of the earliest traces of human occupation in the Maghrib. Somewhat later but better attested are sites at Ternifino and Sidi Abd er-Rahmane (both in Morocco). The former produced hand axes associated with *Atlanthropus mauretanicus*, a hominid more primitive than other Neanderthaloids of the same period. Sidi Abd er-Rahmane also produced evidence of *Atlanthropus*, with a date of 200,000 BC at least.

Succeeding these early hand-ax remains are the Levalloiso-Mousterian industries similar to those of the Levant. It is claimed that nowhere did the middle Paleolithic evolution of flake-tool techniques reach a higher state of development than in North Africa. Its high point in variety, specialization, and standard of workmanship is named Aterian, after the type site of Bir el-Ater in southern Tunisia; assemblages of this material occur all over the Maghrib and the Sahara. Radiocarbon testing from Morocco indicates a date for early Aterian material of *c.* 30,000 BC. Its spread appears to have taken place during one of the periods of desiccation, and the carriers of the tradition were clearly adept desert hunters. The few asso-

ciated human remains are Neanderthaloid, with substantial differences between those found in the west and those in Cyrenaica. In the latter area, a date of *c.* 43,000 BC for the Levalloiso-Mousterian has been obtained (at Haua Ftoah). The tools and a fragmentary human fossil of Neanderthaloid type are almost identical to those of Palestine.

The earliest blade industries of the Maghrib, associated as in Europe with the final supersession of Neanderthaloids by *Homo sapiens*, are named Oranian (type site, La Mouilla, near Oran in western Algeria), a culture of obscure origin, which seems to have spread along all the coastal areas of the Maghrib and Cyrenaica between *c.* 15,000 and 10,000 BC. Following the Oranian was the Capsian, the origin of which is also obscure. Its most characteristic sites are in the area of the great salt lakes of southern Tunisia, the type site being al-Maqṭa' (el-Mekta), near Qafṣah (Capsa). The climate during both Oranian and Capsian appears to have been relatively dry and the fauna one of open country, ideal for hunting. Between *c.* 9,000 and 5,000 BC, upper Capsian spread northward to influence the Oranian and also eastward to the Gulf of Sidra, and by the 3rd millennium BC, if not earlier, a uniform human type appears to have been established through the Maghrib. Since there is much evidence that the Neolithic culture of the Maghrib was not introduced by invasion but through the acceptance of new ideas and technologies by the Capsian peoples, it is possible that they were the ancestors of the Libyans known in historic times.

Neolithic culture

The spread of early Neolithic culture in Libya and the Maghrib occurred during the 6th and 5th millennia BC and is characterized by the domestication of animals and the shift from hunting and gathering to self-supporting food production (often still including hunting). The pastoral economy, with cattle the chief animal, remained dominant in North Africa until the classical period. Although the new type of economy may have originated in Egypt or the Sudan, the character of the flint-working tradition of the Maghribian Neolithic argues in favour of the survival of much of the earlier culture, which has been called Neolithic-of-Capsian tradition. Accordingly, the transition, if not of independent local origin, is best explained by the gradual diffusion of new techniques rather than by massive immigration of new peoples.

The Neolithic-of-Capsian tradition in the Maghrib persisted at least into the 1st millennium BC with relatively little change and development; there was no great flourishing of late Neolithic culture nor little that can be described as a Bronze Age. North Africa was wholly lacking in metallic ores other than iron, hence most tools and weapons continued to be made of stone until the introduction of ironworking techniques.

Prehistoric rock carvings flourished in the southern foothills of the Atlas south of Oran and in the Hoggar and Tibesti ranges. While some are relatively recent, the great majority appear to be of the Neolithic-of-Capsian tradition. Some show animals locally or even totally extinct, such as the giant buffalo, elephant, rhinoceros, and hippopotamus in areas now covered by desert. While Egyptian influence may be discerned, the character of the rock art is so different from that of Egypt that it can hardly be said to derive from it. On the other hand, it is very much later than the rock paintings of Paleolithic times in southwest Europe, and an independent development is not excluded. The art is primarily that of a culture that remained largely, though not exclusively, dependent on hunting and that survived on the Saharan fringes until historical times.

There are many thousands of large, stone-built surface tombs in North Africa that appear to have no connection with earlier megalithic structures found in northern Europe, and it is unlikely that any of them is earlier than the 1st millennium BC. Large structures such as the tumulus at Mzora (54 metres in diameter) and the mausoleum known as the Medracen (40 metres in diameter) are probably of the 4th and 3rd centuries BC and show Phoenician influence, though there is much that appears to be purely Libyan.

THE CARTHAGINIAN PERIOD

The Phoenician settlements. North Africa (with the exception of Cyrenaica) entered the mainstream of Mediterranean history with the arrival in the 1st millennium BC of Phoenician traders on its coast. The Phoenicians were not looking for land to settle but for anchorages and staging points on the trade route from Phoenicia to Spain, a source of silver and tin. Points on an alternative route by way of Sicily, Sardinia, and the Balearic Islands also were occupied. The Phoenicians lacked the manpower and the need to found large colonies as the Greeks did, and few of their settlements grew to any size. The sites chosen were generally offshore islands or easily defensible promontories with sheltered beaches on which ships could be drawn up. Carthage (from the Phoenician Kart-Hadasht, New City), destined to be the largest Phoenician colony and in the end an imperial power, conformed to the pattern.

Tradition dated the foundation of Gades (modern Cádiz; the earliest known Phoenician trading post in Spain) to 1110 BC, Utica (Utique) to 1101 BC, and Carthage to 814 BC. The earlier dates appear legendary, and no Phoenician object earlier than the 8th century BC has yet been found in the west. At Carthage some Greek objects have been found, datable to about 750 or slightly later, which comes within two generations of the traditional date. Little can be learned from the romantic legends about the arrival of the Phoenicians at Carthage transmitted by Greco-Roman sources. Though individual voyages doubtless took place earlier, the establishment of permanent, or at any rate seasonal, posts is unlikely to have taken place before 800 BC, but they antedate the parallel movement of Greeks to Sicily and southern Italy.

Material evidence of Phoenician occupation of 8th-century-BC date comes from Utica, and of the 7th or 6th century BC from Hadrumetum (Sūsah, Sousse), Tipasa (east of Cherchell), Siga (Rachgoun), Lixus, and Mogador, the last being the most distant Phoenician settlement so far known. Finds of parallel date have been made at Motya (Mozia) in Sicily, Nora (Nurri), Sulcis, and Tharros (Torre di S. Giovanni) in Sardinia, and Cádiz and Almuñécar in Spain. Unlike the Greek settlements, however, those of the Phoenicians long remained politically dependent on their homeland, and only a few were situated where the hinterland had the potential for development. The emergence of Carthage as an independent power, leading to the creation of an empire based on the secure possession of the North African coast, resulted less from the weakening of Tyre, the chief city of Phoenicia, by the Babylonians than from growing pressure from the Greeks in the western Mediterranean; in 580 BC some Greek cities in Sicily attempted to drive the Phoenicians from Motya and Panormus (Palermo) in the west of the island. The Carthaginians feared that if the Greeks won the whole of Sicily they would move on to Sardinia and beyond, isolating the Phoenicians in North Africa. The successful defense of Sicily was followed by attempts to strengthen limited footholds in Sardinia; a recently discovered fortress at Monte Sirai is the oldest Phoenician military building in the west. The threat from the Greeks receded when Carthage, in alliance with Etruscan cities, checked the Phoenicians off Corsica in 535 and succeeded in excluding the Greeks from contact with southern Spain. A further success occurred in Africa itself; in 514 BC a Spartan named Dorieus attempted to found a settlement at the mouth of the Cinyps River (Oued Oukirri) in Libya, but the Carthaginians, regarding this as an intrusion into their own territory, were able to expel the Spartans with the help of native Libyans.

Relations with the Greeks

Carthaginian supremacy. By the 5th century BC, active military participation by Tyre in the west had doubtless ceased; from the latter half of the 6th century it was under Persian rule. Carthage thus became the leader of the western Phoenicians, and in the 5th century formed an empire of its own, centred on North Africa, which included existing Phoenician settlements, new ones founded by Carthage itself, and a large part of modern Tunisia. The actual stages of the growth of Carthaginian power are not known, but the process was largely completed by

the beginning of the 4th century. The whole of the Cap Bon (Jazīrat Sharīk) peninsula was occupied early, ensuring Carthage a fertile and secure hinterland. Subsequently, penetration extended southwestward as far as a line running roughly from al-Kāf to the coast at Thaenae (now the ruins of Thīnah, or Tina). Penetration occurred south of this line later, Theveste (Tabassah, Tébessa) being occupied in the 3rd century BC. In the Cap Bon peninsula, where the Carthaginians developed a prosperous agriculture, the native population may have been enslaved, but elsewhere these people were obliged only to pay tribute and furnish troops.

Carthaginian settlements

Carthage maintained an iron grip on the entire coast, from the Gulf of Sidra to the Atlantic coast of Morocco, establishing many new settlements to protect its monopoly of trade. These were mostly small places, probably of only a few hundred inhabitants. The Greeks called them *emporia*, markets where native tribes brought articles to trade, which could also serve as anchorages and watering places. Permanent settlements in modern Libya were few and dated after the attempt of Dorieus to plant a Greek colony there. Though in time fishing and agriculture played a part in their wealth, Leptis with its neighbours Sabratha and Oea (Tripoli) became rich through trans-Saharan trade; Leptis was the terminus of the shortest route across the Sahara linking the Mediterranean with the Niger. A Carthaginian named Mago is said to have crossed the desert several times, but doubtless much of the trade (in precious stones) came through intermediate tribes. Other stations on the Gulf of Gabes included Zouchis, known for its salted fish and purple dye, Gigthis (Bū Ghirārah), and Tacapae (Qābis, Gabes). North of Thaenae was Acholla, traditionally an offshoot of the Phoenician settlement on Malta, Thapsus (Rass Dimas), Leptis Minor, and Hadrumetum, the largest city on the east coast of Tunisia. From Neapolis (Nabeul), a road ran direct to Carthage across the base of the Cap Bon peninsula.

West of Carthage there have been changes in the course of the Bagradas (Majardah) River; as a result, Utica, a port in Carthaginian and Roman times, is now some seven miles from the sea. Utica was second only to Carthage in importance among the Phoenician settlements and always maintained at least a nominal independence. Beyond Cape Farina (Ra's Sīdī ʿAlī al-Makkī) as far as the Straits of Gibraltar, the coast offered a number of anchorages, but few of the stations reached anything like the prosperity of those on the Gulf of Gabes and the east coast of Tunisia. One of the more important was Hippo Diarrhytos (Banzart, Bizerte), whose natural advantages as a port were utilized at an early date; another Hippo, later called Hippo Regius (Bône), was also probably of Carthaginian origin. Along the same stretch of coast were Rusicade (Philippeville, Skikda) and Collo (Chullu). Still farther west, a number of place-names known from the Roman period betray an earlier Phoenician interest through the incorporation of a Phoenician element, *rus*, meaning "cape"; *e.g.*, Rusuccuru (Dellys) and Rusguniae (Matifou). Tingi (Tangier) was already settled in the 5th century BC.

Trade. Ancient sources agree that Carthage had become perhaps the richest city in the world through its trade, yet very few traces of its wealth have been discovered by archaeologists. This is no doubt because most of it was in perishables—textiles, unworked metal, foodstuffs, and slaves; its trade in manufactured goods was only a small part of the whole. There can be no doubt that the most profitable trade was that inherited from the Phoenicians in the western Mediterranean, in which tin, silver, gold, and iron were obtained in exchange for manufactures and consumer goods of small value. Carthage ruthlessly maintained its monopoly of this trade from the late 6th to the end of the 3rd century BC by sinking intruders and exacting recognition of its position from other states. Its wealth is attested by the vast mercenary armies it was able to raise and the mintage of gold coins in the 4th century far in excess of that known for other advanced states.

It was apparently in connection with this trade that during the 5th century there occurred two voyages of exploration and trade, evidently of particular importance since reports of them were known to later generations of Greeks and Romans. One was along the Atlantic coast of Morocco, the other northward along the Atlantic coast of Spain. They were led by Hanno and Himilco, respectively, both members of a leading family in Carthage. Hanno's voyage is generally associated with an account in Herodotus, writing about 430 BC, of Carthaginian trade on the Atlantic coast of Morocco. Herodotus describes a system of dumb barter with primitive peoples, by which the Carthaginians exchanged manufactured goods for gold. It is not known where the exchanges took place; the Río de Oro is a possibility, and it is probable that Hanno's expedition went beyond Cape Verde. Nevertheless, the "gold route" did not survive the fall of Carthage and was unknown to the Romans. This has led some scholars to argue that the Carthaginians' interest in the Atlantic coast of Morocco was stimulated by the more prosaic attraction of the abundant fish.

Voyages of exploration

Himilco's voyage also was known to the Greeks and Romans. He sailed north along the Atlantic coast of Spain, Portugal, and France and reached the territory of the Oestrymnides, a tribe living in Brittany. The purpose of this voyage was apparently to consolidate control of the trade in tin along the Atlantic coast of Europe. It followed the route used by the Tartessians, a people of southern Spain in the area where Cádiz had been founded, who knew of Ireland and Britain. This trade was no doubt the latest phase of contact between the various areas of the Atlantic seaboard that went back to Late Neolithic times. There is no evidence that Himilco reached Britain, nor indeed has any Phoenician object ever been found in the island, but probably Cornish tin was obtained through the tribes of Brittany. Tin was also obtained from northwestern Spain. It is notable that, at Cádiz, the Carthaginian tombs found at intervals over the past century have produced nothing earlier than the 5th century, which would indicate that it was not until that date that it became a large and permanent base for the exploitation of trading opportunities in the west.

Trading contacts with the Greek world had been substantial from the earliest period of Phoenician colonization, in spite of the intermittent wars with the Greeks of Sicily. Pottery from Corinth, Athens, Ionia, Rhodes, and other Greek centres has been found at Carthage, Utica, and many other sites, as well as imports from Phoenicia itself and from Egypt. It is known that Selinus, a Greek city in Sicily, grew wealthy from trade with Carthage, probably in foodstuffs, before Carthage conquered the neighbouring hinterland. During the 5th century there appears to have been a decline in imports from the Greek world. One factor that inhibited trade was the lack of a Carthaginian coinage before the early 4th century, though most important Greek states had had their own coinages for at least a century before that. Carthaginian merchants, however, did not cease to frequent Greek ports, and a number of them were established at Syracuse in 398. From that date, economic contacts with advanced states seem to have revived, especially after the conquests of Alexander the Great in the eastern Mediterranean created a new market for the cheap Carthaginian manufactured goods. The Carthaginian merchant became such a familiar figure in such economic centres of the Greek world as Athens and Delos that there were Greek comedies in which the central figure was the Carthaginian trader.

Revival of Economic Contacts

Wars outside Africa. Except in backward or thinly populated areas Carthage's foreign policy was nonexpansive. One major departure was a disaster: in 480 Carthage intervened in intercity struggles among the Greeks of Sicily and suffered a heavy defeat at Himera. After a long period of peace, it went in 410 to the help of Segesta, an ally in Sicily, and turned the war into one of revenge for the earlier defeat. After initial successes, including the destruction of Himera, a treaty confirmed Carthage's control of the west of the island. During the 4th century most of the wars were caused by the attempts of various rulers of Syracuse to drive the Carthaginians out of Sicily; three of these (398–392, 382–375, and 368) were with

Dionysius I of Syracuse. Most of the time the eastern limit of Carthaginian power in the island was recognized as the Halycus (Platani) River. The only occasion in which Carthage suffered directly (since its armies were largely mercenary) was in 310, when the ruler of Syracuse, Agathocles, under heavy pressure in Sicily, launched a daring invasion of Africa, the first experienced by Carthage. Over a period of three years he caused great devastation in Carthaginian territory in eastern Tunisia but in the end was defeated.

Treatment of subject peoples. Carthage was notorious in antiquity for oppressing and exacting excessive tribute from its subjects. There were, however, different categories of subject community, the most favoured being the original Phoenician settlements and the colonies of Carthage itself. There is little evidence of opposition among them to Carthaginian control. Similar institutions and laws may be attributed to a common cultural background rather than to an attempt to impose uniformity. Carthage exacted dues on imports and exports and levied troops and probably sailors. Carthaginian subjects of various nationalities in Sicily also received favourable treatment, at least in economic matters. Relatively free trade was allowed until the end of the 5th century, and a number of cities had their own coinage. In the 4th century, some Sicilian Greek states became subject to Carthage, paying a tribute amounting apparently to one-tenth of their produce. It was the Libyans of the interior who suffered most, though few were reduced to slavery. During the First Punic War, Libyans had to pay one-half of their crops as tribute, and it is supposed that the normal exaction was a quarter, a burdensome imposition. They were also required to provide troops, and from the early 4th century they formed the largest single element in the Carthaginian army; it is unlikely that they received pay except in booty before the Punic Wars. The Carthaginians are said to have "admired not those governors who treated their subjects with moderation but those who exacted the greatest amount of supplies and treated the inhabitants most ruthlessly." This judgment (by the Greek historian Polybius) was made in connection with the Libyans, and a destructive revolt—one of a number known—that followed the first Punic War. In this revolt (241–237 BC), mercenaries, unpaid after the Carthaginian defeat in the First Punic War, revolted and for a while controlled much of Carthage's North African territory. It was fought with great atrocities on both sides, and the Libyans were among the most fervent of the rebels. They even issued coins on which the name Libyan appears (in Greek), which probably indicates a growing ethnic consciousness. Notwithstanding this relationship, Carthaginian civilization had profound effects on the material culture of the Libyans (see below).

Political and military institutions. Hereditary kingship prevailed in Phoenicia down to Hellenistic times, and Greek and Roman sources refer to kingship at Carthage. It appears not to have been hereditary but elective, though in practice one family, the Magonid, dominated in the 6th century. The power of the kingship was diminished during the 5th century, a development that has its parallels in the political evolution of Greek city-states and of Rome. Roman sources directly transcribe only one Carthaginian political term—*sufet*, etymologically the same as the Hebrew *shofet*, generally translated "judge" in the Old Testament but implying much more than merely judicial functions. At some stage, probably in the 4th century, the *sufets* became the chief magistrates of Carthage and other western Phoenician settlements. Two *sufets* were elected annually by the citizen body, but all were from the wealthy classes. The chief power rested with an oligarchy of the wealthiest citizens, who were life members of a council of state and decided all important matters unless there was serious disagreement with the *sufets*. A panel of judges chosen from among its members had obscure but formidable powers of control over all organs of government.

Carthaginian magistrates

During the 6th and 5th centuries, most military commands were held by kings, but later the generalship was apparently dissociated from civil office. Even in the time of the kings, military authority appears to have been conferred upon the kings only for specific campaigns or in emergencies. The generals are said to have been regarded as potential overthrowers of the legal government, but in fact there is no record of any army commander's having attempted a coup d'etat.

Up to the 6th century, the armies of Carthage were apparently citizen levies similar to those of all city-states of the early classical period. But Carthage was too small to provide for the defense of widely scattered settlements, and it turned increasingly to mercenaries, officered by Carthaginians, with citizen contingents appearing only occasionally. Libyans were considered particularly suitable for light infantry, Numidians and Mauretanians for light cavalry; Iberians and Celtiberians from Spain were used in both capacities. In the 4th century the Carthaginians also hired Gauls, Campanians, and even Greeks. The disadvantages of mercenary armies were more than outweighed by the fact that Carthage could never have stood the losses incurred in a whole series of wars in Sicily and elsewhere. Very little is known about the manning of the Carthaginian fleet; technically, it was not overwhelmingly superior to those of the Greeks, but it was larger and had the benefit of experienced sailors from Carthage's maritime settlements.

The city. The Romans completely destroyed Carthage in 146 BC, and a century later built a new city on the site, so that little is known of the physical appearance of the Phoenician city. It is almost certain that the ancient artificial harbour—the Cothon—is represented today by two lagoons north of the bay of al-Karm (el-Kram). In antiquity it had two parts, the outer rectangular part being for merchant shipping, the interior, circular division being reserved for warships; sheds and quays were available for 220 warships. Its small size probably means that it was chiefly used in winter when navigation almost ceased. The city walls were of great strength and 22 miles in length; the most dangerous section, across the isthmus, was over 40 feet high and 30 feet thick. The citadel on the hill called Byrsa was also fortified. Between Byrsa and the port was the heart of the city, its marketplace, council house, and temples. In appearance it may have been not dissimilar to towns in the eastern Mediterranean or Persian Gulf before the impact of modern civilization, with narrow winding streets and houses up to six stories high. The exterior walls were blank except for a solitary street door, but they enclosed courtyards. A figure of 700,000 for the city population is given by the geographer Strabo, but this probably included the population of the Cap Bon peninsula. A more reasonable figure could be about 400,000, including slaves, similar to that of Athens.

Physical appearance of Carthage

Religion and culture. The Carthaginians were notorious in antiquity for the intensity of their religious beliefs, which they retained to the end of their independence and which in turn influenced the religion of the native peoples. The chief deity was Baal Hammon, the community's divine lord and protector. A sombre god, he was identified by the Greeks with Cronus and by the Romans with Saturn. During the 5th century a goddess named Tanit came to be widely worshipped and represented in art. It is possible that her name is Libyan and that her popularity was connected with the acquisition of land in the interior, as she is associated with symbols of fertility. These two overshadow other deities such as Melkart, principal deity of Tyre, identified with Heracles, and Eshmoun, identified with Aesculapius. Human sacrifice was the element in Carthaginian life most criticized; it persisted in Africa much longer than in Phoenicia. The child victims were sacrificed to Baal (not to Moloch, an interpretation based on a misunderstanding of the texts), and the burnt bones buried in urns under stone markers, or stelae. At Carthage thousands of such urns have been found in the "Sanctuary of Tanit," and similar burials have been discovered at Hadrumetum, Cirta, Motya, Calaris, Nora, and Sulcis. The whole character of Carthaginian religion was sombre, being one of the weakness of human beings in the face of the overwhelming and capricious power of the gods. The great majority of Carthaginian personal names, unlike those of Greece and Rome, were of reli-

gious significance; *e.g.*, Hannibal, "Favoured by Baal," or Hamilcar, "Favoured by Melkart."

Carthaginian artistic and intellectual achievements

In comparison with the extent of its power and influence, the artistic and intellectual achievements of Carthage were small. What limited remains of buildings survive—mostly in North Africa and Sardinia—are utilitarian and uninspired. In the minor arts—pottery, jewelry, metalwork, objects in terra-cotta, and the thousands of carvings on stelae—a similar lack of inspiration may be felt. The influence of Phoenician, Egyptian, and Greek artistic traditions can be observed, but they failed to stimulate as they did, for example, in Etruria. There is no evidence that Greek philosophy and literature made much impact, though certainly many Carthaginians in the city's later history knew Greek and there were libraries in the city. One work is known, a treatise on agriculture by a certain Mago, but this may have been based on Hellenistic models. On the whole, the Carthaginians adhered to traditional modes of thought, which no doubt gave them a sense of solidarity amid more numerous and hostile peoples. Their fanatical patriotism enabled them to offer a more prolonged resistance to Rome than any other power. Their influence on North African history was, in the first place, to bring it into the mainstream of the advancing civilization of the Mediterranean world; more particularly it introduced into North Africa more advanced techniques leading to agricultural progress, which implied in turn a change by many Libyans from a seminomadic to a stable way of life, and the possibilities of urbanization, which were fully realized in the Roman period.

Carthaginian Empire.

Carthage and Rome. In the 3rd and 2nd centuries BC, Carthage was weakened and finally destroyed by Rome in the three Punic Wars (*q.v.*). Treaties between Carthage and Rome had been made in 508 and 348, and for a long period the two powers had no conflicting interests. But by the 3rd century Rome dominated all southern Italy and thus approached the Carthaginian sphere in Sicily. In 264 Rome accepted the submission of Messana (Messina), though this state had previously had a Carthaginian garrison, partly because of exaggerated fears of a possible Carthaginian threat to Italy and partly because of hopes of gain in Sicily. For Carthage, a Roman foothold in Sicily would upset the traditional balance of power on the island. The ensuing First Punic War, which lasted until 241, was very costly in human life, with losses of tens of thousands being recorded in some naval engagements. Contrary to expectation, the Carthaginian fleet was worsted on several occasions by the newly built Roman; on land the Romans failed to drive the Carthaginians out of Sicily, and a Roman invasion of Tunisia ended in catastrophe. Carthage made peace after a final naval defeat off the Aegates Islands, surrendering its hold on Sicily. Sardinia fell to Rome in 238.

In response to the defeat, Carthage, under the leadership of Hamilcar Barca and his successors (usually described as the Barcid family), set about establishing a new empire in Spain. The object appears to have been to exploit the mineral wealth directly rather than through intermediaries and to mobilize the manpower of much of Spain into an army that could match that of Rome. Hamilcar and his son-in-law Hasdrubal built up an army of over 50,000 Spanish infantry and occupied half of the Iberian Peninsula. Finally, in 219, Hannibal, Hamilcar's son, ignored Roman threats designed to prevent the consolidation or extension of the new empire. His invasion of Italy and the crushing defeats he inflicted on the Romans at Lake Trasimene (217) and Cannae (216) were the gravest danger Rome had ever faced. The majority of Rome's allies and subjects in Italy remained loyal, however, and Hannibal found increasing difficulty in getting supplies and reinforcements. In 204 Scipio Africanus landed near Utica with a Roman army, and in 203 Hannibal was recalled from Italy; but he was defeated by Scipio at Zama (Sabʿ Biʾār) in 202. Carthage made peace soon afterward, surrendering its fleet, its overseas possessions, and some of its African territory. During the next 50 years it retained some measure of prosperity, although frequently under pressure from the Numidians under King Masinissa. From 155 BC irrational fears of a Carthaginian revival were stimulated at Rome by Cato the Elder, and in 149, on flimsy pretexts, the Carthaginians were forced to choose between evacuating their city and settling inland, or a doomed resistance. They chose the latter, and, after a three-year siege, the city was destroyed and its site ceremonially cursed by the younger Scipio.

New empire in Spain

The Greeks in Cyrenaica. The natural contacts of Cyrenaica were northward with Crete and the Aegean world. Its coast was visited by Cretan fishermen in the 7th century, and the Greeks became aware that it was the only area in North Africa still available for colonization. A severe overpopulation on the small Cyclades island of Thera (Santorini) led to the foundation of Cyrene (*c.* 630) on a site in easy reach of the sea, well watered, and in the fertile Jabal al-Akhḍar plateau. The founder's name was, or was changed to, Battus, a Libyan word meaning king. For some time friendly relations existed with the local peoples, and there was more intermarriage with non-Greek women than was usual in colonies. Later, when more colonists were attracted by the increasing prosperity, hostilities occurred in which the settlers were successful. Cyrene also repulsed an invasion by the Egyptians (570) but in 525 submitted to Persia. Meanwhile, Cyrene had established other Greek cities in the area—Barca (al-Marj), Taucheira (Tūkrah), and Euhesperides (Benghazi), all of which were independent of their founding city. During the 6th century, Cyrene rivalled the majority of other Greek cities in its wealth, manifested in part by substantial temple building. Prosperity was based on grain, fruit, horses, and, above all, on an apparently extinct plant, *Silphium*.

The dynasty of Battus ended *c.* 440 BC with the establishment of a democratic constitution like that of Athens, and the general prosperity of Cyrenaica continued through the 4th century in spite of some political troubles. Cyrenaica submitted to Alexander the Great in the late 4th century and subsequently became subject to the Ptolemies. The cities nevertheless enjoyed a good deal of freedom in running their own affairs. The constitution of Cyrene was elaborated as a fairly liberal oligarchy, with a citizen body of 10,000 and two councils. During the 3rd century a federal constitution for all the Cyrenaican cities was introduced. Apollonia, the port of Cyrene, became a city in its own right; Euhesperides was refounded as Berenice, and a new city, Ptolemais (Ṭulmaythah), was founded, while Barca declined; the term Pentapolis came to be used of the five cities Apollonia, Cyrene, Ptolemais, Taucheira, and Berenice. In 96 BC Ptolemy Apion bequeathed it to Rome, which annexed the royal estates but left the cities free. Disorders led Rome to create a regular province in 74 BC, to which Crete was added seven years later. After Mark Antony temporarily granted it to his daughter Cleopatra Selene, Augustus re-established it with Crete as a senatorial province.

Constitutional changes in Cyrene

THE RISE AND DECLINE OF NATIVE KINGDOMS

Between the destruction of Carthage and the establishment of effective Roman control over the Maghrib there was a period that saw a brief flourishing of native kingdoms. Amid the shifting tribal nomenclature of the sources of various periods, two main groups of relatively sedentary tribes may be distinguished: the Mauri, living between the Atlantic and the Moulouya or perhaps the Chelif rivers, who gave their name to Mauretania; and the Numidae, in the area to the west of that formerly controlled by Carthage. A third group, the Gaetuli, was a largely nomadic people of the desert and its fringe. The various tribes first emerge into history in the late 3rd century BC, no doubt after a period of evolution resulting from contact with Carthaginian civilization. This is difficult to trace, as Carthaginian products were scarce in the interior of the Maghrib before the 2nd century BC, but the large tumuli at Mezora, Sīdī Sulaymān, Souk el-Gour, and the Medracen, apparently royal tombs of the 4th and 3rd centuries BC, testify to a developing economy and society. No doubt service in the Carthaginian mercenary armies was a major stimulus to native Libyan progress. This was most noticeable in Numidia and reached a high point under Masinissa. The son of a chief of the Massyli, a tribe dominating the area between Carthaginian territory and the Ampsaga River (Wādī al-Kabīr), he had been brought up at Carthage and was 20 years old at the outbreak of the Second Punic War. At first his tribe was at variance with Carthage, but in 213 BC it became reconciled when its powerful western neighbours, the Masaesyli, under Syphax deserted Carthage. From 213 to 207 BC Masinissa commanded Numidian cavalry in Spain for the Carthaginians against Rome. On the latter's victory at Ilipa in 207, he returned to Africa where Syphax, now reconciled with Carthage, had occupied some of his tribal territory, including Cirta (Constantine), and his own claims to succession to the chieftainship were disputed. When the Romans landed in Africa in 204 he rendered them invaluable assistance. Recognized by the Romans as king, he annexed the eastern part of Syphax' kingdom and reigned with success until 148 BC. The Greek geographer Strabo said that he "turned the nomads into a nation of farmers." This is exaggerated, since cereal culture had long been established in parts of Numidia, yet there is no doubt that the area of grain production was much enlarged. This was achieved by deliberate encouragement of Carthaginian civilization. Along with new techniques, Carthaginian language, religion, and art penetrated rapidly inland, and Masinissa's capital, Cirta, took on the aspects of a Carthaginian city; incipient urbanization of a number of native villages is also possible. Masinissa issued copper, bronze, and lead coinage for local use, as did some of the Carthaginian coastal towns under his rule.

King Masinissa of Numidia

On his death in 148, his kingdom was divided among his three sons, possibly on the insistence of the Romans, but the latter did not prevent its reunification under Micipsa (148–118 BC). The progress begun under Masinissa continued as refugees from the destruction of Carthage fled to Numidia. Meanwhile, the Romans had formed a province of the area of Tunisia northeast of a line from Thabraca to Thaenae but showed little interest in exploiting its wealth. The attempt by the Roman reformer Gaius Gracchus in 122 BC to found a colony on the site of Carthage failed, though individual colonists who had taken up allotments remained. When Micipsa died, another division of Numidia among three rulers took place, in which Jugurtha (118–105 BC) emerged supreme. He might have been recognized by Rome, but he provoked war when he killed some Italian merchants who were helping a rival to defend Cirta. After some successes due to the incompetence of Roman generals, he was surrendered by Bocchus I, king of Mauretania. The kingdom was again reconstituted under other descendants of Masinissa. The boundaries of the Roman province were slightly enlarged in the area of the upper Majardah, where veterans of the army of Gaius Marius received lands. During the next 50 years there was further immigration by individual Roman settlers and merchants but no deliberate state action. The last relatively formidable king of Numidia was Juba I (*c.* 60–46 BC), who supported the Pompeian side in the Roman civil war between Pompey and Julius Caesar but fell to the dictator in 46 BC at Thapsus. A new province, Africa Nova, was formed from the most developed part of the old Numidian kingdom east of the Ampsaga; it was subsequently (before 27 BC) amalgamated with the original province of Africa by the emperor Augustus. In 33 BC Bocchus II of Mauretania died, bequeathing his kingdom to Rome, but Augustus was unwilling to accept responsibility for so large and relatively backward an area. In 25 BC he installed Juba II, son of Juba I, as king; he ruled until his death about AD 24. He was married to Cleopatra Selene, daughter of Mark Antony and Cleopatra, and under them Iol, renamed Caesarea (Cherchel), and also Volubilis, near Fès(Fez), a secondary capital of the rulers of Mauretania, became centres of late Hellenistic culture. Juba himself was a prolific writer in Greek on a number of subjects, including history and geography. His son Ptolemy succeeded but was executed for unknown reasons by the Roman emperor Caligula in AD 40. A brief revolt followed but was easily suppressed, and the kingdom was divided into two provinces, Mauretania Caesariensis, with its capital at Caesarea, and Mauretania Tingitana, with its capital at Tingi.

Formation of Africa Nova

ROMAN NORTH AFRICA

Administration and defense. For over a century from its acquisition in 146 BC the small Roman province was governed by a minor Roman official from Utica; but changes were made by Augustus, reflecting the growing importance of the area. The governor was henceforth a proconsul, residing at Carthage, after its refounding by Augustus as a Roman colony, and responsible for the whole territory from the Ampsaga in the west to the border of Cyrenaica. The proconsul also commanded the army of Africa and was thus one of the very few provincial governors in command of an army and yet formally responsible to the Senate rather than to the emperor. This anomaly was removed in AD 39 when Gaius entrusted the army to a *legatus Augusti* of praetorian rank. Although the province was not formally divided until 196, the army commander was *de facto* in charge of the area later known as the province of Numidia and also of the military area in southern Tunisia and along the Libyan Desert. The proconsulship was normally held for only one year; like the proconsulship of Asia, it was reserved for former consuls and ranked high in the administrative hierarchy. In the 1st century it was held by several men who subsequently became emperor; *e.g.*, Galba and Vespasian. The commanders of the army normally held the post for two or three years. In the 1st and 2nd centuries AD it was an important stage in the career of a number of successful generals, but in the 3rd century Africa became a military backwater. The two Mauretanian provinces were governed by men of equestrian rank who also commanded the substantial numbers of auxiliary troops in their areas. In times of emergency the two provinces were often united under a single authority.

Tribes on the fringe of the desert and beyond constituted more of a nuisance than a threat as the area of urban and semi-urban settlement gradually approached the limit of cultivable land. A number of minor conflicts with nomadic tribes are recorded in the 1st century, the most serious of which was the revolt of Tacfarinas in southern Tunisia, suppressed in 23. As the area of settlement extended westward as well as south, so the headquarters of the legion moved also; from Ammaedara (Ḥaydarah) to Thevеste under Vespasian, thence to Lambaesis under Trajan. Tribal lands were reduced and delimited, which compelled the adoption of sedentary life, and the tribes were placed under the supervision of Roman "prefects." A southern frontier was finally achieved under Trajan with the encirclement of the Aurès and Nemencha mountains and the creation of a line of forts from Vescera (Biskra) to Ad Majores (Besseriani). The mountains were penetrated during the next generation but were never developed or romanized; nevertheless, they rarely appear to have been a source of disturbance. During the 2nd century, stretches of continuous wall and ditch—the *fossatum*

Westward movement of settlement

Africae—in some areas provided further defense against desert nomads and also marked the division between the settled and nomadic ways of life. To the southwest of the Aurès a fortified zone completed the frontier defensive system or *limes*, which extended for a while as far as Castellum Dimmidi (Messad), the most southerly fort in Roman Algeria yet identified. South of Leptis Magna in Libya, forts on the trans-Saharan route ultimately reached as far as Cydamus (Ghudāmis).

In the Mauretanias the problem was more difficult, because of the rugged nature of the country and the distances involved. The encirclement of mountainous areas, a policy followed in the Aurès, was again pursued in the Kabylie ranges and the Ouarsenis. The area round Sitifis (Sétif) was successfully settled and developed in the 2nd century, but farther west the impact of Rome was for long limited to coastal towns and the main military roads. The most important of these ran from Zarai (Zraia) to Auzia (Aumale) and then to the valley of the Chelif. Subsequently, the frontier ran south of the Ouarsenis as far as Pomaria (Tlemcen). West of this area, it is doubtful whether a permanent road connected the two Mauretanias, sea communication being the rule. In Tingitana, the frontier ran south of a line from Meknès to Rabat. The tribes of the Rif must have lived in virtual independence, and they were probably responsible for a number of wars recorded in Mauretania under Domitian, Trajan, Antonius Pius (which lasted six years), and others in the 3rd century. The effect of these was limited; they did little or no damage to the urbanized areas and never necessitated a permanent increase in the African garrison. For Numidia and the military district in the south of Tunisia and Libya, this amounted to one legion and auxiliaries, about 13,000 men; the Mauretanias had auxiliary units only, totalling some 15,000. This may be contrasted with the position in Britain, where three legions and auxiliaries were required. From the middle of the 2nd century AD the African garrison was largely recruited locally.

The growth of urban life. The most notable feature of the Roman period in North Africa was the development in Tunisia, northern Algeria, and some parts of Morocco of a flourishing urban civilization. This was due in the first place to control of nomadic and pastoral movements, which opened large areas of thinly settled but potentially rich land to consistent exploitation. In addition, there was the incipient urbanization of some parts due to the Carthaginians and the ambitions of Libyan rulers such as Masinissa; and, lastly, the settlement in Africa of Italian immigrants, who, though relatively few in comparison with the population as a whole, provided the impetus to expansion. Julius Caesar settled many veterans in colonies, mostly coastal towns; and, equally important, he established a military adventurer named Publius Sittius along with many Italians at Cirta, beginning the romanization of Numidia. Caesar planned to refound Carthage, and this was effected by Augustus. The number of his original settlers was 3,000, but the colony grew with quite remarkable rapidity because of its favourable geographical position in relation to contact with Rome and Italy. A number of other colonies were founded in the interior of Tunisia and at widely separated places on the Mauretanian coasts. There was also immigration from Italy by private individuals at this time. Colonial foundations of veterans in Mauretania occurred under Claudius (*e.g.*, Tingi, Caesarea, Tipasa). Cuicul (Djemila) and Sitifis were founded by Nerva, and Thamugadi and a number of places nearby, in the area north of the Aurès, by Trajan. The army was a potent vehicle in the spread of Roman civilization and played a major part in the romanization of the frontier regions.

Italian settlers

Though at first inferior in status to the Roman towns, native communities enjoyed the local autonomy that was the hallmark of Roman administration. Between 400 and 500 such units were recognized, the majority of them villages or small tribal fractions. Many, however, advanced in wealth and standing to rival the Roman colonies, acquiring in the process the grant of Roman citizenship, which put the seal of imperial approval on the prosperity, stability, and cultural evolution of developing communities. Naturally, the earliest to show signs of increasing prosperity were the surviving Carthaginian settlements on the coast and places, particularly in the Majardah Valley, where the Libyan population had been much influenced by Carthaginian culture and which now also had numbers of Roman immigrants. Leptis Magna and Hadrumetum received Roman citizenship and the status of a colony from Trajan, and Thubursicu Numidarum (Khamissa) and Calama (Guelma) probably the rank of a municipality. But it was under Hadrian, the first emperor to visit Africa, that the flood tide of such grants occurred; Utica, Bulla Regia (Hammam Derradji), Lares (Lorbeus), Thaenae, and Zama achieved colonial rank, and the process continued throughout the 2nd century. Finally, Septimius Severus, who originated from a rich family of Leptis Magna, and of largely mixed descent, became emperor in AD 193 and showed a great deal of favour to his native land.

In the Maghrib, Roman rule replaced no civic oligarchy, as in the hellenized provinces of Asia Minor, nor a strongly based tribal aristocracy, as in Celtic Gaul. The creation of new wealth and a new social leadership depended on the activity of individuals, and Roman African society became a notable example in antiquity of a self-made bourgeoisie, the wealth being largely in ownership of land. In the 1st century AD there were a few very large estates owned by absentee Roman senators, but they were subsequently absorbed in the extensive imperial estates; the general pattern was of landowning on a more moderate, though still substantial, scale by residents. These landowners made their homes in the towns, not on their estates, and provided the local municipal aristocracies. There was also a numerous class of smaller landowners, but the majority were small tenant farmers with considerable security and traditional rights, on a sharecropping basis. The proportion of slaves is unknown but may well have been smaller than in Italy.

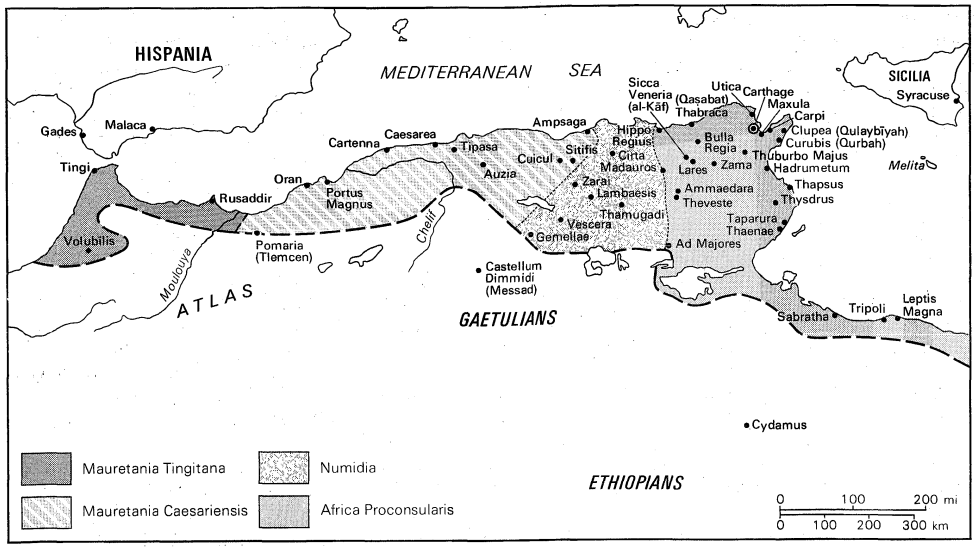
Growth of new social elite

Many of the wealthier Africans entered the imperial administration. The first African consul held office in the reign of Vespasian; at the beginning of the 3rd century, men of African origin held one-sixth of all the posts in the equestrian grade of the administration and also constituted the largest group of provincials in the Senate. It is uncertain what proportion were of native Libyan or mixed origin, but in the 2nd century they were certainly the majority.

During the 2nd and early 3rd centuries the wealthy classes in the towns expended vast sums on their communities in gifts of public buildings such as theatres, baths, and temples; statues; public feasts; and distributions of money. This was a general phenomenon due partly to the lack of alternative profitable investment opportunities and also to a strongly felt social obligation, but the Africans adopted it with particular avidity.

Economy. The density of the towns in no way implies the predominance of trade or industry; all but a few were residences of both landowners and peasants, and their prosperity depended on agriculture. By the 1st century AD, African exports of grain provided two-thirds of the needs of the city of Rome. Some of this, for distribution by the emperors to the urban proletariat, came from the imperial estates and from taxes, but much went on to the open market. An estimate of grain production of something over 1,000,000 tons, of which 25 percent was exported, has been made. Areas of grain production were the Cap Bon peninsula, the valleys of the Miliana and Majardah, and tracts of relatively level land north of a line from Sitifis to Madauros (M'Daourouch). Cereal crops were the most important in the above areas, but fruit, figs, grapes, and beans were also produced.

The production of olive oil became almost as important as cereals by the 2nd century AD, particularly in southern Tunisia and along the northern slopes of the Aurès and Bou Taleb mountains. By the 4th century Africa exported oil to all parts of the empire. Successful cultivation of olives demanded careful management of available water, and the archaeological evidence indicates that much attention was paid to irrigation in the Roman period.



Roman Africa in the 3rd century AD.
Adapted from J.D. Fage, *An Atlas of African History* (1966); Edward Arnold Publishers

Livestock was an important part of the economy of Roman Africa, though direct evidence is slight. African horses were used in racing and no doubt also in the Roman cavalry. Cattle, sheep, pigs, goats, and mules were also raised. Africa was the major source of the wild animals for shows in Rome and other major cities of the empire, in particular panthers, lions, elephants, and monkeys. Fishing, which had been developed along the coast as far as the Atlantic in the Carthaginian period, continued to flourish. Timber from the forests along part of the north coast, and marble, the most important North African source being Simitthu (Shimṭū), were also exported.

There were no large-scale industries even by ancient standards in North Africa, though traditional arts and crafts were practiced. Pottery flourished, and lamps of North African manufacture were marketed in the northern provinces of the empire. Mosaic pavements were extremely popular among the wealthy throughout North Africa, and well over 2,000 have been discovered, with enormous variations in quality. The majority were made by local craftsmen, though some of the designs originated elsewhere. It is also clear that the building trades were major consumers of both skilled and unskilled labour.

Population increases

Prosperity under the Romans undoubtedly led to a rise in the population of the Maghrib in the first two centuries AD; in the absence of reliable statistics, estimates have varied between 4,000,000 and 8,000,000 (the latter being also the population about a century ago). The most recent study proposed about 6,500,000, of whom about 2,500,000 were in present Tunisia. Some 40 percent (but perhaps more) lived in the towns. Of these, Carthage was in a class of its own, reaching at least 250,000. The next largest was Leptis Magna (80,000), followed by Hadrumetum, Thysdrus (el-Djem), Hippo Regius, and Cirta, with between 20,000 and 30,000 each. Many towns in close proximity to each other, especially in the Majardah Valley, averaged between 5,000 and 10,000.

The road system in Roman Africa was the most complete of any western province; a total of some 12,500 miles has been supposed, though only a small proportion was fully surfaced. In origin most roads were military but were open to commerce, and a number of minor roads linking towns off the main routes were built by the local communities. The main arteries were: Carthage to Theveste; Carthage to Cirta through Sicca Veneria; Theveste to Tacapae through Capsa; Theveste to Lambaesis; Cirta to Sitifis; Cirta to Rusicade; and Cirta to Hippo Regius. Carthage handled by far the greatest volume of overseas official traffic and trade, being the natural port for the wealthiest area of North Africa. Nevertheless, most of the ports originally founded by Phoenicians and Carthaginians expanded during the Roman period; in view of the high costs of land transport, it was natural that agricultural products would go to the nearest port for shipment.

Later Roman Empire. The whole Roman Empire underwent a grave crisis between the death of Alexander Severus (235) and the accession of Diocletian (284), resulting from outside attacks, internecine wars, and a total collapse of the monetary system. Africa suffered less than most parts of the empire from the first two factors, though there was an unsuccessful revolt by landowners in AD 238, against the fiscal policies of the emperor Maximinus Thrax, which ended in widespread pillage. There were tribal revolts in the Mauretanian mountains in 253–254, 260, and 288, and the situation finally brought a visit from the emperor Maximian in 297–298, but the revolts had little effect on urbanized areas. On the other hand, the towns were injured by economic difficulties and inflation, and building activity almost ceased. There was some return of confidence under Diocletian (284–305) and Constantine (312–337). Administrative changes introduced at this time included the division of the province of Africa into three separate provinces: Tripolitania (capital Leptis Magna), covering the western part of Libya; Byzacena, covering southern Tunisia and governed from Hadrumetum; while the northern part of Tunisia retained the name Africa. In addition, the eastern part of Mauretania Caesariensis beame a separate province (capital Sitifis). In the far west, the Romans gave up much of Mauretania Tingitana, including the important town of Volubilis, apparently because of pressure from the tribe of the Baquates. In the general reorganization of the Roman army by Diocletian and Constantine, the field army (*comitatenses*) in Africa, numbering on paper some 21,000 men, was put under a new commander, the *comes Africae*, independent of the provincial governors. Only the governors of Tripolitania and of Mauretania Caesariensis also had troops at their disposal, but these were second-line soldiers, or *limitanei*. The whole frontier region along the desert and mountain fringes was divided into sectors and garrisoned by *limitanei*. The latter were locally recruited and closely identified with the farming population of their areas. The Tripolitanian Jabal, which was increasingly exposed to nomad attacks by the Austuriani, is notable for a large number of fortified farms.

Reforms under Diocletian

Africa, like the rest of the empire, experienced the economic difficulties and governmental pressures that were a feature of the later Roman Empire. The power of the landowners increased at the expense of their tenants and of smaller farmers, both of whom the imperial government sought to bind to the soil in a state of quasi-serfdom. In the cities, the tasks of local government that had earlier been eagerly undertaken by the wealthy became burdensome, and again the imperial government sought to make them compulsory and hereditary; while the

councillors themselves sought by any means to enter the imperial administration or professions that provided immunity. The process is well attested in Africa. Nevertheless, urban life withstood these pressures better in Africa than in the west generally.

Christianity and the Donatist controversy. Christianity grew much more rapidly in Africa than in any other western province. It was firmly established in Carthage and other Tunisian towns by the 3rd century and had produced its own local martyrs and an outstanding apologist in Tertullian (*c.* 160–240). During the next 50 years there was a remarkable expansion; over 80 bishops attended a council at Carthage in 256, some from the distant frontier regions of Numidia. Cyprian, bishop of Carthage from 248 until his martyrdom in 258, was another figure whose writing, like that of Tertullian, was of lasting influence on Latin Christianity. During the next half-century, its spread was primarily in Numidia (at least 70 bishops known in 312). The reasons for its exceptionally rapid growth are disputed. In northern Tunisia, urban communities provided a similar social and economic environment to that in which it had first spread in Anatolia and Syria, but this hardly accounts for Christianity's early acceptance in distant parts of Numidia. The existing religious situation may be part of the explanation; in the intermingling of religious currents of Libyan, Carthaginian, and Roman origin in the first two centuries, the cult of Baal Hammon, now under the Roman name of Saturn, became increasingly prominent and may have facilitated a transition to a monotheistic religion. It is certain also that African Christianity always included a vigorous and fanatical element that must have had its effect in spreading the new religion, even though there is little evidence of positive missionary efforts.

Christians were still a minority at the end of the 3rd century, particularly among the wealthy and educated classes; but they were in a good position to benefit from Constantine's adoption of the religion and his grants of various privileges to the clergy. At this time (AD 313), a division occurred among the African Christians that lasted over a century. Some Numidian bishops objected to Caecilian, a newly chosen bishop of Carthage, on the ground that his ordination had been performed by a bishop who had weakened during Diocletian's persecution of the church and hence was invalid. They consecrated a rival bishop, and, when he died, another named Donatus, who gave his name to the ensuing schism. The imperial government recognized Caecilian as the true bishop of Carthage, and those in communion with him as the Catholic Church in Africa and hence alone the recipients of imperial favour. A series of appeals by the Donatists to Constantine resulted in investigations and judgments, all of which went against them. Confiscation of their churches led to some deaths, the victims being honoured as martyrs, but in 322 Constantine rejected further pressure. The Donatists increased rapidly, and for the rest of the century probably equalled the Catholics. The Donatists were strongest in Numidia and Mauretania Sitifensis, the Catholics in the proconsular province; the position in the Mauretanias was more even, but Christianity did not spread rapidly there until the 5th century. In 347 the emperor Constans exiled a number of bishops and took strong measures against the *circumcelliones*, an obscure group of either wandering religious fanatics or seasonal farm workers who were particularly enthusiastic Donatists. But in 362 Julian the Apostate allowed the return of the exiles, who were welcomed with enthusiasm, and the movement proved as strong as ever. Some Donatists appear to have been associated with the revolt of a Mauretanian chieftain, Firmus, and in 377 the first of a series of laws condemning Donatism was issued. Nevertheless, these laws were only sporadically enforced, partly because the provincial governors and many of the local magistrates were still pagan and, at a time of growing weakness in the imperial government, were inclined to ignore instructions they found unwelcome. Donatism was further supported by Gildo, brother of Firmus and *comes Africae* 387–397. Then Augustine of Hippo Regius applied his enormous powers of leadership and persuasion in stimulating the Catholics to resolute action, evolving at the same time a theory of the right of orthodox Christian rulers to use force against schismatics and heretics. In 411 an imperial commission summoned a conference at Carthage to establish religious unity; the Donatists had to obey, though the decision against them was a foregone conclusion. The laws that followed their condemnation were more generally enforced and, though there was some resistance, broke the heresy as a powerful movement; some communities still existed in the 6th century, however.

Beginning of schism

Much controversy surrounds the interpretation of the significance of Donatism; an important view considers it in some sense a national or social movement. It is said to have been particularly associated with the rural population of less romanized areas and with the poorer classes in the towns, whereas Catholicism was the religion of the romanized upper classes. The identification of the imperial government with the Catholics would have intensified the strength of the movement, and the *circumcelliones*' violence constituted incipient peasant revolt. Thus the movement is claimed as analogous to Monophysitism in Egypt and Syria, which produced a vernacular literature and a passive rejection of Greco-Roman culture. The hostility of the Donatists to the existing society was typified by Donatus' remark: "What has the emperor to do with the church?" Against this view it may be said that Donatism in the strictly unromanized tribal areas was certainly weak, and the relationship of the sect with Firmus and Gildo was of little importance. In Numidia it was at least as strong in the towns as in the rural areas, and in any case the distinction between the two is exaggerated. The entire controversy was conducted in Latin, and no vernacular literature was produced; in fact, until the time of Augustine, most of the educated class, of the same social background as Augustine himself and fully imbued with Roman tradition, were Donatists if they were not pagan. It was precisely the reluctance of the landowners to have their peasants disturbed, and the negligence of many provincial governors (both attacked by Augustine), that long protected the Donatists. Lastly, in spite of the remark attributed to Donatus, there is no evidence that the movement attacked the imperial system as a whole, as opposed to individual emperors and officials, and it made full use of its many opportunities to defend itself at law both against the Catholics and against divisions in its own ranks.

Donatism as national movement

Nevertheless, although it is difficult to sustain the view that Donatism, especially in Numidia, represented in some way a resurgence of local pre-Roman culture, and still more hypothetical to suggest that something similar led to the emergence of heretical movements of Islām in the same areas, Donatism certainly appealed to deep-seated traditions of African Christianity. Its fanatical devotion to the memory of martyrs, its doctrinal conservatism and total refusal to compromise on its claim to be the true church while its opponents were contaminated by the stain of weakness in the persecutions, were fully in line with the heroic days of Tertullian and Cyprian.

Extent of romanization. The question whether Roman civilization in the Maghrib was a superficial phenomenon affecting only a small minority of the population who were economically successful, or whether it had profound effects on a majority, is similarly disputed. A priori the former view may be supported by the fact that whereas Gaul and Spain emerged from the Dark Ages with a language and religion derived from their Roman past, in the Maghrib both disappeared, arguably because they were superficial. It is not disputed that in the mountainous areas, such as the Aurès, Kabylie, and Atlas, native Libyan language and culture continued little affected by Roman civilization, though the majority appear to have been Christian by the 7th century; nor that Libyan and Carthaginian traditions survived in other areas and affected the modes of acceptance of Roman civilization. As regards language, the late form of Phoenician known as Neo-Punic was still spoken fairly widely in the 4th century; for example, in the hills near Hippo Regius. Inscriptions in the language and script occurred often at

the beginning of the Roman period but are very rare after the end of the 1st century AD. An exception may be in Tripolitania, where a form of Neo-Punic was inscribed in Latin perhaps as late as the 4th century. There was also a Libyan script known solely from funerary stelae and akin to the script of the present Tuareg; it was known in some sense over most of the Maghrib but may not have been used later than the 3rd century. On the other hand, there is no evidence that the languages were ever literary languages, and the inscriptions are negligible in number compared with the Latin. It may also be observed that the areas in which Libyan inscriptions occur do not correspond with the later areas of Berber dialects. The Latin language unquestionably became general through the whole Maghrib, though to a limited extent in the mountains; it is impossible to define any precise social level at which it was unknown. There is a good deal to be said for the view that the spread of Christianity, whether Catholic or Donatist, completed the victory of Latin among elements which up to that time had perhaps still not used it. Further, there is no evidence for the survival of Neo-Punic or Libyan after the 4th century outside the mountains. Similarly in Gaul, the native Gallic language does not seem to have lasted beyond the 5th century. The fact that there and in Spain Romance languages and Christianity survived, while in North Africa they did not, was perhaps not so much due to a greater depth of romanization as to subsequent historical developments.

Victory of Latin language

The Vandal conquest. The effect of the Donatist controversy on the economy and administration of the African provinces cannot be measured. At the very moment of the effective victory of the Catholics, the rest of the Roman Empire was crumbling to ruin. In 406 the Rhine was crossed by Vandals, Alani, Sueves, and others who overran most of Gaul and Spain within the next few years. In 408 Alaric and the Visigoths invaded Italy and in 410 sacked Rome. Although the empire in the west survived for some time longer, the emperors were increasingly at the mercy of their barbarian generals. Meanwhile, large tracts of imperial territory were lost by the settlement of the invading tribes. Africa escaped for a while, though only death prevented Alaric from leading his tribe across the Mediterranean. Its retention became ever more vital to the survival of what was left of imperial authority. In this situation the *comites Africae* were increasingly tempted to intrigue for their own advantage. One of them, Bonifacius, is said to have invited the Vandals, who at the time were occupying Andalusia, to his aid, but it is more likely that the Vandals were attracted to Africa by its wealth and needed no such formal excuse. Led by their king Gaiseric, the whole people, 80,000 in all, crossed into Africa in 429 and in the next year advanced with little opposition to Hippo Regius, which they took after a siege during which St. Augustine died. After defeating the imperial forces near Calam, they overran most of the country, though not all of the fortified cities. An agreement made in 435 allotted Numidia and Mauretania Sitifensis to the Vandals, but in 439 Gaiseric took and pillaged Carthage and the rest of the province of Africa. A further treaty with the imperial government (442) established the Vandals in Africa Proconsularis, Byzacena, Tripolitania, and Numidia as far west as Cirta.

Vandal impact on the economy

Although the Vandals were probably no more deliberately destructive than other German invaders (the notion of "vandalism" stems from the 18th century), they accelerated the economic decline that had already set in. The imperial authorities had to reduce the taxes of Mauretania by seven-eighths as a result of their devastation. Over much of northern Tunisia, landowners were expelled and the properties handed over to Vandals. Although the agricultural system remained based on the peasants bound to the soil, the expulsions had a serious effect on the towns with which the landowners had been connected. The Vandals, like other invading tribes except the Franks, were divided from the mass of their subjects by their Arian heresy. Although their persecution of the Catholics was exaggerated by the latter, Vandal kings certainly exercised more pressure than others. This was no doubt in reaction to the vigour of African Christianity, which kept the loyalty even of those who had little to lose by the substitution of a Vandal for a Roman landlord.

Gaiseric was perhaps the most perceptive barbarian king of the 5th century in realizing the total weakness of the empire. He rejected the policy of formal alliance with it and from 455 used his large merchant fleet to dominate the western Mediterranean. Rome was sacked, the Balearics, Corsica, Sardinia, and part of Sicily were occupied, and the coasts of Dalmatia and Greece were plundered. Although there was no general cessation of trade, this activity accelerated the breakup of the economic unity of the western Mediterranean, already threatened by the creation of the barbarian kingdoms. Gaiseric's successors were less formidable; Huneric (477–484) launched a general persecution on the Catholics, apparently from genuine religious fanaticism rather than for political reasons, but his successor adopted a milder policy. Under Thrasamund (496–523) there is evidence that many Vandals adopted Roman culture, but the tribe retained its identity until the Byzantine reconquest.

A significant development of the Vandal period was the emergence of independent kingdoms in the mountainous and desert areas, largely of Libyan character. They appeared first in the Mauretanias, where the Roman frontier, already drawn back under Diocletian, receded further under the Vandal kings. By the end of Vandal rule, independent kingdoms existed in the region of Altava (Lamoricière), in the Ouarsenis and the Hodna. After 480, towns to the north of the Aurès, such as Thamugadi, Bagai, and Theveste, were sacked by the inhabitants of another kingdom in the Aurès. All of the names of the known chieftains are Libyan in character, though the survival of romanized elements within some of the kingdoms is attested by epitaphs in Latin and the use of Roman names. Finally, as a harbinger of a serious threat to settled life, whether Roman or Libyan, tribes that had retained a nomadic life on the borders of Cyrenaica and Tripolitania and caused much damage in the 4th century, began to push westward and were already a serious threat to the southern parts of Byzacena by the end of Vandal rule.

The Byzantine period. North Africa held an important place in the emperor Justinian's scheme for reuniting the Roman Empire and destroying the Germanic kingdoms. His invasion was undertaken against the advice of his experts (an earlier attempt in 468 had failed disastrously), but his general Belisarius succeeded, though partly through the incompetence of the Vandals. He landed in 533 with only 16,000 men and within a year the Vandal kingdom was destroyed; some of its people were transported to the Orient, others soon merged with the existing population. A new administrative structure was introduced, headed by a praetorian prefect with six subordinate governors for civil matters and a master of soldiers with four subordinate generals. It required some 12 years, however, to pacify Africa, due partly to the resistance of the Mauri to the re-establishment of an ordered government, partly to lack of support to the army in men and money, leading to frequent mutinies. A remarkable program of fortifications, many of which survive, was rapidly built under Belisarius' successor Solomon. Many were garrison forts in the frontier region, which again seems to have run, at least for a while, south of the Aurès, and then northward from Tubunae to Saldae. But many surviving towns in the interior were also equipped with substantial walls; *e.g.*, Thugga and Vaga (Béja, Bājah). After the death of Justinian (565) there were further difficulties with the Mauri, but the most serious damage was done by the nomadic Louata from the Libyan Desert, who on several occasions penetrated far into Tunisia.

Administrative reorganization

Africa shows a number of examples of the massive help given by Justinian in the building, and particularly the decoration, of churches, and the re-establishment of Catholic orthodoxy was widely welcomed, though it inevitably brought the persecution of surviving Donatists. Seriously weakened though it had been under the Vandals, some traces of the vigour of the African Church remained when it led the opposition of the Western churches to the theological policies of emperors at Con-

stantinople; *e.g.*, those of Justinian and also of Heraclius and Constans II immediately before the Arab invasions.

Little is known of the Byzantine period in the Maghrib after the death of Justinian. The power of the military element in the provinces grew, and between 585 and 591 a new official, the exarch, was introduced whose powers were almost viceregal. The economic conditions continued to decline because of the increasing insecurity and also the notorious corruption and extortion of the administration, though whether this was worse in Africa than in other parts of the Byzantine Empire it is impossible to say. It is certain that the population of the towns was only a small proportion of what it had been in the 3rd or even 4th century. The court of Constantinople tended to neglect Africa because of the more immediate dangers on the eastern and Balkan frontiers. Only once in its latest phase was it the scene of an important historical event; in 610 Heraclius, son of the African exarch at the time, sailed from Carthage to Greece in a revolt against the unpopular emperor Phocas, and succeeded him the same year. That Africa was still of some economic importance to the empire was shown in 619; the Persians had overrun much of the east including Egypt, and Africa alone appeared able to sustain an empty treasury and provide recruits. Heraclius thought of leaving Constantinople for Carthage but was prevented by popular feeling in the capital.

Maghrib on the eve of Arab conquest

In view of the lack of evidence for the Byzantine period, and the still greater obscurity surrounding the period of Arab conquest (643–698) and its immediate aftermath, conclusions on the state of the Maghrib at the end of Byzantine rule are speculative. Much of it was in the hands of tribal groups, among which the level of Roman culture was in many cases no doubt negligible. The Byzantine administration was in a sense foreign to the Latin population also, which may have added to the dislike felt for its notorious corruption. Few traces of the former prosperity of the settled areas remained. The Byzantine military forces were inadequate and incompetent, and it is significant that in the period of Arab conquest the most determined resistance came from the Libyan tribes, which frequently appear not so much as allies as leaders in the struggle. The total decay of town life (except in a few places on the east Tunisian coast) and of the ordered agricultural system occurred within a century after the end of Byzantine rule, though some scholars consider that a modicum survived until the invasions of further nomads, the Banū Hilāl, in the 11th century. Latin was still in use on Christian epitaphs at en-Ngila (Tripolitania) and al-Qayrawān (Kairouan) in the 10th and 11th centuries, and other Christian communities are known to have survived as long. The Arab conquest has its part in the widely discussed theory of Henri Pirenne, that the essential break between the ancient and medieval worlds came with the destruction of the unity of the Mediterranean world not by the Germanic but the Arab invasions. It is obvious that this is true of the Maghrib, but there is much to be said for the view that its earlier conquerors, the Vandals, were the major agent in the destruction of the economic unity of the Mediterranean. Whether this is the key to the problem is another matter.

Roman Cyrenaica. Much of the Roman period in Cyrenaica was peaceful. Some Roman immigrants resided there at an early date, and some of the Greeks received Roman citizenship. A famous inscription of 4 BC contains a number of edicts of the emperor Augustus regulating with great fairness the relationship between Roman and non-Roman. The character of its civilization, however, remained entirely Greek. Jews formed a considerable minority group in the province and had their own organizations at Berenice and Cyrene. They took no part in the great revolt of Judaea in AD 66 but in 115 began a formidable rebellion in Cyrene that spread to Egypt. No reason for it is known. It caused great destruction and loss of life, and Hadrian took special measures to reconstruct Cyrene and also sent out some colonists. Peaceful conditions returned, but in 268–269 the Marmaridae, inhabiting the coast between Cyrenaica and Egypt, gave trouble. In the reorganization of the empire by Diocletian, Cyrenaica was separated from Crete and divided into two provinces, Libya Superior, or Pentapolis (capital Ptolemais), and Libya Inferior, or Sicca (capital Paraetonium, Marsā Maṭrūḥ). A regular force was stationed there for the first time under a *dux Libyarum*. At the end of the 4th century, the Austuriani, a nomad tribe that had earlier raided Tripolitania, caused much damage, and Cyrenaica began to suffer from the general decline of security throughout the empire, in this case from desert nomads. A notable phenomenon of the 5th and 6th centuries, as in Tripolitania, is the number of fortified farms, most frequent in the Jabal itself and south of Boreum (Bū Qurādah) and also apparently in the region of Benghazi.

Christianity no doubt spread to Cyrenaica from Egypt. In the 3rd century the bishop of Ptolemais was metropolitan, but by the 4th century the powerful bishops of Alexandria consecrated the local bishops. The best known Cyrenaican is Synesius, a citizen of Cyrene of philosophic tastes who was made bishop of Ptolemais in 410 partly because of his ability to obtain help for his province from the imperial authorities. Under Justinian a number of defensive works were constructed as elsewhere in Africa; *e.g.*, Taucheira, Berenice, Antipyrgos (Tobruk), and Boreum. Recent excavations of a series of churches in the province also reveal the expenditure he devoted to their beautification, in what was a province of minor importance. On the eve of the Arab conquest (AD 643) the general condition of Cyrenaica would appear to have been on a par with most of the other eastern provinces of the empire, or perhaps slightly better, since it was not as greatly disturbed by the divisions within the church.

(B.H.W.)

II. From the Islāmic conquest to 1830

STRUCTURE AND MENTALITY OF THE PRE-ISLAMIC BERBER WORLD

In order to understand the Islāmic conquest of North Africa and how Islāmic life in the country was organized, it is necessary to examine the social structure of the North African world.

In the 7th century, the vast majority of the North African people were probably Berbers who, though of rather diverse physical types, possessed a common background of language and civilization. Society was tribal in structure. The homeland was not the land per se but rather the race; every social grouping conceived itself only as an assembly of men stemming from a common ancestor, frequently fictitious, whose name they continued to bear.

Berber society

Berber society was, and remained, remarkably fragmented within itself; the basic grouping was the segment, which, among a sedentary population, brought together 200 or 300 households in a territory with a radius of about four to six miles. This was a minuscule state—a tiny republic managed by a council of family heads and magistrates of temporary tenure who maintained order and assured the fair distribution of the profits and of the burdens of the small community. Among the nomads the douar (*dūwār*)—the collection of tent dwellers who lived and migrated together—was frequently of even more limited dimensions. The tribe, which comprised about ten subunits, had an assembly, and in time of war it often selected for itself a single chief. The confederations of tribes—except for moving livestock and for the nomads who needed to have living space assured them—were little more than a framework of regrouping for common defense by force or through alliances.

In political formations of variable size and cohesiveness there was profound democratic sentiment and an extreme mistrust of personal power. What mattered was the preservation of freedom and the autonomy of the small social cells by which the Berbers ordered their existence. Opposing factions grouped themselves into two opposite leagues, or *leffs*; thus, in case of oppression by a chief or by neighbours, they were able to call upon their *leff* brethren for help, and the latter would usually impose arbitration. Armed conflicts remained rare and limited. Without attaining the level of a nation-state or of a nation, Berber society attained equilibrium and peace in a fragmentation that did not facilitate the accomplishment of great collective tasks.

ISLAMIC NORTH AFRICA TO C. 1250

The Islāmic conquest and domination by the Umayyad (Banū Umayyah) caliphs. After a swift conquest of Syria, Egypt, Mesopotamia, and Iran, Islām halted before the steppes of Central Asia and the boundaries of India. Byzantium was organizing a belated but effective resistance on the frontier of Anatolia. Thus, blocked on the east and on the south, Islām lost no time in launching new conquests in the western Mediterranean. In spite of difficulties, this task was undertaken again and again, and it finally succeeded. Beginning in 642, Islāmic troops launched attacks from Egypt into Cyrenaica and into Tripolitania; an expedition reached the southern part of Tunisia, where it defeated the Byzantine patrician Gregory. The northern part of the country was not occupied, however, and the Byzantines finally induced the invaders to leave after paying them tribute.

Muslim penetration into North Africa

Conflicts between the caliphs ʿAlī (ruled 656–661) and Muʿāwiyah I (ruled 661–680), and the founding of the Umayyad caliphate by the latter, halted the Islāmic expansion toward the West until 670, when ʿUqbah ibn Nāfiʿ penetrated Tunisia and there founded al-Qayrawān (Kairouan). Toward the year 683 ʿUqbah undertook a large-scale expedition toward the West that brought him as far as Sūs (Sous) in southern Morocco. North Africa appeared to be adapting itself readily to the authority of Islām; but on his return, ʿUqbah was beaten and slain by a Berber chief, Kusaylah, and the Muslim troops were forced to fall back through Cyrenaica.

For 15 years, despite the incessant efforts of the Umayyad caliphate, then at the apogee of its power, the Berbers, under the command of Kusaylah and later of a woman, Kāhinah, offered stubborn resistance in Tunisia and in Constantine (Qusṭanṭinah, in what is now eastern Algeria). Finally, from 703 to 711, Mūsā ibn Nuṣayr, following somewhat the route taken by ʿUqbah, encountered only local resistance and brought all North Africa under the Islāmic domain.

This Muslim conquest was not really an Arab invasion. North Africa received only about 100,000 Arab militiamen, most of them stationed in Ifrīqīyah (Tunisia and eastern Algeria). But these Arab elements proved to be tyrannical. Their cupidity—their exactions and slave levies—led to a mass revolt in the country. The motivation and leadership for this revolt were furnished by a Muslim heresy—Khārijism, which in the East rallied to its side all the enemies of the Umayyad dynasty. The rebellion, originating in Morocco in 740, conquered all North Africa in two years; the caliphate armies were defeated in Morocco, and the Umayyads were barely able to save al-Qayrawān.

Rebellion against Arab occupation

The Umayyad caliphs, already in a stage of decline, could not reconquer North Africa. In 750 they were replaced as caliphs in the East by the ʿAbbāsids, who became the new masters of the Muslim world and transferred the seat of the caliphate to Baghdad.

The North Africans were unable to use this respite to consolidate their victory and to fortify their independence; from 742 to 746 they continued fighting among themselves in the name of the various sects of Khārijism. The ʿAbbāsids succeeded in conquering only Tunisia and the eastern part of Constantine; their governor in al-Qayrawān, Ibrāhīm I ibn al-Aghlab, while apparently remaining the faithful vassal of the caliphs of Baghdad, became independent in fact. Throughout the rest of North Africa, Khārijī kingdoms were founded, but a great many tribes remained independent.

Although the Khārijī revolt brought about the dismemberment of the caliphate in the Western lands, the people in the West remained faithful to Islām. Thenceforth there existed a Muslim West, which intended to seek the paths of political life and of Islāmic civilization.

Formation of North African Islām. After the 9th century, eastern North Africa remained under the dynasty of the Aghlabids (Banū al-Aghlab), a theoretical vassal of the ʿAbbāsids of Baghdad. The rest of the Muslim West —the Maghrib and Spain—was solving by itself and without foreign interventions the problems posed by its political organization in the framework of the new faith.

The Maghrib was inhabited by various political and religious groups. The most important of the new independent kingdoms was that of the Rustamids of Tāhart, which had an annex in the Jabal Nafūsah in Tripolitania; it was Khārijī, as indeed were the kingdoms of Tilimsān (Tlemcen) and of Sijilmāssah. In the Atlantic plains of Morocco, the confederation of the Barghawāṭah rallied to the cause of a particular heresy, diverging from Khārijism as well as from orthodoxy. The Ghumārah of northern Morocco followed the precepts of their prophet Hā-Mīm and constituted a new sect. Idrīs I, a descendant of ʿAlī, founded a Shīʿah kingdom in northern Morocco. This diversity of sects, theoretically and unequally Islāmic, attests to the fact that North Africa was an exemplar of great religious tolerance. Outside these more or less stable and organized states, there often lived a good many tribes and independent confederations that seem to have practiced Khārijism. The three foremost kingdoms of that time—the Idrīsid, the Rustamid, and the Aghlabid—represent three different forms of Muslim organization.

Political and religious fragmentation

The Idrīsid (al-Idrīsiyūn) kingdom (789–926). Idrīs was a descendant of ʿAlī and hence a *sharīf* (noble, or illustrious one). Fleeing the persecution of his people by the ʿAbbāsids, he succeeded in gaining support in northern Morocco, where he founded the Idrīsid kingdom. His son, Idrīs II, founded the capital city of Fez (Fās, modern name Fès). Upon the death of Idrīs II, the kingdom was divided into a series of principalities.

The Idrīsid kingdom was the first in Morocco to derive support from a mixed Arab and Berber central government and militia. The founding of Fez—an Islāmic city inhabited in part by people from al-Qayrawān and by Andalusians that rapidly developed its own mode of life outside the world of tribes and where influences coming from the Orient by way of al-Qayrawān and later by way of Córdoba were welcomed and diffused—played an important role in the history of Morocco. The Idrīsids combatted Khārijism and particularly strove to convert the tribes that had remained pagan. The political efforts of the Idrīsids were confined to the western and eastern parts of Morocco and were ephemeral, but their civilizing task bore vast and enduring consequences.

The Rustamid kingdom of Tāhart (787–911). ʿAbd ar-Raḥmān ibn Rustam entrenched himself in the central Maghrib, where he founded the city of Tāhart. In 787–788, by concluding peace with the ʿAbbāsids, he succeeded in consolidating his kingdom, which, despite the presence of an oriental colony, remained Berber. Frequent conflicts among the clans gave the kingdom a turbulent history. Ibn Rustam showed himself to be quite generous toward the adherents of orthodoxy and of other Khārijī sects. The Rustamid state lived in peace with its neighbours; thus Tāhart was able to become the centre of an active caravan trade and to maintain economic relations with the Orient.

The Aghlabids (Banū al-Aghlab) of Ifrīqīyah (800–909). Whereas the greater part of North Africa sought its path in diverse sects or heresies, Ifrīqīyah was actively organizing its Muslim life within the realm of orthodoxy. The Aghlabids gloriously fulfilled the obligations of a holy war by inflicting upon the Christians the conquest of Sicily. They did not penetrate the Maghrib, however; they contented themselves with ruling over old lands of sedentary population, abounding in cities—namely, Tunisia and the eastern fringe of Constantine. These were the only lands populated extensively by the Arabs. Al-Qayrawān, an Islāmic centre, became an active point of religious life and soon had its own learned men, for the most part of the Mālikī juridical school; the city soon extended its intellectual and religious influence over all North Africa and paved the way for the triumph of orthodoxy.

The influences proceeding from Baghdad and the ʿAbbāsid world were felt in all domains. Aghlabid art—which left a major imprint in the great mosque of al-Qayrawān—mingled more and more oriental forms with the inherited traditions of Rome and the Byzantines. Following the example of the ʿAbbāsid caliphs, whose luxury they wanted to imitate, the Aghlabid emirs ordered the

Aghlabid art and architecture

construction, in the suburbs of al-Qayrawān, of veritable governmental cities, where they erected their palaces. Within the culture of Ifrīqīyah, Aghlabid was a bridgehead from the Orient.

North Africa in the 10th century. After two centuries of Islām, North Africa appeared profoundly transformed. Along with substantial strata of the population, Islāmization won to its side the independent tribes themselves—the minor non-Islāmized groups were only exceptions to the rule. A considerable portion of Berbers still belonged to Islāmic sects, especially to Khārijism, but these divergent attempts at religious proselytizing finally redounded to the advantage of orthodoxy.

Arab colonization remained at a low level. Except for Ifrīqīyah, which had absorbed about 100,000 Arabs in race and language, no small "Eastern" groups existed. Virtually the entire region remained inhabited by Berbers. Linguistic Arabization remained confined to four regions: the Tunisian Sāḥil (Sahel); northern Constantine, between the city and the sea; the country between the coast and Tlemcen; and Fez and a part of northern Morocco in the Idrīsid domain. But the region experienced the attraction of two great centres of Muslim civilization: from the 9th century, that of al-Qayrawān; and after the 10th century, that of Córdoba. Large cities adopted and disseminated a civilization that was authentically Islāmic.

Predominance of sedentary population

The sedentary population greatly exceeded the great camel-riding nomads, who were found only in a pre-Sahara or Sahara zone. The horseback-riding nomads migrated toward the steppes or plains zones and to the high plateaus; but they seemed to be in particular search of good land for settling. All the fertile plains and mountains were inhabited by sedentary peasants, clustered in villages that had fields, gardens, and orchards. The greater part of these rustics lived comfortably and were of a pacific disposition.

Social fragmentation permitted only limited conflicts. Large-scale wars and their ruinous aftermaths came only with the founding and actions of the great empires.

The Fāṭimid crisis. Shīʿism, a branch of Islām, claimed to be the legitimatist sect of the religion; its followers—the Shīʿites—believed that the head of the Muslim community could only be a descendant of the Prophet through his daughter Fāṭimah, spouse of ʿAlī, and rejected the claims of the Sunnī majority to orthodoxy. Under the ʿAbbāsids the ʿAlids became an opposition and were persecuted; Shīʿism organized itself into secret sects.

By its doctrine, Shīʿism was opposed to Khārijism; it had not spread into North Africa except in the realm of the Idrīsids, who undoubtedly were practicing only a mitigated form of Shīʿism. But in Little Kabylie, Abū ʿAbd Allāh, a missionary of ʿUbayd Allāh, the Shīʿī pretender, was warmly received by the Kutāmah and their brethren of the Kabyle race. Abū ʿAbd Allāh then led them into battle against the Aghlabids, who represented both Muslim orthodoxy and ʿAbbāsid power. In 910 he entered al-Qayrawān, putting an end to the Aghlabid dynasty, and shortly afterward he installed there his master, ʿUbayd Allāh.

The new Fāṭimid Empire had its base among the Kabylie Ṣanhājah, who constituted the best element in its military forces. But the sovereigns were "orientals" in source and in mentality; their constant ambition was the conquest of the Muslim "Orient." Several attempts against Egypt failed before the conquest was finally accomplished; in 972 the Fāṭimid ruler al-Muʿizz entrenched himself in his new city of Cairo, leaving the government of his North African domain to his Berber lieutenant, Yūsuf Buluggīn ibn Zīrī.

Before emigrating eastward, however, the Fāṭimids needed to develop an African policy. On many occasions they sought to enlarge their western possessions. They succeeded at times in imposing their authority on central Maghrib and on northern Morocco; but they came into conflict with the Zanātah tribes, traditional enemies of the Ṣanhājah. The Zanātah were supported by the Umayyad caliphs of Córdoba, defenders of Muslim orthodoxy, who had dreaded a Fāṭimid attack against the Andalusian coast and who possessed the skill of constantly regrouping in the Maghrib and establishing a protective curtain of Berber allies. The struggle between the Ṣanhājah, fighting for the Fāṭimids, and the Zanātah partisans of the Umayyads of Córdoba was the 100 Years' War of North Africa.

But, even in their own realm, the Fāṭimids were unable to banish orthodoxy; they were little more than a Shīʿite government at the head of a country that remained, for the most part, Sunnī. Furthermore, the Zanātah who joined the Umayyad alliance rallied to the side of the Sunnī.

The thrust of orthodox opinion was felt by the Berber dynasties of the Zīrids and of the Ḥammādids, who occupied the North African domain of the Fāṭimids. They were led to reject obedience to the caliphs of Cairo and to return officially to Sunnah. This religious conflict was bound to entail burdensome economic and social consequences for North Africa.

The Arab invasion of North Africa. The Fāṭimids, more and more absorbed in eastern affairs, did not possess the means for reconquering the country from which they had departed and from which they had always drawn their best military elements. In 1051 they launched an attack against North Africa, using entire Arab tribes then stationed in Upper Egypt, namely, the Banū Hilāl and the Sulaym, which were followed by the Maʿgil. But these Bedouins could not found an Arab dynasty. They overwhelmed the country, however, which they often ravaged, and they imposed tributes on both the cities and the countryside.

The coastal area of Tunisia having been reduced, the Zīrids maintained themselves until 1148. In 1090–91 the Ḥammādids abandoned their capital, Qalʿah, only to regroup themselves at the port of Bejaïa (Bougie).

In the middle of the 12th century the Bedouin inundation had reached the region of Ṣatīf (Sétif) in the West. Then and there the North African dynasties collided with the Arab problem without achieving satisfactory solutions.

Reunification of the Maghrib

The great Moroccan empires. A Berber confederation, which comprised the Lamtūna, the Gudālah, and the Massūfah, occupied Mauritania and the countries south of the "loop" of the Niger; it controlled a part of the caravan routes of the Atlantic Sahara and in the 9th century achieved victories over the black kingdoms. This Mauritanian confederation then experienced an eclipse but revived again in the 11th century. Its chief, Yaḥyā ibn Ibrāhīm, made a pilgrimage to Mecca and brought back a scholar from Morocco, ʿAbd Allāh ibn Yāsīn, to improve his people's rather summary Islām. The missionary attempt of ʿAbd Allāh ibn Yāsīn at first achieved success; but when opposition developed he resorted to force, and was supported by a Ṣanhājah chief, ʿAbd Allāh, whose partisans, called the Almoravids (al-Murābiṭūn, or saints), considered their action a holy war.

The Almoravids, in response to an appeal from their racial brethren of the Tāfīlālt against the Zanātah, who imposed their authority on the Moroccan oases, fled back toward North Africa, whence they had departed a century before; and there they were going to change the destiny of the Muslim West.

The Almoravid (al-Murābiṭūn) empire. The Almoravids, between 1054 and 1059, conquered southern Morocco, where they founded Marrakesh, base of operations for future conquests and thenceforth capital of the Almoravid empire. ʿAbd Allāh ibn Yāsīn had been slain in combat. Yūsuf ibn Tāshufīn (Tāshfīn) became the sole chief of the movement, and from 1062 to 1092 he conquered northern Morocco and the Maghrib as far as Algiers (al-Jazāʾir). For the first time since the Khārijī revolt, the Maghrib territories were united under a single power of Saharan origin but rooted in Morocco. In theory the Almoravids represented a religious reform that was nothing more than an "outbidding" of orthodoxy; they were the champions of Sunnism and of Mālikism (a school of Islāmic law), which had already attained a dominant role in the Maghrib.

Muslim Spain was beginning to knuckle under to the local Christians; the kings from the north were imposing costly protectorates upon the *amīr*s, who had divided

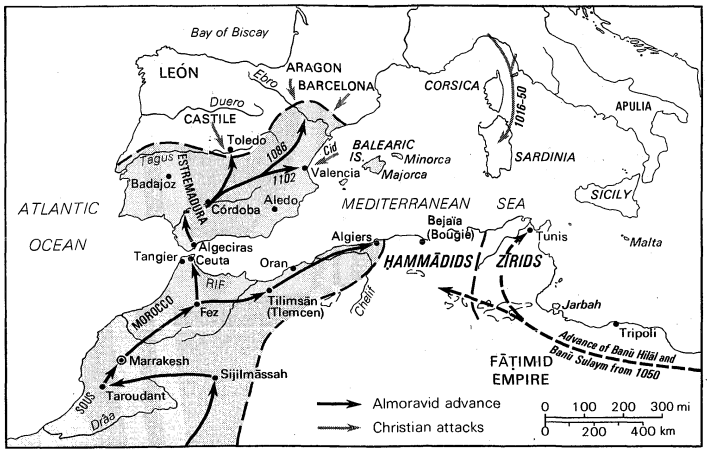


Figure 3: The Almoravid Empire.

among themselves the domain of the Caliphate of Córdoba. In 1085 Alfonso VI of Castile and León entered Toledo and annexed the major portion of what was to constitute the new Castile. The *amīr*s appealed to the Almoravids, and Yūsuf ibn Tāshufīn disembarked with a Berber army and, in 1086, won a victory over Alfonso VI at az-Zallāqah, in Estremadura. In 1068 Tāshufīn tried to check a Castilian thrust into eastern Andalusia; feebly supported by the *amīr*s, he tried unsuccessfully to seize the Christian fortress of Aledo and was obliged to retreat to Morocco. Several of his old allies fell again under Christian vassalage. Having arrived on the scene as the saviour of Spanish Islām, Yūsuf ibn Tāshufīn became its conqueror in 1091 by deposing all the local rulers. The Cid, the famous Spanish captain, halted the Almoravid forces before Valencia until his death in 1099; by 1103 the Almoravids were masters of all of Muslim Spain and several times had triumphed over the Castilians.

Relations with Muslim Spain

From Algiers to Castile, Yūsuf ibn Tāshufīn was the undisputed sovereign of the Muslim West. The Christian reconquest was halted for 20 years. The Almoravids achieved completely the type of domination analyzed subsequently by the Arab historian Ibn Khaldūn (1337–1406)—namely, a clan at the head of an empire, of which it was the vital force and the beneficiary.

A close symbiosis was thenceforth established between the Maghrib and Muslim Spain. Undoubtedly the Spanish Muslims were never thoroughly reconciled to African domination, but they had to bend to the service of their new masters. The great beneficiaries of this political union were the cities in Morocco, which were won over by the Andalusian civilization, of which they became secondary focuses. The Almoravid sultans erected in the Maghrib very beautiful monuments, where Spanish Muslim art reigned unrivalled.

The empire of the Almoravids, founded in Morocco as in Spain on a minority of conquerors, maintained itself under a paradoxical formula—to array Berber armies against the Christians from Spain, but in Morocco to reinforce their own troops with Christian mercenaries. In spite of the minor advances by the Christian forces, Almoravid power maintained itself in the Iberian Peninsula; but after 22 years of fierce fighting in the Maghrib, it succumbed in the face of the revolt of another family of Berber tribes—the Maṣmūdah of the Moroccan Atlas, who themselves fought in the name of religious reform.

The Almoravids had implanted traditions, however, which subsequent dynasties inherited: they paralleled a Berber army staff with a central government of the Hispanic type. But orthodox Islām as well as Mālikī Islām, whose triumph they consolidated, were not transformed and improved by their action—they had Mālikī jurists of an extremely conservative frame of mind, under whose influence the Almoravids enforced in Spain a veritable Muslim inquisition and sought to banish movements that were in quest of genuine spirituality, thus remaining outside what was best in the religious life of their times.

The Almohad revolt

The Almohad (al-Muwaḥḥidūn) empire. The revolt that crushed the Almoravid empire arose in the mountain that borders on the horizon of Marrakesh, the Great Atlas. A Berber from the Atlas, Muḥammad ibn Tūmart, permeated by an intensely religious fervour, was an avowed enemy of Mālikī formalism, which was triumphing under the Almoravids. From the Tunisian port of Mahdīyah, he began a slow "trek" to Morocco; he built around himself a group of faithful disciples and began to preach his own doctrine. He demanded above all a rigorous conception of divine unity, whence was derived the name al-Muwaḥḥidūn (the "unitarians"), which his partisans adopted; at the same time he imposed puritanical reforms in the customs. Upon his return to Marrakesh, he lost no time in coming into conflict with official circles. On the verge of being arrested, he fled into the Atlas, where he raised the standard of rebellion against the Almoravids, whom he regarded as heretics who must be fought with fire and sword by all the tribes of his race—the Maṣmūdah from the mountain. Muḥammad ibn Tūmart preached the Almohad doctrine as well as urging rebellion, which soon encompassed the Anti-Atlas and the Great Atlas.

The Almoravids proved incapable of subduing this revolt, which was shielded by the mountains, but a first thrust by the Almohads against Marrakesh failed. Muḥammad ibn Tūmart died in 1130; his favourite disciple and successor, ʿAbd al-Muʾmin, after a 17-year campaign, finally succeeded in gaining possession of both northern and eastern Morocco. He defeated the Almoravids at Tilimsān (Tlemcen) and returned to Marrakesh, which he took by storm, thus putting an end to Almoravid domination.

The apogee of Berber Islām

ʿAbd al-Muʾmin was bent on expanding his domain. In two campaigns (1151 and 1158–59) he brought all North Africa under his control. This constituted the apogee of Berber Islām—a Berber was ruling with all the dignity of a caliph over all his racial brethren.

Upon returning from his first campaign, however, ʿAbd al-Muʾmin collided in the Ṣatīf region (in Constantine) with a powerful Arab coalition of tribes. He defeated them but found himself incapable of putting an end to the creeping invasion that, for an entire century, was undermining eastern Barbary. He attempted to rally the Arabs for a holy war in Spain and also in order to consolidate his dynasty. But the Arab problem became increasingly critical for his successors. Under the third Almohad ruler, Abū Yūsuf Yaʿqūb al-Manṣūr (reigned 1184–99), Almoravid chiefs from the Balearic Islands, who had disembarked at Bougie in 1184, rallied all the Arabs around them. In spite of vigorous resistance, repeated bloody revolts ravaged the east and the centre of the empire for 20 years. It became necessary to send to Tunis, with sovereign powers, a great Almohad personality, Abū Muḥammad ibn Abī Ḥafṣ, to end the uprising. But deportations of Arab tribes to Morocco served only to open up the whole Barbary to those who proved themselves to be the worst dissidents and malcontents.

By succeeding the Almoravids, the Almohads were obliged to lead the conflict against the Christians and,

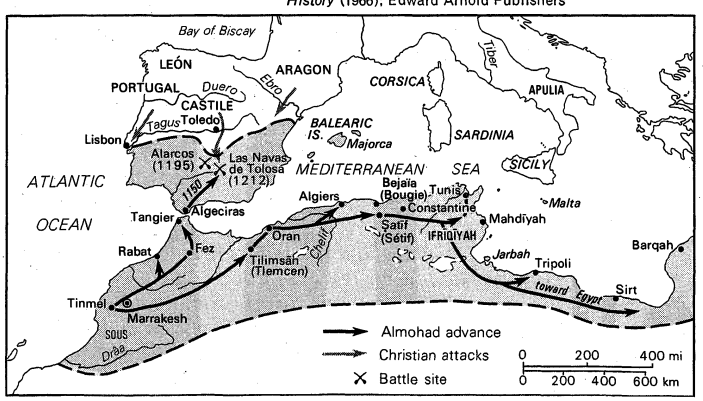

Figure 4: The Almohad Empire.

consequently, become in turn the masters of Muslim Spain. The Christian thrust came to be felt more and more. On several occasions the Almohads dispatched into Andalusia numerous troops from Morocco. Despite the magnitude of this effort, the Christians recorded gradual advances. A great Almohad victory at Alarcos (1195) by Ya'qūb al-Manṣūr led the Christian kings to organize themselves for a crusade. In 1212, at Las Navas de Tolosa, the Almohads were badly beaten. This was followed by a swift decline of the dynasty; and the great Christian reconquest, delayed for a moment, was unloosed after 1230.

The Almohads made no attempt to redress the situation in Spain. Anarchy reigned in Marrakesh, while the Arabs, by that time scattered throughout the plains and plateaus of Barbary, were ruining the country and participating in all the internal conflicts. It was a Berber-Zanātah push, however, by the Banū Marīn, that engaged the last Almohads in battle and in 1269 gained possession of Marrakesh.

Achievements of the Almohads

The efforts of the Almohads had achieved a scope and at times a success that no other dynasty of the Muslim West ever attained. And the Almohad hereditary traditions—their errors as well as their successes—continued to have an impact on the Barbary for several centuries to come. Their reign signalizes the apogee of Berber Islām. But they did not settle the Arab problem, nor were they able to utilize to good advantage the Bedouin tribes, whose expansion toward the West they helped. On the religious plane the Almohad reform movement failed. Still, the Almohads caused Spanish and North African Islām to move in a more liberal milieu, and they favoured a great mystic movement, Ṣūfism, which had penetrated the West before their reign.

Like the Almoravids, they were the devoted servants of Andalusian civilization; by virtue of their struggle against the Christians they gave it a respite of a century. In the arts, these ancient puritans at times invested their mosques with remarkable decorative restraint, which made possible the development of a style of classic purity; and they created some of the most beautiful monuments of Islāmic art.

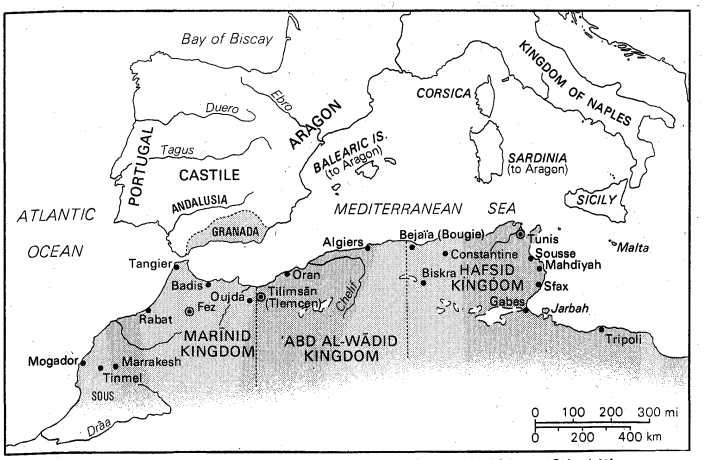

Figure 5: Last medieval dynasties in North Africa, 13th–14th centuries.

FROM THE 13TH CENTURY TO THE BEGINNINGS OF EUROPEAN DOMINATION (1830)

The east medieval dynasties of North Africa (13th–15th centuries). The decline of the Almohad empire can be attributed largely to the mediocrity of its rulers and its government. Anarchy reigned in Marrakesh, where the viziers were fighting each other, making and unmaking sultans amidst the mounting ruins of empire. Three kingdoms divided North Africa among themselves. In Tunisia a kingdom developed under the dynasty of the Ḥafṣids (Banū Ḥafṣ), descendants of the governor, Muḥammad ibn Abī Ḥafs. The founding of the two other kingdoms was due to Zanātah-Berber groups; the 'Abd al-Wādids (Banū 'Abd al-Wād) organized the kingdom of Tilimsān,

The Ḥafṣids, 'Abd al-Wādids, and Marīnids

while the Marīnids first settled in east Morocco, accomplished the conquest of the north, took Fez as their capital, and crushed the last Almohads at Marrakesh (1269).

The Arab problem. These three kingdoms had Berber dynasties at their head; but their politics were constantly dominated by the Arab problem. The Bedouins had by this time invaded all the plains and all the transitional areas; Ma'qil groups had spread throughout the pre-Sahara zone. Although undisciplined and militant, the Arab tribes, from the 13th to the 15th centuries, furnished the bulk of the military forces available to the sultans. Their top leaders joined the government and, through marriage or adoption, were often allied with the royal families. Above all, the Arabs exerted a disastrous influence on the economic life. Even in the most fertile plains they practiced a paradoxical nomadism, into which they dragged along the Berber population, which gradually amalgamated with them.

The Arabs' arrival was frequently accompanied by devastation; in every possible way they undermined the sedentary peasant way of life, which had constituted the strength and good fortune of North Africa in the first centuries of Islām as in ancient times. Roving tents replaced villages and rural hamlets. Gardens and orchards were abandoned while the forests retreated. Only the mountains escaped these disastrous transformations. The ancient and normal economy of North Africa was perverted into swift impoverishment.

It is against this background of progressive ruin, frequently one of disorder, that the histories of the Marīnids, the 'Abd al-Wādids, and the Ḥafṣids are inscribed. The 'Abd al-Wādids were the most feeble in the face of the Arabs. The old towns of the Ḥafṣid kingdom presented a certain counterweight to the Bedouin instability. The Marīnids first adopted a policy of resistance and fell back to the Atlantic Sahara of the Ma'qil tribes, who attempted to sweep back into Atlantic Morocco; but they too were submerged by the Bedouin tidal wave.

Political life. In the 12th–14th centuries no outside danger threatened North Africa, which dwelt in almost complete isolation. Economic relations with Europe remained open, but maritime commerce never flourished. Only the Marīnids intervened overseas; but their incursions into Andalusia, at the end of the 13th century and again in the first half of the 14th, served only to aid in the consolidation of the kingdom of Granada (Arabic, Gharnāṭah) without ever setting back the Christian reconquests.

Conflicts were frequent among the three kingdoms. A stubborn racial hatred was incessantly brewing between the 'Abd al-Wādids and the Marīnids. Many a time the Marīnids invaded the kingdom of Tilimsān. On two occasions the Marīnids, at the apogee of their dynasty, became masters of the central Maghrib for a few years; but they were unable to maintain the conquest of Tunisia. Their grand design to remold the Almohad empire failed, and Morocco remained thenceforth within its present boundaries. In the 15th century the military hegemony passed into the hands of the Ḥafṣids, but they too were no longer able to achieve any enduring conquests.

Religious life. The failure of the Almohad reform consolidated the victory of the Mālikī juridical school. But under this entrenchment of official Islām, religious life became transformed profoundly. Muslim mysticism, or Ṣūfism, which had come from the East and had undergone a rapid development in the 12th century in Muslim Spain, won all North Africa and, after the 13th century, resulted in the formation of numerous brotherhoods: holy personages, both living and dead, and the chiefs of the brotherhoods played the role of intercessors. This development of Ṣūfism of the marabout type (from the Arabic word *murābiṭ*) was in general more intense in the Berber lands than in the "Arabianized" plains.

Influence of Ṣūfism

Intellectual life. Intellectual life remained closely linked with Islām, but it was not locally vigorous; for the most part it consisted of an adoption of the genres and style of the Arab literature of Spain. Jurists and chroniclers contented themselves with compiling the works of their predecessors. All this intellectual activity imported

from Spain thrived in rather restricted circles, mainly those of the large cities and the courts of the rulers. Enlivened for a brief time by the arrival of Andalusian refugees in the 13th century, it was not long before it became a victim of ossification. In this entire process there was one magnificent exception—the historian and statesman Ibn Khaldūn, who composed a veritable sociology of Muslim kingdoms of the Middle Ages.

Artistic life. In the 13th century, artistic workshops modelled after those of Muslim Spain succeeded in taking root in Morocco; thus, at the beginning of the 14th century, Hispano-Moorish architecture and decoration appeared to be fully acclimatized in the large cities of the Maghrib. In Tilimsān and in Fez this art can be distinguished only by slight nuances from that of Granada. In Tunisia, the arrival of Andalusian refugees was reflected in Ḥafṣid art through important and enduring Hispanic contributions, which intermingled with local traditions.

This art underwent no further development, and that of Granada itself declined. But North Africa had nevertheless participated in the classical age of Hispano-Moorish art. Morocco preserved this art faithfully without breathing new life into it.

Ottoman North Africa. The extension of the Ottoman Empire into North Africa in the 16th century was not the result of a planned conquest but is attributed to particular and genuinely African factors. At the beginning of the 16th century the Portuguese had already established themselves in various ports of the Straits of Gibraltar and of northern Morocco and were extending their undertakings to Morocco's Atlantic coast. Meanwhile, the Spaniards launched a vigorous effort on the rest of Barbary and occupied Melilla, Peñon de Velez, Mers-al-Kebir, Oran, and the Peñon of Algiers (an islet in the harbour of Algiers). The ʿAbd al-Wādids and the Ḥafṣids at times were obliged to accept the protectorate of Spain.

Khayr ad-Dīn Barbarossa and his successors

The founding of the regency of Algiers. Five brothers, including ʿArūj and Khayr ad-Dīn (nicknamed "Barbarossa"), who came from the island of Lesbos and engaged in piracy in the neighbouring archipelago, decided around 1505 to transfer their undertakings to the western Mediterranean. They achieved swift success, and the Ḥafṣid sultan permitted them to settle on the island of Jarbah (Djerba). The populations conquered or threatened by the Spaniards appealed to these new leaders. ʿArūj established himself in the city of Algiers, then recaptured Tlemcen from the Spaniards. But the latter reoccupied the city and slew ʿArūj.

The possessions of the pirates were seriously threatened. Barbarossa, in order to procure aid, decided to join his possessions with the Ottoman Empire. He rendered homage to the sultan Selim I, who confirmed him in his command with the title of *beylerbey* and dispatched 6,000 men with artillery to him. Thus, in a quasifortuitous fashion, the greater part of North Africa, after centuries of isolation, again became a dependency of an Eastern caliphate.

Thanks to this support, Barbarossa succeeded in extending his dominion toward the east by occupying Bône (Annaba), Collo, and Constantine. In 1529 he drove the Spaniards from the Peñon of Algiers, and Algiers became the capital of Turkish Algeria. In 1534 Barbarossa gained possession of Tunis. But in the following year the Holy Roman emperor Charles V (Charles I of Spain) recaptured the city, erecting a fortress at La Goulette, and again imposed a protectorate over the Ḥafṣid sovereign (Tunisia came under Turkish control again in 1574); Barbarossa regained his prestige by an incursion into Mahon. The sultan then invited him to Istanbul and appointed him as admiral in chief of the Ottoman fleet (*kapudan paşa*).

From 1536 to 1587 the *beylerbeys* (Barbarossa and his successors), residing in Algiers, governed Turkish North Africa; they piled up success after success over the Spaniards and solidified Ottoman domination. After repelling an attack by the first Saʿdī sultan of southern Morocco, the *beylerbeys* intervened in Morocco, where for a certain time they imposed the Waṭṭāsid ʿAlī Abū Ḥassūn, enemy of the Saʿdī, upon Fez. The conquest of Morocco remained among the designs of the *beylerbeys*, but their struggles against the Spaniards absorbed their best fighting units. In 1587 the title of *beylerbey* was abolished, and the three regencies of Algiers, Tunis, and Tripoli were entrusted to different pashas. Turkish North Africa thus merged into the general organization of the Ottoman Empire.

Ottoman administration of Algeria

The structure of the Algerian state was of a military type; it rested at the same time on local privateers and the Janissaries (the Ottoman standing army), both enjoying considerable privileges. The Janissaries constituted an excellent professional army, stationed in barracks, equipped with modern weapons, and thoroughly trained and endowed with an extraordinary esprit de corps. The army was reinforced by the native cavalry (the *sipāhīs*) and by Kabylie contingents from northern Algeria that were as sturdy as the Janissaries.

Barbary pirates were particularly powerful in the 17th century and made Algiers an important city; it became a great slave market. The city, which boasted a population of about 60,000, welcomed some Moors expelled from Spain—namely, the Tagarins.

Power soon slipped out of the hands of pashas, who now enjoyed only honorary roles; it passed into the hands of military leaders (*aghas*) and later into the hands of the *deys* (Janissary commanders). In the 18th century the *deys*, designated by the militia, maintained control of the province of Algiers and presided over the remnants of the central government. Three provincial regions (the *beyliks*) were headed by officials called *beys*. These provinces were divided into cantons commanded by *qāʾīds* (*caids*) or by *shaykhs*. Thus under a Turkish general staff there were the classic divisions of the country into tribes and segments of tribes. Conflicts with the neighbouring regency of Tunis were numerous, but the regency of Algiers did not succeed in any way in modifying in durable fashion its eastern borders.

Despite the harshness manifested by numerous *deys* of Algiers, the *deys* themselves, who were dependent on the militia, were no more than "despots without freedom." Their governments and they themselves frequently had difficulty in exacting taxes from the interior tribes.

The Ottomans belonged to the Ḥanafī juridical school; they at times constructed new mosques, and they had their own particular judges. But Mālikism remained dominant. There was no disturbing competition between the two juridical orthodox rites; likewise, in both of them doctrine and jurisprudence were stabilized. Maraboutism (a branch of Ṣūfism) had not undergone any change, and in Algeria as in Morocco the brotherhoods remained the most vital element in this North African Islām.

Architecture under Ottoman rule underwent little change but accepted a new type of decor—a floral ornament of oriental origin replaced almost everywhere the classic Hispano-Moorish decoration. The art of Turkish Algeria was thus a hybrid art that preserved some medieval forms.

Ottoman domination in Tunisia

Turkish and Ḥusaynid Tunisia. Ottoman domination in Tunisia was established with finality only after 40 years of warfare against the Spaniards, allied with the last Ḥafṣid sultans.

After 1574, Tunisia, which like Algeria had become an Ottoman province, strove to limit the influence of the Turkish government in the internal affairs of the country while at the same time availing itself of the Turks' protection against the Christian and Algerian enemies. This clever policy of a rather weak country was fairly successful. The regency of Tunis, as well as that of Algiers, was at first controlled by pashas appointed for three years, assisted and often dominated by the militia. After 1520 the militia itself appointed its chief, who took on the title of *dey*, with the pasha now playing, as in Algiers, only an honorary role.

The 17th century was likewise in Tunisia a golden age of privateering. Order prevailed throughout the country thanks to the Turkish garrisons, to biannual military rounds that assured the levying of taxes, and also to the old administrative tradition of the country transmitted by the Ḥafṣids. The arrival of Moors expelled from Spain in

1609–12 enabled the Tunisian economy to record important progress both in agriculture and in the crafts.

From 1640 to 1705 the *beys* (provincial governors) exercised effective power and constituted de facto dynasties. After 1705 the Ḥusaynid *beys* formed a veritable local dynasty recognized by the Turkish government. As far as Europe was concerned, the regencies of Algiers and Tunis came to be regarded more and more as being independent.

Whereas Turkish Algeria was deprived of deep unity and at times proved difficult to govern, Ḥusaynid Tunisia presented the aspect of a real state and was partly opened to European influences. A peace-loving country, its government rejoiced in 1830 when the French conquest of Algiers delivered it from a frequently menacing neighbour.

Sharīfian Morocco. In Morocco, from 1428 to 1459, the Marīnid sultans fell under the protection of a dynasty of viziers—the Banū Waṭṭās (Waṭṭāsids)—who finally replaced them. This new dynasty, feeble from its very beginnings, was obeyed only in parts of northern Morocco and was obliged to confront an occidental world in full flush of renaissance.

The Banū Waṭṭās

Morocco was directly affected by Portuguese incursions against its coasts. From 1415 to 1486 these attacks were directed against the ports of the Straits of Gibraltar and of northern Morocco. But from 1486 to 1550 the Portuguese settled at various points on Morocco's Atlantic coast, from Oum er-Rbia to Sous. In the face of these new problems the Banū Waṭṭās remained peaceful; they took virtually no action against the Portuguese. Resistance to these Christian assaults was offered by local chiefs as well as by the brotherhoods. Ṣūfism had continued to develop in Morocco during the entire Marīnid period and had resulted in the formation of numerous brotherhoods. The latter, however, while often enjoying the role of arbiters among the tribes, possessed no political powers. The Christian incursions against the Moroccan coasts and the attempts at penetration into southern Morocco impelled the religious leaders to become the instigators and, at times, the leaders of a holy war. From the 15th century on, marabouts (*murābitūn*; popular Ṣūfī religious leaders) became a political force, often challenging the power of the sultans.

Furthermore, the actions of the Arabs culminated in disastrous consequences; the country was impoverished, and, amidst growing distress, anarchy gained the upper hand. From the time of the Marīnids, the Atlas region and a substantial portion of the Sahara confines had evaded the authority of the sultans. Morocco split into two zones: the Bled Makhzen (land under government control) and the Bled Siba (land of dissidence), where the mountain people organized their own lives while limiting contact with the cities and the plains.

The Banū Waṭṭās struggled for 30 years against the increasing thrust of a Marabout dynasty—that of the Saʿdī *sharīf*s, who finally seized the city of Fez in 1548. A Waṭṭāsid restoration supported by the Turks in Algiers was defeated in 1554.

Saʿdī Morocco (1548–1659). The Saʿdīs had settled since the 13th century in the oasis of the Drâa. Until the 16th century they played no political role in extreme southern Morocco. After the founding of Agadir, the Portuguese attempted to develop an aggressive policy in the Sous region; the marabouts of the Sous resisted and designated a Saʿdī as leader in the holy war, but without notable results. The Saʿdī, however, were summoned against the tribes that were fighting the Portuguese of Safi. Giving priority to their personal ambitions, the Saʿdī took advantage of this situation to conquer southern Morocco and Marrakesh and then came into conflict with the Banū Waṭṭās. The Saʿdī gained new prestige by capturing the Portuguese position at Agadir in 1541, but they needed ten more years to conquer the northern part of the country and to become the sultans of Morocco.

The Saʿdī had risen out of the marabout crisis. But their struggle against the Christians had frequently been no more than a pretext for the conquest of Morocco. Their dynasty had no native support apart from some contingents from the Sous and most often had to use Arab militias.

Saʿdī foreign policy

The Saʿdī foreign policy was dominated by a fear of the Turkish peril; thus, reluctantly and with meagre results, they allied themselves with the Spaniards in Oran, who were battling against the Turks of Algiers. One Saʿdī sultan, dethroned by two of his uncles, had taken refuge in Portugal. The youthful and visionary Portuguese king Don Sebastian (ruled 1557–78) attempted to restore him to power in Morocco, but both he and his protégé were defeated and slain in the "Battle of the Three Kings" (1578). This Saʿdī victory created the impression that Morocco constituted a formidable force by virtue of having defeated in a single encounter a European power. The sultan Aḥmad al-Manṣūr (reigned 1578–1603) adroitly capitalized on this illusion. Aḥmad al-Manṣūr succeeded in reinforcing his army with mercenary Turk and Kabylie units, as well as with emigrants from Andalusia. He had a luxurious palace erected for himself at Marrakesh, called the "Badi," where he received European ambassadors with great pomp. His only expedition abroad was undertaken against a Muslim country, the Sudan, where his troops, largely Andalusian, captured Timbuktu, from which he drew gold and numerous slaves. He procured financial resources by any means within his power. The cultivation of sugarcane and the trade in sugar became his monopoly. His fiscal mismanagement, however, provoked revolts.

Though al-Manṣūr maintained friendly relations with the great European powers, which permitted Morocco to carry on a minimum of foreign trade, he did not open the country to European influences. He jealously guarded his insulation from the Christian world. Having risen out of the marabout crisis, the Saʿdī were destined to die of it. Following the death of al-Manṣūr in 1603, the Saʿdī princes began to dispute among themselves over authority; thenceforth the dynasty experienced a rapid decline. Throughout Morocco, marabout forces arose and fought each other in order to aggrandize their domain. One of them, the marabouts of Dila, seemed for a moment on the verge of restoring the unity of Morocco. But it was a second Sharīfian dynasty, that of the ʿAlawīs, that ended this anarchic fragmentation and succeeded in reuniting under its authority—actual or theoretic—the Moroccan lands.

Morocco under the ʿAlawī (or Filālī) sultans (1689–1830). The ʿAlawī *sharīf*s had for a long time been established in the Tāfīlālt, and with the decline of Saʿdī power they became the political leaders of the oasis. Mawlāy ar-Rashīd gained possession of Fez (1666), conquered all the local rulers who were disputing among themselves over the Moroccan lands, and restored the political unity of the country. He died accidentally after having consolidated his task of reorganization. Nevertheless, the country remained in a state of turbulence. His brother and successor, Mawlāy Ismāʿīl (1672–1727), had to assert his authority by force; with a militia of black slaves and Arab troops, he attempted a veritable military occupation of his own country through garrisons stationed in fortresses. Despite his efforts, Mawlāy Ismāʿīl proved incapable of subjugating effectively mountainous Morocco, which remained in a state of dissidence. He attempted incursions into Tlemcen in vain, but he did succeed in recovering some of the coastal areas still occupied by the Christians—namely, Maʿmūrah, Tangier, and Larache.

Reunification of Morocco

The crushing tax burden imposed by Mawlāy Ismāʿīl, who launched an ambitious military effort and built at Meknès immense palaces, led to numerous revolts among the tribes. Upon his death the country found itself exhausted and prey to sanguinary anarchy for a period of 30 years.

Sīdī Muḥammad ibn ʿAbd Allāh (1757–90) restored order in the country; with him the ʿAlawī dynasty confined its ambitions and defined its policy. The rulers maintained a minimum of business contacts and diplomatic relations with Europe, with the rest of North Africa, and with the Orient.

In the interior the sultans strove to check, but could not

prevent, the incursions of Berber tribes of the Central Atlas and Moyen Atlas into the Atlantic plains. Revolts were common, even in the area under subjection, and the sultans often had to undertake military expeditions in order to assure the levying of taxes.

These events were but the continuation of a series of expedients dating back to the Middle Ages. Despite the goodwill and the application by the sultans of the 18th century and the early 19th century, Morocco proved incapable of taking advantage of its last period of isolation to bring about its own reform.

Thus in Sharīfian Morocco, as in Turkish Algeria and Tunisia, there was no renaissance, no manifestation of a firm will or of clearcut evolution and progress. Revolutionary and imperialistic wars absorbed all the energies of Europe and paradoxically prolonged this North African status of isolation. Transformations could no longer occur except through foreign influences. The seizure of Algiers by the French in 1830 opened a new era; however, Europe's interventions were to be felt in the three countries at different dates and as a result of diverse methods.

Unity and diversity in Muslim North Africa. Within the scope of this article it is helpful to look back over these 11 centuries of Muslim history in North Africa by investigating in what epochs and to what degree the regions that constituted Tunisia, Algeria, and Morocco experienced political unity and a unity of civilization, or alternatively to what extent they followed their autonomous paths in these domains.

Eleven centuries of Muslim history in North Africa

In the 8th and 9th centuries, after the resistance that Barbary had offered against its conquerors (particularly in its eastern portion), the region rallied to Islām and organized its Muslim way of living. This was done either through the path of orthodoxy or through the diverse sects of Khārijism (even in its particular heresies). Except for the Aghlabid *amīr*, a theoretical vassal of Baghdad, this evolution proceeded within an entirely independent policy and even through fragmentation; but this splintering and these differences of detail must not conceal the profound unity of this great movement toward the organization and elaboration of North African Islām.

The transformation resulting from the efforts made during the 5th and 9th centuries made possible the achievements wrought in the 10th, 11th, and 12th centuries by the great African empires. The first among those—that of the Fāṭimids—was, from the Barbary point of view, an inconclusive endeavour, deficient in the long run. It ran contrary to the religious evolution of the country and devoted its utmost effort toward the conquest of Egypt, where the dynasty emigrated in 972 and became Eastern in fact, which it had been at heart previously.

To the contrary, the two great Moroccan dynasties—the Almoravids and the Almohads—laboured at the same time for the political and cultural unity of the Barbary. The Almoravids, after unifying the Moroccan lands, conquered the Maghrib. The Almohads subjected all of North Africa to their control, thus attaining the apogee of Berber Islām. Because they were also the masters of Muslim Spain, the Almoravids and the Almohads were able to further successfully the cultural unity of the Muslim West. Thus they became the *serviteurs* of the Andalusian civilization, which prevailed in the cities of the Maghrib and in Tunisia mingled with the local traditions. The political apogee of the Barbary was accompanied by the unification of its culture.

The disintegration of the Almohad empire served as the foundation, on the political level, for the tripartite division of North Africa; but it did not undermine the unity of its civilization of Spanish origin. In Tunisia the Hispanic influences were never greater than under the Ḥafṣids (13th, 14th, and 15th centuries). To this unity of Muslim culture, however, a common misfortune was added; in the three kingdoms of Tunis, Tlemcen, and Fez, the destructive depredations of the Arabs undermined the power of the dynasties and ruined the traditional economy of the country, which thenceforth became impoverished.

The beginnings of modern times, which in Europe were distinguished by profound and fruitful transformations, failed to inspire North Africa with the desire to change. The Portuguese ventures into Morocco served only to let loose a prolonged marabout crisis, which became deeply xenophobic in character. Under the Sharīfian dynasties, Morocco dwelt in isolation, adamant against innovations; it continued on its traditional path, which was prolonged until the 20th century—a paradoxical "Middle Ages."

It was a fortuitous fact—the policy of a family of pirates who had become the leaders of a holy war—that linked Algeria and Tunisia with the Ottoman Empire, which modified their civilization through a wave of Eastern influences. The political and cultural unity of the Barbary was thenceforth shattered, and the ossification of civilization in the three countries served only to consecrate the division. (H.-L.-É.T.)

III. North Africa since 1830

The restoration of European rule in North Africa was initiated in 1830 by the French conquest of Algiers city and followed in time by the occupation of the hinterland. In 1881 the French occupied Tunisia also, and in 1911 the Italians expelled the Turkish government from Libya, following this up by the progressive conquest of the Arab inhabitants. The process was completed by the Franco-Spanish occupation of Morocco, which followed the signing of the Treaty of Fès in 1912. The regimes of European colonial type that followed created entirely new conditions and by degrees gave birth to modern nationalist movements. Strengthened by the circumstances of World War II, these resulted in the establishment of Libya as an independent state in December 1951 and the independence of Morocco and Tunisia in 1956. In 1960 a new state, Mauritania, was created to the south of Morocco; and, last of all, in 1962 Algeria achieved its independence.

ALGERIA

The period of the French conquest. The French conquest of the regency of Algiers was not the result of a clearly thought out plan. Too little was known about the regency's internal constitution to have permitted such a thing, even if British opposition to the installation in North Africa of a potentially dangerous rival could have been ignored.

Beginnings of French interference

In 1830, when a blockade of Algiers imposed by the French for an alleged insult to the French consul had proved ineffective, the French government decided on a full-scale attack on the city of Algiers. For the benefit of the Arab inhabitants a proclamation was prepared in Arabic and published in French in *Le Moniteur*, stating that the French were coming not to take permanent possession of the city but to expel the Turkish foreigners and make the Arabs masters of their own country; as issued later in Algiers, however, it simply stated that the French were coming to make war on the rulers and not on the people of the country. In addressing the European powers, the French gave as their motive the intention of ending a piratical regime that practiced the enslavement of Europeans. In fact, however, the possession of European slaves had been limited from the end of the 18th century to the state, from which they could be hired for domestic purposes. In any case, the decay of privateering and a British bombardment of Algiers in 1816 had already reduced their number to virtually nothing. In fact, the French decision had been determined by the desire to gratify the officer corps by a military success and thereby to strengthen the restoration regime of Charles X.

An attempt at mediation by the nominally suzerain Ottoman power was brought to naught by a French interception of the Turkish envoy. The collapse of privateering had by then left the regency a mere shadow of its former self and had caused the *dey*'s government to provoke the Arab and Berber population by increasing taxation to make up for the lost income. In consequence, the landing at Sidi Ferruj, 16 miles west of Algiers, on July 5, 1830, of a force of 37,000 French troops led to the capitulation of the *dey*'s government within three weeks. The *dey* was banished, together with the majority of the Turkish officials and volunteer forces. Within a

fortnight of this success, the regime of Charles X was itself overthrown and succeeded by that of Louis-Philippe, which, in the circumstances, was as unwilling as its predecessor had been to define future North African policy. But this did not prevent the new minister of defense, himself a general, from instructing the new commander in chief, Gen. Bertrand Clauzel, to favour colonization. This was an example of the determining role French army officers played in deciding French action in Algeria during the next 40 years.

Left without any clear guidance from Paris, Clauzel decided to exercise control in Algeria through princes of the ruling family in Tunisia, whose ruler was allowed to understand that the whole regency might finally be entrusted to him. This prospect was gratifying to the Tunisian rulers, over whom the Algerian *deys* had made several efforts to establish their supremacy. The Tunisians briefly occupied Oran in 1830 but were unable to hold it and withdrew.

After only five months, Clauzel himself was withdrawn and was succeeded from February to December 1831 by Gen. Pierre Berthezène. Ordered to suspend the incipient colonization, of which he himself disapproved, Berthezène rapidly became unpopular with would-be settlers and the many speculators. He was succeeded by the Duke of Rovigo, who had been chief of police under Napoleon. After Rovigo's withdrawal 14 months later, because of illness, his drastic methods were criticized by a commission of inquiry, which charged some of the occupiers with barbarity. The commissioners concluded, however, that the regency of Algiers for reasons of utility, expediency, and necessity, should be definitely occupied by France. Accordingly, the officer responsible for the administration was known as "governor general of the French possessions in Africa" until 1845, when Gen. T.-R. Bugeaud, after achieving the conquest of the greater part of the country, was named "governor general of Algeria" (the latter name was a novelty introduced to describe the newly acquired territory).

Before this occurred, however, another ten years were to pass, during which the declared aim was to restrict French direct rule to the coastal area while authority inland was left in the hand of Algerians who, it was hoped, would cooperate with the invaders. In the east the outstanding opponent of the French was the *bey* Ahmad of Constantine (Qusṭanṭinah), where a first attempt to capture the city in 1836 failed disastrously. Resistance in the west, organized by the famous Abdelkader (ʿAbd al-Qādir ibn Muḥyī ad-Dīn), developed a more national character and lasted 17 years.

Resistance to the French

Abdelkader, who was a *sharīf*, had been elected in 1832 on the plain outside his native town of Mascara as leader in the struggle against the Christian invasion and greeted by popular acclaim with the title of *amīr*. In this capacity he regarded himself as *khalīfah*, or representative, of the Moroccan sultan Abdurrahman. In 1833 the French, hoping to use Abdelkader as French agent, signed with him a convention that recognized his local position. Four years later the French government made a last attempt to limit its direct control, at least in western and central Algeria, to the coastal areas. General Bugeaud, now commanding in the Oran area, accordingly concluded with Abdelkader the Treaty of Tafna, which allotted Abdelkader Tlemcen and the whole of the western province except for the cities and environs of Oran, Arzew, and Mostaganem. In central Algeria, Abdelkader was ceded Titteri, while the French were limited to the coast and the Mitija plain, and were excluded from Constantine.

The French governor general, the Comte de Damrémont, disapproved of the arrangements and made a second attack on Constantine; this proved successful, though at the cost of his own life. His successor soon came into conflict with Abdelkader, who for the moment, however, was fully occupied in establishing an orderly form of government in the West.

In 1839, however, Abdelkader denounced with some reason French violation of the Treaty of Tafna and then attacked the Mitija, destroying the settlers' farms, until Bugeaud, converted to the idea of total conquest, was given command and supplied with adequate resources from France. A six years' struggle followed, involving the wholesale destruction of Algerian villages, the spreading of desolation far and wide, and the death by hunger of thousands of refugees.

Total conquest of Algeria

In 1844 Abdelkader was forced westward into Moroccan territory, whereupon the sultan Abdurrahman, alarmed at the French advance, sent an army to the frontier. This was ignominiously defeated by Bugeaud on August 14 at Isly near Oujda. Meanwhile, French ships bombarded the Moroccan ports of Tangier and Mogador. The sultan was thus forced to agree to expel Abdelkader or hand him over to the French.

Abdelkader nevertheless fought on for more than two years. In 1847 Bugeaud, now promoted to a marshal of France and designated governor general of Algeria, decided to complete the conquest of the Kabylie Berber area, employing the same methods of devastation as in the west. Though successful, he was forced to resign for having acted without the sanction of the minister of war. His place was taken by the Duc d'Aumale, son of King Louis-Philippe. During the four months during which d'Aumale held the post, the sultan's troops expelled Abdelkader, who had again taken refuge in Morocco, and who finally surrendered with the promise that he would be allowed to live in the Orient.

In spite of this, Abdelkader was detained, first at Pau and then in the château of Amboise, until released by Napoleon III. He was then permitted to live in Damascus, where he saved the lives of a great many Christians during the massacres of 1860. Though Abdelkader's exile marked the end of what may be called resistance on a national scale, smaller operations continued, such as the occupation of the Saharan oases (Zaatcha in 1849, Nara in 1850, and Wargla in 1852). The eastern Kabylie country was only subdued in 1857, while the final great Kabylie rising of Moqrani was suppressed in 1871. The Saharan regions of Touat and Gourara, hitherto Moroccan spheres of influence, were occupied in 1900; the Tindouf area, previously regarded as Moroccan rather than Algerian, was only attached to the latter region after the French occupation of the Anti-Atlas in 1934.

French Algeria. The French thus carried on the policy, initiated by the Turks, of making Algeria the base of their rule in North Africa and of increasing their territory by bringing under Algerian control areas that had hitherto looked rather to the older established regimes of Tunis or Morocco both for spiritual leadership and for defense against outside attack. The final outcome of this process was to be the creation of what was known as French Algeria.

Administration. For the French officer corps the preservation of the conquest became a vocation and a point of honour. In the political field their influence was represented by the governor general, almost invariably drawn until 1880 from the armed forces, and by the Bureaux Arabes, whose members (officers with an intimate knowledge of local affairs and of the language of the people), having no direct financial interest, often sympathized with the outlook of the people they administered rather than with the demands of the European colonists.

European–Muslim relations. A large-scale confiscation of cultivable land, following the crushing of resistance, made colonization possible. By 1880 the coastal area had become a predominantly Christian area of mixed European origin (mainly Spanish in and around Oran; French, Italian, and Maltese in the centre and east). For long the presence of the non-French settlers was officially regarded with alarm; but, with time, the influence of French education, of the Muslim environment, and of the Algerian climate created in the non-French a European-Algerian, subnational sentiment. This would probably have resulted, in time, in a movement to create an independent state if Algeria had been situated farther away from Paris and if the inhabitants had not feared the potential strength of the Muslim majority. As it was, however, each weakening, even temporary, of the authority of the French government led to the

Influence of European settlers

increased influence of the settlers and to a renewed rising and suppression of the Muslims.

On the overthrow of Louis-Philippe's regime in 1848, the settlers succeeded in forcing the newly appointed governor general, Louis-Eugène Cavaignac, to return immediately to France. By the time he was able to come back, a few weeks later, the settlers had achieved their aim of having the territory declared French and the three former Turkish provinces converted into departments on the French model, while colonization was developed with renewed energy.

On the establishment of the French Empire in 1852, responsibility for Algeria was at first transferred from Algiers to a minister in Paris. Very soon, however, the emperor, having formed his own opinion on the problem, reversed this disposition. While expressing the hope that an increased number of settlers would forever keep Algeria French, he also declared that France's first duty was to the 3,000,000 Arabs. He envisaged the Muslims as devoting themselves to agriculture, while the colonists occupied themselves with industry and matters requiring technical skill. With considerable accuracy he declared that Algeria was "not a French province but an Arab country, a European colony, and a French camp."

This attitude aroused certain hopes in Arab minds, but they were destroyed by the Emperor's downfall in 1870. This was followed by a settler demonstration in which the new governor general, Walsin Esterhazy, was compelled to re-embark for France the day after he arrived, and authority was for six months exercised by settler committees.

Meanwhile, the abortive hopes that the Emperor's ideas had raised, followed by a French defeat in the Franco-Prussian war, resulted in the last great Kabylie rising (1871) under Muḥammad al-Moqrani. Its suppression was followed by the sequestration of another 11,000,000 acres of land and the imposition of an indemnity of 36,500,000 francs; these measures together provided land for refugees from Alsace and capital with which to exploit the land.

Domination by European population

During the 50 years that followed, the European population at last felt free to establish over the country and its native inhabitants a political, economic, and social domination, which it believed would last indefinitely. The Muslims had learned that medieval religious faith and unlimited courage could not prevail against modern education and arms. At the same time, new communications, the installation of hospitals and medical services, and modern education—dispensed to a very limited extent and in French to the Muslims, while generally available to the Europeans—created a minority of Algerians of a new type.

For Algerians, service in the army and in the factories of France during World War I was another eye-opening experience. When peace returned, some 70,000 Algerians remained in France, and by living with extreme economy they were able to support many thousands of their relations in Algeria.

The French believed that the Algerians did not want independence but to merge themselves in France. In thinking thus, the French were fixing their gaze on the tiny minority who had received a French education and who saw the salvation of the mass of their compatriots in the extension to them of a similar assimilation. But the French ignored two other groups. Algerians mainly in France, under the leadership of Messali Hajj, had formed an Algerian and nationalist movement that, from 1936, took the title of the Parti Populaire Algérien. In Algeria itself there came into being another movement, led by a man of Muslim religious learning, Shaykh Abdulhamid ben Badis; this was the Association of Algerian Ulama, which founded schools that gave education in Arabic.

The government in Paris was well disposed toward the assimilationist movement, but when in 1937 it took tentative steps in that direction the opposition of the settlers brought its efforts to nothing.

World War II and the independence movement. World War II brought with it the collapse of France and, in 1942, the Anglo-American occupation of North Africa. The occupation forces were to some extent automatically agents of emancipation, while broadcasts in Arabic both from Allied and Axis stations began to compete with promises of a brave new world for formerly subject peoples. The effect was heightened by the promise of the emancipation of Syria and Lebanon, given in June 1941 by the Free French and backed by the British authorities in the Middle East.

The Algerian Manifesto

In December 1942 the former assimilationist leader Ferhat Abbas drafted an Algerian Manifesto, for presentation to the Allied as well as to French authorities, seeking recognition of the political autonomy of Algeria as a sovereign nation. In December 1943 Gen. Charles de Gaulle declared that, because of loyalty shown, France was under an obligation to the Muslims of North Africa, and in March 1944 French citizenship was extended to certain categories of Muslims. This was by then, however, far from enough to satisfy Muslim opinion. A display of Algerian nationalist flags at Sétif in May 1945 led to an unorganized rising, in which 84 European settlers were massacred. The suppression that followed was indiscriminate, and it resulted, according to a French committee of inquiry, in not less than 1,800 deaths.

On September 20, 1947, a statute of Algeria was finally voted by the French Assembly, defining the country as "a group of departments endowed with a civic personality, financial autonomy, and a special organization." The statute created an Algerian Assembly of 120 deputies, elected in equal numbers by two electoral colleges—one composed of 370,000 Europeans and 60,000 assimilated Muslims and the other of 1,300,000 Muslims. After lengthy debates the statute was passed by a small majority, with 15 Muslim members abstaining. Muslims were at last to be considered as full French citizens with the right to keep their personal Qur'ānic status and were granted the right to work in France without further formalities. The military territories of the south were to be abolished, and Arabic was to be taught in schools at all levels.

Unfortunately, the implementation of this law was poor and the subsequent elections were "managed" by the administration, while most of the reforms laid down by the statute remained a dead letter. In spite of this, Algeria remained quiet. In reality, the principal change had been the fact that some 350,000 Algerian workers were able to establish themselves in France and, by living with extreme frugality, to remit money annually to their families in Algeria.

The Algerian War. Signs of approaching storm, however, were only too apparent. In 1950 the French police discovered that a robbery from the Oran post office had been the work of the Organisation Secrète, an offshoot of the party led by Messali Hajj, which had now taken the name of the Movement for the Triumph of Democratic Liberties (MTLD). The leader in the robbery was Aḥmad ben Bella, who had been highly commended during the fighting in Italy with the Free French. In 1952 Ferhat Abbas, when tried for a trivial offense, was defended by three lawyers—one Muslim, one Christian, and one Jewish; these combined to deliver an impressive attack on the administration. About the same time, Aḥmad Mezerna, acting head of the MTLD, took the unprecedented step of personally seeking support in Egypt. The head of the Association of Algerian Ulama toured the Arab East and secured scholarships from the Arab governments for Algerians who wished to pursue their studies in Arabic.

The Front of National Liberation

The storm burst on the night of October 31, 1954. It was organized by a few young men who, dissatisfied with Messali Hajj's leadership, had decided that justice for Algeria could only be realized by the stimulus of open rebellion. The movement took the title of the Front of National Liberation (FLN) and issued a leaflet stating that the aim was the restoration of a sovereign Algerian state. It advocated social democracy within an Islāmic framework and citizenship for any resident in Algeria, with the same rights and duties as other citizens. A preamble recognized that Algeria had fallen behind the other Arab states in emancipating itself socially and nationally, but it claimed that this could be remedied by a difficult and prolonged struggle. Two weapons would be

used—guerrilla warfare at home and diplomatic activity abroad, particularly at the UN, where the support of the Arab countries and other states would be invaluable. The FLN military objective was to make the position of the administration untenable by sudden raids, ambushes, and sabotage.

Though the first outbreak, which occurred in the region of Batna and the Aurès, was ineffective militarily, it led to the arrest of some 2,000 members of the MTLD, who had not in fact been in favour of open rebellion. In mid-February 1955 Jacques Soustelle arrived in Algiers as governor general; in June he announced a new plan, which, however, was to prove too little and too late. On August 20 a new rising at Aïn Abid, about 27 miles from Constantine, and at the mine of al-Alia near Philippeville (now Skikda) degenerated into another massacre of Europeans, followed by summary executions of Muslims. In January 1956 the electoral victory of the Republican Front in France and the premiership of Guy Mollet led to the appointment of the moderate and experienced Gen. Georges Catroux as governor general. When Mollet personally visited Algiers, however, to prepare the way for the new governor general, he was bombarded by the European populace with tomatoes. Yielding to this pressure, he allowed Catroux to withdraw and named in his place the pugnacious Socialist Robert Lacoste as resident minister. Lacoste's policy was described as pacification, but in fact it relied on forcible suppression.

French forces sent to Algeria

A French army of 500,000 men was sent to Algeria to counter the control that the rebels had managed to establish in the more out of the way portions of the country while collecting money for their cause and taking reprisals against fellow Muslims who would not cooperate with them. By May the rebels had won over the majority of previously noncommitted political leaders; and Ferhat Abbas and Tawfiq al-Madani, of the Association of Algerian Ulama, had joined FLN leaders in Cairo.

Externally, the event of 1956 was the French decision to grant full independence to Morocco and Tunisia and to concentrate on retaining "French Algeria." The rulers of the newly independent states—the Moroccan sultan and Premier Habib Bourguiba of Tunisia—hoping also to find an acceptable solution to the Algerian problem, prepared to hold a meeting in Tunis with five principal Algerian leaders who had been guests of the sultan in Rabat. French intelligence officers, however, managed to divert to Algiers the plane chartered by the Moroccan government to fly the Algerians to Tunis. The Algerian leaders were then arrested and confined in prison in France for the next six years. Far from decapitating the rising, this act provoked an outbreak in Meknès that cost the lives of 40 French settlers before the newly independent Moroccan government could restore order.

The next year, 1957, saw a rebel attempt to paralyze the administration of Algiers by terrorism. This was defeated by French parachute troops, who used torture to extract information. The French also cut Algeria off from independent Tunisia and Morocco by barbed wire fences, illuminated at night by searchlights; this separated the resistance bands within Algeria from some 30,000 Algerian armed forces who occupied positions between the fortified fences and the actual frontiers of Tunisia and Morocco, from which they drew supplies. These troops had the advantage of a friendly people and government as a base; they could not, however, penetrate into Algeria proper but could only harass the French line.

Provoked by these assaults, the French air force in February 1958 bombed the Tunisian frontier village of Sāqiyat Sīdī Yūsuf, killing a number of civilians, including children from the local school. This led to an Anglo-American mediation mission, which negotiated the withdrawal of French troops from various districts of Tunisia and their concentration in the naval base of Bizerte (Banzart).

From April 27 to 30 a meeting—the Maghrib Unity Congress—was held in Tangier under the auspices of the Moroccan and Tunisian nationalist parties and the Algerian FLN. This recommended the establishment of an Algerian government in exile and of a permanent secretariat to promote Maghrib unity. The latter proposition had little permanent result, but a government—the Provisional Government of the Algerian Republic (GPRA)—was set up on September 19.

By then, however, conditions had been radically changed by events of May 13, 1958; these began as a traditional settler rising—thousands of European Algerians sacked the offices of the governor general and, with the tacit approval of the army officers, called for the integration of Algeria with France and for the return of de Gaulle to power. The Muslims were clearly taken aback, but soon there was a relatively friendly mixing of Muslim demonstrators with the Europeans and a general hope of better times to come. In the crisis caused by this rising, de Gaulle returned to power in France.

Changes under de Gaulle

On June 4 de Gaulle visited Algiers amid scenes of great enthusiasm. He gave no clear indication, however, that he shared the settlers' enthusiasm for integration, which, in their minds, meant the submergence of the Algerians in an enlarged France. All Muslims, however, were now granted the full rights of French citizenship, and on October 30 de Gaulle announced in Constantine a plan to provide adequate schools and medical services for the Muslim population, to create employment for the vastly increasing Muslim masses, and to introduce Muslims into the higher ranks of the public services.

The European population was troubled by the lack of insistence on the theme of integration. This came to a head in September 1959, when de Gaulle, in anticipation of the opening of the UN General Assembly, declared publicly that the Algerians had the right to determine their own future. From this time it gradually became clear that while he would retain as close links between France and Algeria as he believed possible he was nevertheless prepared to go even to the length of granting independence if peace could not be secured on any other terms. The agitation of the Europeans now became extreme.

On January 24, 1960, a fresh settler rising collapsed after nine days from lack of military support. A year later, however, as the prospect of negotiations with the GPRA became more probable, there was another rising, this time organized by four generals, of whom two—Raoul Salan and Maurice Challe—had previously been commanders in chief in Algeria. De Gaulle remained unshaken, and the rising, lacking substantial support from the army, collapsed after only three days.

It became clear that the Armée d'Afrique, which had once created French Algeria, was no longer going to receive government support to fight for it. In fact, in May 1961, negotiations were opened in France with representatives of the GPRA. This body had by now long been recognized by the Arab and Communist states, from which it received aid, though it had never been able to establish itself on Algerian soil. Negotiations were broken off in July, after which the veteran Ferhat Abbas was replaced as premier by the much younger Yusuf ben Khedda. Settler opposition was meanwhile organized by a body calling itself the Organisation Armée Secrète (OAS); this began to employ terrorism as brutal as that of the rebels had sometimes been.

On March 8, 1962, negotiations were resumed, and on the 18th agreement was finally reached. Algeria would thenceforth be independent, provided only that a referendum, to be held in Algeria by a provisional government, confirmed the desire for it. In case of approval, French aid would continue; Europeans could depart, remain as foreigners, or take Algerian citizenship, as they preferred. This announcement produced a violent outburst of terrorism and attempted resistance by the OAS; but in May the terror subsided as its futility became obvious. On July 1, 1962, the referendum recorded some 6,000,000 votes in favour and only 16,000 against. After three days of unbounded Muslim rejoicing, the GPRA entered Algiers in triumph, while the departure of the Europeans, which had long since begun, assumed mass proportions.

Independence for Algeria

Meanwhile, however, the GPRA itself was torn by dissensions, and its authority was challenged by Col. Houari Boumedienne, who commanded the Algerian army on

the Tunisian side of the frontier fences. In this he was supported, after some hesitation, by Ben Bella, now released from captivity in France, and by Muḥammad Khider, secretary general of the FLN. It was not until three months later that the small-scale civil war that ensued was finally settled by the recognition of Ben Bella as premier, Boumedienne as chief of staff, and Khider as head of the party organization. By then not more than a tenth of the former 900,000 Europeans remained in the country; and the abandoned houses and apartments in the towns were rapidly taken over by Algerians from the outer suburbs.

Independent Algeria (since 1962). The Europeans who had abandoned the country included the overwhelming majority of senior administrators and managerial and technical experts. The chief exception was a group of some 10,000 French schoolteachers who remained, with great courage, often in very isolated posts.

During the six previous years some 10,000 French officers and men and possibly as many as 250,000 Muslims had lost their lives in the fighting; dozens of villages had been destroyed and 2,000,000 peasants had been moved to new sites. Nevertheless, many public services such as the post office, the railways, and the electricity supply continued to work remarkably well. On farms and in factories, however, management had largely vanished, though the workers were still there. Production fell while unemployment and underemployment reached extreme levels. Workers were able to carry out routine tasks, but matters of planning, purchasing, and marketing presented enormous problems.

Ben Bella's popularity, his style of simple living, and his courage were great assets, but his personal style of government and his reckless promises of support for revolutionary movements with which Algeria was not directly concerned were not conducive to orderly administration. The problem was complicated by the large number of leaders who had distinguished themselves in the revolutionary struggle but who now found themselves offered only posts they felt were far below their merits.

On the other hand, there were two factors of great assistance: one was the revenue from the very extensive oil fields and from the natural gas that had recently been discovered and exploited in the Sahara; the other was the improved financial position caused by the cessation of the imports required by the settlers and of the expenditure of foreign currency formerly necessitated by their journeys to France. Moreover, the Algerian workers were still able to proceed to France and to remit large sums to Algeria.

A serious problem was presented in April 1963, however, by the resignation of Muḥammad Khider and by his subsequent departure abroad, taking with him the funds of the FLN. He was subsequently assassinated in Madrid. Little by little, the gradual elimination of other dissident leaders appeared to leave Ben Bella in entire control.

Quarrel with Morocco

In the autumn of 1963 a quarrel with Morocco over the Tindouf area, which the French had attached to Algeria, led to an Algerian surprise attack on a Moroccan frontier post. Morocco, replying with vigour, had the best of the fighting. Peace was restored by the intervention of the emperor of Ethiopia and the Organization of African Unity; but the issue remained in suspense until a rapprochement between the two countries, which took place at the end of 1969, led in 1970 to an agreement for joint exploitation of the valuable Gara Jebailat iron ore deposits under Algerian sovereignty but using a Moroccan port for outlet.

Long before this, however, a totally unexpected coup in June 1965 led to the arrest and seclusion of Ben Bella and his replacement as chief of the government by Col. Houari Boumedienne. The change in government resulted in a more orderly administration.

In 1967 Algeria dispatched a force to the United Arab Republic to assist in fighting against Israel and maintained it there until 1970. Having received much assistance from the Communist states during the insurrection, Algeria gladly accepted their subsequent assistance in various forms after peace was established (for example, Bulgarian medical missions). An acute problem facing the government was the winemaking industry, which the French had established, in a Muslim country opposed by religious belief to the consumption of alcoholic liquor. With the departure of the Europeans, the internal market for wine vanished, and the French, for the benefit of French producers, were no longer interested in buying this Algerian product. The U.S.S.R. afforded relief when it undertook to buy the annual surplus.

Algeria's foreign-exchange position in general was greatly assisted by the export of oil, of which two-thirds went to France, and of natural gas, of which two-thirds went to Great Britain, in liquid form. Private investment from abroad virtually ceased, but the lack was largely made up by such international institutions as the World Bank and by other forms of international aid. By 1970 Algeria appeared to be a stable republic facing its innumerable problems with considerable determination, friendly with the Communist states but resolutely independent.

TUNISIA

European influence (1830–81). In 1830, at the time of the French invasion of Algiers, Tunis was a dominion of the Ottoman Empire but independent in its internal affairs. Educated Tunisians had not forgotten that neighbouring Algiers had in great part been created by the Turks out of Tunisian territory. Quite recently Algiers had claimed a kind of suzerainty over Tunis and even the right to tribute. In these circumstances the reigning *bey* of Tunis, Ḥusayn ibn Maḥmūd, lent ready credence to French assurances that they had no permanent claims on Algiers and welcomed the suggestion of the appointment of Tunisian princes as governors of Constantine and Oran and hints that Tunis might eventually take over the neighbouring regency. It soon became clear that this scheme had no prospect of success and it was abandoned. The next *bey*, Muṣṭafa (1835–37), would indeed have been glad openly to assist the Algerians against the French had he been in a position to do so. Meanwhile, the Ottoman suzerain had seized the opportunity of a disputed succession in Libya to depose its ruling dynasty and to re-establish direct Turkish rule. The possibility of a similar intervention in Tunis was forestalled by the dispatch of a French naval force in 1836, and a similar threat in the following year by renewed warnings. During the succeeding reign of Aḥmad Bey (1837–55), the emergence of Tunisia as a distinct state continued; and Aḥmad abolished all slavery, permitted the opening of Christian schools, emancipated the Jews, and employed European advisers to help create a modern army and navy. The latter effort, however, proved costly and produced little result. The expense of these reforms, combined with the personal extravagance of the ruler, led to increasing financial difficulties, particularly since Tunisia, like the other North African states, no longer profited from privateering. Higher taxes, imposed to make up the loss of income, provoked revolts in 1840, 1842, and 1843. As Muslim strength in Africa and in Turkey decayed, a struggle ensued between rival European powers, principally Britain and France, for a controlling interest. Britain was interested mainly in preserving weak Muslim governments along the sea route to Egypt, while France hoped to extend its control from Algeria eastward over Tunis and westward over Morocco, with a land link across the Sahara to its central and West African colonies.

Growth of financial difficulties

The influence these two powers exercised was made clear when the *bey* Muḥammad (1855–59) sanctioned the execution of a Jew for blasphemy. Joint action by the British and French consuls induced the *bey* to issue the "Fundamental Pact" (*'ahd al-amān*; September 9, 1857), a kind of declaration of the rights of man. The final collapse of the regency occurred during the reign of Muḥammad as-Sadiq (known in France as Saddok or Sadoq; 1859–82), who attempted to modernize his state and even proclaimed a constitution, or *dustūr*. Meanwhile, expenditure continued to mount and with it taxation, which the people attributed to the foreign influence. As rivals for influence, the French and English were joined after 1860 by the representative of united Italy. The

position was worsened by the foreign loans negotiated on exorbitant terms by the *khazandār* (treasurer) Muṣṭafa.

In 1864 Muhammad, faced with an armed rising, reduced the *majbā*, a new tax that had been introduced during the preceding reign, and also abolished the constitution. This was accompanied by a movement to invoke the intervention of the Turkish suzerain, which, however, was brought to naught by French opposition. Four years later (1868) the *bey* found himself compelled to accept the appointment of an international commission. By its decision Tunisia was constrained to devote half the state revenues to repayments, an arrangement for which the customs receipts served as guarantee. When the *khazandār* Muṣṭafa was at last dismissed (1873), his place was taken by the Circassian Khayr ad-Dīn, who had been a supporter of liberal measures for several years and in 1871 had secured from the Ottoman sultan a *firman*, or edict, reaffirming Ottoman sovereignty while renouncing any claim to tribute. This had successfully averted a threatened Italian naval demonstration. In 1878, however, he was dismissed by the *bey*, without having achieved any material improvement in the position. At the Congress of Berlin in 1878, the British objection to French ambitions in Tunisia was withdrawn in return for French consent to the British occupation of Cyprus. Without British support, on which Tunisia had long relied as a counterweight to other powers, it was left face to face with France and Italy, whose interests were in occupation, not in the maintenance of Tunisian independence.

The end came in 1881, when the French, on the pretext that some Tunisian tribesmen had moved into Algerian territory, landed troops at Bizerte (Banzart) and sent others into Tunisia by land from Algeria. Advancing without difficulty to the *bey*'s palace, the Bardo, at Kassar Said (modern al-Qaṣr as-Saʿīd), a short distance outside Tunis, they imposed a treaty that sanctioned a French military occupation, transferred to France the *bey*'s authority in foreign relations and finance, and provided for the appointment of a French resident minister as intermediary in all matters of common interest. This provoked a rising in southern Tunisia during which Sousse (Sūsah) was bombarded and captured in July 1881; al-Qayrawān was then captured in October, and Gafsa (Qafṣah) and Gabes (Qābis) in November. After the death of the *bey* as-Sadiq, his successor, Ali, was constrained to sign an undertaking to introduce such administrative, judicial, and financial reforms as the French government might consider useful. This agreement, known as the Convention of Marsa and signed in 1883, made French control complete.

French occupation

The protectorate (1881–1956). The arrangement thus arrived at was very different from that in Algeria. The basis was a treaty, not an outright conquest. The *bey*, known as Ṣāḥib al-Mamlakat at Tūnisīyah ("Possessor of the Kingdom of Tunis"), remained in theory an absolute monarch; two Tunisian ministers were still appointed, and the framework of the old government machinery was preserved. Tunisians continued to be subjects of the *bey*. There was no confiscation of land; mosques were not converted into churches; and Arabic remained an official language. Nevertheless, the supreme authority passed in fact into the hands of the French resident general and his staff. Under French guidance the finances were soon brought into order and a modern communications system established. Valuable phosphate mines were brought into operation near Gafsa in the south, while the extensive establishment of French and Italian colonists in the Majardah Valley resulted in a considerable export of vegetables. For a quarter of a century the country developed without serious disturbance, while the Muslim population adjusted its ways of thought, within a French framework, to the outlook and the science of the modern world. Though there was none of the wholesale confiscation of land and displacement of population that had occurred in Algeria, the most fertile portions of northern Tunisia, comprising the Majardah Valley and the Cap Bon peninsula, passed largely into the hands of Europeans. Many Europeans, especially the Italians and the Maltese, also competed with the indigenous Muslims in such humble occupations as driving taxis.

By 1906 the Tunisians had begun to demand a more active part in the government of their country, and in 1907 the Young Tunisian Party was founded, which financed a paper in the French language, *Le Tunisien*. Four years later, popular resentment of European domination was greatly intensified by the Italian invasion of Turkish Tripoli. The outbreak of World War I, however, rallied the Tunisians behind the French government. Nevertheless, the war accelerated the rate of change. Tunisians saw no reason why the Fourteen Points of the U.S. president Woodrow Wilson should not apply to themselves as much as to the subject peoples of Austria-Hungary and Germany. The Russian Revolution also made its impact. In 1920 the Destour Party, as the progress party now called itself, presented to the *bey* and to the French government a document that in effect demanded the establishment of a constitutional form of government in which Tunisians would possess equal rights with Europeans. The immediate result was the arrest of Abd al-Aziz al-Thaalibi, the Destour leader. Two years later, the aged *bey* Muhammad an-Nasir, under the influence of his sons, took the occasion of the coming visit of the French president, Alexandre Millerand, to request the adoption of the program of the Destour, failing which he threatened to abdicate within 48 hours. The resident general, Lucien Saint, responded by surrounding the *bey*'s palace with troops, with the result that the demand was withdrawn. Saint thereupon introduced repressive measures together with minor reforms that pacified Tunisian sentiment and weakened the nationalist movement for several years.

Young Tunisian Party

In 1934 a young Tunisian lawyer, Habib Bourguiba (*q.v.*), broke with the Destour Party to form a new organization, the Neo-Destour (now the Socialist Destour Party), which aimed at gaining mass support. Under Bourguiba's vigorous leadership the new party, after a sharp and often bitter struggle, completely supplanted the existing Destour and its old-fashioned leaders. Attempts by the French to suppress the new movement spread rather than reduced its popular appeal. The arrival of the Popular Front to power in France in 1936 enabled the Neo-Destour to extend its propaganda there also. When the Popular Front collapsed, renewed repression in Tunisia was followed by civil disobedience; and in 1938 serious disturbances resulted in the arrest of Bourguiba and other leading members of the party, which was officially dissolved. On the outbreak of war in 1939, they were deported, still untried, to France for greater security, until released by the Nazis when they later occupied Vichy France in 1942. Since Hitler regarded Tunisia as a sphere of Italian influence, they were then handed over to the Fascist government in Rome. Here they were treated with deference, in the hopes of eliciting a declaration favourable to the Axis. Bourguiba, however, steadily refused, in spite of the suggestions of some of his companions. In March 1943, after a noncommittal broadcast by him, they were finally allowed to proceed to Tunis, where the reigning *bey*, Muhammad al-Munsif (Moncef), formed a ministry of Destour sympathies. The subsequent assumption of power by the Free French, after the Nazi retreat, resulted in complete disillusionment. The *bey* himself was deposed, while Bourguiba escaped imprisonment only by a flight in disguise to Egypt (1945). Though ill at ease in the Middle Eastern environment, he now began a vigorous campaign of propaganda for Tunisian independence, by stages and, as far as possible, with the aid of France. In view of the emancipation of the eastern Arab states, and later of the neighbouring, relatively backward Libya, the French felt compelled to make concessions. In 1951 a government with nationalist sympathies was allowed to take office, of which the secretary general of the Neo-Destour, Salah ben Youssef, became a member. Bourguiba himself was allowed to return to Tunisia. When, however, this government wished to go farther and establish a Tunisian parliament, the result was a further bout of repression. Bourguiba was confined to the little island of Galite (now called Jāliṭah) in the Bay of Tunis, while the ministers were put under arrest, apart from Salah ben Youssef and one other who managed to escape to Cairo. This resulted, for the first time, in outbreaks of terrorism;

Emergence of Bourguiba

Outbreak of terrorism

and nationalist bands began to operate in the mountains, virtually paralyzing the country.

In July 1954 the French premier, Pierre Mendès-France, flew to Tunis, accompanied by Marshal Alphonse Juin, and promised to grant complete autonomy to Tunisia, subject to a freely negotiated convention. The negotiations were conducted in France, where Bourguiba, who was now released, was able to supervise them without directly participating. In June 1955 the convention was finally signed by the Tunisian delegates, though it imposed strict limits in the fields of foreign policy, education, defense, and finance. A mainly Neo-Destour ministry was formed, and Bourguiba himself, on returning from France, received a delirious welcome from the Tunisian people. Salah ben Youssef now came back from Cairo, denounced the agreement as too restrictive, refused to attend a specially summoned congress unanimously supporting Bourguiba, and organized armed resistance in the south, where his influence was greatest. This rising, however, was quickly put down, and Ben Youssef fled the country. (Ben Youssef was assassinated mysteriously in West Germany in 1961.)

Independence (1956–70). In March 1956, when full independence was granted to Morocco, it became inevitable that France should behave with equal liberality to the more developed Tunisia. A new Franco-Tunisian declaration was issued on March 20, and Bourguiba himself now headed the Ministry. The transfer of power was carried out successfully, Tunisians replacing Frenchmen as ministers without disturbance. In November Tunisia was admitted to the United Nations. On July 25, 1957, the rule of the *beys* was abolished and a republic declared, with Bourguiba as both president and prime minister. A major difficulty of the new government now arose from the continued fighting in Algeria and the use of the Tunisian frontier as a base by the Algerian insurgents. This problem became acute when, in February 1958, the French air force from Algeria bombarded the Tunisian frontier village of Sāqiyat Sīdī Yūsuf, inflicting many casualties, including school children. International opinion strongly supported Tunisia, and, by the intervention of a joint Anglo-American mission, French troops were withdrawn from the interior and concentrated at the naval fortress at Bizerte. Three years later, General de Gaulle was still unwilling to withdraw these remaining troops. This led to Tunisian demonstrations in the summer of 1961 during which French parachutists from Algeria inflicted heavy losses on the demonstrators. The French finally evacuated Bizerte in 1963.

The Bizerte incident

During the protectorate, Tunisia had been regarded as the North African country with the most peaceable and civilized inhabitants and has since preserved this reputation with the Western powers in general, receiving from them great financial and moral support. Its relations with France, however, at times have been extremely tense. The Bizerte affair alone resulted in 1,000 Tunisian and 20 French casualties; and in the following year all French aid was suspended when the National Assembly abruptly decided on the immediate nationalization of all land held by foreigners. The position was not modified nor were the various trade preferences restored until 1966.

Tunisia's relations with the progressive Arab states, notably the United Arab Republic and later Algeria, were also subject to violent oscillations, and both countries were on occasion accused of plots against the president's life. There was a violent dispute with the United Arab Republic and the majority of Arab states when Bourguiba in 1965 urged a softer approach toward Israel. During the 1967 Arab–Israeli war, however, Tunisian reactions were similar to those of the rest of the Arab world; and on the occasion of the Jordanian civil strife of 1970, the Tunisian prime minister was asked to mediate.

MOROCCO

Decline of traditional government (1830–1912). During the French invasion of Algeria in 1830, the sultan of Morocco, Moulay Abd ar-Rahman (1822–59) briefly sent troops to occupy Tlemcen but withdrew after French protests. The Algerian leader Abdelkader offered his allegiance to the Sultan and in 1844 took refuge from the French in Morocco. A Moroccan army was sent to the Algerian frontier; the French bombarded Tangier on August 4, 1844, and Mogador on the 15th. Meanwhile, on August 14 the Moroccan army was totally defeated at Isly near the frontier town of Oujda. The Sultan then promised to intern or expel Abdelkader if he should again enter Moroccan territory. Two years later, when again driven into Morocco, the Algerian leader was attacked by Moroccan troops and forced to surrender to the French. The dominating foreign power in Morocco at this time, however, was Britain. In 1856 the British secured a treaty granting them trade privileges, including the right of according "protection" to Moroccan citizens, making them largely independent of their national government. Immediately after Abd ar-Rahman's death in 1859, a dispute with Spain over the boundaries of the Spanish enclave at Ceuta led to a declaration of war by Madrid and to the Spanish capture of Tetuan in the following year. Peace had to be bought with an indemnity of $20,000,000, the enlargement of Ceuta's frontiers, and the promise to cede to Spain another enclave—Ifni. The new sultan, Sidi Muhammad (1859–73), attempted without any marked success to modernize the Moroccan army. After his death, his son Moulay al-Hassan I (1873–94) struggled to preserve the independence of his medieval empire. His time was consumed in unceasing journeys to restore order and collect taxes, for the machinery and means of a modern government were completely lacking. Like his predecessor, he was unsuccessful in his efforts to reform the army. After his death, his chamberlain, Ba Ahmad, ruled in the name of the young sultan Moulay Abd al-Aziz until 1901, when the latter began his direct rule. Abd al-Aziz surrounded himself with European companions and adopted their customs, scandalizing his subjects, particularly the religious leaders. His attempted introduction of a modern system of land taxation resulted in complete confusion because of a lack of qualified officials. Popular discontent and tribal rebellion became even more frequent, while a pretender, Bu Hamara, established a rival court near Melilla. European powers seized the occasion thus offered to extend their own influence. In 1904 coming events were foreshadowed when Britain gave France a free hand in Morocco in return for a French undertaking not to interfere with British plans in Egypt. Spanish agreement was secured by a French promise that northern Morocco should be treated as a sphere of Spanish influence. Italian interests were satisfied by a French undertaking not to hinder Italian designs on Libya. Possible German claims were ignored, thus enabling the Sultan to arrange an international conference at Algeciras in 1906 to discuss the whole Moroccan question. The Algeciras conference confirmed the integrity of the Sultan's domains; the right of all countries to trade in Morocco on equal terms was ensured by the imposition of customs dues at a uniform rate of 12½ percent on all imports. At the same time, however, the conference sanctioned French and Spanish policing of the ports and collection of the customs dues. Two years later, the Sultan's brother, Moulay Abd al-Hafid, led a rebellion against him, denouncing him for his departure from Muslim ways. Defeated, Moulay Abd al-Aziz took refuge in Tangier. Moulay Abd al-Hafid then made an abortive attack on French troops, which had been occupying Casablanca since 1907, before proceeding to Fez (Fès), where he was duly proclaimed sultan and recognized by the European powers (1909). The new sultan proved unable to control the country. Disorder increased until, besieged by tribesmen in Fez, he was forced to ask the French to rescue him. When they had done so, he had no choice but to sign the Treaty of Fès (March 30, 1912) by which Morocco became a French protectorate and the French government was authorized to introduce such reforms as it thought fit. In return the French guaranteed to maintain the status of the Sultan and his successors. Provision was also made to meet the Spanish claim for a special position in the north of the country; Tangier, long the seat of the diplomatic missions, retained a distinctive administration.

Attempts at modernization

French intervention

The French protectorate (1912–56). In establishing their protectorate over Morocco, the French had behind them the experience of the conquest of Algeria and of their protectorate over Tunisia; and they took the latter as model for their Moroccan policy. There were, however, important differences, owing both to the later date of its establishment and to the special circumstances of Morocco. The date was only two years before the outbreak of World War I, which was to bring with it the new attitude to colonial rule. Secondly, Morocco had a tradition of a thousand years of independence and had been strongly influenced by the civilization of Muslim Spain, while it had never been subject to Ottoman rule. These circumstances and the proximity of Morocco to Spain created a special relationship between the two countries. Morocco was also unique among North African countries in possessing a coast on the Atlantic, in the rights that various nations derived from the Act of Algeciras, and in the privileges that their diplomatic missions had acquired in Tangier. Thus, the northern tenth of the country, with an Atlantic and a Mediterranean coast, together with the desert province of Tarfaya in the south adjoining the Spanish Sahara, was excluded from the French-controlled area and treated as a Spanish protectorate. In the French sector, the French resident general became the real ruler of the country, subject to the approval of the Paris government. He worked through newly created departments manned by French officials. The outward forms of the traditional Moroccan government (*makhzan*) were preserved, though the role that it played in reality can be estimated from the fact that the grand vizier on the installation of the protectorate, Muhammad al-Moqri, still held the same post on the recovery of independence 44 years later, when he was over 100 years old. As in Tunisia, country districts were administered by *contrôleurs civils*, except in certain areas such as Fès, where it was felt necessary that officers of the rank of general should supervise the administration. In the south, certain Berber chiefs, of whom the best known was Tihami al-Glawi, were allowed to remain semi-independent.

The protectorate's government

The pre-World War II period. The first resident general, Gen. (later Marshal) L.H.G. Lyautey, was a soldier of wide experience in Indochina, Madagascar, and Algeria. He was of aristocratic outlook and possessed a deep aesthetic appreciation of the artistic qualities of Moroccan civilization. The character he gave to the administration exerted an influence throughout the period of the protectorate. As early as 1920 he submitted a report saying that "a young generation is growing up which is full of life and needs activity. . . . Lacking the outlets which our administration offers only sparingly and in subordinate positions they will find an alternative way out." Only six years after Lyautey's report, young Moroccans both in Rabat, the new administrative capital, and in Fès, the centre of traditional Arab learning and culture, were meeting, quite independently of one another, to discuss demands for reforms within the terms of the protectorate treaty. They asked for more schools, a new judicial system, the abolition of the regime of the Berber *qā'īd*s (*caid*s) in the south, for study missions in France and in the Arab East, for the cessation of official colonization, and for the suppression of licensed prostitution—objectives that would only be fully secured when the protectorate ended in 1956. Moulay Abd al-Hafid could not reconcile himself to the new regime and, after a few months, joined his brother as a French pensioner in Tangier. In his place a more amenable brother, Moulay Yusuf, was recognized as sultan and succeeded in cooperating with the French without losing the respect of his own people. A new administrative capital was created on the Atlantic coast at Rabat. At the same time, a commercial port was developed at Casablanca. By the end of the protectorate, Casablanca was a flourishing city, with nearly a million inhabitants and a considerable industrial establishment. Lyautey's policy was to build new European cities beside or at some distance from the old Moroccan towns, thus preserving the country's ancient monuments. The remarkable rhythm of innovation was little interrupted by World War I. Though the French government had proposed to retire to the coastal area, Lyautey managed to retain control of all of the occupied area. After the war one major problem was the pacification of the former Bled es-Siba outlying areas in the Atlas Mountains over which the sultan's government often had had no real control. This was finally completed in 1934. Another problem was the extension of the rising of Abd el-Krim from the Spanish to the French zone (see below *The Spanish Zone*). In 1926 Marshal Lyautey was succeeded by a civilian resident general. This marked a change to a more conventional colonial regime, accompanied by the extension of official colonization, the growth of European population, and the increasing impact of European thought on the minds of the younger generation, some of whom had by now received a French education. On the death of Moulay Yusuf (1927) the French choice as his successor was his younger son, Sidi Muhammad (Muhammad V). Chosen in part for his retiring disposition, this sultan was in time to reveal outstanding diplomatic skill and determination. Another significant event was the French attempt to utilize the differences between Arabs and Berbers to counterbalance the Arab character of the Sultan's government. This led to the issue of the Berber Decree of 1930. The Berbers had hitherto been brought to accept the Arab way of life by a gradual process rather than by any sort of compulsion. Now, however, the Berber areas were to be given a perpetual exemption from the Muslim law of the kingdom. This at once stimulated Arab nationalism and brought it widespread backing from the Arab and Muslim world in general. The resulting outcry forced the administration to give ground and to modify its proposals. In 1933 the nationalists initiated a new national day called the Fête du Trône to mark the anniversary of the Sultan's accession. When he visited Fès in the following year, he received a tumultuous welcome, accompanied by anti-French demonstrations that caused the authorities to terminate the visit abruptly. This episode was soon followed by the organization of political parties of nationalist sentiment. These events coincided with the completion of the occupation of southern Morocco, which brought with it the Spanish occupation of Ifni. In 1937 rioting occurred in Meknès, where French settlers were suspected of diverting part of the town water supply to irrigate their own lands at the expense of the Muslim cultivators. Thirteen of the rioters were killed and 100 were wounded. In the ensuing repression, Allal el-Fasi, the main nationalist leader, was banished to Gabon in Equatorial Africa, where he spent the following nine years. The tendency of French policy at this time is shown by a circular, issued to departmental chiefs, stating that insufficient attention was being given to "native policy," implying that the affairs of the French settlers, now numbering some 300,000, were the chief care of the administration, while the mass of the population was a matter of "native" policy.

The development of Casablanca

The Berber Decree of 1930

World War II and the attainment of independence. At the outbreak of World War II in 1939, the Sultan issued a call for wholehearted cooperation with the French; and a large Moroccan contingent, mainly Berbers, served with distinction in France. The collapse of the protecting power in 1940 and the installation of the Vichy regime naturally produced an entirely new situation. The Sultan marked his independence by refusing to approve anti-Jewish legislation. When in 1942 the Anglo-American landings took place, he refused to comply with the suggestion of Resident General Auguste Noguès that he retire to the interior. In 1943 the Sultan was much influenced by his meeting with the U.S. president Franklin D. Roosevelt, who came to Morocco for the Casablanca Conference and was unsympathetic to continued French presence there. The majority of the people were equally affected by contact with the American and British troops, who put them in touch with the outside world to an unprecedented degree. Among the people at large, the effect of the newly introduced broadcasts in Arabic with which the combatants, Allied and Nazi alike, sought to attract Arab listeners to their side, was very considerable. In these circumstances, the nationalist movement took

The Allied invasion

the new title of Hizb al-Istiqlal (Istiqlal Party)—the "Party of Independence." In January 1944 they submitted to the Sultan and the Allied (including the French) authorities a memorandum asking for independence under a constitutional regime. The nationalist leaders, including Ahmad Balafrej, secretary general of the Istiqlal Party, were immediately arrested on an improbable charge of collaboration with the Nazis. This caused rioting in Fès and elsewhere in which some 30 or more demonstrators were killed. In the situation thus created, the initiative passed to the Sultan, who, in 1947, persuaded a new and reforming resident general, Eirik Labonne, to gain the French government's permission for him to make an official state visit to Tangier, passing through the Spanish Zone on the way. The journey became a triumphal procession; when the Sultan finally made his speech in Tangier, it was under the emotion of the stirring reception in the Spanish Zone and Tangier. While emphasizing the links of Morocco with the Arab world of the East, he omitted the flattering reference to the French protectorate that had been anticipated. The result was the replacement of Labonne by Gen. (later Marshal) Alphonse Juin, of Algerian settler origin. With long experience in North African affairs, Juin expressed sympathy for the patriotic nationalist sentiments of young Moroccans and promised to comply with their wish for the creation of elected municipalities in the large cities. At the same time he aroused opposition by proposing to introduce French citizens as members of these bodies, thus taking a step toward a state of co-sovereignty. The Sultan thereupon used his one remaining prerogative and refused to countersign the resident general's decrees, lacking which they had no legal validity. A state visit to France in October 1950 and a very flattering reception did nothing to modify the Sultan's views, and, on returning to Morocco, he received a wildly enthusiastic welcome from the Moroccan crowds. On December 12 General Juin dismissed a nationalist member from a meeting of the Council of Government, which discussed the budget proposals; the ten remaining nationalist members walked out in protest. This event was hailed by the local French press as a victory for their cause, though a very different view of the matter was widely held in France. For his part, General Juin now began to think of the possibility of utilizing the Berber feudal notables, such as Tihami al-Glawi, to counter the nationalists. Thus, at a palace reception on December 21, 1950, al-Glawi told the Sultan to his face that he was not the Sultan of the Moroccans but of the Istiqlal and that he was leading the country to catastrophe. The Sultan forbade him to visit the palace again, while the local French press hailed al-Glawi's action as displaying the true Muslim spirit and suggested that the nationalists were Communists.

The regime of Gen. Juin

In the face of Sidi Muhammad's continued refusal to cooperate, General Juin surrounded the palace with tribesmen, after having provided a guard of French troops supposedly to protect the Sultan against his outraged people. Faced with this threat, Sidi Muhammad was constrained to disown "a certain political party," without specifically naming it, but still withheld his signature from many decrees, including that admitting French citizens as municipal councillors. General Juin's action was widely criticized in France, and on August 28, 1951, he was replaced by Gen. Augustin Guillaume. The Sultan, on the anniversary of his accession (November 18), declared that he was hoping for an agreement "guaranteeing full sovereignty to Morocco" but (as he added in a subsequent letter addressed to the president of the French Republic) "with the continuation of Franco-Moroccan cooperation." This troubled situation continued until December 1952 when the trade unions in Casablanca decided to organize a protest meeting over the assassination of the Tunisian trade union leader, Ferhat Hashad (Hached), supposedly by French terrorists. A clash with the police followed; hundreds of nationalists were arrested and were held in detention for two years without being tried.

In April 1953, the head of a religious confraternity, Abd al-Hai al-Kittani, together with a number of Berber notables, headed by al-Glawi, with the connivance of a number of French officials and settlers, began to work for the deposition of the Sultan, whom they accused of un-Islāmic conduct. The government in Paris, preoccupied with internal affairs, finally demanded that the Sultan should transfer his legislative powers to a council, composed jointly of Moroccan ministers and French directors, and append his signature to all the blocked legislation. The Sultan yielded but this was not sufficient for his enemies. On August 18, 1953, al-Glawi delivered what may be called an ultimatum to the French government. The latter thereupon deported the Sultan and his family to Madagascar, appointing in his place the more subservient Moulay ben Arafa. This did nothing to improve the situation. Sidi Muhammad became at once a national hero, and an attempt was made on the life of the substitute sultan. The authorities in the Spanish Zone, who had not been consulted about the measure, did not conceal their disapproval. The Spanish Zone thus became a refuge for Moroccan nationalists. In November 1954 the French position was further complicated by the outbreak of the Algerian rising. In June 1955 the Paris government decided on a complete change of policy and appointed Gilbert Grandval as resident general. His efforts at conciliation were obstructed by the tacit opposition of many officials and the outspoken hostility of the majority of the French settlers. Before he could get his proposals accepted by the French government, a massacre of French settlers at Oued Zem (August 20, 1955) led to his recall. A conference of representative Moroccans was then summoned to meet in France and at this it was agreed to replace the substitute sultan by a crown council. Sidi Muhammad gave his approval to the proposal, but it still took weeks to persuade the puppet sultan to withdraw to Tangier. Meanwhile, a Liberation Army began to operate against French posts near the Spanish Zone. On October 26 al-Glawi, wishing to secure the future of his family, declared publicly that only the restoration of Sidi Muhammad could restore harmony. The French government agreed to allow the Sultan to form a constitutional government for Morocco. In November Sidi Muhammad returned to Rabat, where he was greeted by huge welcoming crowds. On March 2, 1956, independence was proclaimed, and the Sultan formed a government representative of the various elements of the indigenous population, while the departments formerly headed by Frenchmen became ministries headed by Moroccans.

The Sultan's exile

Independent Morocco (1956–70). The protectorate had been highly successful in developing communications, in adding modern quarters to the cities, and in creating a flourishing agriculture and a modern industry of a colonial type. Most of these activities, however, were managed by Europeans who, by the end of the protectorate, numbered 360,000 in French Morocco; in the constitutional field there had been virtually no development. Though the government was in practice in the hands of the French, the Sultan remained in theory an autocrat; and when independence was finally conceded he became so again in fact, subject only to his undertaking to the nationalists to introduce a constitution. By French insistence, the first cabinet was composed of ministers representing the various tendencies in Moroccan society, and it included a Jew. Mubarak Bekkai, an army officer who had shown his loyalty to the Sultan during the independence struggle but was not a party man, was selected as premier. The Sultan (who officially adopted the style of king in August 1957) selected the ministers personally and himself retained control of the army and the police; he did, however, nominate a Consultative Assembly of 60 members. His eldest son, Moulay Hassan, became chief of staff and by degrees successfully integrated the irregular Liberation Forces, after they had promoted a rising against the Spanish in Ifni (1957) and against the French in Mauritania. In general, the change to Moroccan control, assisted by French advisers, took place smoothly. Relations with France, however, were badly strained because of the continuing Algerian problem, but independent Morocco remained greatly dependent on French technology and finance. There was a shortage of trained professionals; for example, out of a total of 900 physi-

The national government

cians in the country not more than 70 were Moroccans. In the sphere of education, Morocco had to rely on the continued service of thousands of French teachers. Another problem was the lack of confidence in the future felt by French industrialists and the consequent difficulty of maintaining capital investment. This lack was mitigated by international aid. European farms in Morocco remained under French control until 1963. Progress was made in some areas. The maintenance and extension of the fine roads in the French Zone and the bringing of the roads in the Spanish Zone to the same standard was successfully carried out. The mining of phosphates, of which Morocco is one of the world's leading producers, was extended to some 10,000,000 tons annually; and a vast plant was created at Safi for conversion into superphosphates. Assembly plants were established for cars and trucks. A major political change occurred when the Istiqlal Party split into two sections in 1958. The main portion remained under the leadership of Allal el-Fasi, while a smaller section, headed by Mehdi ben Barka, Abdullah Ibrahim, and Abd er-Rahim Bouabid, formed the National Union of Popular Forces (UNFP). Of these groupings the original Istiqlal represented the more traditional elements, while the UNFP was formed from the intelligentsia of the new industrial cities and favoured socialism with republican leanings. Muhammad V made use of these dissensions to assume the position of an arbiter above party strife. He nevertheless continued the preparations for the creation of a parliament until his unexpected death from minor surgery in 1961. Moulay Hassan succeeded him and carried on his policies.

Division in the Istiqlal

In 1963, when parliamentary elections were finally held, the two halves of the former Istiqlal Party formed an opposition, while a party supporting the King's government was created out of miscellaneous elements, known as the FDIC (Front for the Defense of Constitutional Institutions). This included a new, predominantly Berber, rural group opposed to the Istiqlal. The ensuing near deadlock caused the King to dissolve Parliament after only one year, resuming personal government with himself or his nominee as premier. In 1970 a new constitution was promulgated that provided for a one-house legislature. In foreign affairs, Morocco sided with the western European powers rather than with the eastern block, while sharing the general outlook of Arab states on such questions as Palestine. Its relative moderation did not prevent a large-scale Jewish emigration. Claiming Mauritania as a sphere of influence, the Moroccan government refused to recognize that country's independence before 1970. Nor would it recognize the western frontier where territory had been attached to French Algeria at Morocco's expense. This was of importance because of the vast iron ore deposits 80 miles southeast of Tindouf; the dispute resulted in an armed clash in autumn 1964. Peace was restored with the aid of the Organization of African Unity, and in 1970 it was agreed that the iron ore would be exploited by both countries under the Algerian flag but exported through a Moroccan port. At the same time, a rapprochement with Mauritania signified an alignment of the three Maghrib states against a Spanish plan to develop the phosphate-rich Spanish Sahara into an independent state associated with Spain. In 1964 the exiled Moroccan socialist leader Mehdi ben Barka attacked the Moroccan government over Algiers radio at the time of the Moroccan–Algerian frontier fighting; for this he was sentenced to death *in absentia*. A year later, while on a visit to Paris, he was kidnapped with the aid of two French police inspectors and was never seen again. After investigations, the French president, Charles de Gaulle, accused the Moroccan minister of the interior, General Oufkir, of responsibility. As General Oufkir was unwilling to go to Paris to answer the charge, the French ambassador was withdrawn from Rabat and French economic aid cut off. Relations were not fully restored until de Gaulle's abandonment of the presidency in 1969.

Border conflict with Algeria

The Spanish Zone (1912–56). The Spanish intervention in Morocco had roots in remote history. In a sense, Spain and Morocco form an intermediate unit between Europe and black Africa to the south and between Europe and the Arab world in the east. These historical and geographical facts forced the French to share their protectorate with the Spaniards and provided a very different background to the two regimes. The outward form given to the protectorate was similar since the Spaniards appointed a *khalīfah* or viceroy, chosen from the royal family, as nominal head of state, and provided him with a puppet Moroccan government created for the purpose. This enabled them to conduct affairs independently of the French Zone while nominally preserving the unity of the whole country. In 1904 the French had been prepared to leave Spain the whole northern half of the kingdom, including Fès and the Atlantic coast as far as Salé. The Spanish government of that time, however, did not feel sure of its ability to deal with such a large area and asked only for about one-tenth of the kingdom, from Larache on the Atlantic to 30 miles beyond Melilla (already a Spanish possession) on the Mediterranean. This was in the main a mountainous, Berber-speaking area that had often escaped the sultan's control. In addition, the Spanish received a strip of desert land in the south, adjoining the Spanish Sahara and known as Tarfaya or Tekna. Finally, in 1934, when the French occupied southern Morocco, the Spanish took possession of the strip of territory on the Atlantic coast known as Ifni. Tangier, though it had a Spanish-speaking population of 40,000, received a special international administration, under a *mendub* or resident, theoretically appointed by the sultan, actually by the French. In 1940, after the defeat of France, Spanish troops occupied Tangier but withdrew again in 1945 after the Allied victory. The Spanish Zone surrounded the ports of Ceuta and Melilla, which Spain had possessed for centuries, and included the iron mines of the Rif from which some 3,000,000 tons of ore were exported by Spanish companies annually through the latter port. As capital, the Spanish selected Tétouan, which they had occupied during the war of 1860–61. As in the French Zone, European-staffed departments were created; the country districts were administered by *interventores*, corresponding to the French *contrôleurs civils*. The first area to be occupied was that on the plain, facing the Atlantic, with the towns of Larache, Alcazarquivir (now Ksar el-Kebir), and Asilah. That area was the stronghold of the former Moroccan governor Raisuni, half patriot and half brigand. The Spanish government found it difficult to tolerate his independence, and in March 1913 he retired into a refuge in the mountains, where he held out until captured by another Moroccan leader, Abd el-Krim, 12 years later. Muhammad Abd el-Krim was a Berber, a good Arabic scholar, and had a knowledge of both the Arabic and the Spanish languages and ways of life. Imprisoned after World War I, probably because of his outspoken hostility toward the French, he was later transferred to Ajdir in the Rif, the mountainous district overlooking the Mediterranean near al-Hoceima. There he made full use of his knowledge of Spanish affairs to plan a rising. In July 1921 he destroyed a Spanish force sent against him and then established a Republic of the Rif, which endured for five years. It was only when his followers resisted French expansion in the north that French and Spanish forces combined, the latter landing at al-Hoceima and the French advancing from Fès, which had been in peril; Abd el-Krim was then finally overwhelmed by a total force of over 250,000 fully equipped men. In May 1926 he surrendered to the French and was exiled to the island of Réunion in the Indian Ocean. The remainder of the period of the Spanish protectorate was relatively calm. Thus, in 1936 Gen. Francisco Franco was able to launch his attack on the Spanish Republic from Morocco and to enroll a large number of Moroccan volunteers, who served him loyally in the Spanish Civil War. Though the Spanish had fewer resources than the French, their subsequent regime was in some respects more liberal and less subject to racial discrimination; instruction in schools was in Arabic, not Spanish, and Moroccan students were encouraged to go to Egypt for a Muslim education. There was no attempt to set Berber against Arab as in the French Zone, though this may have been prevented by the introduction of Muslim law by

The Rif Republic

Abd el-Krim himself. After the end of the Rif Republic, there was little cooperation between the two protecting powers. Their disagreement reached a new height when in 1953 the French, without consulting the Spanish, deposed the Sultan. The Spanish high commissioner did not recognize this action, and Muhammad V was still regarded in the Spanish Zone as the legitimate sovereign. Nationalists were, moreover, for the first time given departmental office, and the zone served as a refuge for those who had had to leave the French area. In 1956, however, when the French decided to grant independence to Morocco, the Spanish authorities were taken by surprise and hesitated before following suit. A corresponding agreement was nevertheless reached on April 7, 1956, and was marked by a visit of the Sultan to Spain. The Spanish protectorate was thus brought to an end without the troubles that marked the termination of foreign control in the French Zone. With the end of the Spanish protectorate and the withdrawal of the Spanish high commissioner, the Moroccan *khalīfah*, and other officials from Tétouan, the city became again a quiet, provincial capital. The introduction of the Moroccan franc instead of the peseta as currency, however, caused a great rise in the cost of living, and difficulties were also caused by the introduction of French-speaking Moroccan officials. In 1958–59 these various changes gave rise to disorders in the Rif. Tangier, too, lost much of the superficial brilliance that it had developed as a separate zone, as by degrees its special status was modified and its privileges were withdrawn. As in the former French Zone, there ensued a great drop in the number both of European and of Jewish inhabitants, while the fact that Ceuta (76,000 in 1966) and Melilla (80,000 in 1965) remained Spanish possessions, with an overwhelmingly Spanish population, provoked periodic Moroccan discontent. The southern protectorate area of Tarfaya was handed back to Morocco in 1958, while Ifni, in return for which the Spaniards had vainly hoped to gain a recognition of their right to Melilla and Ceuta, was finally unconditionally handed over in 1970.

Independence for Morocco

LIBYA

In 1834 the Pasha Yusuf abdicated and was succeeded by his son, Ali II. In 1835 a dispute over this succession provided the pretext for resuming direct rule of Tripolitania and Cyrenaica, which the Ottoman government thought to be the only sure means of averting a European occupation. For 77 years the area was administered by officials from Istanbul and shared in the limited modernization common to the rest of the empire. In Libya the most significant event of the period was the creation of the Sanūsīyah, an Islāmic order, or fraternity, that preached a puritanical form of Islām to the Bedouins, giving them instruction and material assistance and so creating in them an added sense of unity. The first Sanūsī *zāwiyah*, or lodge, was established in 1843 at al-Bayḍā', near the ruins of Cyrene in eastern Cyrenaica. The order spread principally in that province but also found adherents beyond its borders, particularly in the south. In order to avoid the cosmopolitan influences of the coastal region, the Grand Sanūsī, as the founder came to be called, moved his headquarters to the oasis of Jaghbūb near the Egyptian frontier, and in 1895 his son and successor, Sayyid Muḥammad al-Mahdī, transferred it farther south into the Sahara at Kufrah. Though the Turks welcomed the order's opposition to the spread of French influence northward from Chad and Tibesti, they regarded the political influence it exerted within Cyrenaica with suspicion. In 1908 the Young Turk revolution gave a new impulse to reform; in 1911, however, the Italians, with banking and other interests in the country, launched an invasion.

The Sanūsīyah

The Turks were soon forced out of the country, but the Italians found it more difficult to subdue the native population. By 1914 they had occupied most of the country but during the course of World War I were reduced to a few coastal towns—Zuwārah, Tripoli, and Homs in Tripolitania and Benghazi and Derna in Cyrenaica. At the end of the war, the liberal Italian government tried to cooperate with a rudimentary republic, formed during the fighting, by Tripolitanians advised by Abdurrahman Azzam, later first secretary general of the Arab League. In 1921, however, a more vigorous policy was inaugurated by the Italian governor, Giuseppe Volpi, and much facilitated when the Fascists came into power in Rome the following year. The coastal areas of Tripolitania were subdued by 1923, but in Cyrenaica the Sanūsī resistance, led by Omar al-Mukhtar, was maintained until 1932 and only overcome when the population had been herded into concentration camps with much loss of life.

The Italian government displayed great constructive activity in building fine new towns, with harbours at Tripoli and Benghazi, and admirable roads. Some 30,000 Italian peasant families were then settled on the Gefara Plain of Tripolitania and on the Jabal al-Akhḍar heights of Cyrenaica. The local Muslim nomads were moved nearer the desert and were subject to racial discrimination in such matters as the use of public means of transport. This new order, meticulously organized, lasted until 1940, when Italy entered World War II on the side of the Nazis. In 1942 Cyrenaica was totally evacuated by Axis troops and by the Italian settlers and officials; and in 1943 the last Axis troops also were driven from Tripolitania.

After the war, the future of Libya gave rise to long discussions. In view of the contribution to the fighting made by a volunteer Sanūsī force, the British foreign minister pledged in 1942 that the Sanūsīs would not again be subjected to Italian rule. During discussions, lasting four years, suggestions included an Italian trusteeship, a United Nations trusteeship, a Soviet mandate for Tripolitania, and various compromises. Finally, in November 1949 the United Nations General Assembly voted that Libya should become a united and independent kingdom not later than January 1, 1952.

Libyan independence

A constitution creating a federal state with a separate parliament for each province was drawn up, and the pro-British Sanūsī chieftain Muhammad Idris al-Mahdi was chosen king by a national assembly in 1950. On December 24, 1951, King Idris I as-Sanoussi declared the country independent. Political parties were banned and the King's authority was fundamental. Though not themselves Sanūsīs, the Tripolitanians accepted the monarchy largely in order to profit by the British promise that the Sanūsīs would not again be subjected to Italian rule. King Idris, retiring by disposition, showed a marked preference for living in Cyrenaica, where he built a new capital on the site of the original Sanūsī *zawiyah* at al-Bayḍā'. Though Libya joined the Arab League in 1953 and in 1956 refused British troops permission to land for the Suez Canal expedition, the government in general adopted a pro-Western point of view in international affairs. After being entirely dependent, for seven years, on international aid and on the rent for an American air base and a British air training base, the discovery of very rich oil deposits in 1959 both in Tripolitania and Cyrenaica, within easy range of the seacoast, assured Libya of resources on a vast scale. There followed an enormous expansion of all government services and of building and a corresponding rise in the economic standard and the cost of living.

What would happen on the King's death had always been a matter for speculation since his heir was without his uncle's outstanding qualities. The eventuality was anticipated early in 1969 when a group of young army officers led by Col. Muammar Qadafi seized power while the King was undergoing a cure in Turkey. The new regime was passionately Arab and puritanically Muslim, forbidding the sale of alcoholic liquor. Breaking the former close relations with Britain, the new government formed an alliance with the United Arab Republic and The Sudan and cancelled a very extensive order for arms that the previous government had placed in Britain, acquiring arms instead from France as well as from the Soviet Union. It also won withdrawal of U.S. and British bases and adopted a stronger Arab line toward Israel.

MAURITANIA AND THE SPANISH SAHARA

When the French completed the occupation of Morocco in 1934, they sent a force south to link up with another

expedition advancing from their West African colonies. The intervening country was constituted as a territory of French West Africa under the name of Mauritania. Its population was Arabic-speaking in the north; the Negro inhabitants of the south spoke various African languages. In 1946 it became an overseas territory of France.

Independent Mauritania (1960–70). Attaining independence in 1960, Mauritania was admitted to the United Nations in 1961. It lies between Morocco on the north, the Spanish Sahara and the Atlantic on the west, Senegal on the south, Mali on the east, and Algeria on the northeast. Formerly Berber-speaking, it was the homeland of the medieval Almoravid dynasty. It was converted to Arabic speech in the 14th century with the coming of an Arab tribe, the Banū Maʿqīl. Because of the longer period of French rule over them, the Negro population of the south gained a certain advantage in modern education over the Arabic-speaking north, which, however, had a high tradition of Islāmic learning. The form of Arabic used is known as Ḥassāniyah. The political supremacy of the Arabs has resulted in an unusual class structure: warriors of Arab origin; a scholarly and religious class known as *zwaya* of Berber origin; and *harratin* or workers of mainly Negro, and originally slave, origin.

The Arabic speakers, who form 80 percent of the population, tend to insist that Arabic should be an essential qualification for government service; this has led to periodical disturbances. The country's chief commercial asset is the iron ore at Fort-Gouraud. Before the coming of the French, the Arabic-speaking population looked to the sultan of Morocco for defense against foreign rule and as their religious head. For this reason Morocco refused to recognize Mauritanian independence until 1969. In that year, King Hassan invited the Mauritanian president, Mokhtar Ould Daddah, to attend an Islāmic summit meeting in Rabat, foreshadowing a united front of Morocco, Algeria, and Mauritania against the continuation of Spanish rule in the Sahara. Though not a member of the Arab League, Mauritania shares the Arab attitude with regard to the Palestine issue.

The Spanish Sahara (1884–1970). Spanish connections with this area date back to the occupation of the Canary Islands in the 15th century. The present Spanish claim stems from the interest aroused in the area at the time of the European "scramble for Africa," between 1870 and 1880. In 1884 the Spanish government laid claim to a protectorate over land between Cape Blanco and Cape Bojador and occupied the site of Villa Cisneros in the Río de Oro. Güera, adjoining Ouadibou (Fort Saint-Étienne), was occupied in 1920, and Semara in the Saquiat el-Hamra in 1934. The total area is about 100,000 square miles but has an indigenous population of only some 60,000, half of whom are nomads who live there only in the rainy season. Considerable phosphate deposits make it a valuable territory, which Spain retained after 1960 in spite of the claims of Morocco and Mauritania. In 1969 the Spanish government sought to come to an agreement with Morocco for the joint exploitation of the deposits, while themselves retaining sovereignty, to be based on a plebiscite of the very few and impoverished inhabitants. Anti-Spanish disturbances in el-Aïoun in July 1970 made it seem unlikely that Spain would be able to present a convincing case for retention of the territory to the United Nations, with which the question of the future of the area is periodically raised.

North America

One of the most developed regions of the world, the North America of the 1970s enjoys an average income per person nearly twice as high as that of Europe; a food intake nearly a third greater than the average for Asia; and a per capita consumption of energy five times as great as the average of all the other continents. With an area of some 9,420,000 square miles (24,400,000 square kilometres) shaped like a huge inverted triangle, it is third in size among the world's continents. The home of over 320,000,000 people, or only about 8 percent of the world's population, it nevertheless produces over a third of all the factory-made goods of the globe. Yet, before the coming of European settlers and their African slaves, North America was not nearly as fully developed as the then contemporary Europe or Asia or parts of Africa. The subsequent extraordinary efflorescence can be attributed, in the opinion of many North Americans, to the free and dynamic nature of their societies, led by that of the United States. European colonizers did indeed set sail at a time of great scientific and technical innovation and were able to apply and develop new skills in lands untrammelled by the conventions and practices of the past, but it was North America's great natural wealth that accounted for much of the expansion, offering as it did extensive and, at the time, seemingly inexhaustible deposits of metals and fuels, vast forests, ample water resources, and a wide and stimulating range of climate and soils.

The name America is derived from that of the Italian merchant and navigator Amerigo Vespucci, one of the earliest explorers of what is now North America. He is thought by some authorities to have discovered and reached the mainland of the continent in 1497. There is no doubt that this claim was widely accepted after the publication, in 1507, of an account of his travels. The newfound lands that came to bear his name extended from Labrador in the north to Patagonia in the south, and it became convenient to designate those portions that widened out north of the Isthmus of Panama as North America, reserving South America for those that broadened to the south. It should be noted that some authorities take North America to begin, not at the Isthmus of Panama, but at the narrows of Tehuantepec, calling the intervening region Central America. Under such a definition, part of Mexico must be included in Central America, although that country lies mainly in North America proper. To overcome this anomaly, the whole of Mexico, together with Central and South American countries, may also be grouped under the name Latin America, with the United States and Canada referred to as Anglo-America. This cultural division is a very real one; yet Mexico and Central America (including the Caribbean) are bound to the rest of North America by strong ties of physical geography. Largely Danish-speaking Greenland is also divided culturally from, but connected physically with, North America. Finally, all the above areas are sometimes included under the general terms New World, the Western Hemisphere, or the Americas.

The naming of the continent

The first inhabitants of North America came from Asia, mostly by way of the Bering Strait out of eastern Siberia. Over the centuries, they had moved north and east away from the main centres of Old World civilization. They were comparatively primitive when they arrived and remained Stone Age hunters and fishermen for a very long time; indeed, many were still in this state when the first Europeans saw them. Their societies were not without interest in themselves, but most of them were ignorant of, or saw no use for, the wealth of metals and fuels at their disposal; they failed to use the vast waterpower resources and hardly tapped the timber reserves of the continent. Agriculture was only developed south of the Ottawa River and east of the Missouri Valley. Cities eventually appeared on the plateaus of Guatemala, Yucatán, and Mexico. Despite the great strides of the civilizations developed by the Mayans, Toltecs, and Aztecs, those peoples showed relatively little mechanical aptitude or commercial enterprise. They were no match for the Spaniards, who were scarcely lacking either attribute and who thus soon took over, conquering Mexico in 1519. The Spaniards were followed by the French, who set up a colony at Port Royal, in what was to become Nova Scotia, Canada, in 1605; and by the British, whose first Virginia settlement, at Jamestown, in 1607, was closely followed by that at Plymouth, Massachusetts, in 1620.

The Europeans soon began to piece together their own sense of the geography of the continent. In the south, the

Spaniards discovered a mountain arc swinging through the West Indies into Central America, together with a low, coastal plain around the Gulf of Mexico reaching up to lofty mountains bordering the high Mexican Plateau. Explorations revealed that the Mexican Sierras continued north in the Rocky Mountain and Cascade ranges. The British, meanwhile, had crossed the Atlantic Coastal Plain, a continuation of the Gulf Coastal Plain, penetrated the barrier of the Appalachian Highlands, and pushed into the vast Interior Basin centred on the Great Lakes. The French bypassed the Appalachians by sailing up the Gulf of St. Lawrence and, skirting the huge and inhospitable Laurentian Plateau to the north, moved deep into the interior, pressing on to discover the Great Plains skirting the Rockies. In the Far North, the British ventured into the Canadian Archipelago and explored the Mackenzie Basin down to the Arctic Ocean. Sailing up the Pacific coast, they circumnavigated Vancouver Island and penetrated the great Coast Range. In the space of 200 to 300 years, the European explorers had thus traced out the main limits of the North American continent.

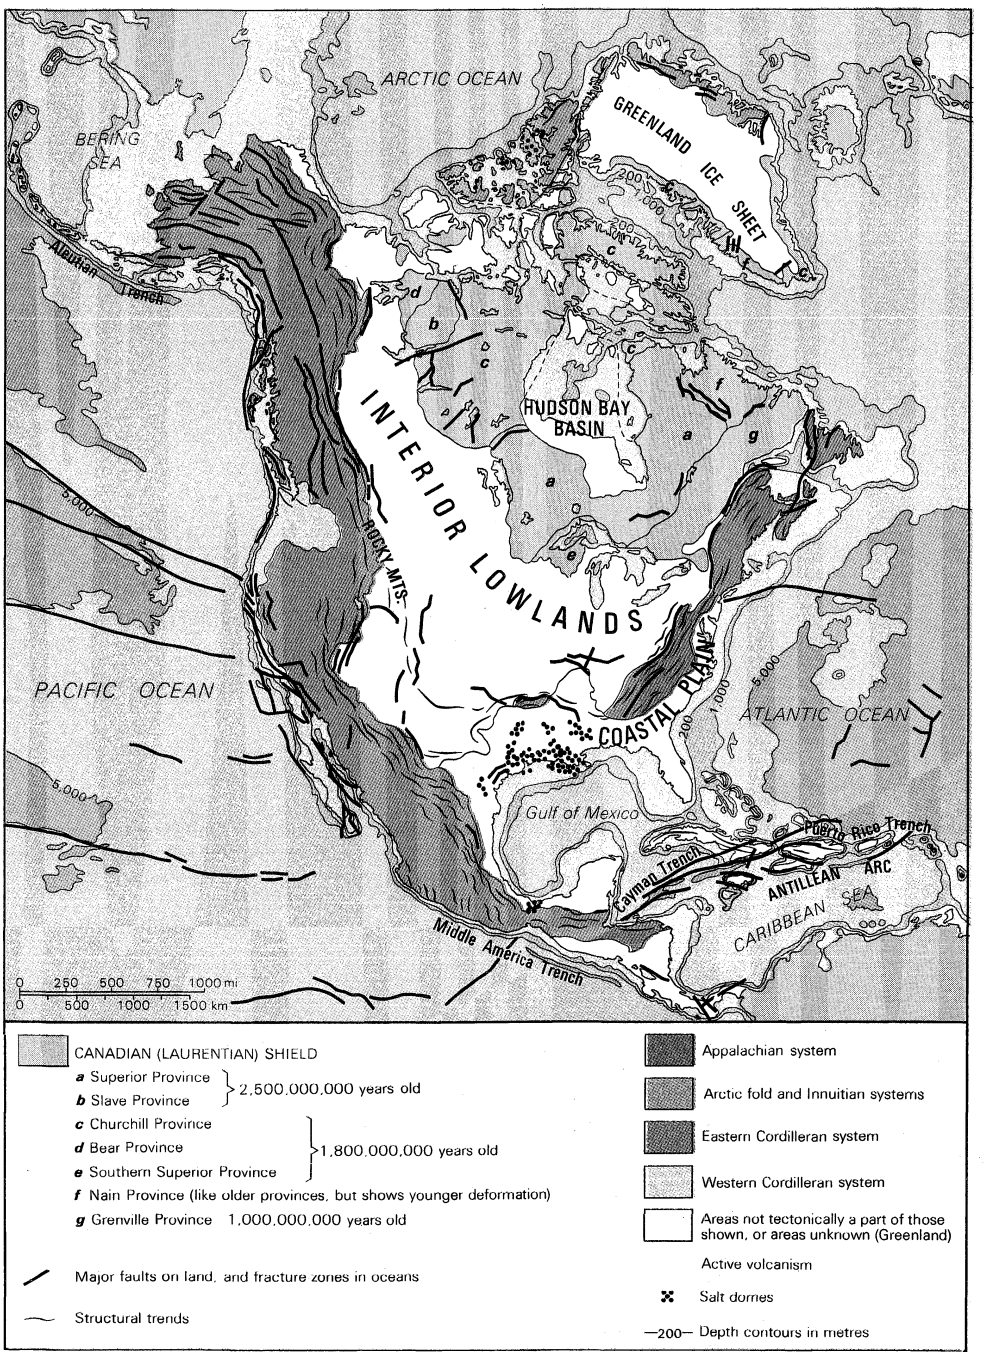
In due course, the Europeans also discovered a number of things about the continent: that the coastal and interior lowlands offered great scope for agriculture; that extensive reserves of timber occurred on the Appalachians, the Laurentian uplands, the northwestern Pacific ranges, the Southern Sierras, and the Central American mountains; that huge coalfields flanked the western Appalachians and underlay the Ohio and Central Mississippi basins; that rich deposits of iron lay on the edges of the Laurentian Plateau; that nonferrous ores were abundant in the Rockies and Western Sierras; and that oil and natural gas lay in pools under the Great Plains and the Gulf of Mexico lowlands.

These great resources were at first developed by the European empires: Spanish colonies in the southern parts of the continent; British colonies from Georgia to Newfoundland between the Atlantic shore and the Appalachians; and French colonies in the St. Lawrence–Great Lakes Basin and down the Mississippi in the continental interior. Later, the Russian Empire was to take over Alaska. North American societies, in essence, became European outposts in the New World, and they retain very strong ties with European cultures. Subsequently, first the United States, then Mexico and the Central American countries won their independence; the power of France gave way before that of British North America, and Canada became a self-governing country within the British Commonwealth. Swift progress was then made in developing North American styles of life, which became strongly Latin American south of the Rio Grande and Anglo-American to the north; slavery and its heritage added a significant minority culture of African origin. With this varied and often turbulent legacy, the continent became a powerful centre of world influence, instead of being on the margins of the civilized world, as in Indian times. The position of this new major power base between the two most densely populated regions of the Earth—western Europe and eastern Asia—has, for good or ill, given North America and its peoples immense global significance.

Evolution of North American societies from colonial to independent status

This article covers, in detail, the geological history and physical environment of the continent and offers an overview of its resource base, including human resources, and the patterns of economic and social development. Although this article covers the physical evolution of North America in terms of that larger definition of the continent which includes Greenland and the Caribbean islands, the sections covering human resources offer a conspectus primarily of mainland North America. There are separate articles on the major physical features of the continent; on its nation states and on their history; on the Canadian provinces and territories and the individual states of the United States; as well as articles on the major cities of the region; see also CONTINENTS, DEVELOPMENT OF.

This article is divided into the following sections:



Structural features of North America.

I. Geological history

North America has a latitudinal span of over 76°, stretching from southern Panama to Cape Columbia, in northern Canada, and extends over 175° of longitude from Cape Nordost Rundigen, in eastern Greenland, to Attu Island, in Alaska. This enormous reach gives it every climate from the virtually equatorial to the Arctic, but the shape of the continent, very narrow in the south and very wide in the north, reduces the amount within the tropics and expands the area in the temperate and polar zones.

ELEMENTS AND PROCESSES IN THE MAKING OF THE CONTINENT

The shape of North America may have resulted from the fact that, over a vast period of geological time, the continental landmass drifted away from Europe and North Africa. A glance at the globe shows that the vast northern edge of North America would fit into the correspondingly receding edge of Europe and that its narrowness in the

south could correspond to the huge bulge of western Africa. Geologists have worked out a theory of continental drift based on rigid areas in the crust, like plates, with zones of weakness in between. These are affected by currents in the molten rock material, or magma, beneath the Earth's crust. Immense pressures on the so-called plates led them to move into new positions, squeezing out the weak zones, marked by deep depressions, or geosynclines, on their margins. These became filled in with sediments and were then squeezed out and upward into fold mountains. Faulting—a vast shearing process along lines of structural weakness in the Earth's crust—occurred subsequently between continents as they were torn apart from each other. Faulting was followed by renewed and extensive folding on the outward advancing continental fronts. In the formation of North America, it is thought that a very stable area called the Canadian or Laurentian Shield parted from the Baltic and Iberian shields of Europe in Jurassic times, about 170,000,000 years ago. The ensuing gradual widening of the Atlantic Ocean led to extensive faulting along the east coast of North America; and the push of the continent against the "plate" underlying the Pacific area produced widespread folding in the west.

Other geologists have sought to explain the evolution and growth of North America in terms of its present position, first by a hardening of the Earth's crust through immense granitic intrusions, or upswellings of molten rock, which formed the Laurentian Shield, and then by the rise of great geosynclines where sediments, stripped from the shield over millennia by the forces of erosion, depressed the margins of the continent. From a stable core, at the heart of the Laurentian Plateau, great downwarps are then thought to have developed in contact with the Atlantic, Arctic, and Pacific oceans. These became so burdened by the debris of the eroded shield as to form lines of crustal weakness, which, in turn, grew into zones of volcanic activity and fold-mountain systems. The continent thus evolved by the outward expansion and final immobilization of marginal geosynclines. Indeed, there is an outward regression in age from a very old centre, where the rocks are nearly 4,000,000,000 years old, to younger margins, usually less than 600,000,000 years.

Conflicting theories of continental origin

Both of these theories have attractive features: each accounts for a central shield flanked by belts of marginal mountains. The extensive faulting in the north and east, separating Greenland from Canada, and the breaking off of the apparent connections between the Appalachians of North America and the Caledonian and Hercynean mountain-fold systems of Europe might well correspond to a shore torn from the Old World by the widening of the Atlantic and Arctic oceans. Similarly, the lofty region of mountain building in the west would correspond to an advance on the Pacific basin. On the other hand, the outward progression of geosynclines, formed by the weight of waste material washed from a central core and turned into lines of marginal mountains, would also explain existing North American structural patterns adequately.

Recent work on the Atlantic, emphasizing active widening by periodic vulcanism and faulting, strongly supports the drift theory. Ocean-floor spreading—a movement away from the centre line of the ocean basin, leaving a great midocean ridge, flanked by deeper parts, and often ending in major depressions toward the continents—is seen as the mechanism for the breaking up of the continents. It has been suggested that the North Atlantic began to open up in the Upper Triassic and the Lower Jurassic, between 187,000,000 and 172,000,000 years ago, while the South Atlantic started to widen in the Upper Jurassic, about 138,000,000 years ago. The major rifting of Europe and North America was not accomplished until the Lower Cretaceous, about 93,000,000 years ago. Greenland and Canada started to split up in the Upper Cretaceous, while Greenland and Europe moved apart somewhat later, in the Cretaceous–Paleocene, say 63,000,000 years ago. From that time on, North America became a truly separate continent, still drifting west, it is claimed, at a rate of just over half an inch, or about one and a quarter centimetres, a year. The "plate" flooring the Pacific basin, meanwhile, may have been thrust under the advancing continent.

The four chief structures of North America are a central shield; marginal mountains; interior lowlands between the shield and the mountains; and coastal plains. All have taken a long time to evolve. The shield itself, made up of the oldest rocks in North America, took longer to form than the rest of the continent put together. After its main structures had been built, it became the core area against which the marginal mountains were thrown up. These grew from immense geosynclines, which served as sites for the accumulation of tens of thousands of feet of material, sorted by the seas and later lifted up and squeezed into mountain ranges. The geosynclines divided themselves into (1) a shallower belt, the miogeosynclines, along the edge of the shield, and (2) a very profound belt, the eugeosynclines, farther out. Mountains evolving from the miogeosyncline were less intensively folded and less subject to volcanic activity than those growing out of the eugeosyncline. The Appalachians were the first mountain system to so evolve, followed by the Arctic fold belt and, in turn, by the comparatively young mountains of the west. Ancient seas, meanwhile, lying between the rising mountains and the shield, spread out the debris eroded from surrounding heights. Horizontally bedded sheets of sedimentary rock thus came to form the interior and coastal plains. Faulting, leading to immense fault-bounded blocks or to sea-drowned depressions, frequently interrupted the building up of these structures. Thus the geological history of North America has, right down to this day, provided the framework for its evolving physical geography.

North America's four chief physical structures

THE EVOLUTION OF THE CENTRAL SHIELD

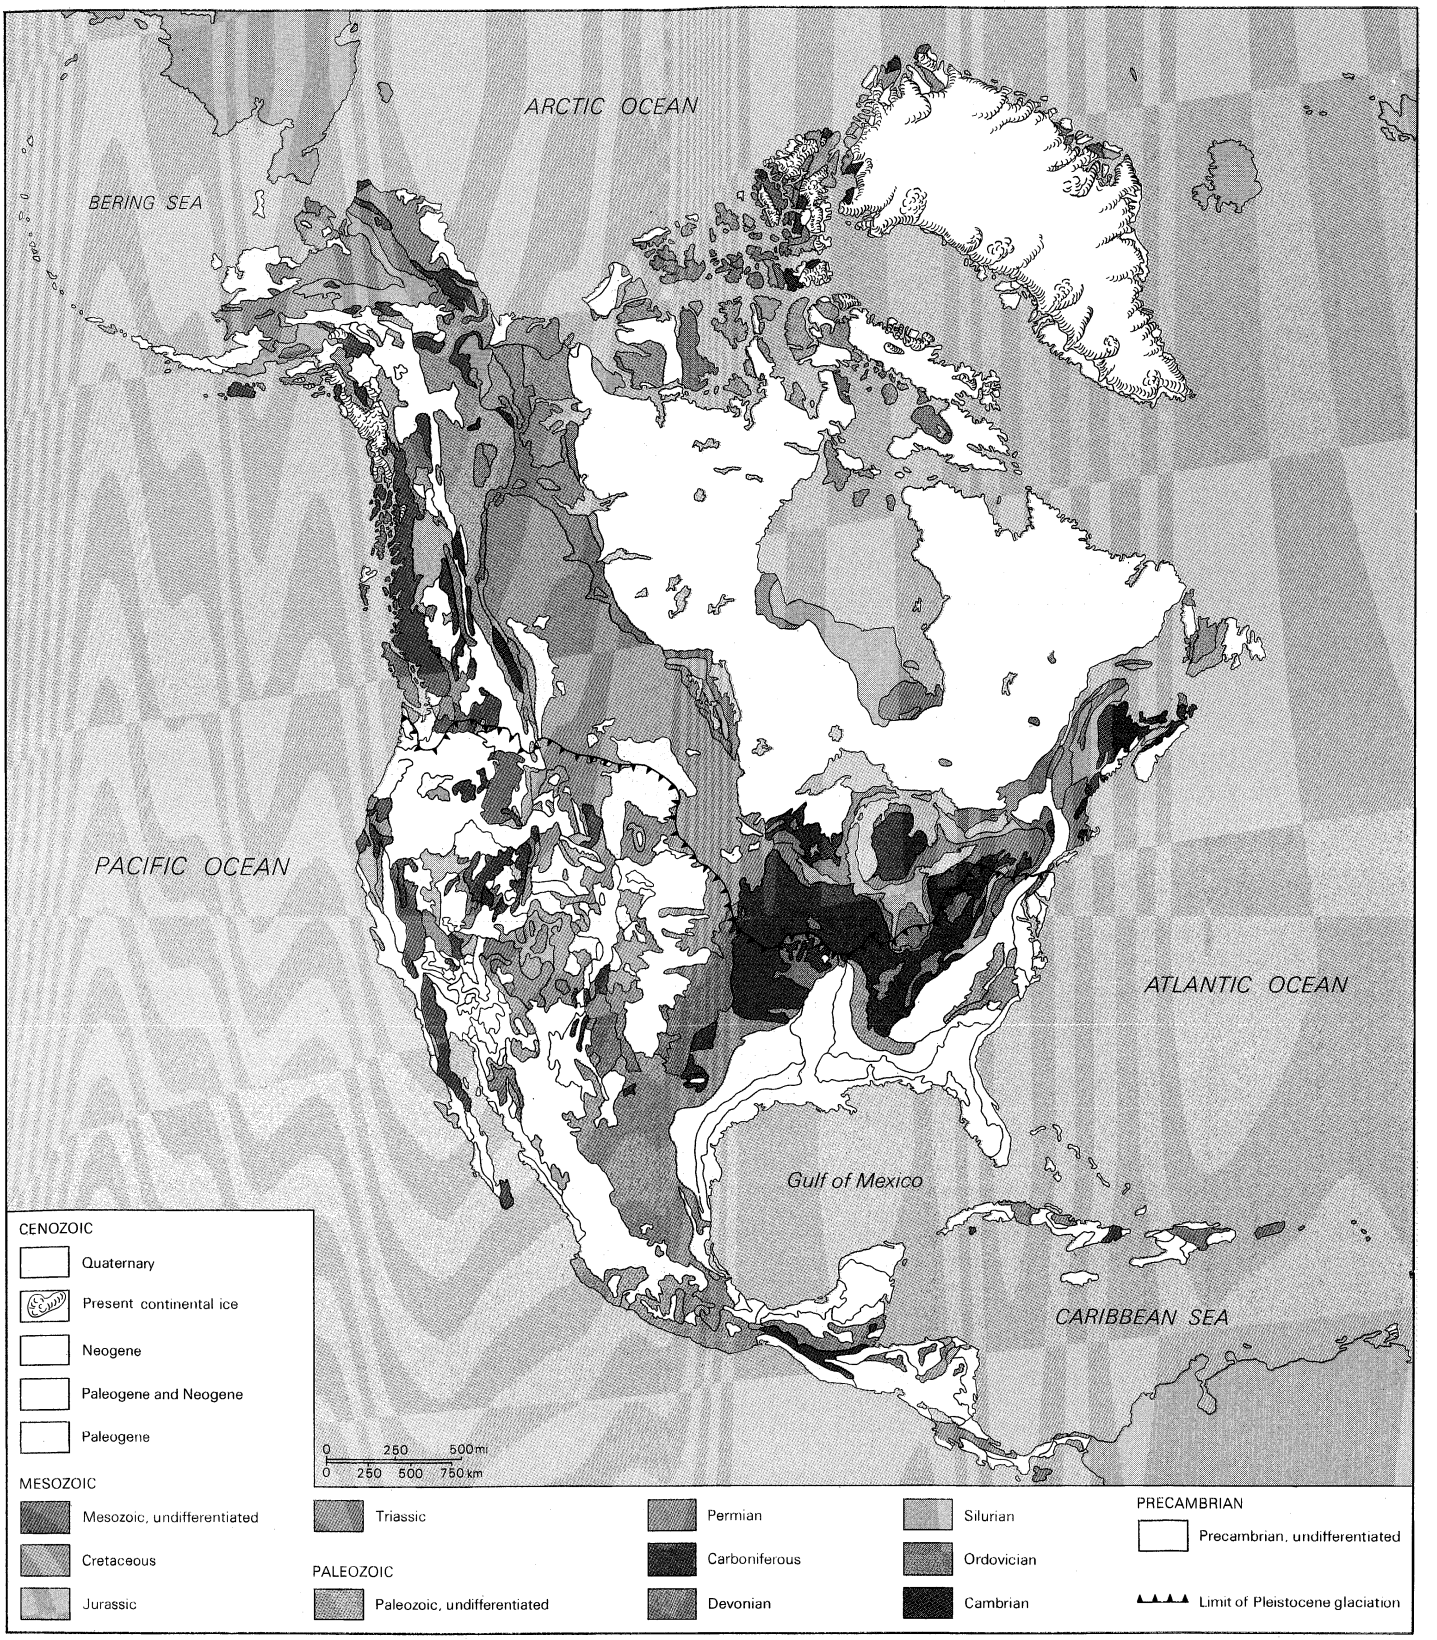
Basic structure. The central shield, variously called Laurentia, the Laurentian Shield, or the Canadian Shield, is the key structure of the continent, extending from the Adirondacks and the Superior Upland just south of Lake Superior, northward through Canada, both east and west of the Hudson Bay, to Greenland. It is, in fact, a group of shields that gradually coalesced, covering a total of 2,550,000 square miles, including 700,000 square miles in Greenland, and is largely composed of Archean and Proterozoic rocks formed in Precambrian times, more than 570,000,000 years ago.

The main trends of the shield sprang from an initial Y-shaped structure identified as beginning west and east of the Hudson Bay depression and then extending, as a subsurface welt, south of the Superior Upland to the Colorado Plateau. This great structure was subsequently tilted up in the east, in Greenland and in Labrador; it was faulted along the south and west to give way to the basins of the St. Lawrence and Great Lakes, of the Red River of the North and Lake Winnipeg, and the Mackenzie and its attendant lakes; and it sank beneath the vast hollow of what is now Hudson Bay to the north. Various accretions, joined to the initial structure, formed the rest of the shield.

The rocks of the shield fall into two main groups, the Archean and the Proterozoic, separated by a long interval of erosion. The Archean formations are subdivided into the Keewatin and Timiskaming, from the Canadian type areas where they were identified. The Proterozoic was accompanied by four great shield-building times, again named from their type areas, the Lower and Middle Huronian, the Animikie (or Upper Huronian), and the Keweenawan.

Development of Archean rocks. The original shield, going back at least 3,900,000,000 years, consisted of a series of volcanoes, with lava tablelands that spread out and filled up innumerable lakes in between. In early Archean, or Keewatin, time (there is great controversy over the dating of this process, and precise figures are meaningless in this context) the initial Y-shaped structure developed from great thicknesses of lava. These flowed out at intervals, were attacked by erosion and coated by weathered material, and then flowed out again, producing sheets of volcanic rock interbedded

Initial Y-shaped structure of shield



Rock strata of North America.

with sedimentaries. In the late Keewatin, prolonged erosion led to wide deposits of conglomerates (rocks made up of different materials) and sandstones on the western and southern edges of the shield. At a later time, these rocks were caught up in the Laurentian mountain-building movements, and, as a result, they were heavily intruded from below by granitic domes.

The shield then became faulted along its southeastern edge, forming a long trough where thick layers of limestone interbedded with shale (typified by deposits at Grenville, near Ottawa) were laid down. More changes took place in Timiskaming time, with the growth of the iron-bearing southern part of the shield, in the Superior Upland. During the structural upheaval known as the Algoman revolution, these rocks west and south of Lake Superior and along the north shore of Lake Huron were

George Hunter—Shostal

widely metamorphosed (or heat altered). Mountains also arose in the vicinity of Great Slave and Great Bear lakes, and the dislocations threw lava beds and sedimentary strata into nearly vertical folds, accompanied by large granitic domes.

Development of Proterozoic rocks. In the Eparchean interlude—a long stretch of time in which the mountains were worn almost completely down—the shield became virtually a plain. But, as the Proterozoic dawned possibly 1,500,000,000 years ago, lava flows occurred, indicating further crustal disturbances. The Lower Huronian series of lavas, conglomerates, and limestones were deposited in the northern part of the Great Lakes depression. Continued activity in the Middle Huronian raised these deposits about 1,700 feet, tilted the shield to the north, and laid down new deposits, preserved in the Cobalt and Chibougamau basins and in the Gulf of Richmond, on its inner edge. Further enlargements occurred in the Lake Athabasca–Darnley Bay area, in the northwest, and the Labrador–Baffin Island–Greenland region, to the east. Upper Huronian, or Animikie, time began with strong erosion that spread iron-associated deposits into flanking depressions from Lake Athabasca around to the Ungava trough. As erosion continued, the burden of material affecting the crust beneath led to volcanic outbreaks and the uplift and squeezing out of the geosynclines. The end of Animikie time saw new injections of igneous masses and the rise of fold mountains in the Great Slave Lake, the Belcher Islands, and the Ungava–Baffin regions.

Final growth of the shield

The final growth of the shield occurred in Keweenawan times. Its southern extension was enlarged by more iron-rich sedimentaries; the great Sudbury norite (granular rock) intrusion was formed; Lake Superior became a distinct elongated trough; and, in the Far North, the great Victoria trough saw a downwarping that gathered the Coppermine series of sandstones and lavas. Further shield extensions into the Arctic islands and Greenland continued. Keweenawan times ended in the massive Killarnean intrusions, east of Sudbury, and in renewed mountain building, especially just north of Lake Athabasca.

By the end of the Proterozoic, at about 570,000,000 years ago, when long periods of erosion had worn down the heights and built out extensive plains, the shield was a virtual lowland stretching from Greenland through to the Great Plains.

Later evolution of the shield. The shield never grew any bigger, but its chronicle of changes was by no means over. With the rise of the Appalachians against its southeastern edge in Ordovician times, about 480,000,000 years ago, the shield sank down in the centre to produce even wider and deeper waters than now occupy Hudson Bay. Further uplift in Middle Silurian times, however, raised the shield so high that Hudson Bay disappeared. Sinking followed; but in Devonian times, renewed strain stemmed from the rise of the Acadian mountains. As a result, the eastern rim was tilted up, and extensive faulting occurred. A long quiescence followed, wearing the whole shield down until Cretaceous times. Renewed disturbances, associated with the rise of the Rockies, then lifted up and broke the western shield edge; while between the Late Cretaceous and the Paleocene, about 65,000,000 to 54,000,000 years ago, the Labrador Sea began to open up between Baffin Island and Greenland. In mid-Pliocene, there was a resumption of ocean spreading in the North Atlantic, a general uplift of the shield, and, especially in the east and north, widespread faulting. The shield became depressed in the Pleistocene, over 1,000,000 years ago, under the enormous weight of the ice cap, and in postglacial times subsequently rebounded to its present level, size, and shape, as the massive core of North America.

Postglacial rebounding to present conditions

THE EVOLUTION OF THE MARGINAL MOUNTAINS

At the end of the Proterozoic, about 570,000,000 years ago, the shield was so massive that it then became the most stable area in North America, and subsequent continental deformation shifted to the great fold-mountain systems. The first of these to develop was the Appalachian fold belt, from the Late Cambrian (about 500,000,000 years ago) through to the Pennsylvanian (about 280,000,000 years ago). This first belt was followed by the Greenland and Arctic fold belts from the Late Paleozoic to the Early Cenozoic (from about 345,000,000 to 65,000,000 years ago), overlapping the Appalachians but continuing beyond them both in time and space; these were succeeded in turn by the Western Cordilleras, which began forming in the Jurassic Period (about 180,000,000 years ago) and continued right on into the Miocene (about 10,000,000 years ago), with a few volcanic outbursts in the Pliocene as late as 7,000,000 years ago.

Growth of the Appalachians. Growing out of a complex and varied system of geosynclines along the southeastern margin of the shield (or its buried extension), the Appalachians exhibited striking early contrasts between their western and eastern portions. The western ridges were lifted up from a comparatively shallow depression, or miogeosyncline, while the eastern ranges rose from a much deeper eugeosynclinal trough beyond the continental edge. The western division is made up of more regularly folded rocks with few igneous intrusions; the eastern parts are intensively folded and faulted and have been heavily intruded by crystalline bodies.

In Cambrian times, new disturbances in North America and Europe developed long depressions on the forefront of the central shield into which sands and clays and vegetable and animal remains were carried outward from the old and stable interior and laid down in such quantity as to create persistent, if slow, crustal subsidence. This pressure, in turn, generated a counterthrust that created island arcs of spouting volcanoes or molten igneous domes, which lifted earlier deposits and transformed them into great land swells. Subsequent folding produced the Appalachian Mountains proper, which depressed the edge of the shield into a sunken platform, buried under strata laid down by invading seas.

The geosynclines were squeezed out in a whole series of mountain-building movements, from Cambrian to Pennsylvanian times, or perhaps for as long as 200,000,000 years. The older northern movements were separated from the younger southern activities by a line running approximately through present-day New Jersey. The northern activity ran through the Maritimes and Newfoundland Island to Greenland, with a possible continuation in the Caledonian and Hercynian mountains of western Europe.

Northern Appalachians. In Cambrian times the northern Appalachians formed themselves into three distinct belts, in which were to mold the whole evolution and eventual relief of New England and of Canada's Atlantic

provinces. The first belt was an inner Laurentian geosynclinal trough along the present St. Lawrence River; the second, a central plateau-like upwelt, running through central New England to Newfoundland; and the third, the outer depression of the Acadian Geosyncline. The inner trough may be referred to as the Taconic Geosyncline from the Taconic orogeny, or mountain-building process, during Ordovician times, of old rugged fold mountains running through eastern New York. Further folding, mainly during the Silurian Period, saw the rise of the parallel ridges in western New England, swinging on to western Newfoundland and perhaps to Greenland and beyond. The central portions, however, remained a relatively stable mass, although they were extensively injected with volcanic rocks. During Devonian times, the outer Acadian trough saw the rise of short, fold ridges in eastern New England and the Maritimes, strengthening themselves in eastern Newfoundland before stretching on to possible European continuations. The zone includes a notable series of Triassic red sandstone beds, cut by ridges of volcanic origin.

The basic tripartite division of the northern Appalachians

Southern Appalachians. The younger southern Appalachians began southward of what is now the Hudson Valley, were interrupted by the Mississippi Basin, became active again in the Ouachitas (in Arkansas and Oklahoma), and may have had a Central American continuation to Venezuela. They arose in Mississippian to Pennsylvanian times, from 345,000,000 to 280,000,000 years ago. Like their northern counterparts, they evolved from inner and outer troughs but lacked the intervening geanticline, or huge upwelt. The inner trough was filled by silts and sands from great deltas pushed out between the rising Appalachians and the shield, together with limestones in deeper gulfs; these layers came to typify the Catskill, Allegheny, and Cumberland plateaus. Distinctive short folding produced the undulating topography now characterizing the central belt known as the Ridge and Valley region. The outer trough saw much volcanic activity, which, together with intense folding, helped to mold the hard granites, slates, and quartzites of the Blue Ridge and the Piedmont. Farther south, the Ozarks continued the sweep of the inner plateaus, while the wavelike surface of the Ouachitas pushed against older Texan rocks to form the great Ouachita Geosyncline.

Arctic fold belts. Structural disturbances then moved north, and, in Greenland and the Canadian Archipelago, the Arctic fold-belt mountains began to emerge as the Appalachian orogeny died down. This process perhaps reflected a distinct torque in continental drift, with a northern twist in North America's main move west. All along the east coast of Greenland, Paleozoic rocks, especially those of the Silurian (from 425,000,000 to 400,000,000 years old), were subjected to folding—possible equivalents of the European Caledonian orogeny. A northeastward trend leads, via a submarine ridge, to Svalbard (Spitsbergen). Greenland's northern shore is crossed by mountains with a west–east axis, considered an extension of ranges sweeping across northern Canada. In the Arctic as in the Atlantic, ocean spreading was putting pressure on North America. An Arctic geosyncline resulted, deepening in late Cambrian and Ordovician times (about 500,000,000 years ago) to attract clays and sands eroded from the Canadian and Greenland shields. Massive Cambrian sandstones overlie Precambrian rocks in eastern central Ellesmere Island; similar rocks and sheets of Ordovician shale and limestone slope northwestward off the high Precambrian spine of Baffin Island; and, far to the west, Ordovician strata overlap the shield in Victoria Island. Silurian rocks lie farther north, typically developed in western Devon Island and the Parry Islands and sloping beneath Carboniferous and Permian beds.

The Innuitian mountain system

The Innuitian mountain system, a major fold belt, rose up in this area, made up of rocks of Mesozoic age, from Prince Patrick Island to Ellesmere; folding may well have continued in Ellesmere until the early Miocene, some 25,000,000 years ago, or well into the mountain-building period typical of the Western Cordilleras.

The Innuitians, nevertheless, resemble the Appalachians more than the Cordilleras. Through Eglinton Island, in the west, and across northern Melville and Bathurst islands, they developed along an undulating series of parallel anticlines and synclines, with a distinct ridge and valley effect. The rocks consist of whitish sandstones with bands of black coal overlain by limestone. Pitching anticlines, with their cigar-shaped hills, and synclines, with their trough-topped ridges, became prominent and gave rise to the zigzag drainage patterns so striking in the inner Appalachians. The intensified folding and intrusions of volcanic rocks, however, are more reminiscent of the outer Appalachians.

The Cordilleras. The last, but certainly the greatest, system of mountains to form in North America, the magnificent Cordilleras rose mainly in post-Jurassic times, less than 136,000,000 years ago, when Atlantic ocean spreading had reached a critical point with the accelerated drift of the continent westward against the Pacific. The spreading of the Pacific floor, meanwhile, thrust eastward against the Pacific borderlands. The two forces must have created tremendous pressures all along the west rim of the central shield and so helped to inaugurate the squeeze-out of the giant geosynclines of the west that gave rise to the Rockies, Cascades, and Coast ranges, from Alaska to Mexico.

Cordilleran geosyncline. Rocks going back to Proterozoic times accumulated in a deep trough at what must then have been the outermost shield edge. Much erosion continued until in Cambrian times, over 500,000,000 years ago, the immense Cordilleran geosyncline developed from Alaska to Central America. It was not deep and may be regarded as a miogeosyncline, or a belt of troughs, often called the Millard zone of crustal weakness. Westward, the land swelled up into a tremendous geanticline of very old rocks underlying the Yukon, Colorado, and Mexican plateaus. Since this upwelling lay between the main lines of mountain building, it came to be known as the Mesocordilleran Geanticline. Its erosion deposited sediments into the Pacific that put pressure on the earth's crust and generated a deep geosyncline, a very complex belt with an inner and an outer division. This eugeosynclinal trough is known as the Fraser zone.

The tripartite division of the Cordilleras

These basic structures dominated the rise of the Cordilleras, dividing them essentially into three great belts: the Eastern Cordilleras, or Rocky Mountain system, along the inner edge of the old continent; a central string of high intermontane plateaus; and the Western Cordilleras, divided into the Cascadian and the Coast Range systems, on the continent's outer edge. A major difference occurred between the outer and inner mountains. Like those of the Appalachians, the inner mountains arose from a shallow miogeosyncline and consist of long parallel folds or blocks of relatively unfolded strata lifted up on high. The outer mountains, reminiscent of the emergence of the outer Appalachians, originated in a profound eugeosyncline intruded by enormous igneous masses, studded with tall volcanoes—some of them active until modern times—and intensively folded and faulted.

Eastern Cordilleras. In the late Jurassic, over 136,000,000 years ago, the Eastern Cordilleras emerged from the deeper Millard zone and spread inward over the buried shield edge. In the ensuing Upper Cretaceous, the Laramide structural revolution brought forth the western Rockies, spreading debris over what are now the prairies. Later still, in Eocene and Oligocene times, as late as 25,000,000 years ago, the eastern ranges of the Rockies started to rise, marked by slow uplift of great blocks of strata.

Western Cordilleras. The Fraser zone had also become disturbed. The Western Cordilleras exhibited Mesozoic conglomerates and coarse sands that were laid down unconformably, or disjointedly, on the older rocks, thus showing that upwells within the troughs had already been lifted up and then eroded. Movement became intensified during the Nevadan mountain-building revolution of the late Jurassic, raising and folding mountains from Central America to Alaska, including the Sierra Nevadas and the Cascades. Enormous igneous bodies were intruded into the rock layers: the largest was the Coast Batholith, or dome-shaped structure, underlying coastal British Columbia. The line of deformation then shifted outward

to a trough overlying the present coast ranges of California and Oregon and along the Columbian Trough, represented by the islands off British Columbia and Alaska. Deposition, from inland, overloaded the geosyncline and caused violent volcanic activity. Intense folding, uplift, and faulting followed, with thrusts toward the continental interior mostly in Late Cretaceous and Early Tertiary times, roughly between 100,000,000 and 50,000,000 years ago. The Late Tertiary Cascadian orogeny raised the western ranges yet again, led to renewed volcanic activity from southern Mexico through California to southern Alaska, and severely faulted the Sierras.

The intermontane plateaus. Lying between the eastern and western fold belts of the Cordilleras, and developed from several very old Precambrian and early Cambrian landmasses, the intermontane plateaus emerged as a broad median mass, or geanticline, that somehow resisted the downsinking, uplift, and folding of the mountain zones on either side. The Grand Canyon of the Colorado has exposed some of the oldest Precambrian rocks in North America; thus, the Colorado Plateau may well have been part of the initial structure of the continent, forming the base of the Y-shaped stable area that expanded in the north into the Canadian Shield. Although shallow seas covered it during the 250,000,000 years or so from Mississippian to Cretaceous times, this base was never depressed, and it divided the western geosynclines from the beginning. It was, however, subject to uplift at each of the mountain-building periods, and it was intruded by igneous rocks. To the north and south of it lie the intermontane basin-and-range provinces of the United States and Mexico, where uplift and faulting have produced a series of sharp-edged ridges between downthrown depressions. Farther north the Columbia Basin lava tablelands and the great igneous intrusions of the Caribou, Omenica, and Yukon plateaus dominate the structure.

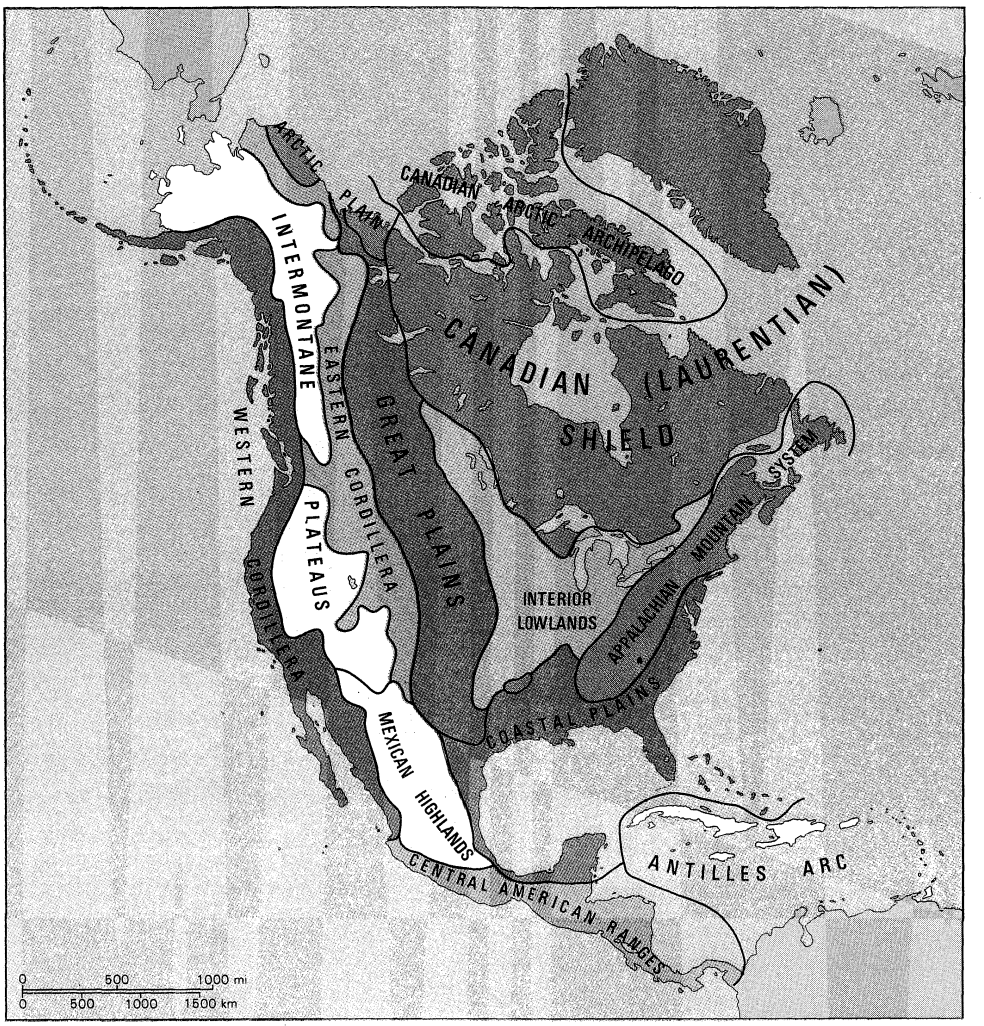
THE EVOLUTION OF LOWLANDS AND COASTAL PLAINS

The Interior Lowlands. While the marginal mountains slowly emerged, the Interior Lowlands of the continent



Physiographic regions of North America.

had been forming, growing between them and the central shield as well as over the shield's platform-like buried prolongations. The lowlands expanded by the infilling of great basins that sank between broad upwarps, or arches, in the buried platform. Seas spread in from the Mexican, St. Lawrence, and Beaufort gulfs and worked over and redistributed the debris being washed down from the surrounding mountains. Central marine and peripheral deltaic deposits built up the Interior Lowlands in the form of all-but-flat strata, a great contrast to the contorted structures of both shield and marginal-mountain belts. A mantle of Paleozoic rocks is preserved in the river basins around the western and southern margins of the shield. The covering Mesozoic rocks have since been worn back to the higher levels of the Great Plains and Peace River plains, often protruding back of such long, low escarpments as the Missouri Coteau. Cap rock of Tertiary deposits, swept out from the Rockies, formed plateau-like sections, or the High Plains, above the main stretches of the Great Plains. Finally, Tertiary marine deposits invaded the Lower Mississippi and Gulf plains to the south and the Arctic lowlands in the northwest.

Role of the buried shield

Pressures from the marginal mountains warped the buried platforms beneath the central plains, occasionally forming low plateaus above the general level of the lowlands; *e.g.*, the Nashville Dome, part of the Interior Highlands reflecting the upwarp of the Cincinnati Anticline. These upwellings have been eroded for so long that the tops of the rises have been worn away to form basins with infacing scarps. In the Ozark Dome, erosion has worn back the overlying deposits to expose a crystalline core represented by the St. Francis Mountains.

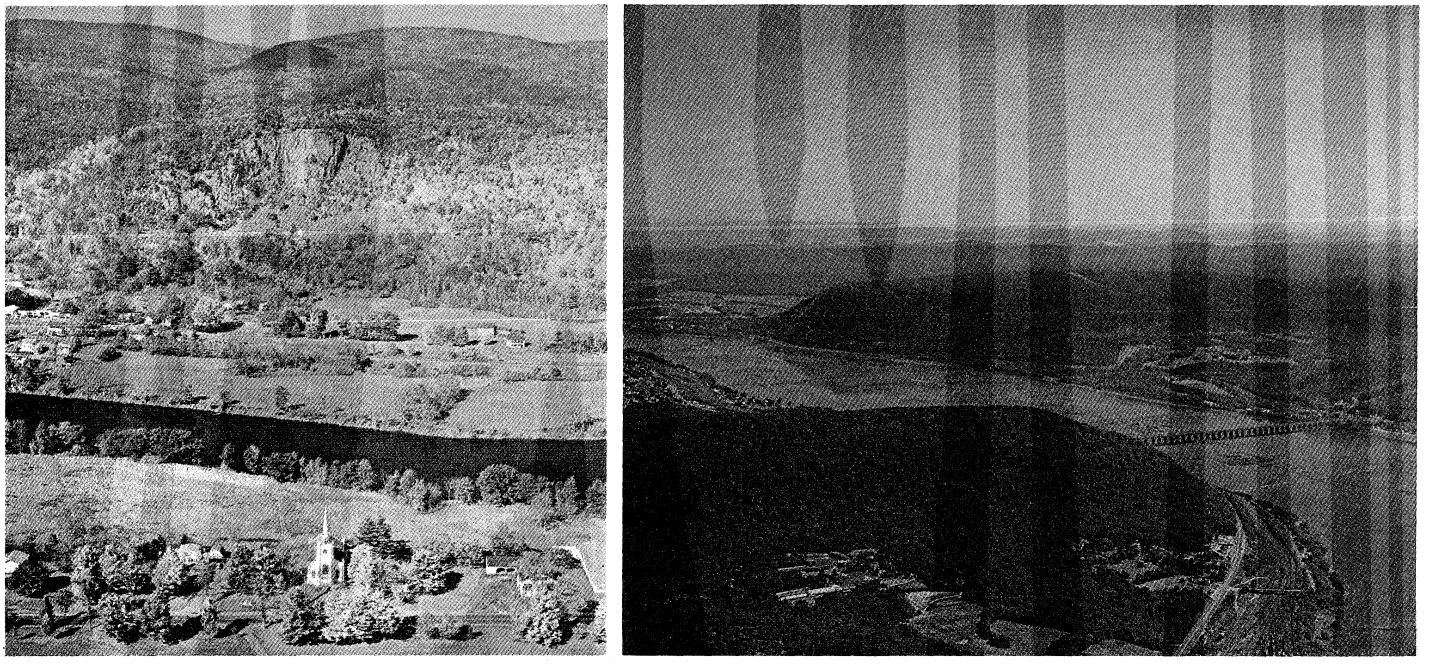
The coastal plains. Coastal plains are poorly developed in North America, mainly because of the extensive faulting that has let much of the land be drowned by the sea or—especially along the Pacific—because the marginal mountains step right down to the ocean. The whole of the west coast is virtually without a plain, except for such small and isolated deltas as those of the Fraser and the Sacramento. Folding and faulting along the northeast and northern coasts have practically eliminated lowland from New England to Ellesmere Island. Only in the southeast and the extreme northwest, along the gently declining shores of the Gulf of Mexico and of the southern Atlantic states or the slowly shelving levels around the Beaufort Sea have any extensive coast plains emerged. The Gulf and the Arctic plains are of interest in that they seem to be sinking into new geosynclines.

II. Physical geography

Although geology has been so important to North America that the 19th-century United States historian Frederick Jackson Turner once contended that the life of America flowed down the arteries of its geology, the continent has nevertheless been altered very considerably by climate and drainage and, to some extent, by soils and vegetation. The resultant physiographic regions dominate the contemporary geography of the continent.

THE CENTRAL SHIELD

Averaging 1,400 feet in height, with a very nubbly surface where old worn mountains and domes rise above ancient basins, the central shield has been left as a low plateau, tilted at its edges, and sinking down to Hudson Bay at its centre. The southern edge has the mountainous Algomans and Laurentians (more than 2,000 feet) and rises to above 4,000 feet in the great dome of the Adirondacks. The eastern edge is much higher, lifting itself near-



Appalachian landscapes.

ly 6,000 feet in the Torngats and 10,000 feet in Baffin Island; in Greenland, too, it tilts up appreciably in excess of 6,000 feet. The western rim is much lower, reaching only about 600 feet in parts. The old Snare and Nonacho ranges west of Hudson Bay lift the edge of the plateau to nearly 2,000 feet. Faulting broke up the northern rim into a series of prongs, extending into southeast Ellesmere Island and across Victoria Island, with sea-drowned channels and low sedimentary basins in between forming the Canadian Arctic Archipelago. The whole shield was under ice in the Pleistocene, and its high eastern rim still contains relics of the ice sheet. Ice-cut valleys in the higher areas, ice-plucked basins everywhere, and the ice-deposited ridges known as eskers and drumlins point to a major centre of ice dispersion over central Labrador, still noted today for its very heavy snowfall. Greenland was also a main glacial centre, while Keewatin in the west was an important secondary focus. After most of the ice had melted, portions of the shield rose, leaving traces of former beaches all along Greenland, Baffin, Labrador, and the Gulf of St. Lawrence, thus providing narrow but vital benches for human settlement. Ice-cut rock basins and ice-dammed streams have left countless lakes that make parts of the shield almost more water than land.

Centres of glaciation over the shield

THE MARGINAL MOUNTAINS

The Appalachians. Erosion also profoundly altered the marginal mountains. The Appalachians have been planed down to such an extent that their crest lines are smooth-topped for hundreds of miles. Several levels at which summits accord with each other in height indicate a series of uplifts followed by planations. In Canada, the highest level lies at about 4,000 feet, in the flattops of the Shickshocks; another exists at 2,000 feet on Mt. Carleton; and lower ones lie at roughly 1,100 and 600 feet in the Acadian ranges. In New England very resistant mountains like Mt. Washington and Mt. Monadnock rise above a broad mass of ridges at just above the 2,000-foot level, which in turn rise above the 1,100-foot-high New England Upland. Glaciation deepened and straightened the valleys, strewed their sides and parts of the coast with debris. Portions of sea-buried end moraines, which mark the limit of the tonguing glaciers, form offshore banks east of Newfoundland, Nova Scotia, and New England. The unglaciated Appalachians, south of the Susquehanna River, have striking accordances of long flat-topped summits at about 2,500 feet and broad terraces at 500 to 600 feet. The Ridge and Valley section's pattern of drainage consists of short, deep gaps across the ridges and long parallel stretches in between. East of the Blue Ridge extends the Piedmont Upland, terminating abruptly in the Fall Line, where its rivers plunge down to the Atlantic Coastal Plain over rapids or falls. The Hudson–Mohawk gap represents a major break between the northern and the southern Appalachians and affords a natural entry to the interior of the continent.

The Cordilleras. Taking up about a third of North America, the Cordilleras completely dominate Alaska and Central America and swell out widely in the United States Rockies.

The Canadian mountains. In Canada the Cordilleras consist of six well-marked zones: the 10,000- to 12,000-foot-high Rocky Mountains continuing north into the Brooks Range of Alaska; the Rocky Mountain Trench, a profound fault feature carrying the headwaters of the Columbia, Fraser, Peace, and Yukon rivers; the interior uplands and old fold mountains from the Selkirks and Okanagans in the south beyond the Cassiar Massif, to the Yukon plateau in the north, mostly lying at about 2,400 feet but with ridges over 8,000 feet; the Coast Mountains extending north into the Alaska Range, and including lofty volcanoes in the north; the Inner Passage from Puget Sound to Alaska, possibly a downfaulted zone flooded by the sea; and a structurally complex outer Island Arc, running from Vancouver Island to the Aleutians. The magnificent scenery of the northern Rockies, including U-shaped valleys often extending westward into sea-drowned fjords, has been heavily glaciated, and some areas still nurse sizable glaciers.

The six zones of the Canadian Cordilleras

Cordilleras of the United States. In the United States the Rockies, typified by flat or gently folded rocks, sweep south from Canada into northern Montana as the Lewis Range. They then change to a group of domes or long anticlines with "parks" or broad basins between them. This park and dome area is characterized by the peeling back of younger rocks from the cores of much older, primary rocks at the heart of the anticlines. The southern Rockies have striking volcanic peaks. Westward is the vast region of the intermontane plateaus, extending from the Selkirks of Canada across the immense lava tablelands of the central Columbia–Snake River Basin. South lies the Basin and Range Province, where the broad central plateau has been split by a great number of fault

ranges, the slopes of which plunge under basins partly filled with debris worn from the ridges—a pattern often repeated in the central Mexican Plateau. The Colorado Plateau is a massive feature with a series of relatively flat bedded ridges, made steplike by faulting action and intruded by domes of igneous rocks. Its slow elevation was matched by the steady downcutting of the Colorado River, producing, in the Grand Canyon, one of the greatest gorges in the world. Westward rise the beautiful high Sierras, reaching to nearly 15,000 feet, intensively folded and faulted, and continued north in the Cascades, marked by some of America's most beautiful extinct volcanoes. Seaward of this lofty mountain zone is a line of depressions marked by Puget Sound, the Great Valley of California, and the Gulf of California. These are separated by knots of volcanoes, as in the Klamath Mountains, and enclosed by the Pacific coast ranges, including the volcanic peaks of the Olympus group. This whole area has been profoundly faulted. Along some of the faults, notably the San Andreas, earthquake shocks occur from time to time, occasionally with devastating results.

Mexican and Central American mountains. In Mexico the folded Sierras to west and east of the central plateau terminate in the grandeur of a mass of high volcanoes, of 15,000 to 17,000 feet, south of the fertile lake-filled basins of Guadalajara and Mexico City.

The structural break at the Sierra Madre del Sur

The Balsas Basin then makes a distinct break. To the south, the Sierra Madre del Sur and the mountains of Guatemala and Honduras exhibit a west–east trend. This structural region includes a sweep of fold mountains of from 4,000 to 6,000 feet, with Caribbean extensions in Jamaica, southern Cuba, the island of Hispaniola, and Puerto Rico. These mountains swing south through the West Indies, a chain of volcanic islands fringed with coral reefs or limestone plateaus. Another arc, of two lines of fold mountains on either side of the Nicaraguan trench, dominates Central America and links it with the folds of western Colombia, in South America.

THE LOWLANDS

Glaciated areas. The lowlands of North America show marked differences between glaciated and unglaciated areas. Long irregular lines of coarse morainic deposits mark the regions where the Cordilleran ice sheet, moving down from the Rockies, met the continental sheet from Keewatin. The huge, tonguing loops of end moraines also occur between the Red and Mississippi rivers and along the south side of the Great Lakes—some running for hundreds of miles and standing 300 or 400 feet above the plain. Four major glacial advances covered the lowlands with debris: the Nebraskan crossed the Missouri River; the Kansan came to the Lower Missouri and the Ohio rivers; the Illinoian overlay these older areas to southern Illinois; and the Wisconsin heaped its moraines over the southern Canadian Prairies and the Great Lakes–Ohio–Mohawk–Hudson plains (see also below *Drainage patterns*).

Unglaciated areas. In the ice-free areas, lowlands are river molded. Streams debouching from the Rockies have spread sands, occasionally whipped up into sand hills, well beyond their banks; those funnelling into the Mississippi have created a vast alluvial plain running out into the Mississippi Delta. The Coastal Plains are marked, in addition, by lines of sand hills, the relics of stranded beaches that eroded as the plains were lifted slowly out of the seas in postglacial times.

THE ROLE OF CLIMATE

Climate has made a great deal of difference to relief—particularly in the extremes of cold or hot and dry or humid landscapes; climate has also, in turn, been affected by relief. The enormous northern width of the continent has meant a great extension of Arctic and cool-temperate climates, while the tapering south has greatly reduced the area under the tropics. The Cordilleras have very wet, windward, Pacific-facing slopes and dry, leeward, interior-facing slopes. Water systems such as the Mississippi–Ohio and the Great Lakes–St. Lawrence tend to funnel the sweep of rainstorms across the central parts of the continent, and the Gulfs of Georgia, Mexico, and the St. Lawrence also concentrate wind streams.

Temperature. While the greater part of North America falls within the temperate zone, a fact that has made it attractive to European settlers in post-Columbian times, large cold areas lie in the north and extend as far south as the Ozarks in winter. The continent's northerly position means that Greenland, the Canadian Shield, the Mackenzie Lowlands, and the northern part of the Cordilleras have an unusually long and cold winter. Much of this land has permanently frozen subsoil and is under snow and ice most of the year. The frequently frozen seas interlacing the Canadian Archipelago, together with innumerable northern lakes, produce an enormous chilling effect on the air above, and the temperatures for this huge regions are 6° to 8° F (3° to 4° C) cooler than the average for their latitude. The North Pacific, warmed by an extension of the Kuroshio current, has a positive anomaly of 8° to 10° F (4° to 6° C) warmer than the average for its latitude. Related trends over the northern part of the North Atlantic affect Iceland and Europe rather than North America but still raise the temperatures off the northeast coasts by perhaps 2° F (1° C). The climate thus shows marked contrasts between the maritime and continental areas. A notable warm loop of temperatures extends up the west coast from Vancouver Island to Alaska, while a great cold loop extends down the Mackenzie plains and the Canadian Shield over the heart of the continent. The chilling effects of the great Greenland ice cap drag cold continental conditions over the northeast coast at least as far as Newfoundland. The average January temperatures of Annette Island in the Alaskan panhandle, 29.5° F (−1.4° C), of Fort Smith, Northwest Territories, −13.8° F (−25.5° C), and of Nain, Labrador, 1.3° F (−17.1° C) show the difference between coastal and continental conditions and also between the west and the east coasts—differences negligible in the tropical parts of North America.

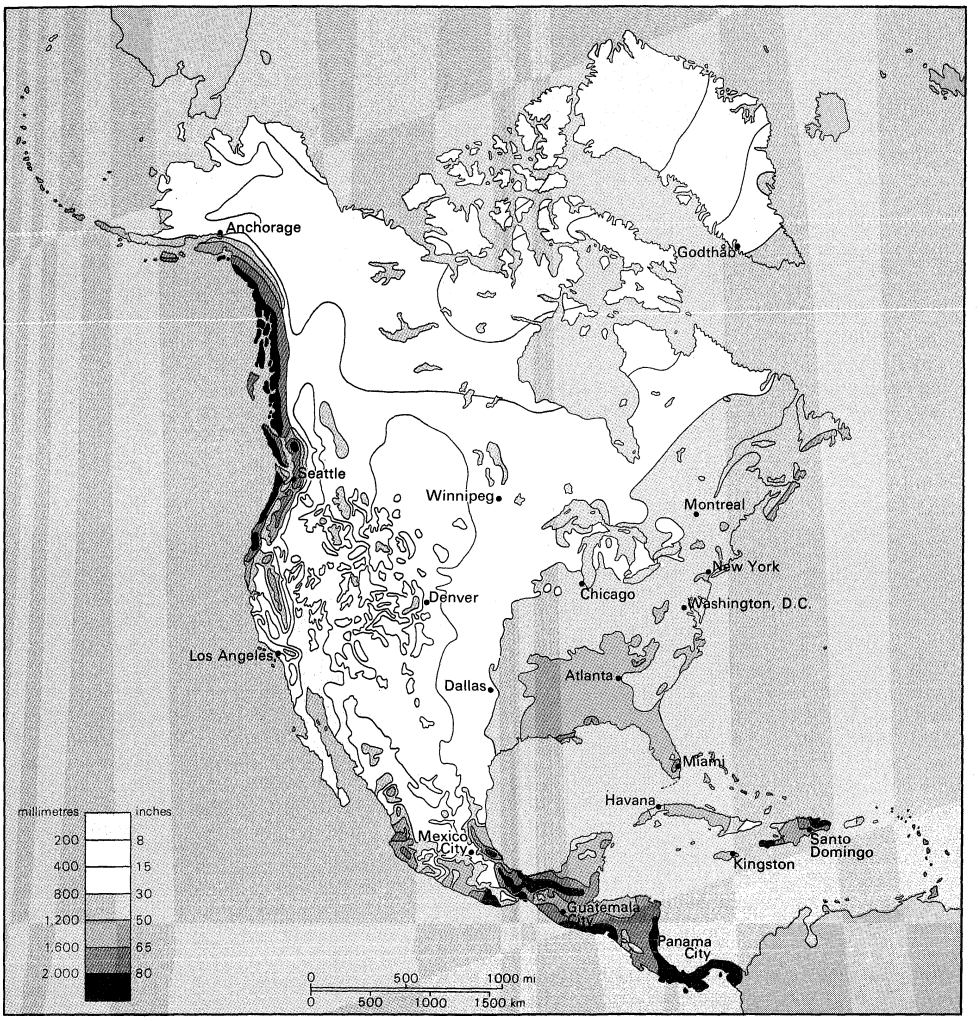
Chilling effect of frozen subsoils and seas

Precipitation. Most of the continent is humid and provides a good water supply for settlement and development. From mid-California north, the Pacific Coast is bathed with rain- or snow-laden Westerlies, giving from 40 to 200 inches (1,000 to 5,000 millimetres) of precipitation a year. Westerlies again reassert themselves east of the Rockies and, especially east of the Missouri River and Red River of the North, bring about moderately wet (20 inches) to wet (45 inches) conditions in the central and eastern regions. There are two main areas of drought: one in the extreme north and northeast, under the influence of very cold and relatively dry winds, with a thin dusting of winter snow and a meagre fall of summer rain in the Canadian Archipelago and Greenland; the other in the southwest, where the mid-latitude high-pressure system leads to dry offshore winds from mid-California to southern Mexico. Since these winds blow from the interior out to sea, they carry very little moisture, with precipitation in that area usually less than ten inches a year.

Two main areas of drought

Air masses. The continent's air masses reflect very different conditions of temperature and precipitation; they include northern and southern components, subdivided into continental and maritime types. In the north are found: the Arctic air mass, over Greenland and the Canadian Arctic Archipelago; the polar continental, over northern central Canada; the polar Pacific, over Alaska and the northern Pacific shores; and the polar Atlantic, off the Atlantic provinces of Canada and New England. The tropical continental air mass, over the intermontane basins of the Cordilleras from Utah south; the tropical Gulf, centred in the Gulf of Mexico and the Caribbean; and the tropical Atlantic off the southeastern states characterize the south-southeast.

The polar continental, the tropical gulf, and the polar Pacific are the most significant air masses. The polar continental reflects the spread of a negative temperature anomaly over much of the continent. It is a cool to cold mass of stable air forming an immense dome of high pressure above the Canadian Shield, with winds blowing outward to sweep over Labrador and New England or south-



Average annual precipitation for North America.

ward across the Great Lakes and the Great Plains. At its maximum, it extends from the Canadian Arctic Archipelago to the Ozarks. In winter it joins with the Arctic air mass over Greenland to make a formidable body of cold heavy air that carries subzero weather as far as the Ohio Valley and may overflow the Appalachians and seep through the Rockies. Exceptionally, it can carry killing frosts into the Great Valley of California, the coast of Texas, and the neck of Florida.

In the spring it shrinks north before the swift advance of the tropical Gulf air, which is drawn northward by low pressures developed in the Mississippi Basin as the heart of the continent heats up. The air mass is warm, wet, and unstable; at its height in late July, it extends two enormous loops of warm air, one northwestward up the Mississippi and down the Mackenzie and the other northeastward up the Ohio and down the St. Lawrence. The July average of 60° F (16° C) is then carried north of Edmonton, in the west, and to Quebec, in the east. The storm-generating polar Pacific air mass is very active from northern California to Alaska, especially in the winter, when its mild, wet air reflects the North Pacific temperature anomalies.

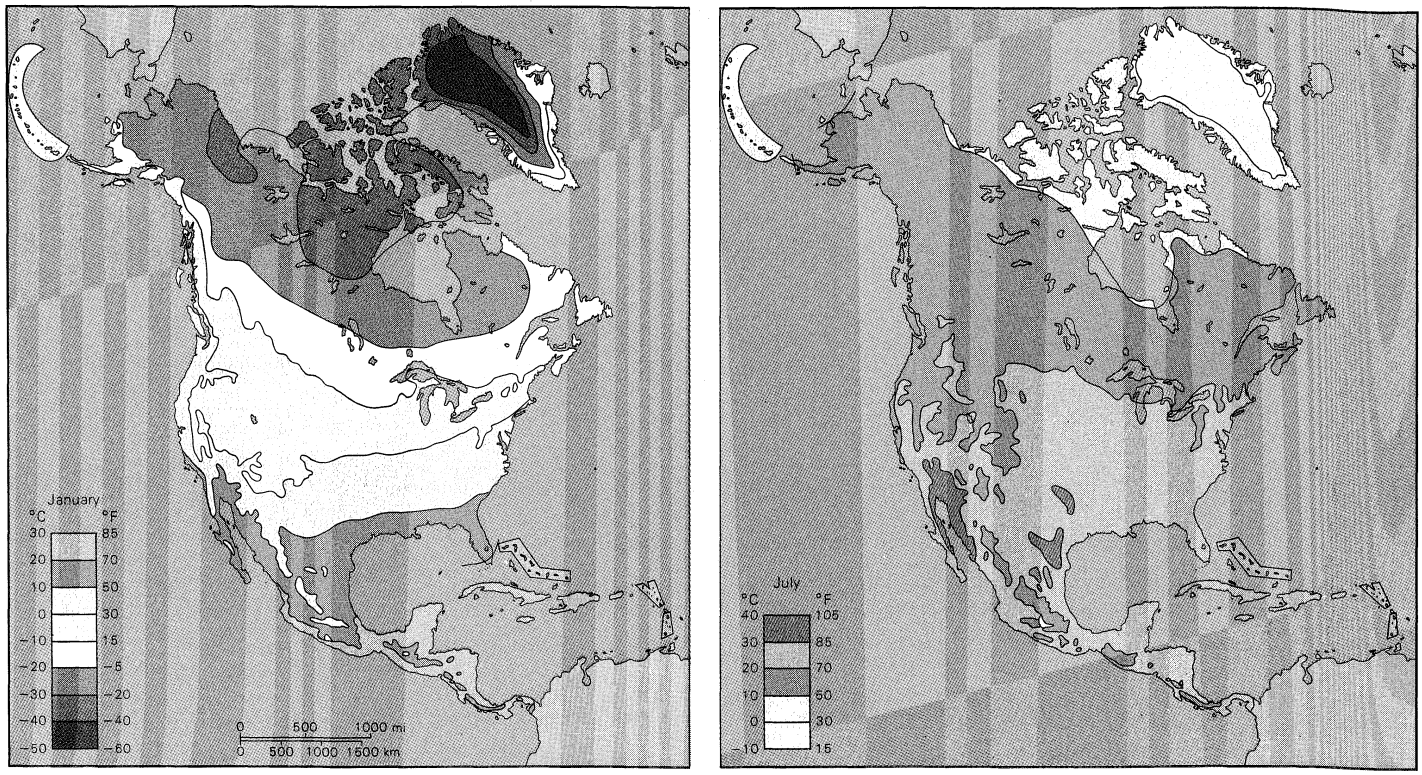
Storm tracks. Where cyclones develop persistently along the advancing air-mass edges, strong storm tracks occur. Pacific storm tracks thread the Gulf of Georgia, Puget Sound, and the Inner Passage to Alaska. In summer they shift north of Prince Rupert; in the depth of winter they migrate south to San Francisco. Moving up the great Columbia and Fraser river valleys, they may pass through the Rocky Mountain passes. An upper stream of Pacific air overtops the mountain barrier and, on descent, starts off lee storms that then traverse the continent. These draw in air from the polar continental air mass on their advancing cold sectors and from tropical Gulf air in their warm sectors. As the polar continental air mass begins to expand in September, a Mackenzie–James Bay line of storms develops, migrating progressively southward to reach a Texas–Ohio track in January. As the tropical Gulf air mass expands north, the successive tracks become activated again until, in August, the Gulf air brings a swirl of storms to the Mackenzie. Most of these storm tracks begin in the western plains, converge on the Great Lakes–Ohio area, and then bunch together in the climatically stimulating St. Lawrence–Hudson–Mohawk zone. The Atlantic Coastal Plain becomes a storm track in winter as tropical maritime air contests the advance of the continental air from the north.

Pacific-coast storm tracks

Climatic regions. Differing continental climatic regions reflect the considerable amount of Arctic land, the great spread of temperate conditions, and the small but significant tropical area; dry climates also stand out in strong contrast to the prevailingly humid ones.

The Arctic zone. Including the northern parts of the Canadian Shield and Alaska, the Canadian Arctic Archipelago, and Greenland, the Arctic zone is dominated by Arctic and polar continental air masses and is perennially cold or cool. Subzero weather lasts for five to seven months, and subfreezing weather lasts for eight to ten months. It is only June to September that temperatures rise above 32° F (0° C). The frost-free season is not more than 60 days. Precipitation is low, with two to four inches of summer rain, plus 30 to 60 inches of winter snow. Most of the Arctic is a cold desert.

The cool-temperate zone. The cool-temperate zone extends from Newfoundland to Alaska and from Hudson Bay to the Ohio. It is dominated by the polar continental



Average temperatures for January and July for North America.

Zone of long, severe winters

air mass. Winters are long and severe. After an "Indian summer" that continues into October, temperatures fall quickly and do not rise substantially until April or early May. In January and February they drop to below 32° F (0° C) on the Ohio and below 0° F (−18° C) north of the Great Lakes, with minima as low as −20° to −80° F (−29° to −62° C). Winter killing of crops and spring and autumn frosts are a hazard in the Canadian parts of the region, where the frost-free season is from 90 to 165 days. A swift transition occurs with spring; tropical Gulf air raises monthly mean temperatures to over 50° F (10° C) in June and from 60° to 78° F (16° to 26° C) in July. Precipitation is moderate, with 15 to 35 inches; as evaporation is low, however, most of it is effective for growth. The maximum precipitation occurs in summer to fall, when the James Bay, Alberta, and Wyoming storm tracks are activated.

Warm-temperate zone. On the southeast coasts of the United States, the warm-temperate zone extends to the Mississippi and over the Gulf plain; the zone is strongly influenced by the tropical Gulf air mass. The long frost-free season lasts more than 200 days. The tropical airs spread north in February and dominate the region until November, when polar continental air makes itself felt. Winters are mild, with January means of from 40° to 54° F (4° to 12° C). July averages are tropical, being as high as 81° F (27° C). This warmth and the long growing season allow for subtropical crops. Rainfall is ample, ranging from 40 to 60 inches, and benefits from the presence of the Colorado and Texas low-pressure systems and from the strong summer movement of tropical maritime air. By then the landmass is intensely heated, and this, combined with the air movement, produces frequent thunderstorms, especially in early summer. Hurricanes are an annual hazard along the Gulf and up the Lower Mississippi.

In the United States Southwest a different regime pertains, with a Mediterranean type of climate; summers are dry, since the tropical continental air is dominant. July means of 70° to 80° F (21° to 27° C) are found, with bright, sunny skies. Winters are mild (45° to 50° F [7° to 10° C]) and wet, with polar Pacific airs swinging south and bringing heavy rain. Frost is rare but may occur when polar continental air thrusts through to the coast. Los Angeles has a record minimum of only 23° F (−5° C). The annual rainfall of from 15 to 30 inches, along with very high evaporation, often is insufficient unless supplemented by irrigation. Drought is a frequent hazard.

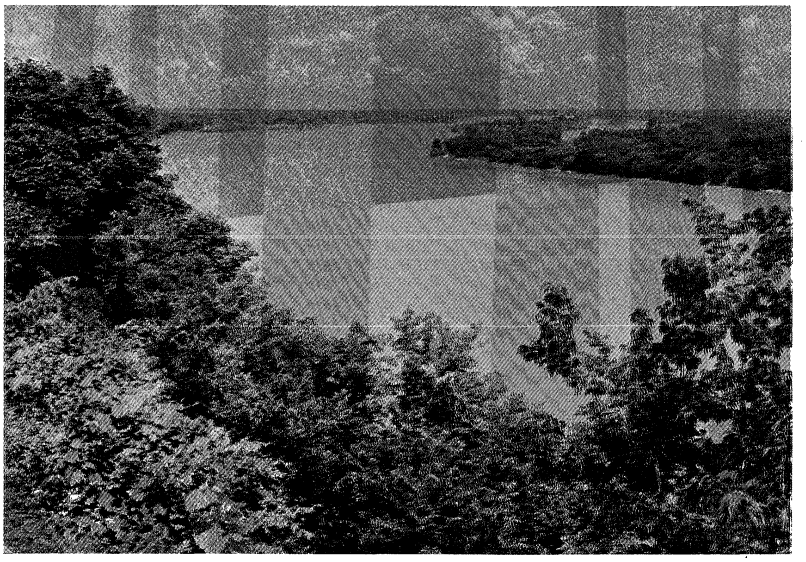
The tropical humid climate. Central America, with its tropical humid climate, knows no winter; even the coldest month averages above 64° F (18° C). With summers of 80° to 82° F (27° to 28° C), the mean annual temperature range is low—markedly different from most of North America. Rain is ample and regular, with 45 to 80 inches where the trade winds blow onshore. Lee valleys are, however, often quite dry. Summer hurricanes frequently recur, causing much damage.

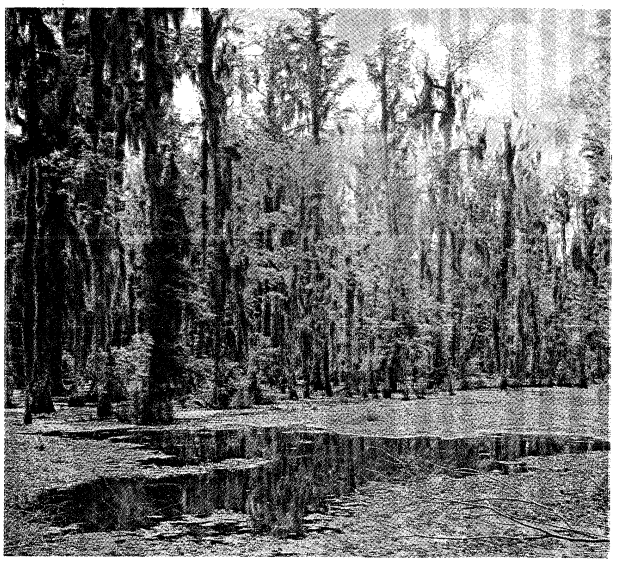
Dry climates. About a third of North America, including Arctic areas, has a dry climate. Chief dry areas lie in the Southwest, where a combination of the mid-latitude high-pressure belt, the tropical continental air mass, and the rain-shadow effects behind the high Western Sierras has led to lack of rainfall. Winds blow from the continent outward, discounting the effect of the Pacific. As the winds move down from high interior plateaus, they become drier as they descend. The intermontane region of the United States and Mexico, from the Columbia Basin to Guadalajara, and the Pacific Coast from San Diego south to Mazatlán are therefore arid, with less than ten inches of rain a year. Some years have no rain. The Great Plains, from the South Saskatchewan River to Mexico, are semi-arid, with from ten to 15 inches of rainfall; the high midcontinental airflow known as the jet stream is depressed over them, strengthening downmoving dry wind from across the Rockies and tending to fend off cyclones from tropical Gulf or polar continental air masses.

Factors in the Southwest's aridity

DRAINAGE PATTERNS

Drainage conditions and water supply are affected markedly by climate, though they also reflect relief. North America has one of the longest rivers in the world (the Mississippi) and also a drainage system with one of the greatest water capacities (the St. Lawrence–Great Lakes system). It is a continent of immense rivers—very largely because of their vast drainage area in the long and broad plains between the central shield and the marginal





Mississippi River Basin.
(Left) The Mississippi River at Hannibal, Missouri. (Right) Coastal swamplands of southern Louisiana, United States, showing moss-draped cypress trees.
(Left) Fred Bond—Publix, (right) Josef Muench

mountains. Rivers rising in the shield, the Appalachians, or the Cordilleras that flow into the Interior Lowlands have a long way to go to reach the sea. The Great Lakes–St. Lawrence on the east and the Mackenzie on the west drain the outer edges of the shield. The Nelson takes advantage of the low saddle in the shield to carry the gathered waters of the Saskatchewan and the Red out by way of Lake Winnipeg to Hudson Bay, which also has fairly long rivers draining into it from the uptilted edges of the shield. The vast Missouri–Mississippi–Ohio system draws from the Cordilleras, the shield, and the Appalachians to unite the Central and Gulf Lowlands, in the heartland of the continent. From the Rocky Mountains, long rivers like the Colorado, Columbia, Fraser, and Yukon continued to flow west to the Pacific even across the Cascade-Nevadan and the Coast ranges as these were lifted up. Fed from eternal snows, they are particularly valuable in the arid Southwest.

There is a marked asymmetry to the continent's drainage: the chief continental divide, along the Rockies, is well to the west, thus shedding the longest rivers to the east. The longest tributaries—the Peace into the Mackenzie, the Saskatchewan into the Nelson, and the Missouri into the Mississippi—coming from the west, tend to displace the mainstreams to the east. The chief gulfs—Hudson Bay, the Gulf of St. Lawrence, and the Gulf of Mexico—taking the discharge of many of the rivers, are also on the east. All these factors helped the European settlers to move from their Atlantic bases into the heart of North America.

Lakes. Lakes abound in North America. Most of them are products of glaciation, which had a vast effect on the continental drainage pattern, notably by the widening of passes through the northern Appalachians and the Cordilleras and the creation of big lakes in ice-deepened basins. The Great Lakes proper have a fascinating history, as Lakes Superior and Huron were vast synclinal depressions even in Precambrian times. In the place of the present Lower Great Lakes, a scarp-and-vale topography existed, with the high front of the Niagara limestone scarp separating vales of shale to the west and east. The glaciers picked out the vales and synclines and deepened them into ice-cut basins, where water gathered; as the ice melted away, the Great Lakes formed. While the ice front of the glaciers still blocked the St. Lawrence outlet, the early lakes drained southward into the Mississippi–Ohio, the Susquehanna, and the Mohawk–Hudson. When the ice retreated from the Gulf of St. Lawrence, the lakes sought the lowest outlet through the St. Lawrence River, lowering the level of the Great Lakes and leaving beaches around them that stand out as raised beaches, or strandlines. The land, depressed under the enormous weight of the ice, has been rising since, lifting the old beaches above the present diminished bodies of water. Similar strand lines follow the Gulf of St. Lawrence, once under glacial Lake Champlain; Lake Winnipeg, once part of the immense glacial Lake Agassiz; and Athabasca, Great Slave, and Great Bear lakes, which are the relics of once deeper and larger glacial lakes. The western lakes were formed by ice blocking the free drainage of water to Hudson Bay or the Beaufort Sea. Much farther south, in the intermontane basins, a pluvial period of climate, matching the ice age in the north, led to the enormous lakes Lahontan and Bonneville. The Great Salt Lake is a relic of Lake Bonneville, the ancient beaches of which are stranded 1,000 feet above the present ones. Similarly, present-day Lake Mexico represents only a small part of the large body of water that accumulated in the Mexican Basin and whose level fluctuated during several pluvial periods. The contribution of all these—and many more—lakes to the drainage of North America has been outstanding. Much of the Canadian Shield is so ridden with lakes as to form an amphibious landscape.

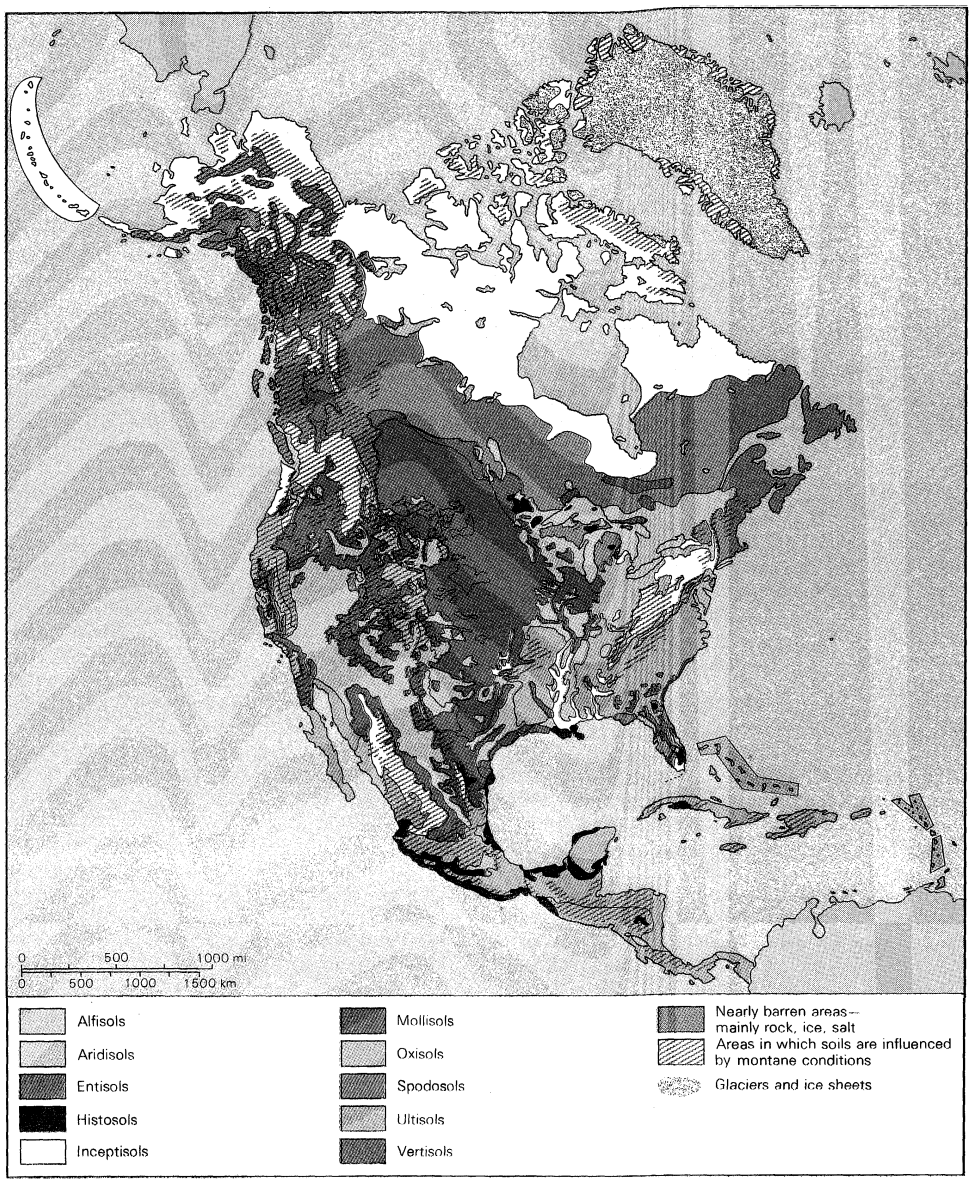
The Great Lakes

River regimes. The river regimes of North America exhibit great variety. Northward-flowing rivers like the Yukon, Mackenzie, Red, Nelson, and the rivers of Labrador freeze up in winter. Because their upper parts then melt before the lower sections are free of ice, they frequently flood, especially if the thaw is late enough to coincide with early summer rains. The Mississippi system is also swollen by spring meltwaters as the winter snows give way in April; flooding can then become a major hazard. River water is kept high by the rains that tropical Gulf air and local convection storms bring until midsummer. A marked falloff then occurs, giving way to full flow in late autumn and winter as polar continental air reactivates midcontinental storm tracks.

The St. Lawrence runs high in spring and early summer; the winter precipitation falls on a frozen surface and serves mainly to heighten the spring thaw. Most other eastern rivers have a double maximum, occuring in early summer and late winter. In the United States Southwest the winter is the main floodtime; rivers dwindle appreciably in the summer. The northern Pacific region, by contrast, has rain at all seasons, though with a winter maximum. In the southern tropical regions, rivers have a much more regular regime, running full all year, except in the dry rain-shadow areas leeward of the mountains.

III. The living environment

The physical factors in the North American environment —geology, relief, climate, and drainage—have a great



Soils of North America.

effect upon the soils, vegetation, and wildlife of the continent. Nevertheless, biotic factors, which govern the multitudinous life-forms of the continent, are also important and help to account for the biogeography of the continent.

NORTH AMERICAN SOILS

Soils reflect the rocks from which they were derived, the way in which they were laid down, conditions of temperature and moisture, and the plants and animals living in or on them. Climate has been used as the main basis for categorizing soils, with a division first into humid and arid groups, and then into subgroups according to the way in which temperature and moisture acted together to produce different horizons, or layers, in the soil. More recently, attention has been focussed on the horizons themselves and on their unique characteristics. In the 1960s the United States Soil Survey used this horizon-based classification to propose a new comprehensive system, which nevertheless still reflects the strongly zonal distribution of soils, following the dominance of climate in the continent.

Horizons as a basis for classifying soils

Humid soils. The humid soils have the widest range in North America and include a number of subdivisions.

Inceptisols. The west maritime temperate-equable climate—swept by frequent polar Pacific storms and with a growing season of up to 300 days and ample rainfall of 40 to 200 inches—has favoured the creation of a deep, acidic, brown-coloured soil, with an upper horizon rich in humus formed by partly decayed organic matter from the region's dense forests. These soils, known as inceptisols, are the fertile soils of the Pacific Northwest and of the British Columbia and Alaska coasts.

Spodosols. The cool-temperate climatic zone is characterized by spodosols, soils with a moderate humus layer at the surface succeeded beneath by a gray, leached, or washed-out, horizon. Rather infertile, acidic, grayish soils, known as podzols, result from this leaching process. They extend under the boreal forests from Alaska to Newfoundland.

Alfisols. Found in the warm-summer subregion of the cool-temperate zone, where mixed forests of conifers and deciduous trees cover the Great Lakes–St. Lawrence to the Ohio area, alfisols are characterized by a deep layer of humus, succeeded by a shallow leached layer, which, in turn, goes down to a wide horizon of both plant and mineral nutrients including oxides of iron and aluminum. These are the moderately fertile gray-brown soils so typical of the northeastern United States.

Ultisols. Farther south, ultisols occur, roughly extending from the lower Ohio and Chesapeake Bay southward to the Gulf Plains. They correspond to the area of the southeastern mesothermal climate, which has more than 200 days free of frost and a rainfall of up to 60 inches a

year. Here a rich deciduous forest supplies a deep layer of humus, some of which is leached down and accumulates with red oxides of iron or yellow hydroxides of aluminum to produce podzolized red-yellow earths of considerable fertility.

Oxisols. The tropical climates of southern coastal Mexico and of Central America, with constantly high temperatures of 65° to 82° F (18° to 28° C) and perennial rainfall of from 80 to 120 inches, have caused very active weathering of rock. The resulting soils, called oxisols, have developed; hydroxide and sesquioxide compounds have produced a thick layer of red laterite, the residual product of rock decay, sometimes mottled with yellow, beneath the surface horizon of rotted humus. A deep, strongly acidic, lateritic soil has developed, which, though fertile when protected from erosion, can be very infertile if the bricklike laterite is exposed.

Semi-arid and arid soils. Semi-arid and arid soils cover an extensive area of North America, including the prairies, deserts, and tundras.

Mollisols. Marking the transition between humid and arid soils, mollisols are found in the open parkland or the tall-grass prairie of the outer Great Plains or in the humid prairies of the western Central Lowlands. They have a moderately deep surface horizon, which is black or chocolate brown in colour from the humus of the closely matted roots set in the dense sod under the thick-growing grasses. With a short rainy period from April to mid-July followed by great evaporation in a dry, sunny summer, whatever leaching occurs is short-lived and not pronounced. The leached layer is very shallow and passes down to a horizon in which the upward movement of water to offset the high evaporation at the surface has brought up basic salts, especially lime in solution. The lime neutralizes the acidity of the surface humus. A very fertile neutral soil—called chernozem, or black earth, by the Russians—has thus developed, seen at its best in the Dakotas and the fertile belt of the mid-Canadian prairies.

Development of black earth soils

Aridisols. Characterizing the dry climates of the United States intermontane basins, of most of the Mexican Plateau, and of the Southwest coast, aridisols are found where vegetation is sparse and where, accordingly, little humus has formed at the surface. Leaching has virtually ceased, and very strong evaporation has led to the upward movement of basic salts through capillary attraction, often working up to ground level in a skin of white crystals. The soils are too rich in lime and potassium to be fertile unless extensively irrigated. They are known as brown desert soils in the more temperate north and desert yellow soils in the subtropical south.

Permafrost soils. In the Arctic tundras, permafrost soils also accumulate very little humus and are strongly leached by the melt of winter snows. The water cannot pass down more than a foot or so before it strikes a permanently frozen horizon, and thus a thin, very acidic, waterlogged, infertile soil has developed. It is of practically no use to man.

VEGETATION AND WILDLIFE

North American vegetation and wildlife are obviously closely allied to soil, as their habitats, too, reflect the powerful influences of climate. Forests dominate the humid regions and once covered about two-thirds of North America; grassland, scrub, or lichen typify the dry third of the continent.

The forests and their inhabitants. *The Pacific coniferous forest.* Offering one of the great spectacles of the continent, the Pacific coniferous forest is made up of immense redwoods and firs forming vast cathedral-like groves, where the tall trunks rise hundreds of feet like great pillars to support a fane of evergreen branches overhead. A long growing season and heavy, constant supply of moisture together have fostered the densest and tallest of North American forests, with redwoods and western cedar along the north coast of California giving way to Douglas fir and western hemlock from Oregon to British Columbia, and Sitka spruce in Alaska. In the south redstemmed arbutuses lend a Mediterranean touch; giant-leaved maple, oak, and ash are common in the middle sector; birch and aspen are subdominants in the north. This coastal forest is still one of the continent's chief sources of construction timber. It is also a major source of pulp and paper and is still a home for a significant number of red deer and mountain elk and also of black bear, lynx, and beaver. Fish-eating hawks and eagles abound. Up the rivers, North America's greatest runs of salmon are seen here, as the fish swarm upstream to spawn in mountain lakes; while off the Queen Charlotte islands lies one of the continent's chief halibut fisheries. The meeting of the Kuroshio, a warm current from across the Pacific with the cool water along the western offshore deeps provides ideal conditions for fish life in great numbers. The faulted and glaciated coasts with great fjords and the perennial rivers attract fish inland and thus make fishing more easy and profitable.

Fish-breeding conditions in the offshore deeps

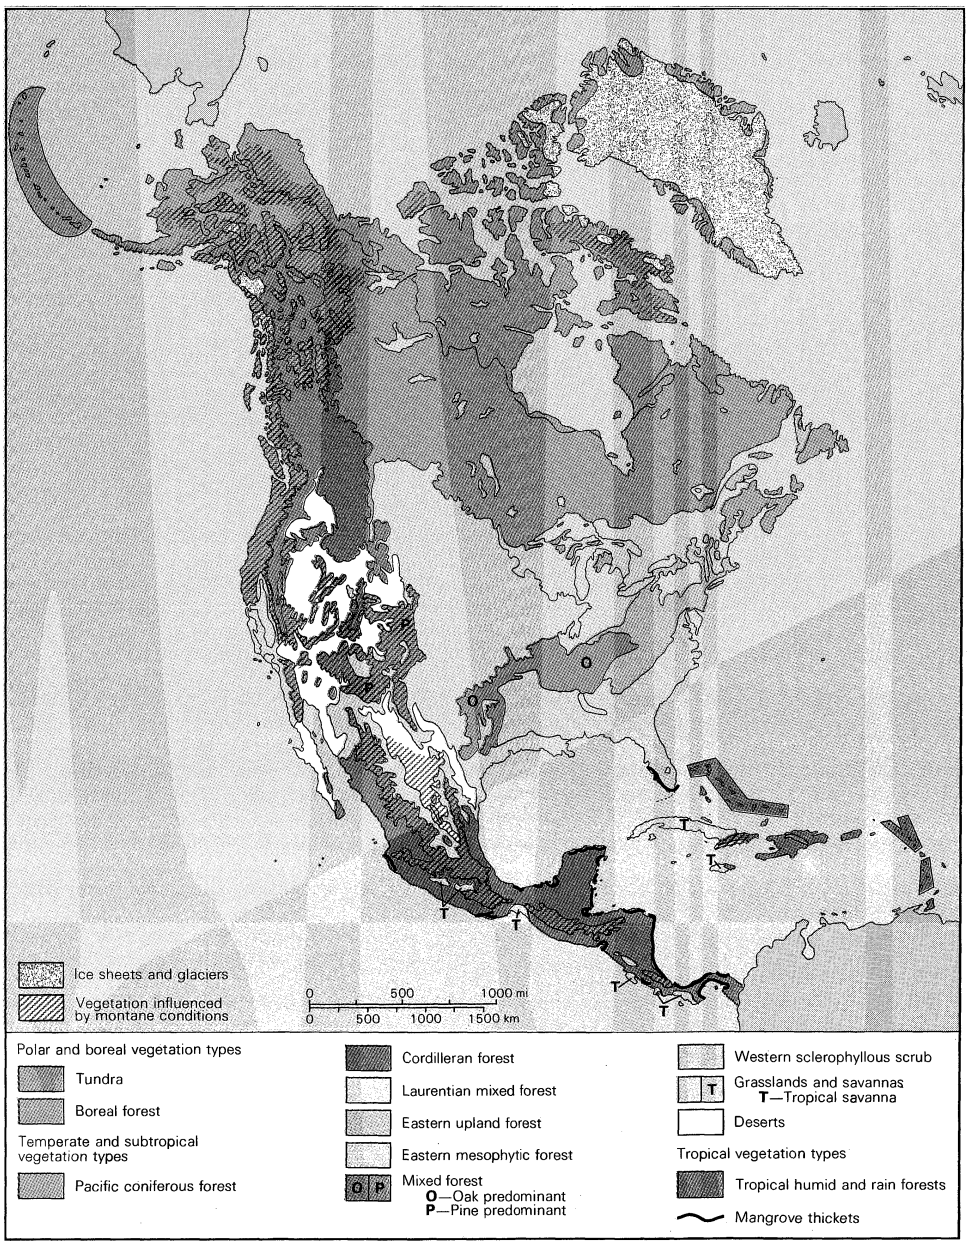
The boreal forest. One of the greatest sweeps of forest in the world, the boreal forest extends in a vast and virtually unbroken sheet of green eastward from the Aleutians through Alaska and northern Canada to the island of Newfoundland. Its conifers are shorter than those of the Pacific Coast but grow in denser stands. The boreal forest is essentially the domain of the spruce, with, however, the contorted pine becoming significant in the west, and the jack pine and tamarak in the east. From Alaska through the Mackenzie plains to Keewatin, the white spruce dominates, while, through eastern Canada and upland New England, the black spruce is common. The whole region is the Western Hemisphere's greatest source of pulpwood.

Great herds of caribou shelter in the northern fringes of this forest in the winter. They are preyed upon by packs of timber wolves. Farther south, deer, elk, and moose are still common, though thinned out appreciably by man. Both the black and the brown bear are frequently seen, especially in berry patches. Many fur-bearing animals, including the marten, squirrel, mink, and beaver, occur; muskrat abound in the marshes. In the spring, pickerel run up the rivers to spawn, and lake trout and whiting like the cool, deep waters of the innumerable northern lakes. Whitefish are caught in great numbers in Great Slave Lake but, because of man-made pollution, are much less prevalent than they used to be in the Great Lakes. Cod and haddock are found in vast numbers on the banks off Newfoundland southward to New England, where the cold Labrador Current mixes with part of the warm Gulf Stream, thus stimulating conditions for fish life.

The Cordilleran forest. The Cordilleran forest lies between the Pacific coniferous forest and the interior boreal forest. On the west, it is made up of cedar and Doulas fir, with Sitka spruce and Englemann spruce at the higher levels; while, in the east, it has more pine and spruce, with lodgepole pine and white spruce making close straight-limbed stands. On the intermontane plateaus and ridges, western hemlock and yellow or sugar pine form groves with parkland between. Altitude and aspect dominate tree distribution, with tall and dense fir woods occurring on the wetter faces at lower levels, spruce clothing the higher slopes, and pine abundant mainly on the drier exposures. Animal life is still rich: elk and deer in the fir–spruce forests, antelope in the open parkland, goat high up on the Alpine pastures. Preying on these are the mountain lion and the occasional pack of wolves. The grizzly bear keeps to higher and less accessible haunts, but the black bear is common in the lower forests. Mountain trout are abundant, and, outside the Far North, this region is the continent's chief game preserve.

Coniferous Cordilleran cover

The Laurentian mixed forest. Lying in the warm-summer region of the cool-temperate zone, the Laurentian mixed forest occurs in the Great Lakes–St. Lawrence, the Upper Mississippi–Ohio, and the New England lowland regions. It is mainly deciduous hardwood—beech, maple, elm, oak, and birch—but has a good deal of coniferous softwood, including pine and the eastern hemlock. White pine, and white and red oak used to be abundant but have largely been cut out for timber. The elm is being killed out everywhere by the Dutch elm disease. The long, hot, wet days of summer, when tropical Gulf air predominates, lead to huge-crowned, large-leaved trees, which



Vegetation zones of North America.

shed their cover with the return of keen winter under polar continental airs. Rain or snow fall most of the year, averaging 35 to 40 inches, and thus provide ample moisture for dense growth. Deer are still common, although the moose is seen less often. Wolves, too, have largely been hunted out, a fate that the bear is also suffering, and beavers have been reduced to a small population. Squirrels still abound, but wild mink and marten are rare, and the carrier pigeon that once made this forest its home has become extinct.

The Eastern Upland Forest. Also known as the Acadian Forest in Canada, the Eastern Upland Forest clothes much of the central and southern Appalachians: here, polar continental airs are pronounced, while altitude modifies the tropical maritime winds. The growing season ranges from 90 to 120 days, and winter cold brings subzero temperatures. The forest, therefore, consists of fast-growing evergreen softwood species such as black spruce and balsam fir, along with alder and birch. Deer are still quite plentiful, as are such small fur-bearing animals as muskrat and squirrel.

The Eastern mesophytic forest. Extending from the mid-Atlantic states to northern Florida, the Eastern mesophytic forest is a mixture of hardwoods and softwoods. On the clays of river bottoms and the coast plain, great-crowned oaks form a tall, dense forest, mixed with hickory, walnut, and yellow poplar on the lower slopes of rivers, and ash and elm on higher slopes. Chestnut at one time was widespread but was virtually eliminated by disease in the 1920s. With summer temperature means of from 75° to 85° F (24° to 29° C), and a rainfall of 45 to 60 inches, many subtropical trees and bushes, such as pawpaws, crape myrtles, magnolias, laburnums, and mimosas flourish. Live oaks and gum trees are also distinctive of the area. On the sandy soils left by old stranded shorelines, magnificent stands of loblolly, longleaf, and slash pines form the Southern Pineries, now one of America's major sources of timber. The Virginia deer, black bear, raccoon and opossum are typical animals. Wild turkey, once very plentiful, but then rare through overhunting, are making a comeback.

Subtropical trees and bushes

Mangrove thickets. Fringing southern Florida and the Mexican lowlands facing the Caribbean, the mangrove thickets are backed by quick-oak and palms. Ibis fleck the woods with their gleaming white feathers. Moccasin snakes are still common in swamps, and alligators occur —not all in "farms."

The Western sclerophyllous scrub forest. In southern California and much of the American Southwest the Western sclerophyllous forest occurs. There trees have to

adapt themselves both to dry, hot summers when the tropical continental air is dominant and to wet, mild winters when polar Pacific air sweeps down from the north. A thin, short, open scrub of chaparral, or stunted evergreen oak, occurs, mixed with yellow pine and sagebrush. Pronghorned antelope, wild rabbit, the mountain puma, coyotes, land turtles, and snakes are common. The hawk is typical, preying on small desert rodents.

The tropical rain forest. The dense covering of all windward slopes in southern Mexico and Central America is provided by the tropical rain forest. The forest consists of such very tall, hardwood, broad-leaved evergreen trees as mahogany, ironwood, and palm, which form a spreading canopy over a lower tier of tree ferns, grape bays, gum trees, rattans, and mangrove, laced with lianas. Numerous species of plants are widely scattered in the forest. Wildlife is also varied with a great number of parrots, cockatoos and nutcrackers, with troops of monkeys, and many snakes. Panthers are still quite common. Ants, beetles, and flies feed on the decaying vegetation, and bacterial activity is high. This is an environment in which such tropical diseases as yellow fever, malaria, and blackwater fever historically have taken a heavy toll. A dry, tropical scrub of thorn trees, cactus, and sagebrush often takes over from forest in a remarkably short distance on leeward slopes and in rain-shadow basins.

Grassland and desert. Covering about a third of North America, grassland and desert are found in the drier and colder regions.

Tropical savannas. Located in patches in subhumid parts of Central America, tropical savannas usually occur at the intermediate levels of lee slopes and on plateaus. They are significant in Guatemala and the Yucatán Peninsula of Mexico. Heavy, though short-lived, summer rains bring on a thick rapid growth of tall grasses: cyclones associated with the northeast trades bring enough rain over the rest of the year to maintain a thin cover.

Temperate grasslands. The temperate grasslands, or prairies, form a belt between forest and desert, mainly on the Great Plains but also on the midslopes of the intermontane basins, above the desert flats. At the "break of the plains" on the eastern subhumid margin, invaded by rain-bearing tropical Gulf airs in spring and early summer, the grasslands are made up of a dense growth of tall grasses, such as the blue-stem sod grass and Indian grass, along with small berry bushes, wild roses, and stunted aspen trees. These are the tall-grass prairies that once were home to most of America's buffalo, before hunters virtually exterminated the breed. "Wet" prairie exists in the Middle Mississippi Basin, where a rainfall in excess of 30 inches occurs; their origin has been attributed to constant fire setting by the Indians, either to stampede buffalo in mass hunts or to burn off trees and thicken grass to provide buffalo pasture. Where rainfall drops below 17 inches (in Texas) or 15 inches (in Alberta), summer evaporation is very high, and tropical Gulf air provides less moisture, only enough for short-grass prairie. There, the vegetation is made up of blue-stem bunchgrass, thin needlegrass, tough grama and wire grasses, along with patches of cactus, sagebrush, or, farther south, mesquite grass. These regions still pasture many small antelopes, although they have been turned mainly into rangeland for raising cattle or sheep.

The "break of the plains" and the tall-grass prairies

Deserts. Creosote bush, mesquite, and cactus offer a very thin, open, stunted plant cover for the Southwest's dry intermontane basins and arid coasts, where rainfall drops below ten inches a year.

IV. The material-resource base

North America has rich and varied resources. Although it contains only 8 percent of the world's population, it has an extraordinarily high proportion of the world's wealth. By the 1970s, it produced about 24 percent of the world's oil, 18 percent of the iron ore, 21 percent of the steel and ferro-alloys, 38 percent of the copper, and 36 percent of the lead and zinc. With about 25 percent of the world's coal output and 37 percent of the world's electrical power production, it possesses the main sinews of modern world industry.

MINERAL RESOURCES

The shield. With a large shield area and with mountains strongly intruded by igneous rocks, the continent is unusually well endowed with metals. Its vast interior lowlands and some long stretches of coast plain are marked by major fuel formation. Metal-bearing regions include shield structures affected by mountain building or trough development, together with the intensely folded ridges that rose from the eugeosynclines on the periphery. The shield has four main metal-bearing areas: the iron of the Adirondack and of the Superior Uplands in the United States; the iron–nickel–copper and gold belt of Ontario and Quebec, along the old fold zones north of Lake Superior and Lake Huron; the iron of the Ungava trough; and the copper and nickel and the gold and uranium of the fault and fold systems of the shield's western rim. Iron in Baffin Land and cryolite in Greenland are additional outliers of wealth. Three areas are of special importance: the taconite hematite ores of Mesabi and Ungava, mined with relative ease by opencast, or open-pit, methods; the world's largest body of nickel in the norite intrusion at Sudbury, Ontario; and the large copper and gold bodies associated with the greenstone intrusions in northern Ontario and Quebec.

The marginal mountains. The Appalachians have also contributed significantly in metallic deposits, especially in the median mass between the Caledonian and Acadian folds, where lead and zinc are important in Newfoundland and New Brunswick; and also in the eastern or outer intensively folded rocks, with iron deposits in Belle Isle (Newfoundland) and the Trenton prong and in the Birmingham (Alabama) Basin.

The Cordilleras are rich in ores, mainly because of the immense igneous intrusions that underly many of the structures. The median mass between the Laramie–Rockies and the Nevada–Cascade systems has major gold, silver, copper, and iron ores in the old plateau of Colorado–Utah. Large lead, zinc, and copper ores occur in the Selkirks and adjacent ranges of British Columbia. Famous silver, lead, zinc, and gold ores dot the Cassiar Massif and Yukon Plateau, in the north; and far to the south, the Mexican Plateau holds iron, lead, and silver ores. To the east of this long, north–south line of plateaus lie the Rockies, which were not intensively folded and hence are not very rich in metals. But the vast intruded mass of the Idaho Batholith and the igneous bodies in the "dome and park" region were associated with copper, silver, and lead ores of great importance. The west Cordilleran ore deposits are widespread. They are found linked with the intensively folded and intruded rocks of the Nevadan–Cascade–Coast systems, notably the copper–gold ores of south and west Alaska; they also consist of the copper, lead, zinc, and iron of the enormous Coast Batholith of British Columbia; of the gold, copper, and iron deposits of Arizona and of the Nevadas in California, where the discovery of gold touched off the famous Gold Rush of 1849; and of the copper, gold, and silver of the Western Sierras of Mexico.

THE FUEL BASE

The fuel wealth of the continent is also great: coal, natural gas, and oil are found in large quantities. These fuels accumulated as vegetative, or carbon, deposits in the lakes and shallow seas of the great lowlands stretching between the shield and the marginal mountains. They also underlay the coast plains and the continental shelf, particularly in the Atlantic and Arctic.

Coal deposits. Coal deposits were preserved in basins between gentle upwarps in the buried extensions of the shield beneath the Interior Lowlands and also in mildly folded rocks in the miogeosynclines of the inner, less disturbed parts of the Appalachians and Cordilleras. Below the Mississippi–Ohio lowlands and the Great Plains, the outer edge of the shield became depressed and buried and then buckled into basins and warps. The Cincinnati Anticline created a vast elongated basin between mid-Ohio and the Appalachians, in which the western Pennsylvania, West Virginia, and Kentucky coalfields were preserved—probably the single largest coal reserve in the

Coal reserves of the Cincinnati Anticline

world—together with the Lima (Ohio) oil field. The Kankakee rise, south of the Great Lakes, has preserved coal and oil in the Michigan (Saginaw) Basin, to the north of it, and the Indiana and Illinois basins, to the south. The last named, also known as the Eastern and Western Interior fields, are separated from each other but kept close to the surface by the La Salle Anticline. The Llano uplift has similarly helped to preserve the Southwest Interior field in Texas.

An enormous midcontinental arch, the stem of the ancient Y-shaped structure connecting the Canadian Shield with the Colorado Plateau, separates the interior from the western coalfields lying in basins in front of the Rocky Mountains. Tolerably good bituminous coal occurs in the Raton Basin, which is cut off from the Denver Basin by the Las Animas uplift. The huge Williston Basin extends farther north, though it contains rather low-grade coal. Beyond this lies the vast Alberta Basin, with coal exposed in the foothills of the Rockies. Here, too, is one of the largest coal deposits in the world.

Oil and natural-gas deposits. The same coal-containing "rises" and basins in the buried shield also have controlled the distribution of oil and natural gas. The Appalachian oil and gas basin, on the west flanks of the Appalachians, was the first to be developed. The Illinois, Kansas, and Oklahoma basins lie in the huge quadrilateral formed by the Cincinnati Anticline and midcontinental arch to east and west and by the Kankakee rise and Ozark Dome to north and south. Between the Ozarks and the Eastern Sierras of Mexico are the tremendously wealthy fields of west and east Texas and of the Gulf Coast. Northward, between the midcontinental arch and the Rockies, are found a number of important fields including the Denver, Big Horn, and west Alberta fields, close to the Rockies, and the Williston, east Alberta, and Mackenzie Valley areas, halfway toward the shield. Small fields of oil and gas lie on the flanks of folded mountains within the intermontane zone, as at Paradox, Utah, and San Juan, New Mexico. The western basins, bordering the Coast Ranges of California, are of moderate size but very rich. In the extreme north, the Prudhoe Bay Basin of Alaska and Mackenzie delta oil have proved that the potentialities of the Arctic shore are real; domes —very much like the salt and sulfur domes of the Gulf Coastal Plain, associated with Louisiana's oil and gas— go with oil on the plains sloping away from the Innuitian fold mountains in the Canadian Archipelago.

WATER AND WATERPOWER

Availability and use. Considered as a resource, water and waterpower are also abundant, although rather unevenly distributed. The average rainfall in North America is 30 inches a year, which produces some 51,000,000,000 acre-feet of water. About a half of this is lost through evapotranspiration, which is direct evaporation plus transpiration from plants. A further sixth is lost through rapid runoff, while yet another sixth percolates down into the groundwater. The amount available from rivers and lakes is thus relatively limited, a fact of growing concern as the demand for water grows. It takes 16,000 gallons of water, for example, to produce one ton of steel; while an average steam-generated power plant requires 4,000 cubic feet of water per second. In 1960, the United States was using a little less than half its potential available water supply of 3.5×10^{14} gallons per year, but, by AD 2000, it will be needing over two-thirds of that supply. The gap between use and availability is narrowing, though through the pumping up of artesian water, and through the desalinization of seawater, the supply may be considerably increased.

The narrowing gap between water use and availability

Regional distribution. The water resources of the continent vary with regions. In northern Alaska, the Canadian north, and Greenland, they are low, mainly because they are locked up in ice most of the year; when the summer melt comes, runoff is high. Central Alaska and Canada midnorth have a moderate precipitation of from 12 to 15 inches per year, but again much of this is tied up in winter ice. The spring melt leads to extensive flooding, which makes the control of water difficult. Late summers are dry, but evaporation is low. Though rivers dwindle, they carry enough water for present needs.

Water problems in the Great Plains

The Great Plains area also has marked high- and low-water periods, the latter posing serious problems. Most rivers rise in mountains with an extensive snow supply. Meltwater gives an early spring flush; high flow is continued into early summer through storms generated by the tropical Gulf air. In late summer and the fall, however, dry air descends from the tropical continental air mass behind the mountains, the storms cease, and the rivers drop. Streamflow originating within the region may dry up; the bigger rivers sink into braided channels between bars of sand. Evapotranspiration also exceeds precipitation, resulting in a net loss of water—not made up again till early winter with the return of polar-front storms. Surface water therefore is scarce for four to five months and often needs to be supplemented from groundwater.

The intermontane basins stretching from southern British Columbia to central Mexico exhibit a strikingly unequal pattern, with areas of water surplus in the mountains lying adjacent to areas of a marked water deficit in the basins. Major rivers like the Columbia, Colorado, Grande, and the Guadalajara rise in snowy or rainy mountains and supply enough water, especially where their waters are trapped by dams, to serve the basins through which they flow. Lesser rivers, however, often peter out and are intermittent. Groundwater supply in areas with artesian wells alleviates the situation.

The eastern parts of southern Canada and the United States are well watered, with rainfall in most months, as the southern movement of polar continental air and the northern expansion of tropical Gulf air draw storms regularly across the area. Rainfall is from 30 to 60 inches a year, and evapotranspiration is not in excess of precipitation except in late summer. Streamflow is perennial, averaging over ten inches in depth per stream per year.

Finally, the tropical areas in the trade-wind belts in Central America are well supplied with water, yet less is available than might be expected due to swift runoff after heavy rains and high evaporation. Rivers are relatively short and steep and are likely to flood quickly.

FOREST RESOURCES

Forests are another of North America's magnificent natural resources. By no means all the forested land, however, may be regarded as a source for pulp or timber. Probably two-thirds of the boreal forest, for example, is not usable because of the thinness of the cover, the shortness of the trees, the very slow rate of natural recovery after cutting, and the inaccessibility of the northern parts of the region. The southern third provides a major base for pulp and paper industries. Most of the northern mixed forest and eastern hardwood forest likewise has become of little service. Good timber was cut out long ago, with much of the forest completely cleared for agriculture. What remains, though it looks plentiful, is commercially unattractive second- or third-growth bush. This woodland, however, is gaining value for the buildup of wildlife and for recreational purposes. The Pacific coast forest and some of the Cordilleran forest still make excellent stands for timber, and, though cutting has sometimes exceeded natural replacement, yet, with controlled use, growth is generally rapid enough to produce a continual yield. The Southern Pineries, long left untouched by agriculture because of their sandy soils, now have become the main source of timber and pulpwood in the United States. The tropical hardwood forests are also important for timber, but they have been cut down to some extent and also have been replaced by banana plantations or by poor second growth. Oak–pine forests above 2,000 feet, in the *tierra templada* ("temperate land") remain a useful resource.

THE FUTURE OF THE NATURAL ENVIRONMENT

The early attitude of the Europeans in North America favoured the clearing of the forests and the killing off of the wildlife, with the aim of making room for crops and domesticated animals. In a continent that was so vast and at the same time so empty, they also developed the idea that environmental resources were unlimited

and only awaited the coming of the white man to be tapped. It should also be remembered that many of these immigrants were to come from a Europe in which, during the Agricultural and Industrial revolutions, there had been an increasing attack on natural resources, particularly associated with the rise of industrial cities. When the United States and Canada became industrialized, they used coal, oil, iron, other metals, and wood with extravagance, a process involving great waste. The waste products of the factories of these nations started to pollute air, land, and water; and, as the multimillion cities began to appear, the majority of people came to live in a man-desecrated as well as a man-improved environment. By the mid-20th century, the people of the United States had killed off about four-fifths of the nation's wildlife, cut over half its timber, and used up two-fifths of its high-grade iron ore; the nation was consuming its oil so fast that, even with its great resources, it began to import from Canada, Venezuela, and other areas. Conscious of the great drain on the resources of the nation, and suffering from the increasing ill effects of pollution, the United States began to conserve its valuable reserves of forest, soil, water, fuels, and minerals; and today the country leads the world in its conservation programs, particularly in renewing the forests and grasslands, repairing the soils, and effectively controlling the waters. Canada, too, has an active conservation program and was the first North American country to pass a clean-water act to help fight the pollution of its lakes and streams. Mexico likewise has an active, though small, conservation service. The nations of North America seem determined in the 1970s to undo the damage done and to pass on to future generations a revivified environment.

Conservation programs

V. Human resources

North America long remained a relatively empty and undeveloped land in global terms, but, with the coming of the Europeans and the Africans they introduced, it began to fill up rapidly with people of diverse traditions and skills. The section that follows covers primarily the peoples of mainland North America. The ethnohistory of Greenland, which, simply because of distance, is quite distinct from that of the rest of North America, is covered in the articles GREENLAND and WESTERN ARCTIC CULTURES. For the human resources of the Caribbean, see the articles on the states of the region and their history and the articles CARIBBEAN CULTURES; CENTRAL AMERICAN AND NORTHERN AMERICAN CULTURES. See also NORTH AMERICAN PEOPLES AND CULTURES; MIDDLE AMERICAN PEOPLES AND CULTURES; and articles on individual cultural areas of mainland North America (*e.g.*, AMERICAN SUB-ARCTIC CULTURES; CALIFORNIAN INDIANS; and NORTH MEXICAN INDIAN CULTURES).

THE NORTH AMERICAN INDIAN HERITAGE

The Indians themselves arrived late in North America. Having originated in Asia, they had a long way to travel —through Siberia and across Alaska—before getting into the heart of the continent. The Ice Age began shortly after man emerged and blocked any northern advance into Siberia and Canada throughout most of the Pleistocene. It was only during the interglacial periods between ice advances that man was tempted to move north. He may have come to North America before the Wisconsin advance, about 60,000 years ago. It is more probable he chose an interglacial period during a recession in Wisconsin time, probably before the Mankato readvance.

The Indians came in as Stone Age hunters leading a nomadic life, and many remained in this condition until the white man came. In moving down from the narrow neck at Alaska to the broad expanse of the continent between Florida and California, the tribes tended to separate out and hunt in comparative isolation. Until they came to the narrows of southern Mexico and the confined spaces of Central America, there was little of the fierce competition or the close cooperation between them that might have stimulated progress. Though they made great progress in those southern regions, they made fewer advances in the use of metals, the growth of industry, or the development of transport and trade than, for example, did the contemporaneous civilizations of Asia, Europe, and parts of Africa. City life arose first among the Olmecs, in the strategic narrows between Mexico and Central America, and the Mayans, in the plateaus of Guatemala and Yucatán. Subsequently the Toltecs and the Aztecs rose to power and developed notable cities in the high Mexican Basin. These people flourished on a rich agriculture based on maize, beans, and squash, along with manioc, potatoes, tomatoes, tobacco, and cacao. They also raised cotton and worked leather.

Some authorities contend, however, that these civilizations already were on the decline before the Europeans came, having been divided by wars and riddled by disease, with much of their land wasted by erosion. Louis de Velasco, a 16th-century Spanish governor, put the total population of the West Indies, Mexico, and Central America at probably 5,000,000 Indians. The population of the less developed Indians of what now is the area of the United States and Canada has been variously estimated at somewhere between 600,000 and 1,200,000. The Indians there had not developed intensive agriculture or a city way of life, though it is true that the raising of maize, beans, and squash supplemented hunting throughout the Mississippi–Ohio and the Lower Great Lakes–St. Lawrence river regions, as well as along the Gulf and Atlantic Coastal Plains. In those areas, semisedentary peoples had established villages, and among the Cherokees and the Iroquois quite powerful federations of tribes had arisen. Elsewhere, however, on the Great Plains, the Canadian Shield, the northern Appalachians, and the Cordilleras, fishing and hunting constituted the basic economic activity and required an extensive territory to support and feed a small population (see also NORTH AMERICAN PEOPLES AND CULTURES).

THE EUROPEAN HERITAGE

The white concept of the environment. When European colonizers arrived, they regarded much of the continent as empty and waiting to be developed. To William Bradford, the early historian of New England, the white races were moving into a virtual wilderness offering a wonderful opportunity for settlement and development. The indigenous agriculture was rudimentary and scarcely opened up the forest; there were no herds or flocks to make a better use of natural pasture other than those of moose or deer; the value of the forests for making homes, buildings, fences, roads, and tools seemed unknown; no mills exploited the waterfalls along which the whites were soon to establish the Fall Line of manufacturing cities; the deposits of iron and coal had not been developed. Seen through the world view of the Europeans, who had had a long tradition of iron and steel making, of maximizing use of the forest for fuel through charcoal, of coal mining and the mining of a great range of metals, of linen and woollen weaving, and of harnessing both water and wind for the operation of mills, the comparative backwardness of most of North America offered both a challenge and an opportunity. They saw no reason why they should not claim land that they could use to better advantage, and hence they bought out or pushed out the Indian and took over the country.

The dispossession of the Indians. The process of removing the Indians from their lands led to bitter disputes, which the British tried to end by setting up the Proclamation Line of 1763 along the Appalachian divide, allowing whites to take over what lay to the east but attempting to reserve what lay to the west as Indian territory. After independence the Americans continued to adopt this ideal of virtually a two-nation state, but in practice it soon collapsed as they pushed the Indian line to the Ohio, then to the Mississippi, and then to the Missouri. The Indians in the east were swiftly displaced to the west and pushed into Indian territories on the Great Plains and in the intermontane basins. Even there their land and their way of life were not respected, as ranchers, the railways, and the homesteaders opened up the West. The Indian "territories" soon were reduced to isolated "reservations." As a

result, most of the contemporary Indian population in the United States is found west of the Missouri—indeed, a great deal of it farther west between the Rockies and the Sierras in the dry climates unsuited to extensive agricultural settlement. The most recent policy of the United States government has been to encourage Indians to leave the reservations and mix with the whites in the great cities of the Midwest and the West, a process that some—including many younger and ethnically conscious Indians—would claim to pose as many dangers to the individual and social well-being of Indians as the communal misfortunes visited upon them by history, though others see it as a means of ending white–Indian differences.

Canadian policy and system of reservations

In Canada, the system of reservations was early adopted and protected Indian settlements throughout the east, even in rich agricultural areas like the Montreal plain or peninsular Ontario or next to great cities like Montreal. As the whites moved west, more care was taken to retain Indians in part of their lands, even on such fertile plains as the Red River Valley or the Fraser Delta. Intermarriage between whites and Indians was much more common than in the United States and led to the nation of the French-and-Indian Métis, which in the Riel Rebellion unsuccessfully attempted to set up a separate state in the Canadian prairies.

In Mexico, racial admixture has gone on much further, and the mestizo, of mixed Indian and white descent, accounts for fully 55 percent of the population. Pure-blooded Indians amount to only about 29 percent; whites make up 15 percent, and Mexicans of African descent one percent of the population. European immigration to Mexico and Central America since the original Spanish conquest has been negligible. When de Velasco made his 1574 count of 5,000,000 Indians under him, there were only 150,000 Spaniards in the New World.

The policies of the colonizers. *Spanish policy.* Colonial policies strongly affected the evolving human resources of North America. It is often stated that Spanish interests centred around God and gold—the Christianizing of the Indians and quick wealth from gold and silver. This is, of course, an overstatement. They were also interested in land, which they wished to develop as great ranches or plantations; but this land was carved up into big estates, to be worked by tenants or by direct labour in the form of serfs or peons. As a result, not many Spanish settlers were attracted. Spanish policy brought a highly competent entrepreneurial and professional group: mineowners, the owners of great estates, merchants, administrators, and priests to North America, but comparatively few from the middle and working classes. Little industry was set up, and, though towns were important, they served mainly as centres of trade and services. Even today the whites remain very much of an elite in the area.

French policy. The policy of France was much the same. The first Frenchmen on the continent were mainly entrepreneurs interested in the fur trade; they hired Indians to collect and carry furs from the hinterland to the French trading posts, and they opposed, sometimes violently, the idea of farm settlements. France, nevertheless, felt it necessary to have a stronger French-population base in its new colonies. To induce settlement, therefore, it gave large seigneuries, or grants, to landed proprietors who promised to bring in settlers, clear the forest, and develop the country. The seigneurs came with the French ideas of tenant farming, under which the seigneury was divided into many small holdings, each paying rent for the land. Once again, few Frenchmen were moved to go to the New World under Old World conditions. As a consequence, when the British took over from the French in Canada in 1763, there were only about 80,000 Frenchmen in Acadia and Quebec, whereas the British on the continent then numbered 3,000,000. The French, however, had been there for more than 150 years, and, since they were allowed by the British to retain their own language, religion, school system, and laws, they kept up their traditions in a remarkable way. Today the people of French origin in Canada total about 27 percent of the population and are firmly entrenched in the province of Quebec, with sizable communities in New Brunswick and Ontario. They form a distinctly Latin element within the Anglo-American realm, and, indeed, some of them would like to see an independent French-speaking country, based on a free Quebec, a situation that has generated some intercommunal strife since the 1960s.

The Quebec French community

British policy. British policy encouraged the large-scale settlement of its colonies by religious refugees, landlords anxious to get New World estates, freemen seeking land of their own to develop for themselves, businessmen trying to found new enterprises, millowners and workers engaged on necessary domestic industries, and craftsmen and professional men out to capitalize on their own skills and callings. The British colonies, therefore, attracted many white settlers with a wide range of competence. The British also opened their colonies to non-British white settlers, notably such religious minorities as the Huguenots, from France, and the Mennonites, from Germany. Under the Hanoverian regime, many German mercenaries were also settled. In Canada, the British opened up the Canadian west to Germans, Scandinavians, Ukrainians, and Poles on a large scale and later accepted Chinese and East Indian settlers.

United States policies. The newly independent United States took over many British policies but gave more scope for freehold land and especially—after the overthrow of the Southern plantation system of chattel slavery—for capitalist business and industry. It also adopted the Open Door Policy to refugees and others from Europe in the belief that America would become, at least for the white races, the "melting pot" of the world and thus in a sense develop what the historian Turner called a "new race of men." These views exerted a powerful attraction for British, Irish, and continental Europeans, and, perhaps to a lesser extent, for people from the Middle East, China, and Japan. Subsequently, as free land was used up, and as the United States became more interested in skilled workers and professional men, a quota system of immigration limited nationalities according to their proportion of the total population after World War I. Still later, a personal selection policy was adopted to choose those of any race or creed who, as individuals, were deemed best able to serve national needs.

THE AFRICAN HERITAGE

North Americans of African descent were originally brought to the continent involuntarily, as Negro slaves. In the United States alone, black citizens now number almost 23,000,000 (authorities concede there is some under-representation in official census data), or more than the entire population of Canada. The whole question of the transatlantic slave trade and its turbulent legacy is still fraught with deep emotions, a not unexpected development considering that this tragic episode set in motion forces and counterforces that molded much of European and African, as well as North American, society over the course of nearly four centuries. Slaves were not widely used in Mexico or Canada but were imported in great numbers to the Southern states of the United States, where they laboured on tobacco, cotton, and sugar plantations. The importation of slaves to the United States was officially abolished in 1808, but illicit traffic and natural increase kept the black population growing in conditions that took a high toll in terms of difficult physical existence, disrupted social and family life, and harm to the individual's psychological makeup. The abolition of slavery in 1865 gave Negroes, in theory if not in practice, freedom to work and live where they liked. Many saw no alternative to staying on plantations as impoverished tenants or sharecroppers. Economic forces in the 20th century—particularly the mechanization of farming—brought increasing numbers of black Americans to the great ghettos of the Northern cities, where new problems of racial discrimination had to be faced. The resulting social and racial polarization struck at the very roots of United States society and challenged the sincerity of its professed egalitarianism. Although the black citizens' struggle to win full equality made some progress, especially during the 1950s, 1960s, and beyond, their battle remained far from won, well over a century after the Emancipation Proclamation. Schooling, housing, social services, and,

The slave trade and its consequences

above all, access to employment opportunity on an equal basis remained key areas of concern. Perhaps because of this systematic exclusion from the mainstream of United States society, the African contribution to the life of the major nation of the continent has generated a rich and unique Afro-American culture.

Problems in race relations have also molded the attitudes and institutions of the white majority, not least in its dealings with the peoples and races of other continents. Hawaii has nevertheless been successfully incorporated as a state, and the United States as a whole has taken in numbers of Polynesians and many more Japanese. It has become quite a polyglot nation. The resulting rich ethnic mix, while posing immense problems, may perhaps ultimately prove an asset rather than a liability in the evolving world community.

THE NATIONS OF THE CONTINENT AND THEIR ALLIANCES

The United States and subsequently Mexico and the Central American countries cut off their ties with Europe and became independent republics. They continue to recognize each other's independence and also their need for each other in various regional groupings and alliances, including the Organization of American States (OAS). Cuba has nevertheless taken a different course of political, social, and economic development than the rest of North America and the Caribbean region. Canada has not joined the OAS because, unlike other American states, it has ties with the United Kingdom and other members of the Commonwealth of Nations. It has adopted the British parliamentary system of government rather than the American system of checks and balances. Both Canada and the United States are, nevertheless, members of the North Atlantic Treaty Organization (NATO), along with most other countries of western Europe. The United States in addition is a member of the Southeast Asia Treaty Organization (SEATO) and of the Australia, New Zealand, and United States agreement (ANZUS). North America thus has a strong hemispherical unity and in addition is firmly linked up with the British Commonwealth, with western Europe, Southeast Asia, and Australia and New Zealand. There are also vital trade links with South America, Africa, and Japan. North America's major ties are with other predominantly industrial nations, but all these connections are of immense importance for the continent's security and prosperity.

Position of Canada in ties with regional groups

VI. Resource development

AGRICULTURE

The various peoples that have developed North America have made it a world economic leader and, in general, a well-used and productive continent. Agriculture, though no longer the principal economic activity, except in the southern Latin nations, is still important.

Tropical areas. In tropical areas, the Spaniards made the most of the strong altitudinal zonation by raising sugar in rainy parts of the low *tierra caliente* ("hot land"), wheat and cattle in the middle levels of the *tierra templada,* and sheep on the upper slopes in the *tierra fria* ("cold land"). Later, orange groves, coffee, cocoa, and banana plantations utilized the coast plains and wet windward slopes of the tropical areas; cotton and hemp were grown in the warmer and drier basins of the intermediate zone. These remain important export crops for Central American countries and Mexico, being shipped mainly to the United States and Europe.

Subtropical and warm-temperate areas. An enormous extension of fruit, winter vegetables, cotton, and tobacco farming has occurred in the subtropical and warm-temperate areas of the United States. Citrus fruits do well in east Texas and Florida, where the Ozarks and Appalachians protect them from polar airs, and the Gulf invites warm tropical air with early rain but much late-summer sun. The Central Valley of California—guarded from frosts by the Sierras, with winter rain for growth and prolonged summer sun for ripening—also is a prime citrus-growing area. Drought is a challenge, however, and has been met only by extensive irrigation. Winter vegetables are widely grown on the sandy soils of the Gulf Coast Plain and the southeastern parts of the Atlantic Coast, with a long frost-free season (200–340 days) and ample rain. Cotton has proved a success in areas with less than 60 inches of rain and over 200 days free of frost. Tobacco has concentrated on the sandy soils of old shores and deltas, from Virginia to Kentucky. Many of the tobacco and cotton fields are now intertilled with rye, corn, and winter wheat grown as fodder for cattle or as additional cash crops. These help to maintain the fertility of the soil, which has long been threatened by the practice of monoculture.

The decline of monocultures

Cool-temperate, humid regions. In the continent's cool-temperate, humid regions, crops include hardy fruits grown on the valley sides of the Appalachians and the Piedmont from Georgia through Virginia; the Finger Lakes region of New York; the Niagara Peninsula and the east shore of Lake Michigan; and parts of the Columbia Basin in Washington and British Columbia. In all these areas, aspect, frost, and drainage are important factors.

The zone known as the Corn Belt evolved from a concentration on corn in the warm-summer region eastward from the Ohio River to the Lower Missouri shores, where winter snowmelt, spring rains from the northward surge of tropical Gulf air, and early summer convection showers bring on the plant, while strong late-summer sun, with July means of 70° to 80° F (21° to 27° C), ripen the cob. Most of the corn is fed to fatten pigs and cattle.

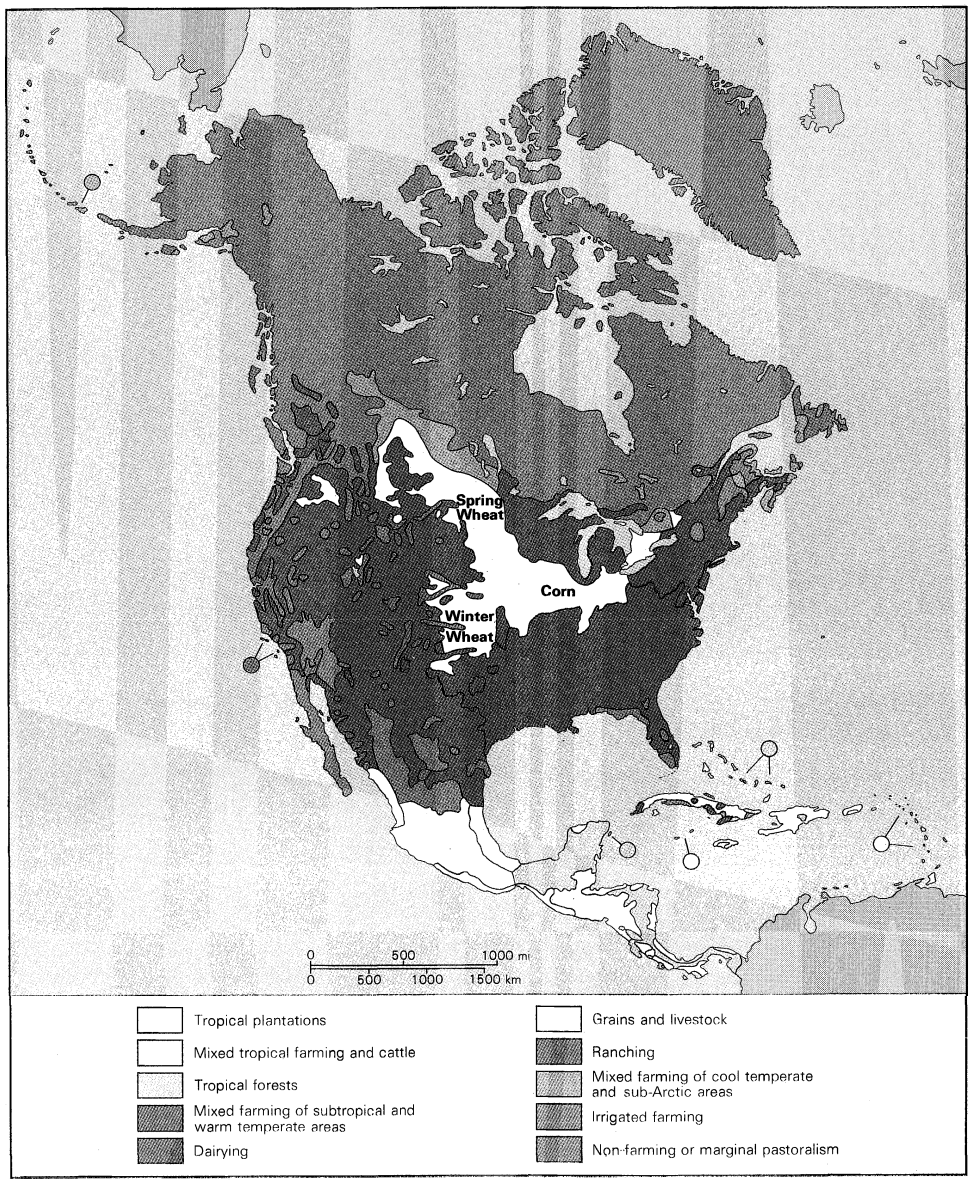
The Dairy Belt, another recognized division, makes use of a shorter growing season and cooler summers in New England and the Great Lakes–St. Lawrence region, where clover, timothy hay, and hardy small grains thrive. Dairying also exploits the lush pastures of the Pacific coast equable climate in Washington and British Columbia.

West of the Corn Belt, in subhumid regions, lie the continent's vast wheat areas. The Winter Wheat Belt, mainly in Nebraska, lies south of killing frosts. As the polar front retreats, the early sweep of rainstorms brings on the grain sown in the previous fall. The Spring Wheat Belt—in the Dakotas, the Canadian Prairies, and part of the Columbia Basin—has a severe winter that forces the postponement of sowing to spring. Then the warmth and wetness of the sudden surge north of tropical Gulf air bring on the new-sown wheat very quickly, which ripens in a usually dry, sunny fall. Wheat farming is being carried on on an ever bigger scale, using more machines and producing more per acre.

Dry regions. Dry areas in the Great Plains and intermontane basins were long left to ranching. The Hereford cattle brought in from England could feed on the short-grass prairies, which were not suitable for the homesteader. The sheep, raised in still drier parts or up in the mountains, are bred mainly for wool. Near rivers or in artesian areas, irrigation for supplementary fodder has greatly helped ranching. Irrigation, however, is being used increasingly for fruit and cotton farming, resulting in a great drain on water supplies.

DEVELOPMENT OF WATER AND HYDROELECTRIC RESOURCES

Water development. Water development is crucial both to circumvent drought and prevent flooding. Irrigation in the United States consumes 85,000,000 acre-feet of water per year as compared with industry, which needs 25,000,000. About 40,000,000 acres of irrigated land have been developed in the United States, with large schemes of dams and conduits in the Columbia and Snake valleys, the Central and Imperial valleys of California, the Salt and Gila tributaries of the Colorado, the Upper Rio Grande, and more recently, the Upper Missouri and the Upper Platte. In western Canada, a vast scheme is developing on the Bow–South Saskatchewan rivers, while in Mexico the Lower Rio Grande, shared with the United States, the Fuerte Basin on the dry west coast, and the Balsas in the south have actively promoted water development. Water transfer from surplus to deficit areas is already taking place, and interstate water transfer proposals include transfers from the Columbia Basin to both the Sacramento and the Colorado, and from the



Agricultural regions of North America.

head of the Missouri system to the Colorado, and thence to the Gila. Flood control is a problem in the Mississippi Basin. The Tennessee Valley and the Ozarks' schemes have involved building many dams to pond up and redistribute river water.

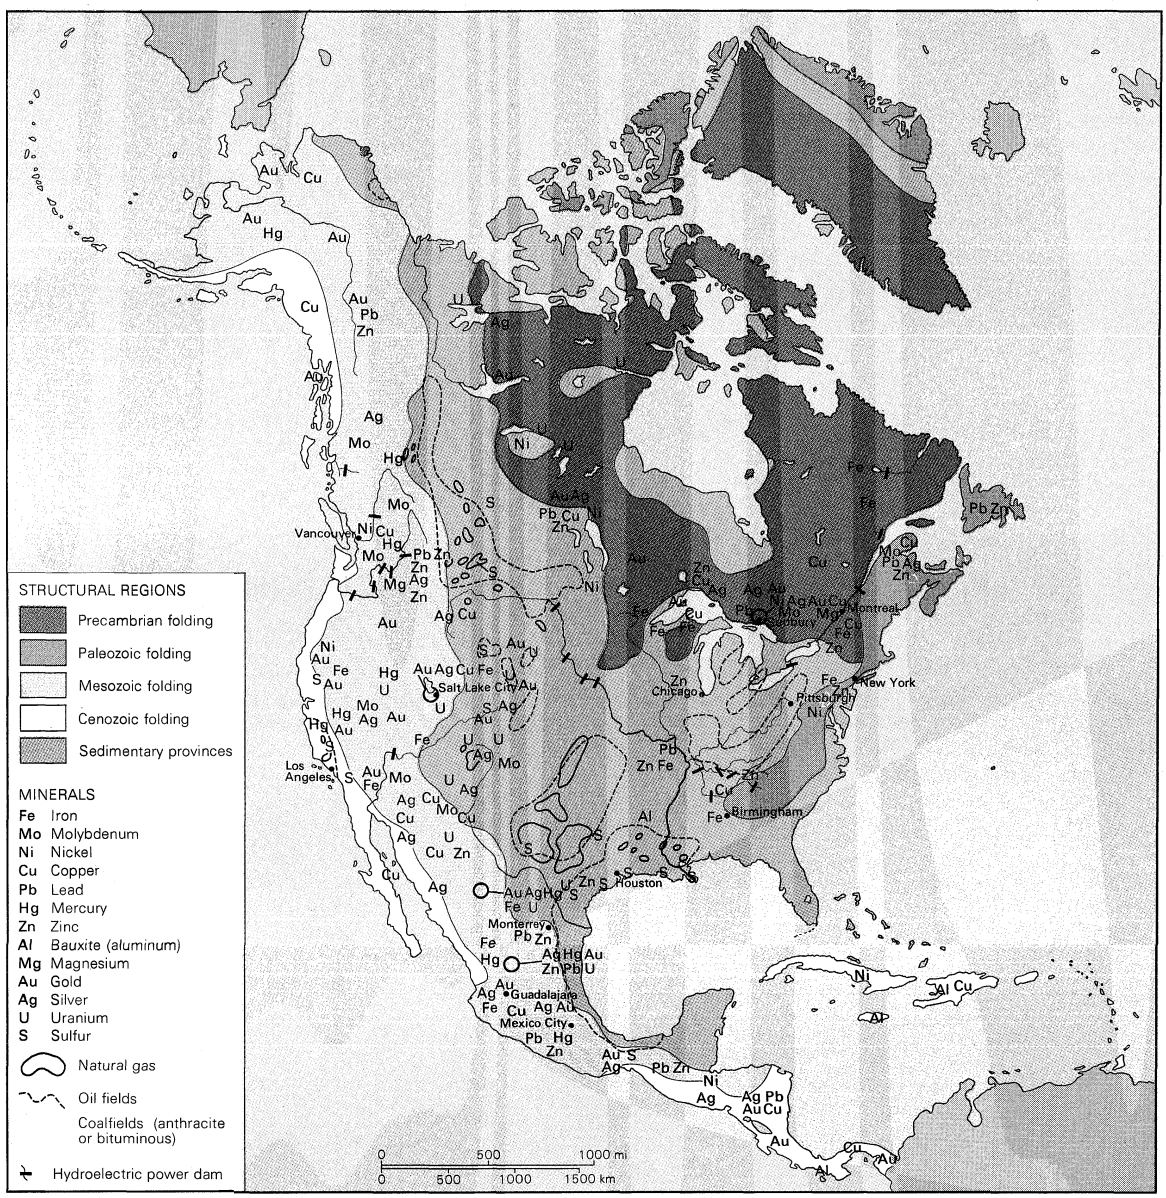
Hydroelectric development. Hydroelectric development has been immense in the United States and Canada, which rank first and second in the world in their installed generating capacity. The rivers of the Canadian Shield, fed from lakes and falling abruptly over the edge of the plateau, provide many sites, especially in Quebec and Ontario: these are linked to such Great Lakes–St. Lawrence sites as Niagara Falls and International Falls, which, in their turn, tie in with a power grid developed from Appalachian rivers. The north central and northeastern areas are thus well supplied.

The snow-fed rivers from the high Cordilleras, where dammed (as at Grand Coulee, Hoover, Glen Canyon, Fort Peck, and Garrison), also provide an immense amount of power. Yet in the U.S. hydroelectric power represents only one-fifth of all electricity generated, the rest coming from coal- or oil-fired plants and nuclear-power stations. In the north, steam plants based on coal are not subject to winter freeze-up, as are hydro plants.

FUEL DEVELOPMENT

Development of new fuel sources has seen the dramatic displacement of coal, from nine-tenths of the energy used to less than a fifth in the 1970s. Oil contributes about two-fifths; and natural gas, just over a third. Although coal production in the U.S. has risen from 510,000,000 tons in 1940 to about 610,000,000 tons in 1970, the industry's work force has been cut by more than two-thirds. The vast reserves of coal are thus being mined more efficiently, and workings are now concentrated mainly where strip mining is effective, in West Virginia and Kentucky, in the Warrior field (Alabama), and in eastern Illinois. Coal is sent to the big power plants and steel works of the mid-Atlantic region and the Lower Great Lakes. One reason why oil and natural gas have replaced coal is their ease of transport. Pipelines carry both fuels from their remote sources in the Gulf fields of Louisiana and Texas, the midcontinental fields of Oklahoma, and the Rocky-front fields to the shoreline cities of the Atlantic, Great Lakes, and Pacific. By the 1970s, there were more than 700,000 miles of gas pipeline as compared with 214,000 miles of railroad. Oil, too, is piped great distances, although much is sent by tanker from the ports close to the Gulf oil fields. Consumption has increased enormously; in spite of the richness of the oil fields in California, that state has become a net importer, piping in oil from Texas. Similarly, the Illinois, Ohio–Indiana, Michigan and west Pennsylvanian fields, though quite important before World War II, cannot possibly supply the Great Lakes and mid-Atlantic regions, which are fed by oil piped from Oklahoma and Kansas. The U.S. now im-

Changes in energy sources



Basic structural regions and principal mineral and hydroelectric sites of North America.

ports much oil. In Canada, the industrial regions at Vancouver and in the Lower Great Lakes–St. Lawrence area are fed gas and oil by pipe from Alberta; and, in Mexico, Mexico City and Monterrey, on the central plateau, are supplied by pipe from the Gulf Coast oil fields around Reynosa and Tampico–Tuxpan.

INDUSTRY

The role of ports in industry

Coastal sites. The industry of North America is its chief contemporary source of wealth. It first grew up at Atlantic Coast and Mississippi River ports, where raw materials transported from abroad or brought by coastwise trade from other colonies could be made into goods for distribution in the interior. Inland products also might be transformed before being exported from such ports, where immigrant labour was plentiful and capital brought in or developed locally was abundant. In many respects, the ports still perform these roles. New England ports bring in wool, leather, hardwoods, and metal from abroad and cotton from the Southern states; New York imports coffee, cocoa, sugar, timber, pulp, and oil; the Philadelphia region brings in great quantities of iron from Canada or Venezuela and oil and petroleum coke from the Gulf; together, these cities manufacture textiles, leather goods, petrochemical products, iron and steel, ships and machines, books, clothes, and foods not only for their own dense populations but for the interior United States as well. In spite of the enormous development of the interior, coastal sites have still remained paramount, especially if the definition includes the shores of the Great Lakes and the Puget Sound and California coast. From Buffalo through Detroit to Chicago, the movement of coal from the Appalachian and eastern interior fields up to the lakeshore, combined with the shipment of iron ore from Lake Superior and Ungava to the lake ports, has led to a vast and dynamic belt of iron and steel, transport facilities, and machine-making cities. The Pacific ports of Seattle, San Francisco, and Los Angeles have developed from an outpouring of forest, fish, farm, mine, and oil-well products, partly abroad and partly by the Panama Canal to eastern America.

Similarly, in Canada both the importing of oil, wool, cotton, leather, and food-based raw materials into the St. Lawrence–Great Lake ports such as Montreal and Toronto and the exporting of Canadian iron, nickel, copper and other metal-based goods, of wood products, and flour from the eastern ports and from Vancouver have concentrated population at the gateways in and out of the country. Mexico's gateway district, at Vera Cruz, is also industrialized. Most of North America's industry and population is thus concentrated at its seaward or Great Lakes' margins.

Inland sites. Sites in the interior are, however, not without importance. The first to develop were the fall-line

power centres, strung out from the falls of the Merrimac at the edge of the New England Upland, then southward along the east front of the Piedmont, to the Coosa south of the Appalachians. Later, with the advent of steam and electric power, these sites continued as major textile, pulp and paper, and engineering locations. A bigger shift inland occurred with the use of coal for power, in the eastern and western Pennsylvanian coalfields around Wilkes-Barre and Pittsburgh, in the Birmingham coal and iron fields, and the Saginaw Bay, Indiana, and Illinois coalfields. Pittsburgh soon used up its local iron ore but was sufficiently near the Great Lakes to bring in Mesabi Range iron ores, which, in combination with the vast amounts of high-quality coking coal at hand, formed the basis for a great iron and steel industry. Except where coking coal is used in the steel plants at Pueblo, Colorado, Geneva, Utah, and Fontana, California, Western coal has been too low grade to attract industry. Oil and natural gas, however, have become the base of active petrochemical industries in Alberta, Oklahoma, and Texas. Since oil and gas can be easily piped, they have not stimulated the development of industry on a big scale near their sources but have fuelled the northeastern and Pacific Coast industrial areas. Modern industry has become less tied to sites where fuel and raw materials are available and more oriented toward the market. Service industries especially have concentrated in the highly populous areas of Boston–New York–Philadelphia, Pittsburgh–Detroit–Chicago, and San Francisco–Los Angeles. Space-age developments have been supported by science-based industries from Texas through Louisiana to Florida. Industries to meet the immense demand for travel and recreation are springing up on the major motorways and in the tourist areas in the Appalachians, the Cordilleras, and along the sea coasts. Though industry is more free to disperse, it nevertheless continues to focus on areas of existing urban agglomeration. In the United States its growth is greatest in the New York–Washington, Cleveland–Chicago, and Los Angeles regions; in Canada, in the Montreal–Toronto and Vancouver districts; and in Mexico, in the Mexico City Basin. These major cities are also unhappily the focus of critical social and economic problems.

More generally, automation is everywhere creating a major problem of technological unemployment, met in part by reducing working hours and retiring people earlier. These trends, in turn, raise the problem of the use of leisure time—now the target for much of America's fastest developing industries.

TRANSPORTATION AND TRADE

Waterways. Industry has been strengthened by the ease of movement in North America. Waterways, widely used by the Indians and early Europeans, are still important. In spite of the barriers of the Laurentian Shield and the Appalachians, the routes up the Gulf of St. Lawrence, the Hudson Estuary, Chesapeake Bay, and the Gulf of Mexico permitted the swift development of coastal ports and allowed the interior to be opened up. The Mississippi–Ohio and the Great Lakes–St. Lawrence waterways drew navigation into the heartland. Connecting these two systems, the Chicago Sanitary and Ship Canal, linking the Illinois River with Lake Michigan, and various Ohio–Lake Erie canals provided a tremendous network, extended by the Erie Canal to the Mohawk–Hudson and by the Intracoastal Waterway to river ports of the Gulf of Mexico. The St. Lawrence Seaway, which overcame the Lachine and International rapids and Niagara Falls, has made ocean ports of Chicago and Toronto. No other continent has such a system of inland waterways.

Railways. *Development of the rail network.* Railways soon offered the challenge of more direct and speedy access than the waterways. Developed principally from bases in Baltimore, Philadelphia, New York, and Boston, they made the most of gaps through the Appalachians, debouched on the Great Lakes or Ohio at Buffalo and Chicago, Pittsburgh, and Cincinnati, and pushed on to the Mississippi at Memphis, St. Louis, and St. Paul–Minneapolis. Other lines were then thrown across the Great Plains and, making the most of Cordilleran passes, built terminals at San Francisco, Seattle, and Los Angeles. Most of the Western railways were given large land grants to encourge immigrants to settle along them, while low promotional rates on long-haul traffic developed transcontinental trade. In Canada, the transcontinental railways linked up the Maritime Provinces with the St. Lawrence–Great Lakes, and thence, from Montreal and Toronto, they crossed the shield to converge at Winnipeg; here, reinforced by large land grants, they fanned out across the prairies to be drawn together by the Fraser down to Vancouver.

Development of Canada's railway system

Mexico overcame difficult grades in building a railway from Vera Cruz to Mexico City and added extensions north and south along the Gulf Coast, with lines into Monterrey and to Mérida. Eventually lines were pushed through the Western Sierras at Guadalajara to the Pacific coast.

Railways and urbanism. Railroads had a tremendous impact on urban development. The major railroad cities are New York, Chicago, St. Louis, and Los Angeles, in the United States, and Montreal, Winnipeg, and Vancouver, in Canada. Mexico City dominates the network in Mexico. Railroads led to the rise of east–west over north–south lines and rapidly displaced most waterways, particularly the Mississippi. The main economic axis in the United States lies along the railway belt from New York to Chicago. Inadequate overall planning in major metropolitan regions resulted in crucial transportation problems by the 1970s, and inner-city rapid-transit systems often fared no better.

Motorways. North America's road network first began to offer serious competition to the railways after World War I. The United States government financed over 200,000 miles of transcontinental highways, and U.S. Highway 20 (from Boston to Portland, Oregon) became the axis of midcentury America. In Canada, the Trans-Canada Highway offers a coast-to-coast through route, while from Mexico, the Pan-American Highway links all the countries of Central America. These highways have enabled trucks to take over short-haul routes, and the financially plagued railroads have had to concentrate on long-haul, low-cost routes. Truck and train are, however, being integrated in "piggyback" containerized carriage. The car, meanwhile, has displaced commuter trains in many cities, and radial and ring routes are drawing the cities well out into the countryside. The attendant problems of congestion and pollution have approached the critical stage in many cities.

Air transport. Air transport has taken most of the long-distance passenger traffic from the trains, and air-freight has cut deep into truck-freighting trade. Intense overall competition is thus a recurrent feature of North American transportation systems. Airways have tended to centre on the larger cities and to magnify their importance, so that intervening intermediate and smaller cities have declined in importance. Links with Europe and Asia make North America the chief crossways of air routes in the world. The United States alone accounts for more than a third of all the world's air traffic. Of the ten chief airports in the world, nine are in the United States—two in New York and one each in Chicago, Los Angeles, San Francisco, Atlanta, Washington, Miami, and Dallas. Montreal in Canada and Mexico City in Mexico are also of major importance.

Trade patterns. North American trade patterns offer interesting contrasts. Canada, with a small population but with immense resources and high productivity, has a low home consumption and depends on foreign trade more than any other developed country on the continent. The United States, on the other hand, with a vast internal market and the highest per capita consumption of goods in the world, depends mainly on internal trade; only 8 percent of its total trade is with countries abroad. Mexico and Central America, by contrast, still have large areas where people live at a subsistence level and produce little more than goods for local trade. Production of certain metals, oil, and tropical crops, however, is expanding rapidly for sale in foreign markets.

The Canadian segment. Canada's internal trade is dominated by the provinces of Ontario and Quebec. Together they make 81 percent of all manufactured goods, which they ship across Canada in exchange for fish, lumber, and fruit from British Columbia, wheat and meat from the Prairies, and pulpwood, iron ore, and fish from the Atlantic provinces. Most of Canada's trade abroad consists of raw or semiprocessed materials, including pulp, paper, timber, iron ore, nickel, lead and zinc, uranium, and asbestos, sent to Britain, the United States, and Japan; and wheat, exported to Britain, the Soviet Union, the People's Republic of China, and Japan. Some oil and natural gas are sold to the United States.

Until World War II, Canada traded mainly with Britain; until that time the United States still produced a surplus of most of the things Canada raised and thus was not a major customer. Canada, in fact, bought far more from the United States than it sold to it. By the 1970s, however, the United States had become short of metals, wood, pulp and paper, power, and water and was importing these items from its neighbour on an increasing scale. It has thus replaced Britain as Canada's chief market, taking about 68 percent of Canada's export trade compared with 8 percent by Britain. The European Economic Community and Japan also are growing in importance as customers for Canada's metals, wood products, and wheat.

The United States segment. Internal trade in the United States is enormous, often surpassing that among sovereign states on other continents. It is dominated by New England's need for fuel, cotton and wool, leather, wood products, and metals; by the mid-Atlantic states' demand for coal, oil, natural gas, iron ore and other metals, and food products; by the Pittsburgh region's need for iron, copper, oil, and gas; by the Lower Great Lakes–Lake Michigan area's need for coal, oil, gas, iron, pulp and paper, and wood; and by the Los Angeles–San Francisco regional demand for steel, aluminum, cellulose products, oil, and chemicals.

Most of the other areas of the United States trade their raw materials or semifinished goods to these major manufacturing regions, though of course there are local industrial centres of importance. Trade is concentrated in servicing, or in being served, by such giant metropolitan centres as New York, Chicago, and Los Angeles. These also handle a great deal of America's foreign trade. Almost a third is cleared through the New York–New Jersey area. Southeastern ports send out cotton, tobacco, and wood products; and the mid-Atlantic coast ports send out wheat, corn, meat, and a wide range of manufactured products.

The giant metropolitan centres

With the development of the St. Lawrence Seaway, great cities like Chicago, Detroit, Cleveland, and Buffalo have been exporting directly the steel products, cars, planes, agricultural machinery, cereals, and meat for which the northern Midwest is famous. New Orleans still continues as a notable exporter of cotton, corn, and other agricultural products from the vast Mississippi hinterland; while Houston is the most rapidly expanding southern port, basing its trade on oil and chemical products. Los Angeles dominates the West, with its sales of aircraft, ships, films, and chemicals. Seattle is important for its trade in fish and forest products. American imports include a wide variety of products: tropical fruits, woods, fibres, rubber, and vegetable extracts, mainly from Latin America, West Africa, and Southeast Asia; oil from the Caribbean, Canada, Mexico, Venezuela, and Africa; tin from Bolivia and Malaysia; wool from Australia and South America; and a wide range of machines, textiles, instruments and books from Britain, western Europe, and Japan.

United States trade has a worldwide distribution and impact: of its export total, about a third goes to Britain and western Europe; a fifth to Canada; another fifth to Japan, Southeast Asia, Australia, and New Zealand; a tenth to South America; and a tenth to Mexico, Central America, and the West Indies. Of almost equal importance has been the widespread influence of United States aid: while, initially, this helped United States trade by being tied to the use of American equipment, it is now much more free and enables countries to develop their agriculture or industry in the most satisfactory way.

The Mexican and the Central American segment. The Latin American portion of the continent includes some highly sophisticated regions, along with many as yet undeveloped areas. In Mexico's internal trade the capital region predominates, producing almost four-fifths of the nation's manufactures, which are then distributed through regional cities. Mexico City consumes much of the oil piped up from the coast, the metals of the Cordilleran mines, the cotton of the irrigated central and western basins, and hemp from Yucatán. Mexico's external trade, like that of Canada, is mainly in foods and raw materials. Agricultural exports include maize (corn), meat, hides, winter vegetables and fruits, and cotton and sisal-hemp and account for over two-fifths of total exports. Metals are extensively exported, mainly to the United States; with oil, they make up another fifth of the exports. Manufactured goods, including canned and prepared foods and textiles, are rapidly increasing, amounting to just over a fifth of the export total, and chemicals, wood products, and fish are also significant.

Imports consist predominantly of manufactured goods or else of parts or of materials needed for Mexican exports. Machinery, vehicles, and consumer goods are the chief items. The United States has the greatest share of Mexico's foreign trade, providing five-eighths of the imports and taking two-thirds of the exports. With the establishment of the Latin American Free Trade Association, however, an increasing amount of Mexico's trade has been oriented toward Latin America, which takes only about 8–10 percent of Mexican exports. Mexico is also trying to send more winter fruits and vegetables, textiles, and leather goods to Canada.

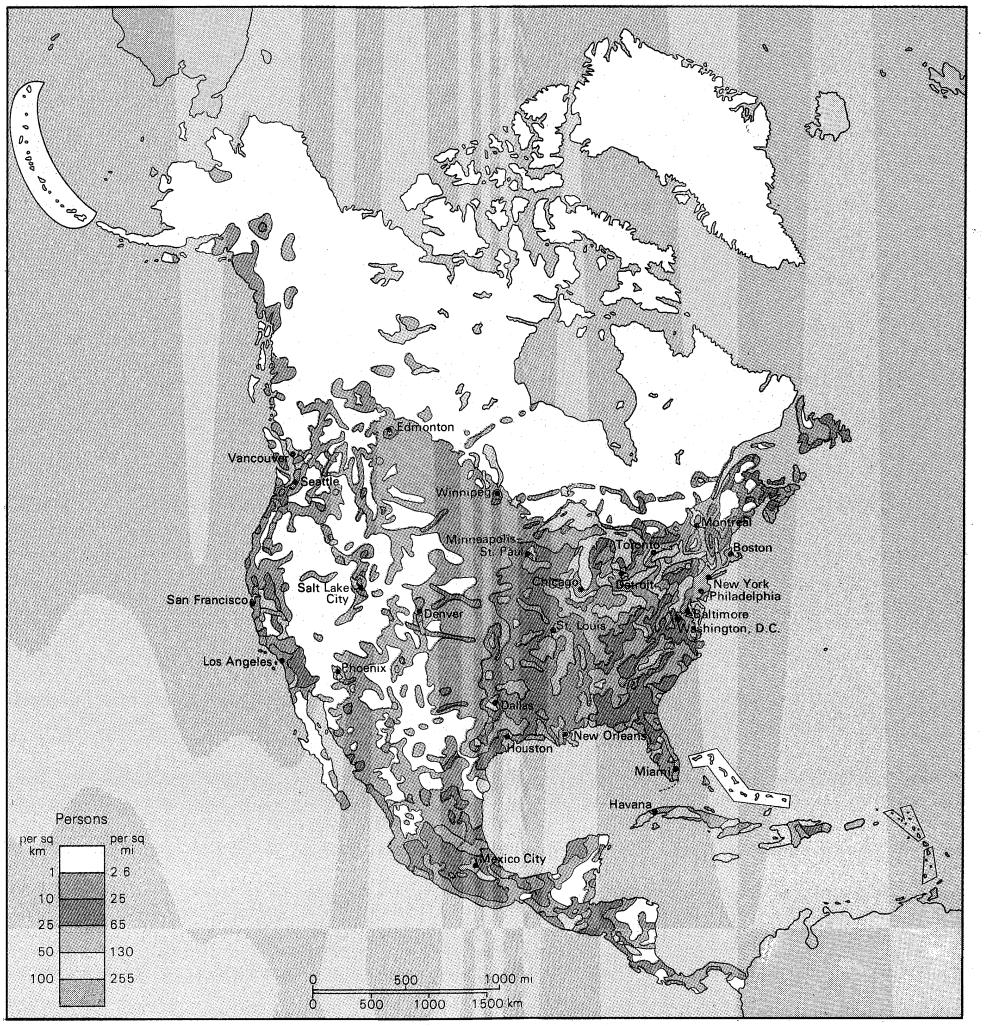
Mexico's trading partners

Central America has not as yet developed much trade. By far the greatest amount is in tropical fruits, fibres, and minerals (especially from the Caribbean), which are sent to the United States in exchange for American manufactured goods. Increasingly, virtually the whole of North America is being integrated in its economic development with the growth of the United States.

PATTERNS OF RESOURCE DEVELOPMENT

Favourable and unfavourable regions. The natural resources of North America and their developing use have led to the emergence of distinct national patterns, which are usually reflected in population distributions. As an area of late exploitation, North America does not have the high settlement densities of Europe and Asia; yet, with great natural wealth and an advanced technology, its population is growing rapidly and is concentrated in regions of comparative advantage, such as the coasts, the lowlands, and the humid and the temperate zones. The 2,500,000 square miles of shield and the 2,000,000 square miles of mountainous land remove nearly a half of the continent from continuous settlement. The frost-ridden areas of the Arctic coast plain, the Mackenzie, and the Hudson Bay lowlands restrict settlement still more. Similarly, the drought conditions in districts of intermontane America and Mexico detract from their use, while the disease-ridden, wet, tropical lowlands of Central America have remained comparatively empty. Further, the empty lands are getting emptier, as people who want to live well and in comfort crowd the already crowded regions. The more populated areas include the Atlantic coast plain from Nova Scotia to Florida; southern Canada in the humid, cool-temperate belt, where there are warm summers; the United States east of the Missouri, in the humid, warm-temperate zone, centred in the vast Mississippi–Ohio plain; the mild, moist Pacific coast from British Columbia south to California; and the temperate, yet warm, and well-watered Mexican Basin. Within these areas of advantage, growth is focussed still further on the great cities, especially those associated with the Hudson–Mohawk gap, the St. Lawrence–Great Lakes system, the Ohio Basin, the Middle Mississippi, Puget Sound and the Fraser Delta, and the California coast.

Geographic distributions. *Canadian share.* Canada's share of the total continental population is small, with



Population density of North America.

22,000,000 people out of a total of about 335,000,000. With an area of 3,560,000 square miles, its overall population density amounts to barely six persons per square mile. Most of Canada—the shield, the northern Appalachians and Cordilleras, and the tundra and boreal forest zones—thus is empty. Population is concentrated in the south, around the Bay of Fundy, the St. Lawrence–Lower Great Lakes, the southern prairies, and the Columbia and Fraser valleys. About 9 percent of the national population is engaged in primary production, nearly 26½ percent in manufacturing and construction, and 64½ percent in service occupations. Wealth is still based on iron and nickel and other metals, oil and natural gas, wheat, meat, fish, and forest products; most of its industries are developed from these resources. Mechanization and automation give a high per capita production, and Canada is only a little behind the United States in general affluence. It raises far more than it can consume and thus sells much abroad.

The makeup of Canada's population

A member of the British Commonwealth, its population is still 40 percent British by extraction and 60 percent English-speaking. It nevertheless grew out of the two founding nations of France and Britain and is 27 percent French by mother tongue. About 19 percent habitually speak French only. Some 30 percent of the people come from northern, southern, or eastern Europe; and most of these are English-speaking. About three-quarters of Canada's population is native-born, but immigration is still active, with rather more non-British (including Americans) than British settling in the country. Canada is thus a bilingual, multicultural nation, with strong attachments to Britain and Europe. It is economically dependent on the United States, which owns over 60 percent of the capital invested there and supplies 70 percent of Canada's imports. The country has a moderate population-growth rate of about 1.7 percent per annum. The most rapidly growing element is the native Indian population, now totalling about 240,000. Ontario and Quebec still lead in attracting population, but Alberta and British Columbia in the west are expanding rapidly. Over three-quarters of the Canadian people live in cities; indeed, about a quarter live in Montreal and Toronto, the leading industrial and business centres.

The role of the United States. The United States dominates the continent with approximately 210,000,000 people or 65 percent of the total continental population. Unlike the other countries, most of its area is habitable; although the higher parts of the Appalachians, the Cordilleran ridges, and the dry intermontane basins are empty. The average density of 59 persons per square mile is much higher than that of Canada, though still low by European or Asian standards. Its most populated parts are the mid-Atlantic states (340 per square mile), New England (167), and the Great Lakes states (148). In the early 1970s, Florida, Arizona, and California were the states that were drawing most of the increase of population. That influx was partly because of the many affluent people retiring in those areas and partly because of the emphasis on growth industries and services. America has gone further in the development of its service occupations than any other New World nation, with 63 percent of its population thus employed. Rather less than 32 percent are in manufacturing, and only 5 percent are in primary production jobs, like farming, fishing, and lumbering. America's consumption of food and goods is the highest per capita in the world.

Occupational structure of the United States

The United States, which long drew its settlers from Europe, by the 1970s had a population only 5 percent

foreign-born. Its population increase comes overwhelmingly from the native-born, among whom the most rapidly expanding groups are the Indians and the Negroes. Only about 30 percent of the black Americans remain in the rural South, most of them living in the Northern cities, predominantly in overcrowded ghetto areas. Washington and Newark are major cities with a black majority. Blacks also account for more than a third of the total population in Cleveland, Detroit, and Chicago and are strongly represented in New York, Pittsburgh, St. Louis, and Los Angeles. The inner-city concentration of blacks, one of the most noteworthy features of urban life in North America, is highlighted by a strong white population shift to the suburbs. About 65 percent of the current United States population growth is, in fact, in metropolitan suburbs, often exacerbating the problems of inner-city decline.

There are four main areas of metropolitan growth known popularly as Boswash (Boston–New York–Philadelphia–Washington) with 40,000,000 people, or 20 percent of the population; Chipitts (Chicago–Detroit–Cleveland–Pittsburgh) with 30,000,000, or 15 percent; Sansan (San Francisco–Los Angeles–San Diego) with 20,000,000 people, or 10 percent; and Jackdal (Jacksonville–Mobile–New Orleans–Houston–Dallas) with about 16,000,000 people, or 8 percent of the total. Fifty-five percent of the American people thus are concentrated within four huge urbanized belts, which comprise less than 10 percent of the country's area.

The role of Mexico, the Caribbean, and Central America. The combined areas of Mexico, the Caribbean, and Central America have a population of almost 100,000,000 (or 50,000,000, 33,000,000, and 17,000,000 people, respectively) and are rapidly growing. Compared with the United States growth rate of 1.2 percent per annum, Mexico is expanding at a rate of almost 3.5 percent per annum. Costa Rica, with a 3.4 percent increase per year, is expected to double its 1,800,000 1970 population within less than a generation. Crude birth rates of from 34 per 1,000 for Costa Rica, to 44 per 1,000 for Honduras compare with the 17 per 1,000 typical of both Canada and the United States. With death rates declining appreciably, a population explosion is under way. Yet, as elsewhere in the developing world, the economy can scarcely support the present population. In Mexico 41 percent of the population is engaged in primary production, and about 21 percent in industry; in Honduras the ratio at the 1961 census was even more unfavourable: 67 percent in primary occupations, and only 9 percent in industry. Great advances in manufacturing and services are needed. Massive United States capital investment and an aid program have been aimed at helping Central America and the Caribbean to help themselves; both factors have been major influences in the region's development, though the influence of their giant northern neighbour has not been without its local critics. Such progress tends to be concentrated in the capital cities. Mexico City has over 8,500,000 people in its metropolitan area and is the largest city between New York and Buenos Aires. Its influence is swiftly modernizing the state.

The population explosion and the economy

THE OUTLOOK

North America is a very dynamic social, demographic, and economic entity, with a geographical position that gave it a commanding role in the world once its huge reserves of metals and fuels and its rich resources of water, soil, and vegetation were developed by its peoples, both native and immigrant. Its peoples, who used their rapidly growing numbers and their varied traditions and skills to bring the continent to the forefront of history, present a formidable challenge to the peoples of the developing world as they, too, begin to seek an equitable share in global resources. The internal problems of the North American continent, some would claim, appear of greatly diminished significance in the face of this wider relationship with the evolving world community.

BIBLIOGRAPHY. General works on North America usually emphasize either a regional or a topical approach. O.P. STARKEY and J.L. ROBINSON, *The Anglo-American Realm* (1969), is an up-to-date regional treatment. G.H. DURY and R.S. MATHIESON, *The United States and Canada* (1970); and J. PATERSON, *North America*, 4th ed. (1970), combine the treatment of topics and regions. J.W. WATSON, *North America*, 2nd ed. (1967), is mainly topical, with a strong historical and human bent.

Geology and physical geography are covered by many texts, the more recent of which are: T.H. CLARK, *The Geological Evolution of North America* (1960), giving a broad picture of the growth of the continent; G.M. KAY (ed.), *North Atlantic: Geology and Continental Drift* (1969), stressing the role of the ocean basins in the grand relief of the Earth, with special reference to North America; C.B. HUNT, *Physiography of the United States* (1967); and H.E. WRIGHT and D.G. FREY, *The Quaternary of the United States* (1965), showing the influence of the last ice age on the landscape.

Biogeography is represented by a collection of works on climate, soils, vegetation, and wild life, since there is no overall text. W.E.D. HALLIDAY, "A Forest Classification for Canada," *Can. For. Serv. Bull. 89* (1950), gives the best account of northern forest types. R.J. PRESTON, *North American Trees* (1961), is a good description of the main trees and their habitats. The *United States Department of Agriculture Yearbooks* are invaluable sources, both from a scientific and economic point of view; see especially those on *Climate and Man* (1941); *Grass* (1945); *Trees* (1949); and *Soils* (1957). R.E. LEGGETT, *Soils in Canada* (1961), is the best account of northern soils.

The resource base is widely covered in governmental and other literature. The Canadian Geological Survey handbook, *Geology and Economic Minerals of Canada*, 4th ed. (1963, revised periodically), gives a good overall view of Canada's mineral wealth; the United States government offers excellent surveys of American resources in the following Information Circulars of the Bureau of Mines: *Supply and Demand for Energy in the United States, by States and by Regions*, pt. 1, *Coal*, pt. 2, *Utility Electricity*, pt. 3, *Dry Natural Gas*, and pt. 4, *Petroleum and Natural Gas Liquids* (1969); and in *The American Land* (1968), a publication of the Soil Conservation Service. Scholarly studies of the general resource situation are: G.W. WILSON, SCOTT GORDON, and STANISLAW JUDEK, *Canada: An Appraisal of Its Needs and Resources* (1965); matched by H. BROWN, *Resource Needs and Demands* (1970). Interesting forecasts of land use and development are given in H.G. BORLAND (ed.), *Our Natural World, the Land and the Wild Life of America As Seen and Described by Writers Since the Country's Discovery* (1969); and H.H. LANDSBERG, *Natural Resources of U.S. Growth: A Look Ahead to the Year 2000* (1964). Of special interest are A.N. LAYCOCK, "Water," in J. WARKENTIN (ed.), *Canada: A Geographical Interpretation* (1968); and A.WOHNAN, *Water Resources: A Report to the Committee on Natural Resources of the National Academy of Sciences-National Research Council* (1962). An important overview of the Latin American resource situation is given in J. GRUNWALD, *Natural Resources in Latin American Development* (1970).

Human resources include race, population, rural and urban development and changes in standards of living. D.J. BOGUE, *The Population of the United States* (1959), is still the standard American work; it should be supplemented by the government publications—*Population Challenge: What It Means to America* (1966), and *200 Million Americans* (1967). On early America, L.A. BRENNAN, *The American Dawn: A New Model of American Prehistory* (1970), gives a good review of theories of early men in North America. H.E. DRIVER, *Indians of North America*, 2nd ed. (1969), is a comprehensive survey of Indian cultures. Case studies of Indians and a summary of U.S. and Canadian relations with the Indians are provided by W.H. OSWALT in *This Land Was Theirs* (1966). Studies of the American Negro are legion, but few are geographical. The UNITED STATES DEPARTMENT OF COMMERCE, BUREAU OF THE CENSUS, *Changing Characteristics of the Negro Population* (1968), offers a useful geographical basis. The ethnic problem in the United States is handled well in M.A. JONES, *American Immigration* (1960). Changing rural trends are discussed in S.R. OGDEN, *America the Vanishing: Rural Life and the Price of Progress* (1969). Urban geography is well represented by J. GOTTMANN and R.A. HARPER, *Metropolis on the Move* (1967); and L.O. STONE, *Urban Development in Canada* (1967). More general statements of metropolitan trends are found in H. BLUMENFELD, *The Modern Metropolis* (1967); and R.A. MOHL and N. BETTEN, *Urban America in Historical Perspective* (1970).

Resource development has developed a vast field of literature. Useful from the geographic point of view are two general works: F.J. MARSCHNER, *Land Use and Its Patterns in the United States* (1959), the classic study of its kind; and

P.R. and A.H. EHRLICH, *Population, Resources, and Environment* (1970), a modern overall assessment. Several studies of transportation are valuable, including W.L. GARRISON, *Highway Development and Geographic Change* (1959); G.P. GLAZEBROOK, *A History of Transportation in Canada* (1964); K.J. KANSKY, *Structure of Transportation Networks* (1963); J.F. STOVER, *The Life and Decline of the American Railroad* (1970); and C.A. TAFF, *Commercial Motor Transportation* (1969). The growing concern with the environment is reflected in R.A. COOLEY and G. WANDESFORDE-SMITH, *Congress and the Environment* (1970); and in the UNITED STATES DEPARTMENT OF AGRICULTURE, *Outdoors USA* (1967); and *The Environmental Decade (Action Proposals for 1970's)* (1970). C.I. JACKSON, *The Spatial Dimensions of Environmental Management in Canada* (1970), is a model study. Mexico and Central America are well represented in two penetrating studies: F. JOHN MATHIS, *Economic Integration in Latin America* (1969); and C.T. NISBET, *Latin America: Problems in Economic Development* (1969).

Development patterns as they affect the geography of North America are set out in three key works: S.B. COHEN (ed.), *Geography and the American Environment* (1968); J. WARKENTIN (ed.), *Canada: A Geographical Interpretation* (1968); and P.E. JAMES, *Latin America,* 4th ed. (1969). A.N.J. DEN HOLLANDER and S. SKARD, *American Civilization* (1968), presents a masterly account of trends in American life. Recent trends in Central America and Mexico are described in L.B. FLETCHER, *Guatemala's Economic Development* (1970); D.E. RAMSETT, *Regional Industrial Development in Central America* (1969); and C.W. REYNOLDS, *The Mexican Economy: Twentieth Century Structure and Growth* (1970).

(J.W.W.)

North American Desert

A vast, irregular belt of inhospitable terrain stretches down the western side of the North American continent, covering 1,000,000 square miles (2,600,000 square kilometres) from southern Canada to northern Mexico and roughly corresponding to the sheltered and hence rain-starved intermontane region lying between the soaring barrier of the Rocky Mountains and the fertile coast ranges fringing the Pacific. The physical geography and human utilization of this huge area exhibit great internal variety, but its overall aridity, associated with an excess of evaporation over precipitation, great temperature extremes, frequent winds (sometimes producing dust storms and dust devils), localized storms, and a predominance of starkly eroded sunbeaten landscapes, which often have a harsh but breathtaking beauty, give it an unquestioned unity. Scientists, in naming this whole ecological complex, or biome, the North American Desert, are merely echoing the legend of a "Great American Desert" established as early as the 1820s by the vivid reportage of an expedition led by the pioneer explorer and engineer Stephen H. Long.

All forms of life, from lowly plants and insects to man himself, have had to struggle to survive in the region, and the North American Desert has thus had enormous importance in the development of the continent. Descendants of the earliest inhabitants, the desert-culture Indians, are still found in the area. Their ranks were swollen in the 19th century by tribes thrust westward in the great dispossession that followed the advance of Anglo-European settlement from the Eastern Seaboard into the continental interior, and the region is now the home—often in severely straitened circumstances—of the bulk of the United States Indian population. The legacy of much earlier population movements from farther south has lent a distinctly Spanish element to the area, while modern American settlement has added its own contribution in the form of sheep and cattle grazing, military installations, and small but often rapidly expanding oases of mining and manufacturing. All the peoples of the North American Desert, whatever their origin, have their lives molded by the basic and all-pervading lack of water.

The legacy of history

This article describes the North American Desert as a biome and also its overall human geography (for individual physical features see BASIN AND RANGE PROVINCE; COLORADO RIVER; DEATH VALLEY; GRAND CANYON; GREAT SALT LAKE; and RIO GRANDE; for a detailed treatment of human geography see the articles on the appropriate constituent states of the United States).

Exploration and scientific study. The Indians of the region accumulated a rich natural lore during the thousands of years of their adaptation to the desert environment, but it was left to Francisco Vázquez de Coronado and other 16th-century Spanish explorers to provide the first written descriptions of the region, particularly of the southwestern portion. The famous Lewis and Clark Expedition of 1804–06 described portions of the northern sector, and Stephen H. Long's pioneer work in the 1820s foreshadowed a host of reports often generated by the huge land grants made to railroads and land companies and written by 19th-century surveyor-engineers. In 1878 the geologist John Wesley Powell made a significant report on the arid west, accurately forecasting the detrimental consequences of imposing on arid regions ways of life more appropriate to humid lands. More diversified studies followed—the first arid-lands research laboratory was founded at Tucson, Arizona, in 1903—and contemporary studies include the important International Biological Program of ecological investigation.

The natural environment. *Regional divisions.* Differences in latitude, elevation, climate, topography, vegetation, soil, and human use allow the subdivision of the North American Desert into regions of cold midlatitude and hot midlatitude desert.

The basic divisions of the desert

The cold midlatitude desert regions cluster in the northern sectors and include the Columbia Plateau (extending across southeastern British Columbia and eastern Washington), the Great Sandy Desert (lying in the Harney Basin of eastern Oregon), nearly all of Nevada (including the volcanic Black Rock Desert), the Snake River Plains of southern Idaho, most of Utah (including the desert associated with the Great Salt Lake), the Painted Desert and the beginnings of the Grand Canyon in the Colorado Plateau west of the Rockies; straddling the Continental Divide, these regions extend from southern Montana into the Red Desert of Wyoming.

Around the southern end of the Sierra Nevada and the scorching landscapes of Death Valley (the continent's lowest point), the Great Basin Desert merges into the hotter midlatitude desert region characterized by the Mojave (Mohave) Desert, bounded on the east by the exotic Colorado River and on the southwest by the extremely hot, barren, and arid Colorado Desert and the sandy Yuma Desert. The last continues into Mexico and merges into the coastal Vizcaino Desert (Desierto de Vizcaíno) of Baja California. To the east, the undulating plains and foothills of the Sonoran Desert blend into the southern Arizona Upland (Saguaro) Desert, thrust further east into the huge Chihuahuan Desert, and stretch over the Mexican states of Chihuahua, Coahuila, and San Luis Potosí. The Sonoran Desert also extends northward into the arid portions of southeastern Arizona; it includes the dazzling gypsum dunes of White Sands National Monument, New Mexico, and crosses the Mexican Plateau and Trans-Pecos of Texas to the Rio Grande.

Landform characteristics. Most of the North American Desert—and all the salty-lake remnants—occupies areas covered by geologically recent (less than 2,500,000 years old) Quaternary deposits and mountains thrown up and folded by movements in Tertiary time (or about twice as old, with some plains and plateaus of Mesozoic sediments, up to 225,000,000 years old).

Because of long periods of erosion, the landforms produced from these rocks are characteristically sharp and angular (except in the very heavily eroded badlands regions) and contain some of North America's finest scenery. The action of wind, temperature changes, ephemeral streams, and floods have all been involved in this molding process. The individual deserts are characterized by plateaus, gorges, ravines, and alluvial fans washed out at the feet of mountains. Deserts of the bolson types contain playas (dried up lake remnants) and mud and salt lakes and flats. Deserts of the hammada type are characterized by extensive rocky surfaces with boulder or gravel coverings, sometimes blackened and wind scoured, with magnificent buttes, mesas, and other isolated mountain remnants rising high above the flat landscape. Stretches of shifting sands known as ergs—the extensive

Algodones Dunes of the Colorado–Yuma desert are a notable example—are found at lower elevations, with the shallow troughs of arroyos carrying intermittent streams from surrounding uplands to be lost in the sands.

Soils. The soils of the North American Desert have origins similar to those of more humid regions, but they are less enriched by organisms and less leached of constituents. Most belong to the "aridisols" dry-soil group, but local variations occur, reflecting differing salt and mineral composition and presence or absence of organic matter. With proper management, the more fertile ones can be quite productive. The rawest soils belong to the less developed group known as "entisols."

Plant and animal life. In the North American Desert, moisture—its quantity, quality, availability, and frequency—is the most critical factor for life. Local environmental factors are also significant in determining the nature of desert plant communities and their dependent animal life. Most desert plants are xerophytes (plants adapted to arid conditions) or phraetophytes (plants dependent on a permanent water supply) and survive only through their root systems and adaptive mechanisms for resisting drought. Sagebrush characterizes the Great Basin region, with Joshua trees, creosote bush, and burroweed typical of the Mojave. The Sonoran Desert has a thorn scrub of shrubs (mesquite, paloverde, ironwood, burrobush, smoke tree, and cat's claw) and a variety of moisture-preserving succulents. The Arizona Upland Desert is noted for the giant saguaro cactus, while the Chihuahuan Desert is characterized, notably in its eastern part, by a ground cover of open mesquite, a scattering of larger trees, and shrubby undergrowth, including the yucca, prickly pear, and other varieties of cactus. Plant life and associated algae, lichens, mosses, and insects become more complex as temperature and moisture conditions improve.

The North American Desert harbours an abundant variety of insects, including grasshoppers that occasionally reach destructive proportions. Lizards, snakes, and other reptiles, the most conspicuous animals, are dependent on plant fluids or devoured animals for moisture. Birds are largely independent of water sources (and are seen almost everywhere), as they live on insects and spiders as well as being preyers and scavengers. Rodents (mice, rats, squirrels, and rabbits) and bats are the most numerous mammals; essentially nocturnal, they remain underground during the heat of the day and, like the birds, obtain moisture from their food. Higher up the food chain are such carnivores as coyotes, bobcats, foxes, and skunks, and the largest desert mammal, found at higher elevations, is the bighorn sheep. Protective coloration, often remarkably complex, is an important feature of desert life.

The desert food chain

The human imprint. As ancient dwellings, rock paintings and carvings, and other archaeological remains testify, desert-culture Indians had developed a distinctive way of life within the approximate boundaries of the North American Desert thousands of years before the coming of the white man. Spanish explorers were the first to penetrate the southwestern area, and their legacy has molded much of the character of the region. It was only in the 19th century that a great wave of settlement, often attracted by the lure of mineral wealth, swept over the whole area on its way to the more fertile coastal regions, leaving a residue of settlement focussed on mineral wealth and irrigated regions and, more sparsely, in the vast areas given over to sheep and cattle grazing. Large areas of the contemporary landscape are occupied by Indian reservations, a legacy of the white man's continental expansion. Military installations, some associated with the testing of nuclear weapons, also take up huge areas. The various types of agriculture encompass dryland farming, sheep and cattle grazing, and more intensive developments on irrigated oases. Mineral exploitation has continued, often to the detriment of the natural environment, and manufacturing industry has become associated with growing urban settlement in the more favoured regions. The tourist trade has also grown immensely. In spite of the increasing development of dams, reservoirs, and canals, the lack of water is still a severe limitation to agricultural, urban, and industrial expansion, and the development of a low-cost water-supply system remains the key to an increased utilization of the entire North American Desert.

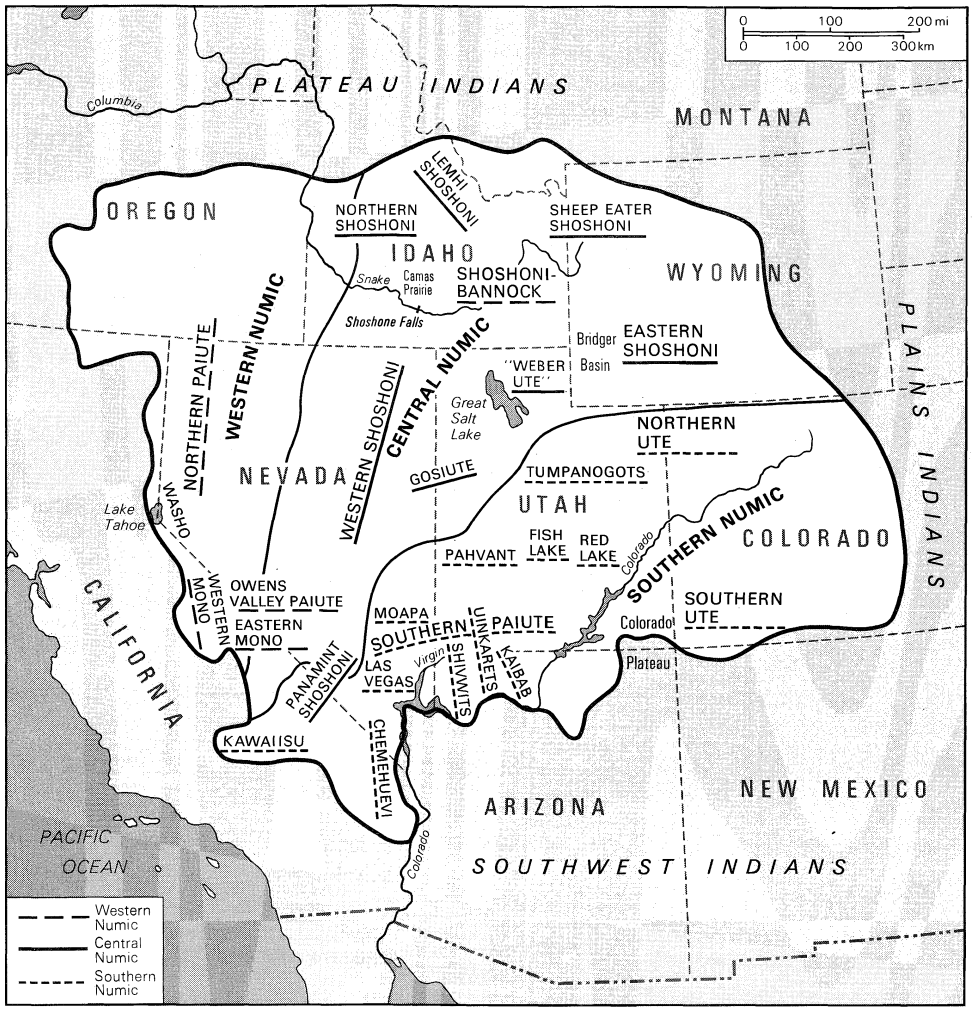
(R.E.C.)

North American Great Basin Indians

The Great Basin Indians in aboriginal times occupied a 398,000-square-mile (1,031,000-square-kilometre) area of interior western North America. The area includes the physiographic Great Basin—the interior mountain and basin region of present-day southeastern California, Nevada, southeastern Oregon, and western Utah—and the Snake River Plain of Idaho, the mountains to the northeast, the Bridger Basin of southwestern Wyoming, the Colorado Plateau area of Utah and Colorado, and the mountains of central and southern Colorado. The entire region is arid to semi-arid, annual average precipitation being four inches in the lowlands to 20–25 inches in the mountains. The precipitation falls primarily in the form of winter snow. Ecologically, the area is characterized by a vertical succession of life zones, each with a dominant xerophytic (desert-type) flora and related fauna.

Aboriginal population density was sparse, ranging from 0.8 to 11.7 persons per 100 square miles.

Peoples and languages. The languages spoken by the Indians are of two widely divergent language families. The Washo, whose territory centred on Lake Tahoe, speak a Hokan language related to languages spoken in parts of California, Arizona, and Baja California. The remainder of the Great Basin culture area was occupied by speakers of Numic languages. Numic, formerly called Plateau Shoshonean, is a division of the Uto-Aztecan language family, a group of related languages widely distributed in the western United States and Mexico. Linguists distinguish three Numic branches, Western, Central, and Southern, each branch having a pair of languages. Western Numic languages are Mono, spoken by the Eastern Mono and Owens Valley Paiute of California, and Northern Paiute, spoken by the several Northern Paiute groups of northeastern California, western Nevada (Paviotso), and southern Oregon and by the Bannock of southern Idaho. Central Numic languages are Panamint, spoken by the Koso, or Panamint Shoshoni, near Death Valley, California; and Shoshone, spoken by the Western Shoshoni of Nevada, the Gosiute of west-



Distribution of Numic languages and major groups of Great Basin area Indians.
From H. Driver *et al.*, *Indiana University Publications in Anthropology and Linguistics* (1953)

ern Utah, the now extinct "Weber Ute" of northern Utah, the Northern Shoshoni of Idaho, the Lemhi and Sheep Eater (Tukuarika) Shoshoni of the northeastern Idaho mountains, the Eastern (or Wind River) Shoshoni of western Wyoming, and the Comanche of the southern Plains. The Comanche separated from the Eastern Shoshoni in late prehistoric times, moved southward through the Rocky Mountains and became Plains Indians culturally. Southern Numic languages are Kawaiisu, spoken by the Kawaiisu band of southern California, and Ute, spoken by the several Southern Paiute bands, including the Chemehuevi of southeastern California and the Las Vegas, Moapa, Kaibab, Shivwits, and Uinkarets bands of southern Nevada, southern Utah, and northern Arizona. Ute is also spoken by the several Ute bands, the Fish Lake, Red Lake, Pahvant, and Tumpanogots of central Utah, the various Northern Ute bands of eastern Utah and the several Southern Ute bands of southern Colorado. The distinction between Southern Paiute and Ute is cultural rather than linguistic: Ute speakers who had horses in the early historic period are regarded as Ute; those without horses were Southern Paiute. The Numic peoples called themselves "Numa" or "Numu," meaning "people" or "human beings." The Washo called themselves "Washoe," meaning "Washo people" as distinguished from people of other tribes.

Linguistic and archaeological evidence indicates that the Washo had long been separated from other California Hokan-speaking groups, possibly for several millennia. Similar evidence indicates that the Numic-speaking peoples spread across the Great Basin from southeastern California sometime after the year 1000.

Social and cultural patterns. Great Basin Indians of the early historic period (1800–50) were divided into horse-using and non-horse-using groups. Horse-using groups generally occupied the northern and eastern sections of the Great Basin culture area. The Southern Ute and Eastern Shoshoni were among the first Indians north of the Spanish settlements of New Mexico to obtain horses, perhaps as early as 1680. There is some evidence that these bands acted as middlemen in the transmission of horses and horse culture from New Mexico to the northern Plains in the 1700s. As the Northern Shoshoni of Idaho obtained horses in the 18th century, they were joined by Northern Paiute speakers from eastern Oregon and northern Nevada to form the Shoshoni-Bannock bands of historic times. By 1800, the Southern and Northern Ute, the Ute of central Utah, the Eastern Shoshoni, the Lemhi Shoshoni, and the Shoshoni-Bannock were well equipped with horses, lived in skin tepees, and were oriented toward the Great Plains, the pursuit of bison, and warfare with other tribes. To the south and west in the Great Basin proper and on the western Colorado Plateau, the people did not take up the use of horses until 1850–60. The Washo did not use horses prior to white settlement, and rarely used them thereafter.

Basic social organization

The basic Great Basin social and cultural patterns were those of the nonhorse bands. The people were closely adapted to their arid environment. Small family bands moved through an annual cycle, exploiting available food resources in the various ecological zones of a particular valley and adjacent mountains. The exigencies of the food quest structured Great Basin society and culture. Food supplies were seldom adequate to permit groups of any size to remain together for more than a few days. Consequently, social organization was fluid and atomistic. For most of the year the people lived in small local groups, coming together into larger aggregates only for

certain brief periods—during rabbit drives or when fish were spawning, as the Washo did at Lake Tahoe in the spring, or during the pinyon nut season in the autumn. But despite periodic gatherings, there was no sustained sense of political cohesion or "tribalness," as that term is understood for other Amerindian groups.

The same fluidity of social organization was characteristic of the horse-using bands. Possession of horses permitted larger numbers of people to remain together for much of the year, but such aggregation did not lead to the development of formal tribal organizations. Among both horse- and non-horse-using groups, a particular leader was followed as long as he was successful in leading people to food, or in war. If he failed, people would leave to join other bands, or to form their own bands.

Kinship, marriage, and rites. The basic local social unit usually was one or more "kin cliques," consisting of a nuclear family (parents and their dependent children) or two brothers and their families, in addition to assorted other individuals related by blood or by marriage to someone in the core group.

Kin ties were reckoned bilaterally through both the mother's and the father's sides and were widely extended to distant relatives. Such extension permitted people to invoke kin ties and move from one group to another if circumstances warranted.

Marriage practices varied, with a tendency among some groups to marry true cross-cousins (mother's brother's or father's sister's child), or pseudo cross-cousins (mother's brother's or father's sister's stepchild). Both the sororate (compulsory marriage of a man to his dead wife's sister) and the levirate (compulsory marriage of a widow to her dead husband's brother), were practiced, as were their logical extensions, sororal polygyny and fraternal polyandry. Usually the latter was not formalized, consisting only of a man extending sex privileges with his wife to a brother for a time. Marriages were brittle and divorce frequent. Yet to survive, it was necessary to be married, as most men and women were throughout their adult lives. There was no set pattern of postmarital residence. A newly married couple might live with the bride's family for the first few years until children were born, but the availability of food supplies was the determining residence factor.

Children began to learn about and participate in the food quest as soon as they were old enough. There was little emphasis on puberty rites except among the Washo, who held a special dance and put a girl through various tests at the time of menarche.

Death rites were minimal. An individual was buried with his possessions or they were destroyed. The Washo abandoned or burned a dwelling in which a death occurred. Occasionally, old people who could not keep up with the group or who could no longer produce their share of the food supply were abandoned.

Technology and economy. The Numic people and the Washo built two types of shelters; semicircular brush windbreaks in the summers, and domed brush, bark-slab, grass, or reed-mat dwellings in the winter. The horse-using groups used Plains-style tepees but sometimes built grass or brush houses. Winter villages were sited along the edge of valley floors, near water, food caches, and firewood. Summer encampments were near food areas and were shifted as necessary. Horse-using groups camped along wooded stream bottoms near firewood and forage areas for their horses.

Tools and food-gathering

Tools were simple and portable: the bow and arrow, stone knife, rabbit stick, digging stick, several types of baskets and nets, and flat seed-grinding slab and handstone. Some Western Shoshoni and Southern Paiute groups made a coarse brown-ware pottery; some Northern Shoshoni made steatite jars and cups. In fishing areas, lines and hooks, harpoons, nets, and willow fish weirs were used. The Northern Paiute used duck decoys made of tule reeds covered with duck skins. Rodents were taken with snares and traps or pulled from burrows with long, hooked sticks. Rabbits were driven into nets and clubbed, or they were shot with bow and arrows. Antelope were driven into corrals and traps. Waterfowl were netted, trapped, or shot with bunt arrows (arrows with rounded heads, intended simply to stun). Deer, elk, and mountain sheep were taken by individual hunters with bow and arrows.

The people followed an annual round, exploiting plant and animal resources as they became available in the several ecological zones. Well over 70 percent of the food supply was vegetal. Over 200 species of plants were named and used, principally seed and root plants. Pinyon pine groves were found in upland areas of Nevada and central Utah, and large quantities of pinyon nuts were collected in the autumn and cached for winter use. Rabbit drives were also held in the autumn. The drives provided an occasion for larger numbers of people to come together for gambling, dancing, and courting. Winter was spent in small villages, living on cached foods and such game as might be taken. Early spring was a poor time; stored resources were often exhausted, and the people were forced to seek early greens and roots for food. Late spring and summer were devoted to collecting seeds, roots, insects, fishing where possible, and continued hunting.

Some Southern Paiute bands practiced limited horticulture along the Colorado and Virgin rivers. Some bands of Mono and Northern Paiute reportedly irrigated patches of wild seed plants to increase the yield.

The horse-using groups also followed an annual round but ranged over a much larger area. In some years, they ventured onto the Northern Plains for bison in the autumn, returning to the Bridger Basin, the Snake River area, or the Colorado Mountains for the winter. In the spring and summer, Shoshoni and Shoshoni-Bannock obtained roots from the Camas Prairie in Idaho and salmon from the Snake River, below Shoshone Falls. Deer, elk, and mountain sheep were taken when possible. Seed and root foods were collected as they became available.

Clothing consisted of sage bark aprons and breechclouts and rabbit-skin robes in the winter. The horse-using peoples wore Plains-style, tailored skin garments. Artwork was largely confined to basketry decoration. Among the horse-using bands, quill and beadwork decorated clothing and rawhide shields, and bags and containers were painted.

Trade was minimal among western Great Basin groups, although there is some evidence of the use of strings of shells as a medium of exchange in aboriginal times. Horse-using groups were more active, trading among themselves and with other tribes. The Eastern Shoshoni and some Ute bands participated in the fur trade between 1810 and 1840. Between about 1800 and 1850, mounted Ute and Navaho bands preyed on Southern Paiute, Western Shoshoni, and Gosiute bands for slaves, capturing and sometimes trading women and children to be sold in the Spanish settlements of New Mexico and southern California.

Religious concepts. Religious concepts derived from a mythical cosmogony, beliefs in "power" beings, and a belief in a dualistic soul. Mythology provided a cosmogony and cosmography of the world. Mythical animals, notably wolf, coyote, rabbit, bear, and mountain lion, were believed to be the progenitors of the modern animals. They lived prior to Indian life but were anthropomorphic, speaking and acting as people do in the present world. They created the world and were responsible for present-day topography, ecology, food resources, seasons of the year, and the distribution of Indian tribes. They set the nature of social relations—that is, defined how various classes of kinsmen should behave toward each other—and set the customs surrounding birth, marriage, puberty and death. Their actions in the mythic realm set moral and ethical precepts and determined the physical and behavioral characteristics of the modern animals. Most of the motifs and tale plots of Great Basin mythology are found widely throughout North America.

Power beings were animals, birds, or natural phenomena, each attributed with a specific natural power according to an observed characteristic. Some such beings were thought to be benevolent, or at least neutral, toward men. Others, such as Water Babies—small, long-haired creatures who lured men to their deaths in springs or

lakes and who ate children—were malevolent and feared. There were conceptions of various other vague beings, such as the Southern Paiute *unupits,* mischievous spirits who caused illness.

Shamanism

Shamans, or curers, were prominent in all Great Basin groups. Both men and women might become shamans. Shamans received their powers to cure disease, foretell the future, and, sometimes, to practice sorcery from a power being who came unsought to a prospective shaman. It was considered dangerous to resist being given a shaman's power, for those who did sometimes died. The being became a tutelary spirit, instructing an individual in curing and sources of power. Some shamans had several tutelary spirits, each providing instruction for specific types of treatment. Among Northern Paiute and Washo and probably elsewhere, a man who had received power apprenticed himself to an older, practicing shaman and from him learned rituals, cures, and feats of legerdemain associated with curing performances. Curing ceremonies were performed with family members and others present and might last several days. The widespread Amerindian practice of sucking an object said to cause the disease from the patient's body was often employed. Shamans who lost too many patients were sometimes killed.

In the western Basin, some men had powers to charm antelope and led communal antelope drives. Beliefs that some men were arrow-proof (and after the introduction of guns, bulletproof) are reported for the Northern Paiute and Gosiute but were probably general throughout the area.

Among the Eastern Shoshoni, young men sought power beings through a visionary experience. The active seeking of power beings through visions is a practice the Eastern Shoshoni probably learned from their Plains neighbours, although the characteristics of the beings sought were those common to Great Basin beliefs.

There was a concept of soul-dualism among most, if not all, Numic groups. One soul, or soul aspect, represented vitality or life; the other was the individual as he was in a dream or vision state. During dreams or visions, the latter soul left the body and moved in the spirit realm. At death, both souls left the body.

Impact of white settlement. Contact with white civilization drastically altered Great Basin societies and cultures. The Southern Ute were in sustained contact with the Spanish in New Mexico as early as the 1600s, but other Great Basin groups had no direct or continued contact with whites until after 1800. The fur trade, between 1810 and 1840, brought new tools and implements to the eastern bands. Settlement began in the 1840s, as did the surge of emigrants through the area on their way to Oregon and California. Mining, ranching, and farming activities destroyed or closed off traditional Indian food-gathering areas. Pinyon groves were cut for firewood, fence posts, and mining timbers. The Indians attempted to resist white encroachment. Mounted bands of Ute, Shoshoni, Shoshoni-Bannock, and Northern Paiute preyed on ranches and wagon trains and tried to drive the intruders away. The struggle culminated in several local "wars" and "massacres" in the 1850s and 1860s. After 1870, Indians were forced onto reservations or into small groups on the edges of white settlements, thus reducing their land base to a small fraction of its former size. This forced the abandonment of aboriginal subsistence patterns in favour of limited agriculture or stock raising, where possible, and wage work, especially as farm and ranch hands.

In 1870 and again in 1890, so-called ghost dances started among the Northern Paiute of western Nevada. The dances were millenarian in character. Prophets foretold that if the Indians danced and prayed, the whites would go away and the "old days" would be restored. The 1870 dance, led by a man named Wodziwob, centred in Nevada and California. The 1890 dance, led by Wovoka, or Jack Wilson, of Smith Valley, Nevada, spread to many Indian tribes in the western United States.

A Peyote Cult was introduced to the Ute and Eastern Shoshoni in the early 1900s by Oklahoma Indians. It later spread to other Great Basin peoples. Most peyote groups are now members of the Native American Church, a nationally recognized organization. Great Basin peyote rituals are a mixture of aboriginal and Christian elements. Ceremonies are led by "road chiefs"; that is, those who lead believers down the Peyote Road or Way. A ceremony, which lasts all night, includes singing, praying, and eating peyote buttons or drinking a concoction made therefrom, producing a mild hallucinogenic experience. The tenets of the Native American Church stress moral and ethical precepts and behaviour.

In postreservation times, the Eastern Shoshoni and Ute adopted the sun dance from the Plains Indians. The four-day dance is performed yearly to achieve health and valour for the participants, and partly as a tourist attraction.

Present-day reservations

Present-day reservations and the people living on them are: Wind River, Wyoming (Eastern and Sheep Eater Shoshoni); Fort Hall, Idaho (Shoshoni-Bannock and Lemhi Shoshoni); Uintah and Ouray, Utah (Northern Ute); Kaibab, Arizona (Southern Paiute); Skull Valley and Goshute, Utah (Gosiute); Moapa River, Nevada (Southern Paiute); Ruby Valley, Te-moak, Duckwater, and Yomba, Nevada (Western Shoshoni); Duck Valley, Nevada–Idaho (Western Shoshoni and Northern Paiute); Fort McDermitt, Nevada–Oregon (Western Shoshoni and Northern Paiute); Burns and Warm Springs, Oregon (Northern Paiute); Summit Lake, Pyramid Lake, Walker River and Stillwater, Nevada (Northern Paiute); and Fort Bidwell, California (Northern Paiute). There are also over 20 "colonies" of 25 to 200 people adjacent to cities and towns in Nevada, eastern California, and southern Utah. The Washo do not have a reservation as such but live in the Reno and Carson City, Nevada, colonies as well as at Dresslerville, Nevada, and Woodfords, California.

The Indian Reorganization Act of 1934 led to the establishment of local elected "tribal councils" for the various reservations and colonies. Councils have sought to develop various economic activities including ranching, light industry, and tourism.

Indian children were sent to federal day schools and boarding schools beginning in the 1880s. In the past few years, federal schools have been phased out and Indian children attend local schools and universities.

Great Basin Indian peoples retain some of their traditional culture in crafts, dances, and visiting patterns. Older people still speak the native languages, but many of the younger people fail to learn or use them. Many people still live on the reservations, but others have moved to towns and cities, where they are employed in many different capacities.

BIBLIOGRAPHY. There is no general monograph on all Great Basin Indians. CATHERINE S. FOWLER, *Great Basin Anthropology: A Bibliography* (1970), lists some 6,500 sources on the area. Summary articles on various aspects of Great Basin anthropology are contained in W.L. D'AZEVEDO *et al.* (eds.), *The Current Status of Anthropological Research in the Great Basin: 1964* (1966); and in E.H. SWANSON, JR. (ed.), *Languages and Cultures of Western North America* (1970). The earliest systematic study of Great Basin Indians was by JOHN WESLEY POWELL; see D.D. and C.S. FOWLER (eds.), *Anthropology of the Numa: John Wesley Powell's Manuscripts on the Numic Peoples of Western North America, 1868–1880* (1971). Modern ethnographic studies include J.H. STEWARD, *Basin-Plateau Aboriginal Sociopolitical Groups* (1938); R.H. LOWIE, *Notes on Shoshonean Ethnography* (1924); R.F. and Y. MURPHY, *Shoshone-Bannock Subsistence and Society* (1960); V.C. TRENHOLM and M. CARLEY, *The Shoshonis: Sentinals of the Rockies* (1964); JAMES F. DOWNS, *The Two Worlds of the Washo, an Indian Tribe of California and Nevada* (1966); and I.T. KELLY, *Southern Paiute Ethnography* (1964). Religious beliefs are treated by W.Z. PARK, *Shamanism in Western North America* (1938); and B.B. WHITING, *Paiute Sorcery* (1950). Important linguistic studies include E. SAPIR, *Southern Paiute Texts and Dictionary* (1930–31); W.H. JACOBSEN, JR., "Washo Linguistic Studies," and W.R. MILLER, "Anthropological Linguistics in the Great Basin," both in W.L. D'AZEVEDO (*op. cit.*). Great Basin prehistory is summarized in J.D. JENNINGS "The Desert West" in J.D. JENNINGS and E. NORBECK (eds.), *Prehistoric Man in the New World,* pp. 149–174 (1964).

(D.D.F./C.S.F.)

North American Indian Languages

The term North American Indian languages usually refers to those languages that are indigenous to the United States and Canada, and that are spoken north of the Mexican border. A number of language groups within this area, however, extend as far south as Central America. The present article will concentrate on the languages of Canada and the United States. (For further information on languages of Mexico and Central America, see MESO-AMERICAN INDIAN LANGUAGES).

The Indian languages of North America are both numerous and diverse. Their original number has been estimated at 300; these tongues were spoken by a native population of approximately 1,500,000. The number of languages still used was estimated at around 200 by the American linguist Wallace Chafe in 1962. Some of these had only one or two elderly speakers. The numbers continue to drop, but with some notable exceptions—*e.g.*, Navajo is steadily increasing in number of speakers. As a consequence of the growing trend toward extinction in the American Indian languages, the field of study is becoming more concerned with the past than the future. Even so, the rich diversity of these languages provides a valuable laboratory for linguistic theory; certainly the discipline of linguistics could not have developed as it has, especially in the United States, without the native American languages. In this article, the present tense will be used in referring to both extinct and surviving languages.

Within the diversity of the North American Indian languages, no general characterization is possible; various features of structure are common to them, but there is no feature or complex of features shared by all. At the same time, there is nothing primitive about these languages. They draw upon the same linguistic resources and display the same regularities and complexities as do the languages of Europe. If historical connections are sought among the Indian tongues, some languages clearly show numerous and systematic resemblances comparable to those between Spanish, French, and Italian. These similarities strongly suggest classification as a linguistic family. North American languages can then be grouped into some 57 families. On this level, too, the diversity of some areas is notable. Thirty-seven families lie west of the Rockies and 20 in California alone; California thus shows more linguistic variety than all of Europe. Some families seem to be related to each other in more remote historical groupings, often called phyla. Such classifications border on speculation, however, partly because data are lacking on many languages (because they are extinct or still unstudied), and partly because of the difficulty in distinguishing, at the deeper historical levels, between resemblances caused by common origin and those resulting from linguistic borrowing.

Language families and phyla

In any case, no theory of common origin for the North American languages has become established. Although most anthropologists believe that North America was populated mainly by people who migrated across the Bering Strait from Asia, attempts to relate native American languages to Asian languages have not gained general acceptance. (There is one possible exception—the relationship of Eskimo-Aleut to certain Siberian languages.) The linguistic diversity of North America suggests, indeed, that the area was populated as a result of several waves of migration by peoples of distinct linguistic stocks of Asia; these stocks may have no modern survivors.

Classification. The first comprehensive classification into families of the North American Indian languages was made in 1891 by the American John Wesley Powell, who based his study on impressionistic resemblances in vocabulary. A principle of nomenclature adopted by Powell has been widely used ever since: families are named by adding *-an* to the name of one prominent member; *e.g.*, Caddoan is the family including Caddo and other languages. For this most obvious level of relationship, the Powell classification remains essentially unchallenged. Various scholars, however, have attempted to group the families into larger units that reflect deeper levels of historical relationship. Of these efforts, one of the most ambitious and best known is that of Edward Sapir, which was first published in the *Encyclopaedia Britannica* in 1929. In Sapir's classification, all the languages are grouped into six phyla—Eskimo-Aleut, Algonkian-Wakashan, Na-Dené, Penutian, Hokan-Siouan, and Aztec-Tanoan—established on the basis of very general grammatical resemblances. In 1958, research of the American linguist Mary R. Haas revealed precise sound correspondences between the Algonkian languages and a "Gulf" group in the southeastern United States that Sapir had assigned to the Hokan-Siouan phylum. Since that time, various reconsiderations of Sapir's groupings have been proposed. A classificatory map published by Charles F. and Florence M. Voegelin in 1966 offers one such classification, and it is likely to serve as a standard reference point for some time. Although preserving Sapir's Eskimo-Aleut, Na-Dené, Penutian, and Aztec-Tanoan groups, it also proposes reconstituted Macro-Algonkian, Macro-Siouan, and Hokan phyla, and allows nine families to remain unclassified, pending further research.

Sapir's six phyla

The Table, based on the Voegelin map, gives approximate indications of the aboriginal home territories and of the number of speakers remaining in 1962 as estimated by Chafe (see also ESKIMO-ALEUT LANGUAGES; MESO-AMERICAN INDIAN LANGUAGES).

Language contact. The Indian languages of North America, like all languages in the world, have always existed in contact with other tongues. From this situation bilingualism, or multilingualism, has resulted; the extent is determined by sociological factors. The Indian languages show varying degrees of linguistic acculturation; *i.e.*, there may be borrowing between languages not only of vocabulary items, but also of phonological, grammatical, and semantic features. In aboriginal times, in areas where bilingualism was most important (*e.g.*, the Northwest), there tended to be well-defined linguistic areas in which languages of diverse genetic affiliations came to share numerous structural characteristics through the process of borrowing. As noted above, such phenomena create difficulties for attempts at genetic classifications. In a few cases, situations of language contact have given rise to a pidgin or compromise language that is composed of elements from various sources and is used as a second language, especially in trading. An example is the Chinook Jargon of the Northwest; this came to be used by many whites and absorbed many loanwords from French and English before its eventual obsolescence.

Pidgin languages

In more recent times, contact of Indian languages with European languages—French, English, Spanish, and Russian—has again resulted in bilingualism. With the Indian languages generally relegated to a socially subordinate position (and with many of them headed for extinction), borrowing, however, has involved the relatively superficial level of vocabulary more often than the deeper levels of language structure, such as the sound system or grammar. The effects on European languages are apparent mainly in place names like Massachusetts and Seattle and in names like squash and abalone for native American plants and animals. Among the Indians, the type and degree of linguistic adaptation to European culture has varied greatly, depending on sociocultural factors. For example, among the Karok of northwestern California, a tribe that suffered harsh treatment at the hands of whites, there are only a few loanwords from English (*e.g.*, *ápus* "apples"), a few calques or loan translations (the "pear" is called *vírusur* "bear," because English "pear" and "bear" are merged in Karok pronunciation), but a large number of new formations from native materials; *e.g.*, a hotel is called *am-naam* "eating place."

Grammar. The term grammatical structure as used here refers to both the traditional categories of morphology—how words are made up—and syntax—how words are combined into sentences. It should again be emphasized that in grammar, as well as in phonological or semantic structure, neither the American Indian languages nor any other languages in the world display anything that could be called primitive in the sense of undeveloped or rudimentary. Every language has a structure

Distribution of North American Indian languages.

From C.F. and F.M. Voegelin, *Map of North American Indian Languages;* copyright 1966 by University of Washington Press

as complex, as subtle, and as efficiently adaptable to cultural needs as that of Latin or English, for example.

The North American Indian languages display great diversity, so that it is not possible to characterize them as a group by the presence or absence of any particular grammatical peculiarities. At the same time, there are some characteristics that, though not unknown elsewhere in the world, are sufficiently widespread to be considered typical of the continent or of particular linguistic areas within North America. The phenomenon of polysynthesis, in which many sentence elements are expressed within the boundaries of a single word by compounding and affixation, is especially characteristic of Eskimo and Algonkian, but is also found elsewhere. An illustration from the Algonkian group is the Menominee form *nekees-pesteh-wenah-nɛɛwaaw* "but I did see him on the way." Incorporation, the compounding of a noun with a verb, is rarely used in English (*e.g.*, "to baby-sit") but is common in some Indian languages; *e.g.*, Mohawk *ke-wēna-weiẽhō* "I-language-understand." (The symbols used that are not found in the Latin alphabet have been adopted from phonetic alphabets.)

Polysynthesis and incorporation

Some especially common characteristics of North American languages are the following:

1. In verbs, the person and number of the subject are commonly marked by prefixes; *e.g.*, Karok has *ni-'áhoo* "I walk," *nu-'áhoo* "he walks." In some languages, the prefix simultaneously indicates the object as well as subject; *e.g.*, Karok *ni-mmah* "I see him," *ná-mmah* "he sees me."

2. Tense and aspect of verbs are usually marked by suffixes, as in many languages throughout the world. But in some areas—*e.g.*, among the Athabascan languages—prefixes are used. For example, Chipewyan *hɛ-tsaɣ* means

"he is crying," *ɣĩ-tsaɣ* is "he cried," and *ɣwa-tsaɣ* is "he will cry."

3. In noun forms, the concept of possession is widely expressed by prefixes indicating the person and number of the possessor. Thus Karok has *ávaha* "food," *nani-ávaha* "my food," *mu-ávaha* "his food," etc. When the possessor is a noun, as in "man's food," a construction like *ávansa mu-ávaha* "man his-food" is used. Many languages have inalienable nouns, which cannot occur except in such possessed forms. These generally designate such things as kinsmen or body parts; *e.g.*, Luiseño, a language in Southern California, has *no-yó'* "my mother," *o-yó'* "your mother," but no word for "mother" in isolation.

4. Nouns in many languages have forms with a meaning of location; *e.g.*, Karok *áas* "water," *áas-ak* "in the water." Such a construction is reminiscent of the case forms of Latin, and case systems do indeed occur in California and the southwest. For example, Luiseño has the nominative *kíiča* "house," accusative *kíiš*, dative *kíi-k* "to the house," ablative *kíi-ŋay* "from the house," locative *kíi-ŋa* "in the house," instrumental *kíi-tal* "by means of the house."

The following five grammatical features are less typically North American, but are nevertheless distinctive of many areas. First person pronouns in many languages show a distinction between a form inclusive of the addressee—"we" denoting "you and I"—and an exclusive form —"I and someone other than you." Some languages also have a distinction in number between singular, dual, and plural pronouns. Reduplication, the repetition of all or part of a stem, is widely used to indicate distributed or repeated action of verbs; *e.g.*, in Karok, *imyah* means "breathe," *imyáhyah* means "pant." In Uto-Aztecan languages, reduplication sometimes is associated with plural nouns, as in Pima *gogs* "dog," *go-gogs* "dogs." In many languages, verb stems are distinguished on the basis of the shape or other physical characteristics of the associated noun; thus in Navajo, in referring to motion, *'á*^{n} is used for round objects, *tá*^{n} for long objects, *tí*^{n} for living things, *lá* for ropelike objects, etc. Similar distinctions may refer to dual and plural number. Karok has *ikpuh* "one swims," *iθpuh* "two swim," *ihtak* "several swim."

Inclusive and exclusive pronouns

Verb forms also frequently specify the location or direction of an action by the use of prefixes or suffixes. In Karok, for example, from *paθ* "throw" is derived *páaθ-roov* "throw upriver," *páaθ-raa* "throw uphill," *paaθ-rípaa* "throw across-stream," and as many as 38 other similar forms. Some languages also specify the instrument of an action, generally by prefixation; *e.g.*, Pomo *phi-de-* "to move by batting with a stick," *phu-de-* "to move by blowing," *pha-de-* "to move by pushing with the end of a stick." Lastly, many languages have evidential forms of verbs that indicate the type of validity of the information reported; such distinctions may assume the importance played by tense and aspect in European languages. Thus Hopi distinguishes *wari* "he ran, runs, is running" as a reported event, from *warikŋwe* "he runs (*e.g.*, on the track team)," which is a statement of general truth, and from *warikni* "he will run," which is an anticipated event. In other languages verb forms consistently discriminate hearsay from eye-witness reports. Such a system might be very welcome in other societies; *e.g.*, especially as regards the reliability of news reports.

Phonology. The languages of North America are as diverse in their systems of pronunciation as they are in other ways. In terms of the number of contrasting sounds (phonemes), the Northwest Coast is characterized as a linguistic area by the unusual richness of its systems. A language like Tlingit has approximately 50 consonants and vowels (a comparable count for English would number 35). By contrast, Karok has only 23. The richest sound inventories seem to occur where bilingualism was commonest, and sounds were borrowed between languages.

Consonant features

The large number of consonants that is found in many Indian languages is based on the use of a number of phonetic contrasts that are relatively unfamiliar in European languages. In English, different consonants are produced by vibrating the vocal cords (which results in voiced sounds) or by not vibrating them (which gives unvoiced sounds); by shutting off the air momentarily, thus producing stops, or by letting the airstream pass through the mouth with friction (producing fricatives); and by placing the tongue in a variety of positions. The Indian languages also use these mechanisms, but sometimes others as well. The glottal stop, an interruption of breath produced by closing the vocal cords (as in the middle of English *oh-oh!*) is a common consonant. A related phenomenon, widespread in western North America, is the use of glottalized consonants, as when a *t* is produced with near simultaneous closure and reopening of the vocal cords. This is recorded with an apostrophe; it differentiates terms like Hupa (Athabascan) *teew* "underwater" from *t'eew* "raw."

The number of consonantal contrasts is also frequently expanded by distinguishing a larger number of tongue positions than do most European languages. Many languages distinguish two types of velar sounds (sounds made with the back of the tongue)—a *k* much like an English *k*, and a uvular *q*, produced further back in the mouth. Some languages even differentiate three such *k* sounds—front, middle, and back. Labiovelars, velar sounds that have simultaneous lip-rounding, are also common. Thus Tlingit has 21 phonemes made in the velar area alone: *g*, *k*, uvular *G*, *q*, glottalized *k'*, *q'*, labiovelar g^{w}, k^{w}, k'^{w}, G^{w}, q^{w}, q'^{w}, in addition to the corresponding fricatives ɣ and *x*, with uvular *X*, glottalized *x'*, *X'*, and labiovelar x^{w}, X^{w}, x'^{w}, X'^{w}. In comparison, English has only two sounds, *k* and *g*, made in the same area of the mouth.

Another class of sounds common in North America, especially in the West, is that of the laterals, which are produced by stopping the breath with the central part of the tongue but allowing it to escape at the sides. Alongside the common lateral *l*, such as exists in English, many Indian languages have a voiceless counterpart, similar to the Welsh *ll*; this sound is approximated by the *thl* in northwestern place names such as Cathlamet. To this some languages also add glottalized varieties, as well as a close-knit *tl* unit, which may in turn be aspirated or glottalized, so that there may result, as in Navajo, a total of five distinguishable lateral sounds.

In some Indian languages, as in English, stress is significant in distinguishing the meaning of words. In others, musical pitch plays a linguistic function, as it does in Chinese; *e.g.*, in Navajo, *bíní'* is "his nostril," *bìní'* is "his face," and *bìní'* is "his waist." (High and low pitches are indicated with the acute and grave accents, respectively.)

A peculiarity of some northwest coast languages is their use of complex consonant clusters, as in Bella Coola *tlk'^{w}ix^{w}* "don't swallow it." Some words even lack vowels entirely; *e.g.*, *nmnmk'* "animal."

Phonological change

Processes of phonological change, in which differences of sound are associated with grammatical distinctions (as with English *f* and *v* in "half," "halves," "to halve"), are also found in North American languages. In some languages, for example, consonantal change is related to diminutive meaning: thus Luiseño *r* changes to *d* in *ŋarúŋru-š* "pot," *ŋadúŋdu-mal* "pot-small." Vowel harmony, a process whereby vowels change to resemble adjacent ones, is further attested in North America. Yurok in northwestern California, for example, has an unusual *r* vowel, comparable to the sound in English "bird"; when this occurs in a suffix, stem vowels change to agree with it, thus *lo'óɣè* "black" + *-'r'y* (animate suffix) yields *lr'rɣr'r'y* "black animal."

Vocabulary. The word stock of American Indian languages, like those of other languages, is composed both of simple stems and of derived constructions; the derivational processes commonly include affixation (the use of prefixes, suffixes, etc.) in addition to compounding in some languages. A few languages use internal sound change, similar to the case of English "song" from "sing"; *e.g.*, Yurok *pontet* "ashes," *prncrc* "dust," *prncrh* "to be gray." New vocabulary items are also acquired by borrowing, as mentioned above.

It should be noted that, in languages generally, the

meaning of a vocabulary item cannot be adequately inferred from a knowledge of its historical origin or from knowing the meaning of its parts. For example, the name of an early 19th-century trapper, McKay, entered Karok as *mákkay*, but with the extended meaning of "white man." It was then compounded with a native noun *váas* "deerskin blanket" to give the neologism *makáy-vaas* "cloth"; this in turn was compounded with *yukúkku* "moccasin" to give *makayvas-yukúkku* "tennis shoes." At each stage of vocabulary formation, meaning is determined not simply by etymology but also by arbitrary extensions or limitations of semantic value.

Semantic structure of Indian languages

It is in the area of semantic structure that American Indian vocabulary is likely to present some surprises to the investigator. It is frequently observed that the immense diversity of the physical universe is reduced by every society to a manageable set of classifications embodied in its vocabulary. But there are few universals in such classification, and every language makes its unique semantic divisions. One language may make many specific discriminations in a particular area, while another is content with a few general terms; the difference is correlated with the importance of the semantic area for the particular society. Thus English is highly specific in classifying bovines (bull, cow, calf, heifer, steer, ox), even to the point of lacking a general cover term in the singular (what is the singular of cattle?), but for other species it has only cover terms like camel, llama. North American Indian vocabularies, as would be expected, embody semantic classifications that reflect native American environmental conditions and cultural traditions.

Interest in the semantic classifications of American Indian languages, especially in Hopi, has been particularly stimulated by the work of the American investigator, Benjamin Lee Whorf. When English discriminates "airplane," "aviator," and "flying insect," Hopi generalizes with a single term *masa'ytaka*, roughly "flier"; but when English uses a single general term, "water," Hopi differentiates *pāhe* "water in nature" from *kēyi* "water in a container."

The vocabularies of different languages may differ not only in the categorization of particular items but also in the general principles of semantic organization; such differences may be found even between neighbouring languages in a single culture area. English, for example, tends to exhaust the universe of flora and fauna with multilevelled hierarchical classifications such as "plant, bush, berry bush, gooseberry bush" or "animal, insect, louse, body louse," but the languages of northwestern California, by contrast, have relatively few generic terms and many vocabulary items that do not fall into any such hierarchy. The generic terms of Yurok refer, roughly, to "quadruped mammal," "fish," "snake," "bird," "tree," "bush," "grass," "flower," and "berry"; the organization in the neighbouring Tolowa language is simpler, lacking "quadruped mammal" and "fish." In such frameworks, a term like Yurok *wrrɣr* "body louse" cannot be subsumed in the larger classes of "louse" or "insect" because none exist. The placing of terms in semantic pigeonholes tends to be replaced, in these semantic systems, by identifying them in terms of similarity. A Yurok speaker, asked to identify a flowering bush for which he knows no name will describe it not as "a kind of bush," but as *sahsip seɣon* "similar to wild lilac." Such evidence suggests that the semantic structures of some American Indian vocabularies are based on classes defined less by their boundaries than by their centres.

Kinship terms

Another type of semantic structuring is illustrated by certain systems of kinship terms. In Fox, an Algonkian language, the term for maternal uncle also includes maternal grandmother's sister's son's son (a kind of second cousin). This can be accounted for by recognizing some very simple rules, rules that apply to the other terms of the kinship system as well: (1) siblings of the same sex, as linking relatives, are reckoned as equivalent; (2) a father's sister, as a linking relative, is equivalent to a sister, and conversely, a mother's brother's child is equivalent to a mother's brother. Then a mother's mother's sister's son's son, by rule 1, is equivalent to a mother's mother's son's son; but because one's mother's son is one's brother, this is the same as a mother's brother's son; and this in turn, by the converse of rule 2, is equivalent to a mother's brother. It is clear that the semantic systems of American Indian languages exhibit not only structures of hierarchy and similarity but also rules of semantic equivalence.

Language and culture. The exotic character of American Indian semantic structures, as manifested not only in their vocabularies but also in the relationships expressed by their morphological categories and syntactic patterns, has led a number of scholars to speculate on the relationships between language, culture, and habitual thought patterns or "world view." It was hypothesized that the unique organization of the universe that is embodied in each language might act as a determining factor in the individual's habits of perception and of thought, thus forming and maintaining particular tendencies in the associated nonlinguistic culture. As Edward Sapir put it,

> Human beings do not live in the objective world alone, . . . but are very much at the mercy of the particular language which has become the medium of expression for their society . . . The fact of the matter is that the "real world" is to a large extent unconsciously built up on the language habits of the group . . . We see and hear and otherwise experience very largely as we do because the language habits of our community predispose certain choices of interpretation.

The Whorfian hypothesis

This idea was further developed, largely on the basis of work with American Indian languages, by Sapir's student Benjamin Lee Whorf, and is now often known as the Whorfian hypothesis. Whorf's initial arguments focussed on the strikingly different organization of experience that can be found between English and Indian ways of saying "the same thing." From such linguistic differences, Whorf infers underlying differences in habits of thought. It then remains to show how these habits are manifested in nonlinguistic cultural behaviour. Thus, Whorf points out that, in Hopi, words referring to units of time (*e.g.*, "day") differ from other nouns in that they have no plural form; furthermore, they cannot be counted with the cardinal numerals ("one," "two," etc.) but only with the ordinals ("first," "second," etc.). From this he infers that when the English speaker speaks of "ten days," as if the days were an aggregate of separate units, the Hopi speaker, on the other hand, thinks in terms of the cyclic recurrence of a single phenomenon. Whorf attempts to support this idea by reference to Hopi ceremonial behaviour, which involves repeated preparation for future events. If, in the Hopi view, each day is really a recurrence, rather than something new, then it is reasonable to believe that the daily repetition of ceremonial acts will have a cumulative effect on the future. As Whorf says, the Hopi belief is diametrically opposed to the English proverb that "Tomorrow is another day."

More investigation is necessary to either prove or disprove the Whorfian hypothesis. In any case, the diversity of American Indian languages and cultures has continued to provide a rich laboratory for investigation. A particularly interesting problem is found in the area of northwestern California, where several small tribes have very similar cultures, but use languages of very diverse types. These are Karok, genetically classified as Hokan; Yurok and Wiyot, which are Algonkian; and Hupa and Tolowa, Athabascan languages. By the Whorfian hypothesis, one might expect that the difference in languages would have produced a greater diversity in the cultures; or failing that, one might expect the languages to have grown more similar to each other. In fact, both linguistic diversity and cultural uniformity seem to have made modest accommodations to each other. As an example of Whorfian linguistic determinism, the systems of biological taxonomy of Yurok and Tolowa, referred to in the previous section, may be noted. The Yurok have a larger number of generic classifications, which means they have more choice in nomenclature, because either a generic or a specific term can be used. This is consistent with the high degree of choice afforded in Yurok grammar, in which word order is nearly free and many morphological categories are optional. The sparser taxonomy of Tolowa offers less

choice, corresponding to a much more rigid grammatical structure.

Language, culture, and prehistory

A different kind of relationship between language and culture is of more interest to the student of North American prehistory, namely, the fact that language retains traces of historical changes in culture and so aids in reconstructing the remote past. Here again the pioneering work was done by Sapir, who pointed out, for instance, that the original home from which a group of related languages or dialects has dispersed is more likely to be found in the area of great linguistic diversity; *e.g.*, there are much greater differences in the English dialects of the British Isles than of the more recently settled areas such as North America or Australia. To take an American Indian example, the Athabascan languages are now found in the Southwest (Navajo, Apache), on the Pacific Coast (Tolowa, Hupa), and in the Western Subarctic. The greater diversity of the Subarctic languages leads to the hypothesis that the original centre of Athabascan migration was from that area. This northern origin of the Athabascans was further confirmed in a classic study by Sapir in which he reconstructed parts of prehistoric Athabascan vocabulary, showing, for example, how a word for "horn" had come to mean "spoon" as the ancestors of the Navajo migrated from the far north (where they made spoons of deerhorns) into the Southwest (where they made spoons out of gourds). The correlation of such linguistic findings with the data of archaeology holds great promise for the study of American Indian prehistory.

Writing and texts. Although a writing system was in use among the Mayas of Meso-America at the time of first European contact, none was known in North America. All writing systems that have been used for North American Indian languages have resulted from the stimulus of European writing, or have actually been invented and introduced by whites. Perhaps the most famous system is that invented by Sequoyah, a Cherokee, for his native language. It is not an alphabet but a syllabary, in which each symbol typically stands for a consonant–vowel sequence. The forms of characters were derived in part from the English writing system, but without regard to their English pronunciation. Well suited to the language, the syllabary fostered widespread literacy among the Cherokee until their society was disrupted by government action; its use, however, has never died out, and attempts are now being made to revive it.

Other writing systems, invented by missionaries, teachers, and linguists, have also included syllabaries; *e.g.*, for Cree, Winnebago, and some northern Athabascan languages. Elsewhere, alphabetic scripts have been used, adapted from the Roman alphabet by the use of additional letters and diacritics. White educational policy, however, has generally not encouraged literacy in Indian languages. A rich oral literature of American Indian myths, tales, and song texts has been in part published by linguists and anthropologists, and there is now increasing encouragement for the training of Indians to transcribe their own traditions—*e.g.*, among the Navajo. It is possible that there may yet be a flowering of American Indian literature, not only in spoken but also in written form.

(W.O.B.)

North American Peoples and Cultures

The American Indians had their origins in Asia and are basically Mongoloid in physical type. The New World may be dismissed as the home of early hominid development because no fossil progenitors of modern man have been found and the evolution of the Primates clearly occurred in the Old World. The date of first arrival in North America as yet has not been accurately established, but it is assumed to have occurred sometime during the last glacial period, about 20,000 to 35,000 years ago (though some authorities have recently argued for an even earlier date, some 50,000 years ago or more). By the time that Europeans arrived in the 15th century, the descendants of these and later waves of migrants had spread over the Americas and developed cultures adjusted to various ecological conditions.

Comparison of New and Old World traits

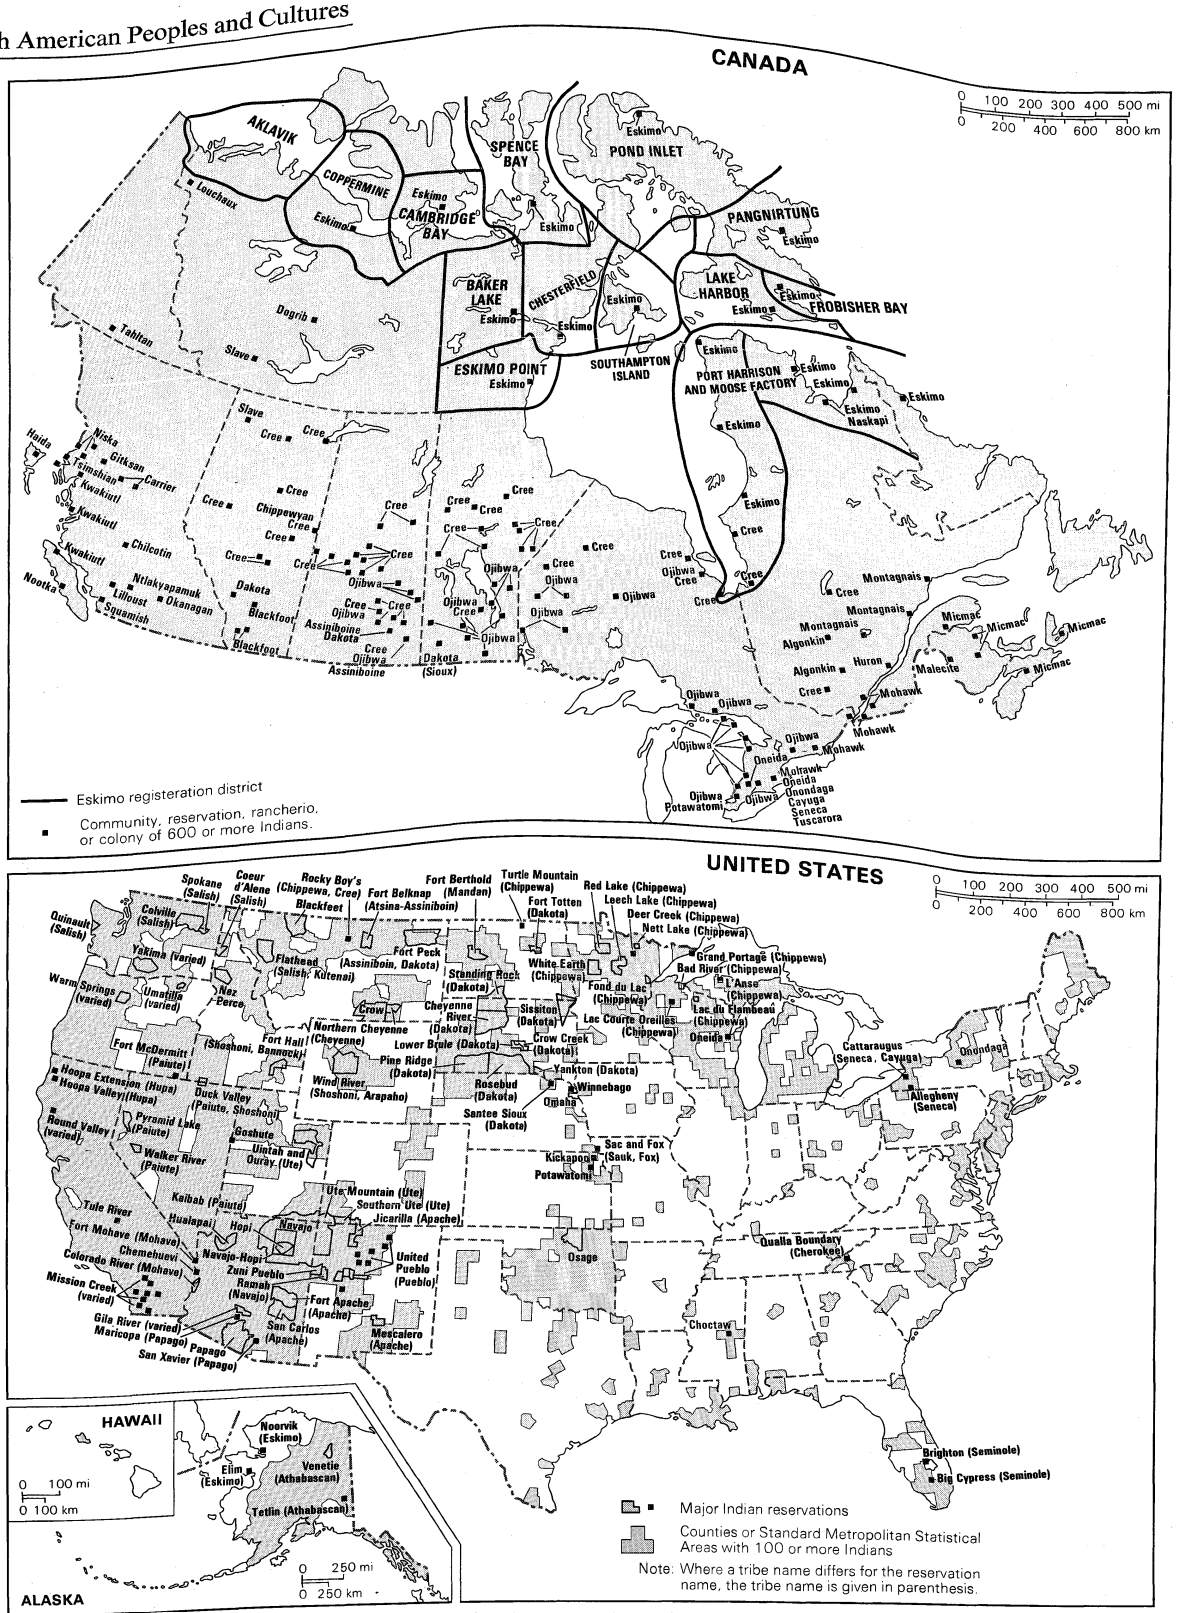
The waves of Asian incomers to the New World possessed a series of traits that were relatively ancient and were shared with most cultural groups in the Old World. These included the use of fire and the fire drill; the domesticated dog; stone implements of many kinds; the spear thrower, harpoon, and simple bow; cordage, netting, and basketry; various rites and healing beliefs and practices. Important traits lacking in the New World but known in the Old World included various significant domesticated animals, plants, and artifacts—including cattle, sheep, goats, pigs, horses, camels, and reindeer; wheat, barley, and rice; the wheel and the plow; iron; and stringed instruments. Most New World cultures depended on hunting and gathering, but the economic base of the American higher cultures came to be horticulture, with maize, beans, and squash as the staple crops. These crops were cultivated from the St. Lawrence River, in the north, to the Río de la Plata, in South America. The plants were tended by hand, using only a simple digging stick or a hoe.

The North American continent into which the Asian migrants descended is divided roughly into three major physiographic landforms: the high Cordilleras in the west, the relatively lower Appalachian Highlands and Piedmont in the east, and, between them, the Great Plains, which spearhead from the Arctic Ocean to the Gulf of Mexico in a great triangle. The Western Cordilleras are a series of parallel north–south ranges cutting from Alaska to Central America; in the area of Canada and the United States they enclose, from north to south, a large plateau of grasslands and forests, an even broader, arid plateau known as the Great Basin, and a desert plain and range area of Arizona and New Mexico (as well as northwestern Mexico). The Cordilleras along the Pacific Coast separate a plethora of basins and plateaus from the coastlands. The central Great Plains, in the extreme north, consists of Subarctic land that is swampy and coniferous and similar to the taiga and tundra of Siberia; to the south, the great Mississippi drainage system divides the relatively drier high plains to the west from the low, well-watered prairies and rolling hills to the east. The Appalachian Highlands and Piedmont contain, to the north, the great eastern woodlands and, to the south, a series of highlands and foothills descending to lowlands on the coast of the Atlantic and the Gulf of Mexico.

THE PEOPLE

Mongoloid characteristics of American Indians

Physical types. Although American Indians are fundamentally Mongoloid, considerable variation is found. The generally uniform physical features are these: the hair is usually straight, coarse, and uniformly black; the skin is reddish brown, the eyes dark, and the body hair scant; the cheekbones are prominent; and the facial size is generally large. Such features as cephalic index, nasal form, and stature, however, are extremely variable.



Distribution of North American peoples and cultures (top) in Canada and (bottom) in the United States.

The uniform features are definitely Mongoloid; the variable features are more difficult to assess. Some scholars believe that the early migrant populations were essentially Mongoloid and that the variations came about through adjustment to American environments. Other scholars argue that the New World was peopled by a variety of physical types, with later mixtures but some marginal survival in isolated regions.

Archaeologically, the earlier populations were generally long headed (dolichocephalic) and showed fewer Mongoloid characteristics. These early peoples were slight in build with well-developed brow ridges, and many represent either a proto-Mongoloid type or an unspecialized early Caucasoid form related to the Ainu of Japan.

The distribution of blood groups among the American Indians may eventually aid in solving the problem of their origins. Thus, blood type B is generally absent in the aboriginal population of the Americas (though its inci-

dence is high among Asian Mongoloids), and type A is found mainly in North American Indians.

Modern genetic theory would explain much of the variation found in terms of such factors as mutation, selection, admixture, and random genetic drift. In the small-scale groups involved in the early peopling of the New World, relatively rapid changes were possible and could account for all of the variation found.

Population and languages. Estimates of the aboriginal population are based on information supplied by explorers, traders, missionaries, and other early reporters and are only as good as the reporters' observations were trustworthy. A more serious impediment to an accurate count is that some tribes, by the time they were visited, had already been depopulated by European diseases and weapons. The estimates in the Table, it should be noted, are given an approximate dating.

The American anthropologist Alfred Louis Kroeber submitted a population total for the area north of Mexico almost identical to that given in the Table, since he used the same figures except for California. He subgrouped the material, however, to accord with subsistence areas rather than geographical boundaries. In addition, he ranked the areas according to population densities, expressed in numbers of persons per square kilometre: California area, 43.40; northwest Pacific Coast, 28.30; southwestern United States, 10.70; Columbia–Fraser river area, 7.15; eastern area, 6.95; Arctic coast, 4.02; Great Basin, 2.47; and northern area, 1.35. Although agricultural areas of the east and southwest contained the greater population (about 405,000 in all), Kroeber believed that the predominantly fishing economy of the Pacific Coast (Bering Strait to southern California) had greater relative density of population. His estimates were Pacific Coast, 25.2 persons per square kilometre; agricultural areas, 10.1; remaining area north of Mexico, 2.2.

The population of a little over 1,000,000 for North America north of Mexico contrasts with the estimated 5,000,000 for Mexico and Central America and with the estimated 25,000,000 for the Western Hemisphere as a whole. (These uncertifiable estimates must, however, be approached with caution.)

Aboriginal Indian Population North of Mexico

	date	estimated population
North Atlantic		
New England, New York, New Jersey, Pennsylvania	1600	55,600
South Atlantic		
Delaware, Maryland, Virginia, West Virginia, the Carolinas, except Cherokee country	1600	52,200
Gulf States		
Georgia, Florida, Alabama, Mississippi, Louisiana, Arkansas, Tennessee, Cherokee country	1650	114,400
Central States		
Ohio valley from Alleghenies to Mississippi, Chippewa in Canada	1650	75,300
The Plains (Canada to Gulf)		
Northern	1780	100,800
Southern	1690	41,000
Columbia River basin		
Washington, most of Oregon, northern half of Idaho	1780	89,300
California	1769	260,000
Central mountain		
Nevada, Utah, parts of surrounding states	1845	19,300
New Mexico and Arizona	1680	72,000
Subtotal United States (except Alaska)*		849,000

The outstanding characteristic of American Indian languages is their diversity. There were more than 60 language families in North America, comprising over 500 languages, but these have been reduced to a smaller number of superstocks by modern linguists. The American linguist and anthropologist Edward Sapir, for instance, proposed six linguistic groups for North America (including the Arctic): Eskimo-Aleut, Algonkian-Wakashan, Na-Dené, Penutian, Hokan-Siouan, and Aztec-Tanoan (see NORTH AMERICAN INDIAN LANGUAGES). No American language has any genetic relationship to any language group in the Old World that has yet been fully demonstrated. It may be concluded from this that the ancestors of the Indians left the Old World so long ago that any relationship was lost through linguistic change.

Diversity of languages

Culture areas. At the time of European contact there were perhaps as many as 240 different tribal entities in North America. Groups of these tribes, however, have been classified by anthropologists into a more convenient limited number of culture areas, determined very much by physiographic or environmental differences: the Subarctic, the Northwest Coast, California, the western Plateau, the western Great Basin, the Southwest, the Plains, the Eastern Woodlands, and the Southeast. This article, in dealing with the major culture areas of North America, excludes the Arctic Eskimo and Aleuts (see ARCTIC PEOPLES AND CULTURES) and the peoples of Mexico and other parts of Middle America (see MIDDLE AMERICAN PEOPLES AND CULTURES).

Subarctic. The population of the American Subarctic was always relatively small, given the vast area from Alaska to Labrador. The various tribes—Algonkian speakers in the east and Athabascan speakers in the west—were hunters, fishers, and gatherers of wild plant foods; and social organization tended to be simple and territorially very limited. The largest cohesive group tended to be a small kinship group or no more than a band or village of related families (see AMERICAN SUBARCTIC CULTURES).

Northwest Coast. The peoples of the Northwest Pacific Coast depended for their livelihood almost entirely on salmon, supplemented by other fish, sea mammals, shellfish, birds, and some food plants; they also took advantage of the woods of the forests for constructing homes and canoes and developed the use of bark fibres and mountain-goat wool to make clothing and blankets. So rich were their resources and so intensively were the resources exploited that the density of population, as calculated by Kroeber, was greater on the Northwest Coast than in most places in North America north of Mexico. Although social organization centred on the village rather than a larger tribe, it tended to be fairly sophisticated and highly stratified (see NORTHWEST COAST INDIANS).

Importance of fishing

California. From very early times until European contact, California was marked by a great complexity of tribal groups and languages. In some instances a group of not more than 500 individuals, speaking a distinct language, would live near another group of similar size that spoke a different language, and neither seemed to impinge on the other. The diversity is partly attributable to the complex of mountains and valleys and coastlands. In spite of the great complexity of linguistic and demographic factors, however, the California culture area presented no striking deviations. Agriculture was not practiced except along the Colorado River, since throughout the vast central portion and southward along the coast a method of leaching acorn pulp and converting it into flour supplied abundant and constant food. Elsewhere, fishing and hunting were equally productive (see CALIFORNIAN INDIANS).

Plateau. The northern plateau area, bounded by the Rocky Mountains and the Coast and Cascade ranges, was a land of vast rolling treeless areas, dense forests, and snow-covered mountains. Because the area is drained largely by two great river systems, the Fraser and the Columbia, most of the peoples of the area depended primarily on fishing for salmon, though other fish, game, and wild plants were also taken. Although the material accomplishments of the Plateau Indians were modest, their political achievements were sometimes impressive.

The primary political unit was the village, but a sense of larger tribal and cultural unities led sometimes to representative government, with village hierarchies, tribal chieftainships, and even confederations (see NORTH AMERICAN PLATEAU INDIANS).

Great Basin. The Great Basin, a large area centering on Nevada and Utah, though perhaps fertile during and just after the great Ice Age, became arid and impoverished in modern times. Before European contact, the Shoshonean-speaking inhabitants were divided into loosely affiliated family units that subsisted on wild seeds, small mammals, and insects. Each family was independently nomadic during most of the year and joined other families only briefly for certain hunts or dancing. Some groups acquired horses in the 18th and early 19th centuries, however, and formed bands of mounted hunters and warriors and adopted many cultural characteristics of the Plains Indians (see NORTH AMERICAN GREAT BASIN INDIANS).

Southwest. The Southwest, centering on Arizona and New Mexico, but including parts of Utah, Colorado, Texas, and Mexico, has been the site of a number of agricultural and hunting and gathering peoples. Best known are the Pueblo Indians, from the Zuni and Hopi on the west to the Rio Grande groups on the east, who built architecturally remarkable multiple apartment houses of adobe and stone masonry and developed to a high state agriculture, arts, and crafts. Their ancestors occupied the Southwest thousands of years ago, and their high cultural development began in the 1st millennium AD with the arrival of influences from Mexico. Two other major groups, the Athabascan-speaking Navajo and the Apache, undoubtedly came from the far Canadian north and probably did not initially reach the Southwest until AD 1000 or later. The Navajo borrowed extensively from the Pueblo Indians—agriculture, weaving, and arts—but the Apache remained basically hunters and gatherers; only a few groups engaged in supplementary cultivation of corn and other vegetables (see SOUTHWEST AMERICAN INDIANS).

Plains. Until the late 16th century the Great Plains were occupied only sparsely or intermittently. Toward the year 1600, however, Spanish horses were introduced and spread northward from the region of New Mexico, reaching almost the entire Plains area by 1750. Horses revolutionized the hunting of bison, making it much more profitable, and not only improved the conditions of resident peoples but also seem to have drawn peoples from surrounding areas into the plains to develop a new way of life. Thus, most tribes thought by Europeans to be typical nomadic horse Indians—such as the Cheyenne, Arapaho, and Dakota (Sioux)—were newcomers to the area and had been farmers and village dwellers not many generations before their first European contacts. In any event, the Plains Indians, with their bands organized into assemblages of tribes, their buffalo hunts and tepee villages, and their elaboration of warfare and raiding (much facilitated by the horse), became the tribes of North America often regarded now as "typical" American Indians (see NORTH AMERICAN PLAINS INDIANS).

Revolution of the horse

Eastern Woodlands. The peoples of the eastern woodlands, largely Iroquoian and Algonkian speakers, were semi-sedentary, living in villages and cultivating maize, beans, and squash. The forests provided much of their material cultures—their wigwams and longhouses made of coverings of bark sheets, their dugout and bark canoes, and their clothing made of wild animal skins—and added game and fish to their diet. A village band of a few hundred persons was the social and economic unit, though several bands might be loosely organized into tribes. The honour of warfare was engrained in most of the Eastern Woodlands Indians (see EASTERN WOODLANDS INDIANS).

Southeast. The southeastern Indians, most of them Muskogean speakers, were primarily agricultural, planting maize, pumpkins, beans, cane millet, tobacco, and other crops; they also gathered wild nuts and fruits and hunted deer or, in the west, bison. Their settlements were straggling; the "town" contained a square, on which were public and religious buildings; "villages" were often outlying. The towns were autonomous and essentially constituted tribes. They might unite into confederacies, such as those of the Creek and Choctaw, directed by councils; such confederacies might break up and recombine. In contrast to the fairly well organized political institutions, economic life was rather unsophisticated; there was little property, almost no stored wealth, and limited trade before the coming of Europeans (see SOUTHEAST AMERICAN INDIANS).

PREHISTORY

The earliest records of the peopling of North America are scanty, and it is difficult to characterize their culture beyond calling it a hunting and gathering economy. The first settlers seem to have crossed the Bering Straits region from Asia during the expansion of the glacial sheets of the Ice Age (or Pleistocene Epoch). As the great ice sheets developed and expanded, they not only covered major land areas in the Northern Hemisphere but also brought considerable areas of the continental shelves above sea level. In the Arctic this provided a tundra coastal plain across which man could move from Asia to North America. The amount of the Earth's moisture incorporated into the ice probably lowered the sea level hundreds of feet. Asia and America were thus not separated by the gradual rise of the sea until about 9,000 or 10,000 years ago; likely sites of the earliest migrants are now below sea level.

Early migrations from Asia

The Americas were the last major land mass, with the possible exception of Australia, to be occupied by prehistoric man, who first had to develop the cultural equipment to exist in the Arctic area. Once this adjustment was made, he was able to move by way of ice-free, open-land routes into the Mackenzie Basin and down into central North America. In addition to the Mackenzie route southward, at a later time the Yukon River valley also offered an ice-free route, and still later (8,000–10,000 years ago) the Liard and Peace river systems were available for intromontane travel. The Pacific Coast slope was probably available for travel at about the same time. Some migrations may also have occurred by way of the Aleutian Islands, but this would have taken place at a considerably later date.

Early Cultures. The earliest well-defined cultures in the New World have been placed by radiocarbon dating at about 10,000 to 8000 BC. At this period, two distinct traditions in North America are known: the Paleo-Indian big-game hunters of the West, the Great Plains, and eastern North America; and the Desert culture peoples of the western Basin–Range region.

Paleo-Indian hunting cultures. In spite of regional differences in detail, there was a remarkable similarity in the economic complex of the hunters. They lived in a variety of environments, from mountain passes and valleys in the west to the then better watered grasslands of the Plains and the varied forest and park-land environment of the eastern woodlands. The variety of their bone tools indicates that one of their major food supplies came from animals, the hides of which provided clothing. In the western Plains and the Southwest they hunted such extinct North American animals as the camel, ground sloth, tapir, mammoth, and horse.

In the Great Lakes area of the eastern woodlands they may have hunted mastodon, but other commoner animals, such as the elk and deer, presumably formed the bulk of their meat diet. Some of their bone and wooden tools were probably used for working and ornamentation. These early hunters had temporary shelters and moved about as small bands in search of game. Their physical type is not clearly known, but it was related to that of an eastern Asian Early Stone Age population and is less Mongoloid than many groups of American Indians of the historic period.

Archaeologically, the oldest remains of the Paleo-Indian tradition are found on kill sites, where large Pleistocene mammals were killed and butchered. The most distinctive artifact type of this horizon is the Clovis Fluted projectile point (named after the site of first discovery, near Clovis, New Mexico); this was a lance-shaped point

Oldest archaeological remains

of chipped stone that had had one or more longitudinal flakes struck from the base of each flat face. These points are accompanied by side scrapers and, in one instance, by long cylindrical shafts of ivory. They are most frequently associated with mammoth. A second Paleo-Indian horizon, which seems in part to be contemporary with the Clovis material and partially to postdate it, is the Folsom phase of the central High Plains (Folsom, New Mexico, being the site of initial discovery). It is characterized by lance-shaped points of more careful manufacture (including broader fluted surfaces) than Clovis, associated with the remains of extinct *Bison antiquus*. The Lindenmeier site, a Folsom campsite in northeastern Colorado, has yielded a wide variety of end and side scrapers, gravers, and miscellaneous bone artifacts. Clovis sites have been dated at about 9000 BC and Folsom sites at about 500 to 1,000 years later.

The Desert culture. In the western United States, from Oregon to northern Mexico and from the Pacific coast to the eastern foothills of the Rocky Mountains, there was a distinctive cultural adaptation to the dry, relatively impoverished upland environment. There, in the relative absence of large game resources, vegetation was exploited to a great extent, with the development of grinding tools and related equipment. The Cochise Desert culture (named from Cochise County in southern Arizona, where it was discovered) ran from about 8000 BC through several stages, down to the historic period in some areas.

Development of seed milling

The Desert culture people lived as small bands of wandering seasonal food gatherers, collectors, and hunters. They ate a wide variety of animal and plant foods and developed techniques for small-seed harvesting and processing; an essential feature of Desert assemblages was the milling stone, for use in grinding wild seeds. Their best known habitations were caves and rock shelters, and they had twined basketry, nets, mats, cordage, fur cloaks, sandals, wooden clubs, and digging sticks. They also had the spear thrower, with darts of pointed hardwood or with points of flint and later of obsidian. Their rough stone implements were shaped by percussion, and consequently many of their choppers and scrapers had an Earlier Stone Age appearance. Their projectile points, however, showed excellent craftsmanship and followed continent-wide styles. The domesticated dog, another migrant from Asia, was known by about 4000 BC in the Desert culture (though by this time the dog was also known elsewhere in North America).

The far west. On the far west coast in California, the marked variety of geographical situations developed a number of regional complexes dependent upon intensive exploitation of the local resources. None of these was agricultural. In the southern desert area the people subsisted upon plant seeds and small game and used crude flint tools, grinding stones, and (later) arrowheads. In the mountainous areas and in the better watered central areas, larger game animals such as the elk and deer, supplemented by acorns, fish, and birds, were the major food supply. By at least 2000 BC, in this central area, the utilization of the local resources plus cultural intrusions from the north resulted in full adaptation to the area. The coastal groups from north to south depended upon the sea for their food supply, some subsisting mainly on shellfish, some on sea mammals, others on fish, and still others on a mixture of all three.

In the north Pacific part of the United States and in western British Columbia, some of the early sites of the hunters have yielded fluted blades, crude choppers, and cutting tools. Between 9000 and 7000 BC there were varied economic activities but with an emphasis on hunting. By about 8000 BC there was a strong orientation toward salmon fishing, particularly during the salmon runs, and the peoples tended to emphasize the use of bone and antler tools. The burin, a chisel-like bone working tool, has been found in such sites, along with prepared cores and blades. During the postglacial warming period that culminated between 3000 and 2000 BC, the inhabitants of the drier areas without permanent streams took on more of the traits of the Desert culture to the south, while others turned toward riverine fishing and marsh resources or to food from the sea. In the 1st millennium BC, the so-called Marpole complex, a distinctive ground slate complex, was known in the Fraser River area, with basic resemblances to the northwest coast historic culture in maritime emphasis, woodworking, large houses, and substantial villages. The emphasis on ground slate and woodworking tools is like that in the Eastern Woodlands Archaic (see below) and recalls similar emphasis in certain northwestern Siberian cultures. In most of the areas of the Northwest Coast, clear indications of the beginnings of the historic cultures were not known until about AD 1300.

The Archaic cultures. *The Eastern Archaic.* With the retreat of the ice sheets in the north, beginning about 10,000 years ago, the cool, moist climate gradually became hot and dry in the Great Plains and Great Basin regions, with consequent extinction or migration of Pleistocene animal life. The High Plains were largely deserted by man for a considerable period. In the eastern woodlands area, partly as a result of the variety of forest environments, climatic differences, and physiographic features, there developed a series of regional readaptations to local food supplies. The change from the primarily hunting economy of the early American hunters was gradual and is clearly seen in slowly evolving projectile point and other implement changes. The pattern of life became one of mixed hunting and collecting, with some groups developing by 6000 BC a taste for riverine and coastal living with abundant fish and mollusk resources to supplement such vegetational products as acorns, seeds, berries, and tubers.

Change from hunting economy

During the long Eastern Archaic, from 8000 to 1500 BC, regional social and economic diversification was developed, and it was during the Archaic that significant early linguistic differentiation also probably occurred and during which varieties of physical types developed.

The typical Archaic house was a small circular structure with wooden posts for the wall and roof supports; the covering was probably bark. Cooking was done in the open by boiling in containers of wood, bark, or hides or by baking in pits or by roasting and grilling. Identification lists of mammal, fish, and bird bones from Archaic sites read like a listing of the early historic fauna. Various game-gathering devices, including nets, traps, and pitfalls, were used along with the spear and dart thrower. Fishhooks, gorges, and net sinkers were known, and in some areas fish weirs were built. River, lake, and ocean mollusks were consumed, and probably a great many native roots, berries, fruits, and tubers known in the early historic period were incorporated into the diet during the Archaic. The extensive lists of plant medicines recorded by the early colonists were probably a part of the primitive Archaic pharmacopoeia.

The large variety of chipped-flint projectiles, knives, scrapers, perforators, drills, and adzes reflect regional styles and changes during the long Archaic period. The late Archaic was distinguished by the gradual development of ground and polished, grooved stone axes, pestles, gouges, adzes, plummets, and forms attached to the spear thrower. This was a reflection of a growing versatility in the technology and economy. Trade and exchange are also known from the distribution of native copper implements from the Michigan–Wisconsin area to as far south as Louisiana and Florida and the finds of southeastern marine shells as far north as the upper Mississippi–Great Lakes area. An extensive system of trails and water routes was probably in existence during the Late Archaic.

Developing trade and technology

The great boreal forest zone of spruce, fir, and pine that now runs from New England and the maritime provinces of Canada westward to the Canadian plains and the Mackenzie Valley gradually acquired its present distribution following the retreat and melting of the Arctic ice cap. Its present distribution was reached by about 2500 BC. The forest cover and climate had a limiting effect on the cultural development and on the general pattern of hunting and fishing. These efforts were supplemented by some use of plant material.

In the upper Great Lakes area there was an Old Copper

culture, which has special interest because copper implements and weapons were made from the native copper of the Lake Superior basin. This culture appeared about 3000 BC and lasted about 2,000 years. It was a northern expression of the Late Archaic. Its tools and weapons, particularly in the adzes, gouges, and axes, clearly indicate an adaptation to the forest environment. In the area south of James Bay to the upper St. Lawrence about 2000 BC, there was a regional variant called the Laurentian Boreal Archaic and, in the extreme east, the Maritime Boreal Archaic. In this eastern area, slate was shaped into points and knives of forms similar to those of the copper implements to the west. Trade between the eastern and western areas has been recognized, and this evidence, along with general similarities of the culture, suggests that water transportation by canoe was known at this time.

Along the southern border of the central and eastern boreal forest zone between 1500 and 500 BC, there developed a distinctive burial complex, reflecting an increased attention to burial ceremonialism. These burials, many including cremations, were often accompanied by red ochre, caches of triangular blanks, fire-making kits of iron pyrites and flint strikers, copper needles and awls, and polished stone forms. The triangular points of this complex may have represented the introduction of the bow and arrow from the pre-Eskimo cultures east of Hudson Bay. The earliest Woodland pottery appeared in the Great Lakes area about 1000 BC. It is another of the culture traits derived from northeastern Asia and across northern Alaska to northwestern Canada. The route by which it reached the Great Lakes is not known.

The Plains Archaic. In the western Plains from about 8000 to 3000 BC the fluted blade points were no longer made, and many styles or types were produced that have been identified by such local names as Plainview, Angostura, Milnesand, Agate Basin, and Scottsbluff. These minor varieties of dart and spear point and their primarily hunting culture may be included in the term Plano. The Plano complex or culture type was a direct descendant from the fluted-blade early American hunters. Their primary game animal was the bison, for the larger animals of the preceding period had died out or were exterminated.

Plano culture

The stone complex associated with the Plano hunters was markedly similar from site to site over a considerable period of time during which the climate became increasingly warmer and until the major warm period was reached, about 3000 to 2000 BC. As the climate moderated, peoples of the Late Plano complex moved north into Saskatchewan and Alberta with the grazing game animals and, by 3000 BC, had reached the Arctic tundra zone in the Northwest Territories of Canada at Grant and Dismal lakes and Great Bear River. Important elements of this culture also moved east in the Mississippi valley and western Great Lakes area. Many of the sites of this culture type were kill sites with abundant bison bones that accounted for the number of implements and tools associated with hunting and leatherworking. In the tundra zone the major game animal was the caribou. Choppers, pounders, and milling stones have been found there.

Early agriculturalists. *Early southwestern planters.* Primitive agricultural practices began in Mexico by 6000 to 4000 BC and by approximately 2000 BC were known on the northern fringe of the Middle American culture area. Maize was not the only crop plant, for gourds, squash, peppers, cotton, and varieties of beans were also domesticated. Maize was grown in the southwestern United States by 2000 to 1000 BC, but most of the other domesticates did not arrive until just before and after AD 1. The early introduction of maize in the Southwest had no marked effect on cultural development, and the existence of pottery, storage pits, and domestic houses with semi-subterranean floors and lateral entryways were not known until about AD 1. These houses had wood uprights for walls, central roof supports, radiating beams, and wattle-and-daub plastered walls. The small settlements of the early Puebloan, or Basket Maker, people of the Four Corners area (namely northwestern New Mexico, southwestern Colorado, southeastern Utah, and northeastern Arizona) were among the first village agricultural societies in the Southwest.

Ohio Valley farmers. In eastern North America one of the earliest known phases in which corn cultivation appears to have had a role in subsistence is the Adena, which occupied the middle Ohio River Valley by about 800 BC (Adena takes its name from an estate near Chillicothe, Ohio, the site of a discovered burial mound). The stimulus of the Adena farmers was apparently instrumental in bringing about the spectacular Hopewell culture in the Illinois and Ohio valleys. (Hopewell is similarly named after a farmsite in Ohio). The success of the Hopewell peoples (200 BC to AD 200) seems to have been due largely to their combining elements of the preceding Archaic cultures with elements of the Adena culture and perhaps with some features of a local cultivating tradition. It is evident that the Hopewell culture included a well-organized village-based society in which surplus resources were used in the construction of elaborate earthworks and were concentrated as wealth by a restricted group of individuals. The most outstanding feature of Hopewell culture is a burial complex that called for the deposition of concentrations of wealth in tombs of one or several deceased individuals. The interment procedure was elaborate and involved the construction of a large log tomb, later burned and covered by an earth mound. Artifacts found within these burial mounds indicate that the Hopewell were able to obtain goods from widespread localities in North America. Obsidian and grizzly bear teeth were apparently derived from the Rocky Mountain region; copper from the northern Great Lakes; and conch shells and other exotic objects from the southeast and along the coast of the Gulf of Mexico. Ohio, particularly, served as a distributing centre for ceremonial goods and special products over a wide area in the eastern United States. The ceramics of the Hopewell appear to be based in two major traditions: one derived from northern Asia, which reached eastern North America by about 1000 BC, and the other from Middle America, where certain decorative techniques, characteristic of finger Hopewell pottery, existed several hundred years prior to the earliest appearance of the Hopewell culture. In less favourable areas of eastern North America, a "generalized Woodland" culture paralleled the Hopewell in time, probably based more on collecting than on cultivation for subsistence.

Adena and Hopewell cultures

There is a clear evidence of cultural regression between AD 200 and 700 in the north central United States following the Hopewell expansion and florescence. This is attributed to a minor cold phase that did not allow a continuation of agriculture in this area under the techniques then current. Although there was concurrent change in the south, this did not take the form of a lowering of the cultural level.

Mississippi Valley and peripheral woodlands. The last major cultural development in the eastern United States is called Mississippian because its primary centre was in the valleys of the Mississippi River and its major tributaries and in the southeast. This predominantly agricultural complex was a marked cultural advance over earlier stages in the east. Its initial growth and expansion was at approximately the same period (AD 700–1200) as that of the southwestern Puebloan complex. The initial growth was along the Mississippi between modern St. Louis and Vicksburg. It was stimulated by the introduction of concepts, religious practices, and improved agricultural procedures from northern Mexico, which resulted in a sedentary societal organization. By AD 1000, large villages were in existence with subsidiary villages and farming communities nearby. Regional specialized production in pottery, projectile points, house types, and other utilitarian products reflected the tribal groupings of the period. An outstanding feature of this culture type was the earthen temple mound, which served as a raised platform on which the major community buildings were placed. These council houses and temples served as the political and ceremonial centres. The platform mounds were placed on the sides of a central plaza that served as a ceremonial

The Mississippian culture complex

centre for the tribal community during important recurrent functions or during times of crisis. The more permanent buildings, both family and community, were of wattle-and-daub construction, usually rectangular in floor plan. In some areas large, circular charnel houses received the remains of the dead, but burial was normally made in large cemeteries or in the floors of dwellings. The size of the ceremonial tribal centres varied from 10 to 100 acres (four to 40 hectares). Important household industries involved the production of mats, baskets, clothing, and a variety of vessel forms for specialized uses. Food surplus was kept in ground storage pits and in storage cribs above the ground.

One of the more striking developments was the production of ceremonial costumes and ornaments, for use in the religious ceremonies that were conducted by an organized priesthood with a well-established ritual. The religious symbolism spread throughout the Mississippian complex, and a number of centres of production of specialized ceremonial items are known. Other innovations were walled fortifications with timber palisades and bastions surrounding the village, which reflected an increase in intergroup aggression and a tendency, continuing into the historic period, toward the development of confederacies. The intergroup conflicts apparently were primarily quests for prestige and revenge instead of a means of territorial expansion or economic control.

Spread of Woodland culture

Along the eastern and northern periphery, some tribes, while retaining the older Woodland complex, were somewhat influenced by the Mississippian culture. The extent of this influence seems to have depended on their nearness to the more advanced cultural complex and on their ability to maintain an agricultural economy along with hunting and gathering. There was a spread of Woodland culture from about 200 BC to AD 200 into the eastern part of the Plains from Oklahoma to North Dakota, with some sites, particularly in eastern Kansas, clearly forming a part of the Hopewellian complex. In the Plains there was evidence of corn and bean cultivation during this period, and later there was cultivation of gourds and squash, but between about AD 300–400 and 800 there was little occupation of the western part of the Plains by agricultural people because of the relative aridity.

After 800, however, Late Woodland populations had spread west to the eastern slopes of the Rockies and were in contact with eastward-moving Puebloan people. A favourable agricultural period was indicated by the marked increase in village size and in population density for the next 400 years, during which hospitable areas along major streams were occupied by various interrelated cultural groups collectively known as the Plains Mississippian cultures. Part of this complex was connected to the developing Mississippi complexes to the east by diffusion and, to some degree, by a migration of such groups as the Omaha and Ponca from the St. Louis area by about AD 1000.

Between AD 1500 and 1700 the High Plains from New Mexico to Wyoming and in eastern Oklahoma, Kansas, and Nebraska were pre-empted by horse-using, semi-agricultural peoples of the plains—the Apache and Comanche. Prehistoric village agriculturalists of a plains Mississippi tradition came into the historic period as the Pawnee, Arikara, Mandan, Hidatsa, Crow, and Wichita.

Southwestern village farmers. *Anasazi, Mogollon, and Hohokam cultures.* The southwestern village farmers were distributed from eastern Utah and southern Colorado through most of New Mexico and Arizona. The effective agricultural area varied with fluctuations in climate that profoundly affected the ability of the Indians

Pre-Pueblo cultures

to occupy marginal regions. Although corn and some other agricultural plants were introduced from Mexico between 2000 BC and AD 1, the first village complexes, with five to 15 pit or surface houses, ceremonial buildings, refuse pits, and pottery, did not appear until shortly before AD 1 in southern Arizona and New Mexico. Two of the major farming complexes began at this time: Mogollon was located in the mountainous belt of west central New Mexico and east central Arizona, while Hohokam was located in the desert area of the Gila basin of southern Arizona. The latter group depended upon irrigation for its crops, whereas Mogollon depended upon rainfall and stream diversion over floodplains. Mogollon became the pattern of agriculture that later was developed in the Anasazi or Puebloan culture, the third major farming complex of the Southwest.

The geographical expansion, population growth, and striking development of permanent villages with multiroom and multilevel buildings came during the period from AD 700 to 1200, which coincided with a minor climatic period of favourable distribution of rainfall for plant growth over the entire Southwest. For the same climatic reasons, there was an expansion of population and cultural movement from central and western Mexico into northwestern Mexico. Trade and cultural stimuli then moved from northwestern Mexico into the American Southwest at a time when the climate in both areas was most favourable for population and cultural growth. Indicating such cultural movement, cast copper bells, parrots, ball courts, shell trumpets, and pottery vessel shapes and designs have been found; they clearly reflect the transmission of religious beliefs and ceremonies. These southern influences were blended into local and regional complexes.

The Anasazi village agricultural complex had expanded by AD 900 to occupy northeastern Arizona, southwestern Colorado, and northwestern New Mexico. By AD 1100, expansion had taken place into the Virgin River valley of southeastern Nevada, north as far as the Great Salt Lake and northwestern Colorado, to the east into southeastern Colorado and to the Pecos and upper Canadian river valleys of New Mexico. During this period there was probably a development of priestly offices and of rituals and ceremonialism. The increasing population concentration in large pueblos was apparently organized into households according to lineage. Control of the agricultural activities was presumably in the hands of clan leaders, who were also the priests who officiated in the rain-producing ceremonies. During this period some of the larger village populations ranged from 300 to more than 1,000 people.

Primarily because of increasing aridity there was a marked retraction of Anasazi culture between 1100 and 1300. As a result, a concentration of the pueblos took place in northeastern Arizona, along the Rio Grande and its immediate tributaries, and in the present Zuni area of western New Mexico. The Anasazi groups maintained their societies by sand-dune farming with floodwater and some canal irrigation. The increased importance and elaboration of religious rain-producing ceremonies between 1300 and 1540 is deduced from paintings on walls and from symbolic pottery decoration.

Mogollan and Hohokam cultures

The Mogollon complex in its early phases, from 200 BC to AD 700, consisted of relatively small villages of pit houses grouped near a large ceremonial structure. No organization of the village structures into a pattern is apparent, however, and trash disposal was random. Although the initial impetus for sedentary village life appeared early in the Mogollon area, there was a period of apparent cultural quiescence about AD 400 to 600. With the growth and spread of the Anasazi complex in the period after 700, the main flow of culture was from that area, and Mogollon villages from AD 900 to 1100 were a blend of local development strongly influenced from Anasazi. During the climatic deterioration after AD 1200, much of the Mogollon territory in southwestern New Mexico was abandoned.

The Hohokam culture of southeastern Arizona was primarily limited to main river valleys. Agriculture was made possible by extensive irrigation canals that required cooperation between villages. The people lived in villages of scattered pit houses made of brush and mud that were dispersed along the streams and canals. Their main settlements and major culture growth took place also during the period AD 700–1200. Following this for 200 years, there was a blend with Anasazi and Mexican elements and a tendency toward the construction of more compact settlements surrounded by compound walls with a few massive multiroom and two-story buildings. There is relatively little evidence of trade and influences from north-

western Mexico. Such historic groups as the Pima and Papago are descended from the Hohokam people.

Pueblo culture. Best known of the prehistoric and historic southwestern peoples are the Pueblo Indians proper, whose ancestors built great cliff villages now seen in ruins and equally remarkable multiple apartment houses of adobe and stone masonry. Some of the latter are still occupied, and the Pueblo Indian inhabitants speak languages and observe ceremonies that are at least pre-Spanish in origin.

Pueblo culture periods

The beginnings of Pueblo culture, in the 1st millennium AD, are obscure. The traditional type of aboveground, straight-line, or crescent-shaped multiple house continued to be built, two rooms wide; stone masonry, however, began to replace the earlier pole-and-mud and adobe construction. Agriculture, including several varieties of corn, may have been augmented at that time by the cultivation of a native long-staple cotton. Pottery was not much changed, but it included a greater variety of shapes and decoration. Basketry was much less common. These early phases of Pueblo culture are termed Developmental Pueblo.

The great Classic Pueblo period followed in about AD 1050–1300, a period most popularly associated with the term Pueblo. It was the time of the great cliff houses, such as Mesa Verde, and the large apartment-like structures in Chaco Canyon (Pueblo Bonito) and elsewhere. An actual shrinking in area took place as inhabitants of the outer fringes moved in to build the large dwelling units. Also, because a number of outstanding structures were built in quite inaccessible canyons and mesa walls, there is the possibility that hostile strangers had reached the outlying districts. The most notable advance over previous periods was in architecture and pottery. Masonry walls were greatly thickened, dressed stones being used in many localities to bear the greater weight of massive structures. These community structures had from 20 to as many as 1,000 rooms and from one to four stories. Each of the larger houses was in effect a single village. Windows and doors were quite small, and usually no openings were made in the lowest rooms, which were entered by ladder through the roof. Floors were terraced or set back, and the terraces were much used as outdoor living space. Roofs were constructed to carry great weights by laying heavy beams covered with a mat of smaller poles and brush, then laying on a coat of adobe six to eight inches thick. Some semi-subterranean ceremonial chambers, known as kivas, were enlarged to as much as 80 feet (25 metres) in diameter. Craftsmanship in pottery reached a high level, and specialization became so pronounced in the different centres, as in Chaco canyon, Mesa Verde, Kayenta, and a number of others, that the style of each can be recognized easily. To the earlier black-on-white and red-on-white designs were added polychromes of three or more colours applied more lavishly. Cotton cloth, blankets, and bags were woven, and yucca fibre also entered into various articles of clothing and such utility objects as mats. Feather-cloth robes were worn in cold weather.

Abandonment of the cliff houses and large community buildings marked the close of the great Pueblo period. In part this may have resulted from incursion into the northern part of the territory by nomadic Athabascans (Navajo and Apache) and a prolonged drought that occurred in the late 13th century. It is also possible that lack of central leadership led to internal dissensions.

The next period (AD 1300–1700), called Regressive Pueblo, was characterized by a general movement southward and eastward, and new villages, some larger than those of Classic Pueblo, were built on the Little Colorado, Puerco, Verde, San Francisco, Rio Grande, Pecos, upper Gila, and Salt rivers. Pottery showed new developments; geometric patterns were largely replaced by naturalistic representations of birds, animals, insects, and the human figure; glazing was frequently used. The modern Pueblo period is usually dated from the beginning of permanent Spanish settlement at the close of the 17th century. From 1540 on, when the Spaniards first entered the Pueblo country, the number of Pueblo settlements declined considerably, though much of the culture and many of the skills in agriculture and crafts continued down to present times.

EVOLUTION OF CONTEMPORARY NORTH AMERICAN INDIANS

The great diversity that marked Indian cultures also persisted into modern times. After the arrival of the Europeans, some tribes disappeared by amalgamation with others or by wars and epidemics, and some languages perished. The process of adaptation to white encroachments and of acculturation to European ways worked at varying rates within the various Indian societies, transforming and devitalizing segments of custom and practice. Nevertheless, many Indian populations north of Mexico continued to manifest an unexpected viability. Although the total Indian population of the area in the 1970s was only about one-half or two-thirds of what it was at the time of the first European contacts, it was increasing, at least in the United States, faster than the general population—this, despite rates of poverty, death, and disease far greater than those for the general population. As for Indian attitudes, customs, or values, it is obviously not possible to state in quantitative terms how much they continue to function; nevertheless, their persistence does seem undeniable. It is clear that American Indians are not a vanishing race, as was once thought.

Colonial policies. The formulation of public policy toward the Indians was of concern to the major European colonizing powers. The Spanish tried assiduously to Christianize the natives and to remake their living patterns. Orders were issued to congregate scattered Indian villages in orderly, well-placed centres, assuring the Indians at the same time that by moving to such centres they would not lose their outlying lands. This was the first attempt to create Indian reservations. The promise failed to protect Indian land, according to the Franciscan monk and historian of Mexico, Juan Torquemada, who reported about 1599 that there was hardly "a palm of land" that the Spaniards had not taken. Many Indians who did not join the congregations for fear of losing what they owned fled to mountain places and lost their lands anyway.

Early Spanish policies

The Russians never seriously undertook colonization in the New World. When Peter I the Great sent Vitus Jonassen Bering into the northern sea that bears his name, interest was in scientific discovery, not overseas territory. Later, when the problem of protecting and perhaps expanding Russian occupation was placed before Catherine II the Great, she declared (1769):

> It is for traders to traffic where they please. I will furnish neither men, nor ships, nor money, and I renounce forever all lands and possessions in the East Indies and in America.

The Swedish and Dutch attempts at colonization were so brief that neither left a strong imprint on New World practices. The Dutch government, however, was probably the first (1645) of the European powers to enter into a formal treaty with an Indian tribe, the Mohawk. Thus began a relationship, inherited by the British, that contributed to the ascendancy of the English over the French in North America.

France handicapped its colonial venture by transporting to the New World a modified feudal system of land tenure that discouraged permanent settlement. Throughout the period of French occupation, emphasis was on trade rather than on land acquisition and development, and thus French administrators, in dealing with the various tribes, tried primarily only to establish trade relations with them. The French instituted the custom of inviting the headmen of all tribes with which they carried on trade to come once a year to Montreal, where the governor of Canada gave out presents and talked of friendship. The governor of Louisiana met southern Indians at Mobile. The English, reluctantly, found themselves competing on the same basis with annual gifts. Still later, United States peace commissioners were to offer permanent annuities in exchange for tribal concessions of land or other interests.

Early English policies

In contrast to the French, the English were primarily interested in land and permanent settlements; beginning quite early in their occupation, they felt an obligation to bargain with the Indians and to conclude formal agree-

ments with compensation to presumed Indian landowners. The Plymouth settlers, coming without royal sanction, thought it incumbent upon them to make terms with the Massachuset Indians. Cecilius Calvert (the 2nd Baron Baltimore) and William Penn, while possessing royal grants in Maryland and Pennsylvania respectively, nevertheless took pains to purchase occupancy rights from the Indians. It became the practice of most of the colonies to prohibit indiscriminate and unauthorized appropriation of Indian land. The usual requirement was that purchases could be consummated only by agreement with the tribal headman, followed by approval of the governor or other official of the colony. At an early date also, specific areas were set aside for exclusive Indian use. Virginia in 1656 and commissioners for the United Colonies of New England in 1658 agreed to the creation of such reserved areas. Plymouth Colony in 1685 designated for individual Indians separate tracts that could not be alienated without their consent.

In spite of these official efforts to protect Indian lands, unauthorized entry and use caused constant friction through the colonial period. Rivalry with the French, who lost no opportunity to point out to the Indians how their lands were being encroached upon by the English; the activity of land speculators, who succeeded in obtaining large grants beyond the settled frontiers; and, finally, the startling success of the Ottawa chief Pontiac in capturing English strongholds in the old Northwest (the Great Lakes region) as a protest against this westward movement, together prompted the king's ministers to issue a proclamation (1763) that formalized the concept of Indian land titles for the first time in the history of European colonization in the New World. The document prohibited issuance of patents to any lands claimed by a tribe unless the Indian title had first been extinguished by purchase or treaty. The proclamation reserved for the use of the tribes "all the Lands and Territories lying to the Westward of the sources of the Rivers which fall into the Sea from the West and Northwest." Land west of the Appalachians might not be purchased or entered upon by private persons, but purchases might be made in the name of the king or one of the colonies at a council meeting of the Indians.

This policy continued up to the termination of British rule and was adopted by the United States. The Appalachian barrier was soon passed—thousands of settlers crossed the mountains during the American Revolution—but both the Articles of Confederation and the federal Constitution reserved either to the president or to Congress sole authority in Indian affairs, including authority to extinguish Indian title by treaty. When French dominion in Canada capitulated in 1760, the English announced that "the Savages or Indian Allies of his most Christian Majesty, shall be maintained in the lands they inhabit, if they choose to remain there." Thereafter, the proclamation of 1763 applied in Canada and was embodied in the practices of the dominion government. (The British North America Act of 1867, which created modern Canada, provided that the parliament of Canada should have exclusive legislative authority with respect to "Indians, and lands reserved for the Indians." Thus, both North American countries made control over Indian matters a national concern.)

United States policy. The first full declaration of U.S. policy was embodied in the Northwest Ordinance (1787), which stated:

> The utmost good faith shall always be observed toward the Indians, their lands and property shall never be taken from them without their consent; and in their property, rights, and liberty, they shall never be invaded or disturbed, unless in just and lawful wars authorized by congress; but laws founded in justice and humanity shall from time to time be made, for preventing wrongs being done to them, and for preserving peace and friendship with them.

This doctrine was embodied in the act of August 7, 1789, as one of the first declarations of the U.S. Congress under the Constitution.

The final shaping of the legal and political rights of the Indian tribes is found in the opinions of Chief Justice John Marshall, notably in decision in the case of *Worcester* v. *Georgia*:

> The Indian nations had always been considered as distinct, independent, political communities, retaining their original natural rights, as the undisputed possessors of the land, from time immemorial. . . . The settled doctrine of the law of nations is, that a weaker power does not surrender its independence—its right to self-government—by associating with a stronger, and taking its protection. A weak state, in order to provide for its safety, may place itself under the protection of one more powerful, without stripping itself of the right of government, and ceasing to be a state.

The first major departure from the policy of respecting Indian rights came with the Indian Removal Act of 1830. For the first time the United States resorted to coercion, particularly in the cases of the Cherokee and Seminole tribes, as a means of securing compliance. The Removal Act was not in itself coercive, since it authorized the President only to negotiate with tribes east of the Mississippi on a basis of payment for their lands; it called for improvements in the east and a grant of land west of the river, to which perpetual title would be attached. In carrying out the law, however, resistance was met with military force. In the decade following, almost the entire population of perhaps 100,000 Indians was moved westward. The episode moved Alexis de Tocqueville to remark in 1831:

Indian Removal Act of 1830

> The Europeans continued to surround [the Indians] on every side, and to confine them within narrower limits . . . and the Indians have been ruined by a competition which they had not the means of sustaining. They were isolated in their own country, and their race only constituted a little colony of troublesome strangers in the midst of a numerous and dominant people.

The territory west of the Mississippi, it turned out, was not so remote as had been supposed. The discovery of gold in California (1848) started a new sequence of treaties, designed to extinguish Indian title to lands lying in the path of the overland routes to the Pacific. The sudden surge of thousands of wagon trains through the last of the Indian country and the consequent slaughtering of prairie and mountain game that provided subsistence for the Indians brought on the most serious Indian wars the country had experienced. For three decades, beginning in the 1850s, raids and sporadic pitched fighting took place up and down the western Plains, highlighted by such incidents as the Custer massacre by Sioux and Cheyenne Indians (1876), the Nez Percé chief Joseph's running battle in 1877 against superior U.S. army forces, and the Chiricahua Geronimo's long duel with authorities in the Southwest, resulting in his capture and imprisonment in 1886.

Indian wars

Toward the close of that period, the Ghost Dance religion, arising out of the dream revelations of a young Paiute Indian, Wovoka, promised the Indians a return to the old life and reunion with their departed kinsmen. The songs and ceremonies born of this revelation swept across the northern Plains. The movement came to an abrupt end December 29, 1890, at Wounded Knee Creek, South Dakota. Believing that the Ghost Dance was disturbing an uneasy peace, government agents moved to arrest ringleaders. Sitting Bull was killed (December 15) while being taken into custody, and two weeks later units of the U.S. 7th Cavalry at Wounded Knee shot down more than 200 men, women, and children who had already agreed to return to their homes.

A further major shift of policy had occurred in 1871 after congressional discussions lasting several years. The President, with the advice and consent of the Senate, had continued to make treaties with the Indian tribes and to commit the United States to the payment of sums of money. The House of Representatives protested, since a number of congressmen had come to the view that treaties with Indian tribes were an absurdity (a view earlier held by Andrew Jackson). The Senate yielded, and the act of March 3, 1871, declared that "hereafter no Indian nation or tribe" would be recognized "as an independent power with whom the United States may contract by treaty." Indian affairs were brought under the legislative control of the Congress to an extent that had

not been attempted previously. Tribal authority with respect to criminal offenses committed by members within the tribe was reduced to the extent that murder and other major crimes were placed under the jurisdiction of the federal courts.

Radical land allotment legislation

The most radical undertaking of the new legislative policy was the Dawes General Allotment Act of 1887. By that time the Indian tribes had been moved out of the mainstreams of traffic and were settled on lands that they had chosen out of the larger areas that they had formerly occupied. Their choice in most cases had been confirmed by treaty, agreement, act of Congress, or executive order of the president. The tribes that lived by hunting over wide areas found reservation confinement a threat to their existence. Generally, they had insisted on annuity payments or rations, or both, and the U.S. peace commissioners had been willing to offer such a price in return for important land cessions. In time the view came to be held that reservation life fostered indolence and perpetuated customs and attitudes that held Indians back from assimilation. The strategy offered by proponents of this theory was the Allotment Act authorizing the president to divide the reservations into individual parcels and to give every Indian, whether he wanted it or not, a particular piece of the tribally owned land. In order not to make the transition too abrupt, the land would be held in trust for a period of 25 years, after which ownership would devolve upon the individual. With it would go all the rights and duties of citizenship. Reservation land remaining after all living members of the tribes had been provided with allotments was declared surplus, and the president was authorized to open it for entry by non-Indian homesteaders, the Indians being paid the homestead price.

A total of 118 reservations was allotted in this manner, but the result was not what had been anticipated. Through the alienation of surplus lands (making no allowance for children yet unborn) and through patenting of individual holdings, the Indians lost 86,000,000 acres (35,000,000 hectares), or 62 percent, of a total of 138,000,000 acres in Indian ownership prior to 1887. A generation of landless Indians resulted, with no vocational training to relieve them of dependence upon land. The strategy also failed in that ownership of land did not effect an automatic acculturation in those Indians who received individual parcels. Through scattering of individuals and families, moreover, social cohesiveness tended to break down. The result was a weakening of native institutions and cultural practices with nothing offered in substitution. What was intended as transition proved to be a blind alley.

Indian population had been dwindling through the decades after mid-19th century. The California Indians alone, it was estimated, dropped from 100,000 in 1853 to not more than 30,000 in 1864 and 19,000 in 1906. Cholera in the central Plains in 1849 struck the Pawnee. As late as 1870–71 an epidemic of smallpox brought disaster to the Blackfeet, Assiniboin, and Cree. These events gave currency to the concept of the Indian as "the vanishing American." The decision of 1871 to discontinue treaty making and the passage of the Allotment Act of 1887 were both founded in the belief that the Indians would not survive, and hence it did not much matter whether their views were sought in advance of legislation or whether lands were provided for coming generations. When it became obvious after about 1920 that the Indians, whose numbers had remained static for several years, were surely increasing, the United States was without a policy for advancing the interests of a living people.

Indian Reorganization Act of 1934

A survey in 1926 brought into clear focus the failings of the previous 40 years. The investigators found most Indians "extremely poor," in bad health, without education, and lacking adjustment to the dominant culture around them. Under the impetus of these findings and other pressures for reform, Congress adopted the Indian Reorganization Act of 1934, which contemplated an orderly decrease of federal control and a concomitant increase of Indian self-government and responsibility. The essentials of the new law were as follows: (1) allotment of tribal lands was prohibited in the future, but tribes might assign use rights to individuals; (2) so-called surplus lands not pre-empted by homesteaders might be returned to the tribes; (3) tribes might adopt written constitutions and charters of incorporation embodying their continuing inherent powers to manage internal affairs; and (4) funds were authorized for the establishment of a revolving credit program, for land purchases, for educational assistance, and for aiding the tribes in forming organizations. Moreover, the act could be rejected on any reservation by referendum.

The response of the Indian population to the 1934 act was indicative of their ability to rise above adversity. About 160 tribes, bands, and Alaska villages adopted written constitutions, some of which combined traditional practices with modern parliamentary methods. The revolving credit fund helped Indians build up their herds and improve their economic position in many other ways. Borrowers from the fund were tribal corporations, credit associations, and cooperative groups that loaned to individual Indians and to group enterprises on a multimillion-dollar scale. Educational and health services were also improved through federal aid.

Originally, the United States exercised no guardianship over the person of the Indian; after 1871, when internal tribal matters became the subject of national legislation, the number and variety of regulatory measures multiplied rapidly. In the same year that the Indian Reorganization Act was passed, Congress significantly repealed 12 statutes that had made it possible to hold Indians virtual prisoners on their reservations. Indians were then able to come and go as freely as all other persons. The Snyder Act of 1924, extending citizenship to all Indians born in the United States, opened the door to full participation. Few Indians took advantage of the law, and because of their lack of interest a number of states excluded Indians from the franchise. Organization of tribal governments following the Reorganization Act, however, seemed to awaken an interest in civic affairs beyond tribal boundaries, and when Indians asked for the franchise, they were generally able to secure it eventually, though not until 1948 in Arizona and New Mexico, after a lengthy court action.

The federal courts consistently upheld the treaties made with Indian tribes and also held that property may not be taken from Indians, whether or not a treaty exists, "except in fair trade." The latter contention was offered by the Hualapai Indians against the Sante Fe Railway. The company was required by the courts in 1944 to relinquish about 500,000 acres it thought had been granted to it by the U.S. The lands had been occupied since prehistory by the Indians, without benefit of treaty recognition, and the Supreme Court held that, if the occupancy could be proved, as it subsequently was, the Indians were entitled to have their lands restored. In 1950 the Ute Indians were awarded a judgment against the United States of $31,750,000 for lands taken without adequate compensation. A special Indian Claims Commission, created by act of Congress on August 13, 1946, received many petitions for land claims against the United States and awarded, for example, about $14,789,000 to the Cherokee nation, $10,242,000 to the Crow tribe, $3,650,000 to the Snake-Paiute of Oregon, $3,000,000 to the Nez Percé, and $12,300,000 to the Seminole.

Search for new policies

The period from the early 1950s to the 1970s was one of increasing federal attempts to seek new policies regarding the Indians, and it was also a period in which Indians themselves became increasingly vocal in their quest for a better measure of human rights and the correction of past wrongs. The first major shift in policy came in 1954, when the Department of the Interior began terminating federal control over those Indians and reservations deemed able to look after their own affairs. From 1954 to 1960, support to 61 tribes and other Indian groups was ended by the withdrawal of federal services or trust supervision. The results, however, were unhappy. Some Indian groups, in extreme poverty, lost more acreage in deals for the private exploitation of Indian land and water resources. Indians in certain states became subject exclusively to state laws that were less liberal or sympa-

thetic than federal laws. Finally, the protests of Indians, anthropologists, and other interested groups became so insistent that the program was decelerated in 1960. In 1961 a trained anthropologist was sworn in as commissioner of Indian Affairs, the first anthropologist ever to hold that position. Federal aid expanded greatly, and in the ensuing decade Indians were specifically brought into various federal programs for equal economic opportunity. Indian unemployment remained severe, however—in some areas, as much as 10 times the rate for the general population.

During these decades, new Indian organizations, such as the National Congress of American Indians, arose with authority to speak for the various tribal groups, and for the first time in American history Indians were taking a truly active role in deciding their own futures. American Indians came more and more into public attention in the 1960s and 1970s as they sought (along with other racial minorities) to achieve a better life. One of the most dramatic demonstrations was their temporary seizure of the abandoned island of Alcatraz. Although the response of the federal government has been uncertain and there is still a groping for better policies, there does seem to be better recognition of the plight of the Indians and of the need for more favourable policies and programs.

BIBLIOGRAPHY. Some of the more notable general surveys of the American Indians are CLARK WISSLER, *Indians of the United States*, rev. ed. (1966), and *The American Indian: An Introduction to the Anthropology of the New World*, 3rd ed. (1938); H.E. DRIVER, *Indians of North America*, 2nd ed. rev. (1969); A.L. KROEBER, *Cultural and Natural Areas of Native North America* (1939); RUTH M. UNDERHILL, *Red Man's America* (1953); PAUL S. MARTIN, GEORGE I. QUIMBY, and DONALD COLLIER, *Indians Before Columbus* (1947); FRED EGGAN (ed.), *Social Anthropology of North American Tribes*, 2nd ed. (1955); and E.B. LEACOCK and N.O. LURIE (eds.), *North American Indians in Historical Perspective* (1971). An extensive listing of books and articles on particular Indian groups is given in GEORGE P. MURDOCK, *Ethnographic Bibliography of North America*, 3rd ed. (1960). Names, locations, and historical events are summarized in FREDERICK WEBB HODGE (ed.), *Handbook of American Indians, North of Mexico*, 2 vol. (1912, reprinted 1968); and JOHN R. SWANTON, *The Indian Tribes of North America* (1952).

For archaeology and prehistory some useful introductory works are J.D. JENNINGS and EDWARD NORBECK (eds.), *Prehistoric Man in the New World* (1964); DIAMOND JENNESS (ed.), *The American Aborigines* (1933); KENNETH MACGOWAN and J.A. HESTER, JR., *Early Man in the New World* (1962); and H.M. WORMINGTON, *Ancient Man in North America*, 4th ed. (1957). For physical anthropology some important surveys are W.S. LAUGHLIN (ed.), *Papers on the Physical Anthropology of the American Indian* (1951); T.D. STEWART, "A Physical Anthropologist's View of the Peopling of the New World," *SWest. J. Anthrop.* 16:259–273 (1960); and T.D. STEWART and M.T. NEWMAN, "An Historical Résumé of the Concept of Differences in Indian Types," *Am. Anthrop.*, 53:19–26 (1951).

There are no general surveys of all the Subarctic Indians, but FREDERICK JOHNSON (ed.), *Man in Northeastern North America* (1946); and DIAMOND JENNESS, *The Indians of Canada*, 7th ed. (1967), provide a useful introduction to most of them. Only two general surveys of the Northwest Coast Indians are available, both by the same author, PHILLIP DRUCKER: *Indians of the Northwest Coast* (1963) and *Cultures of the North Pacific Coast* (1965). For Californian Indians, useful surveys are contained in A.L. KROEBER, *The Handbook of the Indians of California* (1925); JACK FORBES, *Native Americans of California and Nevada* (1968); and ROBERT HEIZER and ALAN ALMQUIST, *The Other Californians* (1971). The Plateau Indians are treated in E.H. SWANSON, *The Emergence of Plateau Culture* (1962); and in two works by V.F. RAY: *Cultural Relations in the Plateau of Northwestern America* (1939) and *Culture Element Distributions: XXII, Plateau* (1942). There are no general surveys of all the Great Basin Indians, but some information can be found in E.H. SWANSON (ed.), *Languages and Cultures of Western North America* (1970). Important accounts of the southwestern Indians are contained in EDWARD H. SPICER, *Cycles of Conquest* (1962); FRED EGGAN, *Social Organization of the Western Pueblos* (1950); EDWARD P. DOZIER, *The Pueblo Indians of North America* (1970); and CLYDE KLUCKHOHN and DOROTHEA LEIGHTON, *The Navaho* (1946). The Plains Indian tribes, individually and generally, have been the subject of many volumes by many hands; among the useful introductory books are CLARK WISSLER, *North American Indians of the Plains*, 3rd ed. (1927); and R.H. LOWIE, *Indians of the Plains* (1963). For the Indians of the northeast or the eastern woodlands there are a number of works, including FREDERICK JOHNSON (ed.), *Man in Northeastern North America* (1946); ROBERT E. and PAT RITZENTHALER, *The Woodland Indians of the Western Great Lakes* (1970); and GEORGE T. HUNT, *The Wars of the Iroquois* (1940). For the southeast, JOHN R. SWANTON, *The Indians of the Southeastern United States* (1946, reprinted 1969), is the standard introduction.

North American Plains Indians

The Indians of the North American Plains are popularly regarded as the typical American Indians. They were essentially big-game hunters, the buffalo being a primary source of food and equally important as a source of materials for clothing, shelter, and tools. Until supplanted by the white man from the 16th century onward, they occupied the area between the Mississippi River and the Rocky Mountains, which includes portions of both the United States and Canada. It is a vast grassland stretching from northern Alberta and Saskatchewan in Canada to the Rio Grande border of Texas.

The climate is in general a continental one, with a wide seasonal range. Temperatures in winter may go below 0° F (−18° C) and in summer as high as 110° F (43° C). The plant cover varies with the amount of moisture, the tall grass of the prairies in the east giving way at about the 100th meridian to the shorter grass of the High Plains in the west. The area is drained principally by the Missouri–Mississippi river system.

Peoples and languages

The peoples of the Plains are designated by the languages they speak. It is permissible to call them "tribes" or "nations," bearing in mind, however, that in some cases, for example the Dakota (popularly known as Sioux), the designation covers several completely autonomous political divisions. The northern and southern divisions of the Cheyenne retained their unity as a tribe, while the Pawnee on the other hand comprised at least four independent groups. Many of the tribes of the Plains, such as the Cheyenne, migrated into them from the prairies and woodlands of the east. In addition, some of the tribes to the west of the area—the Ute and Jicarilla Apache, for instance—were influenced to a degree by the Plains culture and can be regarded marginal to the area.

Six distinct language families or stocks were represented in the Plains area, although none of them was confined to it. The speakers of the several languages within a stock might or might not be geographically contiguous. Some of the languages, moreover, were more closely related to each other than to others within the same stock. Thus languages belonging to the Algonkian stock included the Blackfoot (Piegan–Blood–Northern Blackfoot), Arapaho–Atsina (Gros Ventre), and Plains Cree, Plains Ojibwa, all in the Northern Plains, while Cheyenne, also an Algonkian language, was in the central part of the area. The Siouan language stock embraced Mandan, Hidatsa, Crow, Dakota–Assiniboin, Omaha–Ponca–Osage–Kansa, and Iowa–Oto–Missouri. The Pawnee–Arikara and Wichita were Caddoan languages, whereas Wind River Shoshoni and Comanche were of the Uto-Aztecan stock. The Athabascan (Na-Dené) stock was represented by the Sarcee (Sarsi) in the northern part of the area and by the Kiowa–Apache in the southern. Finally the Kiowa–Tanoan stock was represented in the area by one language, Kiowa.

Sign language provided a common, if limited, means of communication among tribes speaking different languages. This was a system of fixed hand and finger positions symbolizing ideas, the meanings of which were known to the majority of the tribes of the area.

General cultural characteristics

In aboriginal times the only domestic animal was the dog, which served some tribes for food but was in general use as a pack animal. Dogs were also made to draw the travois, a vehicle consisting of two poles in the shape of a V, the point of the V dragging on the ground; the ends were attached to the animal, and a platform was put across to carry the burden. The Spaniards introduced the

horse in the 16th century, in the southwest, and its use gradually spread northward. By the middle of the 18th century or earlier, all of the Plains Indians were equestrian. There was also a flowering of what one authority has termed luxury developments—"showy clothing, embroidered footgear, medicine-bundle purchases, elaborate rituals [culminating in the sun dance], [and especially] gratuitous and time-consuming warfare." The fighting seldom involved major tribal forces; it was carried out mainly by raiding parties of a few warriors, to avenge a death, to steal horses, and especially to gain glory. Touching an enemy's body was considered among many groups of greater moment than killing or scalping him.

In many of its aspects, Plains culture emphasized intense individualism and aggression, placing a high valuation on violent experience. Rivalry and hostility between men were part of the pattern, so much so that military organizations had to be established to maintain order at tribal assemblies. Nevertheless, a man who became eminent in war could enhance his status by showing generosity to the poor, sharing his goods with relatives, engaging in lavish hospitality, and behaving cooperatively with others.

The tribes who were marginal to the Plains generally borrowed only the external traits of Plains culture and not the religious, ceremonial, or social customs. On the other hand, the southern tribes of the Siouan language family, along with the Pawnee, Mandan, Hidatsa, and Arikara, while possessing most of the typical Plains Indian cultural traits, had a number of others, such as horticulture, pottery, and residence in fixed villages for part of the year; they may be said to constitute a subculture within the Plains Indians.

Distribution of North American Plains Indians.

SOCIAL ORGANIZATION

Local and territorial units. Among the nomadic tribes the local units were bands—*i.e.*, groups of people wandering together in search of food. The size and composition of the bands varied. Comanche bands were loosely organized, each centring its activities in a vaguely defined area within the tribal territory. Only the larger bands received permanent recognition and a name. The bands did not fight one another, but neither did they act in concert as a tribe. The Teton Dakota tribe comprised seven independent bands, the largest being the Oglala. The Cheyenne, however, were more highly organized than the Teton; their ten bands sent representatives to a council of 44 peace chiefs, whose decrees were binding on all the bands. Only in late spring and summer, as a rule, did the nomadic band or tribe come together as a unit on the open Plains, when they engaged in the communal hunt and held major ceremonies. During the remainder of the year, the members dispersed in small groups to more sheltered areas.

Villagers

The semi-sedentary prairie dwellers lived in villages. The three Hidatsa villages were each independent of the others, whereas the Skidi Pawnee villages were united. The seasonal round of the village peoples may be illustrated by the Arikara, who spent the period between planting their crops and harvesting them on the summer hunt living as nomads. After the harvest small groups went to the Plains for another hunt, returning not to their permanent villages but to protected areas in the bottomlands, going back to the permanent villages to plant their crops in the spring.

Family and kinship units. Each local band or village was composed of families and wider kinship units. Every group had regulations governing the mating of kin. Some, such as the Atsina and Blackfoot, did not tolerate marriage between consanguineal relatives, no matter how distant the tie, and others proscribed marriage within varying degrees of relationship. On the other hand, marriage between those who were already relatives by marriage was often prescribed or preferred; the custom of a man marrying the widow of his deceased brother was widespread, as was also the replacement of a deceased wife by her sister. Most marriages were monogamous, but a man might have several wives, sisters being preferred.

Ideally, marriages were arranged between the families of the bride and groom, the latter usually paying a bride-price; sometimes, as among the Mandan, each side provided exactly equivalent gifts. Virginity was highly prized among most of the tribes, particularly the Cheyenne. Among the Blackfoot, women known to be chaste were selected for roles in important ceremonies. The double standard prevailed, however, and men in all of the tribes were expected to make sexual conquests. A husband who had evidence of his wife's infidelity might disfigure her by cutting off her nose or demand compensation from her lover. Romantic love and elopement were not unknown, but attitudes varied; the Teton tolerated the couple on their return, while the Cheyenne considered the girl disgraced forever.

Most Plains tribes had definite rules governing conduct between in-laws, such as the widespread "mother-in-law taboo" in which a man and his wife's mother showed their mutual respect by not speaking to, or in some cases not even looking at, each other. In some tribes, as among the Arapaho, the taboo was extended to include a woman and her father-in-law. The Atsina and a few other tribes required brothers-in-law to be very circumspect in their speech, avoiding any reference to sex no matter how indirect. Yet many of the tribes adhering strictly to this respect taboo permitted the greatest freedom between a man and his sister-in-law. Among the Crow they were expected to romp with each other and to talk to each other in vile language; the Atsina encouraged mutual practical joking and teasing; the Blackfoot allowed the same freedom as between man and wife. It is notable that, according to marriage rules on the Plains, the parties to this joking relationship were potential mates.

Family lines

While some of the Plains societies reckoned descent bilaterally—that is, equally in both the male and female

lines—others reckoned descent exclusively in either the male or female line. This did not mean that there was no recognition of the other parent and his or her relatives. The Hidatsa had a matrilineal clan system (*i.e.*, they traced their descent through females back to a common ancestress), yet there were important relationships to the father and his clansmen; they were always treated with respect and often presented with gifts; before battle a man would ask his clan father to paint his face; the clan father would give personal names to a clansman's son; and ceremonially the father's clan folk played an important part in performances such as the sun dance.

The Mandan and Crow also had matrilineal clan systems. The Oto and Missouri are reported to have had them as well, but there is little information on these groups. The patrilineal clan system was characteristic of the Iowa, Kansa, Omaha, Osage, and Ponca. There is some question as to whether or not the Blackfoot and Atsina had clans, since there was a tendency for the child to be a member of his father's subdivision, and marriage within this subdivision was frowned upon. The organization of the eastern Dakota and the Assiniboin is likewise in doubt.

Among some groups certain clans regarded themselves as more closely related to each other than to other clans. Among the Kansa the 16 clans were grouped into seven larger units. Often the larger units, or phratries, had no important function, although presumably in some cases they regulated marriage. Occasionally there was a further, higher grouping of phratries into two complementary units, or "moieties," as anthropologists call them. The Ponca moieties were composed of two phratries, each consisting of two clans. A similar dual division also existed among societies lacking clans and phratries. The Pawnee, for instance, were divided into the Summer People and the Winter People.

Social rank and warfare. There were no hereditary social classes, but there was ranking of individuals. A poor man, with the help of supernatural power, could win wealth and standing, mainly through prowess at war; but the son of a wealthy family would have an advantage over an orphan.

Most tribes ranked war exploits, but they did not all evaluate particular deeds alike. The taking of scalps was common, but many tribes considered scalping of lesser merit than counting coups—touching one's enemy. Stealing a valuable horse that had been picketed at its owner's lodge was considered a feat.

Most tribes had a number of clubs or associations, religious and secular. Among the latter were the military societies that often functioned as police for the tribal hunt. Some organizations were rivals. Among the Crow, for example, there were two outstanding societies, the Lumpwoods and the Foxes, that were of equal rank but competed violently in feats of war. The Arapaho, Atsina, Blackfoot, Mandan, and Hidatsa differed from the other Plains tribes in that their military societies were ranked in an ordered series. Distinctive regalia and membership privileges in each society were purchased collectively by one group of roughly the same age from an older group. Then the sellers as a group bought from the next older group, the exchange continuing until the oldest group sold out completely and retired from the system. The number of societies varied. The Hidatsa at one time had as many as ten military societies.

Women participated in many of the associations, often playing important roles. Among the Mandan and Hidatsa, women's societies existed similar to the men's graded societies.

Child rearing

Socialization and education. Training began early for Plains children, as part of their play. A very small boy would be given a bow and blunt arrows; as he grew stronger, he would receive larger, heavier bows and be shown how to stalk small game and to hit moving targets. Groups of boys engaged in shooting matches and sham battles, the winners receiving acclaim from their elders; the losers were praised if they had fought bravely. Competition marked almost all of the boys' games.

Girls were taught domestic skills. A father might make toy scraping tools for a girl, which her mother would teach her to use. She would learn to sew by making clothes for her doll and be given a toy tepee to put up while her mother was erecting the big one. In general the line between work and play was not sharply drawn.

The young were encouraged to behave in desired ways by praise and reward, special attention being given in many of the tribes to the first success. Thus an Oto father publicly gave away property to honour his son when the boy first walked, when he brought in his first small game, when he killed his first deer, and when he returned from his first war party. When a Crow boy killed his first big game animal, he was given public recognition; a song celebrating the achievement was sung at a ceremony similar to that which would mark his return from a first war party. Progress toward maturity was generally rewarded by removing restrictions and granting special privileges. Blackfoot boys who won shooting matches were allowed to wear feathers in their hair. As soon as he went on his first war party, the Cheyenne boy was relieved from the duty of herding horses and also from the necessity of listening to long lectures on proper behaviour.

Relatives helped to train children. Grandparents were often consultants and advisers. In a number of tribes, the mother's brother and the father's sister played important roles as mentors and disciplinarians. Among the matrilineal Hidatsa, the maternal uncle was responsible for the direction and supervision of his nephews; he guided them and punished them, but also praised them. Arapaho parents relied on the father's sister to instruct a girl in proper behaviour and to reprimand her when necessary. Physical punishment was seldom employed. Praise and reward for achievement seem to have been generally emphasized more than ridicule and admonishment for failure.

Though the quest for supernatural power through a vision or dream was important among all of the Plains tribes, the experience was not sought primarily at puberty, as was the case in other areas. Again, while fear of menstrual blood was universal, only a few tribes, including the Cree, marked the occurrence of the girl's first menses with an adolescent rite.

ECONOMIC SYSTEMS

Housing

The nomadic tribes lived throughout the year in portable dwellings, while the semi-sedentary peoples used them only seasonally. The tent, or tepee, was conical in shape, the foundation being either three or four poles with other poles placed around them to form a circular base. The cover was made from dressed buffalo skins carefully fitted and sewn together. Since the fireplace was in the centre, a smoke hole was left at the top that could be closed in bad weather.

When the whole tribe assembled, a camp circle was usually formed, leaving the space in the centre for ceremonial structures. Among some peoples, such as the Cheyenne and Atsina, each subgroup had a defined place in the circle. Among many tribes, too, the orientation of the lodges and the opening of the circle was toward the rising sun.

The earth lodge of the semi-sedentary peoples was a permanent structure much larger than a tepee; it was dome shaped, roofed with earth, and entered by a covered passage. The Pawnee, the Mandan, and some other tribes excavated the floor so that their dwellings were partly subterranean. The Osage and Wichita houses differed from those of the other horticultural tribes; the dwellings of the Osage were oval in ground plan, composed of upright poles arched over on top, interlaced with horizontal withes, and covered with mats or skins, while the Wichita houses were conical in shape and thatched with grass.

Technology

The nomads depended for subsistence primarily on big game: buffalo, antelope, deer, and elk. These were also important in the diet of the semi-sedentary tribes. While the animals could be hunted by individuals, the usual methods involved the whole tribe in driving the game down a cliff or into a corral or encircling it by fire. The introduction of the horse increased hunting efficiency, allowing larger numbers of game animals to be killed

more quickly. The mounted hunter continued to prefer the bow and arrow over guns.

The semi-sedentary tribes practicing horticulture raised principally maize (corn), but also beans, squashes, and sunflowers. The plots were cultivated by the women, using only a rake, a digging stick, and a hoe made from the shoulder blade of an elk or a buffalo.

Animal skins were used for clothing. On the Northern Plains, men wore a shirt, leggings reaching to the hips, moccasins, and a buffalo robe—the robe being painted to depict the war deeds of the owner. Women's clothing consisted of a long dress, leggings to the knee, and moccasins. Among the villagers and some southern nomads, men traditionally left the upper part of the body bare. Clothes were decorated with porcupine-quill embroidery, fringe, and, in later times, beadwork. Ordinarily the head was not covered, the feathered warbonnet and other elaborate headgear being reserved for ceremonial occasions.

Receptacles of various kinds were made from rawhide and leather. Traditional tools were of bone, horn, antler, and stone—before the introduction of metal by Europeans. Pipes were usually of stone. Basketry and pottery were characteristic products of the villagers; some of the nomads, including the Cheyenne, Comanche, and Arapaho, were said to have made flat coiled gambling trays, while the Atsina, Blackfoot, and Cree, among others, had traditions of having once made earthenware.

Property and exchange

Some anthropologists have argued that Indians could not have lived on the Plains before the introduction of the horse. Others, pointing to the fact that Francisco Vásquez de Coronado's expedition in 1541 encountered fully nomadic buffalo-hunting tribes on the Southern Plains who lacked horses and depended on dogs for transport, claim that the acquisition of the horse produced only minor changes. One consequence of the horse was the creation of great differences in wealth. Horse stealing became a major motive for warfare. The man who had horses to give away or to offer as bride-price was at a distinct advantage in social prestige.

There was very little intratribal trade in material goods, although there was much exchange of intangibles. The transfer of war medicine and of curing rites brought high prices in horses and other goods among practically all of the tribes. For the spiritual benefit believed to accrue from viewing the contents of a sacred pipe bundle (*i.e.*, a pack containing various sacred objects) of the Mandan, the individual had to pay, in the 1830s, the equivalent of what was then $100. Among the Hidatsa a person wishing to learn to chip flint and make arrows had to buy the rights and receive the instructions from those with ceremonial rights who possessed bundles carrying arrow-making songs.

Intertribal trade was fairly common, one form being that between nomads and villagers; *e.g.*, the exchange of skin robes for grain. The Cheyenne were middlemen in the trade of horses between the Indians of the Southern Plains and those of the north central Plains. Guns and other materials such as blankets, beads, cloth, and kettles, introduced into the northeast by the British and French, were highly valued by the Comanche, Kiowa, and other groups, who were willing to give horses in exchange for them.

BELIEF SYSTEMS

Communication with spirits

The Plains Indians did not distinguish sharply between the sacred and the secular nor between religion and magic. They attached much importance to visions. Success in life was believed to depend in large measure on the intervention of friendly spirits. The usual procedure for obtaining spirit help was to go to some lonely spot to fast, mortify the flesh, and beg for aid. If the suppliant was successful, the spirit would appear to him or be audible to him and would give him detailed instructions to follow to win immunity in battle, ability to cure illness, or various other kinds of power. The spirit might assume the form of an animal or a bird. Not everyone was successful in this quest, and, among the Crow and some other tribes, those with power were permitted to transfer it to others less fortunate. Among the Atsina and Teton Dakota, women might be vouchsafed visions, although they did not usually seek the experience.

All of the tribes had medicine men, or shamans, who had received supernatural powers. Arapaho, Atsina, and Cheyenne medicine men would walk on fire as a proof of their powers. More important was the ability of the shaman to cure illness. While, in most of the groups, ordinary illnesses such as dysentery or headaches would be treated with herbal remedies, a shaman was called in to diagnose and treat more serious illnesses. It was widely believed that illness was caused by intrusion of a foreign substance in the body and that the medicine man could cure the patient by extracting the object. If the medicine man failed, the reason was that there had been some unwitting infraction of the rules as laid down by his supernatural sponsor. He was not required to take every case; among the Teton Dakota he could refuse after examining a patient. Other services a medicine man might render included locating enemies and game animals and even finding lost objects.

In some tribes it is difficult to distinguish the role of medicine man, who had direct contact with the supernatural, from that of the priest who obtained his knowledge from other practitioners. The Cheyenne medicine man is thought to have been more of a priest than a shaman, since his main road to supernatural power was through acquisition of ritual knowledge from one who was already a priest, although some did seek power through visions. The same individual may have acted in some situations as a shaman and in others as a priest.

Among the tribes having a clear belief in a spirit superior to all other spirits were the Cheyenne, the Atsina, and the Pawnee. The Cheyenne, for instance, held that "the Wise One above" knew better than all other creatures; long ago he had left the Earth and retired to the sky. In smoking ceremonies the first offering of the pipe was always made to him. Some of the other tribes, such as the Crow, are not known to have believed in such a supreme deity.

Ceremonial and ritual were well developed on the Plains. They ranged from very simple rites to complicated proceedings requiring weeks of preparation, the final performance lasting for days. A number of common ritual elements were used alone or combined in various ways by the several tribes. Medicine bundles figured prominently in rituals throughout the area. In some cases the bundle was a personal one, the contents of which had been suggested to the individual by a supernatural sponsor, while in others it was a tribal property originating in the mythological past. It was handled reverently and opened according to definite rules. The opening of the Cheyenne sacred arrow bundle, for instance, was the focus of an elaborate tribal rite extending over four days.

The sacred number for most tribes was four, entering into the rituals in many ways. A less common number was seven. Many rituals centred on a kind of altar, a specially prepared space in a ceremonial structure for arranging sacred objects or smoking them with incense. The dimensions of the altar and the symbols that were used varied with the ceremony. Ritual purification in a sweat lodge was a widespread practice, required in connection with many ceremonies.

The sun dance

One important ceremony found among about 20 tribes is known inaccurately in English as the sun dance. The native terms varied: the Cheyenne phrase may be translated as "New Life Lodge"; the Atsina term means "Sacrifice Lodge." While the central features were the same among all the tribes, there were many differences in detail. The sun dance was always held in summer, when the whole tribe gathered, and was usually performed in fulfillment of a vow by someone who had promised it if he were relieved of some grave difficulty. The ceremony was an annual event among the Teton Dakota but occurred at quite irregular intervals among the Crow. The pledger was instructed by a priest or medicine man, and some weeks were needed for gathering food and other preparations. A ceremonial structure was built in the centre of the camp circle, and, before it was erected, offerings were placed in the fork of the central log. Within the structure was an altar upon which buffalo skulls

were laid. The pledger and other participants fasted and danced for several days, praying for power. A widespread, though not universal, feature of the ceremony was self-torture by some of the participants. The skin of the breast or back was pierced, and a wooden skewer inserted. One end of a rope was tied to the skewer, the other end being attached to the centre pole. The dancer leaned back till the line was taut and he strained until he tore himself loose. The Teton elaborated on this torture by dragging around buffalo skulls attached to skewers on the dancers' legs.

THE IMPACT OF THE WHITE MAN

Cultural changes

With the coming of the white man, the Plains Indians began to acquire manufactured articles such as guns, metal utensils, axes, knives, blankets, and cloth. This led to a decline of the native arts and crafts. Paradoxically, however, some aspects of social life were intensified as a result of the fur trade. Since women dressed the hides, the successful hunters secured more and more wives to do the dressing for them, and therefore polygyny increased on the Northern Plains. Religion was affected insofar as wealth brought by the fur trade encouraged more frequent transfer of medicine bundles, at higher prices.

With the coming of immigrant wagons, the building of railroads across the Plains, and the encroachment of white settlements, warfare became a unifying force. During the latter half of the 19th century, tribes that had formerly been hostile to one another often united against the intruders. Not infrequently the Indians were successful, although in the end they were overwhelmed. Eventually the buffalo disappeared, the system of status and rank collapsed, and the tribes were placed on reservations. The culture of the Indians was radically changed.

The United States government hoped to make the Indians into literate farmers, but the agents sent to teach them encountered many obstacles. The nomadic groups were loath to settle down, looking upon cattle as a poor substitute for buffalo. The reservation land was often unsuitable for agriculture. The semi-settled village peoples, among whom digging-stick cultivation was traditionally considered women's work, resisted the change in division of labour brought by the plow. Much confusion resulted when officials insisted on listing families by surnames, which Indians did not possess. Many misunderstandings arose among the matrilineal tribes when inheritance rules were changed so that land passed from father to son.

Schools were established on and off the reservation. Boarding schools had the advantage of facilitating the learning of the white man's language and customs. While some individual Indians adapted to the new conditions and were able to make their way among whites, those who returned from school to the reservations often found themselves in a difficult and marginal position.

Many Indians were Christianized. A new religious movement known as peyotism, combining pagan and Christian elements, spread among the Plains Indians in the latter part of the 19th century. It centred on a species of cactus that when eaten or imbibed caused hallucinations. Since it was considered dangerous by the government as well as by the missionaries, efforts were made to suppress it. But groups practicing the peyote religion were incorporated in 1918 as the Native American Church, and, by the 1960s, the church claimed 200,000 members.

BIBLIOGRAPHY. ROBERT H. LOWIE, *Indians of the Plains* (1963), is a short but authoritative general work. Accounts of particular tribes include the same author's *The Crow Indians* (1935); ALFRED W. BOWERS, *Mandan Social and Ceremonial Organization* (1950) and *Hidatsa Social and Ceremonial Organization* (1965); ALICE C. FLETCHER and FRANCIS LAFLESCHE, *The Omaha Tribe* (1911); JOHN C. EWERS, *The Blackfeet* (1958); GEORGE B. GRINNELL, *The Cheyenne Indians*, 2 vol. (1923); and E. WALLACE and E.A. HOEBEL, *The Comanches* (1952). GEORGE P. MURDOCK, *Ethnographic Bibliography of North America* (1960), covers the Plains in general and each tribe specifically. Records by early observers include JEAN LOUIS BERLANDIER, *The Indians of Texas in 1830*, ed. by JOHN C. EWERS (1969); and GEORGE CATLIN, *North American Indians*, 2 vol. (1926). GORDON MACGREGOR, *Warriors Without Weapons* (1946), is a study of the society and personality of the Teton Dakota under reservation conditions.

(R.F.-He.)

North American Plateau Indians

The North American Plateau is both a complex physiographic unit and a native cultural area. It is bounded on the west by the Canadian Coast Mountains and the Cascade Range, on the south by the Blue Mountains and the Salmon River (excepting a narrow corridor to California), on the east by the Rocky Mountains and the Lewis Range, and on the north by low extensions of the Rocky Mountains, such as the Cariboo Mountains. It may be defined as the drainage territory of the Columbia and Fraser rivers and as the high plateau between the main range of the Rocky Mountains and the coastal mountain system. In the south the natural area of the Plateau gradually merges with the Great Basin natural area: the boundaries between the corresponding culture areas are indeed also very imprecise. Previously, anthropologists included both culture areas as one, the Plateau.

The climate is a harsh, continental type. Temperatures range from −30° F (−34° C) in winter to 100° F (38° C) in summer. Precipitation is low, except in the mountainous areas, and forms a snow cover during the winter. There are three different provinces of vegetation, which correspond to three subcultures: the Middle Columbia area, a steppe of sagebrush and bunchgrass fringed by yellow pine on higher levels, is the territory of the Sahaptin groups and some Salish; the Upper Columbia area, a mainly wooded area with grassland in river valleys, is the home country of such Salish groups as the Okanagon and Flathead, and of the Kutenai; and the Fraser area, with a semi-open coniferous forest interspersed with dry grassland and a partly maritime flora, is the tribal ground of the northern Salish groups. The fauna is not rich, but there are deer and elk in the mountains and salmon and trout in the rivers.

Distribution of North American Plateau Indians.

Peoples and languages

The Indians of the Plateau belong mainly to four linguistic families: Salish, Kutenai, Sahaptin, and Klamath-Modoc (Lutuami). The majority of Plateau groups speak Salishan and Sahaptian. The Salish may be conveniently divided into Northern Plateau and Interior Salish (there are also Coast Salish on the Northwest Coast). To the

Northern Plateau group belong the Shuswap, Lillooet, and Thompson (Ntlakyapamuk) Indians; to the Interior group belong (mostly in the Upper Columbia area) the Okanagon (with Sinkaietk), the Lake (Senijextee), the Wenatchee, Sanpoil and Nespelim, the Spokan, Kalispel (with Pend d'Oreille), Coeur d'Alene, and Flathead. Some early works term all Salish "Flathead." The Sahaptin may be subdivided into three main groups: the Nez Percé, the Cayuse-Molala, and the Central Sahaptin (Umatilla, Yakima, Wallawalla, Tenino, and others).

TRADITIONAL CULTURE PATTERNS

The main characteristics of the Plateau cultures are best discernible against a historical background, for the Plateau cultural pattern was not stable. Opinion is divided as to whether its origins lay with the "desert culture" of arid Western North America, a primitive, seed-gathering culture, or with the "old Cordilleran culture" of the Plateau and North Pacific Coast, a culture with hunting, fishing, and gathering activities. It is certain, however, that the latter subsistence pattern predominated after 1500–1000 BC. By AD 1200–1300 the "classic" Plateau culture, characterized by permanent winter villages with semi-subterranean earth lodges along the main rivers and by summer camps with mat-covered conical lodges on the meadows, had emerged. There is evidence that the Plateau culture expanded as far south as the Snake River, including for some time Shoshone groups in Idaho. During the centuries that followed, the Plateau area was influenced by cultural elements from the highly specialized Northwest Coast culture. Thus, mat and plank houses, carving in wood and bone with animal motifs, and cremation and scaffold burial appeared. Part of this diffusion was possibly brought about by a Chinook group, the Wishram, who migrated from the coast into the Cascade Mountains.

"Classic" Plateau culture

During the 18th century there were influences from the east. The Shoshone had become mounted by this time and furnished their closest neighbours on the Plains and the Plateau with horses. White traders, from the beginning of the 19th century, testified that tribes such as the Nez Percé, Cayuse, Wallawalla, and Flathead had more horses than the tribes of the northern Plains.

Other elements of Plains culture came with the horse, particularly in the Middle Columbia area. Sahaptin Indians, for example, soon appeared in Plains beaded dresses and warbonnets and started to use tepees. Similar innovations occurred on the eastern periphery, in particular among the Flathead and the Kutenai. The northwestern Salishan groups, however, retained their original Plateau culture. Due to pressure from the Blackfoot, the Flathead and Kutenai had to withdraw from their home quarters on the plains of western Montana about 1800. They resettled in the intermontane valleys of the Rockies and from there made occasional buffalo hunts on the Plains in the company of other Plateau tribes, such as the Coeur d'Alene and Nez Percé.

The kind of military ethos found among the Plains Indians was not found uniformly among the Plateau Indians. The Thompson and Shuswap groups, and also the Sahaptin and Klamath further south, did make occasional war raids, dressed in elk hide or wooden slat armour and armed with bows and clubs. Other groups remained peaceful; the Flatheads, in particular, were well regarded by white settlers for courtesy, hospitality, honesty, and courage.

Social structures. Before the introduction of Plains culture, the village always formed the sociopolitical unit. The Thompson Indians, for example, had informal village meetings for decision making, and in matters of general interest the consent of all the villagers had to be obtained. The Sanpoil, on the other hand, had a more formal political structure: the village had a chief, a subchief, and a general assembly in which every adult had a vote (except for young men who were not married). The Nez Percé had a similar organization until the buffalo hunts on the Plains started. Each village had a chief whose office was hereditary, except in the case of poorly qualified sons. Sometimes groups from several villages came together at certain fishing sites or camas (edible lily) meadows, and on these occasions the leading men of the villages constituted an informal council. Early in the 19th century this organization was overruled when families from different villages joined to form bands for the autumn hunts on the Plains. The authority of the village chiefs lapsed as good hunters and fighters became band chiefs. As a result of pressure from missionary and governmental agencies, a tribal head chief was appointed in the 1840s, but he was unable to win any influence over the people. A truly tribal political organization existed among the Flathead, who had a head chief of great power and band chiefs under him. The head chief decided on matters of peace and war and was not bound by the recommendations of his council.

In many Plateau societies chiefs played a more prominent role than in Plains Indian culture, and they were also to a greater extent hereditary. But, although Sahaptin chiefs could exert their authority through whipping (perhaps a Spanish trait), social control was as a rule achieved through social pressure and public opinion. Nobody was coerced into following the advice of a chief or the decisions of a council meeting, and those who did not want to conform could move to another village or another band.

Kinship patterns

The simple, bilateral-descent system prevailed in typical Plateau groups. The average Plateau kin group consisted of the nuclear family and the closest relatives on the father's as well as the mother's side. This is the case among, for instance, the Tenino. Their kinship terminology reveals the close connection between family relatives of the same generation on both paternal and maternal sides, so that all female cousins are called by the same terms as those used for sisters. Marriages do not occur among first cousins (in distinction to the custom in clan-organized societies), and newly wedded couples may put up their residence with the father's or the mother's group. The Tenino also show a patterned kinship behaviour that has possibly existed in other Plateau groups, such as a "joking relationship" between a father's sister's husband and his wife's brother's child, and permitted sexual license between a man and his sister-in-law. All over the Plateau, marriages between one man and several wives (polygyny) were practiced, although they were not common.

It has been observed that kin term distinctions and ranked status distinctions tend to counteract each other: the Coast Salish have a ranked society with reduction of kinship terminology, whereas the majority of Plateau Salish have prevalence of descriptive kin terms and few status distinctions. Among the Sinkaietk or Southern Okanagon, chiefs were hereditary and the most important persons in the tribe in regard to moral influence, for the chief and his family were supposed to exemplify the virtues of the group. He was, on the other hand, not necessarily the wealthiest man in his group, although he was economically supported by his people. The chief had a female relative among his advisers. Such highly respected women also existed in other groups, such as the Coeur d'Alene, and bear witness of the independence of women in Plateau society (excepting the Plains-influenced Kutenai and Flathead). Although marked off as hereditary in his office, the Plateau chief did not separate himself from his group. The general spirit was one of equality and personal autonomy, particularly among the Interior Salish. The Northern Plateau Salish, however, and several other groups kept slaves, as did the Indians on the Northwest Coast, and traded them between each other. The tribes on the eastern fringe who shared the Plains values had a rank of honoured warriors and war chiefs.

The life cycle of the individual was marked by fixed ritual acts that opened the gateway to the different social roles he had to enact. One could say that it started before birth. Among the Sinkaietk, for example, a pregnant woman was not supposed to give birth to her child in her regular home but in a menstrual lodge or another separate lodge. The newborn baby spent its day strapped in a cradle of the flat board type. At the age of one the child was ceremonially conferred a name from the wealth of names in the family. The training of the child was left to the mother and grandmother, but even as a small boy a

Sinkaietk could accompany his father on fishing and small-game hunting trips, while the little girls helped their mothers about the house and gathered roots in the fields. Grandparents saw to it that the child was hardened by such practices as bathing in cold streams. Disobedience was rare but could sometimes result in the child being whipped.

Puberty rites

At puberty the boy was sent out to spend some days fasting on a mountain top and probably to receive a blessing vision from some spirit. Upon returning to the community, he took his place among the adult men. The girl who had her first menstruation was secluded in a menstrual lodge some distance from the village. Her hair was bound up in rolls, and she was only allowed to touch it with a small comb. Her face was painted red or yellow, and she wore undecorated clothing. She was not allowed to drink directly from a well but had to use a drinking tube, and she cleansed herself after the flow in a sweathouse. After a long time—one or several months—she finished her seclusion with prayers in the evening on a hill. Then she returned to the village, a full-grown woman.

Marriage was an entirely informal affair, as was divorce; a woman who was tired of her husband or had been expelled by him returned to her parents if they were alive. She could then remarry if she wished.

Two forms of burial predominated in the Plateau area, pit burials and rockslide burials. The pit burials took place in sand or gravel near the river banks and were often marked with piles of boulders. The rockslide burials were also located close to the river flats, with a cedar stake as a marker. Some cremation burials occurred in the Yakima Valley and at The Dalles and also in the Lillooet-Thompson area. The bereaved had to observe certain taboos, and a widow was supposed to dress poorly and wail at the grave, sometimes for as long a period as a year. There are reports that the house where the death occurred was torn down so that the dead person would not reappear there.

Economic life. The Plateau villages were generally located on waterways and particularly at rapids and other places where fish were abundant during the winter season. Each village had an upland for hunting; in contradistinction to the fishing localities, these uplands were mostly open for people from other villages as well. There were also permanent or semipermanent summer camps for hunting and root gathering in mountain valleys. River villages were permanent winter quarters and could at least temporarily lodge several hundred people. A Kalispel village, for example, numbered 300–400 and a Yakima village as many as 2,000.

Winter dwellings were of two main types, the semi-subterranean earth lodge and the mat-covered surface house. The latter was apparently more recent and existed only in the southern Plateau, where it had replaced an older earth lodge. It was replaced in its turn by the Plains Indian tepee. The average earth lodge was circular, with a pit 4–6 feet (1–2 metres) deep and a diameter of 10–40 feet (3–12 metres). The roof was conical or flat and was supported by leaning poles fastened to some central posts. The smoke hole in the top was also the entrance, the floor being reached by an inside ladder or notched log. The other type of dwelling was formed of two walls of varying length leaning together and covered with tule mats. It was a "longhouse" with a series of hearths in the middle, each one of them shared by two families, one on each side. During the summer people housed in conical mat lodges of small size or in simple windbreaks.

Food-gathering techniques

Fishing was the most important source of food. The Plateau Indians used one- or three-pronged fish spears, traps, and nets when taking their staple fish—eels, suckers, trout, and especially salmon. Large quantities of fish were dried on elevated wooden racks or kept in storage pits and preserved for winter consumption. Roots were dug with digging sticks provided with cross handles of antler or wood. The main root was the camas bulb (*Camassia esculenta*), but bitterroot, onions, wild carrots, and parsnips were also gathered. They were then cooked in earth ovens heated by hot stones. Berries—serviceberries, huckleberries, blueberries—were harvested as well. Hunting occasionally played an important role, even in the winter. Equipped with bow and arrows and perhaps a short spear, the Indian hunted deer first of all but also bear and caribou. In the winter he tracked the animals on long and narrow snowshoes; in the summer he could use a canoe—a dugout in the southern Plateau, a dugout or a bark canoe in the northern Plateau.

In historical times all Plateau peoples used tailored skin garments of the type well-known from the Plains. In prehistoric days both sexes wore a bark breechclout or apron and a twined bark poncho falling a little below the waist. During the cold season men wrapped their legs with fur, and women had leggings of hemp. Rabbit-fur robes or other skin robes were worn in winter. Sahaptin women had twined basket hats, whereas men everywhere had headbands; caps of fur and feathered headdresses appeared with the Plains influences. Both sexes braided their hair. The Chinook practiced flattening of the infant's head as sign of free birth. Curiously, the Flathead never shared this custom.

The village community owned the land, in particular the fishing sites. Household tools, weapons, traps and snares, and similar items were the property of individuals, except for larger weirs that were communal property. Food resources were in most places distributed according to needs. A more restricted system prevailed on the northern Plateau, where gift-giving ceremonies occurred, reminiscent of the potlatches of the Northwest Coast Indians: after some days of games and contests, gifts were distributed to the guests, who in their turn reciprocally handed over presents to their hosts. Although possessions were valued in many parts of the Plateau, the Klamath paid greater attention to them than any other group and held wealthy persons in great esteem. This value orientation, most probably derived from the Northwest Coast, contrasted with the general Plateau pattern of equality and sharing of necessities.

Belief and aesthetic systems. Religion was, like the rest of the culture, closely intertwined with Plateau ecology. In many ways religious beliefs echoed North American religions in general: there was a "great spirit," among the Okanagon conceived of as a bearded white man, and there were spirits of the atmosphere (winds, thunder, etc.) and a host of zoomorphic lesser spirits serving as personal guardian spirits.

Religious rituals

The main rituals were the guardian-spirit quest, the firstling rites, and the winter dance. The guardian-spirit quest was compulsory for boys and recommended for girls and was usually performed in connection with the puberty ceremony. The spirits who granted their blessings in lonely places were very specialized. Some made their clients into hunters, others into warriors or medicine men. Both boys and girls, but preferably the former, could become medicine men. Medicine men were much feared and sometimes very wealthy. They cured diseases by extracting the bad spirit that had entered the patient's body, and on the Northern Plateau they brought back souls that had been stolen by the dead, describing their feats in a dramatic pantomime.

The firstling rites concentrated on the first salmon or berries (roots, fruits) that had been caught or gathered during the summer season. The first salmon ceremony celebrated the arrival of the salmon run with the ritual cutting and eating of the first fish and the ritual throwing of the bones back into the water, in this way ensuring a good return next year. Some Salish had a "salmon chief" who surveyed the rituals. The Okanagon, Thompson, and Lillooet had similar rites for the first berries, which were eaten ceremonially, whereas they lacked the salmon ritual.

The winter or spirit dance, finally, was a ceremonial meeting at which participants personified their respective guardian spirits. The dramatic performances and the songs were, among the Nez Percé, thought to bring warm weather, plentiful game, and successful hunts.

Plateau mythology and folklore revolved around the culture hero and transformer, mostly the Coyote but in some places the Bluejay or another mythical personage. He is a beloved character in the stories, creator and trick-

ster at the same time. The Coyote cycle is well-known from adjacent areas as well.

There is nothing distinctive about Plateau art. On the contrary, most art historians divide it into a western branch, peripheral to the Northwest Coast, and an eastern branch, peripheral to the Plains. Plastic art is on the whole very rare, except in the vicinity of the Northwest Coast. Decorative art consisted of pictographic designs with a symbolic content, referring to supernatural beings and cosmic things. The same division between east and west characterizes musical styles.

DEVELOPMENTS SINCE THE COMING OF EUROPEANS

The preceding description of traditional Plateau culture demonstrates that the culture was neither static nor unitary but changed with time and place. The most dynamic development was introduced when the first impulses from white civilization penetrated the area: the coming of the horse in the beginning of the 18th century, the appearance of epidemics from 1780 onward, and the arrival of eschatological ideas, adapted in the Prophet Dance from perhaps the same time. The latter, which was the origin of the famous Ghost Dance, was a mixture of aboriginal and Christian elements: by dancing like the dead in the other world the Indians thought they could hasten the renewal of the world and the return of the dead. The Prophet Dance seems to have been a reaction against the increasing disruption of traditional culture through the new influences.

Early in the 19th century the fur trade brought Indian and white trappers from the east into the country, particularly to the northern Plateau. Catholic Iroquois trappers propagated Christian ideas among the Flathead, who thereafter visited St. Louis to call on missionaries. The great invasion of white settlers and gold seekers in the 1850s and 1860s and the ensuing Indian wars (of which the Nez Percé War of 1877 is the most famous) resulted in the reduction of Indian territories, the creation of a series of small reservations, and the isolation and deprivation of the Indians in "white" surroundings. Only during recent decades have Indians tried to take part in modern development outside their reservations.

The blending of aboriginal and white cultures has accelerated with every year and produced a variety of mixed cultures on the reservations, some more conservative, others more Europeanized. The Kutenai, for instance, have turned into ranchers or ranch hands during the warm season but use their fishing traps during the winter, a seasonal pattern that in a way conforms with the old culture. The Nez Percé, on the other hand, have at least partly become farmers. Their cultural assimilation has been furthered by political and religious factionalism. Summarily, it may be said that the Plateau Indians have retained their group feelings, part of their old economics, and in places much of their religion, whereas technology and material culture have long been characteristic of white poverty levels.

BIBLIOGRAPHY. The archaeological background has been described by E.H. SWANSON, *The Emergence of Plateau Culture* (1962); and B.R. BUTLER, *The Old Cordilleran Culture in the Pacific Northwest* (1961). A noteworthy paper is R.D. DAUGHERTY, *Archaeology of the Lind Coulee Site, Washington* (1956). General ethnological perspectives have been presented in two papers by V.F. RAY, *Cultural Relations in the Plateau of Northwestern America* (1939) and *Culture Element Distributions*, pt. 22, *Plateau* (1942). There are several good monographs on single tribes: J.A. TEIT, *The Thompson Indians of British Columbia* (1900); H.J. SPINDEN, *The Nez Percé Indians* (1908); LESLIE SPIER, *Klamath Ethnography* (1930); V.F. RAY, *The Sanpoil and Nespelem: Salishan Peoples of Northeastern Washington* (1932); and the work edited by LESLIE SPIER, *The Sinkaietk or Southern Okanagon of Washington* (1938). Demographic, linguistic, and sociopolitical analyses may be found in V.F. RAY, "Native Villages and Groupings of the Columbia Basin," *Pacif. NW. Q.*, 27:99–152 (1936); T.R. GARTH, "Early Nineteenth Century Tribal Relations in the Columbia Plateau," *SWest. J. Anthrop.*, 20:43–57 (1964); and W.W. ELMENDORF, "Linguistic and Geographic Relations in the Northern Plateau Area," *ibid.*, 21:63–78 (1965). Kinship systems are discussed in M. JACOBS, "Northern Sahaptin Kinship Terms," *Am. Anthrop.*, 34:688–693 (1932); and W.W. ELMENDORF, "System Change in Salish Kinship Terminologies," *SWest. J. Anthrop.*, 17:365–382 (1961). LESLIE SPIER, *The Prophet Dance of the Northwest and Its Derivatives: The Source of the Ghost Dance* (1935), has become a classic, but must now be checked against D.E. WALKER, JR., "New Light on the Prophet Dance Controversy," *Ethnohistory*, 16:245–256 (1969). Modern culture contact problems are dealt with in a skilful way in D.E. WALKER, *Conflict and Schism in Nez Percé Acculturation* (1968).

North Carolina

One of the 13 original states of the United States, North Carolina lies on the Atlantic coast midway between New York and Florida. In recent decades it has become the leading industrial state of the South, and it is also, after Florida, the South's most populous state. More than one-half of the nearly 5,100,000 inhabitants recorded in 1970, however, lived outside urbanized communities, giving it one of the largest rural populations in the nation.

General character of the state

North Carolina's beginnings are tied closely to the earliest attempts at English colonization of the New World. Roanoke Island in the northeast, a part of the heavily indented and island-fringed coast, was the site of the famous Lost Colony that vanished sometime after the original landing in 1587. This eastern region today retains much of the flavour of colonial life, while the higher Piedmont region centred around the capital, Raleigh, has become the industrial and population hub, and the mountains of the west remain the focus of a lively folk culture and the home of the largest group of American Indians east of the Mississippi River.

Bounded on the north by Virginia, on the east by the Atlantic Ocean, on the south by South Carolina and Georgia, and on the west by Tennessee, North Carolina has an area of 52,586 square miles (136,198 square kilometres). Its 3,788 square miles of inland water, the fifth largest such area of any state, are concentrated both in the extensive marshlands of the coastal tidewater and in the lakes of the Piedmont and Appalachian regions. These three physical regions are related to major diversities in life styles among the people of the state, almost creating three North Carolinas within the common boundaries. (For information on related topics, see the articles UNITED STATES; UNITED STATES, HISTORY OF THE; and NORTH AMERICA.)

THE HISTORY OF NORTH CAROLINA

The proprietary and royal colony. Following the abortive attempts of Sir Walter Raleigh and others to colonize the coastal regions in the 1580s under patents from Queen Elizabeth I, the region remained Indian territory for many decades. A grant by King Charles I in 1629 for the lands south of Virginia brought the term Carolana into being, but no permanent settlement was made until farmers from Virginia moved into the Albemarle Sound area of the northeast in the 1650s. This resulted in a grant from Charles II in 1663 that created Carolina, but for years the settlers resisted the ineffective government imposed by the proprietors in England. Between 1712 and 1729, the separate province of "North Carolina" was ruled by a deputy dispatched from Charleston, which had become the centre of proprietary government. The boundaries between North and South Carolina were agreed upon in 1735 but not surveyed until 1815.

Difficulties of settlement and government

North Carolina's growth was hampered by restrictions on shipping imposed by Virginia on its already significant tobacco crop; by economic and religious quarrels with absentee proprietors that led to rebellions in 1677 and 1708; by war with the Tuscarora Indians (1711–13); and by coastal piracy involving Edward Teach (Blackbeard) and others. Unlike other colonies, which had grown up around the coastal towns that represented the first settlements, North Carolina had no town until Bath was settled by French Huguenots from Virginia after 1700. By 1729, when the colony came under royal rule, several other communities had been founded.

The decades of royal rule saw a turnabout in the colony's fortunes. The population rose rapidly, settlement

spread across the Piedmont, and the wealth and quality of life expanded toward that of the other colonies. A large slave population maintained an agricultural economy based on tobacco, rice, and naval stores from the extensive pine forests. Prior to the American Revolution, the seeds of an intense east-west hostility had flowered into several insurrections, but joint antipathy to British rule united North Carolinians and forced the flight of the royal governor in 1775.

Statehood. The Revolution in North Carolina comprised not only a miniature civil war involving the many Tories in the new state but also suppression of Cherokee uprisings in the west. Much of the state's energy was directed to resolving the conflicting interests of the eastern counties and those of the west until constitutional reforms in 1835 broke the dominance of the east. A period of great economic and social progress first under the Whigs and continued after 1850 by the Democrats was slowed by the increasing furor over slavery and ended by the Civil War.

The Civil War and its aftermath

Unlike South Carolina, whose strident proslavery voices led the South into secession, North Carolina left the Union reluctantly, seeking compromise to the last moment. Once committed, however, the state fought with the Confederacy and with it experienced the ignominy of defeat and the years of political corruption and social instability that characterized the postwar Reconstruction throughout the South. The "Bourbon Democrats" who controlled the state after readmission to the Union were oriented to the growing railroad and industrial interests, and they largely ignored the small farmer. Constitutional amendments in 1900 virtually disfranchised the state's Negro population.

North Carolina in the 20th century has been a part of the national experience of changing economic cycles and, especially since the 1950s, of racial tensions. The state has benefitted, however, from its rise to a ranking among the top one-third of industrial states, a factor that in terms of statewide wealth has tended to balance its huge rural population and agricultural activity; and from the concern with higher education as an integral part of the life of its citizens that has characterized it since its early years as a state.

THE NATURAL AND HUMAN LANDSCAPE

The physical and biological—as well as the human—characteristics of North Carolina's Coastal Plain (or Tidewater), Piedmont, and Appalachian Mountain regions are quite different. As the land reaches westward from sea level, it rises gradually to the Fall Line, a zone some 30 miles in width separating Coastal Plain from Piedmont. In the latter, the topography becomes irregular and rises about five feet a mile to the base of the Appalachians, a distance of about 140 miles. The mountains, many reaching well over 6,000 feet, have a worn, rounded appearance, reflecting their older geological origin than the rugged peaks of the American West. Mt. Mitchell, rising to 6,684 feet (2,037 metres), is the highest peak east of the Mississippi.

The state's regions. *The Coastal Plain.* Comprising some 45 percent of the state, the Coastal Plain divides into a gently rolling, well-drained interior and a swampy tidewater portion close to the coastline. The latter region was the first to be explored and settled. A long chain of islands, the Outer Banks, extends from Virginia to South Carolina, generally covered with sand dunes from a few feet to over 100 feet in height. Three capes—Cape Hatteras, Cape Lookout, and Cape Fear—jut out into the ocean in an area known as the "Graveyard of the Atlantic," a reference to the many ships that have gone down in the dangerous offshore waters. The entire area averages less than 20 feet above sea level, but in spite of the watery environment only small craft navigation is possible because of silting and shallow sounds and estuaries. The Intercoastal Waterway threads its way between the Outer Banks and the mainland on its way from New Jersey to the Gulf of Mexico. The inner Coastal Plain extends from 120 to 140 miles westward to the Piedmont.

Eastern North Carolina has been the citadel of the state's history since Raleigh's grand dream of colonization came to so mysterious an end. Close to Roanoke Island, are the sand dunes of Kitty Hawk, over which in 1903 Wilbur and Orville Wright ushered in the age of powered flight. Legends tell of fabulous pirate treasure buried beneath the dunes of the Outer Banks, off whose shores rusting smokestacks, masts, and boilers protrude from the water, testimony to the more than 2,000 ships that have gone down. Nearby Nags Head got its name, according to tradition, because unscrupulous settlers tied lanterns to horse's necks and drove them along the coast to lure unsuspecting sea captains to the reefs. On Ocracoke Island, so named by Blackbeard, visitors are astonished at the Elizabethan English of the residents, for whom "high tide" is "hoigh toide."

Diverse ways of life from coast to mountains

Further south in New Bern, the state's second-oldest town and one named by its Swiss settlers, is Tryon Palace, a restored palace and garden that has been called the most beautiful building in the colonial Americas. Along the southern coast, fishermen set out to battle the large deepwater fish of the close-by Gulf Stream, and in Edenton memories survive of the colonial ladies who held one of the first tea parties to protest the duties imposed by the British. Morehead City and Wilmington are the state's two deepwater ports, both significant in world trade, while in the area several major military installations add to the state's economic life.

The Piedmont Plateau. Containing about 38 percent of the state's area, the North Carolina Piedmont is a region of rolling, forested hills. The prominent ridges and hills of the eastern Piedmont may be the remains of an ancient mountain chain that paralleled the Appalachians, from which numerous spurs extend into the western Piedmont. The area is well drained by rivers flowing into the Coastal Plain or South Carolina. Dams on the Catawba and Yadkin rivers are important sources of hydroelectric power.

This region is a prime symbol of the "New South," in which modern industry has largely replaced the traditional agriculture. The pulsating main street of industry runs in a sweeping crescent westward and southward from Raleigh to below Charlotte, the state's largest city. Such cities as Durham, Greensboro, and Winston-Salem have made North Carolina the capital of the nation's tobacco industry. The colleges and universities that have been so influential in the state's history are centred in this region.

In spite of industry, the many antebellum homes in these cities maintain an aura of serenity, and cotton and tobacco fields are still found close to the city limits. The many lakes and the upper reaches of the rivers provide quiet havens for fishing and camping, and in many small towns the amply stocked general stores still serve the rural populations. Under the city streets of Charlotte—described by Lord Cornwallis, the English general of Revolutionary fame, as "a piddlin little place"—are the traces of early gold-mine shafts, which once produced many tons of the precious metal.

The mountains. The mountain region comprises a highly desiccated intermontane plateau bounded by two ranges of the southern Appalachians. On the east is the Blue Ridge, which rises steeply from the Piedmont to peaks of 3,000 to 4,000 feet and a few of 6,000 or more. In the far west, the Unaka Mountains contain the Great Smoky Mountains that roll westward into Tennessee. This region is divided into several cross ridges and a number of smaller plateaus and basins. One of the chief ridges is made up of the Black Mountain group. In all, 43 peaks rise over 6,000 feet and 80 over 5,000 in western North Carolina.

In North Carolina's mountains, ways of life change slowly. Many communities, relatively isolated since the early history of the state, have become self-sufficient. Wood carving, basketry, needlework, rug and bedspread making, and ceramics are among the many cottage industries whose crafts have been passed down through the generations. Today the serenity is beginning to be broken, however, both in the mountains and in the resort centre of Asheville. Winter and summer sports are becoming popular on the slopes, and the Pisgah National Forest is

Traditional cultures of the isolated communities

among the areas that attract a growing number of tourists and campers. One of the world's largest satellite tracking stations is located at Rosman.

Climate. North Carolina's climate ranges from that of the mountain region, which experiences a medium continental type, although summers are cooler and rainfall heavier, to the subtropical conditions of the state's southeastern corner. The growing season ranges from 275 days along the coast to 175 days in the mountains. Mean annual temperature ranges from 66° F (19° C) in the eastern region, to 60° F (16° C) in the central, and 55° F (13° C) in the mountains. July and August are the wettest months, and October and November are the driest. Annual rainfall varies from 46 to 54 inches (117 to 137 centimetres) on the coast, 44 to 50 inches (112 to 127 centimetres) in the Piedmont, and 40 to 80 inches (100 to 200 centimetres) in the mountains. Severe storms are rare and heavy snow infrequent. Occasional hurricanes occur along the coast, and there have been tornadoes inland.

Plant and animal life. Soil and vegetation are quite different over the state because of the geographical and climatic differences of the three main regions. Trees that once covered the landscape as dense forests have been cut and burned and now cover only 56 percent of the state. Erosion and leaching of the soils necessitates large amounts of lime to neutralize acidity and fertilizers to replace the leached nutrients.

A greater variety of plant life is to be found in North Carolina than in any other state in eastern North America. There are many species of hardwood trees. Sub-Arctic spruce and balsam fir are found in the mountains, and the subtropical palmetto and the carnivorous Venus's-flytrap in the south coastal area.

The common fauna of North America, including rabbits, squirrels, raccoon, oppossum, deer, and also bear and wildcats, are found within the state. The commonest birds are the cardinal, wren, mockingbird, chickadee, and many varieties of woodpecker and warbler.

Inland-water fish such as bluegills, crappies, bass, and sunfish are common. Brook and rainbow trout are found in the mountains.

THE PEOPLE OF NORTH CAROLINA

Archaeologists have found traces of human habitation in the state that date back some 16,000 years. It is estimated that when the first white explorers arrived there were between 35,000 and 50,000 Indians in the region. The Indians were finally crushed in the late 1830s with the forced removal of the Cherokee to lands west of the Mississippi, recorded in history as the "Trail of Tears" (1838–39). In the early 1970s only approximately 30,000 live in the state, the largest group east of the Mississippi River and the fifth largest group in the United States.

Early settlement. The coast was first explored by the French, Spanish, and English. The first English colony failed, and the fate of its members is still a mystery. Settlers came into North Carolina in the 1650s from the English colony at Jamestown, Virginia. Others came from Philadelphia and down through Virginia on the great wagon road from Pennsylvania through the Great Appalachian Valley into the Piedmont. Many came by sea lanes from Europe, all yearning for a plot of land and freedom from rigid class and religious restrictions.

Disease, poor roads, the closing of Currituck Inlet by silt, abandonment of worn-out fields, and limited trade with England slowed early settlement. The population in 1694 was 3,000, living mostly in the Albemarle Sound area. By 1729 the population was perhaps 30,000. The first United States census of 1790 showed the state had grown to over 390,000 persons.

Ethnic and religious backgrounds of early settlers

The early North Carolinians were a heterogeneous group, representing a variety of religious faiths, economic and social classes, and nationalities. The Anglican Church was established by law in the early 18th century, but there were also Presbyterians, Quakers, Moravians, Lutherans, Reformed, Baptists, Methodists, and a small number of Jews. Nationalities represented were English, Scottish, Irish, Welsh, French, German, and others.

The Negro component of the early North Carolina population, brought in from Virginia and South Carolina, was most important, as it furnished the labour for clearing and working the land and producing the naval stores of tar, pitch, rosin, and turpentine. The total slave population in 1790 was more than 100,000, one-third of the total population. Approximately 5,000 Negroes were free men. The labour-demanding crops of rice, indigo, tobacco, and cotton accounted for the spread of slavery in the state, especially after the perfection of the cotton gin.

Demographic trends. The 1970 census showed North Carolina to be the 12th most populous state in the nation. The population density was 104.1 persons per square mile, compared to 114.9 for the South Atlantic region, and 57.5 for the United States as a whole. Racially, the population is 76.8 percent white and 23.2 percent nonwhite. The black population declined from 27.5 percent in 1940 to 22.2 percent in 1970, mainly as a result of blacks seeking employment in the northern and western sections of the United States and because of the continued mechanization of agriculture. The migration, in and out, of whites has tended to equalize.

The state's white population has a considerably lower death rate than does the nonwhite, reflecting the wide variations between races in socio-economic status. Degenerative rather than infectious diseases have become the more important killers. Whites enjoy far greater protection from preventable diseases than do the nonwhites.

North Carolina's population is more rural than urban, despite the large industrial employment. The reason for this is that many industrial plants are located in small towns, and workers tend to commute long distances and live in rural areas. Rapid urbanization and the persistence of extremely rural areas accentuate the demographic contrasts in the state. In the eastern region, rurality is typified by tenancy and sharecropping, while in the mountain region the traditional folk rurality is continued on farms operated on a subsistence level.

THE STATE'S ECONOMY

North Carolina's economy depends on manufacturing and agriculture, but tourism is gaining in importance.

Components. North Carolina is endowed with numerous resources that are of great value to manufacturers. The state has one of the nation's largest known phosphate reserves; other important minerals include kaolin, mica, feldspar, granite, copper, limestone, marble, marl, olivine, talc, sand, gravel, and shale. Forestry and fishing are other important sources of income.

In annual industrial output, the state ranks 12th in the nation. Some 20 percent of the labour force is employed in the metalworking, electronic, chemical, paper and paper products, plastics, and food-processing industries.

The state ranks first nationally in farm population and second in the number of farms. The principal crops are tobacco, corn, grain, soybeans, peanuts, and hay. Home consumption of crops and livestock is higher than in any other state. Forest products are used for furniture and as a source of pulp for paper. An active reforestation program has resulted in a growth of forest reserves.

Tourism brought to North Carolina an estimated income of over $800,000,000 annually in the early 1970s. The industry has a diversified base, including the attractions of both ocean and mountains as well as the memorials to the state's past.

Transportation. Geographically, the state is one day's trucking time to New York or to the rapidly expanding Florida market. More long-distance interstate motor carriers are domiciled in the state than in any other. Eight commercial airlines, operating out of 14 airports, serve the state.

Marine traffic

North Carolina has two Atlantic gateways to world markets. Modern ports are found at Wilmington and Morehead City, both of which are equipped to handle any type of cargo. More than 50 steamship lines make calls, and both ports are served by rail and motor transport. In addition, 20 feeder ports are equipped to handle barges and small ships.

There are some 4,300 miles of rail line in the state, serving 92 of the 100 counties. Rail rates are consider-

ably lower than in the rest of the nation. The principal motor passenger carriers transport more than 3,000,000 passengers each year.

ADMINISTRATION AND SOCIAL CONDITIONS

Government. The structure of the government of North Carolina is based on constitutions of 1776 and 1868. There have since been numerous amendments.

State level. Administration of the state is supervised by elected executives, including the governor, lieutenant governor, the heads of numerous state agencies, all of whom serve four-year terms. The governor has great appointive powers but no veto over legislation—the only governor in the nation who lacks this power. All state fiscal and management agencies are consolidated in one department, the Department of Administration. The court system has, as its base, 30 district courts that deal with less serious civil and criminal cases. The superior courts, of which there is one for each judicial district, take the more serious criminal and civil cases. Superior court judges are elected in general elections for a term of eight years. There are eight special superior court judges appointed by the governor for four-year terms.

Above the superior courts are the Court of Appeals and the Supreme Court. The latter is the highest state court; it has seven justices elected for eight-year terms. The Court of Appeals was set up in 1967 to help relieve the North Carolina Supreme Court by hearing the less important cases. It has nine judges, all of whom are elected for eight-year terms.

Local government. North Carolina is divided into 100 counties. The county governments act for the state in providing education, health, and welfare services. Locally elected officials include county commissioners, the sheriff, the register of deeds, the clerk of the superior court, and the school board. There may be other elected officials in counties having larger populations. Town and city governments also provide local services.

The social milieu. In spite of its progressive and expanding economy, North Carolina remains below national averages in such areas as the per capita income of its population and its expenditures for social services. In addition, a wide economic gulf separates the black and white communities of the state.

Education. The public school system, supported by the state since 1933, has been improving steadily for several decades, though it is still below national levels. Other problems include a relatively low salary scale for teachers and a racial integration that is far from complete.

Institutions of higher education

In higher education, however, North Carolina has a number of institutions of national standing. The public university system is headed by the University of North Carolina whose main campus is in Chapel Hill; opened in 1795, it is one of the oldest state universities in the nation. Other campuses are located in Greensboro, Asheville, Charlotte, and Wilmington. The state also has 9 state universities, 13 community colleges, and more than 35 technical institutes in its system. These combined facilities make it the fifth largest university system in the nation. Among the dozens of private institutions around the state, most of them supported by various Protestant denominations, Duke University (established 1924; formerly Trinity College) in Durham is noted for its undergraduate and postgraduate programs.

Health and welfare services. State-funded hospitals cover a number of specialized areas such as crippled children, alcoholism, retardation and mental illness, cerebral palsy, and tuberculosis. An effective public health program has been in operation since 1877, and each county has a local health department. State aid is provided also to the aged or disabled, to families with dependent children, and for various counselling and other social service programs.

Race relations. In spite of continuing disparities between white and black living conditions, the black has had an impressive rise during the 20th century in the arts, sports, business, education, and politics. In the early 1970s, Chapel Hill had a black mayor, Charlotte a black mayor *pro tem*. The major areas of polarization remain in educational and religious institutions.

Services. Per capita direct general expenditure by the state and local governments in such areas as education, hospitals, sanitation, police, and welfare is $390, compared to an average in the United States of $578.

CULTURAL LIFE

The fine arts. An arts council was established in 1964 to assist in bringing the highest obtainable quality in the arts to the greatest number of people in the state and to expand the role of the arts. The council sponsors numerous projects, dance workshops and tours dominating its activity.

The North Carolina Museum of Art was the first in the country to be established by a state and to be supported mainly by state funds. The museum sends out travelling exhibits to schools, libraries, civic clubs, and other museums throughout the state. The North Carolina State Art Society donates funds for the purchase of additional works of art.

The North Carolina Symphony has the distinction of being the first state symphony in the country. The orchestra, which has 65 members, tours the state from October through April. More than half of the performances are free matinees for children. The North Carolina Symphony Society tries, through membership drives, to raise enough money to sponsor local adult and children's concerts and to stimulate interest in music.

The folk arts and pageantry. It is in the field of the folk arts and of historical pageantry that North Carolina excels. The many cottage industries of the western mountains combine with those of the coastal water-oriented communities to offer some of the richest folk culture in the United States. Summerlong outdoor pageants are held in Manteo on Roanoke Island, where the drama *The Lost Colony* revives the colonizing escapades of Sir Walter Raleigh in the court of Elizabeth and on the soil of Roanoke itself; in Boone, where *The Horn of the West* recreates such characters as Daniel Boone; and in Cherokee, where *Unto These Hills* is played by the descendants of the Cherokee Indians upon whose history the saga is based. A major force in the cultural life is the Carolina Playmakers. The group was founded in 1918 at the University of North Carolina by Frederick Koch, an advocate of folk drama who had a strong influence on numerous playwrights and movements in American theatre.

Historical dramas

PROSPECTS

North Carolina is changing rapidly as a result of expansion of urban areas, slum clearance, new housing, schools, recreational facilities, and industrial plants.

Economically, the state has two major problems. Tobacco is the state's main crop, and it is possible that its consumption may decline rapidly as a result of the national antismoking campaign. Textiles, also a very important segment of the economy, have been hurt by imports, and a number of mills have closed. That there is room for improvement in the performance of the administration is suggested by the fact that a national survey made in 1970 ranked the General Assembly 47th of the 50 states in performance.

North Dakota

Officially classed as one of the seven west north central states of the United States, North Dakota is a land of clear skies, seemingly endless grain farms, and vast cattle ranches. North Dakota is even more rural, more agricultural, and more sparsely populated than the six other states of the region, and has less manufacturing. Its terrain rises through three regions from east to west, incorporating parts of the two major physiographic provinces that separate the Appalachian and the Rocky Mountain systems.

The state's 70,665 square miles (183,022 square kilometres) according to the 1970 census had only 617,761 inhabitants, showing a decrease of 2.3 percent from 1960. The largest city, Fargo, had fewer than 55,000 inhabitants, and Bismarck, the centrally located capital, some 35,000.

Among the last regions of the American frontier to be settled, the area admitted in 1889 as the state of North Dakota had experienced comparatively little of the fighting, lawlessness, and gold-rush excitement that give other frontier areas a colourful or lurid history. Instead the region had developed first as the home of hunting and farming Indian peoples, then as a trade hinterland for white fur traders and for steamboats working the upper Missouri from St. Louis, and last as a rich farming land for settlers. The cool, subhumid climate of its location made it ideal for spring wheat and for cattle ranching. With white settlement, the area inevitably developed a way of life dependent on outside centres of population, industry, and economic power. With adaptation to the environment, however, the people of North Dakota developed also constructive reactions to the circumstances that made their state dependent. (For information on related topics, see the articles UNITED STATES; UNITED STATES, HISTORY OF THE; NORTH AMERICA; and GREAT PLAINS.)

THE HISTORY OF NORTH DAKOTA

The recorded history of North Dakota falls into three periods: the period of Indian trade, from about 1738 to 1871; the period of white settlement, from 1871 to 1915; and the period of adaptation, since 1915.

Explorers and traders. Although European goods were traded among the Indian peoples before his arrival, the first-known white visitor to North Dakota was Pierre Gaultier de Varennes, sieur de La Vérendrye, a native of Canada who visited a cluster of earthen-lodge villages near present-day Bismarck in 1738. Traders from Hudson Bay and Montreal began to come on a regular basis in the 1790s. The most famous visitors of the early years were Meriwether Lewis and William Clark, whose expedition made winter camp in 1804–05 near present-day Stanton.

In the 1820s and 1830s American traders made the upper Missouri country a hinterland to St. Louis. They brought in guns, kettles, blankets, and axes, as well as liquor and disease. The white man's goods made the Indians dependent on the traders, his liquor demoralized them, and his diseases killed them. In 1837 smallpox, carried up the Missouri by passengers aboard a steamboat of the American Fur Company, reduced the Mandan population from about 1,800 to 125 in a few months. Indian hostility grew when steamboat traffic increased after the discovery of gold in Montana in 1862 and when the United States Army built forts along the rivers. In 1876 Col. George A. Custer and the 7th Cavalry set out from Ft. Abraham Lincoln, south of present-day Mandan, for their fateful encounter with the Sioux and Cheyenne on the Little Bighorn River.

Pioneering and statehood. The fur trade declined in the 1860s, and white settlement began in earnest in 1871, when railroads reached the Red River from St. Paul and Duluth. A flood of pioneers took up land under the Homestead Act and turned to wheat farming. During the period known as the Dakota Boom (from 1878 to 1886), the many giant farms advertised the new country, and North Dakota wheat made Minneapolis, Minnesota, the milling centre of the nation in the 1880s. The Northern Pacific and Great Northern railroads vied with one another to reach the richest grain centres. Dependence on wheat unified the farmers and strengthened the populist revolt against eastern monopolistic practices. The Dakota Territory was divided in 1889, and both North and South Dakota were admitted to the Union on November 2, 1889.

Populist strength

The modern state. Revolt against outside exploitation reached a climax soon after the period of pioneer settlement ended in 1915. Controlling the state government after the 1918 election, the Nonpartisan League enacted a socialistic program that included a state-owned bank and a state-owned flour mill and grain elevator. The league soon lost political control, but the North Dakota Farmers Union (founded in 1927) launched a strong cooperative movement to control the selling of grain and the purchase of farm supplies. Such radical farm movements made many North Dakotans oppose American intervention in both world wars, because they identified participation with war profits for Wall Street.

From 1915 on, North Dakota's history is marked by continuing adaptations to the cool, subhumid grassland environment. The most important of these have been the ever-increasing mechanization of agriculture, the enlargement of farms, the loss of rural population, and the widespread use of the automobile. After World War II came rural electrification, soil conservation, and highway construction. In the 1950s North Dakota became an oil-producing state, while the 1960s brought air bases, missile sites, and antiballistic-missile installations. National and international trends as well as internal adaptations began to influence the state as never before.

THE NATURAL AND HUMAN LANDSCAPE

Surface features. North Dakota is part of two major physiographic provinces. The eastern half belongs to the Central Lowland that stretches westward from the Appalachians, while the western half is part of the Great Plains that reach to the Rocky Mountains. The state is like three broad steps rising westward: the Red River Valley lies 800 to 1,000 feet above sea level, the Drift Prairie from 1,300 to 1,600 feet, and the Missouri Plateau from 1,800 to 2,500 feet. The highest point in the state is White Butte, at 3,506 feet (1,069 metres). The Central Lowland portion comprises the Red River Valley, a flat, glacial lake bed extending from ten to 40 miles on either side of the Red River of the North, and the Drift Prairie, a rolling country covered with glacial drift. On the west, the Missouri Escarpment separates the Drift Prairie from the Great Plains. The North Dakota portion of the Great Plains is known as the Missouri Plateau. East and north of the Missouri River, it is covered with a thick layer of glacial drift. The Altamont Moraine in this area, one of the principal flyways for migrating wildfowl, is full of potholes, lakes, and sloughs. Like the Drift Prairie, this region has a young drainage system, for rivers are few wherever the great ice sheets covered the land.

River systems

Forty-one percent of North Dakota is drained by the systems of the Red and Souris rivers, whose waters flow eventually into Hudson Bay. The Missouri Plateau and the James River system form a part of the drainage of the Missouri, which flows into the Mississippi and thence into the Gulf of Mexico. West of the Missouri River the landscape has been shaped by running water that has carried away as much as 1,000 feet of sedimentary deposits. In some places, especially along the Little Missouri River, it has carved spectacular cliffs, buttes, and valleys that form a spectacular landscape known as the North Dakota Badlands.

Climate. Its location at the centre of the North American continent gives the state a continental climate: hot summers and cold winters, warm days in summer and cool nights, low humidity and low precipitation, and much wind and sunshine. The western part of the state has lower humidity, lower precipitation, and milder winters than the eastern half. For the state as a whole, the average precipitation is about 17 inches (432 millimetres). The southwestern counties, the warmest, have an annual mean temperature of about 42° F (6° C); the

northeastern counties, the coldest, about 38° F (3° C). The growing season ranges from 134 days at Williston, in the northwest, to 104 days at Langdon, in the northeast.

Vegetation, soils, and animal life. Before settlement, 95 percent of the state was covered by grass, for low precipitation, drought, and grass fires discouraged trees. Long-lived perennial grasses begin to grow early in the spring, produce seed quickly, and go into a dormant state in drought. They protect the soil from erosion and provide food for grazing animals. The heavy grass cover of the Red River Valley and the Drift Prairie formed black soils, while the lighter grass cover of the Missouri Plateau formed lighter, thinner, dark-brown soils. The North Dakota grassland was a natural habitat for great herds of buffalo and antelope. Belts of timber and brush along the rivers provided homes for white-tailed deer, elk, and bear. Small buffalo herds today are protected in parks.

Human habitation. The regions are reflected to some degree in the character of the people. The inhabitants of the Missouri Plateau tend to be more informal and Western in their manners and dress, whereas those of the Red River Valley tend, perhaps, to be more reserved and Eastern. The Drift Prairie is a transition zone in this respect, as it is in climate and in plant and animal life.

The typical landscape of North Dakota

North Dakota is a land of large farms and ranches: a vast, open country with few fences. There is an awesome beauty in the great fields and pastures, the big sky, the endless view of flat or rolling prairie with the black earth of the plowed land, the green blanket of a new crop, or the yellow cover of ripened grain. The clean, dry air and the bright sun give a wholesome look to the land, but the large holdings, averaging more than 1,000 acres in 1970, make the countryside seem lonely and almost uninhabited. Outside of municipalities in 1970 there were only about three persons per square mile. Some 45,000 farms, more than one-half the number existing in 1933, have been absorbed since that year into neighbouring holdings.

With the loss of farm population many small towns have disappeared also, while in others businesses and houses stand empty. The larger cities and towns provide a sharp contrast, with their new stores, public buildings, and housing developments and their air of vigour and prosperity. The sparsity of population affects not only the state's economy but also the character of the people, who tend to be friendly, spontaneously helpful, and straightforward. Distances create isolation, but the electronic media now keep North Dakotans well informed about happenings elsewhere.

THE PEOPLE OF NORTH DAKOTA

Ethnic groups. When white traders reached what was to become North Dakota, several Indian peoples lived in the region: Mandans, Hidatsas, and Arikaras along the Missouri River, Chippewas and Crees in the northeast, Assiniboins in the north, Yanktonai and Wahpeton Dakotas in the southeast, and Teton Dakotas and Crows in the west. The fur trade brought Frenchmen, Scots, Englishmen, Canadians, and Americans, and, by 1800 the Métis, of mixed white and Indian ancestry were an established element in the population.

The earliest white settlers included many Norwegians, Canadians, and Germans whose people had migrated earlier to Russia. By 1890 the foreign-born constituted about 43 percent of the population, a higher percentage than in any other state; and by the census of 1920, when settlement had been completed, only 32 percent of the white population was of native-born American parentage.

Some Indians in North Dakota, like Indians in other states, form a submerged group with more than their share of poverty, ill health, and alcoholism. Others, however, have succeeded as farmers, ranchers, and professional men or in politics or sports.

Demography. After 1930, the population declined in every decade except the 1950s. The 1970 population included nearly 16,000 Indians and 2,500 blacks.

Population losses

North Dakota's birthrate is close to the national average, but for many years North Dakota had one of the lowest death rates in the nation. It would have experienced a rapid growth in population but for the heavy emigration that since 1930 has been greater than the excess of births over deaths. By 1960 nearly half of the persons born in North Dakota and still living resided in other states. Only Wyoming and Arkansas had lost a larger percentage of their natives. The lack of a diversified economy and, hence, of economic opportunities continues to account for most of this loss.

Within the state a steady migration from the farms and villages to the towns and cities has continued. The percentage of the population living in places of 2,500 or more, the U.S. minimum standard of the Bureau of the Census for "urban population," increased from about 17 in 1930 to about 45 in 1970. During the 1960s some counties in the central and western parts of the state lost one-fourth or one-fifth of their population. The four most populous counties, however, contained nearly 40 percent of the state's people. The density of the population declines to the west, as does the rainfall. Thus, in 1970 the eastern tier of counties in the Red River Valley, which contains the two largest cities, Fargo and Grand Forks, had a density of 23.9 persons per square mile; the central tier, 8.9 persons; and the western tier, 4 persons.

Religious affiliations. North Dakotans are a church-going people. Probably less than 10 percent of the population of an age for confirmation are not confirmed church members. About one-half of them are Lutherans, about one-third are Roman Catholics, and most of the rest are Methodists, Presbyterians, and members of the United Church of Christ.

THE STATE'S ECONOMY

North Dakota's cool, subhumid climate and its location far from the nation's markets have shaped its economy. Among the west north central group of states to which it belongs, North Dakota has the lowest farm income, the smallest cities, the lowest rainfall and temperature, the shortest growing season, and the least manufacturing.

Major crops

Agriculture. The state produces beef cattle, is second in the nation in production of wheat, rye, and oats, and is first in barley and flaxseed. It also sends dairy products, sugar beets, and potatoes to outside markets, from which it buys its automobiles and trucks, its farm machinery and equipment, its automotive fuels, its lumber and building materials, and its clothing and television sets and other consumer goods. In 1970 manufacturing accounted for only about 10 percent of the state's income, and its lignite, the largest supply of solid fuel in the United States, plays a minor role in its economic life. Wheat is the most important source of farm income, but the nation's annual per capita consumption of wheat flour dropped significantly during the 1960s.

Although agricultural production largely pays for the things the state buys in outside markets, it employs only about a fifth of the labour force—about 45,000 in 1970 compared to about 160,000 in nonfarm employment. Statistics on personal income show the relative unprofitability of agriculture, with governmental disbursements far exceeding farm income. In 1971 North Dakota ranked 43rd among the states in per capita income. Farming's economic disadvantages contrast sharply with its rapid increase in efficiency since World War II, with increased mechanization and the decline in number but increase in size of farms.

Other sources of income. The discovery of oil at Tioga in 1951 made North Dakota by 1970 the 14th largest producer of crude petroleum in the nation. The production of electrical power increased over 750 percent from 1950 to 1968. In the 1950s and 1960s the economy was stimulated by substantial investment of government funds in Garrison Dam, in highway construction, in rural electrification, in air bases, and in missile installations. Federal expenditures are of continuing importance in the state, which ranked sixth among all states in government payments to farmers in 1968, although the state was only 26th in cash receipts from marketings of crops and livestock.

Transportation. Intrastate and interstate traffic moves primarily over east–west and southeast–northeast routes and secondarily over north–south routes. It flows to and

from the principal trading centres within the state, the nearest metropolis—Minneapolis–St. Paul, in Minnesota—and the Pacific Northwest, with Fargo the chief centre for intrastate traffic. North Dakota's transportation network includes more than 5,000 miles of rail lines, nearly 9,000 miles of hard-surfaced and 57,000 miles of gravelled highways, and three airlines providing scheduled service to seven cities. In 1969 North Dakotans owned one motor vehicle for each 1.5 persons—only Wyoming and Nevada had a higher proportion nationally—and in 1971 the state ranked sixth in the amount spent on highways for each $1,000 of personal income.

ADMINISTRATION AND SOCIAL CONDITIONS

Structure of government. To many observers, North Dakota suffers from too much government. The state government has the usual structure: a governor who is elected for a four-year term, nine elected heads of executive departments, a bicameral legislature of 49 senators and 98 representatives, and several levels of state courts. In addition, it has nearly 150 departments, boards, and agencies, two state-owned industries, and 18 public institutions. In 1967 North Dakota ranked first among the states in number of elected officials per 10,000 population and second in local governments per 100,000 population. By 1971 almost 44,000 persons, including teachers, were employed by state and local government. In 1971 North Dakota ranked 26th in property taxes per capita, 31st in all taxes per capita, but only 43rd in personal income per capita. In the 1960s many of the state's leaders believed that the constitution of 1889, a document of detailed legislation rather than an effective framework for government, had become outmoded. In 1970 the voters authorized a constitutional convention; the new and simpler document was defeated at the polls in 1972.

Extensiveness of governmental machinery

Politics. Voting trends usually favour Republican candidates, but many voters are independent. In the 11 presidential elections from 1928 through 1968, the Republican candidate carried the state eight times, and in the 1960s the voters regularly elected a Republican majority to the legislature and a Democratic governor.

Education. In the late 1960s, 58 percent of North Dakota's high school graduates went on to college, and 17 percent to vocational school. Between 1959 and 1969 the number of school districts was reduced by nearly three-fourths, the number of one-room rural schools by nine-tenths, and the number of high schools by more than 100. The consolidation has been effective in providing better schools, but many observers feel even further reduction is necessary. Many high schools remained too small to provide adequate programs, since enrollments ranged from as few as 18 to almost 3,000.

Higher education has expanded spectacularly. Enrollments more than doubled during the 1960s in the ten state institutions. More than half were in the two universities, the University of North Dakota, in Grand Forks (founded in 1883), and North Dakota State University, in Fargo (1890), which offer a full range of undergraduate and graduate work.

Health and welfare. North Dakotans receive excellent medical care despite the small population scattered over a large area. Few people live more than a two-hour drive from one of the centres. Although some towns of less than 1,000 population have a doctor, medical practice is concentrated in the four larger cities—Fargo, Bismarck, Grand Forks, and Minot—often in group practice in well-equipped clinics. The state has 60 general hospitals, a rehabilitation centre, five regional mental-health centres, and a state hospital for the mentally ill. The state health department and smaller health districts provide public health services. Colleges of medicine and nursing at the University of North Dakota train health personnel.

Economic assistance and social services are provided by the state public-welfare board, county welfare boards, and private welfare agencies, especially denominational groups. The state welfare board gives aid to aged, blind, and disabled persons and to dependent children; it also provides eight regional social-service centres. County welfare boards administer general assistance and medical aid for the aged. Welfare assistance for able-bodied men is a minor expenditure. More than two-thirds of the funds paid to or for welfare recipients are from federal sources, while most of the remainder is from the state. Most of the money for dependent children, the second most expensive program, goes to families broken by divorce, separation, or desertion, although in the state only 36 children out of every 1,000 received such aid, compared with 75 nationally.

CULTURAL LIFE AND INSTITUTIONS

The arts. The traditional North Dakota spirit of self-reliance and voluntary cooperation, except where internal or external pressures have dictated institutionalization, is reflected in the cultural life of the state. Without a large metropolitan centre, North Dakota's cities and towns with universities or colleges provide the main cultural leadership. The three symphony orchestras have headquarters in Fargo, Minot, and Grand Forks, though they make appearances throughout the state. The North Dakota Ballet is located in Grand Forks, where in 1971 the University of North Dakota established the state's first College of Fine Arts. Most of the community art associations, public concert associations, and community theatre groups are also located in college or university towns. A summer School of Fine Arts is held at the unique International Peace Garden, a large and beautiful park that virtually eliminates the border between North Dakota and Manitoba near the Turtle Mountain area.

Interlocking educational and cultural activities

There is a fair amount of federal-assistance funding for arts projects in the state, but most other funds for the arts, apart from those expended by educational institutions, have had to come from public subscription. In 1971, however, the modest state appropriation made to the North Dakota Council on the Arts and Humanities, the agency through which federal funds for the arts are dispensed, was looked on as the beginning of a long-term state commitment to the arts.

Libraries. Among the weakest aspects of North Dakota's cultural life is library service. Because the larger part of the population lives in the country or in small villages, about half of the people have virtually no contact with library facilities. The libraries of the 13 towns with 5,000 or more population vary widely in their adequacy. Civic leaders have sought to meet the needs of the rural population with county and regional libraries. By 1968 there were eight county and four regional libraries, and 15 bookmobiles were operating. In 1969 the State Library Commission had nearly $1,000,000 to improve rural services, 80 percent of which was from federal funds.

Folk culture. Indigenous folk traditions continue within the state among the Sioux, or Dakota, peoples of Fort Totten and Standing Rock Indian Reservation, among the Plains Ojibwa (locally called Chippewa) people of the Turtle Mountain Reservation and area, and among the people of the Three Tribes—the Arikaras, the Hidatsas, and the Mandans—of Fort Berthold. Traditional music and dances, together with beadwork and other crafts, attract many art lovers. The strong, well-defined pottery of the Three Tribes is particularly sought after.

Indian arts and other ethnic activity

Scandinavian cultural traditions remain vigorous. Though none of the 50 Norwegian-language newspapers published, often briefly, between 1878 and 1955 survives, Norwegian language and literature are taught at the University of North Dakota and in several elementary schools. The Sons of Norway have more than 9,000 members in the state. Norwegian costumes, customs, and cookery are observed on many occasions but especially on Norwegian Independence Day, May 17. North Dakotans of Icelandic, Czech, and German ancestry also retain some ethnic customs, and in many families the ancestral languages are still spoken.

Recreations. The individualistic character of North Dakotans is reflected in their sports and pastimes. In 1970 the state issued more than 80,000 fishing and 200,000 hunting licenses, not counting those for taking fur-bearing animals. Snowmobiling was on the increase—18,000 new vehicles were registered in 1968–70—but ice skating, skiing, and ice hockey remained popular winter sports.

Communications. In 1971, 30 AM and 12 FM radio stations and 13 television channels operated within the state. Of the television studios, eight had local colour-production facilities. Cable television, some of it relaying Canadian and educational channels, was established in several communities. There are ten daily newspapers in the state and two semiweeklies, but the 90 weeklies are only a remnant of the nearly 350 that existed in 1915.

Prospects. In the future, North Dakota will probably see the continuation of the two most important trends of the recent past: the decline of the population in the countryside and small towns and the growth of larger geographical units to provide regional services. The first makes the second an essential consequence. As the population becomes sparser, it is necessary to enlarge administrative areas to incorporate enough people and enough potential income to insure the efficient provision of services.

The small population and relative lack of economic and political power sometimes leads North Dakotans to compare their state unfavourably with richer, more populous, and better-known parts of the world, and self-disparagement has almost become a native trait. If the winters are longer and the opportunities are more restricted than elsewhere, however, North Dakota by and large retains a cleaner environment and a closeness to and understanding of the land—qualities of life that in the 1970s were becoming increasingly longed for and sought after, especially in the crowded and polluted cities of America. How or in what direction North Dakota might contribute to satisfying these national needs and wants remains an unknown but intriguing question for the future.

BIBLIOGRAPHY. Two books serve as an introduction to the literature on North Dakota. The FEDERAL WRITERS' PROJECT, *North Dakota: A Guide to the Northern Prairie State*, 2nd ed. (1950), is a survey of all aspects of North Dakota life. Ten tours cover every part of the state and give short histories of every community. ELWYN B. ROBINSON, *History of North Dakota* (1966), is generally judged the definitive account; it covers all aspects of the state's history from the earliest times to about 1960, with more emphasis given to the trends of the 20th century. Both volumes have extensive annotated bibliographies and picture sections.

Three books deal with the flora and fauna of the state: JOHN E. WEAVER and F.W. ALBERTSON, *Grasslands of the Great Plains: Their Nature and Use* (1956); ORIN ALVA STEVENS, *Handbook of North Dakota Plants* (1950), a scientific work; and VERNON BAILEY, *A Biological Survey of North Dakota*, U.S. Department of Agriculture, *Biological Survey Bureau, North American Fauna 49* (1926).

Indian life in the early history of North Dakota is in ALFRED W. BOWERS, *Mandan Social and Ceremonial Organization* (1950). Much detail on the Indians and Métis at Pembina appears in the letters of missionaries found in *Documents Relating to Northwest Missions, 1815–1827*, ed. by GRACE LEE NUTE (1942). Two scholarly works throw some light on the Indians as they deal with related subjects: WILLIAM E. LASS, *A History of Steamboating on the Upper Missouri River* (1962); and JOHN E. SUNDER, *The Fur Trade on the Upper Missouri, 1840–1865* (1965). The conditions of tribes on the Missouri River in 1867–69 is detailed in the diary of an army officer: *Military Life in Dakota: The Journal of Philippe Régis de Trobriand*, trans. and ed. from the French original by LUCILLE M. KANE (1951). An outstanding volume on the Indians' Ghost Dance is ROBERT M. UTLEY, *The Last Days of the Sioux Nation* (1963).

A volume that carries the story from fur trade through settlement is VERA KELSEY, *Red River Runs North!* (1951).

The broadest picture of farming and farm life developments is STANLEY NORMAN MURRAY, *The Valley Comes of Age: A History of Agriculture in the Valley of the Red River of the North, 1812–1920* (1967). An intimate picture of the farming frontier is in AAGOT RAAEN, *Grass of the Earth: Immigrant Life in the Dakota Country* (1950). There are other books on social and cultural life. The story of the German-Russians is well told in ADOLPH SCHOCK, *In Quest of Free Land* (1964); while a vivid picture of farm life in the 1930s is found in *The Bones of Plenty: A Novel* (1962), and *Reapers of the Dust: A Prairie Chronicle* (1964), both by LOIS PHILLIPS HUDSON.

An excellent study of early 20th-century North Dakota political history is ROBERT L. MORLAN, *Political Prairie Fire: The Nonpartisan League, 1915–1922* (1955).

(E.B.R./B.O'K.)

Northern Ireland

The geographical position of Northern Ireland holds the key to much of its unique social, economic, and political development—a process beset by such deep-rooted antagonisms as to make the strife-torn nation globally significant by the early 1970s, perhaps because it seemed to mirror, in microcosm and in the Northern Hemisphere, many of the problems then afflicting evolving nation-states in other areas of the world. Geographic factors also help to account for the beauty of its landscapes, and its location is one of the keys to its culture and distinctive character of its peoples.

The country—created a self-governing state within the United Kingdom by the Government of Ireland Act of 1920—lies in the northeast of the island of Ireland, itself located on that western continental periphery often characterized as Atlantic Europe. Northern Ireland is often referred to as the province of Ulster (and its inhabitants as Ulstermen), though it includes only six of the nine counties which made up that historic Irish entity. It occupies 5,452 square miles (14,129 square kilometres) of land, about a sixth of the whole of the island, and is separated from Scotland, another constituent country of the United Kingdom, by the narrow North Channel, which is at one point only 13 miles wide. Historically, this channel has been a link rather than a barrier, and from the earliest times it has witnessed a constant coming and going of peoples. This interchange gave the northern part of the island a distinctive regional character confirmed during the Industrial Revolution when the province emerged as a linen-manufacturing region, and later strengthened when a shipbuilding and engineering industry, based on imported raw materials, made Belfast a major city. The intrusive influences that brought about this cultural and economic transformation were attenuated in the west and south, and the political border with the Republic of Ireland is more of a compromise conveniently based on long-existing county borders than a clear-cut regional boundary. The political separation of Northern Ireland has merely confirmed its economic position as a region existing within the framework of the United Kingdom as a whole, serving as an extension of the larger unit's industrial resources. Although the cultural links of some of the people of Northern Ireland with the republic of Ireland were still strong—and much in evidence politically—in the early 1970s, it seemed as though these ties were likely to suffer some erosion as state legislation follows economic trends, and progressively caters to educational and social needs along lines similar to those introduced in England, Scotland, and Wales (see also BRITAIN AND IRELAND, HISTORY OF; UNITED KINGDOM).

THE LAND

Relief and soils. Northern Ireland can be thought of topographically as a saucer centred on Lough (lake) Neagh, the upturned rim of which forms the province's highlands. Five of the six counties—Antrim, Down, Armagh, Tyrone, and Londonderry—meet at the Lough, and each has a highland core on the saucer's rim. To the north and east the Antrim Plateau tilts upward toward the coast. It reaches heights of between 1,000 and 1,500 feet, resulting in an impressive cliff coastline of basalts and chalk, broken by a series of the glaciated valleys known as glens, which face Scotland and are rather isolated from the remainder of the province. County Down's rounded landscape of drumlins—smooth mounds of clay left by the retreating ice of the final glaciation—is punctuated by Slieve Croob (1,755 feet [535 m]) and culminates in the Mournes, which rise to Slieve Donard (2,796 feet [852 m]) within two miles of the sea. This impressive landscape of granite peaks is bounded by Carlingford Lough to the south. Topography

Armagh's scenery is gentler, but the land rises to 1,893 feet in Slieve Gullion near the border. West of Lough Neagh the land rises gently to the more rounded Sperrin Mountains, shared by Londonderry and Tyrone: Sawel (2,240 feet [683 m]) is the highest of several hills over 2,000 feet. The sixth county, Fermanagh, is focussed geographically on its own lake basin, occupied by Lough

Erne, in a drumlin-strewn area ringed by hills more than 1,000 feet high.

Much of the Northern Ireland landscape is gentle and, in most low-lying areas, is covered with swarms of drumlins that have played havoc with the local drainage and are interspersed with marshy hollows. Glaciation also gave the land its main valleys, the Bann—draining Lough Neagh to the north—the Blackwater to the southwest, and the Lagan to the east. All of these valleys have been important routeways but none more important than the Lagan, penetrating from Belfast Lough to the very heart of Ulster.

Soils are varied. In spite of the fact that there is much glacially transported material covering the areas below 700 feet, the nature of the soil is predominantly influenced by the nature of the underlying parent rock. Brown earth soils, forming arable loams, are extensive, and are derived from the ancient Silurian rocks of Down and Armagh and from the basalts of Antrim. There are some ash-like podzols in the Sperrins, and the impeded drainage of much of Fermanagh gives acidic soil. Peat soils are common, particularly in the hollows lying between the drumlins, and hill peat is widespread over the province. Although it is of no great commercial value, peat traditionally has been a source of fuel for the peasant farmer and is still cut extensively.

Climate and ecology. Northern Ireland's climate is temperate and maritime: most of its weather comes from the southwest in a series of lows bringing the rain and cloud that often lend character to the landscape. As the country is near the central track of such lows, it often experiences high winds, and in north Londonderry and on the wild Antrim coast, particularly, severe westerly gales are common. Above the 800-foot level, distorted trees and windbreaks testify to the severity of the weather. Rainfall decreases from west to east, but the hills accentuate the amount to over 65 inches (1,650 millimetres) in the Sperrins and the Mournes, compared with 35 inches (900 millimetres) at Lough Neagh and east Down. A relatively dry spring gives way to a wet summer and a wetter winter. Conditions generally are very changeable, but there are no extremes of heat or cold. Normal temperatures vary between means of 41° and 50° F (5° and 10° C). These mild and humid climatic conditions have, in sum, made Northern Ireland a green country in all seasons.

Maritime influences

The general features of the plant and animal life of the province are similar to those in the northwest of Britain. The imprint of man is heavy on the landscape and is particularly evident in the absence of trees. Most of the land has been ploughed and drained and cultivated for centuries. Above the limit of cultivation, rough pastures have been grazed extensively and beyond them lies a zone of mountain vegetation. Only about 3 percent of the land is now under forest, and more than half of this has been planted by the state. Young trees in these plantations are economically unimportant, but locally they are helping to diversify the landscape.

Geographic regions. The geographic regions of Northern Ireland correspond closely to the main topographical elements, although they are also the outcome of the cultural evolution of the province. In Antrim and the Bann Vally, in north Down and in north Armagh, the influence of the Scots and English has been paramount. West of Lough Neagh and in the fastness of the Mournes and of Slieve Gullion or in the more distant Lough Erne region indigenous elements have maintained a distinctiveness that is still apparent. Such relatively isolated pockets as the Antrim glens and Kilkeel have retained a local consciousness that gives colour and interest to the human geography of the province.

Settlement patterns. The overwhelming impression of the province's landscape is of scattered and isolated farms. Occasional relics of tiny hamlets, or clachans, show that peasant crofts once were huddled together in kinship groups who worked their strips in an open-field system. Between the end of the 18th century and the middle of the 19th most of the land was enclosed and the scattered strips consolidated, partly as a policy of the landlords but finally because of the effect on the population of the potato famines of the 1840s. The end result was the orderly, small square fields of today dominating the contemporary landscape. Some landlords rearranged their tenants' land in narrow ribbons, from valley bottom to mountain pasture, giving a characteristic ladder of fields, with the farms strung along the road on the valley side. Drumlins also have had an effect on siting; houses are found away from the peaty bottom but below the windswept skyline. Most farmhouses are small and a few are still thatched. The occasional larger farm often has a Georgian house—simple and dignified and a reflection of the age of consolidation.

Small market towns rather than villages are frequent. Built by the English and Scots planters or by the landlords of the 18th century, they have a foreign touch of orderliness and urbanity. Many are grouped around a "diamond" (meeting place), or square, which is used as a marketplace. Some of them acquired a mill in the 19th century, but in few cases has this marred the essentially rural context.

Market towns

Few of the market centres have grown into substantial towns. In the western half of the province, regional services and administration have enlarged Omagh (12,000 population) and Enniskillen (6,500). Some towns have grown with the introduction of industry, notably Dungannon (7,500), specializing in fabrics, and Carrickfergus (15,000), noted for rayon. Armagh (12,000) is an ecclesiastical centre with two cathedrals, while Lisburn (29,000), Portadown (21,000), and Lurgan (24,000), all in the Lagan Valley, form an extension of the Belfast industrial complex, their size based on the textile industry. Bangor (35,000) is a resort and a residential outlier of Belfast. Londonderry (52,000) is a centre for shirtmaking and textiles. It was formerly the centre of the Lough Foyle lowlands until the hinterland that it served was split by the partition of Ireland, but it still remains the main focus of the west. The size of Belfast (359,000), at the head of Belfast Lough on the northeast coast, underlines its dominance of the region, as well as its significance as an industrial centre and major port. Its economic bases are linen and engineering and, notably, shipbuilding; textile machinery is also important, and the city is the centre of provincial government, finance, and education. Reflecting the city's 19th-century origin, most of the streets are inextricably and bleakly mixed with mills and factories, while the reclaimed land at the head of the Lough is given over entirely to industry.

THE PEOPLE

Cultural origins. The cultural differences that underlie many of Northern Ireland's contemporary social problems have a long and troubled history. The province has had lasting links with parts of western Scotland, strengthened by constant population movements. After the Tudor invasions and particularly after the forced settlements, or plantations, of the early 17th century, the English and Scots elements were further differentiated from the native Irish by virtue of their Protestant faith. Two distinct and often antagonistic elements—the indigenous Roman Catholic Irish and the intrusive Protestant English and Scots—date from that period, and have played a significant role in molding the province's development. The intrusive element dominated County Antrim and north Down, controlled the Lagan corridor toward Armagh, and also formed powerful minorities elsewhere. This situation contributed to the decline of Gaelic speaking, and it is reflected in the contemporary distribution of religions (see map.) Even a century ago Gaelic speaking was confined to the more remote mountain areas—the Sperrins, south of the Mournes, and the glens of Antrim. By the 1970s these areas had been reduced to the merest pockets where Gaelic may still occasionally be heard at a traditional entertainment. The accents given to English, however, are regionally distinctive. The northeastern dialect, dominating Antrim, Londonderry, and parts of Down, is an offshoot of central Scots dialect and reflects the latter in almost all of its features. The remainder of the province, including the Lagan Valley, has accents

Dialects

derived from England, more particularly from Cheshire and southern Lancashire, and the "west country" counties of Gloucester, Somerset, and Devon. The towns show more of a mixture and an overlay of standard English.

Distribution of Roman Catholics in Northern Ireland.

Some 35 percent of the population is Roman Catholic, 30 percent is Presbyterian, and some 25 percent Episcopalian (Church of Ireland), Methodists and members of other sects making up the remainder. The distribution of Roman Catholics and Protestants is, however, very uneven. In country districts, the latter are in a majority in Antrim, north Down, and the Lagan Valley, and in north Armagh. Elsewhere, they are in a minority, though fairly highly localized. Most towns have a Protestant majority: this is the case in Belfast, where Roman Catholics comprise only 30 percent of the population. Towns remote from Belfast—Newry and Londonderry—have higher percentages. In the towns there is a high degree of segregation of the sects and mixing is minimal. Industrial west Belfast is split into two sectors along two axial roads. The Falls Road is as exclusively Catholic as the Shankill Road is Protestant. In many streets adjoining the boundary line segregation is 100 percent. East Belfast has an exclusively Catholic core. In the middle class suburbs segregation is less apparent. Segregation increases as socioeconomic status decreases. Civil disturbances are almost confined to where segregation is highest. The proportions of the sects are changing slightly because of a differential in birthrate. In Belfast, for example, fertility ratios in Catholic districts are very much higher than in Protestant areas. The situation in the province is reflected in the relative decline of Protestants in the last half century, though more or less stable in absolute numbers, and the relative and absolute increase of Catholics. In 1926 the relative percentages were as follows: Roman Catholics 33.5, Presbyterians 31.3, Church of Ireland 27.0. In 1961 the corresponding figures were 34.9, 29.0, and 24.2. But this is unlikely to change the total predominance of Protestants in the province for some time to come.

Demographic trends. The population of Northern Ireland was 1,525,000 in 1971, having grown steadily over the previous half century: it has been estimated that it will probably increase to about 2,000,000 by the year 2000. In 1971, 30.1 percent were under 15 years of age, 54.5 percent were between 15 and 60, and 15.4 percent were 60 and over. The birthrate, which has been falling very slightly since 1965, was 21.1 per 1,000 in 1970, higher than in the remainder of the British Isles. The deathrate in 1970 was 10.9 per 1,000, lower than in the remainder of the British Isles. Marriage rates (8.1 per 1,000) were a little lower than in England, Wales, and Scotland, but fertility rates were considerably higher. In spite of a rate of natural increase running about 17,000 per annum between 1966 and 1970, there was a net outward migration of 6,901 per annum during the 1960s, a little less than the average in the previous decade. Inside the province, some movement from the countryside to the towns is having an effect on the distribution of population. The two eastern counties, Antrim and Down, contain the bulk of the population, with their residents totalling over 650,000 (excluding Belfast), as compared to 490,000 in the west (excluding Londonderry). These two counties are also gaining considerably in population, whereas the others are making only very modest gains, and Fermanagh actually lost population between 1961 and 1966. The countryside also is losing people to urban areas. The apparent slight increase in the rural population is due mainly to urban overspill, and the gross number in the countryside is still less than it was in 1901. On the other hand, some towns have grown considerably. Although there has been comparatively little change in some of the smaller and medium-sized towns—Newry and Newtownards, for example, have lost marginally—most of the industrial centres grew rapidly between 1961 and 1971: Lisburn from 17,700 to 28,904; Portadown from 18,609 to 20,577; Lurgan from 17,872 to 23,853; and Larne from 16,350 to 18,219. Belfast's apparent decline since 1951—from 443,671 to 358,991—reflects its growth outside the borough boundary, much of which is now accommodated in the contiguous new town of Newtownabbey (57,846). Increasing urbanization is most marked in the metropolitan zone existing around Belfast, for more than 500,000 people are now concentrated in the Lagan Valley. The key to this trend lies in the area's industrialization, and it is likely to continue to attract population. The projected city of Craigavon, when complete (it is expected to house 100,000 people by 1981), will further emphasize the importance of this corridor, of which the concentration of people dominates the economic, social, and political life of the whole province. Outside it, the second largest town, the county borough of Londonderry (52,000), is only a weak countermagnet, and there is little to balance the overwhelming dominance of Belfast. The future development of Coleraine (14,851) as a university town may well stimulate a greater range of urban services and a diversification of activities that will give a fillip to the western part of the province.

Urbanization

THE ECONOMY

Economically, Northern Ireland is an integral part of the United Kingdom. Its trade is dominated by imports from the United Kingdom (73 percent of the total) and exports to the United Kingdom (86 percent), though some of the latter are re-exported directly from England, or are the bases of manufactured goods that are subsequently exported. Trade with the Republic of Ireland accounts for about 8 percent of the total, and there are lesser links with parts of the Commonwealth and of Europe.

Compared with its southern neighbour, Northern Ireland is an industrialized country; and the mass of its exports is made up of manufactured goods. This situation, however, has placed a heavy reliance on the import of raw materials, and the Belfast region might well be thought of as an extension of the industrial regions of northwest England and the Clyde. Its own mineral resources are extremely meagre: the amount of coal mined locally is quite negligible, although local chalk, clays, and gravels are used to produce lime, bricks, and cement. Northern Ireland's power resources, too, depend on imported coal and oil.

Agriculture. Northern Ireland does possess considerable agricultural resources, which it is developing as a

major part of its economy. Fundamentally, it is a country of peasant farmers; the great majority of farms are still under 30 acres, and only about 5 percent exceed 100 acres. By the early 1970s, however, this situation was changing. The number of farms—approaching 37,000—was decreasing by some 3 percent per annum, with a substantial increase in average size, which now exceeds 50 acres. Consolidation has meant a better livelihood for fewer farmers, whose total numbers dropped from over 100,000 to under 83,000 over the 1960s. Even so, only half the farms were economically viable, and many were operated on a part-time basis. Almost all farms now have electricity, and there has been a great increase in the numbers of tractors and combine harvesters in use. The frequent rain, the high humidity, and the prospect of wet harvests discourage arable farming, but local conditions produce good grass and rich pasture: nearly all grassland is ploughed and there is very little "rough grazing." Mixed farming predominates, with a seven-year rotation —four years of grass or hay, two of oats, with a root crop, such as potatoes, intervening. About 85 percent of farming income comes from livestock and their produce. By the 1970s, there were well over 1,000,000 cattle, nearly 1,000,000 sheep, 1,000,000 pigs, and 12,000,000 poultry in the country. The production of grass seed and seed potatoes for export is also important. To the south of Lough Neagh lies a rich orchard country, and apples and market gardening are constant features of the landscape of north Armagh.

Consolidation of farms

Miscellaneous manufactured goods	55	7	224	30
Total	829	100	745	101

Industry. Although farming dominates the landscape of the country, it provides a livelihood for only one in ten of Northern Ireland's inhabitants, and the real wealth lies in manufacturing. More than 58,000 people work in the engineering, shipbuilding, and vehicle trades, and nearly 50,000 in the textile industry. Locally grown flax and a plentiful supply of soft water originally stimulated the growth of the textile industry, and spinning still flourishes in many inland towns. The other industrial group is more a product of foresight, as raw materials, capital, and even skills were drawn into Belfast to make it possible.

Flax is now imported, and linen is still synonymous with Northern Ireland, though cotton and artificial fibres, as well as woollen fabrics and carpets, are now important. The clothing industry employs a further 28,000 people. Although all these activities are dominated by Belfast, Londonderry is well known for shirt and pajama manufacturing. Belfast's shipyards are world-famed, and some of the skills developed there have been diverted into the aircraft industry. Engineering grew largely to meet the demands of the textile and shipbuilding industries. Belfast also has chemical plants, rope-making factories, and a large percentage of the food-processing work of the province; tobacco also plays a leading role.

The industrial structure of Northern Ireland is a vulnerable one, and unemployment in the province is considerably higher than in the remainder of the United Kingdom, fluctuating between 6 and 9 percent of the labour force, with a much higher rate among men than women. For over two decades the government has actively encouraged the growth of manufacturing and such economic diversification as broadening the base of the textile industry by introducing man-made fibres. A series of govern-

ment acts has tempted new enterprises into the country by providing factory space and making grants toward capital expenditure. In 1964 an Economic Council, not unlike the regional economic planning boards of the United Kingdom, was set up, and a second development program was initiated for 1970–75. In relation to the remainder of the United Kingdom, Northern Ireland is peripheral and partially isolated. This adds to the difficulty of maintaining local growth. The organization of labour is strongly oriented to Britain: local trade unions are affiliated to the Trades Union Congress, but, in fact, a vast majority of the 228,000 members belong to English- or Scottish-based unions. About 15,000 workers are members of unions controlled from the Irish Republic.

Development programs

Northern Ireland is unified fiscally with the United Kingdom. Its public revenue comes from two sources. Death duties, stamp duties, motor vehicle taxes, and betting duties are collected locally, but customs and excise duties, income tax, and surtax are collected by the United Kingdom with a Joint Exchequer Board deciding the province's share, as well as its contribution to certain United Kingdom services, such as the armed forces, and its share toward paying off the national debt.

TRANSPORTATION

One of the more noteworthy features of the countryside of Northern Ireland is a close network of well-maintained roads, totalling in all some 14,200 miles. The majority are very minor, with over 8,000 "unclassified," but, even so, all parts of the province are accessible. Over 1,000 miles of the roads are first class and 344 miles are trunk roads. There are some 40 miles of motorway linking Belfast with northern Armagh. Public-road transport outside the Belfast municipal service has been nationalized since 1935, and since 1948 the Ulster Transport Authority (since 1967 the Northern Ireland Transport Holding Company) has also controlled the railways. The latter have diminished rapidly—from 824 miles to 200 miles—in the economic reorganization following railway nationalization; a link with Londonderry through County Antrim, and the line to Dublin, via Newry, were all that remained by the early 1970s. Inland waterways have almost disappeared, although a little commercial traffic still uses the lower Bann navigation to Coleraine, and there is some recreational sailing.

The province's links with Britain by sea and air are of paramount importance. Belfast is one of the major ports of the British Isles, handling between 6,000,000 and 7,000,000 tons of shipping and freight annually by the 1970s. Its eight miles of quays now contain modern container-handling facilities. Londonderry and Larne, the only other ports of significance, both handle over 1,000,000 tons of freight annually. Newry and Coleraine handle cargo, but Warrenpoint is likely to have improved facilities, which will replace those of Newry. Larne and Belfast handle passenger transport. The former has services to Stranraer, Ardrossan, and Preston, the latter, to Liverpool, Ardrossan, Preston, Heysham, and the Isle of Man. All services handle car ferries, an important factor in the province's increasing tourist trade; and the Stranraer and Heysham routes also carry mail. The main

civil airport for Northern Ireland is at Aldergrove, which has regular daily air service to major cities in Britain, and, since 1968, scheduled flights to North America. Passengers total over 1,100,000 a year.

ADMINISTRATION AND SOCIAL CONDITIONS

Constitutional framework. Under the Government of Ireland Act (1920) separate parliaments were planned for both northern and southern Ireland, but the plan became effective only for the north, where a Parliament was formally opened in 1921. When the Irish Free State emerged in 1922, Northern Ireland opted to continue its form of government, which was marked by strong ties with the central government of the United Kingdom at Westminster; a commission eventually confirmed a boundary with the south that would contain the six counties. When the Irish Free State seceded from the Commonwealth in 1949, the union of Northern Ireland with the United Kingdom was further confirmed. Paradoxically, its measure of self-government is the result of its determination to preserve union with Britain, and its links with London are safeguarded by the election of 12 members to Westminster.

Political links with the United Kingdom

Until 1972, the crown exercised all legislative power in Northern Ireland through a governor who held office for six years. The Parliament consisted of a Senate and a House of Commons. The former had 24 members elected by the Commons for eight years, and the lord mayor of Belfast was an ex officio member. The House of Commons had 52 members and a maximum life of five years, and in all ways was closely modelled on Westminster, which was responsible for matters relating to the crown, war and peace, the armed forces, and foreign powers, as well as trade, navigation, coinage, and many others. Northern Ireland could make no laws interfering with religious equality. In almost all internal matters it followed Westminster policy. There is universal franchise above the age of 18.

Local government is also derived from the pattern in England and Wales. There are six county councils besides Belfast County Borough Council—all responsible, among other things, for education, health, and welfare. The nine borough and 24 urban councils are responsible for sanitation, housing, planning and development, and care of towns in general, while the 26 rural councils are mainly sanitary and housing authorities. Craigavon has an independent Development Commission, as has Londonderry, but local councils are elected. From 1971, voter eligibility in local elections was to be determined in the same way as for parliamentary elections.

Political developments. Politics since the country's inception has been dominated by the issue of union or separation, and this split has followed religious lines. Protestants have been Unionists, and have always had a majority in Parliament. Roman Catholics have supported the Nationalist Party, advocating reunion with the Republic of Ireland, and have always been in opposition. The Labour Party has made some impact in representing labour, irrespective of religious affiliation. Northern Ireland entered the 1970s with 36 Unionist members of Parliament, six Nationalists, three Independent and unofficial Unionists, three Independents, two Northern Ireland Labour, and two Republican Labour. Electoral geography follows almost exactly a map of the distribution of religious majorities (see map), the west being a stronghold of Nationalism, the east of Unionism: the concentration of people in and around Belfast has assured an overall Unionist majority. Periodically, political and religious antagonisms have flared into civil disorder, most severely in 1921–22, but, since 1968, they have flared again. The main issues were discrimination in housing and employment, and the fact that franchise for local government, based on property ownership, favoured Protestants. Differences rose in the Unionist Party on the speed with which reforms should be pressed, giving rise to protests against the alleged dilatoriness of social reform against a background of economic insecurity. The early stages of recent civil disobedience partly ignored party lines, but continuing violence tended to restore the established religious split, which, accompanied by increased terror, led the British Parliament to suspend Northern Ireland's Parliament and government (March 1972), and place the country under direct rule from London. In March 1973 the British government outlined future proposals to be implemented in a new constitution. They included: the pledge of continued union with the United Kingdom, as long as this was the majority wish; a Northern Ireland Assembly of 80 members to be elected by proportional representation; departmental committees reflecting the religious balance of a province; and a guarantee of no religious discrimination. Earlier, 57.4% of the electorate had voted for a retention of the border and 0.63% against: 41.4% had not registered a vote.

Religious antagonism

The judiciary and civil order. The Supreme Court is under the Parliament of the United Kingdom. Under the chairmanship of the lord chief justice a High Court of Judiciary and a Court of Appeal hold assize courts in the county towns and also sit as a Court of Criminal Appeal. There are also locally administered county and magistrate courts.

Civil order, increasingly controversial in the 1970s, is maintained by the Royal Ulster Constabulary (RUC), which replaced the Royal Irish Constabulary in 1922. In 1971 the RUC consisted of approximately 4,000 officers. Because of the sporadic outbursts of unrest since Northern Ireland came into being, the RUC has been assisted by a volunteer part-time Ulster Special Constabulary. Permanent special constables known as category A disappeared early, and the reserves (category C) were no more than a list: but the "B Specials" number about 8,000. A 1970 act authorized the reorganization of the entire police force under a police authority and the formation of a Royal Ulster Constabulary Reserve to replace the B Specials, whose use had engendered considerable controversy. By 1972, regular British Army troops had entered the country to quell the civil strife.

Services. The social services in Northern Ireland are very closely patterned on those of the United Kingdom, although there is sometimes delay in implementing policy, partly because of historic inertia, and partly because of the dual nature of the society. Nowhere is this more apparent than in education. The 1947 Education Act parallels the 1944 act of England and Wales, but its implementation is hampered by the traditional tenacious denominational control of education and the general reluctance to abandon it. By 1970, a little fewer than half the 1,240 or so primary schools were still under voluntary management, a situation that reflected the religious division. Only 21 of the 81 grammar schools were under the control of county authority. The 80 voluntary county secondary schools are rapidly becoming maintained schools; that is, obtaining most of their financial support from a local authority, together with a measure of public representation on their managing bodies. Northern Ireland has three teachers' training colleges—one of which is nondenominational—and two universities. The Queen's University, established in 1845 as one of three in Ireland, has had a charter since 1908, and in the early 1970s had over 6,500 students; the New University of Ulster at Coleraine (1968) anticipated a student enrollment exceeding 2,000 by 1973.

Denominational education

In health services, as in education, Northern Ireland follows the United Kingdom. The Queen's University has a large medical faculty that supports the health service's 93 hospitals and 18,000 beds. Ulster is also known for its export of doctors and nurses.

As in other regions of Britain, one of the major social problems in Northern Ireland is housing. There is a legacy of much poor rural housing in the countryside, exacerbated by the isolation of many of the small dispersed farms, while in Belfast the province suffers from a grim legacy of 19th-century industrial housing. In the quarter century following World War II, some 40 percent of the houses of Northern Ireland were replaced, rehousing about 600,000 people. A third were privately built, and the remainder were constructed by local authorities and the Northern Ireland Housing Trust. This replacement and growth has not been subject to planning legislation in

the same way as in England and Wales, although some controls have recently been introduced. In 1963 a regional plan proposed a "stop line" for Belfast's growth, and in 1965 a New Town Act was passed. This resulted in the establishment of the town of Craigavon, linking and incorporating Lurgan and Portadown in a linear design. In 1966 Antrim was designated a new town, with its population scheduled to increase from 8,000 to 30,000, and in 1967 Balleymena was similarly designated for a growth from 15,000 to 50,000. In 1967, too, the Londonderry Development Commission took over the future of that city. The central coordination of all planning, though proposed in 1964, had not materialized by the early 1970s.

Living standards. Social conditions and standards of living in the province have not yet entirely overcome a rural tradition of subsistence farming and low cost of living. Nor has this been offset by conditions among industrial workers, whose employment, as a result of the province's peripheral status in the United Kingdom economy, has felt every depression early and has always been slow to recover. High unemployment and more marked differentials between skilled and unskilled workers' wages have aggravated social problems. Generally speaking, although the standard of incomes and living in Northern Ireland and in England and Wales is roughly comparable, there are still many in Northern Ireland who do not achieve those standards.

Unemployment

CULTURAL LIFE

In the arts and in cultural life generally it is difficult—as is the case with most aspects of life in Northern Ireland—to distinguish between native and imported. Few traces remain of any culture predating the Protestant Ascendancy: the occasional *caley*, or traditional Irish group entertainment, is only the faintest echo of a past that faded with the language. Gone, too, are the strolling players and rhyming weavers. Folk participation and recreation are periodically focussed on religious ceremonies and processions—colourful, noisy, and (in recent years) tragically violent demonstrations of sectarian feelings. This fundamental division has also given rise to the nearest approach to folk art, the painting of William of Orange crossing the Boyne, a deeply symbolic representation, adorning the gable end of many a Protestant terrace. In the name of religion, paint, bunting, flags, and arches briefly splash colour over drab grey streets.

In other respects, the cultural milieu of the province is one shared with the remainder of the British Isles and has few distinctive regional characteristics. With the exception of a few country mansions—a legacy of 18th-century English architects—the buildings of Northern Ireland are undistinguished, though this same influence has lent a dignity of proportion and urbanity to some larger farmhouses and to the occasional terrace of houses in the towns. For the most part, however, the industrial growth of the 19th century has completely overshadowed the previous planned phase of growth without contributing any buildings of distinction. It remains to be seen how far larger projects—university buildings and hospitals, for example—have improved the situation, but on the domestic level the Northern Ireland Housing Trust, responsible for rehousing outside urban limits, has made a considerable contribution to both the design and the grouping of houses.

Arts and music

Northern Ireland has an Arts Council, which successfully encourages all aspects of the arts. Its activities tend to be concentrated in Belfast because this city alone can provide for ballet and opera. Belfast also has two theatres; and drama, much of it local, plays a large part in the recreational life of the city. Music is mainly imported, but the city has a symphony orchestra and a youth orchestra, and in the last decade it has fostered one of the largest festivals in Britain. The council also sponsors art exhibitions. Belfast has a permanent gallery, and so does Londonderry, though some exhibitions tour the entire province. The 19th century saw little development in the visual arts, but a new interest in landscape emerged briefly at the beginning of the 20th. A provincial school of painting may now be emerging for the first time and some recognize a school of poetry. But the province is only slowly shaking off the utilitarian, no-nonsense approach to life that underlay its Victorian growth.

The British Broadcasting Corporation has a monopoly in sound broadcasting, but Ulster Television, Ltd., representing the Independent Television Authority, vies with the British Broadcasting Corporation. Northern Ireland also shares the British press: all the national papers are distributed in the province, which also has two morning, one evening, and one Sunday paper. More local news is handled by more than 40 weekly papers.

The Ulster Museum provides an interesting link with peasant origins in Northern Ireland, for one of its most promising aspects is an open-air folk museum, first opened in 1964. This is another reflection of an appreciation of the past that is also shown by the state's care of ancient monuments, both historic and prehistoric.

Of other cultural institutions perhaps the most notable is the observatory at Armagh. Founded by Archbishop Robinson in 1790, it has remained an independently governed institution, though now considerably state-aided. It has links with observatories in South Africa and also has one of the few astronomy libraries in the British Isles.

PROSPECTS

One of the attractions of Northern Ireland is that it is rich in tradition: its tragedy is that it cannot forget its history. Its social problems are an inheritance from its past, aggravated for many by uncertainty of employment and by insecurity. Its stability depends as much on economic prosperity as on religious equality, both necessary conditions for the continuing development of those qualities that have given the province a distinctive personality and of which the Ulsterman is justly proud.

BIBLIOGRAPHY. E. JONES (ed.), *Belfast in Its Regional Setting* (1952), is a general historical, geographical, and social introduction to the province. L. SYMONS (ed.), *Land Use in Northern Ireland* (1964), and R. COMMON (ed.), *Northern Ireland from the Air* (1964), are more strictly geographical. A brief but masterly summary is E. ESTYN EVANS, "The Personality of Ulster," *Trans. Inst. Br. Geogr.*, 51:1–20 (1970), and the character of one part of the province is admirably portrayed in the same author's *Mourne Country* (1951). The best background to the cultural and political history of Ulster is M.W. HESLINGA, *The Irish Border as a Cultural Divide* (1962). D.P. BARRITT and C.F. CARTER, *The Northern Ireland Problem* (1962), deals with the social and political prelude to the current situation; and T. WILSON, *Economic Development in Northern Ireland* (1965), provides the economic background. R. MATTHEWS, *Belfast Regional Survey and Plan, 1962* (1964), looks at possible future developments. The details of the capital city are dealt with in E. JONES, *A Social Geography of Belfast* (1960), which discusses the historical and environmental background to the social situation. Useful factual material is found in the *Ulster Year Book* (annual), as well as in the Census reports for 1961 and 1966.

(E.J.)

Northern Territory

The central section of northern Australia, the Northern Territory is bounded on the north by the Timor and Arafura seas, and by Western Australia to the west, Queensland to the east, and South Australia to the south. It is approximately 1,000 miles (about 1,600 kilometres) from north to south and 600 miles (about 1,000 kilometres) from east to west. Its area is 520,280 square miles (1,347,519 square kilometres)—17½ percent of the Australian Commonwealth. It is largely tropical. The population in 1971 was estimated at 85,500—only 0.67 percent of the Australian population.

Constitutionally, the territory is inferior in status to the states, and it has very limited legislative powers. Its development since 1911, when it was transferred from South Australia, has been a major item of expenditure in terms of works, services, and inducements to producers to accept the risks of an uncertain physical and economic environment. The nature of the climate, the poor soils, distance from assured markets, and problems of recruiting labour have been considerable handicaps.

The landscape. The unspectacular coastline is flat with low headlands and is mostly fringed with mangrove swamps. There are many offshore islands, of which Melville and Bathurst islands and Groote Eylandt are the largest. Inland from the coastal belt there is a gradual rise to the town of Tennant Creek (1,229 feet, or 375 metres) on the vast Precambrian plateau (1,000–2,000 feet) that extends south and west into the neighbouring states. Farther south, Alice Springs (1,790 feet, or 545 metres) is situated on an alluvial plain in the Macdonnell Ranges, of which Mt. Zeil (4,955 feet, or 1,510 metres) is the highest point in the territory. There are some remarkable tors 200 miles southwest of Alice Springs: Mt. Olga (3,507 feet, or 1,069 metres) with 30 separate domes, and Ayers Rock (2,845 feet, or 867 metres), a red, ovoid monolith rising 1,100 feet.

A number of rivers, of which the Finke and the Todd are the largest, flow from the central ranges after rainstorms. Areas north of the plateau are drained by some substantial rivers: the Victoria, 350 miles long, and the Daly, 225 miles long, flow to the Timor Sea; the Katherine flows southwest from Arnhem Land to join the Daly; the Adelaide, Mary, and South and East Alligator rivers enter Van Diemen Gulf; and the Roper and the McArthur flow east and northeast into the Gulf of Carpentaria.

Vegetation and animal life. Some forests with Indo-Malaysian vegetation elements exist in Arnhem Land, but otherwise the northern vegetation is open woodland with low eucalypts and tall grasses of low nutritive value. In the main cattle areas of the Victoria River Downs and the Barkly Tableland, an open-tussock grassland on heavy, gray-brown cracking soils is dominated by Mitchell grass with subdominant Flinders grass and herbs. Between the Barkly Tableland and the ranges a wide belt of pervious sand supports only spinifex. In the Alice Springs district the rocky hills carry spinifex, but on the light-textured soils of the lower slopes and valleys an association of mulga (an acacia tree) with short grasses is a valuable fodder resource. Mixed mulga-spinifex scrub with seasonal herbs and ephemerals occupies the nearby red plains of desert loam, and farther to the west is a desert of hummock grassland composed of widely spaced clumps of spinifex and *Plechtrachne*.

Higher plants exceeding 5,000 species are represented. Species endemic to the Macdonnell Ranges include a cycad, *Macrozamia macdonnellii*; a palm, *Livistona mariae* —a surviving representative of the vegetation that once covered central Australia; and several acacias and eremophilas. A broad-leaved species of mulga, the witchety bush, harbours a grub much sought by Aborigines as food. The baobab tree, with a girth of 30 feet, occurs near the Victoria River.

Exotic animal life

Principal birds are the princess parrot of the central, rocky spinifex country, the flock pigeon of the grasslands of the Barkly Tableland, and lorikeets, parrots, and rock pigeons in rugged areas of the north. The black-banded pigeon is known only in the western escarpment of Arnhem Land. Mammals include one of the egg-laying species—the echidna—and a variety of marsupials. The kangaroo is widely distributed, but some species have restricted habitats: the rat kangaroo is adapted to the arid regions; the rock wallaby and antilopine wallaroo inhabit the rocky ridges of the northwest; and the black wallaroo is restricted to the granitic ranges of Arnhem Land. The unique rock-haunting ring-tailed opossum is an interesting evolutionary development. Formerly domestic animals now existing as large wild populations include camels, buffalos, cattle, pigs, goats, horses, and donkeys. With the exception of the buffalos, which are hunted for hides and meat, these are serious pests. The cattle tick also causes great economic problems.

Climate. There are two seasons: a wet summer, from November to April, and a dry winter. Rainfall is extremely variable and of marked summer incidence. The change from the north, where the annual rainfall is 60 inches, to the southeast, where it is only 5 inches, reflects the diminishing influence of the Australian-Asian monsoon and an increasing dependence on tropical thunderstorms. Only 30 percent of the territory has an annual rainfall of between 15 and 40 inches—the effective limits of agricultural development. The climate is hot and, in the north, uncomfortably humid for eight months of the year. Mean temperatures at Darwin are 84° F (29° C) in January and 76° F (24° C) in July, and at Alice Springs 81° F (27° C) in January and 53° F (12° C) in July. The north is free from frosts.

Patterns of settlement. The pastoral potential of the territory was first recognized during construction of the Overland Telegraph Line, and on its completion, in 1872, areas near Alice Springs and Darwin were stocked with cattle. The establishment of cattle stations on the Barkly Tableland during the 1880s completed the foundations of the pastoral industry. The land is rented from the government, and in 1969–70 there were 322 such holdings. Tenure of pastoral leases is normally 50 years, and the covenants stipulate conditions of maintenance and improvement. These have been minimal, and inadequate safeguards against ill-advised practices of absentee leaseholders have caused great damage to vegetation and extensive soil erosion. Annual rentals are low; on a typical property it was 30 Australian cents per square mile in 1960; this was reappraised at 76 cents in 1970.

The two traditional regions

The territory is traditionally viewed as two regions, roughly delineated by latitude 20° S and commonly referred to locally as the North and the Centre. The two areas differ in topography and climate and represent the spheres of interest of Darwin and Alice Springs. As natural outlets for cattle and mineral concentrates from their respective regions, these centres have developed rapidly, and in June 1970 accommodated 60 percent of the total population. Little urban growth has occurred elsewhere: Tennant Creek and Katherine have urban populations, but there are only four other groupings of more than 20 dwellings.

The people. *Demography.* During the gold boom at Pine Creek in 1872, labour problems led to the engagement of Chinese from Singapore, and by 1881 the population comprised 670 Europeans and 2,781 Chinese. By 1888, when immigration restrictions were imposed, Chinese numbered about 6,000. Subsequent immigration was mostly European, and at the 1966 census the population of 56,504 was 60 percent European, 37 percent Aboriginal, with 3 percent of some 20 other groups. (The racial statistics, based on self-assessment, are only of approximate accuracy.) The increase of 29,000 to June 1971 was predominantly European. Nearly 80 percent of the whites are of Australian birth. Age structure and other population characteristics are typical of Australia. Of the 80 percent claiming to be Christian, one-third is of Catholic and two-thirds of Protestant faith. In 1966, 39 percent of the population was under 21 and 77 percent under 40 years of age. There were 122 males to every 100 females. Whereas most of the white population is concentrated in the towns, about 86 percent of the Aborigines live in rural areas or in the 15 Aboriginal reserves, which total 94,196 square miles.

In 1970 the birth rate was 36.5 and the death rate 8.5 per 1,000 persons. Infant mortality was 48.4 per 1,000 live births, with greatest incidence among Aborigines. The rate of growth of population was 4.9 percent in 1970; most of this increase was at Darwin. Internal movements are small but might be expected to increase as new centres develop. The new town of Nhulumby, for example, was planned to accommodate 5,000 persons associated with a bauxite project upon its completion by 1974.

The Aborigines. Few Aboriginal tribes are wholly nomad. Many have retained their tribal structure and their customs and religious rituals that govern their social relationships. Their religious and magical rites draw on a rich repertoire of songs and dances in which sacred objects and personal adornment play an important part. These are accompanied by a variety of musical instruments. Tribes and dialects are very numerous. Languages are of the agglutinating type; *i.e.*, they combine into single words two or more elements of distinct and separate meaning. Though many of the languages have characteristics in common, the prefixing languages of the north are basically different in structure and vo-

Aboriginal languages

cabulary from the Aranda languages of the south. Many tribes have permitted in the main their languages and religious rites to be placed on permanent record. Government policy on Aboriginal welfare is one of assimilation, promoting their participation in the privileges and responsibilities of citizenship so that they may become an integral part of the Australian way of life.

The economy. *Agriculture and mining.* The traditional dependence of the economy on cattle raising has been substantially changed since 1966 by developments in mining and other primary industries. Agricultural production was small and related to local needs, until, in 1969, 3,000 tons of grain sorghum was exported to Japan. Seven companies commenced prawn fishing and processing in 1969, and in the first year of operations 6,000 tons valued at A$4,900,000 was exported. Pastoral production is confined to beef cattle, grazed largely under open range conditions. In 1969–70 cattle numbered 1,185,000—6 percent of the Australian total. Of the 247,000 cattle marketed, 177,000 were distributed to three states for fattening; the rest were processed by meatworks and slaughterhouses at Katherine and Darwin for export to the United States for use as hamburger and sausage meat.

Income from mining was A$5,500,000 in 1964 and close to A$39,000,000 in 1970. Mining of iron ore at Mt. Bundey and Frances Creek (near Darwin), and of manganese ores at Groote Eylandt (an island off the east coast), commenced in 1965–66. During 1969–70 more than 1,000,000 tons of iron ore was exported to Japan, and most of the manganese ore, valued at $10,800,000, was exported to Europe, Japan, and the United States. Copper and gold ores are mined chiefly at Tennant Creek. A plant with an annual mining capacity of 400,000 tons commenced production from a newly discovered copper–gold ore body in 1971. On the Gove Peninsula (northeast) a large alumina–bauxite project with a planned output of 1,000,000 tons annually is well advanced and should be operational by 1974. Extensive lead–zinc deposits near the McArthur River and at Woodcutters, near Darwin, are being evaluated by several companies.

Manufacturing and services. Secondary industries are small service industries meeting local needs; in 1967–68 production from 188 factories was valued at A$9,000,000. Tourism is increasing, and many visitors are attracted by the climate of Alice Springs and by the stark, colourful scenery of the Macdonnell Ranges and the Mt. Olga-Ayers Rock National Park.

Transport. The Northern Territory has two single-track railways: from Alice Springs to Port Augusta in South Australia, and from Darwin to Birdum. The Stuart Highway (954 miles, or 1,538 kilometres), from Alice Springs via Tennant Creek and Katherine to Darwin, and the Barkly Highway (403 miles, or 649 kilometres), connecting Tennant Creek with Mount Isa, Queensland, are the main road links. Until 1962 these were the only surfaced roads, but in the following decade more than 2,000 miles of all-weather roads were constructed. Air services are well developed: many overseas airlines operate through the international airport at Darwin, and there are services between state capitals and Darwin and intermediate towns, a substantial internal network, and charter services at Darwin and Alice Springs. There are 124 small airports, and most homesteads have airstrips. Shipping of exports from Darwin increased forty-fold between 1965–66 and 1968–69 and necessitated a large extension of port facilities.

Development of air services

Administration and social conditions. *Governmental structure.* The Northern Territory (Administration) Act of 1910–1969 provides for an administrator, appointed by the governor general of the Commonwealth of Australia, to administer the territory on behalf of the commonwealth. There is also provision for a Legislative Council consisting of 11 elected members—of whom one is elected president—and six official members. The council makes ordinances for the peace, order, and good government of the territory but may not propose money votes except upon recommendation by message from the administrator. The Department of the Interior in Canberra is responsible for general administration. Other departments in Canberra administer defense, civil aviation, public health, justice, education (excepting Aborigines), and the provision of basic services. Municipal services are health, justice, education (excepting Aborigines), and the provision of basic services. Municipal services are provided by the administration, except at Darwin, where they are the responsibility of the Corporation of the City of Darwin. The main political groups are the Labor, Liberal, and Country parties. The territory elects one member by adult franchise (including Aborigines) to the 125-member House of Representatives of the Commonwealth Parliament. The legal system and the jurisdiction of the courts are similar to those of the states, but there is no resident judge of the Supreme Court. Law and order are maintained by 235 police, with 30 trackers and other staff. Darwin, as a defensive port, has extensive army, air force, and naval installations.

Health. The Department of Health provides medical and dental services and maintains hospitals at Darwin, Alice Springs, Katherine, and Tennant Creek, and a leprosarium near Darwin. Its aerial services to remote areas are based at Darwin; it also provides the medical personnel for the Royal Flying Doctor Service of Australia, which operates within 500 miles of Alice Springs. Two-way radio consultation usually suffices for minor ailments. Health inspectors visit all settlements, and medical and dental officers make periodical examinations of all schoolchildren.

The Flying Doctor Service

Education. Education is the responsibility of the Department of Education and Science, but there is an agreement whereby curricula and teachers are provided by the South Australian Department of Education. Of the five secondary schools, those at Alice Springs and Darwin provide tuition to leaving and matriculation levels, respectively. Higher education is not provided. Children in remote areas are served by a correspondence school supplemented by School of the Air broadcasts in which pupils may participate by two-way radio. Aborigines attend special schools, a responsibility of the Welfare Branch of the administration, that take account of their cultural background to ensure a smooth transition to their ultimate education in community schools.

Cultural life and institutions. Cultural institutions are naturally limited in a region of small population of very low density. Because of its isolation—Darwin, for example, is nearer to Hong Kong than to Sydney—the territory is largely deprived of opportunities afforded by visiting artists. Partial destruction of Darwin during World War II led to replanning on modern lines, but even though the decade following its proclamation as a city in 1959 saw the population increase from 13,000 to 32,000, Darwin lacked museums and art galleries and a seat of higher learning. There are, however, active art, musical, and dramatic societies, and the performing and fine arts are occasionally brought to the larger towns through the sponsorship of the Arts Council of Australia.

Aboriginal arts

Indigenous arts are those of the Aborigines, which symbolize the ritual of their religion. Throughout the territory there are examples of sculpture, rock carvings, bark and rock paintings, and "X-ray" drawings (which show not only the outlines but the bone structure and internal organs of creatures of esoteric significance). The best of the decorative arts are produced in Arnhem Land and range from gravestones and ceremonial posts to personal ornaments in attractive, polychromatic designs. Aboriginal art has received wide recognition by artists and designers, and Aboriginal motifs figure prominently in the decor of many public buildings in the state capitals.

Regional national broadcasting stations are situated at Darwin, Alice Springs, Tennant Creek, and Katherine, and there is one commercial station at Darwin. The first television station came into operation at Darwin in August 1971. Library services are provided from the five principal centres. Newspapers are published weekly at Alice Springs and Tennant Creek, and the *Northern Territory News* is published daily at Darwin.

Prospects. Since 1946, the Commonwealth Scientific and Industrial Research Organization (CSIRO) has con-

ducted research at Katherine on matters of basic importance to the future of rural industries. A major problem of the cattle industry is the loss of production during winter caused by deterioration of native grasses, but introduction by CSIRO of a legume—Townsville stylo (*Stylosanthes humilis*)—which is either oversown on native pasture or grown as a pure stand to provide high-protein standing hay, has greatly increased potential production. And major changes in the pattern of development of the territory that have occurred since the middle 1960s, chiefly in the mining industry, suggest that its economic prospects are assured and that it will make a growing contribution to the national economy.

BIBLIOGRAPHY. Accounts of investigations of dry-land and irrigation farming, establishment of pastures, and husbandry are published in the COMMONWEALTH SCIENTIFIC AND INDUSTRIAL RESEARCH ORGANIZATION (CSIRO), *Division of Land Research and Regional Survey* (annual). LEEPER (ed.), *The Australian Environment*, 4th ed. (1970); and the annual *Official Year Book of the Commonwealth of Australia and Northern Territory Statistical Summary*.

(A.E.Sc.)

North Mexican Indian Cultures

The generally accepted ethnographic definition of northern Mexico includes that portion of the country roughly north of a convex line extending from the Río Grande de Santiago on the Pacific coast to the Río Soto la Marina on the Gulf of Mexico. This southern boundary coincides in a general way with the northern margins of pre-Columbian Meso-America. Northern Mexico is more arid and less favourable for human habitation than central Mexico, and its native Indian peoples have always been fewer in numbers and far simpler in culture than those of Meso-America. Today, the native peoples are extinct over all of northeastern Mexico; the only Indians present in that area are a group of Kickapoo who immigrated to Coahuila from the United States in the 19th century. In the west the Sierra Madre Occidental, a region of high plateaus that break off toward the Pacific into a series of rugged *barrancas,* or gorges, has served as a refuge area for the Indian groups of the northwest, as have the deserts of Sonora. At present only the northwestern states of Baja California, Sonora, Sinaloa, Nayarit, Jalisco, Chihuahua, and Durango have Indian populations.

Although accurate population data is lacking in parts of this region, estimates place the total population that is still Indian in language and culture at approximately 130,000, a tiny minority among the several million non-Indians of northwest Mexico.

MAJOR INDIAN GROUPS

Surviving Indian peoples of northern Mexico today fall easily into two divisions. By far the greater number are members of the first type, the ten groups which speak some language of the Uto-Aztecan linguistic stock and are traditionally agriculturists. The second type is now reduced to four groups and less than a thousand individuals—the descendants of nomadic bands who resided in Baja California and coastal Sonora and lived by hunting and gathering wild foods. The second type spoke various languages not related to Uto-Aztecan.

Uto-Aztecan peoples

Uto-Aztecan peoples of northern Mexico have been divided into three branches—Taracahitian, Piman, and Aztecoidan. The Taracahitian branch consists of the Tarahumara of the southwestern Chihuahua numbering 50,000; the Varohío, a small people of 1,500 who border the Tarahumara on the northwest and are closely related to them; the Yaqui, with 18,000 in the Río Yaqui valley of Sonora and in scattered colonies in towns of that state and in Arizona; and finally the Mayo of southern Sonora and northern Sinaloa, who still number about 30,000. Another Taracahitian group, the once prominent Opata, have lost their own language and no longer maintain a separate identity. The Piman branch consists of three groups. One of these, the Pima Bajo of the Sierra Madre border of Sonora–Chihuahua, has a population of some 1,500; a few score other Pima are scattered over Sonora. The second group, the 300 Papago of northwest Sonora, are identical with a much larger portion of the same tribe in Arizona. The third Piman tribe is the Tepehuán, one enclave of which is located in southern Chihuahua and another in the sierras of southern Durango and Nayarit; the total Tepehuán population is estimated at about 8,000. The third branch of Uto-Aztecan is the Aztecoidan family, including the Cora located on the plateau and gorges of the Sierra Madre of Nayarit and the Huichol in similar country of northern Jalisco and Nayarit. Cora and Huichol number about 10,000 each. A final member of this branch, locally called the Mexicanero, includes speakers of Nahuatl remnants of central Mexican Indians introduced into the area by the Spaniards. The Mexicanero number only a few hundred and live in the mountains of Nayarit and southern Durango.

Baja Californian and coastal Sonoran peoples

The remnants of the Baja California Indians—the Tipai (Diegueño), Akwa'ala (Paipai), and Kiliwa—live in ranch clusters and other tiny settlements in the mountains near the American border and number fewer than 500 in all. Speaking Yuman languages of Hokan stock, they are little different today from their relatives in American California. Some 300 Cocopa in the Colorado Delta in like manner represent a southward extension of Colorado River Yumans from the American Southwest. Three hundred Seri are found along the desert coast of north central Sonora. This famous group also speaks a language of Hokan origin and is probably related to now extinct peoples who lived across the gulf in Baja California two hundred years ago.

Missions and isolation helped to preserve the several surviving Indian groups of northwest Mexico through the colonial period (1530–1810), but all underwent considerable alteration under the influence of European patterns. Nearly all the agricultural tribes adopted some form of Roman Catholicism and much Spanish material culture. It was at this time that the traditional cultures of northern Mexico were formed, the basic patterns continuing until the present. Many groups faded away—gradually losing their languages and identities and becoming a component of the emerging mestizo, or mixed-blooded European and Indian population, the predominant people of present-day Mexico. Only the Huichol, Seri, and Tarahumara remained primarily aboriginal cultures, but even these groups adopted many items and ideas from the Spanish invaders.

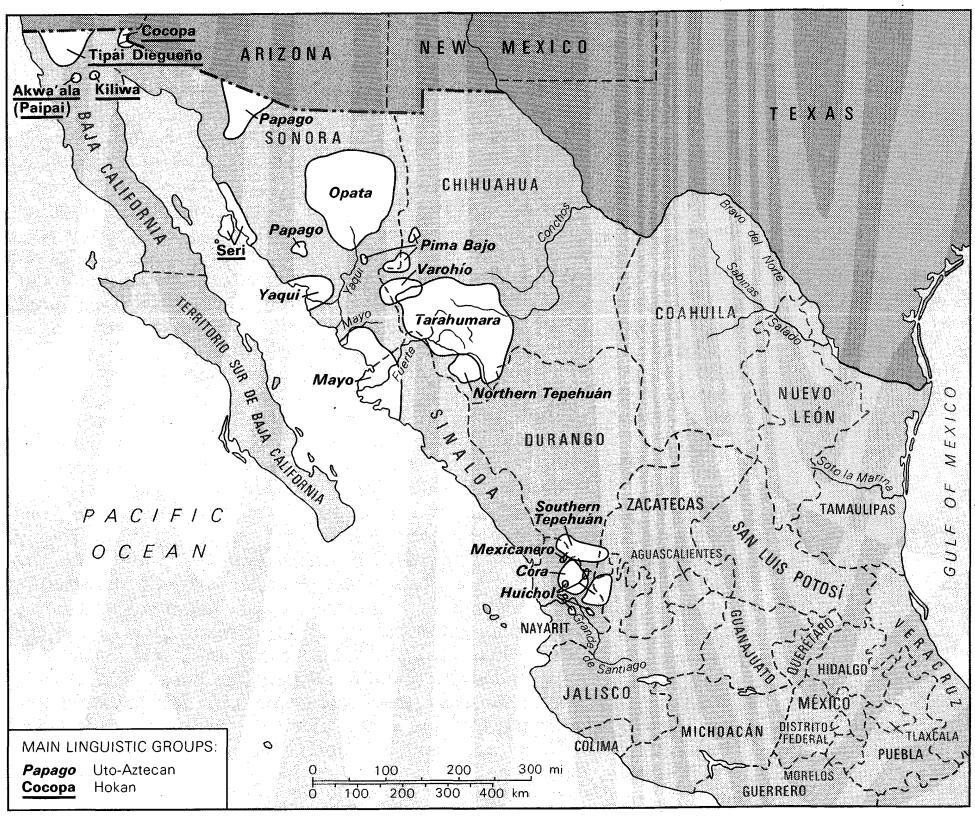
Today, all these peoples exist as ethnic enclaves surrounded by, and in most cases sharing their lands with, non-Indians and manifesting some of the characteristics of ethnic minorities everywhere. There is competition for lands with mestizo ranchers and, in most groups, a conscious desire for survival as distinct cultural entities.

CULTURE PATTERNS

Basic orientation in life

Although in some aspects of culture the Indian groups share much with other rural Mexicans, psychologically they tend to be very distinct. The basic orientation of life of the traditional Indian cultures is primarily religious in that they look to the supernatural to solve their problems and tend to see their own lives as requiring continuous service to the deities. This is in strong contrast to the practical and materialistic orientation of other northern Mexicans. The average Uto-Aztecan Indian in this area is reserved toward outsiders, especially non-Indians, and prefers not to be too much in evidence. The ideal person is industrious, carries out his religious obligations, and does not seek change in his traditional lifeways. In contrast, the Seri and Yuman groups, being of another tradition, are less inclined to secrecy and more aggressive toward outsiders.

Social structures. The social structure of the Uto-Aztecan peoples of northwest Mexico are variations of one basic type, while those of the Seri and Baja California remnants follow other forms.



Distribution of north Mexican Indians in 1970.

The Uto-Aztecan agriculturalists of modern times possess only two real social units, the family and the Indian village community. No real tribal organizations exist, and only among the Cora and Yaqui are there strong feelings of tribal solidarity. For all these peoples the community is the society, and there is little movement in or out—or even interaction with other communities of the same "tribe."

The typical Indian community

The traditional Indian community is largely the result of colonial missionary efforts to concentrate the scattered *rancherías,* or hamlets, of aboriginal times into Spanish-type villages in which the natives could be more easily administrated. Usually furnished with land grants, these communities survived the close of the mission period and remained viable social units. The modern Indian community is built around a political and religious structure having its origin in the village organization set up by early missionaries to carry out church fiestas. It consists of a series of *cargos,* or civil and religious offices, in which most males of the village participate, the higher offices being achieved with age and experience. Some version of this structure or copy of it is or was present among all these groups. Today, among most groups it is still the backbone of the community, serving to produce the village fiestas as well as settle disputes among the people. While serious crimes or major issues are now handled by the Mexican government, in most situations the Indian *gobernador* (governor) and elders are consulted as well.

Kinship patterns. The family is of one type for all the agricultural peoples. Kinship is based largely on descent from both parents, though with some orientation toward the authority of the father. The judgment of the elder males is highly respected, and in most groups the advice and permission of family elders is sought on all important occasions—to produce a ceremony, sell a cow, contract a marriage. Everywhere, however, the role of women is more nearly equal to that of men than is the case among the heavily male-dominated rural mestizo families. Needless to say, there is little of the famous Mexican *machismo* (cult of the male) among the aboriginal peoples of northern Mexico. The normal system of Spanish Christian and family names is present in all these groups.

Marriage customs

Marriage is primarily monogamous, though some informal polygyny occurs. Polygyny is most common among the Huichol (constituting about 5 percent of the marriages), which suggests that it was more common in northern Mexico in aboriginal times. Marriage tends to be brittle, and many unions are not permanent. Parents commonly arrange a match, though the custom is not uniform over the area. Among the Cora and Huichol, the boy's parents must make a series of ritual requests before the match is accepted. In most cases there is little or no ceremony; a few seek church marriages and have wedding fiestas. Among the Cora, the young couple are given formal advice by family elders in the manner of ancient Mexico.

There is a strong tendency for marriages to take place within the community. In most areas intermarriage with the mestizo population is not approved but occurs to a small degree. Among the Mayo and Tepehuán, however, there has been so much outside marriage that the ethnic status of many individuals is uncertain. In most of northern Mexico the offspring of mixed marriages pass easily into mestizo society and tend to ignore their Indian origin.

The Seri have an elaborate system of gift exchange for marriage in which the groom is expected to furnish the family of the bride with certain valuable gifts, such as a rifle, fishing canoe, or, more recently, a pickup truck. His services to the bride's family may continue for several years.

The institution of *compadrazgo,* or coparenthood—that complex of ritual relationships between parents, godparents, and child set up at the baptism of a child—has been deeply integrated into the traditional cultures. Indeed, a copy of it occurs among such non-Christians as the pagan Tarahumara and Huichol. Many minor variations of *compadrazgo* occur among the Indians. It serves everywhere to extend the kinship structure and provide "spiritual" kin on which one can call in times of need. Some Indians may choose mestizos to serve at the baptism of their child; others, such as the Cora, do not favour this.

Egalitarianism

None of the Indian peoples of northern Mexico show even minimal evidence of social stratification. Egalitarian societies exist everywhere, and historical accounts suggest

that this has always been the case, Only among certain extinct coastal peoples of southern Sinaloa and Nayarit is there found some mention of stratification on the Meso-American pattern. Prestige accrues to wealth and ceremonial knowledge, but this seldom passes to the children.

Socialization and education. Socialization and native education follow traditional patterns. A child is given little formal training, but is often admonished by his elders as to proper behaviour. Training in household tasks for the girls and men's work for the boys is through observation and gradually increasing participation until the techniques of maintaining oneself and family are mastered. Both boys and girls are expected to contribute their work as soon as possible. At an early age, children haul water, gather wood, or herd sheep. Small Seri boys spear crabs with miniature turtle harpoons as training for their adult pursuit of the sea turtle. Among the farming peoples all ages take part in the work during critical periods, such as periods of weeding and harvesting.

Rites of passage survive for children among several of the least Hispanicized groups. Cora, Huichol, and Tepehuán have rites in which a newborn is introduced to the gods. The Cora have a ceremony in which children are symbolically introduced to the use of alcoholic drinks.

Today, all Mexican Indian groups have access to schools, usually federal rural schools, and most attend to some degree, though the remote areas in which most Indians live and their lack of interest in education designed for the mestizo world does not make for the most effective program. In some areas native Indians have been trained as teachers with somewhat better results. The Kickapoo have steadfastly refused schools, seeing in them a strong threat to their cherished way of life.

Economic systems. *Settlement patterns and housing.* The aboriginal settlement pattern of the agricultural Indians centred on the *ranchería*, which consisted of a number of household units clustered in spots convenient to cultivation sites or water. When colonial missionaries incorporated these into larger villages, the lowland peoples, such as the Yaqui, Mayo, and Opata, accepted this arrangement. They continue to live in concentrated settlements today. In the Sierra Madre, subsistence patterns did not lend themselves to such towns, and the Indians returned to their *rancherías* when the missionaries withdrew.

Villages and *rancherías*

As a result, all contemporary Indians of the mountain regions live in scattered ranch clusters using the village itself as a religious and political centre. Most Indian villages have a church (often the original mission structure), a school, government buildings used for courts or meetinghouses, and small mestizo-operated stores as well as a few houses owned by Indians who spend most of the year at their ranches. In many areas the once exclusively Indian village has acquired a non-Indian population that resides there permanently. Communities of the Tarahumara, Pima, Tepehuán, Cora, and Huichol follow this pattern. Yaqui and Mayo settlements are more like towns. Many Mayo settlements are now on the outskirts of Mexican towns.

The originally nomadic Hokan peoples now tend to live in small permanent settlements. The Seri have coalesced into two fairly permanent settlements, though they still move about to fish, hunt sea turtles, or sell their crafts.

Housing utilizes the available local material, be it stone, adobe, wattle and mud, planks, bamboo, or even caves, which are occupied seasonally by some of the Tarahumara and Pima. Dwellings primarily consist of one room with a dirt floor and no chimney. The kitchen tends to be an auxiliary structure as does the corn crib. Many Indians sleep on the floor on mats and blankets, but crude bamboo or rawhide beds are also used. Furniture is seldom more than a stool or two, although a few may possess tables. In most areas Indian housing is more primitive than that of other poor rural people. Water, lights, and sanitary facilities are nonexistent.

Subsistence agriculture

Patterns of production. All the Uto-Aztecan peoples of northern Mexico are subsistence agriculturalists raising maize, beans, squash, a few other plants, and some livestock. Maize remains the basis of life and everywhere is a sacred substance, considered, for instance, as a deity by the Cora and Huichol. Cultivation methods range from the primitive digging stick used in slash-and-burn plots on hillsides and ox-plow agriculture in level fields, to some mechanized agriculture among the Yaqui. Characteristically, farm technology is primitive and of low yield. Few of the Indians have any considerable amount of good productive land, and there is competition with mestizos for even the poor mountainside plots of the Sierra Madre Occidental. The corn supply seldom lasts out the year, and in many areas it is significantly supplemented by gathering wild plants, cactus fruits, wild greens, maguey, and the usually abundant seedpods of mesquite, guamuchil, and other treelike legumes. The cash needed for outside items comes from the occasional sale of a young bull or from sporadic wage work in which many Indians engage. Deer and other game once abundant both in the sierra and in the desert are now rare. All the Uto-Aztecan tribes still hunt, but scarcity of game makes hunting relatively unimportant. The rivers yield a few fish and crayfish, which are much esteemed. Among the Seri, hunting of deer and sea turtles as well as fishing is still common but, even so, is of decreasing importance.

Wage labour

For centuries individuals from all these groups have worked for wages first in Spanish and then in Mexican mines and fields. The great silver mines at Hildago de Parral, Chihuahua, in colonial times made use of Tarahumara, Pima, Opata, and Yaqui labour. Yaqui and Mayo have long laboured on ranches and railroads and in mines away from their own country, even in the United States. Today, wage work is a factor in every Indian community in northern Mexico with some members of every group working for wages in the new agricultural areas of the Mexican west coast. The typical pattern is for young men or whole families to go to the coast for a few weeks to pick cotton or harvest corn or tobacco, returning to their own homesteads to plant and care for their maize. Some Tarahumara and Tepehuán work in lumber camps. No matter how important wages are as supplementary income, these peoples all prefer their own agriculture in their own communities, and few are drawn away permanently. It is rare indeed for sierra Indians to live and work in cities. This is not as true for the Yaqui, who have permanent settlements in several large Sonora towns.

About 1930 the Seri adopted commercial fishing and developed a mixed economy that included traditional hunting and gathering. Since 1965 a new industry has grown up in which the Indians have learned to carve animal figurines from the dense wood of the palo fierro, a desert tree. In the 1970s nearly all Seri families were producing figurines for sale to tourists and appeared to be abandoning gathering and fishing as primary means of livelihood.

Property and personal customs. The Indian market system of central Mexico does not exist in northern Mexico. All Indian areas are served by small rural stores almost entirely owned by non-Indians. Here the few but important necessities such as cloth, metal tools, soap, salt, tin cups, and matches are purchased. Money, in use everywhere, is completely a part of modern Indian culture.

Clothing and grooming

Clothing combines the older styles of rural Mexico with modern lower class dress. Only the Tarahumara, some communities of whom still wear a type of loincloth, and the Huichol, with a colourful embroidered costume, have retained forms that stand out as distinct. Some, like the Cora and Tepehuán men, favour the pajama-like muslin garments of two generations ago and today consider them Indian dress. All others wear modern clothing with few reminders of earlier attire. Huaraches (sandals) are generally worn, as are homemade or commercial hats, usually made of palm; people near the United States border, however, prefer modern shoes and cowboy hats. Women's dress throughout tends toward a skirt and blouse with a rebozo, or head scarf.

Long hair is worn by males in some Tarahumara and Huichol communities and by many adult Seri. Elsewhere, short hair is the custom. Women wear the hair loose or, among the more Mexicanized, in braids.

Food is largely vegetable and consists of local varieties of the rural Mexican staples—tortillas, tamales, beans, and cheese. Indians, however, make much use of *atole* (corn mush) and pinole (ground parched corn) both of which were aboriginal favourites and are not as popular with the mestizos.

Crafts, nearly everywhere disappearing, are very largely limited to household necessities and are seldom made primarily for sale. Wool blankets are produced by the Mayo, Tarahumara, and Cora and woven shoulder bags by the Cora and Huichol. Utilitarian pottery and twilled containers and mats are still made in most groups, using native Indian techniques. The only objects produced for the tourist market are copies and elaborations of colourful ceremonial material by some Huichol and figurines and shell beads by the Seri.

Other technology differs but little from that of other rural Mexicans of the northwest. Ranch tools and the paraphernalia used in handling livestock are identical. None of the sierra Indians possess automobiles. Occasional individuals in the other groups, including the Kickapoo, have acquired motor vehicles.

Religion. The northern Mexican tribes, like all Mexican Indians, have had contact with Christian missionaries for centuries, and all the agricultural Indians of northern Mexico are nominal Roman Catholics except for a few communities of pagan Tarahumaras, called "gentiles," and the majority of the Huichol. Even pagan groups, however, have incorporated Christian ideas and ritual practices. It can be generally stated that all the Uto-Aztecan speakers of northern Mexico today practice some form of Roman Catholicism blended with native religion. The extent of aboriginal retentions varies from group to group, with the Huichol approximating pre-Columbian patterns to the greatest degree, keeping their gods, pilgrimages to sacred places, and native religious concepts almost intact. Others like the Cora have fused these, retaining native gods but equating them with Christian personages. The Yaqui and Mayo, both with a strong religious orientation to their culture, have an even more homogenous mixture. It is doubtful, though, whether any of the groups have absorbed Christian philosophy or belief systems to any great degree. Religion retains its aboriginal functions of protecting one's health, bringing the rains, and insuring the abundance of agriculture, rather than as a means to a glorious afterlife.

Blend of Roman Catholicism and native religion

The relationship of many of these peoples to the modern Roman Catholic Church is tenuous. Modern priests tend to discourage folk observances such as the fiestas; the Indians, by and large, produce them without help of a priest. In the southern Sierra Madre, among the Cora, Huichol, and Tepehuán, there are modern Franciscan missionaries, while in the Tarahumara area there are Jesuits. Among all the Uto-Aztecans, religion remains central to the traditional culture, and it is an area in which there is great resistance to outside pressure for change.

Protestants have been active among the Seri and Yumans, achieving their greatest success with the Seri, who in the 1950s were all converted by an evangelical sect and largely abandoned their non-Christian practices. The Kickapoo, though also contacted by Protestants, remain, for the most part, followers of their aboriginal religion.

Shamans, or *curanderos*

The shaman, or medicine man, still exists in most of these groups. Called a *curandero* in Spanish, he uses supernatural means to cure illnesses, to insure the success of crops, or to assist in other situations requiring divine aid. He is very distinct from the mestizo *curandero,* who utilizes European folk medicine. Huichol medicine men, or *marakame,* are especially famous among the tribes of the Sierra Madre for their knowledge and power. Witchcraft still exists among all these peoples. A shaman himself may be accused of being a witch.

EVOLUTION OF THE CULTURES TODAY

The traditional Indian cultures of northern Mexico that emerged from the Spanish colonial world remained remarkably stable throughout the 19th century. Combinations of isolation, poverty, and conservatism resulted in what were essentially static societies. There were sporadically some uprisings, but it was not until the Mexican Revolution of 1911 and after that most Indian cultures were significantly affected by changes taking place elsewhere in Mexico. All these peoples took part in the revolutionary conflicts, and some disorganization took place everywhere. Thousands of individual Indians followed the armies, many never to return. The aftermath of the revolution marked the beginning of governmental concern with the Indians. The Instituto Nacional Indigenista was established and took upon itself the task of raising living standards and gradually integrating the Indians into the national life. Some groups benefitted significantly by the revolution and its results. Many Yaqui and Mayo escaped from hacienda peonage, and the Yaqui had a large portion of their ancestral lands restored to them.

Developments since World War II

It has been only since World War II that real changes have been taking place in the cultures themselves. There are multiple reasons for increased pressures from the outside world, but the primary cause is simply the development of modern transportation and a corresponding loss of centuries-long isolation. A major factor has been the construction of dams in the rivers flowing out of the Sierra Madre and the development of major irrigation projects and large modern cities on the coastal plain. There is now greater interest in the resources of the mountain hinterlands on the part of non-Indians, and there are opportunities for the mountain and desert peoples to engage in migrant farm labour.

Opening of the Mexican west coast highway has brought major changes in the whole area. The desert lands of the Papago, the Sonoran seacoast of the Seri, and the thorn forests of the Yaqui and Mayo are now penetrated by paved roads. A new railroad across the Sierra Madre from the city of Chihuahua to Los Mochis on the Pacific bisects the Tarahumara country, and roads have made numerous villages of this tribe accessible to truck traffic. Truck roads are approaching even the gorges of the Cora and the Huichol. Many parts of the Sierra Madre previously accessible only by animals or by foot are now served by local airlines that fly small planes hauling freight and passengers to most of the mountain communities. It is a common sight at the airport in Tepic, Nayarit, to see rural mestizos, Cora, and Huichol Indians waiting to board a plane for airstrips near their remote homes. Although there are still vast areas in these mountain regions not reached by modern transportation, the outside world has become more accessible, and all of these peoples have been affected to some extent.

Development of modern transportation has greatly increased the possibility that many Indian communities in time will cease to exist. There is growing competition for lands in all areas as non-Indian cattlemen, lumbermen, and farmers exploit these regions more intensely. Almost everywhere Indians find themselves being pushed or crowded out of ancestral lands by more sophisticated forces who have use for their resources. The Instituto Nacional Indigenista has come to the aid of some, such as the Tarahumara and Huichol and given them legal assistance in securing land titles. In most areas, though, Indians having no legal knowledge and, lacking sophisticated leadership, are severely handicapped in dealing with these problems. Without a land base it is doubtful that communally oriented societies such as these can long survive.

The basic strength of the Indian groups today is found in their village organization and associated ceremonial structures that effectively preserve ethnic boundaries. Those retaining the strongest organized communities—the Tarahumara, Yaqui, Cora, and Huichol—while threatened, appear to be in no immediate danger of cultural disintegration. Others, few in number (such as the Pima) or lacking well preserved independent village structures (such as the Mayo), appear less likely to survive the impact of modernization.

Fear of alienation of lands and ultimate loss of ethnic identity has led to avoidance of innovations in many cases. Most still continue to resist social and religious change and avoid too close contact with non-Indians. There is, it is true, less reluctance to adopt material ob-

jects. The last decade has seen the spread of the transistor radio even to the depths of the Sierra Madre, with the result, among other things, that more are learning Spanish. The cast-iron corn mill is now used to grind *masa* (tortilla dough), saving hours of kneeling at a *metate*, or millstone, grinding by hand. Pedal sewing machines and metal containers are common. Nevertheless, most northern Mexican Indians express concern that their lifeways are dying. They fear that loss of community lands, and the cultural seduction of their youth will mean that their days as separate peoples are indeed numbered.

BIBLIOGRAPHY. CARL LUMHOLTZ, *Unknown Mexico*, 2 vol. (1902), gives the first modern account of North Mexican groups and is still a major source. The best modern source is EVON Z. VOGT (ed.), *Handbook of Middle American Indians*, vol. 8 (1969), which contains articles covering each of the groups. A basic source on the history, cultural geography, and ethnography are the following bulletins of the *Ibero-Americana* series that cover western Mexico in depth: RALPH L. BEALS, *Comparative Ethnology of Northern Mexico Before 1750* (1932) *Acaxee: A Mountain Tribe of Durango and Sinaloa* (1933) and *Aboriginal Culture of the Cáhita Indians* (1943); CARL O. SAUER, *Distribution of Aboriginal Tribes and Languages in Northwestern Mexico* (1934) and *Aboriginal Population of Northwestern Mexico* (1935); ALFRED L. KROEBER, *Uto-Aztecan Languages of Mexico* (1934). EDWARD SPICER, *Cycles of Conquest: The Impact of Spain, Mexico, and the United States on the Indians of the Southwest, 1533–1960* (1962), presents the only overview of change since colonial times. CAMPBELL W. PENNINGTON, *The Tarahumara of Mexico* (1963) and *Tepehuan of Chihuahua* (1969), are very good for material culture and ethnogeography of the northern sierra. CARL LUMHOLTZ, *Symbolism of the Huichol Indians* (1900), furnishes much on Huichol gods and belief, as does R.M. ZINGG, *The Huichol: Primitive Artists* (1938). A definitive work on Cora religion is found in K.T. PREUSS, *Die Nayarit-Expedition* (1912), in German.

(T.B.H.)

North Sea

The North Sea is a shallow, northeastern arm of the Atlantic Ocean located between the British Isles and the mainland of northwestern Europe and covering an area of 220,000 square miles (570,000 square kilometres). It is bordered by the United Kingdom and the Orkney Islands to the west; the Shetland Islands to the north; Norway and Denmark to the east; and West Germany, The Netherlands, Belgium, and France to the south. It is connected to the Atlantic by the Strait of Dover and the English Channel and opens directly onto the ocean between the Orkney and Shetland islands and between the Shetland Islands and Norway. The Skagerrak, Kattegat, and Danish sounds provide the connection between the North Sea and the Baltic Sea.

The North Sea has long been important as one of Europe's most productive fisheries. Its grounds alone normally account for over 5 percent of the total world commercial catch. It also serves as a prominent shipping zone among European countries and between Europe and the Middle East. These functions may soon be overshadowed, however, by the enormous reserves of petroleum and natural gas recently discovered beneath the sea floor. Estimates of their size hold out the promise that the North Sea's deposits may end western Europe's dependence upon the Middle East for oil and gas by the 1980s.

The North Sea in history

The North Sea has had a strong influence on European history. Because of its long coastline, and the rivers emptying into it, it has been readily accessible to many areas, providing highways of commerce and of conquest. It was the scene of early development of maritime trade, dating back to before the days of the Hanseatic League. Its waters have protected the British Isles from invasion from the Continent for over one thousand years, yet the North Sea also has served as a springboard for the growth of the overseas empires of the countries bordering on it. Without the interchange of people, goods, and ideas made possible by the existence of the North Sea, the cultural development of northwestern Europe after the Middle Ages might have been greatly retarded.

Geologic history. The extent of the North Sea and the level of its water surface have varied considerably over geologic time. At the end of the Pliocene Epoch (about 2,500,000 years ago) the North Sea Basin south of Dogger Bank was part of the European mainland, and the Rhine River—joined on its left bank by the Thames—emptied into the sea about 250 miles north of modern-day London. During the next 2,000,000 years of the Pleistocene Epoch, the ice sheet advanced and retreated several times and deposited a thick layer of clay on the sea floor. At the time of the greatest advance, the ice covered all of the North Sea from a line joining the Thames estuary with the Dutch coast. The final retreat took place about 6000 BC; and, some centuries later, the expanding sea area broke across the land bridge that linked Britain with France, and the waters joined with the English Channel. The present coastlines of the North Sea probably were not established until some 3,000 years ago.

The physical environment. *Relief features.* Few parts of the North Sea are more than 300 feet in depth. The floor dips to the north and is generally irregular. In the south depths measure less than 120 feet; many shallow, shifting banks, presumably of glacial origin, have been reworked by tidal currents. These present serious navigational hazards. Off northern England the vast moraine (glacial deposit of earth and stones) known as Dogger Bank is covered to depths of only 50 to 100 feet. This is the location of one of the finest fishing areas in the sea. In contrast, the waters deepen in the Norwegian Trench, an unusual trench that runs parallel to the coast of southern Norway from north of Bergen around to Oslo. It is between 15 and 20 miles wide and is some 600 feet deep in the vicinity of Bergen and over 2,400 feet deep in Skagerrak at the entrance to the Baltic Sea. There are also some deep trenches in the western part of the North Sea, including Devil's Hole off Edinburgh, where depths exceed 1,500 feet, and Silver Pit, 318 feet deep, off the Wash of England. These trenches may have been formed at the time of the last glaciation when parts of the North Sea were free of ice, and rivers coming off the mainland could have eroded deep channels in the basin floor.

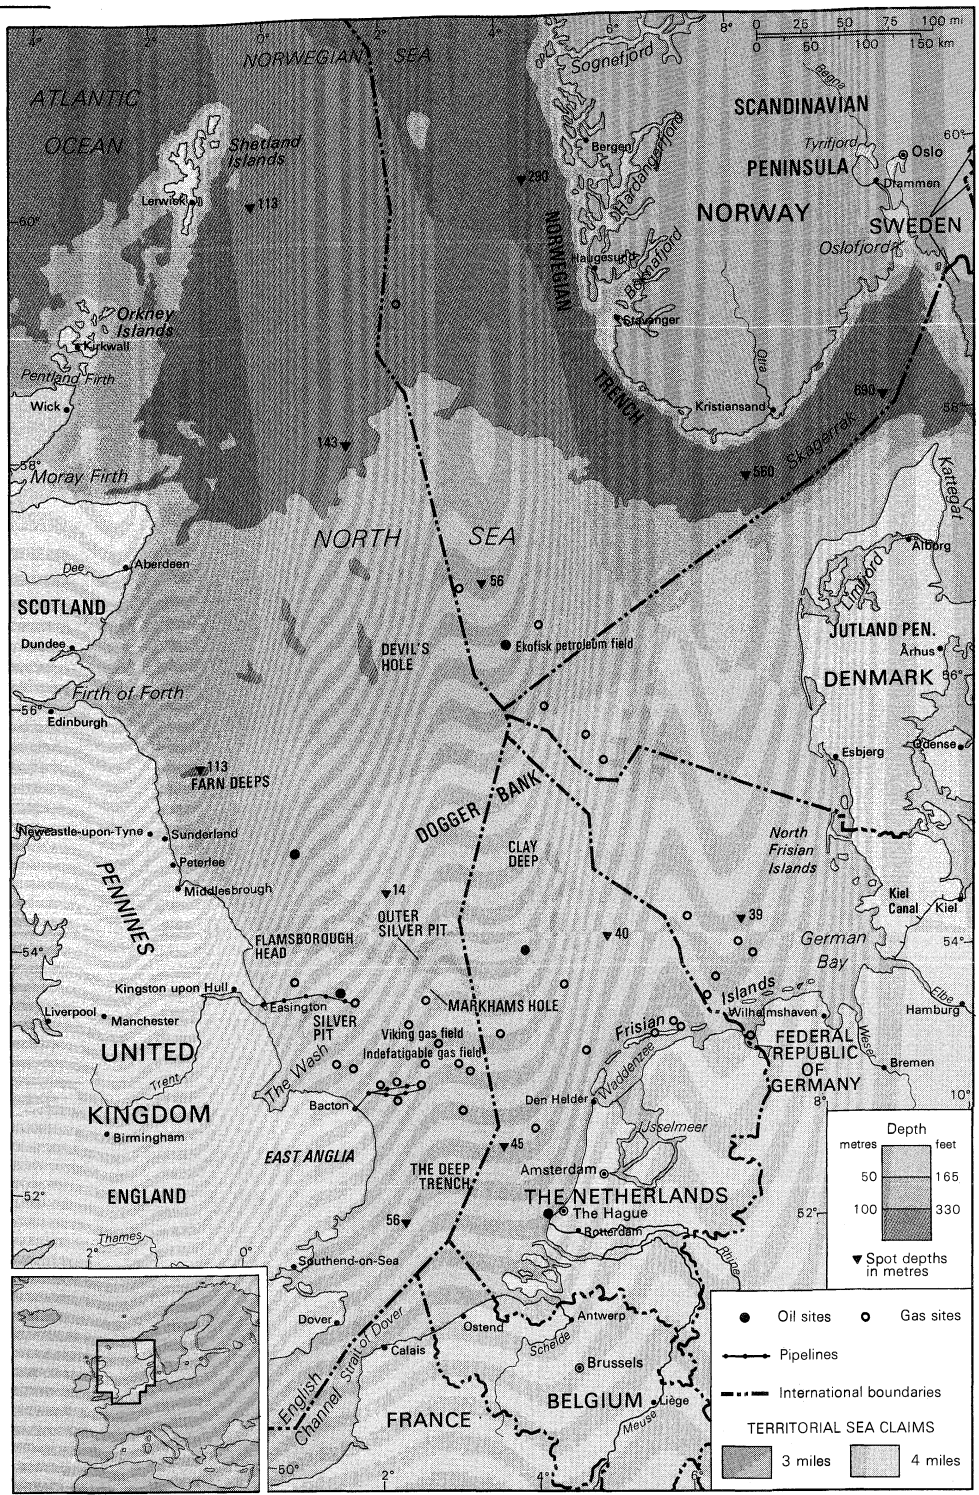
Dogger Bank and the Norway Trench

Coasts. There is a marked difference between the rugged upland coasts of the north and the regular lowland coasts of the south. The glaciated mountain coastline of Norway north of Stavanger is broken by fjords (narrow inlets between steep cliffs), headlands, and an offshore fringe of thousands of rocks and islands. Below Stavanger the coast is less precipitous and there are fewer islands. Scotland's east coast is also composed of uplands—although it is less broken—and the resistant rocks continue south into England. In the vicinity of Flamborough Head the cliffs are lower and their less resistant clays are subject to extensive erosion. In the fens area of East Anglia the coast is low and marshy, as it is in the delta region of The Netherlands. Most of the southern and southeastern coast is straight and sandy. The low, offshore Frisian Islands stretch from IJsselmeer (Zuiderzee) in The Netherlands to southwestern Denmark.

Currents and tides. The North Sea waters are affected by the warm current of the North Atlantic Drift, which moves northward along the western side of the British Isles and enters the Norwegian Sea. Atlantic waters with salinities exceeding 35 parts per thousand enter the North Sea through the English Channel and between the Shetland Islands and Norway. Colder, less saline waters come from the Baltic Sea through Skagerrak, creating a counterclockwise circulation in the basin. Salinities generally range between 34 and 35 parts per thousand, with higher readings occurring off the British coast and lower readings off Norway. Large quantities of freshwater also enter through the Rhine, Thames, and other rivers.

Climate

Average air temperatures vary in January from 32° F (0° C) to 40° F (4° C) and in July from 55° F to 64° F (13° to 18° C). Winters are stormy and gales are frequent. Tidal ranges average between 13 and 20 feet along the British coasts and in the southern estuaries, while the range to the north and east is less than ten feet. Because of the low-lying nature of much of the southern coast, abnormal tides can be disastrous. In 1953 a storm surge of nearly 11 feet above the mean high-water level inundated large areas of the delta region of The Netherlands and caused over 2,000 deaths.



Submarine relief and gas and oil resources of the North Sea.

Resources and their exploitation. *Fisheries.* The constant mixing of waters in the shallow sea basin provides a rich supply of nutrient salts upon which the lower forms of marine organisms—the basis of the sea's food chain—are dependent. The resulting abundance of plant and animal plankton supports a varied and rich supply of commercially valuable fish. The annual North Sea catch exceeds 3,300,000 tons. Herring and mackerel account for almost half of the total catch, and the rest consists of pout, cod, sand eels, whiting, haddock, and plaice, a type of marine flatfish. The major fishing countries and their approximate percentages of the annual catch are Norway 33 percent, Denmark 30 percent, the United Kingdom 11 percent, Sweden 7 percent, The Netherlands 5 percent, the Soviet Union 4 percent, France 3 percent, and West Germany 3 percent.

Oil and gas. Important discoveries of oil and natural gas beneath the sea floor have been made since 1959, when a major natural-gas field was located in the northeastern portion of The Netherlands. Subsequent exploration extended to the shallow waters off the Dutch coast, and in 1966 discoveries were made in the deeper waters off the southeast coast of England. One year later gas from offshore wells was commercially produced by the British. Since then, gas development has also been carried out by Norway, Denmark, and West Germany, in some cases at depths of nearly 200 feet. Although estimated potentials of the offshore wells frequently change, it is

clear that these reserves will have a major impact on the economies of the North Sea countries. The giant Ekofisk petroleum field that was discovered off of southern Norway in 1970 has an estimated capacity of 300,000 barrels per day, and other fields have since been located off Scotland, Norway, and The Netherlands.

Man's influence. The resources of the North Sea are increasingly exploited as the level of the western European economy rises. The volume of shipping to bordering countries and to the Baltic is steadily growing, thereby generating problems of navigation that are exacerbated by the more than 400 gas and oil wells located offshore. Shipping and industrial exploitation in coastal areas contribute to pollution problems, particularly in the southern portions of the North Sea. In 1971 the danger of oil pollution from crippled oil tankers, pipelines, or exploration for petroleum prompted the United Kingdom to legislate against such polluters.

The development of gas and oil industries has resulted in the leasing to major oil companies of large areas of the seabed, and also in offshore boundary disputes, particularly between West Germany, The Netherlands, and Denmark. The fisheries have long been threatened from overfishing, a trend accentuated in the 1970s by the use of more efficient vessels and harvesting techniques.

KING, *Oceanography for Geographers* (1962), an oceanographic text with emphasis on features of the world ocean, including some interesting discussions of the North Sea; *Bulletin Statistique des Pêches Maritimes* (annual), contains extremely detailed statistics of North Sea fisheries; LEWIS M. ALEXANDER, *Offshore Geography of Northwestern Europe* (1963), includes considerable discussions on fisheries and on coastal types in the North Sea area; M.N. HILL (ed.), *The Sea*, vol. 3, *The Earth Beneath the Sea* (1963), a very thorough treatment of geological history of marine areas; contemporary reports from *World Oil* and the *Oil and Gas Journal*, two periodicals that carry concise, current materials on oil and gas developments in the North Sea.

(L.M.A.)

Northwest Coast Indians

The most sharply delimited culture area of native North America was the Northwest Coast. It covered a long narrow arc of Pacific coast and offshore islands from Yakutat Bay in the northeast Gulf of Alaska south to Cape Mendocino in modern California. Its eastern limits were the crest of the Coast Ranges from the north down to Puget Sound, the Cascades south to the Columbia, and the coastal hills of Oregon and northwest California. The Kuroshio (Pacific Ocean current) offshore warms the coast and deluges it with rain. The northern Coast Range, cresting at heights of 5,000 feet and more, rises steeply from the sea and is cut by a myriad of narrow channels and fjords. The shores of Puget Sound, southwest Washington, and the Oregon coast hills are lower and less rugged.

Physical aspects of the Northwest Coast

Coastal forests are dense, predominantly coniferous: spruces, Douglas fir, hemlock, red and yellow cedar, and, in the south, coast redwood. These forests support an abundant fauna. Most important from the cultural point of view was the aquatic fauna, for it was on this that the areal culture depended primarily. Five species of salmon; herring; oil-rich "candlefish," or eulachon; smelt; cod; halibut; and mollusks abounded.

The peoples of the Northwest Coast linguistically consisted of a series of units related to widespread "stocks" of native North America (see NORTH AMERICAN INDIAN LANGUAGES). From north to south the following linguistic divisions occurred: Tlingit; Haida; Tsimshian; northern Kwakiutl, or Heiltsuq; Bella Coola; southern Kwakiutl; Nootka; Coast Salish; Quileute-Chimakum; Kwalhioqua; Chinook. Then along the Oregon Coast and northwest California a series of small divisions occurred: Tillamook, Alsea, Siuslaw, Umpqua, Coos, Tututni-Tolowa, Yurok, Wiyot, Karok, and Hupa.

Major Indian groups

Culturally, Northwest Coast groups can be classified into four subareal units, or "provinces": the northern one, including speakers of Tlingit, Haida, Tsimshian, and the Tsimshian-influenced Haisla (northernmost Heiltsuq or Kwakiutl); the Wakashan province, including all other Kwakiutl, the Bella Coola, and the Nootka; the Coast Salish–Chinook province, which included various enclaves of other speech down to the central coast of Oregon; and the northwest California province plus the Athabascan-speaking Tututni-Tolowa.

The Northwest Coast was densely populated. Estimates of density in terms of persons per square mile mean little in a region where long stretches of coast were uninhabitable cliffs rising from the sea. But early historic sources indicate that many villages had hundreds of inhabitants. One conservative population estimate of 129,000 persons on the coast at the dawn of the historic period must have represented nearly the maximum that the area could support without improvement of the already complex technology.

Distribution of Northwest Coast Indians.

TRADITIONAL CULTURE PATTERNS

Social structure. The Northwest Coast was the outstanding exception to the anthropological truism that "hunting-and-gathering" (in this case "fishing-and-gathering") cultures are characterized by simple technologies, sparse possessions, and egalitarian, loosely organized societies consisting of small bands comprising small total populations. In this area, complex patterns of culture were the rule.

Familial and group organization

The nuclear family—a man, his wife or wives, their children or, in the northern provinces, the man's sisters' sons—was the basic production unit. In the native view, the significant social unit was the local group—that is, a group of men who considered themselves related and who formed a corporate entity holding title to fishing

places, berry-picking and hunting grounds, habitation sites, and a host of incorporeal rights, such as names, songs, dances, and, especially in the north, totemic representations called "crests." Members of each group were graded in an integrated sequence from high to low, according to closeness to the direct line of descent from the group ancestor. The highest in rank, invariably holder of a special title that in each language translated into English as "chief," was administrator of the group's properties. It was he who set the time for the move to the salmon-fishing station, decided when the weirs and traps should be built, when the first catch should be made and the rite propitiating the first salmon of the season celebrated, when other groups should be invited to feasts, and so on. He had many prerogatives and sumptuary privileges, but he was expected to administer efficiently and to tend to social and ritual affairs for the general welfare of his group.

From Tlingit country in the north at least as far south as Puget Sound and perhaps farther, several such local groups assembled at a site in some sheltered cove protected from winter winds to pass the winter. Food-gathering activities were limited by weather but were unimportant; the stores of salmon dried in the fall were adequate. Practice of arts and crafts, jollity, and feasts and ceremonials were the order of the day. These assemblages of several local groups at winter village sites are often called "tribes," but it must be noted that such units were not politically integrated, for each of the component local groups retained its economic and political autonomy. For ceremonial purposes, though, the local groups were ranked in series from highest to next highest, and so on.

Stratification. A signal feature of Northwest Coast society was the emphasis on each individual's hereditary social rank. His position within his local group depended on his genealogical closeness to the legendary group ancestor. When several groups assembled at a common winter site to form a "tribe," the relative rank of the individual's group also was another factor important for ranking purposes.

Individual social ranking

Indian informants tend to oversimplify the situation in casual conversation, describing their former society as a class-structured one with a class of "chiefs," a class of commoners, and below these two a class of slaves. It is true that slaves (*i.e.*, war captives) formed a special social division, but the division into two great classes of "chiefs" and "commoners" is an inadequate explanation. The fact is that each person had his particular hereditarily acquired status, which placed him within his group as though he stood on a step of a long staircase of statuses, with the eldest of the senior line on the highest step, the most remotely related at the bottom. Strictly speaking, each person was in a class by himself.

Nominally, those of high rank were said to have had vast authoritarian powers, and group members of low degree have been described as serflike. In actual fact, mature persons of the latter sort voiced their opinions on group affairs, for they held interest in group properties. The chief refrained from abusing them because they were his kin and also because he was aware that he needed their assistance. Many strong arms and sturdy backs were needed to obtain, assemble, and position the heavy materials needed to build or repair a house, to construct fish weirs and traps, and to launch and paddle the chief's huge dugout canoe. Many singers, dancers, and attendants were necessary to stage an important ceremonial properly. Many bold warriors were needed to defend the group's wealth against foemen. There was enough flexibility in the social structure so that those of low rank could abandon an abusive chief and reside with kindred elsewhere who would welcome them.

Slaves usually were persons captured in childhood and taken or traded so far from their original homes that they had little hope of finding their way back. They were mere chattels, who might be treated well or ill, traded off, slain, or freed at their owner's whim.

The statuses of group members were hereditary, but they were not automatically assumed at birth. They had to be formally and publicly assumed at a "potlatch," a performance given by all coast groups north of the Columbia River. The term comes from a widespread trade jargon and means "to give." A potlatch always involved invitation of another group or groups, who were received as guests with great formality; they served as witnesses to the announcements by the host chief at the assumption or bestowal of prerogatives, such as noble titles, crests, or ceremonial rights, and then were given gifts. The previously assumed statuses of the guests were recognized in the gift-giving, for distribution was made in the order of their rank sequence, and the more splendid gifts were given to guests of highest status. Not only were titles and other honours announced for the host chief or his heir and for his close kin of high position but children of low-rank group members were awarded names from the group stock and, at times, minor prerogatives. Participation of all members in major or minor roles in the proceedings also served to identify them with the social unit. There were some regional variations: in the northern province, a major potlatch was part of the cycle of mortuary observances after the death of a chief, at which his heir formally assumed his rights; in the Wakashan and Salish regions a chief gave such affairs to bestow rights on an heir apparent before his own demise.

Potlatch

Some early anthropologists, and a few modern ones, considered potlatch to be an economic enterprise in which the giver expected to recover a profit on the goods he distributed when his various guests potlatched in their turn. This actually was an impossibility because only a few guests of highest rank would ever stage such affairs and invite their former hosts; those of intermediate and low rank never did so, yet the total amount of gifts bestowed on them was considerable. Indeed, before white traders came and made great quantities of trade goods available, potlatches were few, whereas feasts, though also formal but not occasions for bestowing titles and gifts, were very frequent.

Socialization and education. An interesting aspect of Northwest Coast culture was the emphasis on teaching children etiquette, moral standards, and other traditions of social import. Every society has processes by which children are taught the behaviour proper to their future roles, but often such teaching is not overtly a deliberate process. On the Northwest Coast, particularly northward of the Columbia, children were instructed formally. This instruction began at an age when modern educators would consider children too young to learn effectively—while they were still in their cradles. Children born to high statuses were given formal instruction throughout childhood and adolescence. They had to learn not only routine etiquette but also the lengthy traditions by which the rank and privileges of their particular group were validated and many rituals including songs and formulaic prayers. It was not only the parents (or, in some groups, the mother's brother) who taught children. All elder relatives, particularly grandparents, participated. The educative procedure did not consist of dry, barebones moral lectures. Some of it was given in the form of folktales, amusing and entertaining but with pointed morals: the troubles of the anti-hero, Raven, in the tales were obviously the result of his dissolute way of life, his laziness, his gormandizing, and his lechery.

Early training of youth

Other socialization processes, those that involved public recognition of the attainment of new status, were usual among Northwest Coast groups. One variety included ritual observances considered necessary at each critical stage in a person's lifetime. At the birth of an infant, at a girl's attainment of puberty (there were no boys' puberty rites in the area), and at death, it was considered that persons involved might be in danger or might be dangerous to the society at large. A newborn infant was believed to be in danger from supernatural causes; the infant's parents were both in danger and dangerous. A girl at puberty was similarly viewed, as were the close kin of a deceased person and those who actually participated in preparing and disposing of the body. Such perils were avoided by isolating the persons involved, either within a boarded-off cubicle in the house or in a makeshift hut out in the woods and by limiting his or her diet to old dried fish and water. At the conclusion of the isolation period some sort of

formal ritual purification was carried out, such as ceremonial bathing. The intensity of the restrictions varied considerably, not only in different parts of the coast but within individual groups. Often the pubescent daughter of a chief, for example, was secluded for many months, whereas her low-ranking kinswoman might have to suffer only a few days of confinement.

Over most of the coast there was a very great fear of the dead. A body was removed from the house through some makeshift aperture other than the door, to be disposed of as rapidly as possible. Only in the northern region were bodies of chiefs set up in state for several days while the clan dirges were sung. Disposal of the dead varied. In the northern province cremation was practiced (anciently, interment was customary). In the Wakashan and part of the Coast Salish areas large wooden boxes suspended from branches of tall trees or placed in rock shelters served as coffins. Other Coast Salish deposited their dead in canoes set up on stakes. In southwest Oregon and northwest California interment in the ground was preferred.

Economic systems. Of the various distinctive attributes of Northwest Coast culture, one of the most important was the highly efficient exploitation of natural resources. The resources, particularly the fisheries, were very bountiful; but they were scattered and not equally easy to exploit. Certain species of salmon, for example, ran in certain rivers at various times of the year. The important species for preservation for winter stores were the pink and the chum salmon. Because these species ceased to feed for some time before entering freshwater and their flesh thus had less fat content, they could be smoked and dried and kept for a long period of time. Other species, such as sockeye, coho, and the flavorsome chinook or king salmon, could be utilized immediately or dried and kept for a short period but could not be preserved the whole winter through. Therefore, the principal fishing sites were those along rivers and streams in which pink or chum salmon ran in the fall. In the spring of the year other sorts of fish became available in tremendous schools: herring, which came in to spawn in coves; "candlefish" (eulachon), which entered certain rivers; and, farther south, "smelt," which spawned on sandy beaches in summer. Elsewhere, in the summer months, bottom fishing for such species as halibut was a profitable enterprise on shallow offshore banks.

Reliance on fishing

To exploit the total resources of the region it was most efficient for the people to have various bases of operation. In the winter months when storm winds blew and heavy seas slammed against the coasts, shelter behind some point of land that broke the force of the sea was highly desirable. The Northwest Coast adaptation to this pattern was shifting residence. The people moved from one site to another, according to the season and according to the resources about to become available. This was not nomadism. The Indians moved systematically in certain seasons from one fixed site to another for convenient access to seasonal resources. Typically at these seasonal stations there were either permanent houses or permanent house-frames that could be covered over with planks brought along for the purpose. Occasionally, when the weather permitted or only a short stay was planned, makeshift shelters were erected.

Patterns of production and technology

Aboriginal Northwest Coast economy may be viewed as a system comprised of several mutually supporting subsystems. The first of these subsystems is the efficient techniques for taking fish and other marine resources and for preserving them. The second subsystem consisted in the construction of large rectangular plank houses that made possible the smoking and drying of fish during the torrential rains of autumn. Such houses also provided storage space for the bulky preserved foods. The third subsystem consisted of the water-transport complex. Canoes, both large and small, provided access to fishing grounds and the means of transporting preserved foodstuffs to other habitation areas. It was the combination of these subsystems that made the exploitation of local resources so efficient that the people were able to live with a wide margin of plenty.

Northwest Coast houses shared a few significant traits. All were rectangular in floor plan with plank walls and plank roof, and all but those of northwestern California were large structures designed for multi-family use. At the northern and southern extremes of the area deep central pits were dug within the house. In the north, houses were built on a nearly square plan—averaging about 50 feet wide by 55 feet long—and had gabled roofs; walls and framework were intermeshed to form a permanent structural unit. In the Wakashan province, on the other hand, the houses were rectangular—40 feet by 60 to 100 feet. Huge cedar posts with side beams and ridgepoles comprised the permanent framework, and to these were attached wall planks and roof planks that could be taken down, loaded onto canoes, and transported from one site to another. Some Coast Salish similarly built houses of permanent frameworks with detachable siding and roofing; their houses, however, had "shed-roofs," that is, a roof with only one slope instead of the two of the Wakashan house. Some Coast Salish houses were tremendously long, housing many people. Along the lower Columbia the typical house had a deep large rectangular pit, lined with planks, capped with a gabled roof. Only roof and gable ends showed above ground. The northwestern California house type was designed for single family only. Each house had low side walls of redwood planks and a three-pitch roof. Living space was the plank-lined central pit. Northwestern California also added a specialized structure: the men's combined clubhouse and sweat house, a common native Californian institution.

Water transport was highly important in the area. All groups made efficient dugout canoes. Northern groups, as well as the Kwakiutl and Salish down to Puget Sound, made dugouts with projecting bow and stern pieces, vertical "cutwaters," rounded sterns, and rounded hulls. The Nootka and some of their neighbours made vessels with projecting bow pieces, curving cutwaters, vertical sterns, and angular flat bottoms. Northwest Californian dugouts had upturned rounded ends, rounded hull, a carved seat and foot braces for the steersman. All types were made in different proportions for different purposes: large, beamy ones for moving people and cargo; shorter, narrow ones with racy lines for sea mammal hunting, and so on.

Crafts

Northwest Coast woodworking was facilitated by the natural abundance of easily worked timbers, especially the red cedar and the redwood. Trunks of these trees could be split into planks or they could be hollowed out into canoes, containers, or other useful objects. Along the Northwest Coast as far south as the Columbia, wooden boxes were made of red-cedar boards that were "kerffed"—cut nearly through transversely. The wood was steamed at these points until it was flexible enough to bend into the form of a box. Dishes often were hollowed out of pieces of wood, sometimes plain, sometimes in the form of animals and monsters. Also of wood were spoons and ladles (some were of horn), canoe bailers, trinket boxes, chamber pots, and masks used in ceremonials and rattles for musical accompaniment. A special character of Northwest Coast woodworking was the emphasis on symmetry, neatness of finish, and frequent decoration of the surfaces, with relief carving or with relief carving and painting. All of this woodworking was accomplished with rather limited tools, the principal ones being the adz, mauls and wedges, chisels, drills, curved knives, abrasive stones and sharkskin for polishing. Mountain-goat horn, mountain-sheep horn traded from the interior, and, in the south, elk horn were carved by essentially the same methods as wood.

Another highly developed craft was weaving. The inner bark of red cedar was stripped long and ribbonlike to be woven into mats and baskets in a checkerwork technique. The same bark was shredded into finely divided flexible hanks, which were twined together to make a slip-on rain cape shaped like a truncated cone. The softer inner bark of yellow cedar was made into robes. Persons of high status wore such robes edged with strips of sea-otter fur and a few strands of yarn made of mountain-goat wool. Salish of the Georgia Strait wove robes of mountain-goat wool and also of wool from a special breed of

shaggy little dog. The Chilkat, a Tlingit group, wove robes of mountain-goat wool that was twilled like basketry. Chilkat blankets bore representations of crests in blue, yellow, black, and white.

Twined basketry made from long, flexible splints split from spruce roots was made with great technical skill in several regions. Baskets so tightly woven as to be waterproof were made for cooking in the northern and northwestern Californian regions. Storage containers, receptacles for valuables large and small, and rainhats (Californians' hats were snug and caplike, worn only by women) also were woven. The Coast Salish specialty was coiled basketry.

Clothes

Dress patterns of the area were simple. Only the northernmost Tlingit and the Kitksan of the upper Skeena wore tailored buckskin clothing: breechclouts, leggings, and shirts for men; long gowns for women. Elsewhere, men wore robes of yellow cedar bark or of crudely tanned pelts in cold weather, rain capes in downpours, and nothing but ornaments on the infrequent bright sunny days. Ornaments, such as necklaces, earrings, bracelets, and anklets, were made of various materials, mostly shells, copper, wood, and fur. Some groups practiced tattooing.

Head-flattening was considered a beautifying process from the northern Kwakiutl region to the central Oregon coast. A newborn infant in its cradle had its head bound in such a way as to produce a long subconical form, a strong slope from the eyebrows back, or a distinctive wedge shape in which the back of the skull was flattened.

Belief and the aesthetic systems. *Religion.* Among no group or groups on the Northwest Coast did religion consist of an organized coherent body of beliefs in and attitudes toward the supernatural. Rather, there were several quite unrelated concepts that provided the widespread bases for various kinds of religious activity.

Fish spirits

One concept was that salmon were supernatural beings who voluntarily assumed piscine form to sacrifice themselves annually for the benefit of mankind. On being taken, the spirits of the fish returned to their home beneath the sea, where they were reincarnated if their bones were returned to the water. If offended, however, the salmon-beings would refuse to return to the river. Hence, there were numerous specific prohibitions on acts believed to offend them and observances designed to propitiate them, chief of which was the first salmon ceremony. This rite varied in detail along the coast but invariably involved honouring the first salmon of the main fishing season by sprinkling them with eagle down, red ocher, or some other sacred substance, welcoming them in a formal speech, cooking them and distributing their flesh, or morsels of it, communion-fashion, to all the members of the local group and any guests. The maximal elaboration of this rite was found in northwestern California, combined there with first fruits observances, and dances in which lineage wealth was displayed, in what have been called world-renewal ceremonies. Elsewhere the first salmon rituals were less elaborate but still important (except among the Tlingit, who did not perform them).

Another concept was that of acquiring personal power by seeking contact with a spirit—as through prayer and a vision. Among Coast Salish all success in life—whether hunting, woodworking, accumulating wealth, military ventures, or magic—was bestowed by spirits encountered in the spirit quest. From his spirit or spirits each person acquired songs, special regalia, and dances. Collectively, the dances comprised the major ceremonials of these people; known as the Spirit Dances, they were performed during the winter months. In the Wakashan province and the northern one it was believed that remote ancestors on spirit quests had been rewarded with totemic symbols called "crests." Displaying these hereditary crests and recounting their traditional acquisition formed an important part of the potlatches. In the Wakashan area certain ceremonial cycles called for the dramatization of the whole tale of the supernatural encounter, including the spirit's possession of the seeker and the eventual exorcism of the spirit; such dramas were performed by what were called "dancing societies."

Shamanism differed from other acquisitions of supernatural power only in the nature of the power obtained; that is, power to heal the sick through extraction of disease objects or recovery of a strayed soul. It was commonly believed that some shamans, or medicine men, had power to cause these infirmities as well as to cure them. Witchcraft, to kill or make ill, was also believed to be carried out by malicious persons who knew secret rituals for that purpose.

Art. The Northwest Coast is noted for its art styles. In the northern province low-relief carving accented by painting was essentially an applied art. The motifs were the hereditary crests of the clans or parts of the crests, applied to the magnificent memorial poles and interior house-posts, painted on house-fronts and screens, wrapped around boxes and dishes, painted on basketry hats, woven into Chilkat robes, and carved on the handles of ladles and spoons, on halibut hooks, and even on the triggers of animal traps. There were differences within this style. Haida art tended to be massive, of highly conventionalized balanced elements, and slightly static. In Tsimshian carving and painting there was an effort to leave no open space in or between the conventionalized motifs: filler elements such as eye-designs and miniature figures were used intensively. Tlingit art was slightly less conventionalized, more vigorous by modern standards, with relatively little use of filler elements.

Wakashan representative art was more frankly sculptural than applied, and it was impressionistic and bold. There was a limited amount of simple geometric design on such things as whalebone clubs and whaling harpoon barbs. Their Coast Salish neighbours used some, but less, representative art, similar if cruder in style. On Puget Sound there was little if any representative art; the formless painted designs on the canoe boards were unlike anything else on the Coast. All that is known of Chinook art is represented by a few angular figures incised on mountain sheephorn bowls. In northwestern California art was limited to geometric patterns incised on elkhorn objects and shells.

MODERN CULTURAL DEVELOPMENTS

The impact of white man's culture on that of the Northwest Coast varied at different periods and in different regions. Maritime traders, searching for precious sea-otter pelts, purveyed Euro-American manufactures to the Indians; but the material objects affected native culture only slightly. The Indians picked and chose the articles that had meaning to them—those that could fit well into their existing culture patterns. They acquired steel blades, for example, that could be fitted to their adzes to cut more efficiently than the aboriginal stone or shell blades; they spurned axe and hatchet blades that required a drastic change in motor habits and coordination patterns. In other words, the Indians accepted what they wanted; they were under no compulsion to change their way of life. Contagious diseases—smallpox, venereal infections, and the rest, introduced incidentally—had more effect on native society. The abnormal rate of deaths forced unusual distributions of roles and status positions, involving frequent adoptions, allocation of various titles to the same person, and other makeshift compromises to maintain the social system despite rapid population decline.

The establishment of white trading posts had somewhat more effect; and the great pressures started when white settlers began streaming into western Washington, Oregon, Vancouver Island, and the lower Fraser River Valley about the middle of the 19th century. This foreign occupation was accompanied by removal of the Indians to small reservations in Washington and Oregon under the provisions of formal treaties. In the area that became British Columbia there were no treaties extinguishing Indian title to the land; land transfers were private affairs.

Economic problems

In the closing decades of the 19th century, the Indians were in dire straits. Divested of most of their lands and at the same time more and more dependent upon white American and British-Canadian manufactured goods, the Indians had to develop new economic patterns. The fur trade was inconsequential; logging and mining were still

underdeveloped, requiring skills that the Indians did not have. Northwest Coast concepts of wealth differed from the Euro-American ones, but there were enough general similarities so that the Indians could perceive and accept certain equivalences. Northwest Coast Indians thus came to be more disposed to enter the new economic system, working for wages in a dull day-after-day routine, something that most other North American Indians refused to do. There was at first, however, little hired work available —guiding prospectors, back-packing cargo over mountain passes, cutting cordwood for coastal steamers—until the canned salmon industry developed, principally from the Fraser River northward. It was this industry that most effectively deprived the Indians of their fishing economy by monopolizing salmon streams, while at the same time offering them entrée into the new economy. Indian labour was cheaper than Oriental because it did not have to be imported. The Indians also knew more about the habits of the salmon than anyone else. Of great importance was the fact that the commercial salmon fishery began with a very simple technology. As motive power changed from paddles and oars to two-cycle gasoline engines, to high-speed gasoline engines, to diesel engines; as harvesting changed from gill nets and crude "beach seines" to huge purse seines handled with power gear; and as navigation changed from eyeball piloting to navigation using tide tables, compasses, and charts, the Indians could learn the new skills along with white and Oriental fishermen. The problem now is that the Indians are largely committed to a short-season industry, which ties up capital in expensive boats and nets. When the salmon run is over, there is no significant source of income until the next year.

Effective missionary activity began in various parts of the coast at about the same time that administrative controls were established. Missionaries on the Northwest Coast as elsewhere have been very competent at directed culture change, teaching not only Christian precepts but also etiquette, values of work and sobriety, household hygiene, and a host of other things that the native needed to know in order to participate in modern culture. Formal schooling of Indian children was in the hands of missionaries on much of the coast for many decades.

The aggressive and warlike Northwest Coast Indians never mounted a major war against the whites. There were only a few isolated local conflicts. This pacific pattern was not due to cowardice but to a realistic appraisal of the vulnerability of their coastal villages to naval gunfire.

There were some nativistic movements—that is, attempts to preserve or resuscitate former valued concepts or activities: for instance, the southern Kwakiutl tried to revive potlatch on a splendid scale, despite administrative prohibitions; and the Canadian Coast Salish tried to continue their Spirit Dances. But there is a distinction between these limited efforts of the Northwest Coast Indians and the "revitalization" movements of the Great Plains Indians, who, with their Ghost Dance, sought by supernatural means to evict the oppressor culture and return completely to the "good old days."

In southeast Alaska and later on in coastal British Columbia a different type of organization was created, the "Native Brotherhoods," whose purpose is to foster cultural change. The accomplishments of the Alaska Native Brotherhood have surpassed those of the Canadian organization, but both have been effective in creating a sense of Indian unity and community of interest. The organizations also provide valuable training in modern political processes and negotiations. The Alaskan organization has been partially superseded by the Tlingit-Haida Association, which handles matters related to the successfully prosecuted land claims of those people. Leaders of the British Columbia Brotherhood also have been effective in legal suits for compensation for lands.

BIBLIOGRAPHY. There are only two books that treat Northwest Coast culture on an area-wide basis: P. DRUCKER, *Indians of the Northwest Coast* (1963), and *Cultures of the North Pacific Coast* (1965). The former emphasizes material culture, technology, and art; the second, social and ceremonial organization. There are many good descriptions of individual Northwest Coast divisions: A. KRAUSE, *Die Tlinkit-Indianer* (1885; Eng. trans., *The Tlingit Indians*, 1956); V.E. GARFIELD and PAUL S. WINGERT, *The Tsimshian Indians and Their Arts* (1967); T.F. MCILWRAITH, *The Bella Coola Indians*, 2 vol. (1948); FRANZ BOAS, *Kwakiutl Ethnography*, ed. by H. CODERE (1966); P. DRUCKER, *The Northern and Central Nootkan Tribes* (1951); H.G. BARNETT, *The Coast Salish of British Columbia* (1955); A.L. KROEBER, chapters on Yurok, Karok, and Hupa in *Handbook of the Indians of California*, 2nd ed. (1953).

(P.Dr.)

Northwest Frontier Province

The Northwest Frontier Province, the northernmost province of Pakistan, covers an area of 39,283 square miles (101,743 square kilometres) and is bounded by Afghanistan to the west and north, Jammu and Kashmir to the northeast, Punjab Province to the southeast and Baluchistan Province to the southwest. The population at the start of the 1970s numbered almost 7,600,000. Peshāwar is the provincial capital.

This rugged, mountainous land is noted for the fierce independence and ethnic pride of its Pathan population; those who live within the tribal territories are not subject to Pakistani law. It is a hard land, poor in natural resources, and unsuited to extensive agriculture. The region is strategically important because it contains the Khyber Pass, a gateway through which several times in the course of history invading armies from the north have marched on their way to conquer the Indian subcontinent. (For related physical features see HINDU KUSH [MOUNTAINS]; PAMIR MOUNTAIN AREA; KARAKORAM RANGE; and INDUS RIVER.)

History. *The early period.* The early history of the province relates to the ancient state of Gandhāra, which was comprised of the Vale of Peshāwar and adjoining areas. The kingdom was important because of its strategic location at the end of the Khyber Pass, the most direct and easily negotiable route to Afghanistan, Iran, and Central Asia. Gandhāra was annexed by the Persian Achaemenid Empire in the early 6th century BC, and remained a Persian satrapy until 327 BC. The region then passed successively under Greek, Indian, Indo-Bactrian, Śakan, Parthian, and Kushan rule.

Foreign conquests

Muslim administration was first brought to the region by the Turks, whose ruler, Sebüktigin, gained control of Peshāwar by AD 988. His son, Maḥmūd of Ghazna, invaded northern India several times between 1001 and 1027, bringing a large area of the present province, excluding Hazāra, into his Ghaznavid empire. In 1779 Muʿizz-ud-Dīn Muḥammad of Ghūr captured Peshāwar which remained under his rule until his death in 1206. After the decline of the Ghūrids, the region was held first by the Muslim Afghan dynasties and then by the Mughals. After the invasion of the Persian ruler Nāder Shāh in 1738, the territory remained under a loose form of Afghan Durrānī rule.

The Sikh invasions from the Punjab region of India began in 1818, after which the Sikhs increasingly made themselves the masters of the frontier territory until the coming of the British in 1849.

The British period. The northwestern frontier areas were annexed by the British after the Second Sikh War of 1849. They formed a part of the Punjab (including what is now the Indian state of Punjab) until the Northwest Frontier Province was created in 1901. The new province was administered from Peshāwar by a chief commissioner and agent to the governor general. The territory was not granted the measure of self-rule given to the other Indian provinces in 1919. In 1935, however, the Government of India Act raised its status to that of a governor's province and allowed provincial autonomy.

Independence. After independence in 1947, the region continued to exist as a separate province. The feudal states of Phūlra and Amb were merged with the province in 1950. In 1955, Northwest Frontier Province, along with other provinces, was amalgamated into West Pakistan province. After the dissolution of West Pakistan province in 1970, the region regained its former provincial status, with the states of Swāt, Dīr, and Chitrāl being added to its territory.

Landscape. *Relief and drainage.* The terrain is comprised of mountain ranges, undulating dissected submontane areas, and plains surrounded by hills. In the north, the general orientation of the ranges is longitudinal, while it is transverse south of the Kābul River, which runs from west to east. The Hindu Kush region in the northern part of the province is divided by the Kunar River into two distinct ranges—northern Hindu Kush and the Hindu Rāj. Tirich Mīr rises to 25,263 feet (7,700 metres) and is the highest peak of the northern Hindu Kush. The highest peak of the Hindu Rāj is Shāh Dok at 20,737 feet (6,321 metres). East of Tirich Mīr, the Hindu Kush is extensively covered with snow and lofty glaciers.

To the south of the Hindu Rāj is the rugged country of the Pānjkora, Swāt, and Kandia river basins. Hazāra District in the east contains the Lesser Himalayas and the sub-Himalayas, which form definite ranges broken by hilly country and small plains. The transverse arrangement of the ranges south of the Kābul is markedly represented by the Safed Koh, whose highest peak, Sakaram, rises to 15,620 feet (4,761 metres). This southern area is traversed by the Kurram, Tochi, and Gumal rivers.

The Vale of Peshāwar and Bannu Plain

The fertile Vale of Peshāwar is covered with alluvial sediments that have been subjected to erosion. The tableland in the Kohāt area south of Peshāwar is rugged and cut by streams; the borders of the Bannu Plain southwest of Peshāwar are hilly. Topography has resulted in the development in some places of fascinating examples of the trellis pattern of drainage. In the Dera Ismāīl Khān area, the land is mostly a dry plain intersected by torrents and bordered on the east by the *kachī*, or the narrow Indus riverine tract.

Soils. The northern ridges are generally associated with the Himalayan territory; they contain gneiss (a coarse-grained rock containing bands of minerals) and granite in upper Chitrāl. The transverse hills are mostly formed of nummulitic limestone (limestone formed during the Eocene Epoch between 54,000,000 and 38,000,000 years ago) and sandstone. Much of the Vale of Peshāwar is covered with surface gravels and alluvium, while the rocks of Kohāt are mostly sandstones surrounding outcrops of nummulitic limestones. The Bannu Plain is mostly composed of soft sandstones and conglomerates; the greater part of the Dera Ismāīl Khān plain is covered with gravels, alluvium, and limestone.

Climate. The climate is highly diversified, according to altitude. While the northern mountains have snowy winters and cool summers, the mean annual temperature increases markedly toward the south, rising from 72.9° F (22.7° C) at Peshāwar to 76.6° F (24.8° C) at Dera Ismāīl Khān. Precipitation falls in winter and spring. The mean annual rainfall is 18 inches at Drosh, 14 inches at Peshāwar, and ten inches at Dera Ismāīl Khān. While the rainiest season is usually from January to April, precipitation is generally variable, and droughts may occur in either summer or winter.

Vegetation and animal life. In the far north, where extremes of altitude and climate are experienced, the higher mountains are bare and rocky. Elsewhere in the north, the mountain slopes bear stands of evergreen oak and pine; and broad-leaved deciduous trees such as the plane and poplar grow on the warmer, sunnier slopes. There are also extensive mountain grasslands. The hills to the south are sparsely covered with bushes, acacia, and grasses. About 9 percent of the uncultivated area of the province is forested.

Population. *Demography.* In 1961 the province had a total population of about 7,600,000; there were slightly more males than females. The overall density of population was about 180 persons per square mile. Peshāwar and Mardān (northeast of Peshāwar) are the most densely populated districts—Peshāwar with a density of about 500 persons per square mile—while in 1961 Dera Ismāīl Khān Division had a density as low as about 108 persons per square mile.

Population groups. Muslims constitute 99 percent of the population. Pashto is the predominant language, except in Hazāra and Dera Ismāīl Khān districts, where Punjabi predominates. The province is inhabited by numerous Pathan tribes and *khēl*s, or clans, each taking great pride in its genealogy. The major tribes are the Yūsufzai, Utmān Khēl, Mohmand, Afrīdī, Orakzai, and Wazīrī. Others include the Moḥammadzai, Shinwārī, Zaimukht, Bangash, Khaṭak, Bannūchī, and Maḥsūd.

The Pathans

Patterns of settlement. Only 10 percent of the overall population is urban. This percentage varies from 32 percent in Peshāwar District to only 5 percent in Hazāra District northeast of Peshāwar. Urban growth is generally slower than that of Pakistan as a whole. The province has only one city, Peshāwar; there are seven large towns with populations of between 25,000 and 100,000. There is a generally low percentage of migrants, except in Peshāwar District where the immigrant population numbered 34 percent in 1961.

Administration. *Government structure.* The province is divided into Malakand, Peshāwar, and Dera Ismāīl Khān divisions, which are subdivided into a number of districts. Each district is broken down into several *tahsils* (smaller administrative units). Between the settled districts to the south and the Afghan border is the tribal territory, whose inhabitants enjoy a large measure of independence. The tribal territory is divided into the Mohmand, Khyber, Kurram, North Wazīristān, and South Wazīristān agencies, each headed by a political agent.

The governor is the chief executive. In the directly administered areas, the provincial secretariat is headed by a chief secretary. A commissioner is in charge of each division, and the districts are headed by deputy commissioners. At the district level, judicial functions are performed by district and sessions judges, civil judges, and magistrates. Magistrates also perform some executive functions. In each *tahsil*, an official called the *tahsildār* collects revenue and discharges judicial and executive functions.

The tribal territory. In the tribal territory tribesmen are free to rule themselves according to their own customs. Political agents have power to award or withhold subsidies and to control entry into and departure from the tribal territory. The agent—aptly described as "half ambassador and half governor"—reports to the divisional commissioner and the Ministry of Home and Kashmir Affairs of the central government.

Counselling, judicial functions, intertribal liaisons, and communal dealings with the political agent are performed by the *jirgah* or council of elders. The selection of the *jirgah*'s members is based on tradition; their decisions are unanimously arrived at by consensus.

Social conditions. *Education.* The tribal order is inherently resistant to social change, and educational progress is quite slow. The literacy rate among the total population is lower than that of Pakistan.

There were almost 4,900 primary and middle schools with an enrollment of 480,000 students. High schools and colleges numbered 280 and had an enrollment of about 160,000 students. The university at Peshāwar, together with its constituent professional colleges, has a total enrollment of more than 8,000 students. There are far fewer female than male students.

Health services. Health facilities are inadequate, to the extent of being meagre. In the early 1970s the authorities assigned a high priority to both preventive and curative medical facilities and to the establishment of rural health centres. Among preventive schemes, the greatest emphasis was placed on malaria eradication. A family-planning program was started on a large scale in 1965, after which the birth rate was estimated to have declined to 45 per 1,000.

The government social welfare development program is implemented by 75 urban and 30 rural community development centres. The program aims at inculcating among the people a spirit of self-help, at developing leadership qualities, and at promoting the acquisition of skills.

The economy. The province is poor in natural resources but receives developmental allocations from the central government. The development strategy of the provincial government is to concentrate on productive schemes of a short gestation period. The main emphasis is

placed on agriculture, education, health, and transport and communications. In the early 1970s, emphasis was placed on establishing the development of cooperative and rural credit, on food storage, and on land reform.

Agriculture. The economy is essentially agricultural. Agriculture contributes 40 percent of the total gross provincial product and employs 80 percent of the population either directly or indirectly. Out of a total of 10,700,000 acres, 34 percent is cultivated. The net sown area is 81 percent and the current fallow area 19 percent of the cultivated area. Of the uncultivated land, 40 percent could be cultivated if irrigation or other facilities were made available. Irrigation is carried out on 38 percent of the cultivated land.

Principal crops

Wheat, maize (corn), sugarcane, and tobacco are the major crops. Other crops include millet, barley, rice, and cotton. Wheat production is highest in Peshāwar, Bannu, and Mardān districts, and Hazāra, Mardān, and Peshāwar districts are important maize-producing areas. Peshāwar and Mardān are also important regions of production of sugarcane and tobacco.

Industry. There is little industry; the province contains only about 3 percent of the manufacturing industries located in Pakistan. Industries in the province, which provide employment for more than 27,000 workers, include the manufacture and refining of sugar, the canning and preservation of fruits and vegetables, tobacco processing, and the manufacture of arms and accessories. Other products are cotton textiles, cement, vegetable ghee (margarine), nonmetallic mineral products, furniture, and milled grains. It is believed that the province may contain valuable mineral ores, but prospecting was still in progress in the early 1970s.

Transport and communications. In view of the strategic importance of the region, the British government constructed railways and roads across it, despite tribal opposition and the difficult nature of the terrain. Since independence, these facilities have been improved to help to promote economic growth. The province has 179 miles of broad-gauge and 196 miles of metre-gauge railway track. The length of paved roads totalled almost 4,300 miles in 1970.

Cultural life. The Pathans have a rich cultural heritage in which they take great pride. *Pakhtūnwalī*, or *pashtūnwalī* (the way of the Pathans) constitutes a code of honour, which imposes three chief obligations—*badal*, or revenge, the most important and binding aspect of *pakhtūnwalī*; *nanawātai*, is the right to seek asylum; and *maelmastyā*, which entitles a stranger or even an enemy to hospitality.

The code of honour

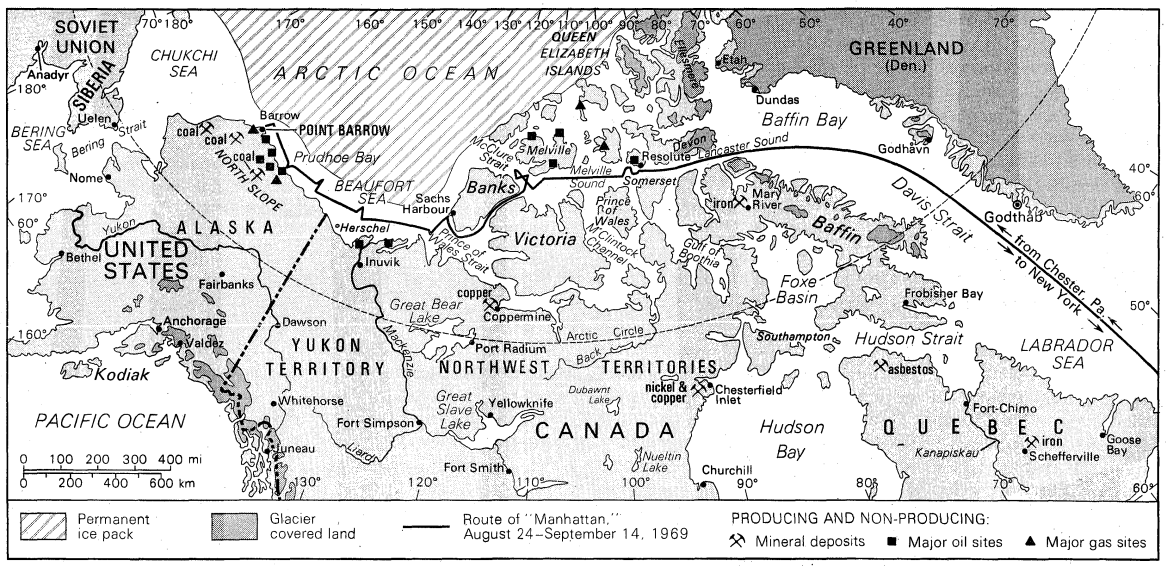
The Pathans are an intensely religious people who uphold a long tradition of preserving their freedom. Their council of elders, the *jirgah*, settles disputes and maintains high standards of justice. In the tribal order the position of the *malik* or *khān*, the head of the tribe, is most distinguished. Each village has one or more guest house, *ḥujrah*, which also serves as a club or town hall. Their festivals are mostly of a religious nature, but entertainments such as tent pegging and the whirling Khaṭak dance demonstrate the people's martial spirit. Folklore is generally related to the theme of Pathan bravery or to other traditional characteristics and often strikes an ethical note. The everyday dress of the Pathans consists of a long shirt, waistcoat, *shalwār* (trousers), and turban. Firearms are often carried. Women usually remain in *pardah* (*i.e.*, secluded from public view).

BIBLIOGRAPHY. Numerous works, principally by British writers, emphasizing strategic aspects include: W.P. ANDREW, *Our Scientific Frontier* (1880); T.H. HOLDICH, *The Indian Borderland, 1880–1900*, 2nd ed. (1909) and *The Gates of India* (1910); A. VINCENT, *The Defence of India* (1922); and C.C. DAVIES, *The Problem of the North-West Frontier, 1890–1908* (1932). General treatment of the area, as a part of the Indo-Pakistan subcontinent, occurs in E.J. RAPSON (ed.), *The Cambridge History of India*, vol. 1 (1922, reprinted 1935); and O.H.K. SPATE and A.T.A. LEARMONTH, *India and Pakistan*, 3rd ed. (1967). The Imperial Gazetteer of India, Provincial Series, North-West Frontier Province (1908), is a reference work on the region. DAVID DICHTER, *The North-West Frontier of West Pakistan* (1967), provides useful geographical coverage. An informative work on landforms and land use in Pakistan is the COLOMBO PLAN COOPERATIVE PROJECT, *Landforms, Soil and Land Use of the Indus Plain* (1958). Basic statistical data is contained in the provincial series of the Northwest Frontier Province of the *Census of India* up to 1941, and in the *Census of Pakistan*, 1951 and 1961; in *Provincial Season and Crop Reports*; and in the *Provisional Census of Manufacturing Industries of West Pakistan 1967–68* (1970). The *Economic Survey and Outlook: North West Frontier Province* (1971), is a useful government publication.

Northwest Passage

Since the end of the 15th century, it has been the elusive goal of Western man to establish a commercial sea route north and west around the American land barrier encountered by Christopher Columbus. This search, by many European nations, for a short water route to the Orient wrought momentous changes in world history. It brought about European colonization of the New World, shifted the centre of world trade from the Mediterranean to the Atlantic, and changed man's perspective of the world in which he lives. Over the centuries, the quest for a Northwest Passage evolved into scientific expeditions by intrepid Arctic explorers, who eventually found a hazardous route through Canada's Arctic Islands. Supply convoys began making limited summer use of it after World War II, as the U.S. and Canadian governments established Arctic weather stations for transatlantic and polar airline flights and built radar stations, air fields, and other defense installations in the frozen north.

With discovery of vast oil deposits in the Alaskan Arctic in 1968, the Northwest Passage again became a goal of global commercial significance. In the fall of 1969, the giant experimental icebreaking oil tanker ss "Manhattan" became the first vessel to batter straight through the pack ice covering the passage, proving that especially designed ships could operate the year round in the Arctic. The economic feasibility of such projects is less certain, due as much to complex governmental policy issues as to the harsh environment and tender ecology of the Arctic. Deployment of a fleet of mammoth icebreaking tankers to haul Alaskan oil through the Northwest Passage would create a new world-trade route, nearly halving the distance between Europe and Asia. Such an accomplishment would realize an objective that has eluded man since King Henry VII of England sent John Cabot in search of a northwest route to the Orient in 1497. Five years earlier, Columbus had set out in search of a westward route after conquest of the Middle East by the Ottoman Turks in the mid-15th century disrupted Europe's overland routes to the East. Vasco da Gama sailed south around Africa to India in 1498; Ferdinand Magellan sailed southwest around South America to the East Indies in 1521; and Dutch explorers vainly sought a northeast passage around Russia. But it was the Northwest Passage that captured the imagination of many of the world's famed explorers, including Jacques Cartier, Sir Francis Drake, Sir Martin Frobisher, and Capt. James Cook. All met with failure, and many with disaster. Sir Humphrey Gilbert, whose treatise on the passage inspired many voyages by others, drowned on his own attempt in 1583. Henry Hudson, his young son, and seven others were cast adrift by a mutinous crew in 1611, when his discovery of Hudson Bay proved to be an icy trap instead of the passage he sought. Knowledge of an Arctic passage came slowly, over hundreds of years, from information gathered during voyages by such explorers as John Davis, William Baffin, Sir John Ross, Sir William Parry, Frederick William Beechey, and Sir George Back, augmented by overland expeditions by Henry Kelsey, Samuel Hearne, and Sir Alexander Mackenzie. The worst tragedy came when Sir John Franklin and 129 men aboard HMS "Erebus" and HMS "Terror" vanished in 1845. One searcher for the lost expedition, Robert McClure, entered the passage from the west, became locked in the ice for two winters, then sledged overland to another rescue ship coming from the east to complete the first Northwest Passage in 1854. Adolf Erik Nordenskiöld led a Swedish–Russian voyage



The Northwest Passage.

First conquests of the passage

through the Northeast Passage in 1878–79, and Soviet polar icebreakers have opened this route to limited use in modern times. But the Northwest Passage was not finally conquered by sea until 1906, when the Norwegian explorer Roald Amundsen, who had sailed secretly to escape creditors seeking to stop the expedition, completed an arduous three-year voyage in the converted 47-ton herring boat "Gjöa." The first single-season transit came only in 1944, when Sgt. Henry A. Larsen, of the Royal Canadian Mounted Police, made it through in the schooner "St. Roch."

THE ENVIRONMENT

The hostile Arctic makes the Northwest Passage one of the world's severest maritime challenges. It is 500 miles (800 kilometres) north of the Arctic Circle and less than 1,200 miles (1,900 kilometres) from the North Pole. It consists of a series of deep channels through Canada's Arctic Islands, extending about 900 miles (1,450 kilometres) east to west, from north of Baffin Island to the Beaufort Sea, above Alaska. Thick pack ice, moving at speeds up to ten miles a day, completely covers its waters about nine months of the year and chokes nearly half the passage all the year round. Arctic water can freeze a man to death in two minutes. Frigid polar northeasterly winds blow almost constantly and can howl to hurricane force in winter. Temperatures plunge to —50° F (—46° C) and rise above freezing only in July and August. Exposed human flesh is subject to frostbite during most of the year, and breathing in open winter air is difficult and can be dangerous. Visibility is often obscured by whiteouts of blowing snow, the area is plunged into four months of 24-hour, midwinter darkness, and thick fog usually shrouds open water during the brief summer. The main channels are more than 1,000 feet deep, but there are uncharted shoals, and little is known about Arctic currents and tides. Navigation is difficult even with the most modern devices: the magnetic compass is useless because the magnetic north pole lies within the passage; the gyro compass can be unreliable at high latitudes; underwater ice distorts sonar depth soundings; and the bleak, featureless Arctic islands provide few distinguishable landmarks for visual or radar checks. Even navigation by space satellite suffers from electronic interference, and Arctic blackouts can block all communications for periods from a few hours to nearly a month. To reach the Northwest Passage from the Atlantic requires a hazardous voyage through a stream of about 50,000 giant icebergs, up to 300 feet in height, constantly drifting south between Greenland and Baffin Island. The bergs are often hidden in dense fog created by collision of the warm Gulf Stream with icy Arctic waters, and small "growlers" up to several thousand tons can be invisible to radar and lookouts. The exit to the Pacific is equally formidable, as the polar ice cap presses down on Alaska's shallow north coast much of the year and funnels masses of ice into the Bering Strait, between Alaska and Siberia.

Navigational hazards

The greatest challenge of the Northwest Passage to shipbuilding technology is the ice pack. It grows only about seven feet thick in an average season, but much of the ice survives from year to year, increasing to 14 feet or more in thickness and becoming much harder as it loses salinity. The polar cap also constantly feeds hard old ice into the passage from the west, through McClure Strait. The twisting, grinding action of the wind and currents on the pack creates pressure ridges, huge cone-shaped masses of ice believed to extend as much as 150 feet below the waterline, and for miles laterally. Early explorers skirted the pack close to shore in shallow draft vessels, and modern supply convoys stick mainly to open summer waters. Commercial use of the passage would require vessels with the power to batter through the ice pack year round.

The ice pack

THE "MANHATTAN" VOYAGE

To evaluate the economic feasibility of such ships, and to gather the data needed to build them, a $50,000,000 project was launched in 1969 by the three international or North American oil companies with the largest holdings of Alaskan Arctic oil. They leased the largest and most powerful commercial ship ever built in the U.S., the "Manhattan," and sliced it into four pieces so that 10,000 workers, from Maine to Alabama, could simultaneously convert it to the world's largest icebreaker and an Arctic research vessel. She was fitted with a massive 725-ton, shark-nosed icebreaking bow, girdled with a 16-foot, 2,200-ton steel ice belt, and her rudders and 22-foot-diameter propellers encased in ice shields. She was equipped with computer-controlled navigational equipment, the latest electronic devices, and charts made by U.S. Navy nuclear submarines. A landing pad for two helicopters was added to her stern. The reassembled giant was nearly as long as the Empire State Building tipped on its side and, at 151,000 tons, displaced about twice the weight of the "Queen Elizabeth." Sailing from Chester, Pennsylvania, August 24, 1969, she plowed into the Baffin Island ice pack September 2, entered the Northwest Passage three days later, and completed a historic transit on September 14, after smashing more than 650 miles of ice. She sailed as far west as Point Barrow, Alaska's northwestern tip, then returned to the passage for extensive ice tests, completing the voyage in New York on November 12. The "Manhattan" broke ice up to 14 feet thick for extended periods and smashed ridges as deep as 40 feet. But she often got stuck in hard polar ice, proved underpowered and underprotected, and was seriously hampered by possessing only one-third as much power to go astern

as to go forward. The most harrowing moments came the night of September 10–11. Attempting to become the first vessel to cross McClure Strait east-to-west, the "Manhattan" was halfway through when she became locked in polar ice grinding north of Banks Island. She escaped only with assistance from the Canadian icebreaker "John A. MacDonald," her constant companion and frequent rescuer on the voyage, and by diverting steam from living spaces to squeeze an extra 7,000 horsepower from her 43,000-horsepower turbines. She completed the Northwest Passage through the narrow Prince of Wales Strait to the south, the likely route for commercial vessels. But the chief mission of the "Manhattan" on the Northwest Passage, and on a second voyage to Baffin Island in the spring of 1970, was to gather mountains of data from which vessels more than twice her size could be designed. More than 400 gauges measured strains on her hull and acceleration through the ice; closed-circuit television recorded action of the ice on her bow and stern; and scientific parties were sent onto the ice pack to drill and analyze the ice. The data were fed into computers for months after her return. Ice smashed a 15- by 30-foot hole in a bow tank unprotected by her ice belt during the first voyage. This incident increased concern for protecting the fragile Arctic ecology by governments and conservation groups mindful of the 1967 disaster when the grounded supertanker "Torrey Canyon" spilled oil over wide coastal areas of Cornwall. Bacterial action that fairly rapidly consumes oil in warmer waters is far slower in the Arctic, and cleanup techniques effective in open waters might not work on oil trapped under the ice pack. Arctic waters teem with seals, walrus, and whales that could be endangered by an oil spill. Canada has claimed jurisdiction over Arctic waters up to 100 miles from its shores for purposes of setting tough pollution control regulations and required a $6,500,000 bond against pollution damage before approving the "Manhattan's" second voyage. It appears certain that vessels using the Northwest Passage will be subject to stringent antipollution measures.

The pollution threat

ECONOMIC SIGNIFICANCE AND POTENTIAL

Opening the Northwest Passage to regular commercial ocean traffic would have worldwide economic significance in natural resources, transportation, and trade relations among nations. The greatest impact would be on the U.S. and Canada, but effects could be felt from the Persian Gulf to Panama, and from Chile to Scandinavia. But competitive developments, governmental policies, and many complex economic issues, are likely to determine how soon, and how much, such a route would be used. The most likely key to opening the passage is oil. Alaska's Arctic North Slope is estimated to contain as much oil as proven 1970 reserves for all the rest of the United States, where steadily rising demand began to exceed productive capacity by 1972. Many believe the lowest cost method of moving Alaskan oil to the major markets in the eastern U.S. will be through the Northwest Passage. Potential advantage of this route is estimated at 35 to 55 cents a barrel under the use of pipelines. This would mean annual transportation savings of $190,000,000 to $300,000,000 on expected 1980 shipments of 1,500,000 barrels a day. The Alaskan oil could significantly reduce the need for East Coast refineries to begin importing major amounts of oil from the Middle East and North Africa to supplement traditional supplies from the Gulf Coast and from Venezuela. The Alaskan oil could cost less than that from Texas and Louisiana. To move it would require a fleet of about 30 mammoth icebreaking tankers, each capable of carrying 250,000 tons or about 1,800,000 barrels of oil, more than twice the "Manhattan's" 115,000 tons. They would cost a minimum of $1,500,000,000 ($50,000,000 each), and the price tag could escalate as high as $3,000,000,000. Building them would require the greatest U.S. shipbuilding program since World War II. The new vessels would modernize, and expand by 250 percent, capacity of a U.S. flag tanker fleet made up largely of small and nearly obsolete ships. Unloading them would mean building, off the shores of the U.S., those terminals, built to handle mammoth vessels, that have been sharply reducing oil transportation costs for many other nations since the late 1960s. Loading them could require an investment of $150,000,000 to $500,000,000, including such options as building a man-made harbour on Alaska's shallow north coast, perhaps using nuclear explosives; a pipeline to a natural harbour on Canada's Herschel Island, off the Yukon Territory; or an underwater pipeline and ice-resistant mooring facility in the Beaufort Sea. Polar icebreakers to assist the tankers would cost about $50,000,000 each, and navigational aids and additional shore installations would be needed in the Arctic.

Oil-transport costs

Such facilities and regular use of the passage would accelerate exploration for minerals in Canada's vast Arctic, and sea transportation could bring commercial development of known major deposits. These include an estimated 1,000,000,000 tons of high-grade iron ore at Mary River on northern Baffin Island; large copper reserves in the Coppermine area of the mainland near the western end of the Northwest Passage; and major amounts of lead, zinc, and sulfur in the Arctic Islands. Nearness to markets and relative security of Arctic ores could make them stiff competitors for those from Africa and South America. Geologists have predicted that drilling will locate oil fields in the Canadian Arctic to rival those in Alaska. Exploratory drilling was spurred in 1970 by the discovery of oil in the Arctic Mackenzie River Delta, and of natural gas in the Arctic islands. The high value of crude oil in the U.S., due to controls on lower cost foreign imports, makes it unlikely much Alaskan oil will move into world markets, except in supply emergencies. But Canadian Arctic oil could become a competitor for that from the Middle East. Through the Northwest Passage, Arctic oil would be only about 4,000 miles from Japan and Europe, compared with the 8,000- and 11,000-mile distances, respectively, that Middle East oil travels to those markets. Canada's Arctic oil would also move to its own east coast refineries, which at the start of the 1970s were supplied almost entirely from Venezuela. Opening the Northwest Passage could bring new settlements to Canada's vast empty northlands, which in 1970 had only about 22,000 people spread over 1,300,000 square miles. Arctic natural gas could make it feasible to process minerals in the Arctic and might even make domed, climate-controlled Arctic cities a reality. Wheat could move from Canada's prairies to world markets through Hudson Bay and the Northwest Passage on a year-round basis, providing competition for the St. Lawrence Seaway. Easier access to the Arctic would aid U.S. and Canadian military defense of North America. The cost of ice-strengthening ships, and the probable high insurance rates for vessels used in Arctic service, however, could inhibit use of the Northwest Passage as a trade route. But it would cut the distance between London and Tokyo, for example, to less than 8,000 miles, from the 14,670 mile route around Africa made necessary by the shutdown of the Suez Canal in 1967. The Northwest Passage would permit use of far larger vessels than allowed by dimensions of the Panama and Suez canals. Icebreaking techniques learned in the Northwest Passage could be applied in other ice-locked waters from the Great Lakes to the Baltic, including the Soviet Union's Northeast Passage with its vast Siberian oil fields. Canada has held sovereignty over the Arctic Islands since 1880, but some authorities contend that much of the Northwest Passage is in international waters. Canada has indicated it would welcome, and permit, international commerce over the route, subject to pollution control regulations.

Mineral deposits

Regional implications

THE OUTLOOK

Modern technology can overcome the hostile Arctic environment of the Northwest Passage, but economic considerations may prove a greater obstacle. Crews of Arctic vessels can be protected by completely enclosed upper decks, Arctic clothing, and life-support capsules in place of lifeboats. Polar icebreakers would be stationed along the route and might convoy groups of vessels through the passage. The "Manhattan" was guided by infrared photographs, laser-beam measurements, and "side-looking" ra-

dar maps made of the ice pack by U.S. and Canadian ice reconnaissance planes. Space satellites fixed the location of the "Manhattan" every 22 minutes to an accuracy of about one-third ship length. The greatest barrier to building icebreaking tankers to haul Alaskan oil may prove to be the Jones Act, which requires vessels used in domestic trade to be built in U.S. shipyards and operated by U.S. crews. This adds about 50 percent to the cost of building and operating such vessels. Any major change in U.S. restrictions on foreign oil imports could make Alaskan oil uncompetitive in east coast markets. Pollution controversies could delay construction of offshore tanker terminals, or use of the Arctic by giant tankers. In late 1970 the chief financial backer of the "Manhattan" voyages stated that evaluation of data collected indicated that the Northwest Passage is a commercially feasible route. But the company announced it was suspending studies of icebreaking tankers to concentrate on pipeline alternatives which appeared to have an economic edge. Proposed construction of the world's largest pipeline from Prudhoe Bay across Canada to the U.S. Midwest could result in a decision to supply the east coast through a connecting pipeline link. Other proposed pipeline competitors for the Northwest Passage include a transcontinental line from Puget Sound, to be filled by conventional tankers loading at the ice-free terminus of a pipeline across Alaska, and a line across Central America, linking Pacific and Atlantic supertankers. The Northwest Passage may be opened by vessels going under, rather than through the ice. A group of five oil companies were studying in the '70s whether to undertake a $3,000,000,000 program to build nuclear-powered submarine tankers, each capable of carrying 255,000 tons of oil, and the underwater terminal to load them. The submarines could travel three times faster under the ice than an icebreaking tanker smashing across the surface, and they would be protected from the harsh Arctic environment. Regular voyages under the polar cap by U.S. Navy submarines, beginning with USS "Nautilus" in 1958, indicate that the idea is operationally feasible. The need for the Arctic's natural resources and the obvious geographical advantages of the Northwest Passage as a trade route are likely to make it an eventual commercial reality.

Northwest Territories

The Northwest Territories comprise over a third of Canada, itself the world's second largest nation in area, and they reach almost from the eastern to the western extremities of the country across the roof of the North American continent. The territories are among the most sparsely populated but habitable regions of the world, their 1,304,903 square miles (3,379,683 square kilometres) containing nearly 35,000 inhabitants, over half of whom are native Eskimos and Indians. In the north, the territory extends far above the Arctic Circle to incorporate thousands of islands, the largest of which are Victoria Island in the west and Baffin Island in the east, as well as the islands within bays and straits of Hudson Bay and Ungava Bay. The land is one of high plateaus separating a virtually Arctic lowland on the east from a western depression of more moderate climate. Thousands of lakes dot its heavily glaciated surface.

There are three administrative districts in the territories. The District of Franklin takes in the Arctic islands of the north and Boothia and Melville peninsulas. The District of Keewatin lies north of the province of Manitoba and includes the islands of Hudson Bay. The most developed region, the District of Mackenzie, borders the Yukon Territory to the west and the provinces of Saskatchewan, Alberta, and British Columbia to the south. The mineral wealth beneath the land of the territories is thought to be immense, but the climate and distance from major population centres have kept the territories in much of a frontier condition. (For information on related subjects, see the articles CANADA, HISTORY OF; and NORTH AMERICA.)

HISTORY

Vikings probably visited parts of the Canadian Arctic during the Middle Ages, but there are no records of exploration until the voyage in 1576 of the English mariner Martin Frobisher in search of a northwest passage to the Orient. Other expeditions in the 17th century also failed to find the route, but they added to knowledge of the Arctic regions. Interest in finding the route waned in the 18th century, but whaling ships became commonplace in the Arctic waters. The first recorded exploration of the mainland was by Samuel Hearne, who in 1770–72 journeyed from the west coast of Hudson Bay to the mouth of the Coppermine River on the northern coast. Other inland explorations were mainly the work of Montreal-based fur traders. In 1789 Alexander Mackenzie of the North West Company travelled down the river that bears his name to reach the Arctic Ocean. In the 19th century there was renewed interest in a northwest passage. Sir John Franklin and others explored much of Mackenzie District and mapped parts of the northern coastline during the 1820s, work that Thomas Simpson continued in 1838–39. Searchers for the lost Franklin expedition of 1845–48 explored and mapped other parts of the eastern Arctic in the following decade. Later a series of expeditions attempted to reach the North Pole; such exploits continued into the 20th century but by then were overshadowed by more practical activities directed at identifying the resource potential of the Canadian north.

Early explorers and map makers

Settlements were first established to serve the whaling fleets and fur traders. Missionaries became active in the Mackenzie valley in 1852 and in the eastern Arctic toward the end of the century. No resident administrative authorities were established within the present limits of the Northwest Territories until the 20th century. Responsibility for the mainland territories that drain into Hudson Bay, known as Rupert's Land, was vested in the Hudson's Bay Company. The remaining part of the mainland, the North-Western Territory, was under nominal British rule until 1870, at which time both it and Rupert's Land were ceded to Canada. In 1880 the Arctic islands claimed by Britain were also placed under Canadian jurisdiction. Separation of the Yukon Territory, creation of new provinces, and enlargement of other provinces reduced the Northwest Territories to its present limits by 1912. The Royal Canadian Mounted Police were made responsible for maintaining law and order and for providing whatever governmental administration was required in the area.

Fur traders, missionaries, and the police directed the life of the Northwest Territories until the 1920s, when discovery of oil near Fort Norman on the Mackenzie River prompted the Canadian government to establish a territorial administration for the area. Mining replaced the fur trade as the most important industry in Mackenzie District in the 1930s. World War II brought much government-financed construction activity to the territories. In the southern Mackenzie area the Canol pipeline, linking the oil field at Norman Wells to a refinery at Whitehorse in the Yukon, and construction of several large airfields in the eastern Arctic did much to open the Canadian north to further exploration and development. After the war, construction of the Mackenzie Highway to Great Slave Lake and the building of the Distant Early

Warning radar network, the DEW line, continued this process. A great expansion of government-sponsored health, education, and welfare services transformed living and social conditions throughout the north.

THE PHYSICAL ENVIRONMENT AND NATURAL LIFE

Two main regions

Two main types of landscape blend into one another along the tree line, which runs southeast from near the Mackenzie Delta on the Arctic Ocean to near Churchill, Manitoba, on Hudson Bay. Southwest of this line lies the northernmost part of the Canadian boreal forest, extending westward to the mountain ranges that separate the Northwest Territories from Yukon Territory. North and east of the tree line stretch the relatively barren grounds of the Arctic, vast reaches of flat, often poorly drained lowlands and of Precambrian rock more than 570,000,000 years old. Within each of these two main regions, the surface vegetation and the animal life it supports vary with soil and climatic conditions.

The Mackenzie Lowlands. The most favourable conditions are found in the Mackenzie Lowlands in the west, where forests of black and white spruce mixed with deciduous species extend north to the Mackenzie Delta. The climate here is relatively mild, with warm and dry summers during which mean July temperatures of 60° F (about 16° C) are recorded at most of the settlements along the Mackenzie River. The winters are long and cold, with an average mean January reading at Yellowknife on the northern shore of Great Slave Lake of −18° F (−28° C). With only about 70 frost-free days, the growing season is short, which limits plant growth. While it lasts, however, wildflowers and grasses flourish and root and cereal crops can be cultivated. Many species of valuable furbearing animals are found, notably muskrat and beaver. Moose, wolves, black and grizzly bears, and mountain sheep and goats are also native to the area. Pickerel, northern pike, and whitefish are among the fish found in the rivers and lakes.

The coolness of the climate limits navigation on the Mackenzie River system to about four months a year and gives rise to a permanently frozen subsoil, or permafrost, except in a small area south of Great Slave Lake. Permafrost creates serious construction problems, especially where the frozen subsoil is an unstable mixture of fine silt and water.

The northeast. East of the Mackenzie Lowlands and the tree line the climate is colder, and the terrain changes to that of the ancient and rocky Precambrian mass known as the Canadian Shield, the edge of which is straddled by the two largest lakes, Great Bear Lake, 12,275 square miles, and Great Slave Lake, 10,980 square miles. Tree growth becomes sparse and stunted and eventually disappears, to be replaced by the light but tough vegetation of the Arctic tundra. East of the tree line the Arctic climate prevails, with average winter temperatures similar to those in the sub-Arctic region to the west, but with summer temperatures not rising above an average of 50° F (10° C) even in July. In these so-called barren lands, annual precipitation is light and the soils, where they exist at all on the heavily glaciated surface, are usually sandy and thin. Mosses, lichens, and many small hardy flowering plants survive in these conditions and support a variety of animal life ranging from small burrowing mammals and their enemy, the white Arctic fox, to the large caribou and musk-ox. Seals, walrus, and polar bears are prevalent along the coasts. Bird life is plentiful in summer, with some species, notably the ptarmigans and ravens, remaining all winter. Mosquitoes and other insects abound during the summers.

Human impact and settlement. The native people of the territories once led nomadic lives, surviving by adapting to the harsh natural environment. But this balance was disturbed when Europeans established permanent settlements and introduced firearms. The numbers of barren-ground caribou were drastically reduced, and the musk-ox was almost exterminated before being protected in 1927. Fuel and game resources near settlements were rapidly depleted once people began to congregate around the trading posts and missions. Climatic and soil conditions made regeneration slow. Attempts to introduce reindeer and other domesticated animals have not been successful, in part because of the difficulty of managing animals on ranges large enough to prevent destruction of the vegetation by overgrazing.

Today, nearly all the population lives in small settlements along the Mackenzie River and along the Arctic coastlines of the mainland and northern islands. The largest town is the capital, Yellowknife, with a population of about 6,000 in 1971. Hay River, on Great Slave Lake; Fort Smith, near the Alberta border, and Inuvik, in the Mackenzie delta are other towns of over 2,500 people in the Mackenzie area. In the eastern Arctic, Frobisher Bay, on Baffin Island between Hudson Bay and the Atlantic, is the only town with more than 1,000 inhabitants.

THE PEOPLE AND THE CONDITIONS OF LIFE

Population composition. The native Indians and Eskimos comprise two distinct groups, differing in appearance, language, and culture and living apart from one another.

Indians. The approximately 6,000 Indians belong to several tribes, all part of the Athabaskan language family. Tribal organization was never strong among the northern Indians, and small bands led by individuals chosen for their skill in the hunt were the effective social unit. This arrangement was easily molded to the needs of the fur trade when it reached the Mackenzie area in the 18th century. Thereafter, the exchange of furs for imported goods became the basis of the Indian economy. Government treaties were made with the groups living south of Great Slave Lake in 1899, with those living farther north, only in 1921. No reservations were established. The decline of the fur trade in the 20th century left much of the Indian population unemployed, and they have had difficulty adapting to wage employment.

The Indian fur-trading economy

Eskimos. The origins of the approximately 11,000 Eskimos living in the territories, largely in the coastal areas, are obscure. Although several dialect groups are represented, all apparently have descended from what is known as the Thule culture, a prehistoric maritime culture living north and west. A distinct group living inland in the District of Keewatin perished when the caribou migrations upon which they depended were disrupted following the advent of the rifle. The coastal Eskimos lived in small, nomadic family groups before the coming of Europeans. Early contacts with explorers and whaling crews introduced new diseases and reduced the population during the 19th century. There was also considerable interbreeding. The fur trade was not well established in the Arctic until early in the 20th century; but the Eskimo way of life adapted quickly to it, and they, like the Indians, came to depend upon outside sources of supply for most of the necessities of life. Construction activity during World War II and in the postwar years further affected their way of life. Eskimos adapted readily to the opportunities for casual employment, and many were quick to abandon the seminomadic trapping and hunting existence for life in the settlements.

Europeans. The other approximately 15,000 people in the territories are mainly of European and mixed European and native descent. Most live in the more economically advanced Mackenzie District, where they find employment in mining, transportation, and public service. Much of this population has always been transient, living only temporarily in the north before returning to the more settled parts of North America.

Demographic trends. Until World War II the non-native population was small, numbering only 2,572 in the 1941 census. The annual rate of natural increase among the more numerous native population was only about four to five per thousand of population until the 1940s, when the birthrate rose sharply, doubling from 1940 to 1950. Subsequent reductions in the death rate due to improved living conditions raised the annual rate of increase even further. Migration into the territories increased during and after World War II and, with the natural increase, raised the total population from just over 12,000 in 1941 to 36,000 in 1972.

The economy. High production costs and transportation problems inhibit development of many of the territories' known mineral resources, including the large iron ore deposits in the eastern Arctic; but prospecting remains active even in the remote Arctic islands, especially for oil.

Mining and power. Mining is the principal industry of the territories; much of this production is accounted for by the large open-pit lead and zinc mines at Pine Point on the south shore of Great Slave Lake. Gold and some silver have been mined at Yellowknife since the late 1930s. Production of radioactive ores at Port Radium on Great Bear Lake ceased in 1960, but silver is now mined in the area. Tungsten, copper, and cadmium are also produced. Petroleum fuels for use in the territories are obtained from a small refinery located at the Norman Wells oil field. Hydroelectric power is supplied to the Pine Point area by an 18,000-kilowatt-capacity generating plant on the Taltson River, and to the Yellowknife area by plants on the Snare and Yellowknife rivers.

Exploitation of minerals

Hunting and fishing. Trapping continues to provide income for some of the native population. Muskrat, beaver, marten, mink, and lynx are the most important furs taken in the Mackenzie area, while the white fox remains the principal fur in the Arctic regions. Fishing and hunting of sea mammals also provides some employment. Whitefish and lake trout are fished commercially on Great Slave and some smaller lakes. Arctic char are fished and exported to southern markets from several communities in the eastern Arctic. Seals and small whales are hunted for food, and some sealskins are marketed commercially. Sport fishing and hunting are major attractions for the small but growing number of tourists who visit each year.

Forestry and agriculture. The western Mackenzie district has most of the 200,000 square miles of forested land, but even there, large stands of merchantable timber are not plentiful. The several sawmills process the timber only for local use. Although there are more than 1,000,000 acres of arable land in the Mackenzie district, farming is not profitable. Some field crops are grown for local use, but most foodstuffs must be imported from the outside, very much affecting their price.

Economic management. Governmental assistance in the development of major resources is provided only in the form of roads, electric-power facilities, mapping, and geological services, but the government participates in a consortium with private companies to search for oil and natural gas in the Arctic region. The government-owned Northern Canada Power Commission operates generating facilities throughout the territories. Another government enterprise, Northern Transportation Company Limited, is the principal carrier on the Mackenzie River waterway. The government also has encouraged establishment of local cooperative enterprises in such smaller businesses as commercial fishing, arts and crafts, fur-garment manufacture, retailing, and logging. By 1970, 34 such cooperatives had been established.

Transportation. Nearly all passenger and much freight traffic is carried by scheduled and chartered air services. Flights link Yellowknife and other major settlements along the Mackenzie Valley to Edmonton, Alberta. Settlements on the west coast of Hudson Bay and in Keewatin District are connected to Winnipeg, and those in the eastern Arctic to Montreal.

Airline services

Surface transportation for heavy freight is mainly by water. Fuel oil for heating, and other bulky supplies, are carried to eastern Arctic settlements by seagoing supply ships organized by the federal Department of Transport. In Mackenzie District, the Mackenzie waterway system, 1,700 miles (2,735 kilometres) long, is the main freighting facility. It is supplemented by the Mackenzie Highway, part of a highway system of about 800 miles in the southern part of the district, and by the Great Slave Lake Railway, connecting Pine Point to the trans-Canadian rail systems at Grimshaw, Alberta. Tractor trains and other overland vehicles using temporary winter roadways carry heavy freight into remote areas. Snowmobiles have largely replaced the dogsled for light winter travel.

Administration and social conditions. Ultimate constitutional responsibility for government in the territories rests with the federal government in Ottawa, but most responsibilities of a provincial nature in Canada have been delegated to a territorial administration sitting at Yellowknife. This consists of a commissioner and a council comprising seven members elected by the people and five members appointed by Ottawa. The territories are represented by one elected member of Parliament. Justice is dispensed by a territorial court, a police magistrate, and several justices of the peace. Law enforcement is by the Royal Canadian Mounted Police.

The federal government retains direct responsibility for all natural resources except game and administers them through its Department of Indian Affairs and Northern Development. The possibility of achieving provincial status for all or some part of the territories in the near future has become a lively political issue in recent years.

Education and health services. Missionaries provided nearly all the education and health care available in the territories until the 1950s, but education is now a government responsibility. A fully integrated system of elementary, secondary, and vocational education is administered by the Education Branch of the Department of Indian Affairs and Northern Development. The provision of health and welfare services has also become an increasingly heavy responsibility of government in recent years. Health services are administered by the federal Northern Health Service. A system of public health and treatment facilities is based on the five major hospitals. There is a universal hospital-insurance scheme, and free treatment is provided for several diseases, including tuberculosis, which has been a major threat to the health of the native people.

Income and housing. Salaries of professional and skilled workers are unusually high to compensate for the high cost of northern living, but because of the extremely low cash incomes earned by persons lacking such skills, the overall level of personal income is lower than in other parts of Canada. Inadequate housing has been a serious problem in most settlements. High building costs and low incomes allow few native people to afford modern housing. Government subsidized housing programs are beginning to alleviate this problem.

Cultural life. Modern forms of transportation and communication have done much to break down the isolation of life in the north, and contemporary North American popular culture is everywhere evident. Radio stations relay programs throughout the territories, and most of the larger settlements have their own newspapers and some have closed-circuit television. In the Mackenzie District, little remains of the traditional culture of the native Indians; but in the eastern regions, elements of the Eskimo culture have been preserved. Public policy in recent years has encouraged the bringing back of Eskimo traditions in arts and crafts, providing an important source of income in some Eskimo communities and making Eskimo culture familiar to collectors throughout the world. Eskimo-language broadcasting is well established, and a new written language has been introduced to encourage Eskimo writing and to facilitate communication among the widely scattered communities.

Preservation of Eskimo culture

Prospects. The immediate problems of the Northwest Territories mainly have to do with improving the social and economic conditions of the native people and other permanent residents. Their interests must be reconciled with those of the business and other outside groups responsible for organizing and financing the major resource development programs. The future of the territories appears to hinge upon constructive approaches to these problems, though any major growth in population seems unlikely in the foreseeable future.

BIBLIOGRAPHY. R.A.J. PHILLIPS, *Canada's North* (1967), the best general account of the development and history of the area; K.J. REA, *The Political Economy of the Canadian North* (1968), an economic history of the Northwest Territories and the Yukon placing emphasis on the economic and political factors in its development as a region; contains much statistical data. Useful material may also be found in

several collections and symposia: V.W. BLADEN (ed.), *Canadian Population and Northern Colonization* (1962); and F.H. UNDERHILL (ed.); *The Canadian Northwest: Its Potentialities* (1959); both contain excellent articles on various aspects of the resources and social problems of the territories. Current statistics on population are available in the 1971 census. The *Canada Year Book* provides most of what little statistical material we have on the Northwest Territories, although most of it is combined with data for the Yukon Territory. Other useful government publications are the annual reports of the Commissioner of the Northwest Territories and the federal Department of Indian Affairs and Northern Development. Some useful background on the most important political issue in the territories, the prospect of provincial status, may be found in the *Report of the Advisory Commission on the Development of Government in the Northwest Territories*, 2 vol. (1966).

(K.J.R.)

Norway

Norway, the "northern way," occupies the western half of the Scandinavian peninsula of Northern Europe. In shape, it has been characterized as resembling a fish with its tail flapping in the Arctic Ocean. Its bulging head, with a wide-open mouth about Oslofjorden, around which region nearly half the 4,000,000 inhabitants of the country live, faces to the south. Norway has always depended heavily on its economic relations with foreign countries; this has been the case during both its periods of independence and those times when it has been politically united with its fellow Scandinavian nations, Sweden and Denmark. These foreign links are illustrated by the heritage of the Vikings, who plundered the coasts from the British Isles into the Mediterranean Sea and across the Atlantic Ocean to North America. Later, in less colourful but more peaceful fashion, the Norwegians have turned to trading in fish and lumber, and the modern nation has emerged as a major maritime transporter of the world's goods. Nearly two-thirds of the physical area of Norway is classed as mountainous territory. Its more than 160,000 lakes and about the same number of islands testify to the glaciers that scourged its landscape and coastlines.

Maritime heritage

Lying on the northern outskirts of Europe and thus avoiding the characteristics of a geographical crossroad, Norway has maintained a great homogeneity among its peoples and their way of life. With Sweden, it has a larger percentage of tall, blond, and blue-eyed persons than any other nation of the world, and its projections for life expectancy, for both men and women, are among the highest in the world. Although it is split politically between Socialists and non-Socialists, the former long ago stopped insisting on nationalization of the nation's industry, and the latter have accepted extensive governmental control of the economy. Such evidences of national consensus, along with abundant waterpower and peaceful labour relations, were a major factor in the rapid growth of Norway as an industrial nation in the 20th century, creating one of the highest standards of living in the world. (For information on related topics, see the articles OSLO; EUROPE; and SCANDINAVIA, HISTORY OF.)

THE NATURAL ENVIRONMENT

Geology. Geologically, Norway belongs to northern Europe's Fennoscandian Shield, its extremely hard bedrock mostly of granite and other heat- and pressure-formed materials, ranging from 1,000,000,000 to 2,000,000,000 years in age.

Terrain. Glaciation and other forces wore down the surface and created thick sandstone, conglomerate, and limestone deposits known as sparagmite, as well as numerous extensive areas, called peneplains, whose relief has been largely eroded away. Remains of the latter include the Hardangervidda, 3,000 feet (1,000 metres) above sea level, in southern Norway, Europe's largest mountain plateau, covering about 4,600 square miles (12,000 square kilometres); and Finnmarksvidda, 1,000 feet (300 metres) above sea level, occupying most of the northernmost and largest county of Norway.

From the Cambrian through the Silurian geological periods, from about 570,000,000 to 395,000,000 years ago, most of Norway was below sea level and acquired a layer of limestone, shale, slate, and conglomerate from 100 to 160 metres thick. Folding processes in the earth then gave rise to a mountain system that is a continuation of the Caledonian System of the British Isles. Erosion was increased by the large foldings of the Tertiary Period, beginning 65,000,000 years ago, which in addition to elevating the Norwegian mountains, particularly along the west coast, also created the Himalayas in Asia, the Alps in southern Europe, and the Andes and the Rockies in the Americas.

Rivers running westward acquired tremendous erosive power. Following fracture lines marking weaknesses in the earth's crust, they dug out gorges and canyons that knifed deep into the jagged coast. To the east, the land sloped more gently, and broader valleys were formed. During the Ice Age of the Quaternary Period, less than 2,500,000 years ago, the scouring action of glaciers tonguing down the then-existing V-shaped valleys created the magnificent U-shaped drowned fjords that now grace the western coast. Enormous masses of earth, gravel, and stone were also carried by glacial action as far south as Denmark and northern Germany. Bedrock, exposed in almost a third of Norway, was scoured and polished by the movements of these materials.

Soils. In the melting periods following each ice age, however, large areas were flooded by the sea because the enormous weight of the ice had depressed the land. Thick layers of clay, silt, and sand were deposited along the present coast and in large areas in the Oslo and Trondheim regions, which rise as high as 650 feet (200 metres) above sea level today. Some very rich soils are found below these old marine coasts. In the large areas covered by forests, the main soil has been stripped of much of its mineral content, creating poor agricultural land. Norway has an average altitude of 1,600 feet (500 metres), compared to 1,000 feet (300 metres) for Europe as a whole.

Climate. Although it occupies almost the same degrees of northern latitudes as Alaska, Norway owes its warmer climate to the Gulf Stream, carrying 4,000,000 to 5,000,000 tons of tropical water per second into the surrounding seas. The Gulf Stream usually keeps the fjords from freezing, even in the Arctic Finnmark region. Even more important are the southerly air currents brought in above these warm waters, especially during the winter.

Effect of the Gulf Stream

The annual mean temperature on the west coast is 45° F (7° C), or 54° F (12° C) above average for the latitude. In Lofoten, above the Arctic Circle, the January mean is 43° F (24° C) above the average for this latitude around the world, one of the greatest thermal anomalies known. Norway lies directly in the path of the North Atlantic cyclones, which bring frequent changes in weather and gales. Western Norway has a marine climate, with comparatively cool summers, mild winters, and up to 80 inches of mean annual precipitation. Eastern Norway, sheltered by the mountains in the centre of the country, has an inland climate with warm summers, cold winters, and less than 40 inches mean annual precipitation.

Plant and animal life. Norway has about 2,000 species of plants, but only a few, mainly mountain plants, are peculiar to Norway. Thick forests of spruce and pine predominate in the broad glacial valleys up to 2,800 feet (850 metres) above sea level in eastern Norway and 2,300 feet (700 metres) in the Trondheim region. Even in the thickest spruce woods, the ground is carpeted with leafy mosses and heather, and a rich variety of deciduous trees—notably birch, ash, rowan, and aspen—grow even on the steepest hillsides. The birch zone extends from 3,000–3,900 feet (1,000–1,200 metres) above sea level, after which there is a willow belt that includes dwarf birch.

In western Norway there are virtually no conifers. North of the Arctic Circle there is no spruce, and only some pine grows in the inland valleys, amid their surprisingly rich vegetation. Wild berries grow abundantly in all regions: they include blueberries and cranberries of small size and yellow cloudberries, a fruit-bearing plant of the rose family that is little known outside Scandinavia and Great Britain.

Mammals

Reindeer, wolverine, lemming, and other Arctic animals are found throughout Norway but, in the South, only in the mountain areas. Elk are common in the large conifer forests and red deer on the west coast. Only 100 years ago large animals of prey were common in Norway, but now the bear, wolf, and lynx are found only in a few areas, mainly in the north. Foxes and many species of marten, however, are common, and in certain areas badgers and beavers thrive.

Most of the rivers and lakes have a variety of fish, notably trout and salmon; the latter is found in at least 160 rivers, often in an abundance that attracts anglers from all over the world.

Of the large variety of birds, many migrate as far as Africa for the winter. In the north, people collect eggs and down from millions of seabirds, and, as far south as Ålesund, small cliff islands often are nearly covered by several hundred thousands of nesting birds. Several kinds of grouse are common in the mountains and in the forests.

THE NATIONAL REGIONS

There are four traditional regions of Norway, three in the south and one (comprising the "flapping fishtail") in the Arctic north. The three main regions of the south are defined by wide mountain barriers. From the southernmost point northward, a swelling complex of ranges jointly described as Langfjellene ("the Long Mountains") divide eastern Norway, or Østlandet, from western Norway, or Vestlandet. An eastward sweep of the mountains separates Østlandet in the north from the Trondheim region, or Trøndelag. And, where the southern half of Norway's total length ends, northern Norway, or Nord-Norge, begins.

Eastern Norway. Østlandet has more than half of Norway's population of about 4,000,000, of whom some 700,000 live in the metropolitan area of the national capital, Oslo. Another 1,000,000 persons live close by, mainly in the many industrial cities and urban agglomerations on both sides of Oslofjorden. By the 1970s almost continuous urbanized belts were spreading from Oslo out into the countryside.

The agricultural core of the Østlandet lies in the lowlands extending eastward and southward to the Swedish border. With suitable precipitation during the growing season, the highest July temperatures in Norway, a soil consisting of relatively rich marine deposits, and large nearby markets, the land is intensively cultivated. There are even a number of large, heavily mechanized farms producing cereal grains, which generally do not grow well in such latitudes.

Most of the farms, however, are small. To supplement their income from domestic animals and vegetables, a great number of farmers pursue forestry as a secondary occupation, since most of the forests are a part of farm acreages. Norway has never had the agricultural villages that are common elsewhere in Europe. The more densely populated areas of the country have grown up around crossroads of transportation from which people have moved to the cities and suburbs. Thus, there is actually little borderline between the rural and urban populations. For many years Oslo has attracted settlers from all over the country, becoming a national melting pot surrounded by the most important agricultural as well as industrial districts of Norway.

Urban and rural populations

In the interior of Østlandet, farms are located along the sides of the broad valleys, the bottoms of which contain only washed-out deposits of soil. Frost is more frequent in spring and fall than in the coastal areas. The largest forests in Norway are found between the Swedish border and the Glåma River east of Oslo. The coastline facing Denmark across the Skagerak passage, stretching from Oslofjorden to the southern tip of Norway, is densely populated and thriving, with small towns, coastal villages, and many small farms. Centred on the city of Kristiansand, this southern area is sometimes set apart as a fifth region, Sørlandet. The idyllic coastline has developed into Norway's foremost summer-vacation area. The land is hilly, but the growing season is slightly longer than around Oslo. The interior, with narrow valleys running up into the beginnings of Langfjellene, is very sparsely populated, and the people of the scattered settlements depend more on cattle raising and forestry. Economically and in view of other practical aspects, however, Sørlandet is usually included as part of Østlandet.

In all, about 50 percent of Østlandet is forested, giving the region 55 percent of Norway's total forest resources, equivalent to its share of Norway's total area of fully cultivated land. In mining and manufacturing, Østlandet has a share of more than 60 percent of the nation's total production value and of its total trade. These lions' shares of the national wealth, combined with the concentration of economic activity around Oslofjorden, secure for Østlandet the highest average income per household of the four regions: 27,700 kroner (7.14 kroner=$1 U.S.; 17.13 kroner=£1 sterling, on December 1, 1970), compared to 25,500 for Vestlandet, 23,200 for Trøndelag, and 23,100 for Nord-Norge (1969).

Western Norway. The narrow coastal zone of Vestlandet abuts into the North Atlantic Ocean; it has many islands and steep-walled, narrow fjords cutting deep into the interior mountain region. The major exception is the wide Jæren Plain, south of Stavanger. With rich glaciated soils, exceptionally mild winters, long growing seasons, and plentiful precipitation, Jæren has the highest agricultural yields in all of Norway, and its farmers are not distracted by the necessity of forestry or fishing.

Stavanger, Norway's fourth largest city, has become an expanding industrial centre, particularly in canning and engineering. It is also the main base for the explorations in the North Sea for undersea oil deposits. To the north, the city of Haugesund thrives on fishing and other industry. The island of Karmøy comprises a notably rich agricultural area. The inland fjord districts of Vestlandet are more sheltered, with rich fruit districts specializing in apples. The flowering of the trees beneath snowcapped mountains adds an extra dimension of beauty to the world-famous "land of the fjords."

The city of Bergen is the natural centre of Vestlandet. Since the late Middle Ages, when it was an active trading centre of northern Europe, the city has had a more international character than any other in Norway. The typical "Bergenser" is often caricatured as an easy-talking city boaster with a "go-ahead spirit" matched only by the people of the Sunnmøre district, farther north on the coast. Sunnmøre, with Ålesund as its local centre, contains many engineering firms, and the bulk of Norway's growing furniture industry is gathered on its rocky coast. Fishing, which predominates farther north, around the cities of Molde and Kristiansund, is a main second occupation, as forestry is in Østlandet. Deep in the Vestlandet fjords lie many of Norway's largest smelting plants, constructed to exploit the great hydroelectric resources of the region.

Central Norway. Trøndelag is Norway's most typical agricultural region, with flat, fertile land around the wide Trondheimsfjord and the city of Trondheim. In addition, 30 percent of its area is forested, and it has a large percentage of Norway's mining industry. The main difference between Østlandet and Trøndelag is the cooler summers in the latter. The typical "Trønder" resembles the stolid farmer or lumberman of inland Østlandet. Trondheim, the second largest city of Norway, and for long periods the national capital, dominates the economic life of Trøndelag.

Northern Norway. Nord-Norge, most of which is above the Arctic Circle, is truly the "land of the midnight sun" in the summer, whereas during December and most of January no real daylight appears at all. Most of the region is filled with mountains with jagged peaks and ridges, even on the many islands. A long string of large islands jutting into the North Atlantic west of Vestfjorden form the Lofoten Wall. Numerous fjords scissor into this narrow strip of Norway's northern tail. Its few roads and severe winters make seaway transportation even more vital than in Vestlandet.

Isolation of the north

Some of the inland valleys have dense forests, but the short summers and poor soil limit agriculture to a largely

subsidiary activity, though the production of milk, meat, and potatoes is surprisingly high in many districts. Fishing continues to dominate the economy except in certain mining and industrial centres.

THE NORWEGIAN PEOPLE

In most parts of Norway, the nucleus of the population is Nordic in heritage and appearance. Between 60 and 70 percent have pure-blue eyes. An influx of Alpine and Mediterranean peoples has been strong in southwestern Norway. In the far north there has been some intermarriage with the *samer*, Lapps, or Laplanders, who live on the plateau called the Finnmarksvidda, moving their reindeer herds down to the coast for summer grazing. The Lapps, dark-haired and of short stature, came to Norway before anyone else, at least 10,000 years ago, probably from Central Asia. Nord-Norge also has about 7,000 *kvener*, immigrants from Finland.

Language and religion. The language of Norway belongs to the North Germanic branch of the Germanic language group and is a relative of English, which belongs to the West Germanic branch. The Norwegian alphabet has three extra letters, *æ, ø,* and *å,* pronounced respectively as the vowels in b*a*d, b*u*rn, and b*a*ll. Modern Norwegian has many dialects, but all of them, as well as the Swedish and Danish languages, are understood throughout all three countries. Until about 1850 there was only one written language, called Riksmål, or "official Norwegian," which was strongly influenced by Danish during the 500-year union of the two nations. Then Landsmål, or "country Norwegian," was created out of the rural dialects. After a long feud, mostly urban–rural in makeup, both forms received equal status under the terms Bokmål, or "book Norwegian," and Nynorsk, or "new Norwegian." For 80 percent of the schoolchildren, Bokmål has been chosen as the main language in local schools.

Dialect status

About 96 percent of Norwegians belong to the Evangelical Lutheran National Church, which is supported out of state funds. The more than 130,000 persons outside this establishment in 1960 included Pentecostalists, Lutheran Free Church members, Methodists, Baptists, and Roman Catholics, in descending order of membership.

Population trends. Since World War II, Norway's birthrate has remained fairly steady at 16 to 20 per 1,000 inhabitants. This compares with about 29 at the turn of the century and a slump to 15 during the 1930s. The mortality rate has declined from about 15 per 1,000 at the turn of the century to ten in the 1970s, due mainly to reduced infant mortality and campaigns against tuberculosis, once a national scourge. The average life expectancy has risen from 50 to 71 years for males and from 54 to 76 for women since 1900.

Patterns of migration

Immigration and emigration are fairly well in balance, at around 15,000 annually, and this, in conjunction with the birthrates and death rates, produces an annual population increase of only about 32,000 a year. Internal migration, however, is steadily increasing due to the shift from rural to urban occupations. In 1968 such migrants numbered more than 180,000. From 1946 to 1965, the percentage of people living in urban areas increased from 49 to 63. Demographers foresee an increase in Norway's population from the present nearly 4,000,000 to nearly 4,700,000 by 1990. Of these, it is estimated that slightly fewer than 20 percent will live in the scattered settlements outside urban centres.

THE NATIONAL ECONOMY

Economic organization. Only about one-fourth of Norway's commodity imports are consumer goods, the rest consisting of raw materials and capital goods. The rate of reinvestment has been extremely high in Norway for many years. This is reflected in the rising employment in building and construction. Even more rapid growth, however, has been registered in commercial and service occupations, as in most countries with a high standard of living. Manpower is in a continuing strong demand.

Of the nearly 18,000 industrial companies in Norway, fewer than 700 have more than 100 employees. Nonetheless, they account for half of the industrial labour force and 56 percent of the production. The smaller companies are usually family owned, whereas most of the larger ones are joint-stock companies. Foreign interests control companies accounting for about 11 percent of total production. Only a few larger concerns are state owned, and even these are usually run with almost complete independence.

Industrial ownership
