The fourth generation of the Kopriiliis still occupied important posts as viziers, governors, and commanders. Numan's son Hafız Ahmed was made vizier on April 20, 1731, and died as the governor of Egypt in 1769. Abdullah's eldest son Abdurrahman became vizier and governor of Van and later of Trabzon (Trebizond; died in 1733). Kara Mustafa's son Ali Pasha was a prominent statesman and general between 1701 and 1720.

Assessment

Most of the Kopriiliis lived on the rich religious endowments that the first two Kopriiliis had made. From the first Kopriilii on they were all interested in careers as *ʿulamāʾ*. The family was said to have God's aid and infallibility. One of them, Numan, was even venerated at his death as a saint. Public attention turned to them at critical times and exerted a strong pressure on the palace to bring them back to power. Also family ties and solidarity played an important role in bringing them to power and maintaining them there. One of the slaves of Kopriilii Mehmed, Siyâvuş, became grand vizier and prepared the way for Mehmed's grandson to grand vizierate. The Kopriiliis followed as a tradition a policy of abolishing abuses in tax collection and had a reputation of treating the common people with justice.

Korea, History of

The Korean people share a common racial origin with other peoples of North Asia, and the Korean language belongs to the Altaic language family of the region. There was a close relationship between Korean culture and that of neighbouring peoples in the Neolithic Period and the Bronze Age. For example, Korean combware pottery, widely used in the Neolithic Period, is commonly found in the region; Korean bronze daggers, belt hooks, and multi-knobbed mirrors also display the traits of bronze tools unearthed in the area. In this manner, the lineage and formation of early Korean culture can be roughly traced. One branch of the cultural ancestry went as far as to the Shantung Peninsula and formed an element of ancient Chinese culture; another went southward to Japan to form the main current of early Japanese culture.

Because of this background, the early Korean people were in constant confrontation with the Chinese. China was antagonistic toward the northern peoples, with whom the Koreans were associated, and naturally assumed an aggressive attitude toward the Koreans. Thus, Korea's formation and development were nurtured in its struggles against China.

After the unification of the Korean peninsula by Silla, Korea maintained friendly relations with China out of the need to deter invasions from the northern nomadic peoples. Later, Manchuria and Mongolia came under the successive control of the northern nomadic peoples and served as a base for invasion of Korea and China. To cope with this threat, Korea and China felt the need for a military alliance.

An even more important reason for friendly relations between Korea and China was cultural homogeneity. After the Iron Age, both China and Korea developed agricultural economies and thus shared many cultural similarities. China's culture was more advanced than Korea's, however, and Korea absorbed much from China—*e.g.,* written Chinese characters, laws and decrees, Confucianism, and painting. Nevertheless, Korea had its own language and invented its own alphabet; it developed its own way of life and adapted and improved upon all its borrowed culture to fit its own needs.

By the late 19th century the influence of the West began to be felt in East Asia. This was chiefly because Japan, the less advanced nation in the region, took the lead after opening its doors to the West. Stimulated by this, Korea tried to carry out reforms, doing away with traditional systems. But Korea fell prey to Japanese imperialism, which took advantage of reform movements in Korea for its own benefit. On liberation from Japanese rule in 1945, Korea was thrown into the vortex of world politics.

THE DAWN OF HISTORY

The Stone Age. Stone artifacts of the Paleolithic Period were unearthed at Kulp'o-ri in North Hamgydng Province (Hamgydng-pukto) and at Sŏkch'ang-ni in South Ch'ungch'ŏng Province (Ch'ungch'ŏng-namdo). Of 13 stratified Paleolithic sites, each cultural stratum produced chipped-stone tools of different shapes. Radioactive-carbon dating indicates the Paleolithic provenance of Sŏkch'ang-ni. Inhabited sites with round fireplaces were discovered there along with carved pebbles that show the way of life in the Paleolithic Period.

Neolithic life

The Neolithic Period was well established by 3000 BC, and a major characteristic was the use of combware pottery, chiefly found at seashore and river-basin sites, where inhabited places and shell mounds were also discovered. Stone spears and flint arrowheads have also been found, as well as bone hooks and stone weights, used for fishing. Remains of the Late Neolithic Period include stone plows and sickles, which indicate the beginning of farming. People lived in dugouts, mostly shallow round or rectangular hollows with fireplaces in the centre and possibly covered with thatched roofs. These shelters were huddled together in groups. The size of such villages is yet to be determined, but legends indicate the family members might have lived together, forming clan communities.

The use of metals and the emergence of tribal states. Bronzeware was probably first used about the 8th century BC, though some scholars think that it predates the 10th century. As the Bronze Age started, the design of pottery changed to undecorated earthenware. The uncovering of such pottery indicates that Bronze Age Korean people lived on hillsides, in dugouts raised slightly above ground. Half-moon-shaped stone knives and grooved stone axes show that rice farming was practiced, and bronze daggers and bronze arrowheads indicate wars of conquest. Dolmens, used as tombs, which were discovered in south Manchuria and the Korean peninsula, show the boundary of ancient Korean culture. Because only important persons were buried in dolmens, their number and location indicate that many small Bronze Age tribal states were probably established by powerful men.

The most advanced state was ancient Chosdn, established in the Taedong-gang (Taedong River) Basin. According to myth, the son of Heaven, Hwanung, descended to Earth and married a bear-turned-girl, who bore a son, Tangun, the founder of Chosŏn. Perhaps Tangun, who called himself a grandson of Heaven, ruled a tribal state in which rituals and politics were not separated. Chosŏn developed into a league of tribes in the area of the Taedong and Liao rivers (*c.* 4th century BC). Around this time ironware came to be used. Iron plows and sickles indicate the use of animals in farming and more efficient harvesting methods. Wooden houses were built on the ground, and ondol, a floor-heating system, was developed. Iron weapons were manufactured. The appearance of horse equipment and coaches indicates that horses and chariots were employed in wars.

Wiman (Wei Man in Chinese), said to have defected from China, became ruler of Chosŏn about 194 BC. More likely, he was indigenous to Chosŏn. Wiman's Chosŏn was overthrown by the Han Empire of China and replaced by four Chinese colonies in 108 BC.

DEVELOPMENT OF ANCIENT STATES

The Three Kingdoms. Apart from Chosŏn, the region of Korea developed into tribal states. To the north, Puyŏ developed in the Sungari River Basin in Manchuria. Chin. south of the Han-gang (Han River), was split into three — Mahan, Chinhan, and Pyŏnhan. These states were leagues, tribal federations centred on a leading state. The tribal league states stretched across a wide area from the Sungari Basin in Manchuria to the southern Korean peninsula. They evolved into three conflicting kingdoms—Koguryŏ, Paekche, and Silla. According to myths, Koguryŏ was founded by Kojumong in 37 BC, Paekche by Onjo in 18 BC, and Silla by Pak Hyŏkkŏse in 57 BC. The actual development of a state, however, was begun for Koguryd by King T'aejo (reigned AD 53–146?), for Paekche by King Koi (reigned 234–286), and for Silla by King Naemul (reigned 356–402).

Common characteristics of the Three Kingdoms

The Three Kingdoms shared several common characteristics. They evolved into statehood through frequent wars of expansion. Centralized military systems were organized, and training institutions (kydndang in Koguryŏ, hwarangdo in Silla) were developed. The power of the king in each state was strengthened. Royal hereditary systems were established.

Another common trait was the appearance of central aristocrats, tribal chiefs who moved to the capital. These

Korea during the Three Kingdoms period (*c.* AD 400)

aristocrats were divided into several social classes and gained certain privileges as they advanced socially and politically. The typical class system was Silla's Kolp'um, or bone-rank system, in which the families of rulers customarily monopolized political power. Silla had a state conference, Hwabaek, composed of men of *chin'gol,* or "true bone" (royal or formerly royal origin), which made important state decisions.

The states all experienced a centralization of power. The nations were divided into administrative units—the largest called *pu* in Koguryd, *pang* in Paekche, *chu* in Silla—that controlled many castles. The central government sent officials to these provincial units, where they saw to it that the people, as royal subjects, provided taxes and corvée labour.

The Three Kingdoms developed highly advanced cultures. Each compiled its history, apparently to consolidate the authority of the state. Also noteworthy was the introduction of Buddhism, characterized at the time as a nationalistic religion praying for the protection and welfare of the state.

Unified Silla. With the support of China, Silla conquered and subjugated Paekche in 660 and Koguryd in 668. Not until 676 did Silla drive out the Chinese and gain complete control of the Korean peninsula. But the surviving Koguryd people in northern Manchuria established Parhae, under the leadership of Dae Cho-ydng, which soon came into direct confrontation with Silla. This period could well be called an age of opposing southern and northern states, but it is customary to place the primary focus on Silla because little is known about Parhae (though it built a highly civilized state that the Chinese referred to as Haedong-sdngguk, the Prosperous Country of the East). After Parhae's collapse its territory was controlled by the northern nomadic peoples and was thus not part of Korean history.

Unified Silla saw the flowering of absolute monarchy, which reduced almost to nothing the influence of the Hwabaek. A central administrative body called Chipsabu was established to execute royal decrees. Aristocrats were now granted salaries and given land, but the latter was to revert to the state after tenure, thus reducing direct control of land and of the governed by the aristocracy. Monarchs built extravagant palaces and annexes and royal tombs. The nation was divided into administrative units: state, county, and ward. Five provincial capitals prospered as cultural centres.

Among the aristocracy, Avatamsaka Buddhism provided the ideological backing for autocratic monarchy. The underprivileged general public was attracted most to the *Sukhāvatī-vyūha-sūtra,* teaching bliss in the next world. The flowering of Buddhism produced many beautiful temples and great works of art, the most remarkable of which were Pulguk-sa, Sokkuram (a grotto shrine), and the bell at Pongdok-sa.

Confucianism prospered among low-echelon aristocrats, who used it as a foothold for political advancement. The National School, Kukhak, was established, and a sort of civil service examination system, called *toksŏ samp'um* kwa, was installed.

Disputes over succession in the 8th century

Emergence of provincial magnates. Frequent conflicts and rebellions over succession took place among the Silla aristocracy in the late 8th century. Aristocrats eventually restored the authority of the Hwabaek, overthrowing royal despotism. Even lower-ranking aristocrats demanded the abolition of restrictions imposed by the strict status system. New powerful families appeared in many provinces and grew because of the weakening of central control. Provincial military fortresses were established to repel Chinese pirates. The most active was the Ch'dnghae fortress led by Chang Po-go, who almost monopolized trade with China and Japan and had a private army of 10,000. Silla settlements in Chinese coastal cities in the Shantung Peninsula were also engaged in trade. Also powerful were the village rulers, who became castle lords by reinforcing control over military, administrative, and economic affairs. Many farmers, taxed both by the central government and castle lords, chose to become drifters or robbers, often staging rebellions.

Largely as a result of these trends, two provincial leaders, Kydnhwdn and Kungye, established the Later Paekche (892) and Later Koguryd, also called Majin or T'aebong (901), kingdoms, which, along with Silla, are commonly referred to as the Later Three Kingdoms. In this period Sdn (Zen) Buddhism was most popular, emphasizing the importance of realizing, through contemplation, the inborn Buddha nature of the individual.

KORYO

Social structure and culture. Koryd was founded in 918 at Songak (Kaesŏng) by Wang Kŏn, who in 936 established a unified kingdom in the Korean peninsula. Wang Kŏn went to great lengths to absorb the people of the overthrown states, even accepting the survivors of Parhae, which had been destroyed by the Khitan (Liao). Proudly declaring itself the successor of Koguryd, Koryd launched active campaigns to recover lost territory, clashing frequently with the Khitan in the north. Koryd eventually expanded its territory to the Yalu River (Korean Amnok-kang).

The Koryd ruling class consisted largely of provincial castle lords and former Silla aristocrats. The rulers regarded their family lineage highly. Marriage into a powerful family, especially a family of royal blood, was an important means for maintaining and elevating social and political status. Sons of a family above the fifth of nine official grades received official posts without going through civil service examinations.

The central government was run by the two supreme organs—Samsong, the highest administrative body, and Chungchuwon, the secretariat to the king. These two formed the Supreme Council of State. Koryd thus practiced aristocratic council-centred politics. Central aristocrats were granted land which was later to be returned to the state. Officials above the fifth grade were given land for permanent possession. Even the land supposed to be returned was actually handed down for generations because the grantees' sons usually became officials. Aristocrats expanded their land by reclaiming, purchasing, or seizing by force, and land became the primary source of wealth.

Aristocrats believed in Buddhism as a religion, for spiritual fulfillment and personal happiness; and in Confucianism, for its political precepts and ethical principles. The same was true of the government, which built grand Buddhist temples, such as Hŭngwang-sa, to observe rituals and pray for the prosperity of the nation, but which also set up a school named Kukchagam to teach Confucianism.

The military coup of 1170

Military rule. Civilian officials constituted the core of the ruling class; the military was generally discriminated against. Indeed, the supreme commander for military affairs was a civilian. Military officials were not eligible for the second grade of the official hierarchy and were excluded from the Supreme Council. Even in the same official grade, military men received less land than did their civilian counterparts. This discrimination eventually led to a military coup d'etat in 1170. The revolutionaries massacred a large number of civilian officials and gained complete control of government. Struggles for hegemony soon occurred among the leaders and were ended by Gen. Ch'oe Ch'ung-hdn, who established a military regime of his own that lasted about 60 years.

The monarch remained as a figurehead, deprived of political power, which was in the hands of the Ch'oe families. The Ch'oes set up a private army for personal security and a new public military organization for national security, but the latter also served, in effect, as their private army. They also established a body of civilian officials to take care of the state personnel administration, thus controlling both military and civilian leaders.

Buddhism was suppressed and retreated to remote mountain areas, where it formed a new Sŏn sect called Choge-jong, which became the main current of Korean Buddhism. The underprivileged farmers, stimulated by a general political atmosphere in which subordinates rose against superiors, staged rebellions across the country over a period of 30 years. The upheavals were at first natural and spontaneous protests against unfair oppression, but they developed into organized campaigns for liberation and for the seizure of power. The rebellions, eventually brought under control through appeasement and the use of naked force, were nevertheless instrumental in improving the lot of the underprivileged.

In 1231 the Mongols invaded Koryd, and the Ch'oe regime resisted for about 30 years. Even farmers and servants stood up bravely, and the Mongols, who had conquered most of Eurasia, could not take Koryd by force. As the exploitation of farmers by the Ch'oe grew more severe, however, the people became estranged, and the regime was finally overthrown by civilian leaders, who concluded a peace treaty with the invaders.

Social change in later Koryŏ. After the peace treaty Koryd was subject to some political interference from the Mongols but retained its political and cultural independence. Koryd went to some lengths to show its national and cultural superiority over the invaders by turning out highly advanced poems and national history books.

This period saw the remarkable development of huge farms, run by powerful aristocrats, which were scattered across the country. The landowners lived in the capital and sent private vassals or servants to collect taxes from the tenants, the common people who farmed the land. These tenants were often required to pay taxes to more than one owner because it became popular for landholders to share ownership. Tenants were also subject to forced labour and military duty for the state. Many farmers chose to become servants, thus getting protection from the aristocrats and avoiding the state duties. Some aristocrats also caught drifters and illegally made them servants. Thus, the number of servants increased, but these servants were actually on a level with tenants. They were not slaves in the Western sense but were more like serfs. The increase in the number of landholders and servants reduced the source of state tax revenue and the number of people to be mobilized in war.

Through civil-service examinations, the central government recruited a new bureaucratic force consisting of ***sadaebu*** (scholar officials), who generally had small farms in their native towns under their own management. These men were usually not satisfied with Buddhism and mere interpretations of the classics, and they adopted Neo-Confucianism, which brought a metaphysical approach to the understanding of the universe. Because of the financial straits of the government the new officials could not receive land commensurate to their rank; thus, their demand for land reform was strong. Eventually, with the support of Gen. Yi Sdng-gye, they seized power and established a new land-distribution system, under which land was granted according to the rank of office. These reforms ended the Koryd dynasty in 1392 and established the Yi dynasty. (K.-b.L.)

End of the Koryd dynasty

THE YI DYNASTY

The establishment of a Confucian state. The Yi dynasty was established and the region under its control named Chosdn with permission of the emperor of China. The Yi dynasty, with 26 monarchs, ruled until the Japanese annexation of Korea in 1910. Hanyang (now Seoul) was made the capital. The Confucian ethical system was adopted officially and replaced Buddhism, which had become corrupt. Many Confucian institutions of learning were set up, and Neo-Confucian scholars gained government posts through civil-service examinations.

The early Yi dynasty flourished intellectually and culturally, especially in the reign of Sejong the Great, the fourth monarch. With the technique of movable-type printing, developed in Korea in 1234, many publications in such fields as medicine, astronomy, geography, history, and agriculture were produced. In 1420 a royal academy called Chiphydnjdn was established, and many promising young scholars engaged in study and research there. In 1443 the Korean phonetic alphabet, Han'gŭl, was completed under Sejong's direction.

In the reign of Sejo, the seventh monarch, a powerful centralized and civilian-oriented government structure emerged. Laws were codified. The highest administrative body was the Supreme State Council. The country was divided into eight administrative provinces, and all officials were appointed by the central government.

Late in the 15th century, Korean scholars made original contributions to the theoretical refinement of Confucianism. In the mid-16th century many of these scholars were recruited to government positions. Idealistic in orientation, they criticized the bureaucratic establishment and recommended drastic measures toward the realization of Confucian ideals. But relentless counterattacks and pressures forced most of the scholars to quit their posts. They set up private academies of Confucian learning, called *sŏwŏn*. These academies produced many eminent scholars, including Yi Hwang (T'oegye) and Yi Yi (Yulgok), whose distinct theories of the universe evolved into mutually antagonistic schools.

Foreign invasions. In 1592 Toyotomi Hideyoshi, the military ruler of Japan, sent a large expeditionary force to Korea in an alleged attempt to invade China. Korean land forces suffered a series of defeats, but Korean naval forces, led by Adm. Yi Sun-shin, secured full control of the sea. Yi won the greatest naval victory in Korean history over the Japanese troops off the southern coast. People of almost all ranks, even Buddhist priests, volunteered to fight the Japanese. Contingents came from Ming China to help Korea. After about a year the Japanese were forced to withdraw. In 1597 Toyotomi launched another invasion, but after his sudden death, in 1598, the Japanese again withdrew. The war left most of Korea in waste. Palaces, government buildings, and private houses were burned; cultural treasures were lost or destroyed. Some scholars and artisans were taken to Japan, where they were required to teach the methods of Korea's more advanced technology.

Korea's greatest naval victory

In the early 16th century, nomadic Manchu violated the borders of both Ming China and Korea. Ming and Korean punitive attacks on Manchu strongholds in 1619 were beaten back, and in 1627 Manchu nomads overran the northern regions of Korea. Only after Korea had agreed to recognize their claim to "brotherhood did the Manchu pull out of the occupied territory. In 1637 the Manchu captured Seoul and wrested an unconditional surrender from the king. The Manchu then overthrew the Ming and established the Ch'ing dynasty. Thus, the tribute that Korea had paid to the Ming now had to be switched to the Ch'ing.

Silhak and popular culture. A series of significant changes in Korea began in the mid-17th century and made a great impact on virtually every sector of Korean society in the 18th century. In agriculture, rice transplantation became popular. Irrigation systems were improved. Advances in farming brought dramatic boosts in agricultural produce and raised the standard of living for farmers. With the cultivation of such special crops as tobacco and ginseng, commerce and trade developed apace. The government started minting coins and collecting farm rents in cash. Markets were held in many places across the country. Particularly active were merchants from Kaesdng, who had a nationwide network that put every fair in the country within their sphere of influence.

In the realm of scholarship, attention shifted from traditional theorizing to matters of relevance to the needs of the society and nation. Such scholars are often referred to as the Silhak, or Practical Learning school. Silhak scholars fell into four major groups. One group advocated comprehensive administrative reform, calling upon the government to rationalize the systems of civil-service examination, education, taxation, and land administration. Another group stressed the need to foster commerce, industry, and technology. A third conducted critical examinations of the Confucian Classics. The fourth group focused on the study of the history, geography, and language of Korea. Their research and publications provided a basis for study for the generations that followed.

Comparable new trends appeared in arts and letters. Mass-oriented literary and artistic works came into fashion, a great change from the tradition of catering exclusively to the upper classes. The new works were not only written in the easy-to-read Han'gŭl but also gave frank expression to popular discontent. Singing dramas or traditional Korean operas, most of them adapted from popular novels, were also popular with the masses. Many artists specialized in pictures of blacksmiths at work, farmers in the field, traditional wrestling matches, and in landscapes of the countryside. Pottery with a simple blue and white glaze was produced in large quantities for mass consumption.

Arrival of Europeans

The introduction of Catholicism. Europeans began to arrive in East Asia in the mid-17th century. In 1656 a Dutch merchant ship went aground off the southern shore of Cheju-do (Cheju Island). The 36 survivors were taken to Seoul for detention. About 13 years later Hendrik Hamel and seven others escaped and returned home. Hamel wrote an account of his experiences—the first book on Korea published in the West.

Along with the European merchants in East Asia came Catholic priests. Korea's first contact with Christianity was through missionaries in China. Korean envoys to China in the 16th century brought back with them a world atlas and scientific instruments made by the priests, as well as literature on science and Christianity. Some Silhak scholars had converted to Catholicism by the late 18th century, even before missionaries reached Korea. Most of the early converts were aristocratic scholars. A number of commoners were later attracted to the Catholic Church, finding a hope of salvation in the Christian doctrine of equality of all men before God and a new source of joy in the Christian belief in life after death. Catholicism spread from Seoul to the provinces slowly but steadily.

The incompatibility of Catholicism with Confucianism posed a serious problem. The two sides could not compromise on the great importance Confucianism attached to ancestor worship, which Catholicism rejected as pure idolatry. The government began to suppress the Catholic Church in the belief that it defied the existing sacrosanct mores of Confucianism. During persecutions in 1801, 1839, and 1866, scholar converts were either put to death or forced to turn renegade; foreign missionaries were ferreted out and beheaded. But rank-and-file Catholics rallied around the church and kept it alive. In 1831 the Holy See set up a Korean parish. French priests smuggled themselves into the country and engaged in clandestine activities.

The advent of Silhak, mass-oriented arts, and Catholicism in the 17th and 18th centuries is an indication of a modern Korea in the making. But in the 19th century, young princes came to the throne, and power-hungry maternal relatives seized power and plunged the government into a state of collapse. One peasant uprising followed another in the provinces, and the whole nation was seething with popular discontent and resentment.

Many farmers sought refuge in religion. A new religion founded (*c.* 1860) by Ch'oe Che-u, a fallen aristocrat scholar, advocated sweeping social reform; it had much in common with traditional animism and it appealed to the farmers. This religion was called Tonghak, or Eastern Learning, as a counterpoise to Sdhak, or Western Learning—*i.e.*, Catholicism.

CONTACT WITH WORLD POWERS

The opening of the door. King Kojong was too young to rule when he ascended the throne in 1864, and his father, Taewŏn-gun, was appointed regent. Taewŏn-gun set out to restore all the powers of the monarchy and pursued a policy of national isolation to devote government efforts to mending its own fences. He put into force bold political reform measures, such as liberal civil service recruitments and the abolition of a great number of private Confucian academies.

During his regency Western men-of-war and merchant vessels came in search of trade and friendship, but the regent refused them. Korean soldiers and civilians burned and sank the merchant ship USS "General Sherman" near P'yŏngyang in revenge for acts of plunder committed by the crew. Korean forces repulsed two attacks by French warships in 1866. In 1871 a United States flotilla came to retaliate for the "General Sherman" but was beaten back. Such incidents strengthened Taewdn-gun's resolve to keep the country's doors closed.

Treaty with Japan

Japan made repeated futile attempts to establish diplomatic relations with Korea. The Japanese military thereupon raised an outcry for a war of conquest on Korea. Meanwhile, Taewdn-gun came under widespread criticism for the enormous financial burden he had imposed on the people. Popular resentment forced him to step down as regent in 1873. Relatives of Queen Min took over the helm of state and initiated policies opposed to Taewŏn-gun's. Japan, which had been watching every development in Korea, now dispatched a fleet and pressured Korea to sign a treaty of trade and friendship. The ports of Pusan, Wŏnsan, and Inch'dn were opened to the Japanese in 1876.

The growing Japanese presence in Korea was disturbing to the Ch'ing rulers of China. When conservative soldiers tried to restore Taewdn-gun, the Ch'ing used it as an excuse for stationing forces in Korea. Thus began a period of open Ch'ing interference in Korean affairs. The Ch'ing forced Korea to sign a treaty of trade that heavily favoured Chinese merchants. Korea signed a treaty of trade and friendship with the United States through the offices of China. Similar treaties with Great Britain, Germany, Russia, and France followed, and resident foreign missions were established in Seoul.

Once the doors were opened, a modernization movement was begun. Students and officials were sent to Japan and China. Western-style schools and newspapers were founded. The government, however, could not push ahead with a consistent policy of modernization, for the King was feebleminded and the ruling classes were hopelessly divided into radicals and moderates.

In a coup of 1884 the Radicals seized power and drew up a bold blueprint for reform. But a Ch'ing contingent moved in and overthrew their three-day-old regime. This led to the signing of the Li-Itō Convention, designed to guarantee a Sino-Japanese balance of power in the Korean peninsula.

The Tonghak Revolt and government reform. Government expenditures greatly increased, largely because of appropriations for machinery imports and government reorganization, and the financial picture was aggravated by obligations to pay reparations to foreign governments. Heavier tax levies were imposed on farmers, who provided the bulk of government revenue. The import of such necessities as cotton textiles upset the traditional self-sufficiency of the farming community. Usurious loans by Japanese rice dealers helped reduce the peasantry to abject poverty. Angry farmers turned increasingly to Tonghak.

Despite ruthless government persecution, Tonghak took deep root in the peasantry. Its followers staged large-scale demonstrations calling for an end to injustice. Negative official response precipitated the Tonghak Revolt (1894), in which the Tonghak followers and the peasantry put up a united front for popular liberation. Government troops armed with Western weapons suffered ignominious defeats in southern Korea, weakening the government's military grip on the country. Foreign intervention seemed the last resort open to the rulers. Ch'ing troops soon moved in at the request of the government. Then Japan dispatched its large units uninvited, and the two alien powers were in sharp and sudden confrontation.

The rebels laid down their arms voluntarily to defuse the threat. But a war broke out in 1894; Japan emerged victorious, and the two powers signed the Treaty of Shimonoseki, recognizing Japanese hegemony in Korea.

Japanese hegemony

The Japanese dictated to the Korean government a wide range of reforms. Korea set up a council to plan and initiate reforms and issued pertinent decrees. Western-style institutions and a cabinet were formed. Civil-service examinations were discontinued. Such social practices as class discrimination were abolished. But public reaction to the reform policy was unfavourable. The government realized that old practices and institutions die hard and that reform takes more than mere decrees and imitation of things Western.

International power struggle and Korea's resistance. Japan's supremacy in Korea and its subsequent seizure of the Liaotung Peninsula in Manchuria was more than Russia, with its long-cherished dream of southward expansion, could tolerate. With German and French support, Russia pressured Japan to return the peninsula to China. At the same time, encouraged by Russia, the Korean government showed signs of drifting toward an anti-Japanese course. The Japanese government, however, promptly engineered the assassination of Queen Min (October 1895), the suspected mastermind behind the anti-Japanese attitude. Fearing for his own life, the King took refuge in the Russian Legation, granting such concessions as mining and lumbering rights to Russia and other powers.

Popular movements for the restoration of Korean sovereignty arose under the leadership of such figures as Sŏ Chae-p'il (Philip Jaisohn). After many years of exile Sŏ organized, in 1896, a political group called the Tongnip Hyŏphoe (Independence Association); he also published a daily newspaper named *Tongnip Sinmun* (The Independent) as a medium for awakening the populace to the importance of sovereignty and civil rights. On the urging of the Tongnip Hyŏphoe, the King returned to his palace and declared himself emperor and the Korean empire equal to other nations.

The Boxer Rebellion in China led to a Russian invasion of Manchuria and to the Russo-Japanese War (1904–05). The Korean government at first declared neutrality. But under Japanese pressure, it signed an agreement allowing Japan to use much of the country for operations against the Russians.

Japan won the war, and the resulting Treaty of Portsmouth (September 1905), signed through the mediation of the United States, recognized Japan's undisputed supremacy in Korea. Its hand thus strengthened, Japan forced the Korean emperor into signing a treaty that made Korea a Japanese protectorate (December 1905).

Although the Korean emperor sent a secret emissary to the international peace conference held at The Hague in 1906 to urge the big powers to intercede with Japan on behalf of Korea, the mission failed, serving only to infuriate Japan. Under Japanese coercion, the Emperor then abdicated in favour of his son, Emperor Sunjong. The Korean Imperial Army was disbanded, and in 1910 Japan annexed Korea.

Japanese annexation of Korea

A Korean Army, led by deposed officials and Confucian scholars, had arisen against the Japanese in the southern provinces following the 1905 treaty. For five years the militiamen effectively harassed the Japanese occupation forces, especially in 1908 and 1909. With the annexation, however, they were driven into Manchuria. Large numbers of Koreans emigrated to Manchuria, Shanghai, and Hawaii around this time.

KOREA UNDER JAPANESE RULE

Military control. Japan set up a government general in Seoul, with the governor generalship filled by generals or admirals appointed by the Japanese emperor. Koreans were deprived of freedom of assembly, association, the press, and speech. Many private schools were closed because they did not meet the standards arbitrarily set by the government general. The colonial authorities used their own school system as a tool for assimilating Korea to Japan, placing abnormally heavy stress on the Japanese language and excluding such subjects as the language and history of Korea. The Japanese built a nationwide transportation and communications network and established a new monetary and financial system. They also encouraged Japanese business activities in Korea while barring Koreans from similar operations.

The government general promulgated a land-survey ordinance that forced landowners to report the size and area of their land. By failing to report, many farmers were deprived of their land. Land and forestry owned jointly by a village or a clan were also appropriated by the Japanese because no single individual could lay claim to them. Much of the land acquired by the government general was sold cheaply to Japanese. Many of the dispossessed took to the woods and became brand tillers; others emigrated to Manchuria and Japan in search of jobs (the majority of Korean residents in Japan today are their descendants).

The March 1st Movement. A turning point in Korea's resistance movement came on March 1, 1919, when nationwide anti-colonial rallies were staged. The former emperor Kojong, the supreme symbol of independence, had died a few days before, bringing mourners from all parts of the country into Seoul. A declaration of independence was read at a rally in Seoul on March 1. Waves of students and citizens took to the streets, calling for independence. This movement took the form of peaceful demonstrations appealing to the conscience of the Japanese. An estimated 2,000,000 persons took part. The authorities responded with brutal repression, unleashing their gendarmerie and army and navy units, and thus ending the demonstrations. They arrested some 47,000 Koreans, of whom about 10,500 were indicted, and killed and wounded nearly 23,000.

In April, independence leaders, including Syngman Rhee, An Ch'ang-ho, and Kim Ku, formed a Korean provisional government in Shanghai. It brought together all Korean exiles and established an efficient liaison with leaders inside Korea. Japan realized that its iron rule had to be replaced with more sophisticated methods. The gendarmerie gave way to an ordinary constabulary force, and some freedom of the press was granted. But the oppressive and exploitative Japanese colonial policy remained ruthless as ever, though with less conspicuous methods.

Korean provisional government in exile

Taking advantage of a wartime business boom, Japan took leaps forward as a capitalist country. Korea became not only a market for Japanese goods but also a fertile and untapped market for capital investment. Meanwhile, industrial development in Japan was achieved at the sacrifice of agricultural production, creating a chronic shortage of rice. The government general enforced projects for the improvement of rice production throughout Korea. Many farmers were ordered to turn their dry fields into paddies. The program was temporarily discontinued during the worldwide depression in the early 1930s. But it was soon resumed to meet the increased needs of the Japanese military when Japan went to war against China, beginning in 1931. Most Koreans were forced to subsist on low-quality cereals imported from Manchuria instead of their own rice.

The end of Japanese rule. Of the several dailies and magazines founded shortly after the March 1st Movement, the newspapers *Dong-a Zlbo* and *Chosun Zlbo* spoke the loudest for the Korean people and inspired them with the ideals of patriotism and democracy. In the academic community, scholars conducted studies of Korean culture and tradition. Many novels and poems were written in colloquial Korean.

A major anti-Japanese mass rally was held in Seoul in 1926, occasioned by the funeral of Sunjong. A nationwide student uprising originated in Kwangju on November 11, 1929, calling an end to Japanese discrimination. These and other resistance movements were led by the New Cadre, composed of a whole spectrum of Korean intellectuals.

In 1931 the Japanese imposed militaristic rule once again. After the outbreak of the Sino-Japanese War (1937) and of World War II (1941), Japan tried to obliterate Korea as a nation, forcing Koreans to worship at *Shintō* temples and even to adopt Japanese names and banning academic societies devoted to Korean studies as well as newspapers and magazines published in Korean. The Japanese needed manpower to replenish the dwindling ranks of their military and labour forces. They drafted hundreds of thousands of able-bodied Koreans to fight for Japan and to work in mines, factories, and military bases.

When Shanghai fell to the Japanese, the Korean provisional government moved to Chungking. It soon formed a liberation army of Korean independence fighters scattered all over China and declared war on Japan in 1942. The small liberation army fought with the Allied forces in China until the Japanese surrender in 1945, which ended 36 years of Japanese rule over Korea. (K.-r.L.)

DIVISION OF KOREA

The Cairo Declaration, issued on December 1, 1943, by the United States, Great Britain, and China, pledged independence for Korea "in due course." The vague phrase aroused the Korean provisional government in Chungking (southwest China) to request interpretation from the United States. Their request, however, received no answer.

At the Yalta Conference held in February 1945, Pres. Franklin D. Roosevelt proposed to Joseph Stalin of the U.S.S.R. a four-power trusteeship for Korea between the U.S., Great Britain, the U.S.S.R., and the Republic of China. Stalin generally agreed to Roosevelt's offer, but they did not reach any formal agreement on the future state of Korea, and after the Yalta meeting there was a growing uneasiness between the Anglo-American Allies and the U.S.S.R.

Initial concord on Korea

Throughout the Potsdam Conference in July 1945, U.S. military leaders insisted on encouraging Soviet entry into the war against Japan. The Soviet leaders asked the U.S. about invading Korea, and the U.S. declined to do so on the grounds that such an expedition would not be practicable until after a successful landing had taken place on the Japanese mainland. The ensuing Potsdam Declaration included the statement that "the terms of the Cairo Declaration," which promised Korea its independence, "shall be carried out. . . ." In the terms of its entry into the war against Japan on August 8, the U.S.S.R. subscribed to support the independence of Korea. On the following day Soviet troops went into action in Manchuria and landed on the northern tip of Korea.

The General Order No. 1, drafted on August 11 by the United States for Japanese surrender terms in Korea, provided that Japanese forces north of the 38th parallel of latitude were to surrender to the Soviet commanders while those south of that line were to surrender to the U.S. commander. Stalin did not raise objections to the contents of the order, and on September 8 American troops arrived in southern Korea almost a month after the first Soviet entry. On the following day the United States received the Japanese surrender in Seoul. There were now two zones, for the Soviets had already begun to seal off the 38th parallel.

The historic decision to divide the peninsula has aroused speculation on several counts. Some believe that the division of Korea was made simply for the sake of military expedience in receiving the Japanese surrender. Others tend to think that the division was politically motivated to prevent the Soviet forces from occupying the whole of Korea. Considering the fact that American policy toward Korea during World War II had aimed to prevent any single power's domination of Korea, it may be reasonably concluded that the reason for the division was to stop the Soviet advance south of the 38th parallel.

The South. The end of Japanese rule caused political confusion among Koreans in both zones. In South Korea various political parties sprang up. Although they were roughly divided into rightists, leftists, and middle of the roaders, they had a common goal; the immediate attainment of self-government. As early as August 16, some Koreans organized a Committee for the Preparation of Korean Independence. On September 6 the People's Republic of Korea was proclaimed by delegates attending a national assembly called by the committee. The republic was headed by Woon-hyung Lyuh, who was closely associated with the leftists. But the U.S. military government, under Lt. Gen. John R. Hodge, the commanding general of the United States armed forces in Korea, refused to recognize the republic, asserting that the military government was the "only government" in Korea, as stipulated in General Order No. 1. The U.S. policy in Korea was to establish a trusteeship that would supersede both the U.S. and the Soviet occupation forces in Korea. The exiled Korean provisional government, on returning, declared itself a political party, not a government.

In late December the Council of Foreign Ministers (representing the United States, the Soviet Union, and Great Britain) met in Moscow and decided to create a four-power trusteeship of up to five years. On receiving the news, Koreans reacted violently. On February 14, 1946, to soothe the discontent, the military government created the Representative Democratic Council, as an advisory body to the military government. This body was composed of Koreans and had as its chairman Syngman Rhee, former president of the Korean government in exile.

In October the military government created an Interim Legislative Assembly, half of whose members were elected by the people and half appointed by the military government. The assembly was empowered to enact ordinances on domestic affairs but was subject to the veto of the military government. The anti-trusteeship feeling came to a climax a few months later, when the assembly condemned trusteeship in Korea. The military government thereupon declared this condemnation as "illegal."

National resentment at treatment by the trustee powers

The North. Unlike the U.S. forces in the South, the Soviet Army marched into the North accompanied by an army of Korean Communists. By placing the latter in key positions of power, the U.S.S.R. easily set up a Communist-controlled government in the North. On August 25 the People's Executive Committee of South Hamgydng Province was created by the South Hamgydng Province Communist Council and other nationalists. The Soviet authorities recognized the committee's administrative power in the province, thus setting a pattern for the committee's role throughout the North Korean provinces. In this way the Soviet Union placed the North under its control without actually establishing a military government. On October 19 the people organized the Bureau of Five Provinces Administration, a central governing body; but this was replaced on February 9, 1946, by a Provisional People's Committee for North Korea. This new agency adopted the political structure of the Soviet Union.

Kim 11-sung, who returned in the uniform of a major of the Red Army, was introduced to the people as a national hero on October 14, 1945. Shortly after his public appearance, Kim was elected as the first secretary of the North Korean Central Bureau of the Communist Party. In February 1946 the Provisional People's Committee for North Korea was organized with Kim as its chairman and took over the existing central administrative bureaus. A year later, in February 1947, a legislative body was established under the name of the Supreme People's Assembly, and with the strong support of the Soviet occupation authorities Kim began to consolidate his political power. The North Korean Workers Party had been created on August 23, 1946. By December of that year its membership had reached 600,000.

***The two* republics.** After the simple discussion on trusteeship between Stalin and Roosevelt at the Yalta meeting, it was not until May 1945, at a meeting with the Chinese Foreign Minister in Moscow, that Stalin confirmed his agreement to set up a four-power trusteeship. The ensuing Moscow Conference, held in late December, created a four-power trusteeship and established a Joint U.S.–U.S.S.R. Commission of the rival U.S. and Soviet military commands in Korea for the settlement of the question of a unified Korea. When the Joint Commission convened in Seoul from March to May 1946, the Soviet delegates demanded that those Korean political groups that had opposed trusteeship be excluded from consultation. The United States refused, and on this rock foundered all attempts by the commission to prepare for the unification of Korea. The commission met again from May to August 1947, but it achieved nothing for the creation of a unified Korea.

The United States presented the entire matter of Korean unification to the United Nations in September 1946. The United Nations General Assembly adopted a resolution, proposed by the United States, rejecting the Soviet position. The resolution called for general elections in Korea under the observation of a UN Temporary Commission on Korea, those elected to make up a National Assembly, establish a government, and arrange with the occupying powers for the withdrawal of their troops from Korea. But the U.S.S.R. barred the Temporary Commission from entering North Korea. The South, however, held elections under the supervision of the Temporary Commission on May 10, 1948. The National Assembly convened on May 31 and elected Rhee as its speaker. Shortly afterward a constitution was adopted, and Rhee was elected president on July 20. Finally, on August 15, the Republic of Korea was inaugurated, and the military government came to an end. On December 12 the UN General Assembly declared that the republic was the only lawful government in Korea.

Construction of the People's Republic

Meanwhile, on November 18, 1947, the Supreme People's Assembly of North Korea set up a committee to draft a North Korean constitution. The committee adopted a new constitution in April 1948, and on August 25 elections for members of the Supreme People's Assembly were held with a single list of candidates. On September 3 the constitution of the Democratic People's Republic of Korea was ratified by the Supreme People's Assembly, which was holding its first meeting in P'yŏngyang. Kim 11-sung was appointed premier of the People's Republic, and on September 9 the Democratic People's Republic of Korea was proclaimed. The U.S.S.R. recognized the People's Republic as the only lawful government in Korea on October 12.

THE KOREAN WAR

South Korea began to organize a police constabulary reserve in 1946. On December 14, 1948, the Department of National Defense was established. By June 1950, when the war broke out, South Korea had a 98,000-man force equipped only with small arms, which was barely enough to deal with internal revolt and border attacks. The United States occupation forces completely withdrew from Korea by June 29, 1949, leaving behind them a force of about 500 men as a U.S. Military Advisory Group to the Republic of Korea to train the South Korean armed forces. On June 7, 1949, in a message to the United States Congress calculating the security measures necessary for the protection of the Pacific from Communist domination, Pres. Harry S. Truman declared that Korea had become a testing ground in the ideological conflict between Communism and democracy. On that ground, he asserted, U.S. aid should be granted with a long range program. On October 6, 1949, the United States granted South Korea $10,200,000 for military aid and $110,000,000 for economic aid for the fiscal year 1950, the first year of a contemplated three-year program. In addition, the U.S. Congress approved $10,970,000 for military aid on March 15, 1950. The military equipment committed under the U.S. military-assistance program was still en route, however, when North Korean troops invaded the South. South Korea was unprepared to resist the total invasion from the North.

Early in 1946 the Soviet authorities in North Korea had organized a 20,000-man constabulary and army units, and in August 1946 the North Korean Army was established, its title being changed to the Korean People's Army in February 1948. The Soviet occupation forces left North Korea in December 1948, leaving behind 150 advisors for each army division for training purposes. On March 17, 1949, the U.S.S.R. concluded a reciprocal-aid agreement with North Korea in which it agreed to furnish heavy military equipment; and by June 1950 North Korean forces numbered 135,000, including a tank brigade. As early as 1946, the Soviets were sending thousands of Koreans to the U.S.S.R. for specialized training, and during 1949–50 the People's Republic of China transferred about 12,000 Korean troops from its army to the North Korean forces. The North Korean forces were thus far superior to the forces of South Korea in training and equipment.

Cost of the war

The North Korean troops launched a full-scale invasion of South Korea on June 25, 1950. The war concluded with an armistice on July 27, 1953, having lasted for three years and one month and having accounted for about 4,000,000 casualties, including civilians. South Korean casualties were some 1,313,000 (1,000,000 civilians); Communist casualties were estimated at about 2,500,000 (including 1,000,000 civilians). The United States lost 33,629 dead in action, South Korea 47,000, and the UN forces 3,194; but the estimated losses of the People's Republic of China in action were 900,000 men and of North Korea 520,000. During the war, 43 percent of Korea's industrial facilities was destroyed and 33 percent of its homes devastated.

UN intervention. On June 26 (June 25, New York time) the UN Security Council approved a resolution describing the invasion of South Korea as a "breach of the peace and an action of aggression" and called upon the members to render every assistance in restoring peace. The Soviet Union was unable to impose a veto because its delegate had been boycotting the meetings to protest the fact that the People's Republic of China had no seat in the United Nations. On June 27 President Truman issued the order for United States air and naval forces to resist Communist aggression in Korea, and that afternoon the Security Council of the United Nations ratified Truman's decision to send air and sea aid to Korea, calling upon the UN members to render such assistance to Korea as might be necessary to restore peace. But Seoul, the South Korean capital, fell on June 28, and most of the South Korean Army was destroyed. On June 30 Truman ordered United States ground forces in Japan into Korea; the first U.S. troops reached the battlefield on July 4. The UN approved the creation of a unified command in Korea, and Gen. Douglas MacArthur was appointed commander. Sixteen member nations sent armed contingents, but the United States furnished the great bulk of the air units, naval forces, supplies, and money.

The North Koreans continued to advance recklessly despite the presence of U.S. troops in the field. In early August the UN retreat came to an end in a defense perimeter along the Naktong-gang (Naktong River) line (forming a semicircle in southeast Korea). South Korea was now almost overrun by the North Koreans, except for the small beachhead around Pusan-hang (Pusan Harbor; in Korea's extreme southeast). On September 15 MacArthur counter-attacked, catching the Communists on the flank by an amphibious attack on Inch'bn (on the coast west of Seoul). They were trapped and either surrendered or fled in panic. By October 1 the UN forces were back at the 38th parallel. On September 27 the U.S. Joint Chiefs of Staff ordered MacArthur to destroy the North Korean armed forces, and two days later Truman authorized him to advance into North Korea. On October 7 the UN General Assembly approved the resolution to permit entry into North Korea and created a UN Commission for the Unification and Rehabilitation of Korea. On October 20 the UN forces entered P'yŏngyang, the North Korean capital, and on October 26 reached the Manchurian border at the Yalu River.

Chinese intervention. The Chinese Communists, who had moved troops along the Yalu after the Inch'ŏn landing, in November entered Korea in overwhelming numbers. By the end of 1952, 1,200,000 Chinese were engaged in the war under the command of P'eng Te-huai. They forced the UN forces to retreat in disorder, and Seoul was re-evacuated on January 4, 1951. But around P'ybngtaek (about 30 miles south of Seoul) the Chinese were halted, and in February the UN General Assembly formally condemned the People's Republic of China as an aggressor. The UN counter-offensive began in late January. By March 31 the UN forces had again reached the 38th parallel. MacArthur now publicly advocated an extension of the war to China because of the Chinese intervention, but this advocacy was regarded as a challenge to the United States president's conduct of foreign policy. Consequently, on April 11, Truman dismissed MacArthur from all of his commands, and Gen. Matthew B. Ridgway took his place. From then until the armistice, the UN forces fought a holding action along the 38th parallel; indeed, in many places the UN forces were slightly north of the line.

Armistice and aid. The Soviet delegate to the United Nations proposed a discussion of a cease-fire and an ar-

Negotiating difficulties

mistice on June 23, 1951, and on July 10 negotiations began between the United Nations and the Communist commanders at Kaesdng, later resumed at P'anmunjdm (both about 30 miles northwest of Seoul; the former in North Korea, the latter in South Korea). Many issues stood between the two negotiators, the first being the Chinese demand that all foreign troops be withdrawn from Korea in the face of the steadfast refusal of the United States to withdraw all UN troops from South Korea. The second issue was the boundary: the Communists demanded the restoration of the 38th parallel, but the United States insisted on the existing battle line. The third and most important issue was that of prisoners. The UN forces held 171,000 prisoners, 50,000 of them unwilling to return to their Communist countries. The Communists, not to lose face, were determined to have all prisoners back. On this matter the negotiations were deadlocked and did not resume until after the death of Stalin in March 1953. The United States administration under Dwight D. Eisenhower was inaugurated in early 1953 and, deeply concerned with balancing the budget, was determined to end the impasse even if this involved resumption of hostilities. On the other hand, the war weariness of the Communists was increasing. In April the first 6,670 Communists and the 684 UN personnel were exchanged at P'anmunjdm. Soon the prospects for armistice negotiations seemed to improve. The Communists agreed to hand over to a neutral commission the UN-held prisoners of war who did not wish to be repatriated, But Syngman Rhee opposed any term that would leave Korea divided and demanded that the military offensive be resumed. On June 18 Rhee suddenly released 27,000 North Korean anti-Communist prisoners in defiance of the United Nations, whereupon the Communists broke off negotiations. On July 20 negotiations were resumed. Rhee gave in and agreed to support the armistice even though he would not sign it. In return the United States promised to extend economic aid and conclude a mutual-security pact to protect South Korea against further aggression.

Armistice signed

The armistice was signed on July 27, 1953. The United Nations had won most of its demands. The military line became the boundary between North and South Korea, and commissions were established to enforce the cease-fire regulations. A Neutral Nations Commission for Repatriation was entrusted with the repatriation of prisoners, 21,809 of whom—among them 7,582 Korean and 14,227 Chinese—chose to stay in South Korea or go to Taiwan.

The U.S. Army provided Korea with $181,200,000 during the occupation period of 1946–48. This money, which was provided under the assistance programs for occupied areas, was spent mainly on preventing hunger and disease. For the period of 1949–52, the U.S. provided $485,600,000 for economic aid and $12,500,000 for military aid. After the war the UN Korean Reconstruction Agency (UNKRA) was established to carry out economic aid to South Korea, 34 member and five nonmember states contributing $148,500,000. The UNKRA came to an end in 1958, but meanwhile UN Emergency Relief also contributed $474,400,000 and other international voluntary agencies $85,000,000. Most of the UN contributions were provided by the United States, and total U.S. aid to South Korea from 1946 to 1978 exceeded $5,893,900,000.

POSTWAR KOREA

South Korea. The political experience of the people of the Republic of Korea since 1948 represents a wide range of variation. They have lived under 12 years of Syngrnan Rhee's authoritarian rule, tempered by the rise of a vocal opposition coalition under semicompetitive conditions; the collapse of this system after student demonstrations that brought the nation close to civil war in April 1960; nine months of multiparty liberalism under the cabinet system of Prime Minister Chang Mydn that permitted competition among conservative and emergent socialist parties; and, since May 1961, a presidential system dominated by the armed forces, which had maintained a tight and effective rule over Korea.

The First Republic. The first Korean republic, established in 1948, adopted a presidential system and elected Syngman Rhee as the first president. He was re-elected in August 1952 while the nation was still at war. Even before the outbreak of the Korean War there had been a serious conflict between Rhee and the opposition-dominated National Assembly that elected him in 1948. The dispute involved a constitutional amendment bill that the opposition introduced in an attempt to defeat Rhee by replacing the presidential system with a parliamentary cabinet system. The bill was defeated, but the dispute was carried down to Pusan, the wartime provisional capital, where the National Assembly was reconvened.

Early disagreement over president's role

When the opposition introduced another amendment bill in favour of a parliamentary system, Rhee counteracted by pushing through an amendment bill that provided for the popular election of the president. Later, in 1954, Rhee succeeded in forcing the National Assembly, then dominated by the ruling party, to pass a constitutional amendment bill providing a life-term presidency for himself. On the basis of the revised constitution, Rhee was able to run successfully for his third term of office in May 1956: Rhee's election for the fourth time, in March 1960, was preceded by a period of tension and violence, followed by student demonstrations resulting in many casualties. Rhee resigned under pressure and fled to exile in Hawaii, where he died in 1965 at the age of 90.

The Second Republic. The second Korean republic, which adopted a parliamentary system in place of the presidential system, lasted only nine months before it was overthrown by a military coup in May 1961. With a figurehead president elected by both houses of the legislature, power was shifted to the office of Prime Minister Chang Mydn, who was elected by the lower house by a narrow margin of 10 votes.

In spite of some strenuous efforts to initiate reforms in a society already blemished by social and economic ills accumulated over a long period of time, the Chang regime was unsuited to deal with the explosive situation created as an aftermath of a violent political change. To make the situation worse, factionalism came to prevail in political life. As the ultimate source of authority now shifted to the office of the prime minister, constant efforts were made by conservative and more moderate factions to coalesce with a group of independents, either to keep or upset the majority within the legislature. Even before the Chang regime launched a full program of economic reform, the Democratic elite was seriously weakened by these factional struggles within its ranks.

Military junta of 1961

The military coup. With the military seizure of political power, postliberation Korean politics entered a new phase characterized by inflow of military officers into the government. The military junta that took over the government on May 16, 1961, dissolved the National Assembly and imposed a strict prohibition on political activity. The nation was then placed under martial law, and the Supreme Council for National Reconstruction (SCNR), headed by Maj. Gen. Park Chung Hee, took the reins and began to establish a new system of national government.

In November 1962 the SCNR made public a constitutional amendment bill that provided for a strong president and a weak, single-chamber National Assembly. The bill was approved by a national referendum held one month later. Then, in February 1963, Chairman Park of the SCNR issued a statement that he would not take part in the civilian government to be formed later in the year if civilian political leaders would uphold a nine-point "political stabilization proposal." On February 27, 1963, Chairman Park made a public pledge not to take part in the new government, for 53 political and military leaders had sworn to support his stabilization proposal.

In March, however, following bitter turbulence in the ruling junta itself and a chaotic situation created by the proliferation of minor political parties, Chairman Park proposed that military rule be extended for four years. The proposal met vigorous opposition from civilian political leaders, but some 160 military commanders, most of general officer rank, submitted a resolution to Park supporting the extension. Under considerable pressure, Park again changed course and announced, on April 8, 1963, a plan for holding elections toward the end of the year. In late May, Park was named presidential candidate of the Democratic Republican Party.

Election of Park Chung Hee

The Third Republic. The election for the president of the Third Republic took place on October 15, 1963. Park, by a narrow margin, defeated the opposition candidate, Yun Po-sun, former president of the Second Republic, who had remained in office (more or less as a figurehead) at the request of the junta to provide constitutional continuity for the military regime. When political activity was permitted to resume, Yun took the initiative in mustering opposition groups and became the presidential candidate of the Civil Rule Party. In May 1967 Park was re-elected to his second term of office, and the Democratic Republican Party won a large majority of the seats in the National Assembly. Members of the opposition New Democratic Party, whose candidate, Yun, had been defeated for the second time, claimed election fraud and refused to take their seats in the National Assembly until some months later.

During his second term, President Park was confronted with the constitutional provision that limited the president to two consecutive four-year terms. After considerable political turmoil and demonstrations by the opposition and the students, Democratic Republican Party members in the legislature passed an amendment that provided for the incumbent president to become eligible for three consecutive four-year terms. The amendment was approved by a national referendum in October 1969. In the presidential elections held on April 27, 1971, Park defeated his opponent, Kim Dae-jung of the New Democratic Party; in elections for the eighth National Assembly, however, the New Democrats made impressive gains, securing 89 seats as compared with the 113 seats of the ruling Democratic Republicans.

The Yushin system. In December 1971, shortly after his re-election to a third term of office, Park declared a state of national emergency on the basis of the "dangerous uncertainties of the international situation," and ten months later, in October 1972, he suspended the constitution and dissolved the legislature. A new constitution, which extended the power and permitted the re-election of the president for an unlimited number of six-year terms, was promulgated in December.

National Conference for Unification

The institutional framework of the Yushin (Revitalization–Reform) system departed radically from the Third Republic. The National Conference for Unification was created as "a national organization based on the collective will of the people as a whole to pursue peaceful unification of the fatherland." The conference is a body of not less than 2,000 nor more than 5,000 members who are directly elected by the voters for a six-year term. The president of the republic is the chairman of the conference, and the conference is charged with the election of the president. Other functions of the conference include approving a list of one-third of the members of the National Assembly, who are appointed by the president for *a* three-year term (other members of the legislature are elected directly by the voters for a six-year term) and approving constitutional amendments proposed by the National Assembly. Under this arrangement, Park was elected without opposition on December 23, 1972, and was re-elected for another term in December 1978.

Under the Yushin system, the Park government continued to achieve a high rate of economic growth. Despite the balance-of-payments difficulties of 1974 and 1975, a consequence of the petroleum crisis of 1973 and a much less favourable international environment than expected, growth in gross national product (GNP) averaged 11.2 percent a year during the third Five-Year Economic Plan (1972–76). Although the net growth in world trade in manufactured goods was sluggish during 1973–76, Korea's export volume more than doubled. At the same time, Koreans experienced great success in obtaining construction contracts in the Middle East. The government projected that the GNP would increase by 9.2 percent a year during the fourth Five-Year Economic Plan (1977–81). Whether South Korea could sustain such a growth rate was contingent on the growth of the world economy; on high rates of growth of exports through export diversification and structural changes in the Korean economy; and on continued government policies attaching high priority to a wider distribution of growth benefits to ensure a stable social order.

The Assassination of President Park. In October 1979, Korea faced a major national crisis that culminated in the death of President Park Chung Hee. According to the government, he was shot by Kim Jae-kyu, director of the Korean CIA on the evening of October 26, 1979, at the CIA dining lodge in Seoul. Five others, all presidential security force members, were also fatally shot. It was the first time in the history of the republic that its president had died in such an abrupt and tragic manner. After the death of the president, Prime Minister Choi Kyu-hah became acting president under Article 48 of the Yushin constitution. Emergency martial law was immediately proclaimed throughout the country, except for Cheju Island, and the army chief of staff, Gen. Chung Seung-hwa, was appointed martial law commander.

The death of President Park left the nation with a number of questions concerning its future, the most serious of all being the matter of effecting a peaceful transition of government. The Yushin consitution states that the National Conference of Unification must elect a successor within three months to fill the remainder of the presidential six-year term, which had begun in December 1978. The opposition, however, had demanded that the Park regime return to a liberal parliamentary democracy system and thereby had closed all avenues for the opposition to compete in the election for the presidency. As Korea moved into the 1980s, basic questions were how the government and opposition would resolve their conflicting positions on succession and whether Korea would develop a more openly democratic political system.

Rise of Kim 11-sung

North Korea. In 1945 Kim 11-sung, the supreme commander of the Korean People's Army, arrived in P'yŏngyang, the capital of North Korea, with the Soviet contingents and was pushed by the Soviet authorities to the forefront of North Korean politics. In 1948, when the Democratic People's Republic of Korea was established, he became the first premier of the North Korean Communist regime and in 1949 he became chairman of the Korean Workers Party.

After 1956, as the Sino-Soviet conflict was intensified, Kim was compelled to shift his positions vis-a-vis the two great powers, Moscow and Peking, no less than three times: from pro-Soviet to neutral, from neutral to pro-Chinese, and from pro-Chinese to independent. The division between the two great powers was also reflected in conflicts within the North Korean leadership. The pro-Chinese group, known as the Yenan faction, was purged by Kim during 1956–58. At about the same time, ha eliminated a pro-Soviet faction from the Central Committee of the Korean Workers Party.

In 1966, after a visit to P'ydngyang by the Soviet prime minister, Aleksey N. Kosygin, Kim announced what became known as the independent party line in North Korea, in which he stressed the principles of "complete equality, sovereignty, mutual respect, and noninterference among the Communist and Workers' Parties." From this statement, the KWP ideologists worked out four principles: "*juche* [autonomy, or identity] in ideology," "independence in politics," "self-sustenance in economy," and "self-defense in national defense."

In the late 1960s the Kim 11-sung regime carried out a program of strengthening the military forces, turning the country into a fortress with a standing army of about 500,000 by the late 1970s and much modem equipment. There was also a strong militia, with a total number estimated at 1,250,000 in the mid-1970s.

North Korea's emphasis on strengthening its military forces proceeded in parallel with its continued stress on the construction of a self-reliant economy. With aid from the Soviet Union, the People's Republic of China, and the east European countries, North Korea implemented a series of economic development plans and made significant gains. When the Soviet Union, under Nikita S. Khrushchev, suspended its aid to North Korea, the Seven-Year Plan (1961–67) of the North Korean regime was seriously affected, as indicated by the extension of the plan for another three years.

North Korea responded favourably to the appeal of the South Korean Red Cross in August 1971 to reunite the families separated by the division of the country in 1945. The Red Cross held several talks in Seoul and P'ybngyang alternately during 1972. While the talks were in progress, on July 4, 1972, the South and North Korean agreement on the principles of Korean reunification was made public by Yi Hu-rak, then the director of the KCIA, who in May 1972 made a secret visit to P'ybngyang, where he met Kim 11-sung and signed the agreement with his North Korean counterpart, Kim Yong-ju, a younger brother of Kim 11-sung. Yi's visit to P'ybngyang was reciprocated by a visit of Park Sung-chul, then vice premier of North Korea, to Seoul on May 29, 1972.

The joint communique of July 4 provided for the establishment of a South–North Korea Coordinating Committee to discuss and implement the means necessary for reuniting the divided families. After holding the last session on March 14, 1975, North Korea unilaterally boycotted the Coordinating Committee and cut off the hot line installed between Seoul and P'ybngyang in 1972. The Red Cross talks continued intermittently until December 1977, but no agreement was reached by the delegates on reuniting the families. The gulf dividing the two parts of Korea is so wide that the representatives of the two governments in the South–North Korea Coordinating Committee failed to achieve even agreement on the agenda to be discussed. South–North Korean relations remain hostile and highly unstable, and the Korean peninsula remains a threat to peace and stability in East Asia. (B.-h.H.)

PAIGE, ***The Korean Decision, June 24–30, 1950*** (1968), a detailed account of the United States decision to intervene in Korea in 1950, a significant contribution to the literature in foreign policy-making theories; and ***The Korean People's Democratic Republic*** (1966), an excellent analysis of the history of the North Korean Communist system, describing changes in economic, political, and ideological aspects; DAVID REES, ***Korea: The Limited War*** (1964), one of the best books dealing with the outbreak of the war; HAHN-BEEN LEE, ***Korea: Time, Change and Administration*** (1968), an imaginative and skillful application of time perception to administrative behaviour under conditions of rapid social change in Korea throughout the postliberation period; SUNG-JOO HAN, ***The Failure of Democracy in South Korea*** (1974), a study of the causes of the collapse of Chang Myŏn's liberal democratic government in May 1961.

(K.-r.L./K.-b.L./B.-h.H.)

Korea, North

The Democratic People's Republic of Korea (Chosbn Minjujuŭi In'min Konghwaguk) occupies the northern section of the Korean peninsula, which juts out from the Asian mainland between the Sea of Japan (East Sea) and the Yellow Sea. The country is bordered by China and the Soviet Union to the north and by the Republic of Korea (South Korea) to the south.

North Korea has an area of 46,800 square miles (121,200 square kilometres), occupying about 55 percent of the peninsula. In the late 1970s, it had an estimated population of about 17,072,000. The national capital, P'ybngyang, is a major industrial and transport centre near the west coast,

North Korea was created in 1948 as a result of the post-World War II military occupation by the United States in the south of the peninsula and by the Soviet Union in the north. In close alliance with China and the Soviet Union, the North Korean government has endeavoured to transform the prewar agricultural country into a self-sufficient industrial nation. Economic programs have been successful, but the industrialization has been at the expense of agriculture and of personal freedom. The government, run by the Korean Workers Party, has attempted to achieve strict production quotas with the use of forced labour, socialization of the entire economy, and ideological indoctrination.

Foreign relations are oriented toward the Communist countries and those non-Communist nations such as Japan that are active in the Afro-Asian solidarity movement. Close economic and political ties have been maintained with the Soviet Union and China, while a hostile attitude has been sustained toward the United States and, generally, South Korea. (For an associated physical feature, see YALU RIVER. For a detailed discussion of the capital city, see P'YONGYANG. For history, see KOREA, HISTORY OF.)

The Kaema Plateau and **Nangnim-sanmaek**

The* landscape.** ***Relief, drainage, and soils. Mountains and valleys characterize most of the country. The Kaema Plateau in the northeast has an average elevation of 3,300 feet above sea level and forms the topographic roof of the entire Korean peninsula. Paektu-san (9,003 feet [2,744 metres]), the highest mountain in North Korea, rises at the northern edge of this plateau; it is an extinct volcano topped by a large crater lake. The Nangnim-sanmaek (Nangnim Mountain Range) runs from north to south through the middle of the country, forming a divide between the eastern and western slopes of the peninsula. The Kangnam, Myohyang, Ŏnjin, and Mybrak mountains, with their roots in the Nangnim-sanmaek, extend parallel to each other toward the southwest. Large river valley plains have developed between the western mountains; they merge along the narrow, irregular coastal plain on the west coast. The Hamgydng mountains, extending from the Nangnim-sanmaek to the northeast, form a steep slope between the Kaema Plateau and the Sea of Japan. The T'aebaek-sanmaek of South Korea extends into North Korea; one peak, Kŭmgang-san (5,373 feet [1,638 metres]), is famous for its scenic beauty.

The longest river of North Korea is the Yalu, known as the Amnok-kang. It rises at Paektu-san (Paektu Mountain) and flows southwest for 501 miles to its mouth on Korea Bay. The Tumen River also begins at Paektu-san but runs northeast for 324 miles to the Sea of Japan. There are no large streams along the east coast except for the Tumen River, and all the significant rivers, such as the Yalu, Ch'dng-ch'dn, Taedong, Chaerydng, and the Yesdng, drain to the Yellow Sea. The relatively large valley plains of the western rivers are major agricultural regions.

More than 60 percent of the soils are locally derived from the weathering of granitic rocks or various kinds of schists (crystalline rocks). The soils are generally brownish in colour, abundant in sandy materials, and low in fertility. Well-developed reddish-brown soils that are derived from limestone are found in North Hwanghae Province (Hwanghae-pukto) and the southern part of South P'ybngan Province (P'ybngan-namdo). The Kaema Plateau shows development of podzolic soils (ash-gray forest soil) as a result of its cold climate and coniferous forest cover. Although most of the soils are infertile and lacking in organic content, the valley plains have relatively rich alluvial soils.

Climate. North Korea has a generally cool continental climate. The winter season from December to March is long and cold; mean temperatures in January range between 21" F (—6" C) in the south and —8" F (—22" C) in the northern interior. The summer, from June to September, is hot, with mean July temperatures above 68° F (20" C) in most places. Accordingly, the annual range of temperatures is large—about 54° F (30" C) at P'ydngyang and about 77° F (43" C) at Chung-gangjin, where the lowest temperature in the Korean peninsula, —46.5" F (—43.6" C), has been recorded. Because of ocean currents and the mountain ranges bordering the narrow coastal lowlands, winter temperatures on the east coast are about 4° or 5° F (2° or 3" C) higher than those of the west coast.

Most of the country receives around 40 inches of precipitation annually. The northern inland plateau, however, receives 24 inches and the lower reaches of the Taedong-gang (Taedong River) Valley 32 inches. The upper Ch'ŏng-ch'ŏn-gang area averages between 48 and 52 inches yearly. Approximately 70 percent of the annual precipitation falls in the four months from June to September; this heavy concentration of rainfall is related to the humid summer monsoon from the Pacific. Less than 5 percent of the total precipitation occurs in winter. There are about 200 frost-free days along the coast and fewer than 150 inland.

Vegetation and animal life. Vegetation on the Kaema Plateau, especially around Paektu-san, is composed of coniferous trees, such as the Siberian fir, spruce, pine, and Korean cedar. The western lowlands were originally covered by temperate mixed forests with many types of plants, but continuous deforestation has resulted in only remote patches of the original forests. Most of the lowlands are now cultivated, except for some of the hills that are covered with small pine groves mixed with oaks, chestnuts, and elders. Along streams that are subject to flooding, or where the ground is too stony for cultivation, reeds, sedges, wild mulberry trees, and Italian poplars are found. Common river fish include carps and eels.

Because of deforestation, the population of deer, mountain antelopes, goats, tigers, leopards, and panthers has greatly decreased and is restricted to the remote forests. In the plains, however, it is still possible to see wild pigeons, herons, cranes (which nest near human habitations), and many migratory water fowl, which alight in the rice fields.

Historic provincial divisions

Traditional regions. Close examination reveals numerous distinct regions, each with a different natural environment and historical background. Of the eight Korean provinces of the Yi dynasty (1392–1910), North Korea contains the three provinces of P'ybngan, Hwanghae, and Hamgyŏng and the northern parts of Kangwŏn and Kydnggi provinces. Each province was not only a political unit but also had characteristics of a cultural region in terms of dialect, customs, and a way of life. North Korea may also be divided into the two larger traditional regions of Kwanso to the west and Kwanbuk to the east, roughly divided by the Nangnim-sanmaek while Kwanso comprises the provinces of North P'ybngan (P'yŏngan-pukto), South P'ybngan (P'ydngan-namdo), North Hwanghae (Hwanghae-pukto), South Hwanghae (Hwanghae-namdo), and Chagang, while Kwanbuck includes North Hamgybng, South Hamgybng, and Yanggang provinces.

Human settlement. Urbanization has increased rapidly since 1953; by 1967, 48 percent of the population were urban. Most of the rural population inhabits the eastern and western coastal lowlands and river valley plains. The inland areas of Chagang and Yanggang provinces are sparsely settled because of the lack of arable land and the cold climate, which is not suitable for rice culture. Villages in the lowlands and valley plains are usually clustered together on the southern foot of hills, which offer protection against the cold northwestern winter wind. Scattered fire fields are tilled by a small number of shifting cultivators in the Kaema Plateau, especially in Yanggang Province. The Upper Yalu and Tumen river valleys contain settlements associated with lumbering, and fishing villages are numerous along the coast, especially on the east.

Urban settlement

Cities that developed during the Japanese occupation (1910–45) were largely associated with the exploitation of natural resources, industry, and transportation. P'yŏngyang is the hub of the national railway system, Namp'o is a western port, Songnim contains an iron-ore refinery, and Sinŭiju contains factories for the production of electrical equipment, chemicals, textiles, and consumer goods. Mining cities include Aoji, Chaerybng, Iwdn, Kilchu, Musan, and Pukchin. The Communist regime's heavy emphasis on manufacturing resulted in the continuous expansion of the early industrial centres and caused a population flow into the urban areas from the countryside. Most of the cities were destroyed during the Korean War (1950-53) and have since been rebuilt. There are no high-rise buildings, but seven- and eight-story buildings line the main streets of P'ydngyang. Workers are expected to live in apartments rather than individual homes, and housing projects are supported almost solely by the government. Heating systems in the apartments and urban water supplies are inadequate. The streets are strangely empty of pedestrians, as the Koreans have few leisure hours.

People and population. *Population groups.* Because they are a nation with a long history, Koreans believe that they belong to a single racial stock. Physical and cultural characteristics vary only slightly from one region

to another. Koreans all have typical Mongoloid physical features; their average stature is a little shorter than that of the northern Chinese and slightly taller than that of the Japanese. All Koreans speak the Korean language. which is related to Japanese and contains Chinese loan words. The Korean script. known in North Korea as Chosdn muntcha (and in South Korea as Han'gŭl), is composed of phonetic symbols for the ten vowels and 14 consonants. In North Korea Chosdn muntcha has been used exclusively without Chinese characters in newspapers and other publications since 1945. About 80.000 Chinese lived in the cities before 1945. but their present population figure is unknown.

The way of life and the value system of Koreans are based fundamentally on Confucian thought. To a lesser extent. Buddhism is also important. Roman Catholic and Protestant beliefs were introduced in the 17th and 19th centuries; Sdn-ch'on and P'ydngyang were major centres of Christian activities. World War II brought repression of Christianity. and all foreign missionaries were expelled from the country.

The monotheistic religion of Ch'dndogyo ("Society of the Heavenly Way"; originally known as Tonghak) was founded by the Confucian teacher Ch'oe Che-u in 1860. A combination of Buddhism. Confucianism. and Christianity. Ch'dndogyo played a leading role in the independence movement of 1919. Shamanism—the religious belief in gods. demons. and ancestral spirits responsive to a

NORTH KOREA

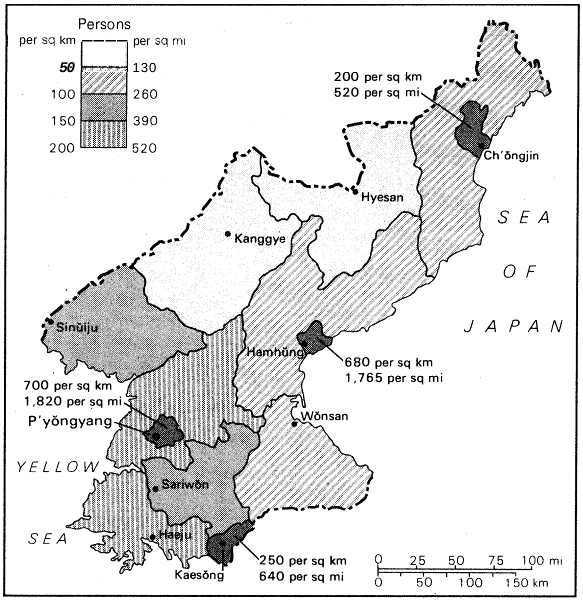
priest, or shaman--existed in Korea before the introduction of Buddhism and Confucianism and still prevails in rural villages.

Religious repression

The Communist regime has constitutionally confirmed freedom of religion but does not practice it, allegedly for fear that it will weaken the Communist Party and the government. Ch'ŏndogyo, however, is used as a means of propaganda. After the Korean War, churches and Buddhist temples were confiscated and looted, and many were converted to other purposes.

Demography. In 1970 the United Nations estimated that during the period 1965–70 the North Korean birth rate was 39 births per 1,000 population, the death rate 11 per 1,000, and the rate of natural increase 28 per 1,000. The total population was estimated at about 14,280,000 in 1971. The movement of population northward during the 1930s and 1940s was reversed after the Korean War, and North Korea lost about 2,000,000 people to its southern neighbour.



Population density of North Korea.

The stress on industrialization since 1945 has promoted migration to the cities, and the farm labour shortage is severe. North Korea is not concerned with overpopulation because an abundant labour force is needed for its unusually high goals of economic achievement. There is a campaign to repatriate Koreans living in Japan. The average population density was 305 persons per square mile in 1971. The coastlines are heavily populated, while the interior only sparsely so.

The national economy. The means of production are socialized, and priorities and emphases in economic development are set by the government. The economy is self-sufficient except for industrial needs such as fuel and machinery. Like other Communist countries, North Korea places special emphasis on capital goods rather than consumer goods.

Natural resources. North Korea contains about 80 to 90 percent of all known mineral deposits on the peninsula. It is estimated that 200 minerals are of economic value, including gold, tungsten, graphite, magnesite (magnesium carbonate), barite (barium sulfate), and molybdenum (a metallic element used in hardening steel).

Major iron and coal deposits

Iron-ore reserves are estimated at about 2,400,000,000 tons; the deposits at Musan, North Hamgydng Province are of low quality, while those of North Hwanghae Province and South P'ybngan Province are of high grade. Rich deposits of anthracite (hard coal) occur along the Taedong-gang, not far from P'yŏngyang, and there are small amounts of lignite (brown coal) at Aoji and Anju. Petroleum was reportedly discovered in the 1950s, but there is no evidence of production.

The northern interior contains large forest reserves of larch, spruce, and pine trees. Most of the coastal slopes have been excessively deforested, however, and reforestation programs stress economic forestry. Hydroelectric-power resources were developed highly during the Japanese regime along the Yalu River and its upper tributaries, such as the Changjin, Pujdn, and Hŏch'ŏn rivers. Power production is based mainly on hydroelectricity, but thermal electricity is becoming important because of the increasing demands of industrialization and the deficiency of hydroelectric power during the dry season.

Sources of national income. Since World War II, North Korea has changed from an agricultural to an industrial nation. In 1946, 59 percent of the gross national product (GNP) was derived from agriculture and 23 percent from industry. As of 1965, agriculture contributed only 22 percent to the GNP compared to industry's 78 percent.

Farm cooperatives

Despite the disproportionately small agricultural contribution due to the labour shortage and low productivity, there has been an increase in cultivated land, irrigation projects, chemical fertilizer supplies, and mechanization through the government program of socialization. By 1958 all farms were incorporated into more than 3,000 cooperatives; each cooperative is comprised of about 300 families on about 1,000 acres. The farm units are controlled by management committees, which issue orders to the work teams, set the type and amount of seed and fertilizer to be used, and establish production quotas. Produce is delivered to the government, which controls distribution through state stores. Each farmer is paid for his labour in money or in kind and is allowed to keep chickens, bees, fruit trees, and a garden.

There are also state and provincial model farms for research and development. The workers are paid in money and are allowed a garden. Livestock husbandry is concentrated on the state farms because the land is little suited to grazing and few feed grains are grown.

The main food crops are grains, such as rice, corn (maize), millet, barley, and wheat. Although production has increased since the 1950s, grain must still be imported. Sweet potatoes, soybeans, and fruit trees are raised extensively. Industrial crops include tobacco, cotton, flax, and rape (an herb grown for its oilseeds).

Forestry has declined since World War II and contributed about 3 percent of total industrial output in 1963. The sea is the main source of protein for North Koreans, and the government has continually expanded commercial fishing since the 1950s. Most fishing activity centres on the east coast and on Tasa-do (Tasa Island) in the mouth of the Yalu River. The annual marine catch includes anchovy, mackerel, pollack, tuna, crustaceans, and seaweed.

Mining is a state enterprise directed by a manager who is appointed by the government. The most emphasis is given to the extraction of coal and iron ore. There are more than 100 small coal mines, an iron mine at Sunhŭng, a nickel mine at Puyun, and a copper mine at Mandŏk.

The three most important industries are concerned with the production of iron and steel, centred at Songnim and Ch'ŏngjin; of industrial and agricultural machinery at Kangsŏn, near P'ydngyang; and of textiles, centred at P'yŏngyang and Hamhŭng. Other industrial products include chemicals, armaments, vehicles, cement, glass, ceramics, and some consumer goods.

Industrial development is related to the country's large supply of electric power. Production has increased steadily, although it has not kept pace with industry, and electricity is sold to China. Most power is provided by hydroelectric facilities, such as those at Sup'ung, Purydng, Kŭm'gang, and Kanggye. There has been expansion of thermal facilities through aid from the Soviet Union and China.

Banking

The North Korean Central Bank is the sole bank of issue. It receives all national revenues and precious metals and provides government agencies with working capital. The Industrial Bank has branches in every farm cooperative; it administers the government insurance system, operates savings accounts for government and individuals, and is the only bank to grant loans. The Foreign Trade Bank handles all foreign transactions and currencies and is supervised by the Central Bank.

More than 80 percent of foreign trade is conducted with the Soviet Union and China. Since the 1960s, trade has been permitted with non-Communist countries, including Japan, France, Australia, West Germany. Hong Kong, The Netherlands, and the United Kingdom. Imports mainly consist of machinery (including machine tools and precision instruments), fuel and related oil, chemical or rubber products; exports are pig iron, magnesia products, iron ore, and nonmetallic minerals.

Management of ***the*** economy. The farm cooperative is not only an economic unit but also the basic unit of technical, ideological, and political control. A Cooperative Farm Management Committee was established in 1961 in each county (*kun*) in order to tighten control over the individual units. Since grain is marketed only through state-operated stores, the government controls production, pricing, and distribution of grain. The industrial sector is organized into state-owned enterprises and production cooperatives. the latter being confined largely to handicrafts, marine processing, and other small-scale operations. In 1963 state enterprises accounted for 91 percent of the gross industrial product, and cooperatives contributed the remainder.

Through the three national economic plans promulgated since 1954, the government has given high priority to manufactures—especially the chemical and heavy industries—at the expense of agriculture. In order to increase the low productivity of labour, the state adopted an independent accounting system and a mass-mobilization measure known as the Ch'bllima ("Flying Horse") campaign.

The nation's railways

Transportation. The 6,500 miles of railroads, the principal means of transportation, in 1963 carried 93 percent of all freight. It is reported that 21 percent of the railroads are electrified. The basic railway pattern runs in a north–south direction roughly parallel to the coasts with branch lines to the river valleys. Because of the high mountains, there is only one east–west railway line between P'ybngyang and Wbnsan. The Kybng–Ui line on the west coast runs from Kaesbng near the South Korean border to Sinŭiju on the Chinese border, connecting the major cities. From this major line a branch from P'yŏngyang southwestward to Namp'o connects centres of machine building and foundries. The Manp'o line, which runs northward from P'ybngyang to Manp'o on the Yalu River, connects the western interior to China's Northeast (formerly Manchuria). The Wŏlla line is the major railway on the east coast; it runs from Wdnsan northward to Najin, and continues to Namyang on the Chinese border. Several branch lines serve the inland areas and mining centres.

Highway transportation is not as important as railroads because few motor vehicles are available. Major roads parallel the rail lines, and there are few east–west roads. Most of the 3,500 miles of roads are not paved.

River transportation plays an important role in transporting agricultural products and minerals. The most important rivers utilized for freight transportation are the Yalu, Taedong, and Chaerybng. Namp'o—the entry port to P'ydngyang—Haeju, and Tasado are the major ports on the west coast, as are Wbnsan, Ch'bngjin, and Najin in the east.

Air services are controlled by the air force. Flights are maintained between the major cities, and international services connect P'ybngyang with Peking and Moscow. Sunan Airport, ten miles north of P'ybngyang, serves as the international airport; domestic airports are located at Hamhŭng, Ch'bngjin, and Wbnsan.

Administration and social conditions. The government. Constitutionally, the 45-member Cabinet, Supreme Court, and Supreme Procurator (an agency that maintains surveillance over all citizens) are responsible to the Supreme People's Assembly, which is the highest organ of state power. The actual source of authority, however. derives from the extraconstitutional political body of the Korean Workers Party headed by Kim 11-sung, who has been the head of the party and the government since 1949. The government is highly centralized and totalitarian in nature and was often officially described as a transmission body of the party.

There are nine provinces (do or to); three special cities (si) of P'ybngyang, Ch'bngjin, and Hamhŭng; and one special region (chigu) of Kaesŏng. These are further subdivided into cities, counties, and ri, the smallest administrative unit. Local people's assemblies elect the members of their people's committees, which execute administration duties and make local economic plans and budgets with the approval of higher authorities.

Control of political activity

There are a number of political parties and social organizations who serve to support the Korean Workers Party. All political activities are sponsored by the party or require its sanction and must closely follow the party line and policies. Elections provide a means whereby assent is registered for the policy and program of the party; they do not allow freedom of expression. There is seldom more than one candidate on the ballot for each constituency, and the electoral system is completely controlled by the party.

The judicial system consists of the courts and the procuracy. They are independent of each other, and actually the procurator's office functions as the fourth branch of the government. The courts consist of the Supreme Court, whose judges are elected for three-year terms by the Supreme People's Assembly, and the provincial and people's courts, whose members are elected by local people's assemblies. Judges are usually party members or are controlled by the party.

The unusually large armed forces total about 401,000 men, about 3 percent of the population. Since 1966 there has been an emphasis on military preparedness, and economic plans have been altered to support military expenditures. In 1971 the military expenses constituted 30 percent of the total budget. The army is the largest force; there is also a 30,000-man air force and an 11,000-man navy. Both men and women are subject to conscription for three to four years service. The paramilitary militia is composed of about 1,250,000 members.

The social sector. Education is directly controlled by the party and serves as a process of indoctrination in Communist ideology and a means to supply skilled workers, technicians, and scientists to meet the government's economic goals. **All** students are required to engage in productive labour along with their studies, which emphasize science and technology. In 1967 education was made compulsory for those between the ages of seven and 16. The system is comprised of four years of primary, five years of middle, and two years of high school. There are also four to six years of university training. Technical schools are usually located near factories.

Health and welfare services

Medical care is free, and there is at least one clinic in each village. There are no recent statistics on the number of medical personnel, but available evidence indicates a significant shortage of doctors and medicine. Medical benefits are provided by social insurance for workers who are temporarily or permanently disabled and women during pregnancy and childbirth. There are also funeral benefits-and old-age pensions. Homes for the aged in each province have been operative under the Ministry of Labour since 1964.

Reconstruction of houses after the Korean War was given high priority, and dwellings are said to have improved considerably. Rural mud-walled, thatched-roofed huts have been replaced by brick buildings with tile or slate roofs. Urban housing is classified into five groups that range from one room and a half-sized kitchen to individual houses with gardens.

The national police and secret agencies under Ministry of Social Security control people's movements and social activities even down to the household level. Because of the high priority for industrialization and defense, the provision of consumer goods and social services is inadequate. It is believed, however, that the material economy and the lot of the peasant have improved since World War II, although it is still necessary to ration such daily goods as food and clothing.

Cultural life and institutions. The compound religious thoughts of Shamanism, Buddhism, and Confucianism have deep roots in Korean culture. Although the country has received continuous streams of foreign cultural influence mainly from China, Koreans have kept their identity and maintained and developed their unique language and customs Westernization, begun in the late 19th century, was in harmony with Korean tradition and slowly transformed the culture without much conflict until the 1940s. After World War II, the occupying Soviets did not recognize the Korean traditional family system or Confucian philosophy; age-old lineage records were burned, and the kinship system was broken. Through education, people were molded to fit the pattern of party idealism, and private life and individual freedom became extremely limited.

The state of the arts

Development plans since the Korean War have demanded almost superhuman patience and labour from the North Koreans. As a result, the people have had to lead an austere existence. The standard of living has improved, but leisure and cultural activities have continued to be regimented and gerred toward organized group activities, such as rallys and museum tours. The government strongly believes in nationalism and is concerned with the maintenance and advancement of the traditional fine arts and other cultural features. The selection of cultural items is based on Communist ideology, and writers and artists attempt to enhance class consciousness and propagate the superiority and independence of Korean culture. Literary works often deal with the personality cult of Premier Kim 11-sung and anti-imperialism.

All of the writers, artists, dancers, and musicians are assigned to government institutions, such as the National Theatre for the Arts, National Orchestra, and National Dancing Theatre in P'ydngyang and to provincial organizations of music, ballet, and drama. Museums have been well sponsored by the government, and many archaeological sites have been excavated to promote the growth of a strong nationalistic feeling. There are more than a dozen museums, including the Korean Revolutionary Museum and the Korean Fine Arts Museum. Archaeological sites are located in Nangnang district of P'ydngyang and at Kungsan, near Yonggang.

Of the approximately 30 daily newspapers, the Korean Workers Party Central Committee's *Nodong sinmun*, the government's Minju Chosdn, and the General Federation of Korean Trade Union's *Nodongja sinmun* have the largest circulations. The Korean Central News Agency controls the dissemination of information, and all papers are strictly censored. The government considers radio and television to be important mass media, and they play a great role in ideological education. Radio broadcasts reach every corner of the country; most people in the rural areas listen to wire receivers given to every village by the government. It was estimated that by the early 1970s almost all North Korean households had access to radio broadcasts as a result of a government project to link household loudspeakers to village receivers. Television broadcasting in North Korea has been made available to all parts of the country, and the number of television sets, both imported and domestically produced, has increased annually.

Prospects for the future. North Korea's future continues to depend upon the correction of economic imbalances and the maintenance of political stability. Unification with South Korea awaits the easing of continued military and political tension. Direct bilateral talks, which began in the early 1970s, have continued but have produced few results.

Korea, South

Korea is a peninsula thrusting from the northeast Asian mainland in a southerly direction for about 600 miles (965 kilometres). It reaches southeast to within approximately 120 miles of Honshu, the principal island of Japan, and to within approximately the same distance of the Shantung Peninsula of China. Elongated and irregular in shape, the Korean peninsula separates the Yellow Sea and the Sea of Japan (called the East Sea in Korea).

Because of its strategic location between China, Japan, and the Soviet Far East, Korea has long suffered from the inroads of aggressive neighbours. The peninsula was partitioned along the 38th parallel in 1945, after World War II, by the military occupation of the United States in the south and the Soviet Union in the north. In 1948, by a United Nations resolution, the Republic of Korea (South Korea) was formed in the south, and in the same year the Democratic People's Republic of Korea (North Korea) was formed in the north. As a result of the Korean War, which began in June 1950, following an invasion of South Korea by troops from North Korea, a demilitarized zone was established in 1953. It runs roughly from the mouth of the Han-gang (Han River) on the west to a little south of the town of Kosdng on the east coast and is about 150 miles in length. The present effective administrative area of South Korea is about 45 percent of undivided Korea: 38,221 square miles (98,993 square kilometres). South Korea is divided administratively into nine provinces (do or *to)* and two special cities (*t'ŭkpyŏlsi*), Seoul (Sŏul) and Pusan. It maintains diplomatic and trade relations with more than 100 countries. South Korea has not been admitted to the United Nations but has joined almost all of the United Nations agencies. The country has made considerable economic progress since the 1950s, with the government pursuing ambitious industrialization programs with special emphasis on mobilization of domestic capital and the promotion of export industries.

The landscape. Physical geography. Korea is largely mountainous, with small valleys and narrow coastal plains. The Taebaek-sanmaek (Taebaek Mountains), forming the backbone of the peninsula, run in a north–south direction along the eastern coastline. From them extend several lower mountain ranges oriented in a northeast–southwest direction. Principal rivers (gang), such as the Han, Kum, and Naktong, all have their sources in the Taebaek-sanmaek, and they flow between the ranges. The mountains are not very high, none exceeding 10,000 feet (3,050 metres) above sea level. The highest peak in South Korea, Halla-san on Cheju-do (Cheju Island) is 6,398 feet (1,950 metres) above sea level. There are comparatively extensive lowlands along the lower parts of the Han, Kum, and Naktong rivers. The eastern coastline is relatively straight, whereas the west has an extremely complicated ria (*i.e.*, creek-indented) coastline with many islands. The Yellow Sea and the complex coastline causes one of the highest tidal ranges in the world—about 30 feet maximum at Inch'dn., the entry port for Seoul.

Geological foundation

Geologically, the Korean peninsula consists in large part of Precambrian rocks (more than 570,000,000 years old), such as granite and gneiss. There are two volcanic islands, Cheju and Ullŭng, and a small-scale lava plateau in Kangwdn Province (Kangwdn-do). Most soils derive from granite and gneiss. Sandy and brown-coloured soils are common, and they are generally well leached and have little humus content. Podzolic soils are found in the highlands owing to the cold of the long winter season.

Climate. Because of continental influences the climate of Korea is characterized by a cold winter and a hot summer. The annual range of temperature is greater in the north and in interior regions than in the south and along the coast. The average monthly temperature in January drops below freezing except along the southern coast, and the July average monthly temperature rises to about 78° F (25" C). The average monthly temperature in January at Seoul is about 23" F (—5" C), and about 78° F (25" C) in August; at Pusan, on the southeast coast, the average January temperature is 35° F (2° C), and the August average is about 78" F (25° C), as in Seoul. The annual rainfall varies from about 40 to 55 inches (1,016 to 1,397 millimetres). Taegu, the driest area, has 38 inches, and Pusan, one of the wettest areas, receives 55 inches of annual rainfall. About 70 percent of the annual rainfall is received during the summer monsoons and shifting polar fronts. Occasionally, late summer typhoons cause heavy showers and storms along the southern coast. The frost-free season varies from 170 to 226 days.

Vegetation and animal life. The long, hot, humid summer is favourable for the development of extensive forests, which cover about two-thirds of the total land area. Because of fuel needs in the long cold winter, however, and the high population pressure, the original forest has almost disappeared. Except for subtropical broadleaf forests in a narrow belt along the southern coast, most areas contain broadleaf and coniferous trees. Wild-animal life is similar to that of northern China and the Manchurian region. Tigers, leopards, lynxes, and bears, formerly abundant, have almost disappeared, even in remote areas.

Patterns of settlement. The pace of urbanization since 1960 has caused decreases in rural population, not only proportionally but also absolutely, and by 1980 it had declined to about 43 percent of the total population. Agriculture is the most important occupation in rural areas, and rural settlements are thus found close to arable lands—mainly in river valleys and coastal lowlands. Agglomerated villages are common, ranging from a few houses to several hundred. Villages are frequently located along the foothills facing toward the south, backed by hills that give protection from the severe northwestern winter monsoon winds. Fields are divided into tiny plots and are cultivated by manual labour and animal power. Two types are found: rice fields and upland fields. Rice fields are usually irrigated, while upland fields are unirrigated dry fields, in which barley, wheat, soybeans, and millet are grown. Along the coastline small clustered fishing villages are found. Although the fishing population is not a large portion of the rural population, fishing is an important industry for export and for obtaining protein foods. Logging, mainly of coniferous trees, is limited to the mountain areas of Kangwdn and Kydngsang provinces. Settlements in mountain areas are usually scattered, in contrast to the lowlands. Logging is usually practiced during the off-season for agriculture.

Urban expansion

Rapid expansion of urban areas in the past decade, especially the expansion of Seoul and Pusan, has resulted in considerable changes in urban landscapes. Before 1960 there were very few high-rise buildings; even in Seoul most structures were lower than 10 stories. By the early 1970s, however, buildings of more than 20 stories had become common in the city. Because of this rapid growth, city services, such as water, transportation, and sewage systems, have not met the increasing needs. The difficulties in improving these services is exacerbated by the fact that old and new buildings are still located side by side; modern high-rise buildings stand next to traditional one-story Korean houses, even in the business district.

The people. ***Ethnic background.*** The Korean people may originally have had links with the people of Central Asia, the Baikal region, Mongolia, and the coastal areas of the Yellow Sea. Tools of Paleolithic type and other artifacts found in Sokch'ang-ni, near Kongju, are quite similar to those of the Baikal and Mongolian areas. The physical characteristics of Koreans show Mongolian racial traits, such as dark straight hair, straight noses, high cheek bones, and the Mongolian eyelid fold. The population is quite homogenous, with only about 30,000 foreigners, most of them urban Chinese, in South Korea.

Religion. There is little uniformity of religious belief in Korea, which is confusing to outsiders. In a typical Korean family, the women may adhere to the Buddhist religion, while the men may be followers of the Confucian ethical system. The teachings of Confucius, including ancestor worship, are probably the most important basic belief and are especially strong in the rural areas. Deep-rooted Buddhism is more popular with women, and old Buddhist temples are part of the typical rural and urban scene. Christianity is relatively new in Korea, although it claims a large number of devoted adherents and has had a profound effect on the modernization of Korean society. In 1980 there were about 8,000,000 Christians, of whom about 1,300,000 were Roman Catholics. An eclectic religion, Ch'dndogyo—a combination of Buddhism, Confucianism, Christianity, and even Taoism—spread widely in the latter part of the 19th century. About 1,200,000 adherents of Ch'dndogyo were reported in 1980. Shamanism still remains strong in the minds of rural people, especially among women. Ch'angga Hakhoe (Value Creation Learning Society), introduced from Japan in 1963, has become popular in the low-income areas of major cities; it is a militant society of followers of the 14th-century Japanese Buddhist Nichiren, organized in Tokyo as the Sōka-gakkai in the early 1930s.

Demography. Since 1960 birth and mortality rates have decreased rapidly. In 1960 the birth rate was about 42 and the mortality rate about 13 per 1,000; by 1980 the birth rate had dropped to about 23 and the mortality rate to less than 7 per 1,000. The rate of natural increase, 2.7 percent in the early 1960s, dropped to an average of 1.8 percent by 1980. The decrease in the birth rate has been caused chiefly by a national campaign for family planning conducted and emphasized since 1965. It has also reflected the increasing number of educated people in South Korea. The country, however, continues to struggle to reduce its population growth rate.

South Korea, Area and Population

	area		population*

Migration patterns

Before World War II, Koreans migrated to two major regions: Manchuria and Japan. People migrating into Manchuria were mainly from northern Korea, while those who went to Japan were mostly from southern Korea. It is estimated that in 1945 about 2,000,000 Koreans lived in Manchuria and Siberia and about the same number in Japan. About one-half of the Koreans in Japan returned to South Korea just after 1945. The most important migration, however, was the north-to-south movement of people after World War II, especially the movement that occurred during and after the Korean War. About 2,000,000 people migrated to South Korea from the North during that period, settling largely in the major cities.

More than one-half of the South Korean population lives in 30 cities and the country's two metropolises, Seoul and Pusan. Seoul, the capital, contains about one-fifth of the total population, which in 1980 was about 37,449,000.

The economy. The South Korean economy has progressed rapidly in the manufacturing and mining sectors under its economic development plans. Export-oriented manufacturing, which received strong government support, was particularly successful, and the country's balance-of-payments has steadily improved, although a payments deficit continued to exist into the early 1980s.

Natural resources. Natural resources in South Korea are meagre. The leading resources are coal, iron ore, graphite, gold and silver, tungsten, lead, and zinc, comprising almost two-thirds of the total value of mineral resources. Iron ore is exported mainly to Japan, and tungsten is exported to the United States. Both are pro-

Urban population distribution and rural population density of South Korea

duced in Kangwŏn Province. Gold and silver are produced mostly in Ch'ungch'dng and Kydngsang provinces, and a large-scale smelter is located at Changhang, on the southwest coast near Kunsan.

Energy production. Energy resources consist mainly of coal, petroleum, and hydroelectric potential. Anthracite coal is the major exploited energy resource, production having increased rapidly since 1960. Production in 1980 was more than 20,000,000 tons. There was a fivefold increase in electric power generated between 1961 and 1971, and a twofold increase between 1972 and 1980. Almost three-fourths of the hydroelectric power stations are located along the Han River, not far from Seoul. Thermal electric-power stations are located in the urban centres, with the exception of one near the coal-producing area. Since the first oil refinery started to produce petroleum products in 1964, power stations have changed over gradually from coal to oil. In contrast to North Korea, thermal electric power is far more important than hydroelectric power, the ratio of generation being about six to one.

Agriculture and forestry. Both the farm population and the proportion of national income from agriculture are gradually decreasing, with less than one-third of the population engaged in agriculture. More than one-seventh of the gross national product comes from agriculture, forestry, and fishing, and less than one-fourth of the republic's area is cultivated for rice, barley, wheat, soybeans and other crops. Rice is the most important crop, constituting about two-fifths of all farm products in value. Double cropping of rice and barley is common in Kybngsang and Chŏlla provinces.

Development of industry

Manufacturing. The four five-year economic development plans carried out between 1962 and 1981 stressed improvement of mining and manufacturing. Heavy industry, including chemical, metal, and machinery industries, continues to be developed and constitutes about one-third of all industrial products in value. The textile industry has been the most important single industry in terms of value and employment, although its share of the market has decreased. In 1980 textile exports accounted for almost one-third of all manufactured goods exported. South Korea's principal export markets are the United States, Japan, and Southeast Asian countries.

During the four five-year plans, the government exercised strong controls on industrial development, giving most support to such large industrial establishments as fertilizer plants and oil refineries. As a result, small and middle industries that were privately managed became increasingly difficult to finance, and consumer goods and consumer spending were discouraged. By the beginning of the Fifth Republic, however, these trends began to be reversed, especially in credit policies, as the government increasingly divested itself of direct involvment in industry.

Transportation. Korea's transportation system has expanded and improved to a considerable extent, especially with the introduction of modern highway and air services. It has not met the needs of the country, however, as indicated by congested urban transportation facilities. Bus transportation networks are well developed and serve most of the rural centres. In the rural areas agricultural products are still hauled by oxcart and by human labour. Internal air transportation began in the early 1970s, under the aegis of Korean Air Lines. Major cities, such as Pusan, Taegu, Kwangju, Cheju, and Kangnŭng, have scheduled air services. The international airport of Kimp'o, near Seoul, serves most international airlines, including Korean Air Lines, connecting with Japan and Southeast Asia. In the 1970s the government expanded port facilities at Pusan, Inch'dn, and Cheju, which increased their freight-handling capabilities more than fourfold.

The bulk of Korean railroads are government owned, and in 1980 they had a total of 3,677 miles of track in service. Until 1960 railway travel was the major means of inland transportation for both freight and passengers, but road transport has since become more important. Railroads are almost all of standard gauge, and the Seoul–Pusan line through Taejdn and the Seoul–Inch'dn line are double-tracked. An 18-mile four-lane highway from Seoul to Inch'dn was opened in 1968, and a 265-mile modern superhighway between Seoul and Pusan was opened in 1970. Road transport has come to account for more than 90 percent of passenger travel and 60 percent of freight transport.

Administration and social conditions. ***Constitutional framework.*** The government instituted after the constitutional referendum in 1980 is known as the Fifth Republic. It is patterned mainly after the presidential system of the United States and is based on separation of powers between the legislature, the executive, and the judiciary. The government system, highly centralized during the Third and Fourth republics, is less so under the Fifth Republic. The president, chosen indirectly by an electoral college of popularly elected delegates, is the chief of state, head of the executive branch, and commander of the armed forces. The State Council, the highest deliberative body, is composed of the president, the chairman, the prime minister, the heads of executive ministries, and ministers without portfolio. The prime minister is appointed by the president and approved by the elected National Assembly. Provincial governors are appointed by the central government,

Provisions for presidential government

The National Assembly and political parties. Extensive constitutional revisions were adopted by referendum in October 1980. Under these reforms the president's term of office was limited to one seven-year term with no reelection, and the size of the electoral college was doubled. The powers of the National Assembly, which had previously been curtailed, were reinstated, with its 276 members chosen, as previously, by a combination of direct and indirect election to four-year terms. Political parties were reinstated and allowed to nominate candidates for National Assembly elections.

South Korea has a two-party system, although since 1972 the power of the pro-government party has increased substantially, while that of the opposition has decreased. The Democratic Justice Party (DJP; until 1981 called the Democratic Republican Party) has been the ruling party since its founding in 1963. The Democratic Korea Party (DKP; until 1981 called the New Democratic Party), founded as a coalition of opposition groups in 1967, has been the major opposition. There are also minor political parties.

The judiciary. The judicial branch comprises the Supreme Court, three appellate courts, 12 district courts, and a family court. The Supreme Court is empowered to interpret the constitution and all other state laws and to review the legality of government regulations and activities. The chief justice is appointed by the president with the consent of the National Assembly, upon recommendation of the Judge Recommendation Council.

Education. Six years of primary school education is compulsory, and by 1980 almost all children of school age were enrolled. About 92 percent of primary school graduates go on to three years of middle school, and a little more than 85 percent of middle-school graduates go on to high school or to technical schools. Some 46 percent of high-school graduates go to higher educational institutions. Before World War II there were only 19 college-level institutions in South Korea, but by 1980 the number had increased to 84. Admission to the colleges and universities is in most cases granted through competitive entrance examinations.

Health and welfare. The availability of medical services has increased, but medical facilities and the number of personnel are inadequate to meet the country's needs. Improvement has been hampered partly by a continuous migration of medical personnel to foreign countries: in 1970, more than 4,500 doctors were practicing in or under contract to foreign countries, mostly the United States and Africa. Within South Korea there were 22,000 doctors by 1980—about six for every 10,000 persons.

Government welfare activities

Government welfare activities are new and limited in range. The programs include care of disabled war veterans, homes for the aged and for homeless and disabled war widows and orphans, vocational training of women. and care of juvenile delinquents. Since the devastation of the Korean War, United Nations agencies, civilian and military agencies of the United States, and private volunteer agencies have played a significant role in improving living conditions in the south. The shortage of housing remains a problem, but it has been partially solved by central and local government-housing programs in metropolitan areas. The national police force is strongly developed in order to counteract Communist infiltration.

Living conditions in South Korea are relatively low, compared to conditions in developed nations, but since the Korean War they have improved steadily. From 1968 to 1979 per capita disposable income increased more than sevenfold. Public health and sanitation have been greatly improved, thus reducing epidemics. Life-expectancy rates rose from about 53 years in the late 1950s to about 66 years by 1980. Despite improvement of social conditions there is little sign of a narrowing of the gap between rural and urban and low- and high-income groups.

Cultural life and institutions. Shamanism, Buddhism, and the philosophy of Confucius constitute the most important background of modem Korean culture. Since World War II, especially after the Korean War in 1950, the modem trends have rapidly progressed. Traditional thought, however, still plays an important role under the surface. Korea belongs to the Chinese cultural realm, although Koreans have maintained a distinct cultural identity throughout their history. The National Museum maintains about 80,000 artifacts of Korean culture, including many national treasures, chiefly in the central museum in Seoul. Its four branches are located at Kybngju, Puyŏ, Kongju, and Chbnju.

Architecture. After the Three Kingdoms period (57 BC to AD 668), Korean culture was strongly influenced by the Chinese, although this influence was given a distinctive Korean stamp. Korean architecture shows Chinese influence, but it is adapted to local needs and environment, utilizing wood and granite, the most abundant building materials. Beautiful examples are found in old palaces, Buddhist temples, stone tombs, and Buddhist pagodas.

Painting and ceramics. One of the earliest examples of Korean painting is found in the mural paintings in the kings' tombs of Koguryŏ (37 BC–AD 688). The best known mural paintings are those in the Sangyong Tomb, at Yonggang, located in North Korea. Ceramic arts became highly developed, flourishing during the Koryŏ period (918–1392) and diffusing to Japan, and every province continues to produce its distinctive ceramic wares.

Dance and music. Folk dances survive, and folk music, accompanied by native musical instruments, is performed occasionally at ceremonies and festive occasions. The government has made an effort to preserve the traditional arts. The National Classical Music Institute (formerly the Prince Yi Conservatory), for example, plays an important role in the preservation of folk music. It has had its own training centre for national music since 1954 and has been graduating 30 musicians each year. The Korean National Symphony Orchestra and the Seoul Symphony Orchestra give concerts in Seoul and Pusan, and in 1970 these ensembles celebrated the 80th anniversary of the introduction of Western music to Korea.

The mass media. Since 1945 there has been a sharp rise in the number of newspapers and in radio and television broadcasting. There are 25 national daily newspapers, including two English-language papers, as well as 21 local newspapers. In 1980 there were 54 radio broadcasting stations and 5 FM stations. Television was introduced in 1956, and there are 26 stations, 21 of which are run by the government.

Prospects. The Republic of Korea has been in a transitional stage between a traditional and an industrial society. An economic structure centred on primary industry is gradually changing into one oriented toward the secondary and tertiary economic sectors. Industrialization has accelerated urbanization and created new problems, such as a rural–urban gap and an overconcentration of population in the large metropolitan areas of Seoul and Pusan. The economy continues to be weak because of heavy dependence on foreign capital and a shortage in its international balance of payments. The U.S. aid program, begun in 1945, was terminated in 1970, but Japan has maintained a flow of investment capital as well as aid to South Korea. Inflation and the price of raw materials, especially oil, also continues to affect the country's rate of economic growth and foreign exchange.

South Korea is faced with the problem of trying to reconcile its differences with the north, while maintaining its relations with its allies, notably the United States and Japan. During the 1970s and early 1980s there were several rounds of low-level talks between the two Koreas, but these ended in a return to mutual hostility. The unification of the two countries, however, remains a high priority.

BIBLIOGRAPHY. SHANNON MCCUNE, ***Korea's Heritage: A Regional and Social Geography*** (1956), and ***Korea: Land of Broken Calm*** (1966), provide a general description of Korea's geography, people, and culture. K.G. CLARE ***et al.***, ***Area Handbook for the Republic of Korea*** (1969), is a good source of general information on social, political, economic, and national security matters. TAE-HUNG HA, ***Guide to Korean Culture*** (1968), is a survey of the varied phases of Korean culture. (C.Le.)

Korean Language

Korean is spoken by an estimated 55,000,000 people on the Korean peninsula and its coastal islands, and many among the approximately 663,000 Korean residents in Japan still speak the language. As the language of a sizable population occupying a strategic position in east Asia between China and Japan, Korean is important both historically and culturally. A considerable body of belles lettres and other literature is written in it.

Origin and classification. The direct precursor of the modern Korean language was the language of the ancient

*The system of phonetic transcription of Korean generally used for scholarly purposes in the United States. †Only seven consonant sounds (*k, t, p, n, l, m, ng*) are pronounced at the end of a word or before a consonant. Others are phonetically "reduced" to one of these seven when they occur in these positions; consequently, different letters may be romanized in the same way. The same letter may be romanized differently in different phonetic contexts because of sound changes. ‡Lenis (lax or softer than the corresponding tense consonant), voiceless, and slightly aspirated at the beginning of a word and typically voiced, except the sound *s*, between voiced sounds: *s* is palatalized as in English "she" when it comes before *i*, or *y* sounds. At the end of a word or before a consonant the sounds *k, t, p* are unreleased. §Tense (fortis or "reinforced"), voiceless, and unaspirated. ‖In South Korean published writing this letter is not found at the beginning of words except in some recent loanwords; in North Korean published writing it is found at the beginning of both Korean and foreign words. This letter, represented by *r*, is pronounced like the *t* in "water" when it comes between vowels or semi-vowels and at the beginning of words; when it comes at the end of a word or before a consonant, it is pronounced like English initial l. There is also a long *l* sound, romanized *ll*, that occurs between vowels or semi-vowels; this is the result of sound assimilations involving l. There is no special letter in the alphabet for it. ¶The sound of this letter in medial position is to be distinguished from *n'g*, which is the combination of *n* + *g* sounds. ♀Voiceless, and strongly aspirated. ðThe *y* part of a diphthong is represented in the Korean orthography by an extra stroke added to the letter for a vowel. □The w part of a diphthong is represented in Korean orthography by the letter for the vowel *o* or the letter for the vowel u. ◇This diphthong has no close approximation in English.

kingdom of Silla (c. 57 BC–AD 935), the original territory of which was in the southeastern part of the peninsula. The language of Silla spread over most of the peninsula when, in the 7th century, that kingdom conquered and annexed the territories of its rival states, Paekche (c. 18 BC–AD 660) in the southwest and Koguryŏ (c. 37 BC–AD 668) in the north. It is believed that the people of Silla and Paekche spoke dialects of the same language, while the people of Koguryŏ spoke a different, though related, language.

Possible relationship to Altaic

The most fruitful hypothesis concerning the affinity of Korean to other languages has been that it belongs to the Altaic family, which has traditionally included the Manchu-Tungus, Mongol, and Turkic groups of languages. Like them, Korean is a language of the agglutinative type, and it shares with them many features of phonology and grammar. (An agglutinative language typically combines into a single word several components, each of which remains relatively distinct in form and meaning.) This theory is supported by a number of cognates (words of similar form that presumably developed from a single ancestral form) and some sets of sound correspondences. The relationship is, however, probably a remote one.

Some scholars have proposed that Korean and Japanese are related. Their grammatical structures are similar in many ways, but their phonologies (sound systems) differ greatly. It is still an open question whether the sound correspondences demonstrated so far rigorously support a genetic relationship.

A standard spoken and written language is taught in the schools and used as the norm throughout Korea. This form of Korean was defined in the 1930s and is based primarily on the speech of the middle class of Seoul, with certain peculiarities excluded. Regional dialects, which are still vigorous, can be grouped into six major divisions: central, northeastern, northwestern, southeastern, southwestern, and Cheju-do, off the southern coast. Generally referred to by the name of the provincial areas with which they have traditionally been associated, these regional dialects differ from one another most conspicuously in intonation (the pitch pattern of a sentence), vocabulary, and the form of some grammatical endings.

Ancient Korean records

Knowledge of the early stages of the language that existed before the introduction of the native Korean alphabet in the middle of the 15th century is still slight. The most extensive records of ancient Korean extant are 25 texts of songs, called *hyangga*, from the kingdom of Silla; these are quoted in works written in Chinese during the succeeding Koryŏ period (935–1392). In these writings Korean is written in Chinese characters used as phonetic and semantic symbols of Korean words.

There are no generally agreed upon dates for the stages of development of the language. A possible dating is as follows: Old Korean (before the 12th century), Middle Korean (beginning of the 12th century to the end of the 16th century), Modern Korean (from the beginning of the 17th century).

The most penetrating external influence exerted on the language has been that of Chinese, from which many words were borrowed over the centuries. This influence has been limited largely to vocabulary. In addition, until the end of the 19th century, the prevailing written language of serious Korean literature was Chinese (*hanmun*) or, later, a deliberately Koreanized version of it.

Standardization of the spoken and written language became an urgent problem toward the end of the 19th century, when Korea undertook large-scale reforms to meet the social needs occasioned by internal changes and by pressures from the West. Efforts by Korean scholars, educators, and writers to develop a standard spoken and written language culminated in the publication by the Chosŏnŏ hakhoe (Society for the Study of the Korean Language) in 1933 of its *Han'gŭl mach'umppŏp t'ongiran* ("A Proposal for Unifying the Orthography") and its P'yojunmal *moŭm* ("Collection of Standard Forms of Words") in 1936. These standards became official only in 1945, upon Korea's liberation from Japanese rule. Some divergencies in the spelling system and in word usage have since developed in the north and in the south.

Native Korean alphabet

The writing system. The native Korean alphabet was introduced in 1446, after centuries of the use of cumbersome methods (known as *idu*) to transcribe Korean with Chinese characters. The new set of 28 letters (not an adaptation of an existing alphabet) was designed by a group of scholars commissioned by Sejong (reigned 1419–50), the fourth king of the Yi dynasty (1392–1910). Although the alphabet was meant to be a "script for the people," as its original name *Hunminjŏngŭm* implies, it did not win acceptance as a respectable form of writing among the literati, or scholar-officials, who continued to write *han*mun. This alphabet, also called Ŏnmun (the common script), did, however, give rise to a body of premodern popular literature. Finally, in the beginning of the 20th century, the alphabet received general recognition as the national writing system. Today it is known as Han'gŭl in South Korea and as Chosŏn Muntcha in North Korea.

Two methods of writing Korean are in use today: the purely alphabetic method and the "mixed script" method, in which Sino-Korean words (Chinese loanwords) may be written in their original characters and read in their Korean pronunciation. In North Korea only the alphabetic method has been in use since 1949; in South Korea both methods are in use, though it has been the government policy to dispense with Chinese characters in gradual stages. Four of the original 28 letters have gone out of use. The accompanying alphabet chart includes combinations of letters that are units in alphabetizing. Letters are grouped into syllable blocks, which contain at least an initial consonant plus a vowel. If the phonetic syllable has no initial consonant, a special letter is used as a filler for the initial consonant space in the syllable block and is silent in that position.

Three-way consonant distinction

Linguistic characteristics. Phonology. The McCune-Reischauer system of transcription is used for the Korean in this article; see the alphabet chart for the phonetic values of the transcription symbols. In the phonology, the consonants show an unusual three-way distinction among a series of lenis (soft) consonants, p, t, k, *ch*, s; a fortis (hard), unaspirated series, pp, tt, kk, *tch*, *ss*; and a fortis, aspirated series, p', *t'*, k', *ch'*. (Aspirated consonants are pronounced with an audible release of air.) These consonants are all typically voiceless (*i.e.*, pronounced without vibration of the vocal cords), but the lenis consonants p, *t*, k, and *ch* are voiced (*i.e.*, pronounced with vibrating vocal cords) when they come between voiced sounds, thus becoming pronounced as b, d, *g*, and *j* (as in "jam").

The central characteristic of the Korean phonological system is that the consonants are more severely restricted as to position of occurrence within a word than within a morpheme (*i.e.*, within the stems and affixes of words). For example, the sound [s] cannot be pronounced at the end of a word, although some word stems do end in *s*; or such sequences as [s] + [k] cannot be pronounced in Korean, but they can result from adding a suffix beginning with k to a stem ending in s. (The square brackets indicate that included letters stand for sounds pronounced rather than the conventional spelling.) The language has an extensive system of sound changes to resolve these conflicts between combining forms and permissible pronunciations. The standard orthography spells words in terms of the morphemes (constituent units) that comprise them, as long as the sound changes are covered by a regular phonological rule. Thus, most morphemes preserve their orthographic identity, although they may not be pronounced as spelled; *e.g.*, the noun stem for "five" is always spelled tascis, whether in the form *tasŏs-i* "five (as subject)," pronounced [tasŏsi], or in the form *tasŏs* "five (as a word by itself)," pronounced [tasŏt], with a final [t]. Forms based on the verb stem pis- "to comb," are spelled pis-6, pis-ko, but are pronounced as [pisb] and [pikko] respectively. If sound changes are not covered by a phonological rule of the language, the principle is to spell words phonetically.

Grammar. Aside from interjections and primary (not derived) adverbs, a word in Korean typically consists of a stem plus an ending. Stems are of two types: (1) nouns and (2) verbs and adjectives. Nouns take endings that mark their syntactic role in the sentence—such as subject, topic (often equivalent to English "as for," as in "As for Korea, it's a peninsula."), object, genitive—or that express such meanings as "to, in, from." They are indifferent as to grammatical number and gender. Verbs and adjectives have much the same pattern of forms and enter into many of the same kinds of constructions. They may take one or a combination of two tense suffixes, roughly designated as past and future tense; the lack of a tense suffix indicates present tense or tenselessness. To the stem or to the stem plus the tense suffix is added an ending that concludes the sentence (called a sentence-conclusive form), or a conjunctive, nominal (noun), adnominal (*i.e.*, attributive), or adverbial form.

Basic clause structure

The basic structure of a clause is subject + predicate; in the predicate the main verb or adjective comes last. An example is [ab6jiga^1 dje^2 segŭmŭl^3 naesiGssiimnida^4] "Father^1 paid^4 his taxes^3 yesterday^2." This order applies to conjunctive clauses (*i.e.*, clauses similar to "but he left early" in "He came, but he left early.") as well as to independent clauses, and it holds, too, for independent clauses regardless of mood—declarative, interrogative, imperative, and so on; *e.g.*, [abdjiga^1 6je^2 segŭmŭl^3 naesiŏssŭmnikka^4?] "Did Father' pay^4 his taxes^3 yesterday^2?"

The mood of the Korean sentence is specified by an ending on the verb or adjective that concludes the sentence. This ending expresses a complex of meanings—not only whether the sentence is a statement, a question, or a command, but also whether the speaker is reporting something from personal observation or from hearsay, and whether the speaker is certain or hesitant, and so on. At the same time, this ending specifies one of several possible levels of address for the sentence, reflecting the social relationship, conventionally defined, between the speaker and the person spoken to. For example, "Where^2 is^3 the post office'?" is [uch'egugi^1 Gdi^2 iss*ŭmnikka*^{3}?] when spoken to a senior or a stranger, [uch'egugi bdi iss*ŏ*?] when asked of a friend, and [uch'egugi ŏdi inni?] when addressed to a child. The relationship between speaker and person spoken to is one of three dimensions of a highly developed system of honorifics (forms showing deference). A second dimension, occurring between the speaker and the person spoken about (*i.e.*, the subject of the verb or adjective), requires a stem marked by the element [(ŭ)si-] when speaking of a senior. Thus, [ab6jiga^1 sanpporŭl^2 ka*s*inda^3] "Father' is going^3 for a walk^2" contrasts with [ch'dlsuga sanpporŭl kanda] "Ch'ŏlsu (a boy's name) is going for a walk."

The third dimension concerns the speaker in speaking of himself before a senior.

Pronouns, especially those for 2nd person ("you"), are used sparingly. The pronoun subject or object may be left out and understood from the linguistic or nonlinguistic context.

Modifying elements precede that which is modified. The most characteristic way to modify nouns is by the use of adnominal (attributive) forms of verbs and adjectives or of whole clauses; examples are [choh*ŭn*^{1} nalssi^2] "weather' that is good'," or, "nice' weather^2"; [naega' tanid*ŏn*^{2} hakkyo^3] "the school^3 that I' attended^2"; [ka*l*^{1} ttae^2] "time^2 to go^1." Adnominal + noun constructions play a variety of important roles in Korean syntax; *e.g.*, in nominalization processes (processes by which nouns or nounlike expressions are formed from verbs or verbal expressions, such as English "unifying" from "unify").

In multiclause sentences the clauses are attached one to the other in linear fashion. The last clause in the sentence is the main clause, containing the verb or adjective with the sentence-conclusive ending. The conjunctive relation is expressed by the conjunctive ending on the main verb or adjective in the preceding clause; *e.g.*, [mari tomada chokkŭmssik tarŭ*jiman*^{1} hakkyoesŏnŭn p'yojunmarŭl karŭch'inda^2] "Speech varies a bit from pro to province, *but*^{1} in the schools they teach the standard language^2."

Vocabulary. Among the Sino-Korean words, which make up more than half of the vocabulary, there are many ordinary as well as learned words. Sino-Korean elements and now also Sino-Japanese ones are the primary resources for new technical terminology. Most Sino-Korean elements are used as nouns or nounlike units in Korean, regardless of their original part of speech. They can be made into verbs or adjectives by adding certain stems that mean "to do," "to be," "to become." This device is also a productive one for native Korean nouns.

BIBLIOGRAPHY. The McCune-Reischauer system of transcription used in this article is the one most widely used; it is described in detail in G.M. MCCUNE and E.O. REISCHAUER, "The Romanization of the Korean Language," ***Trans. Korea Brch R. Asiat. Soc.***, vol. 29 (1939), and in an abbreviated account in ***ibid.***, vol. 38 (1961). For the history and development of the Korean alphabet, see the English resumé in KI-MOON LEE, ***Kugo P'yogippop ui Yoksajok Yon'gu*** (1963). For Chinese characters in Korea, see HYONG-GYU KIM, "Chinese Characters and Korean Language," ***Korea Journal***, vol. 3 (1963). The introductory chapter, "A Short History of Korean Literature," in DOO SOO SUH, ***Korean Literary Reader*** (1965), points out relations between Korean writing systems and literature. Surveys and bibliographies of studies in Korean linguistics are found in FRED LUKOFF, "The Republic of Korea," in THOMAS A. SEBEOK (ed.) ***Current Trends in Linguistics***, vol. 2 (1967), and in KI-MOON LEE, "Linguistics," in SUNG-NYONG LEE (ed.), ***Korean Studies Today*** (1970). The basic western work in the field of Korean grammar, and one which has provided much of the inspiration and direction for studies in Korean historical and comparative linguistics, is G.J. RAMSTEDT, "A Korean Grammar," ***Mémoires de la Société Finno-Ougrienne***, vol. 82 (1939). SAMUEL E. MARTIN, ***Korean Morphophonemics*** (1954), is the most comprehensive technical description of sound alternations in Korean phonology. There is no general grammatical description of Korean in English available as yet. A.A. KHOLODOVICH, ***Ocherk grammatiki koreiskogo iazyka*** (1954), presents a description in Russian of modern Korean phonology, morphology, and syntax. RENE DUPONT and JOSEPH MILLOT, ***Gramnzaire core'ene*** (1965), assumes some familiarity with Korean writing and phonology on the part of the student but serves as a good reference work for modern Korean morphological forms and syntax, illustrated by many example sentences. BRUNO LEWIN, ***Morphologie des koreanischen Verbs*** (1970), contains a concise description of Korean verb forms and an alphabetically arranged list of the endings, with example sentences. The following textbooks constitute complete courses in the elementary spoken language and include explanations of phonology and grammar: FRED LUKOFF, ***Spoken Korean***, 2 vol. (1945–47); CHANG HAI PARK, ***An Intensive Course in Korean***, 2 vol. (1961–65); B. NAM PARK, ***Korean Basic Course***, 2 vol. (1968–69); SAMUEL E. MARTIN and YOUNG SOOK C. LEE, ***Beginning Korean*** (1969). The method of writing and reading ***Han'gul*** is explained and illustrated in the first chapter of ANTHONY V. VANDESANDE and FRANCIS Y.T. PARK, ***Myongdo's Korean '68***, pt. 1 and 2 (1967). A comprehensive dictionary of the spoken and written language compiled for western students of Korean is SAMUEL E. MARTIN, YANG HA LEE, and SUNG UN CHANG, ***A Korean-English Dictionary*** (1967), with the entries in *Han'gŭl* and their pronunciations recorded in transcription.

(F.L.)

Korean Religion

The religions of Korea have developed from native folk traditions as well as from sophisticated religions introduced from abroad.

Nature and types of religion in Korea. ***Folk traditions.*** Though the original residents of the Korean peninsula have not yet been definitely identified, their linguistic and religious trends share many characteristics with the southern Tungus branch of the Altaic-speaking peoples of northern Asia. Their primeval thought form was shamanistic, a belief system centring on the occult, psychic transformation and healing powers believed to be possessed by a particular religious personage called a shaman. According to shamanism, curses on hair, nails, or any parts of the body can doom the whole of the victim; and dreams and omens are viewed not only as signs but also as the causes of happenings. Such practices in shamanism point to the fact that these folk traditions had not yet developed a concept of the whole, which is differentiated into and counterposed with its component parts. (The concept of the whole is a philosophical view that enables a systematic structure—*e.g.*, social or religious—to be built.) They held to a system of appendages, as in the parts of the body, that allowed for a syncretism that was rich in vitality and affluency. Thus, shamanism has withstood the assault of historical changes and preserved many quaint customs of the folk culture.

Shamanistic characteristics

The great religious traditions. The structure of the sophisticated religious traditions in Korea, in comparison with the simplicity of the folk traditions, usually has had a dichotomized form. In the matter of truth and falsity, for example, Confucianism accepts truth as true and falsity as false, whereas Buddhism considers that neither truth nor falsity is a valid criterion for judgment. Taoism, however, claims that truth cannot exist without falsity and that they are two phases of one reality. Western Christianity, by placing its faith in Christ, the God-man or the Creator-creature, accepts paradox as the ultimate form of truth. Such types of religion, out of a dichotomized framework of reference, tend either to negate the existing social structure or, by affirming the status quo, to become the state religion.

History of religion in Korea. ***Prehistoric northeast Asian religion and early Korean primitive religion.*** Recent archaeological findings in the Kongju area in east central South Korea show clear evidence of human occupation of the Korean peninsula over 35,000 years ago.

Shaman in a séance, painting by Shin Yun-bok (1758–1820). In the Hyung-pil Collection, Chun Museum, Seoul.

From the 3rd millennium BC to historical time, Altaic people of northeast Asia moved into the peninsula and became the dominant ethnic group. Among the religious remains of the period are simple dolmens (prehistoric stone monuments), which are common in northeast Asia, though usually absent in China proper. By the 2nd millennium BC, a new wave of Tungus migrated into the country. Like other Altaics, their foundation myth asserted their shaman-king, such as Tangun, as the descendant of Heaven. The god of heaven—as one of three gods (*sam* sin), the other two being the god of earth and the god of ancestors, believed to be more important than the numerous other gods—was worshipped more than any other god. Tangun, a great shaman and the mythical founder of Korea in 2333 BC, established worship of the god of heaven, according to tradition, at a great altar located near Seoul. The Tungus revered the earth in a fertility cult incorporating a ritual pole with a symbolic goose on top. All impressive natural phenomena were accepted as either deities or the works of deities. The shaman propitiated the malice of evil spirits and invoked the protection of the benevolent ones. This form of faith remains strong among some Koreans in the 20th century.

Religion in the Three Kingdoms period

The spread of Chinese religions and Buddhism to Korea. The established religions of China began to penetrate into Korea during the period of the Three Kingdoms (*c.* AD 57–668): The Koguryŏ kingdom in the north, the Paekche kingdom in the southwest, and the Silla kingdom in all of Korea after 668. To match the formation of complex bureaucratic hierarchies, tribal worship and shamanism were supplemented by a sophisticated state cult, usually a blend of Buddhism, Taoism, and Confucianism, that flourished in both China and Korea during the Six Dynasties period of China (AD 222–589). Buddhism was officially accepted at the courts of Koguryŏ in 372, of Paekche in 384, and of Silla in 528. Under King Chinhŭng of Silla (540–576), the traditional drills of the younger members of the nobility, centring on mystical experience in the native cult, military skills, and comradeship for national leaders—called Hwarangdo, the chivalry of Silla—were fused with a messianic faith in Maitreya (the bodhisattva, or "buddha-to-be"). This fusion of a chivalric code and a messianic faith generated an unprecedented zeal to transform Korea into the Buddha land of the world and established the impetus for unification of Korea under Silla.

Under unified Silla (668–935) important Buddhist monks often went to study the *dharma* (Sanskrit: "law") and the many and various Buddhist scriptures in China and sometimes travelled on to India, the land of Buddhism's origin. On returning to Korea, these pilgrims brought back knowledge of various sects then popular in China. The monk Uisang, in 669, brought back many Buddhist scriptures and relics and established the Hwaom (Avatamsaka) sect. Wonhyo, perhaps the greatest monk, strove for a unified outlook in Buddhism and established the Pobsong (*dharmatā*) sect. The Hwaom and Pobsong sects were the most influential of the o-gyo, the "five doctrinal sects" that placed their emphases on the Buddhist scriptures, the other three being the Yolban (based on the *Nirvāṇa-sūtra*) sect established by Poduk, the Kyeyul (based on the *Vinaya Piṭaka*) sect founded by Chajang, and the Pobsang (based on the *dharma-lakṣaṇa*) sect of Chinpo. After becoming a court religion, Buddhism followed a form of geomancy (divination by means of line or landscape conformations) called p'ungsuchirisol (theory of wind, water, and earth) from Taoism in order to select temple sites vital for the national safety. Pulguk-sa and Sokkuram grotto on a high ridge near Kyŏngju, with a commanding view of the Eastern Sea, apparently were intended to protect the country from Japanese marauders. Another task of the period was to make Buddhism popular among the masses. Wonhyo tore down the barrier between the secular and the sacred, asserting that all creatures had inherent and eventual buddhahood; their differences, he proclaimed, were matters of degree in cultivation. All were entitled to the richer promise of worldly rewards and greater hope for coming Nirvāṇa (the state of bliss in which there would be an extinction of suffering).

The zenith and decline of Buddhism

In the Koryd dynastic period (935–1392), Buddhism, though it had been adulterated by Taoistic geomancy and the Yin-Yang theory of opposites (in which earthly and heavenly cosmic forces were seen in various forms of relationship and opposition), was at its height both at the court and among the people. Many temples were built with funds from the national treasury, and monks assumed significant social positions, so much so that in 1197 seven sons of the King became monks. By the 13th century, however, the political frustration under Mongol domination was sublimated in religious devotion; 81,137 blocks of the Korean Tripiṭaka were carved in the exile capital at Kanghwa island, completed in 1251 after 16 years of work, in an effort to win back Buddha's protection against the invaders. The corruption of the Buddhist monks in positions of influence—gained as a result of royal favour—however, brought about outcries of resentment, and, after the advent of the Yi dynasty in 1392, official sponsorship of Buddhism was removed, King Sejong in the 16th century eliminated all but 36 Buddhist temples and merged the existing sects into two group-: Gyo (or Kyo; a doctrinal sect) and the Sŏn (Zen); *i.e.*, Buddhist intuitive meditative sects. Official disfavour and even persecution brought Buddhism to a low state. In its struggle to exist, it often combined with the folk belief maintained in Taoism and shamanism, thus losing its distinctive intellectual characteristics. Yi Sŏng-gye, the founder of the Yi dynasty, had adopted Confucianism as the state religion and recruited government officers through examinations based on the Confucian Classics. During the 16th century, Neo-Confucianism, a reinterpretation of Confucianism based on the views of its founder, Chu Hsi, a Chinese scholar, rose to a position of great significance, encouraging the rise of many Confucian philosophers and scholars. Neo-Confucianism became the only acceptable interpretation of the Confucian Classics, and its teachings were propagated through a school system (Sung Gyun Kwang) ranging from the elementary to the university level. The schools often maintained their own shrines for worship of Confucius and his 72 disciples.

Western influence and the development of native religious movements. In 1592, when the Japanese under Hideyoshi invaded Korea, a Jesuit priest, Gregorio de Cespedes, came with them. His stay was very brief, however, and his influence negligible. By the 17th century, Nestorianism, an Eastern Christian doctrinal view considered heretical by the Western and Eastern Orthodox churches, had come to China and extended its influence even to Korea. Though Korean embassies to Peking often met with Roman Catholic missionaries during this period, it was not until the middle of the 18th century that some Korean tribute envoys visited a Roman Catholic church in Peking and inquired about Christianity and the new sciences. The leading Confucianists of the time, such as Lee Su-kwang and Chong Yak-yong, were attracted by the new science and high ethics of Christianity and initiated a new movement, the "School of Practical Learning," as a means of making up for the now barren Neo-Confucianism of Chu Hsi. A number of discontented lower officers embraced Roman Catholicism and organized a native congregation that invited Chinese and then French missionaries to celebrate mass and to hear confession. The Confucianists in power looked upon Christianity as subversive because it refused to offer cultic service to the ancestors; in 1791 two Christians, Yun Chi-chung and Kwan Sang-yon, were executed on these charges. In 1801 a petition to the Vatican from the Korean church for the dispatch of Western troops to open up missions in Korea was intercepted, and a series of persecutions forced Catholicism underground until 1866. In that same year (1866) Robert Thomas became the first Protestant martyr in Korea. With the establishment of diplomatic relations between Korea and the United States in 1882, U.S. Protestant missionaries gained a free access to Korea. Soon after the Japanese gained control of Korea after defeating Russia in 1905, a religious revival

Arrival of Protestantism and the rise of the new religions swept over the Protestant churches (1907) that strengthened them. Western medicine and education were introduced to the masses. The new education imbued them with a democratic spirit that eventually encouraged them to take an active part in the 1919 revolution. By 1907 there were already 989 Protestant churches and about 70,000 followers. Three years later Japan annexed Korea as part of its empire.

Before the Japanese annexation, an indigenous religious movement that was anti-Western and anti-Roman Catholic — Tonghak (Eastern Learning) — arose. Founded in 1860 by Ch'oe Che-u, who was executed four years later, it emphasized social action and the principle that God and man are one. Tonghak, a syncretism of Taoism, Confucianism, and Buddhism, caused a revolt in 1894 that precipitated the Sino-Japanese War; in 1905 it was renamed Ch'ŏndogyo, or the religion of the heavenly way.

Japanese influence and recent developments in Korean religion. During the period that Korea was under Japanese suzerainty (1910–45), the Japanese used religion as a means to further colonial policy. They first united the Buddhist Gyo and Sdn groups into one Cho-ke-jong in 1911 and bound the various denominations of Christianity into one Reformed Congregation of Churches (1942) and forced Christians to join in Shintō (a Japanese religion combining folk traditions and nationalism) worship. Nearly 1,000 Shintō shrines were erected by the Japanese, but Shinto gained very little support. These modifications in religious organizations and worship disappeared as soon as the nation obtained independence in 1945, after the defeat of Japan in World War II.

During the Japanese occupation, various sectarian movements arose, many of them similar to Ch'ŏndogyo. After the war, more than 170 new religious sects emerged; they were syncretistic, messianic (looking for a saviour and hoping to establish a kingdom of heaven on earth), and shamanistic. Appealing to the masses with their claims of healing and prophetic powers, they demonstrated a potential for social and political power. Among the Christian, Buddhist, and Confucian religions, however, schisms have lessened their effectiveness for social reform. Under the impact of the 1960 student revolution, however, a new wave of social concern has become evident in Christianity and the other religions.

Sources of religious traditions. *Religious texts.* Very few shamanistic texts exist. Early in the 20th century some of the chants used by shamans were collected by Japanese and Korean scholars. The Buddhist *Tripifaka Koreana,* a monumental collection of texts from the Koryd period, together with 4,745 carved blocks of the Silla period, are preserved in the Haein–sa.

Korea did not have its own collections of Taoist writings. Korean Taoists, however, usually used Ko Hung's *Pao-p'u-tzu,* as references. The Confucian scholar Lee Hwang's "Anthology on the Nature of Principle" is a representative collection that included Neo-Confucian works up to the 17th century.

Foundation myths

Mythological texts and traditions. The earliest foundation myth, as recorded in the 12th century, *Samguk sagi,* by the Confucian scholar Kim Pu-sik, states that Hwanin, a divine being, and his son Hwanung descended to earth, intending "to benefit humanity to the broadest extent." He ruled the earth with three minor spirits (wind, cloud, and rain) and 360 subordinate deities in charge of the daily life. During his rule, a bear and a tiger petitioned him to convert them into damsels. Hwanung prescribed a magical herb to be consumed while they were hibernating in a cave for 40 days. Only the bear persisted and became thus a woman. She conceived under a sandalwood tree a son called Tangun, or prince of sandalwood tree, the founder of Korea, who ruled over the tribes of Dragon, Horse, Deer, Crane, Eagle, and Egret and mediated to them the things of heaven.

Another group of foundation myths is concerned with oviparous (external egg) origins. The Silla dynasty claimed that their progenitor, King Bul-ku-nae, was hatched out of an egg left by a celestial white horse. This oviparous myth was of Chinese origin, whereas the earlier myth of a divine ancestor was Altaic. The Koryŏ and Yi dynasties did not fabricate any new foundation myths of their own. The Tangun myth has gained in popularity through the centuries and has become the accepted myth of the country.

Common characteristics and unique features of Korean religion. *Beliefs and doctrines.* Because all impressive phenomena of life were associated with deities, the pantheon of shamanism included deities of fertility, longevity, the household, the township, luck, protection, pestilence, and many other things and conditions. Sometimes deities from Buddhism, Taoism, and even Christianity were added to the shamanistic pantheon. This was because it was believed that a careless omission of any deity might endanger the fortune of an individual as well as society. Sometimes, according to shamanistic belief, one could be seized by the wandering ghost of a person who had died an unnatural death, and thus propitiation was required to send the ghost off to his next incarnation. In such a world in which spirits were of significance, the overall coherence and intelligibility of life was believed to be regulated by the shamans, who, through their propitiative and preventive offerings, enabled a person to sustain his life. Under such conditions, one's morals had to be diffused to meet the requirements of the various deities. Confucianism in Korea from the Koryŏ period on depended heavily on Chu Hsi's Neo-Confucianism. First, Chu Hsi supplemented aphoristic Confucian teachings with a metaphysical foundation borrowed from the *I Ching* ("Classic of Changes"), as well as Taoistic teaching on the Ultimate, or T'ai Chi, made up of the Yin and Yang complex. It was supposed to have permeated profusely all existences.

The Neo-Confucianism of Chu Hsi

Second, Chu Hsi developed a theory that the mind is the cosmic principle in a miniaturized form. Because everyone projects his psychological state to his family activities, social involvement, national welfare, and even to the boundless cosmos, one should attempt to make his nature good by means of gaining the harmony of and equilibrium between any two opposing yet complementary forces, *i.e.*, the Yin and the Yang; the sway of passion to either extreme would cause a person to be deprived.

Third, Chu Hsi believed his teaching could be preserved and carried on through instruction in the five Confucian Classics: *Shih Ching* ("Classic of Poetry"), *Shu Ching* ("Classic of History"), I *Ching* ("Classic of Changes"), *Ch'un Ch'iu* ("Spring and Autumn Annals"), and *Li chi* ("Collection of Rituals"). Finally, emphasis was placed on putting Confucian teachings into social action. Many cooperative ventures, for example, were set up to experiment with Confucian concepts of social propriety (*jen*) between man and man.

Korean Confucianists of the Yi dynasty appropriated Neo-Confucianism and tried to solve their crucial philosophical problems. Li Hwang extended the ethical implications of *jen* to include all-out involvement, reverence, and mindfulness. Neo-Confucianism was thus able to clarify the frequent misunderstanding of its moralistic formalism. Another scholar, Li Yi, refined the anthropological concepts of Neo-Confucianism. Chu Hsi had accepted the dichotomy of man as composed of a rational soul and bodily feeling. The vague term mind was used to connect the two. Li Yi resolved the soul–body relation as follows:

> Principle is principle; Existence is existence
> One at the same time two, but not two
> two at the same time one, but not one
> without change
> without division
> without separation
> without confusion

His achievement laid the Neo-Confucianist keystone, which was parallel to the doctrinal formulations of Western Christology (nature of Christ) at the Council of Chalcedon (AD 451) that were embodied in the Athanasian Creed saying:

Our Lord, Jesus Christ

Complete in Godhead	Complete in Manhood
truly god	truly man
One substance with Father	One substance with us

> One person two natures, not two persons
> distinction is not annulled by union
> without confusion
> without change
> without division
> without separation

In China, Taoism — like shamanism in Korea — was an inclusive receptacle that assimilated other religions and cultural elements. After the Silla dynasty, Taoism was accepted at the court in Korea together with Confucianism and Buddhism as an essential component of organized religion, "one leg of the religious tripod." It became the courtly religion for national safety. At the mass level its teachings and functions were assimilated by and almost superseded by native shamanism. Philosophical Taoism, under strong influences of Confucianism, assumed Zen Buddhistic form. Its teaching on naturalness through non-action helped to eliminate various artificial attempts for enlightenment.

The teachings of Wonhyo

When Buddhism reached Korea, it attempted to win over a people long imbued with shamanism. The various sects of Mahāyāna Buddhism of the north and south dynasties were successful in filling the needs and curiosities of the diverse religious groups of the Three Kingdom period. When Silla intended to unify Korea, Wonhyo propounded a teaching that attempted to harmonize the doctrinal trends of the period. He taught that, somewhat similar to fire on ice, the flame of all mundane desires would melt the frozen buddhahood, thus quenching reflexively man's drive for desire. All teachings, Wonhyo also believed, were not contradictory but complementary to each other, making up one whole truth. Likewise, all men are made of the same buddha nature. The distinction of the sacred from the secular was a matter of difference only in degree. Wonhyo's urging for the equality of all mankind overcame the current insistence on social rank determined by birth, or "bone ranks": unity of all men became the social goal of the time. It offered a religious ground for the long-awaited political unity of Korea.

The Zen Buddhist schools, however, reinterpreted primitive Buddhism by means of Taoist argumentative techniques. By means of neither/nor, or double negation, all complementary items or actions were denied of their validity.

> The things taught by the Tathāgata are, in their essential nature, neither conceivable nor scrutable neither existent nor non-existent neither phenomena nor non-phenomena" (Diamond *Sūtra*).

The above *sūtra* (aphoristic saying) means that neither I, the subject, nor its complement, the world, really exist; *e.g.,* neither the secular nor the sacred have real existence. The double negation, the Zen schools believed, would release man from self-made perplexity and unveil to him the essential nature "as is" (*tathāgata*).

Ritual practices and institutions. Korean shamans have been sensitive to aesthetic tastes; this has enabled them to refine the coarser aspects of the old Tungus culture and to contribute to various spheres of folk culture. In various stages of seances the shaman changed his cloak and magical tools. His five-colour rainbow topcoat became a standard of Korean fashion. The shaman's fan dances and sword dances established basic patterns for Korean dancers. Many of their chantings, both the delicate and the more powerful, became the bases of popular ballads.

Shamans usually did not stand above the people but rather with the people as attentive leaders and counsellors who often were not without humour. From time to time, however, they could indulge in greed for power and gains through sorcery. For these reasons they were suppressed by various dynasties, especially under the Confucian kings of the Yi dynasty.

Cultic practices were occasioned by calendric celebrations as well as by calamities, such as pestilence, famine, drought, or other misfortunes. The procedures in the cultic séances of shamans included purification through incantation, invocation, praise, presentation of the case, the spirits' response, entertainment with song and dance, and the parting. The ordinary comings and goings of daily life were reflected in the worship procedures. This may be the reason why, in parting, some gifts are given to the spirits for their trip back to the other world.

Buddhism, Taoism, and Confucianism, as institutional religions, usually had titular heads, appointed by the state, and clerics who had passed qualification examinations on their canonical writings. The birthday of the founder was celebrated — for Buddha, with offerings, chanting, and lanterns in commemoration of his enlightenment; and for Confucius, with music for cosmic harmony and a courtly offering to supplicate the deceased founder. In passage rites (*e.g.,* at birth or death), Buddhists offered for people in general a propitiatory incantation for a better reincarnation; for the Buddhist devotee, the rituals were performed for the purpose of aiding one to enter Nirvana. Confucians usually presented seasonal offerings to the deceased parents, but these were not, strictly speaking, worship services but rather extensions of this-worldly filiality to be deceased. Because of this custom, the worst curse for traditional Confucianists and those influenced by Confucianism is not to be "damned to hell" but to "die without descendant," so that the deceased has to suffer eternal thirst and hunger without offerings.

Ch'ŏndo-gyo and Tajong-gyo

Contemporary forms of indigenous Korean religions. The contemporary forms of the many indigenous Korean religions are well represented by Ch'ŏndogyo and Tajong-gyo. Followers of Ch'bndogyo chant the formula given by its founder, Ch'oe Che-u: "As one waits on the Lord in Heaven, all creatures would find peace." To them, the human heart in its original nature, as taught by Neo-Confucianists, was the perfect image of heaven. In that blissful state, the cosmic order was in peace. The mind, in gaining the original state, calls forth a desire to reform this disorderly earth into a heaven. A bowl of clear water is placed on an altar to reflect heaven to the bowing worshipper, and a spoonful of rice is set aside daily to be used for making firm the heaven on earth. Their social concerns often plunged the sect into armed rebellions against the government and caused them to participate in the 1919 revolution against Japanese suppression.

Tajong-gyo, or the Tangun cult, was formulated by Na Chul. It worships the Lord, the Light, or the Progenitor of the Heaven. The triune deity consists of Great Wisdom, Power, and Virtue, which is parallel to the mind, body, and breath of humanity. The union and harmony of the Heavenly Trinity with the trinity of humanity, they believe, will generate a redemptive power that will renew humanity and reform society. The trichotomy of man, his universe, and its pursuit of ultimate harmony in terms of Yin-Yang theory were derived mainly from Neo-Confucianism. The cult shifted the Confucian emphasis on the present to the future and is optimistic about the coming millennium that will change this chaotic world.

Korean religious symbolism. Korean shamanism has had very few symbols for a deity or for use in worship. A pair of upright figures at the entrance to a town represent the General of the Heaven and Guardian of the Earth. Most of the shamanistic symbols depict the often negative presences of the invisible ones (ghosts and spirits): tridents have been used to threaten off the plague ghost; and fans were swung to blow away, or attract, hidden spirits.

Koreans shared with other Asian Buddhists the symbols and iconographic elements—*e.g.,* images, lanterns, and pagoda — that depicted various themes about the Buddha, who, being enlightened, came to rest in Nirvāṇa. Developed out of such common characteristics, Paekche sculptures (4th–7th centuries) had a distinct style in which length was exaggerated over width, somewhat like the Spanish artist El Greco's figures or sculptures on western European medieval columns. They reflected the high religiosity of the period. The Zens channelled their creativity into paintings. To them, the expression of the movement or force seen in the object was more important than the objects themselves. The moment of the enlightenment of Bodhidarma, the founder of Zen (or

Ch'an, as it was called in China), was usually depicted with the saint having the glaring eyes of a trance state, having lost consciousness of self and the world. For Confucianists, any part of the body, because it is received from the parents by birth, is sacred. A devotion to the body directed them to be realistic in painting. Because the human heart was assumed to be the counterpart of the Ultimate of the cosmos, "the heart in the middle of the chest" became a constant reference point in ethics. "Put your hand on the chest" meant to swear by the undeceitful and unswaying part of the self.

Symbolism in Confucianism and Taoism

Taoism especially was the Oriental religion that set trends for the arts. The artist must grasp the primal unity that is to be fused with the painting. He should "see without looking" in order to catch the flow of the movement rather than the appearance of the object. Thus, the artist should feel the spirit in its natural state. In landscape painting, he should lead the viewers to the mountain, which melts into a mist and the mist into nothing—"formlessly fashioned, that exists before heaven and earth, without sound, without substance, depending on nothing." The mystical void beyond, according to this view, joins the artist and the viewer in an unnegotiated oneness.

Religion in contemporary Korea. After Japanese control was ended in 1945, the area of Korea north of the 38th parallel came under Communist domination, and freedom of religion was suppressed. In South Korea freedom of religion was guaranteed by the constitution, and a great revival of religions occurred. In the late 1960s there were nearly 7,500 Protestant churches with over 900,000 members; Roman Catholics listed over 1,150 churches and nearly 790,000 members. Also, in the late 1960s, there were over 2,700 Buddhist temples with nearly 940,000 adherents. The Christian churches, having come from the West, have been attempting to accommodate themselves to Korean traditions, but the Buddhists, having absorbed much of native folk traditions, have been attempting to regain their peculiarly Buddhist teachings and practices, as well as reforming the organizational structures of their sects.

Confucianism, in the early 1960s, maintained over 230 *hyanggyos,* or schools, and listed over 170,000 adherents. Though as a dominant cult Confucianism is on the decline, it still provides the moral foundation for Korean society. The new religions of Korea, noted earlier, have appealed to those on the lower levels of Korean society and claim the allegiance of millions. The folk religions imbued with shamanism continue to dominate the lives of millions.

BIBLIOGRAPHY. Most of the important works on this subject are written in Korean and have not been translated into English. These include HYUN SANG YUN, *Chosen Yuhak Sa* (1960), a history of Korean Confucianism; KIM TUK WHANG, *Hanguk Chongkyo Sa* (1963), a general history of religions in Korea; LEE NUNG WHA, *Chosen Bulkyo Tongsa* (1968), a history of Korean Buddhism; *Chosen Musokko* (1927), a study of Korean shamanism; and *Hanguk Dokyo Sa* (1959), a history of Taoism in Korea; YU HONG LYOL, *Hankuk Chonju Kyohoe-sa* (1962), a history of the Catholic Church in Korea; and YU TONG SIK, *Hankuk Jongkyo Wa Kitokkyo* (1965), on the Korean religions and Christianity. KoSciuszko, Tadeusz

A Polish Army officer and statesman, Tadeusz Kościuszko gained fame both for his role in the U.S. War of Independence and for his leadership of the national insurrection in his homeland.

Participation in U.S. War of Independence

Tadeusz Andrzej Bonawentura KoSciuszko was born on February 4, 1746, in Mereczowszczyzna in the Kingdom of Poland (now in the Belorussian Soviet Socialist Republic) to a family of noble origin. He was educated at the Piarist college in Lubieszów and the military academy in Warsaw, where he later served as an instructor. Kościuszko's outstanding abilities soon attracted the attention of King Stanisław II Augustus Poniatowski, who sent him to Paris for further study in military and civil architecture and in painting. Returning home in 1774, he taught drawing and mathematics to the daughters of a Cossack leader, Józef Sosnowski; he fell in love with Ludwika, one of the daughters, and tried unsuccessfully to elope with her. Facing the wrath of her father, he fled to France, and in 1776 he went to America where he joined the colonial forces fighting for independence from the British. That August he was transferred to the Pennsylvania Committee of Defense in Philadelphia, where he took part in planning fortifications to defend the residence of the Continental Congress against the British. For this work he was given the rank of engineer colonel. In spring 1777, he was assigned to the army of Gen. Horatio Gates at Ft. Ticonderoga, in northern New York. Beginning in July he became active in Gates's army, closing by fortifications all roads along the Hudson River and thus contributing to the capitulation of the British army under Gen. John Burgoyne at Saratoga on October 17. He spent the next two years fortifying West Point, New York, where in March 1780 he was appointed chief of the engineering corps. That summer, serving under Gen. Nathanael Greene in North Carolina, he twice rescued the army from enemy advances by directing the crossing of the Yadkin and Dan rivers. In the spring of 1781 in South Carolina he conducted the Battle of Ninety-six and then a lengthy blockade of Charlestown. At the end of the war he was given U.S. citizenship and was made a brigadier general in the U.S. Army.

Kościuszko, lithograph by C. Motte, 1828.

In 1784 he returned to Poland. Because of his association with the radical Czartoryski family, then in opposition to the King, he could not secure an appointment in the Polish Army. For five years he lived in poverty on a small country estate, in debt, moreover, because of his exceptional deed of freeing his serfs from part of their villein service. With the advent of liberal reforms in Poland, in 1789 he returned to military service. Under the protection of his former love, Ludwika, now the wife of Prince Lubomirski, and with the support of local nobility, on October 12 he was granted the rank of general major. At that time the 44-year-old general fell in love with an 18-year-old girl of noble birth, but again he was unable to win the father's permission for marriage.

In 1792 the Russian Army of the empress Catherine II the Great invaded Poland to end Polish internal reforms designed to liberate the nation from the Russian influence. In the ensuing war Kościuszko rose to fame as a division commander during the bloody Battle of Dubienka

(July 18). For this he was raised to the rank of general lieutenant by the king Stanislaw II Augustus Poniatowski, and the new Revolutionary government in Paris granted him honorary French citizenship. But, when the Polish king, fearing defeat, defected from the liberal cause, Kościuszko prepared to resume fighting. In Russian-occupied Poland, however, the reactionary party assumed power, forcing liberal statesmen into exile in Saxony. Kościuszko, against the King's wishes, gave up his commission and joined the exiles.

From Saxony, in January 1793, he was delegated to Paris to seek support for the Polish cause, first from the Girondists and then the Jacobins, pledging in return radical internal reforms in Poland and military diversion against Prussia and Austria, then at war with Revolutionary France. When he returned to Saxony in August, he faced new demands for starting an uprising in Poland in view of favourable indications there. Kościuszko agreed to command the national forces and went secretly to a place near Cracow (Krakow); but, finding preparations inadequate, he delayed the uprising and then went abroad again. His decision proved unwise because time allowed the enemy to undermine the conspiracy through widespread arrests and reduction of the army. Those left in the underground started the uprising on March 12, 1794. On their request Koiciuszko arrived in Cracow on March 24 and, amid an enormous assembly of people, solemnly swore an act of national uprising against all three occupying powers—Russia, Prussia, and Austria. Undertaking all political responsibility and military leadership, he set up an insurgent administration and military force. To do so he had to compensate for the quality of the enemy army with the quantity of his own. Therefore, he introduced conscription to military service, enlarged existing units by incorporating recruits into them, and developed new formations. Having no war industry, his forces could not be equipped with conventional firearms; hence, he armed his peasant recruits with pikes and traditional war scythes.

Leadership of the Polish uprising

After a smashing victory at Racławice (April 4), won by the scythe-bearing formations under his personal command, special new battle tactics were developed based on columns of men attacking on the run and backed by artillery fire. To win more army volunteers ,from the peasant masses, he issued the Manifesto of Polaniec, on May 7, suspending serfdom and reducing in half the existing villein service. This met with some resistance of the nobility. Defeats forced Kościuszko to retreat to his last stronghold, Warsaw. The defense of this city, besieged by Prussian and Russian armies for about two months, remains Koiciuszko's greatest military success, both as strategist and engineer. He managed to use the city population to build earthworks and to defend the city alongside the regular army. In critical moments he himself led the charge with fixed bayonets. Next, he stirred up an uprising in the occupied province of Wielkopolska, at the rear of the besieging armies, forcing the Prussian king Frederick William 11 to retreat. But Russian reinforcements retaliated quickly. Koiciuszko was unable to concentrate adequate forces in time, and he suffered his greatest defeat at Maciejowice, where he was wounded and taken prisoner. Without its leader, the uprising collapsed, and the Third Partition of Poland ended the existence of the country.

Koiciuszko, imprisoned in the Peter-Paul Fortress in St. Petersburg, was slowly returning to health when, upon the death of Empress Catherine II, her son, the emperor Paul I, granted him freedom in 1796. Despite a crippling illness, Kościuszko returned to the United States. On August 18, 1797, he arrived in Philadelphia, greeted enthusiastically by the people but held in suspicion by the incumbent Federalists. In the United States he led an active life in social circles and entered into a long-lasting friendship with Thomas Jefferson, who was then vice president; but, after receiving news of fresh possibilities to promote Poland's cause in France, he secretly left the United States on May 5, 1798. Before that he had appropriated some of his estate for setting free his Negro slaves and for educating them.

His return to France was a disappointment. A true republican, he distrusted Napoleon, and he refused to command Polish legions in a fight only for France, promising cooperation only if the liberation of his country would also be involved in the plans.

Hence, Kościuszko retired from public life and took up residence in Berville, near Fontainebleau. In 1806 Napoleon tried to gain Kościuszko's aid in the event of war with Russia. But Kościuszko again demanded political commitments, and Napoleon secured other, more agreeable Polish supporters for his plans. Kościuszko remained in exile when his country was rebuilt as the Grand Duchy of Warsaw (1807). Consequently, after Napoleon's fall in 1814, the Russian emperor Alexander I sought Kościuszko's help in bargaining for Poland's territories. After the Congress of Vienna and the formation of a new Polish realm under Russian rule in 1815, the emperor Alexander was anxious to be on good terms with Kościuszko and to have him return home. Kościuszko, however, again proposed unrealistic conditions, demanding social reforms and boundaries of the country reaching the Dvina and Dnepr rivers. When no answer came, he went to Solothurn, Switzerland, and freed all his serfs in Poland from villein service.

Kościuszko died at Solothurn on October 15, 1817. His remains were carried to Krakow and were buried in 1819 among the kings' tombs in the cathedral. The people, reviving an ancient custom, raised a huge mound to his memory near the city.

Kossuth, Lajos

Kossuth was the mid-19th-century leader who inspired Hungary's struggle for independence from Austria. Though his brief period of power in the revolutionary years of 1848 and 1849 was ended by Russian armies, he remained a world-famous symbol of revolutionary nationalism.

Kossuth, lithograph, 1856.

Kossuth was born at Monok, in northeastern Hungary, on September 19, 1802. His father came of Slovak, his mother of local German stock. The family was noble and of ancient creation but not wealthy, and Kossuth's father earned his living as an attorney for local landowning families. The Kossuths were Lutherans, and young Lajos studied at the Protestant academy of Sárospatak. After applying unsuccessfully for a post in government service, he found employment in his native county of Zemplén as agent to one of his father's clients, Countess Etelka Andrássy, with whom he formed an attachment. He did notable work during the great cholera epidemic of 1831 but found his life narrow and frustrating; he was also suffering, as he would all his life, from financial embarrassment. In 1832 his employer had him sent to the national Diet in Pozsony (now Bratislava) as "substitute delegate" for one of her relatives.

Political journalism

At this "long Diet" the new generation of Hungary's reformers was mounting its first full-scale offensive against the absolutist and obscurantist system under which Hungary was then ruled from Vienna, and in its excited atmosphere Kossuth developed his political and social philosophy. This was one of advanced radicalism. There was no postulate of the European liberalism of the day that he did not burn to see realized in Hungary—no abuse or injustice there left unremedied. But liberty meant for him, above all else, national liberty; and he felt passionately that until Hungary enjoyed de facto the internal freedom to which its laws entitled it, no social or economic progress was possible. The first battle, therefore, must be the political one. Sanguine and impulsive, he was blind to the dangers involved in too strong a challenge to Vienna.

Kossuth's mandate did not entitle him to participate in the Diet's debates, but he found a way of voicing his views. At that time the Diet's proceedings were not published, and Kossuth hit on the idea of issuing letters describing them. These reports, which were not verbatim records but colourful impressions barely distinguishable from political pamphlets, were copied by hand by enthusiastic young helpers and circulated throughout Hungary. Brilliantly written, they were widely and avidly read; and when the Diet ended in 1836, the county assembly of Pest invited him to write a similar series on its proceedings. Now, however, he was no longer protected by parliamentary immunity, and on May 4, 1837, he was arrested and, after 18 months' detention, sentenced to three years' imprisonment for subversion.

Released under an amnesty in 1840, Kossuth found himself a popular hero. The proprietor of a biweekly journal, the *Pesti Hirlap,* made him its editor. His articles were written in a fluent and beguiling style and gained him innumerable devotees at the same time that they alarmed the Austrian authorities, the Hungarian conservatives, and even Hungary's moderate reformers. He also antagonized the Croats and non-Magyars of Hungary by his chauvinistic insistence on the supremacy of its Magyar element. In 1844 his publisher dismissed him and he was refused permission to start a journal of his own. Metternich offered him journalistic employment in the service of the government, but this he refused. His next enterprise, inspired by the writings of the German economist and industrial promoter Friedrich List, was to found a society for promoting Hungarian industry, with the ultimate objective of achieving greater economic independence. This program proved a fiasco but afforded him a platform for continued agitation.

Role in the revolution of 1848

In 1847 the county of Pest elected Kossuth to represent it in the next Diet, in which he assumed leadership of the "national opposition," which had agreed on an extensive program of political and social reform. The reformers made a little progress in subsidiary fields, but deadlock had been reached on the central issue of political control when the news of the revolution in Paris (February 1848) gave Kossuth his opportunity. On March 3, in a speech of extraordinary power—for his tongue was as magical as his pen—he demanded the removal of the dead hand of Viennese absolutism as the only way to safeguard the liberties of Hungary and of all the peoples of the monarchy. He practically dictated to the Diet an address to the crown, embodying the reformers' program. When news of the revolution in Vienna reached the Diet on March 14, Kossuth expanded the address, and, as a member of the deputation that carried it to Vienna the next day, saw it accepted by the panic-stricken court.

Count Lajos Batthyány, the new Hungarian prime minister, allotted Kossuth the portfolio of finance in his government, a choice that proved dangerous, for the ultimate control of finance proved, with that of the defense services, to be precisely the chief bone of contention between Hungary and Vienna. Kossuth was soon at loggerheads with the new Ministry of Finance in Vienna—meanwhile, he had made himself the life and soul of the more extreme nationalist movement in Hungary, often to the embarrassment of his fellow ministers, who were striving to prevent a breach with Vienna. Kossuth often acted without consulting them or even in defiance of agreed decisions, appealing over their heads to the public in a journal edited and mainly written by himself. Yet they dared not dismiss him and could not even dispense with his services, for his nationwide popularity was their greatest asset.

It was Kossuth who, so far as any Hungarian did so, precipitated the final clash by persuading the Diet, in July, to tie the dispatch of Hungarian troops to Italy to political conditions obviously unacceptable to Vienna, at the same time calling for a big national force to defend Hungary against the danger he declared, not without reason, to be threatening it from the Croats and Serbs. When, in September, the Austrian-inspired Croat army invaded Hungary and Batthyány resigned, Kossuth became head of the committee of national defense appointed by the Diet as provisional authority. He was now virtual dictator of Hungary. The next months brought out all of his greatness and his weaknesses: his magnetism and his courage, his intolerance and his lack of realism, his wanton provocation of insuperable difficulties and his genius at overcoming them. No one but Kossuth could have given his people the heart to face the overwhelming odds against them; but he increased those odds by his intransigence and aggravated difficulties by his jealousy and suspicion of his best general, Artúr Görgey, and by his meddling in military affairs. The refusal of the Diet to recognize the abdication of the Austrian emperor Ferdinand I (December 2) was his work, as was the Diet's declaration of April 14, 1849, proclaiming the dethronement of "the perjured House of Habsburg-Lorraine." The Diet then elected Kossuth himself "governor" of Hungary, but when, after the arrival of the Russian armies, even he had to recognize the hopelessness of the situation, he resigned this post to Gorgey (August 11) and took refuge in Turkey.

Kossuth in exile

The Western powers put pressure on the Sultan to refuse Austria's and Russia's demand for his extradition, and Kossuth spent two years interned in Kiitahya in Anatolia. The United States government invited him to visit America and sent a frigate. He stopped in England on the way, where he addressed a series of mass meetings, speaking in English, which he had learned from the Bible and Shakespeare during his confinement. He was received with unprecedented popular ovations, and his reception in the U.S. was equally favourable, but in neither country could he obtain official support for Hungary's cause. He then settled in London. In correspondence with his followers at home, he endeavoured to keep alive in them the spirit of resistance. At the persuasion of the Italian patriot Mazzini, with whom he became intimate, he joined his revolutionary committee. Having moderated his views on the question of nationalities, he discussed with various circles, including the Moldavian and Serbian courts, plans—never to be realized and perhaps never quite realistic—for uniting Hungary, Croatia, Serbia, and Romania in a Danubian federation.

In 1859, when war between Austria and France was imminent, the French emperor Napolen III invited him in a personal interview to organize revolt in Hungary on the outbreak of war. Kossuth agreed, subject to certain safeguards and conditions. Military preparations were concerted with France and Piedmont, and Kossuth's own eloquence helped to deter Britain from intervening against France; but the plans collapsed when, in July, Napoleon concluded an armistice with Francis Joseph 1, leaving the Hungarians to their fate.

The promising international conjuncture never recurred; and in the following years Kossuth, living abroad in Turin, had to watch Hungary, guided by Ferenc Deák, move toward reconciliation with the monarch. He did so with bitterness in his heart and on the eve of the conclusion of the Austro-Hungarian Ausgleich, or Compromise of 1867, published an open letter calling down woe upon the measure and its author. This "Cassandra letter" stirred the opponents of the Compromise but could not prevent its adoption and subsequent maintenance. He spent his last years in loneliness, near-poverty, and increasing infirmity, sadly aware that Hungary's new leaders rejected the tenets to which he remained unalterably attached. He died in Turin on March 20, 1894. His body was brought back to Hungary and interred there amid nationwide mourning.

In 1841 Kossuth had married Terézia Meszlényi, who died in 1863. Their son, Ferenc Kossuth (1841–1914), was for a time president of the Hungarian Party of Independence.

After his death, Kossuth remained a popular idol in Hungary, his name a symbol of the aspiration for independence. His legend grew with the years and was further cultivated after 1945, when Hungary had lost much of the independence for which Kossuth struggled.

BIBLIOGRAPHY. There is no adequate full-length biography of Kossuth in any language. He himself produced one volume in book form, published in English in 1880 as ***Memories*** of My ***Exile.*** It mainly concerns his activities in 1859–61, and contains valuable material on his interviews with Napoleon III, his dealings with the Italian statesman Cavour, and his correspondence with the Balkan courts in connection with his plans for a Danubian federation. There are several collections of Kossuth's articles and speeches, the most recent and most complete being *Összes **Munkai,*** 15 vol. (1948–61). Many articles have been written about Kossuth, including the two-volume *Emlékkönyv* (1952) and the articles listed in the bibliography of *Magyarország **Tortknete,*** 2 vol. (1967).

(C.A.M.)

Kropotkin, Peter

Russian revolutionary and geographer, Peter Kropotkin was, from the late 1870s until his death in 1921, the foremost leader and theorist of the anarchist movement. Although he achieved renown in a number of different fields, ranging from geography and zoology to sociology and history, he shunned material success for the life of a revolutionist. Addressing meetings, founding periodicals, writing books and articles, and spreading the doctrines of his creed, he did more than any other figure to further the libertarian cause in Europe and around the world.

Brown Brothers

Kropotkin.

Kropotkin was born in Moscow on December 9, 1842, the son of Prince Aleksey Petrovich Kropotkin, and was educated in the exclusive Corps of Pages in St. Petersburg (Leningrad). For a year he served as an aide to Tsar Alexander II and, from 1862 to 1867, as an army officer in Siberia, where, apart from his military duties, he studied animal life and engaged in geographical exploration. On the basis of his observations he elaborated a theory of the structural lines of mountain ranges that revised the cartography of eastern Asia. He also contributed to knowledge of the glaciation of Asia and Europe during the Ice Age.

Conversion to anarchism

Kropotkin's findings won him immediate recognition and opened the way to a distinguished scientific career. But in 1871 he refused the secretaryship of the Russian Geographical Society and, renouncing his aristocratic heritage, dedicated his life to the cause of social justice. During his Siberian service he had already begun his conversion to anarchism—the theory that all forms of government should be abolished—and in 1872 a visit to the Swiss watchmakers of the Jura Mountains, whose voluntary associations of mutual support won his admiration, confirmed him in his libertarian beliefs. On his return to Russia he joined a revolutionary group that disseminated propaganda among the workers and peasants of St. Petersburg and Moscow. Caught in a police dragnet, he was imprisoned in 1874 but made a sensational escape two years later, fleeing to western Europe, where his name soon became revered in radical circles. The next few years he spent mostly in Switzerland until he was expelled at the demand of the Russian government after the assassination of Tsar Alexander II by revolutionaries in 1881. He moved to France but was arrested and locked up for three years on trumped-up charges of sedition. Released in 1886, he settled in England, where he remained for the next 30 years, until the Revolution of 1917 allowed him to return to his native country.

During his long exile Kropotkin wrote a series of influential books—the most important were ***Paroles d'un révolté*** ("Words of a Rebel," 1885), ***In Russian and French Prisons*** (1887), ***Fields, Factories and Workshops*** (1899), ***Memoirs of a Revolutionist*** (1899), ***Mutual Aid*** (1902), ***Russian Literature*** (1905), and ***The Great French Revolution** 1789–1793* (1909)—in which he set forth his libertarian philosophy. His aim, as he often remarked, was to put anarchism on a scientific basis. In ***Mutual Aid,*** which is widely regarded as his masterpiece, he argued that, despite the Darwinist concept of the survival of the fittest, cooperation rather than conflict is the chief factor in the evolution of species. Providing abundant examples, he showed that sociability is a dominant feature at every level of the animal world. Among humans, too, he found that mutual aid has been the rule rather than the exception. He traced the evolution of voluntary cooperation from the primitive tribe, peasant village, and medieval commune to a variety of modern associations—trade unions, learned societies, the Red Cross—that have continued to practice mutual support despite the rise of the coercive bureaucratic state. The trend of modern history, he believed, was pointing back toward decentralized, nonpolitical, cooperative societies in which men could develop their creative faculties without interference from rulers, priests, or soldiers.

Kropotkin's "anarchist communism"

In his theory of "anarchist communism," according to which private property and unequal incomes would give place to the free distribution of goods and services, Kropotkin took a major step in the evolution of anarchist economic thought. For the principle of wages he substituted the principle of needs. Each person would be the judge of his own requirements, taking from the common storehouse whatever he deemed necessary, whether or not he contributed a share of the labor. Kropotkin envisioned a society in which men would do both manual and mental work, both in industry and in agriculture. Members of each cooperative community would work from their 20s to their 40s, four or five hours a day sufficing for a comfortable life, and the division of labour would yield to a variety of pleasant jobs, resulting in the sort of integrated, organic existence that had prevailed in the medieval city.

To prepare men for this happier life, Kropotkin pinned his hopes on the education of the young. To achieve an integrated society he called for an "integral education" that would cultivate both mental and manual skills. Due emphasis was to be placed on the humanities and on the basic principles of mathematics and science, but, instead of being taught from books alone, children were to receive an active outdoor education and learn by doing and observing at first hand, a recommendation that has been widely endorsed by modern educational theorists. Drawing on his own experience of prison life, Kropotkin also advocated a thorough modification of the penal system. Prisons, he said, were "schools of crime" that, far from reforming the offender, subjected him to brutalizing punishments and hardened him in his criminal ways. In the future anarchist world, founded on mutual aid, antisocial behaviour would be dealt with not by laws and prisons but by human understanding and the moral pressure of the community.

Kropotkin combined the qualities of a scientist and moralist with those of a revolutionary organizer and propagandist. For all his mild benevolence, he condoned the use of violence in the struggle for freedom and equality, and during his early years as an anarchist militant he was among the most vigorous exponents of "propaganda by the deed"—acts of insurrection to supplement oral and written propaganda to awaken the rebellious instincts of the people. He was the principal founder of both the English and Russian anarchist movements and exerted a strong influence on the movements in France, Belgium, and Switzerland. But he alienated many of his comrades by supporting the Allied powers during World War I. His action, though prompted by the fear that German authoritarianism might prove fatal to social progress, violated the antimilitarist tradition and touched off bitter polemics that nearly destroyed the movement for which he had laboured nearly half a century.

Return to Russia

Events, however, took a brighter turn with the outbreak of the Russian Revolution. Kropotkin, now in his 75th year, hastened to return to his homeland. When he arrived in Petrograd (now Leningrad) in June 1917, after 40 years in exile, he was greeted warmly and was offered the post of minister of education in the provisional government, which he brusquely declined. Yet his hopes for a libertarian future were never brighter, for 1917 saw the spontaneous appearance of communes and soviets—soldiers' and workers' councils—that he felt might form the basis of a stateless society. With the Bolshevik seizure of power, however, his enthusiasm turned to bitter disappointment. "This buries the revolution," he remarked to a friend. The Bolsheviks, he said, have shown how the revolution was *not* to be made—that is, by authoritarian rather than libertarian methods. His last years were devoted chiefly to a history of ethics, which he was never to finish. He died at the village of Dmitrov near Moscow on February 8, 1921. His funeral, attended by tens of thousands of admirers, was the last occasion when the black flag of anarchism was paraded through the Russian capital.

Kropotkin's life exemplified the high ethical standard and the combination of mental with manual work that he preached throughout his writings. He displayed none of the egotism, duplicity, or lust for power that marred the image of so many other revolutionaries. Because of this he was admired not only by his own comrades but by many for whom the label of anarchist meant little more than the dagger and the bomb. The French writer Romain Rolland said that Kropotkin lived what Tolstoy only advocated, and Oscar Wilde called him one of the two really happy men he had known.

BIBLIOGRAPHY. For Kropotkin's life, see his classic autobiography, ***Memoirs of a Revolutionist*** (1899). The best biography in English is ***The Anarchist Prince*** by GEORGE WOODCOCK and IVAN AVAKUMOVIC (1950). For Kropotkin's place in the Russian anarchist movement, see PAUL AVRICH, ***The Russian Anarchists (1967).***

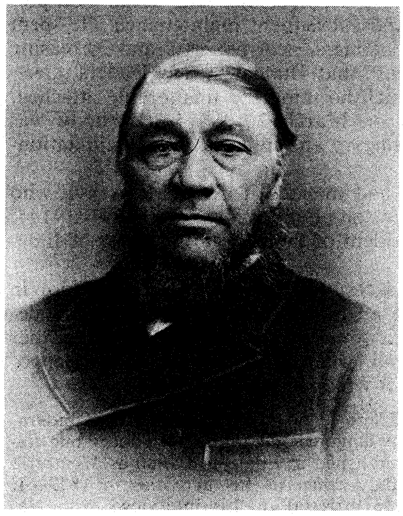
Kruger, Paul

Farmer, soldier, and statesman, Stephanus Johannes Paulus (Paul) Kruger, during the last quarter of the 19th century, made his mark in South African history as the builder of the Afrikaner nation. He became famous as the defender of the independence of the Transvaal, or South African Republic, during the period when British imperialism in Africa was at its zenith.

Culver Pictures



Kruger.

Kruger was born in the Cradock district of the British Cape Colony on October 10, 1825. His parents were respectable farmers of Dutch descent on the northern outskirts of the colony. He had little formal education but was able to express himself clearly in writing. Of more importance was the religious instruction he received from his parents according to the strict tenets of Dutch Calvinism. When he was ten, his family took part in the general emigration of frontier farmers who sought to found an independent political existence in the northern interior. As a young boy, he was strongly influenced by the stirring events of the period when the emigrants had to struggle against the warlike tribes surrounding them and to establish an orderly government of their own.

Early political career

While still in his teens, Kruger played a part in public life as a local field-cornet, a post in which civil and military duties were combined. In January 1852 he was present when the Transvaal leader, Andries Pretorius, concluded the Sand River Convention with representatives of Great Britain, by which the independence of the Afrikaners (Boers) north of the Vaal River was recognized. He took part in 1855–56 as member of a commission that drew up the constitution of the new republic. During the civil disturbances of 1861–64, he played a prominent part as commandant general in unifying and pacifying the country in support of constitutional authority.

With the British annexation of the Transvaal in 1877, he became the recognized champion of his people in the struggle to regain independence. With that purpose in mind, he visited England in 1877 and 1878, and, when he failed to persuade the Disraeli government to undo the annexation, he helped organize a movement of passive resistance to British administration in the Transvaal. In 1880 he pinned his hopes to the promises of Gladstone, the Liberal leader. Disappointed when the new Liberal government failed to live up to his expectations, he succeeded in gaining the sympathy and political support of the Cape Colony against the British attempt to force South Africa, including the Transvaal, into a general federation. In December he led his people into active opposition, and, after a series of military victories that culminated in that of Majuba Hill (February 27, 1881), with great diplomatic skill, he succeeded in negotiating peace based on a limited independence. In 1883 he was elected president of the restored republic, and he held that office until 1902, when the Boers at last submitted to British authority.

Meanwhile, in 1883 he again visited England and, after protracted negotiations, concluded a new convention (that of London, February 27, 1884) with Britain, which rectified the western border and removed any reference to

British suzerainty over the Transvaal. On his return he found his republic embroiled with the Cape colonial authorities over control of the area along the western border, which was considered by Cecil Rhodes, the Cape statesman, to be the "Suez Canal" to the territory north of the Limpopo. In 1885 Kruger was forced to accede to British demands to withdraw from the area in question and to agree to a British protectorate over Bechuanaland. At the same time, the way was opened for the future expansion of the Cape Colony to the north.

Gold rush in the Transvaal

Kruger's greatest problem began in 1886 with the discovery of gold in the Witwatersrand area, where a new metropolis, Johannesburg, arose, some 40 miles south of the tiny republican capital, Pretoria. Large numbers of "outlanders" flocked to the Transvaal and established a cosmopolitan, mainly English community in the midst of a rural Boer society. Kruger saw this as a threat to the separate national identity of his people, "God's people" as he called them, and in 1890 he severely restricted the franchise to men resident at least 14 years. At the same time, he called into being a separate Volksraad (legislative body), in order to represent mining interests, but this did not satisfy the demands of the outlanders. The mining magnates of Johannesburg criticized Kruger's economic and railway policy, which was aimed at promoting the independence of the Transvaal but which resulted at the same time in raising the cost of production of gold. They complained of high railway tariffs, which Kruger's concessionaires, The Netherlands South Africa Railway Company, imposed in order to protect their railroad linking Johannesburg with Delagoa Bay. For political reasons, Kruger had to support this railway against the cutthroat competition of the Cape railways, which he was unable to exploit to his country's advantage.

Rhodes, the Cape premier, who had extensive gold interests and much political influence, hoped to achieve a united British South Africa. He supported the Rand capitalists and the outlander movement against Kruger's regime. When he failed to persuade Kruger to join a South African customs union, he decided to bring matters to a head. Kruger, after all, was the one obstacle that prevented Rhodes from realizing his dream of empire. By 1895 Kruger was aware that trouble was brewing in Johannesburg and that, behind the scenes of the internal conflict within the Transvaal, a larger issue was at stake, that of British supremacy as against republican independence. He felt that the matter of extension of the franchise to the newcomers was merely being used as a cat's-paw to further the schemes of Rhodes.

Prelude to the Boer War

Ever since 1890 he also had to contend with growing opposition of a section of his own people; but when Rhodes, with the full knowledge of Joseph Chamberlain, the British colonial secretary, sponsored an ill-fated raid, the Jameson Raid against the republic at the end of 1895, Kruger handled the affair so successfully that his prestige soared again. In the presidential election in May 1898, he received almost unanimous support. While Rhodes was forced into the background, British imperial interests now came to the front. The Colonial Secretary took up the cudgels on behalf of the outlanders and, in 1897, sent Sir Alfred Milner to South Africa as governor of the Cape Colony and high commissioner. Supported by Chamberlain, Milner began to force the issue and demanded that the residential qualification for voters in the Transvaal should be lowered to five years. In May 1899 a conference took place in Bloemfontein, the Free State capital, between Kruger and Milner. Although no agreement was reached, Kruger decided on a seven-year residential qualification. Milner refused the offer, tension increased, and Britain prepared an ultimatum. Both sides prepared for war, which was precipitated by Kruger when, on October 9, 1899, he presented his own ultimatum, demanding the withdrawal of British troops from the border.

War broke out two days later, and, notwithstanding initial Boer successes, British invading armies occupied the two Boer capitals. Kruger was forced to retreat with the last Boer army along the Delagoa Bay railway. Being too old to keep up with the ensuing guerrilla struggle, he was delegated to Europe, where he lived in Holland to the end of the war in May 1902. He died at Clarens, in Switzerland, on July 14, 1904, and his body found a temporary resting place at The Hague. He was finally buried at Pretoria on December 16, 1904.

BIBLIOGRAPHY. D.W. KRUGER, ***Paul Kruger,*** 2 vol. (1961–63), is the most recent biography, based on original research but popularly written. J.P. LA GRANGE LOMBARD, ***Paul Kruger, die Volksman*** (1925), highlights certain aspects of Kruger's life only; while M. NATHAN, *Paul Kruger,* 4th ed. (1944), has written a popular account based on published sources. C.T. GORDON, ***The Growth of Boer Opposition to Kruger, 1890–95*** (1970), is a recent scholarly work, based on original research and stressing important aspects of Kruger's policy. J.S. MARAIS, ***The Fall of Kruger's Republic*** (1961), is a most important contribution to knowledge of British policy vis-a-vis Kruger and his republic up to the eve of the Anglo-Boer War, 1899–1902. ***Lebenserinnerungen des Prasidenten Paul Kruger*** (1902; Eng. trans., ***The Memoirs of Paul Kruger,*** 1902), is useful for his early life, but of less value later and, notwithstanding the title, for the most part not memoirs but ordinary history written by his secretaries.

(D.W.K.)

Krupp Family

From 1587 to 1968 members of the Krupp dynasty, the world's largest manufacturers of munitions, dominated the German city of Essen, the hub of the industrial Ruhr area (Ruhrgebiet), as surely as the rulers of any medieval fief. When the drums of German conquest rolled in 1870, 1914, and 1939, it was Krupp factories that provided first Prussia and then the German Empire with field guns, shells, tanks, battleship armour, and flotillas of submarines—always at immense profit to the House of Krupp. Until 1918 a suite in Villa Hiigel, the 300-room Krupp Castle in Essen, was always reserved for the reigning emperor. Later the dynasty became deeply committed to Adolf Hitler, and Alfried Krupp von Bohlen und Halbach (1907–67), the last of the line, was convicted of major war crimes at Nuremberg. In 1951 he was pardoned, and before his death he had become the most powerful industrialist in Europe.

Arndt Krupp (died 1624), the first member of the family to settle in Essen, arrived before a plague epidemic and bought large tracts of land from natives fleeing from it. Although Arndt and the four generations of Krupps who succeeded him grew wealthy, the family's rise to international significance did not begin until Friedrich Krupp (1787–1826) founded the dynasty's cast-steel factory ***(Gusstahlfabrik)*** in 1811. He never entirely matched the achievement of the British, who had mastered the art of casting steel, but his son Alfred (1812–1887) succeeded brilliantly. Known variously as "Alfred the Great" and "the Cannon King," Alfred perfected his technique by manufacturing rails and seamless-steel railroad wheels. Then he turned to guns.

"The Cannon King"

Alfred Krupp. An eccentric genius and an insomniac, Alfred lay awake nights scribbling letters and plans for new instruments of death. If not completely paranoid, he was certainly suspicious of everyone around him. Although he worked at forges, he was terrified of fire and built his castle of glass and stone, without a stick of wood. At one point he tried to persuade his workmen to wear uniforms—he himself would have been arrayed as a field marshal. Because he believed that the odour of horse manure was inspiring, he built his study over his stable, with ducts to waft the scent upward. Yet his workmen were fanatically loyal to him. He was the first industrialist to introduce sick pay, a free hospital for his men and their families, pensions, and homes for retired workers.

In 1851 his cast-steel cannon was the sensation of London's Crystal Palace Exhibition, although his name did not become a household word until the Franco-Prussian War of 1870–71. In that conflict, the Prussians largely owed their triumph to Krupp's field guns, whose accuracy and range easily outperformed Napoleon III's bronze artillery. Despite Krupp's production of many peaceful items, his weapons had caught the public fancy. Almost overnight Krupp guns became a status symbol for 19th-century nations.

Alfred Krupp was in many ways the founder of modern warfare. At the time of his death he had armed 46 nations. As much as any other single individual, he had set the stage for the great holocaust that would begin in 1914, and, in recognition of his achievements in war weapons, the grateful governments of his day had awarded him 44 military medals, stars, and crosses, which included multiple honours from Spain, Belgium, Sweden, Romania, Austria, Japan, Russia, Turkey, and Brazil.

The "defensive and offensive weapons seesaw"

Friedrich Krupp. Whereas Alfred had been a blunt man, his son, Friedrich Alfred Krupp (1854–1902)—whom everyone called "Fritz"—was sly, and serpentine. Nevertheless, he shared his father's uncanny business sense and remarkable gifts for management. Probably the most profitable of his strategems was what the amused Emperor William II called the "Schutz- und *Trutzwaffen Schaukeln*," the "defensive and offensive weapons seesaw." It worked this way. Having perfected nickel-steel armour, Fritz advertised it in every chancellery. Armies and navies invested in it. Then he unveiled chrome-steel shells that would pierce the nickel steel; armies and navies invested again. Next he appeared with a high-carbon armour plate that would resist the new shells. But just when every general and admiral thought he had equipped his forces with invincible shields, Fritz once more produced good news for advocates of offensive warfare. It turned out that the improved plate could be pierced by "capped shot," with very expensive explosive noses. The governments of the world kept digging deep into their exchequers; altogether, 30 of them were caught in Fritz's arms game.

In seven years Fritz's fortune tripled, but tragedy stalked him. Although the father of two daughters, he had become an overt homosexual. Incontrovertible evidence of this, including photographs, fell into the hands of the Italian police and was soon published by German newspapers. Distraught and disgraced, Fritz killed himself in 1902, leaving as his heiress his elder daughter Bertha Krupp (1886-1957), then a teen-ager. It was unthinkable for the Reich's most martial industry to be run by a woman, so the Emperor himself conducted a search for an acceptable husband for Bertha.

Gustav Krupp. He chose Gustav von Bohlen und Halbach (1870–1950), a stiff Prussian diplomat. Efficiency was Gustav's religion; one of his oddest hobbies was reading train timetables, looking for typographical errors. With his domed forehead, set mouth, and quick mechanical gestures, he was a parody of Prussian rigidity. The Emperor himself gave the bride away, and, as a surprise for the newlyweds, he had the groom's name changed to Gustav Krupp von Bohlen und Halbach. The couple was thus granted the privilege of passing on not only the family fortune but also the Krupp name to its eldest son.

World War I armaments

In World War I Gustav Krupp, as he was known, provided many memorable contributions to Germany's arsenal. One, named in honour of his wife, was the 98-ton Big Bertha howitzer that shelled Liège and Verdun. Others included the great cannon that bombarded Paris from a range of 82 miles and Germany's submarines, which were built at the family's Kiel shipyards. Because the Germans lost, the war was, on the whole, bad business for Krupp, but not a total loss. Before the war, in 1902, Vickers, Ltd., a British manufacturer of artillery shells, had leased a Krupp fuze patent. Under the agreement, every Vickers shell was stamped KPz (Krupp patent fuze), eventually to be redeemed at 1*s*. 3d. per shell. After the war, Vickers paid off in a settlement based on German artillery casualties, which placed Krupp in the awkward position of having profited from Germany's war dead.

With this money, and with subsidies from the government of the Weimar Republic, Gustav began the secret rearming of Germany within a year of the Armistice. In his words, he was determined that Krupp should be ready "again to work for the German armed forces at the appointed hour without loss of time or experience." Submarine pens were furtively built in Holland; new cannon were covertly perfected in Sweden. Krupp helped finance the Nazi "terror election" of 1933, tightening Hitler's grip on the reins of government, and, as president of the Reichsverband der Deutschen Industrie—Germany's equivalent of the U.S. Chamber of Commerce--expelled all Jewish industrialists and became one of the country's most ardent Nazis. Meanwhile, his eldest son, Alfried—who had been a sponsoring member of the Nazi Schutzstaffel (SS) since 1931—was improving the anti-aircraft, anti-tank, anti-personnel 88-mm gun, which would first be used in the Spanish Civil War and which would, a decade later, become the most famous artillery piece of World War II.

The Lex Krupp

Alfried Krupp. Shortly after the outbreak of the war it became evident that Gustav was drifting into senility. Alfried assumed his duties, and in 1943 Hitler issued an unprecedented decree, the Lex Krupp, which, abolishing in this one case the laws of inheritance, preserved the firm as a family property. Alfried now assumed the name of Krupp and became the sole owner of his mother's vast holdings.

Even before 1939, the extent of the family's wealth had been staggering. Within the Reich, Krupp had wholly owned 87 industrial complexes, held a controlling interest in 110 firms, and possessed substantial investments in 142 other German corporations. Abroad, Krupp smokestacks had stained the sky over almost every continental country; the family owned over 50 percent of the stock in 41 foreign plants and large blocks of shares in another 25. There had been thousands of Krupp ore pits and coal mines, a chain of Krupp hotels, a group of Krupp banks, a Krupp cement works, and a score of private estates.

Now Alfried augmented this empire by seizing property in every country conquered by Germany. Already, in 1943, his salesmen were exporting finished machine products from his new Ukranian plants and selling them in Bulgaria, Turkey, and Romania. When Robert Rothschild refused to sign over his French holdings to Alfried, Rothschild was shipped to the Auschwitz concentration camp and gassed. It was incidents of this kind, together with his exploitation of slave labour, that put Alfried in the prisoners' dock at the Nuremberg war-crimes trials after the war.

Indictment of Alfried

At first the victorious allies, under the impression that Gustav had been in charge throughout the war, had indicted him. In fact, it was Alfried who had been the head of the family and the firm during the years when the inmates of 138 concentration camps worked for Krupp; Alfried who had had a fuze factory built inside Auschwitz to take full advantage of prison labour; and Alfried who had had Jewish prisoners at Auschwitz build a howitzer factory in Silesia. One Krupp camp was reserved for Jewish girls, who lived and worked under almost unendurable conditions before being shipped to the Buchenwald Camp to be killed.

The Nuremberg tribunal sentenced Alfried to 12 years in prison and ordered "forfeiture of all your property both real and personal." Seven months after the outbreak of the Korean War (1950–53), however, John J. McCloy, U.S. high commissioner in American-occupied Germany, granted Alfried amnesty and restored all his holdings. As a lawyer McCloy had been troubled by the confiscation, which, as he pointed out, had the effect of disinheriting Alfried's heir or heirs. Operating with tremendous skill and zeal, Alfried quickly restored the family firm to its former supremacy. By the early 1960s he was worth over a thousand million dollars.

End of the dynasty. Then the family suffered two blows from which it would not recover. The firm had extended long-term credit to firms in Eastern Europe, and Alfried's short-term notes balancing that credit became due in the German recession of 1966–67. The Krupp empire could survive only if he relinquished sole control and opened the firm to outside investment—selling stock on the Dusseldorf Exchange. At the same time Alfried's only son, Arndt, named after the family's founder, decided that he did not wish to take over the family business. In exchange for renouncing his succession rights, rights based upon the Lex Krupp of 1943, Arndt received $500,000 a year for the rest of his life. On the morning of July 31, 1967, Alfried was found dead in Essen, and in the following January the firm became a corporation. The dynasty that had ruled for almost four centuries had come to an end.

Kublai Khan

Kublai Khan, a grandson and the greatest successor of the Mongol conqueror Genghis Khan, was a brilliant general and a statesman of great imagination who conquered China and became the first emperor of its Yüan, or Mongol, dynasty. He was thus at one and the same time the overlord of all the Mongol dominions—which included areas as diverse as that of the Golden Horde in south Russia, the Īl-Khānate of Persia, and the steppe heartlands where Mongol princes were still living the traditional nomadic life—and the ruler of his own realm of China. To govern China, with its long and individual political and cultural history demanded statecraft of a special order. Kublai's career is interesting above all because of the way in which he interpreted—and finally failed to reconcile—his dual roles. As it turned out, he became a Chinese emperor of traditional type. China absorbed his interests and energies to the exclusion of the Mongol homeland, and for years he was actually engaged in civil war with rival Mongol princes of the steppes. Under him, China, and of course the privileged Mongols, enjoyed a brilliant spell of prosperity; but his politics, pursued with less skill by his successors, isolated the Mongols in China from their environment. With the collapse of the dynasty, the Mongols withdrew to the steppes and never again played any role of more than local importance.

By courtesy of the National Palace Museum, Taipei, Taiwan, Republic of China

Kublai Khan, portrait by an unknown artist. In the National Palace Museum, Taipei, Taiwan.

Kublai's major achievement was to reconcile the Chinese people to rule by a foreign and culturally inferior race. It was not until some 30 years after his death that any serious uprisings against Mongol rule were to occur in China. Yet even a man of his energy, will power, and political insight, ruling with the advantage of absolutism unfettered by the old bureaucratic apparatus of China, could not resolve the contradictions inherent in his situation.

Historical background. The Mongols were a parvenu nomadic power. Before the time of Genghis Khan they had been no more than a group of semibarbaric tribes, more or less unknown to history. They lacked all but the most primitive cultural traditions, and, except for some organized hunting and the management of their herds, they had little experience of economic activity. Until a few years before Kublai's birth, they had been illiterate. They had only the most elementary ideas of statecraft. Concepts such as taxation of urban societies were brought to their attention by their foreign advisers, upon whom they relied heavily. This political incompetence contributed much to the rapid collapse of their empire. With a few outstanding exceptions, such as Kublai himself (whom the Mongols always called Setsen Khan, the Wise Khan), the rulers of the Mongols seem to have looked upon power as a personal, at most a family, possession, to be exploited for immediate gain. Hence, except in areas where, like China, there was a firm native political tradition, they never succeeded in organizing a durable state. In China, too, everything depended ultimately upon the will power and ability of the ruler.

The Mongols had come to power in China, as elsewhere, by sheer force of arms; and with this prestige to back him, relying on his dominant personality, and building on the foundations of the brilliant civilization developed by the preceding Sung dynasty, Kublai for a while could maintain the illusion that Mongol supremacy was firmly based. Indeed, his reign must have appeared to be a period of solid expansion and lasting achievement to his contemporaries, including Marco Polo, the Venetian traveller who became Kublai's agent and whose book is the chief Renaissance source of information on the East. Yet Kublai Khan was faced at the outset of his reign by an insoluble dilemma, which was given vivid expression in a memorial presented to him by one of his Chinese advisers: "I have heard that one can conquer the empire on horseback, but one cannot govern it on horseback." In other words, to administer China the inexperienced Mongols would have to adopt Chinese methods, even live according to a Chinese pattern; and to the extent that they did so, they would be bound to become more and more assimilated and perhaps lose their identity altogether. If on the other hand they worked through Chinese and other agents they would become alienated from the mass of the population, which would reject them. In either case, the Mongols, culturally and numerically inferior and used to a different pattern of life, could not continue for long to rule China as a distinct and privileged caste; and only the brilliance of Kublai's personal achievement obscured this truth.

Dilemma of foreign rule in China

Rise to power. Kublai Khan was born in 1215, the fourth son of Tolui, the youngest of Genghis' four sons by his favourite wife. He began to play an important part in the extension and consolidation of the Mongol empire only in 1251, when he was in his middle 30s. His brother, the emperor Mongke, resolved to complete the conquest of Sung China, which had been planned by Genghis' third son, Ögödei, and also to subdue Persia—a task allotted to Kublai's brother Hülegü. Kublai was invested with full civil and military responsibility for the affairs of China. He appears never to have learned to read or write Chinese, but already he had recognized the superiority of Chinese thought and had gathered around himself a group of trustworthy Chinese advisers, Confucians. His attitude toward government was formed under the influence of these learned Chinese, who convinced him of the necessary interdependence of ruler and ruled and reinforced his innate tendency toward humanity and magnanimity. At home, in the fief allotted to him in the Wei River Valley (in modern Shensi Province), he established a competent administration and a supply base. In the field, he stressed to his generals the precepts of his mentors—the importance and effectiveness of clemency toward the conquered. This was a great advance in civilized behaviour compared to the methods of Genghis Khan and those of Kublai's contemporaries in Central Asia, where the massacre of the population was still the expected sequel to the capture of a city.

Kublai took Sung China in the flank, subjugating the Tai kingdom of Nanchao in present-day Yunnan before handing over command to his general Uriyangqadai. In 1257 Mongke assumed personal charge of the war, but he died in 1259. When Kublai, who with another army was besieging a city, heard that his brother, Arigboge, who had been left in charge of the homeland because he was the youngest, was planning to have himself elected khan, he patched up a truce with Sung. In April 1260 he arrived at his residence of K'ai-p'ing, or Shang-tu (the Xanadu of Samuel Taylor Coleridge's famous poem), in southeastern Mongolia. Here his associates held a *kuriltai*, or "great assembly"; and on May 5 Kublai was unanimously elected khan in succession to Möngke. Ten days later he announced his succession in a proclamation drawn up in Classical Chinese. Because primogeniture was not a recognized principle at the time, Arigboge, with some very powerful supporters, held a *kuriltai* at Karakorum and had himself declared khan, ignoring Kublai's action. In spite of Marco Polo's insistence that Kublai was the lineal and legitimate descendant of Genghis Khan and the rightful sovereign, there have always been doubts about this legitimacy. A legend recorded in Mongol chronicles to the effect that the dying Genghis designated the child Kublai as a future khan seems to have been contrived so as to provide retrospective justification of an act of usurpation.

Family feuds

In 1264 Kublai defeated Arigboge in battle and forced him to submit. He died two years later. But the family feud, of which this was one manifestation, continued throughout Kublai's reign. Against him were ranged those who resented the abandonment of the old ways of the steppe and the adoption of an alien, China-centred culture. The split was all the deeper because the leader of the opposition was Kaidu, who, as a grandson of Bgodei, who had been designated personally by Genghis as his successor, represented the cause of legitimacy. The throne had passed from the line of Ögödei to that of his brother Tolui in 1250 as a result of a coup d'etat. Kaidu never relaxed his hostility toward Kublai and remained master of Mongolia proper and Turkistan until his death in 1301.

The war with Kaidu showed how decisively Kublai had identified himself with the Chinese world and turned against the world of the nomads. Genghis had been strong and ruthless enough to compel the Mongols, always inclined to family feuds, to serve his cause; but Kublai, powerful though he was, could no longer control the steppe aristocracy effectively.

Unification of China. Kublai's achievement was to reestablish the unity of China, which had been divided since the end of the T'ang dynasty. This achievement was that much greater because he was a barbarian, nomadic conqueror. Even in Chinese official historiography the Mongol Kublai is treated with respect. As early as 1260 he instituted a reign period, in the Chinese manner, to date his reign; and in 1271, eight years before the disintegration of the Sung, he proclaimed his own dynasty under the title of Ta Yuan, or Great Origin. He never resided at Karakorum, Ögödei's short-lived capital in north Mongolia, but set up his own capital at what is now Peking, a city known in his time as Ta-tu, the Great Capital.

The final conquest of Sung China took several years. Kublai might well have been content to rule the North and to leave the Sung dynasty nominally in control of South China, but the detention and ill treatment of envoys he had sent convinced him that the declining régime in the south must be dealt with decisively. Military operations opened once again in 1267. The Sung emperor was apparently badly served by his last ministers, who are said to have kept him misinformed of the true situation, whereas many Sung commanders went over voluntarily to the Mongols. In 1276 Kublai's general Bayan captured the child emperor of the day; but loyalists in the south delayed the inevitable end until 1279.

Aims to make China centre of the world

With all China in Mongol hands, the Mongol conquests in the south and east had reached their effective limit; but Kublai, seeking to restore China's prestige, engaged in a series of costly and troublesome wars that brought little return. At various times tribute was demanded of the peripheral kingdoms: from Burma, from Annam and Champa in Indochina, from Java, and from Japan. The Mongol armies suffered some disastrous defeats in these campaigns. In particular, invasion fleets sent to Japan in

1274 and 1281 were virtually annihilated, though their loss was due as much to storms as to Japanese resistance. Kublai was never entirely discouraged by the indifferent results of these colonial wars nor by their expense, and they were brought to an end only under his successor. Marco Polo suggests that Kublai wished to annex Japan simply because he was excited by reports of its great wealth. It seems, however, that his colonial wars were fought mainly with a political objective—to establish China once more as the centre of the world.

"Four nationalities policy"

Social and administrative policy. By themselves the Mongols were incapable of ruling China, and, though at the lower levels they made use of Chinese civil servants, posts of importance were allotted to foreigners. Of these Marco Polo is a familiar example. Kublai instituted a "nationalities policy" under which the population of China was divided into four categories. At the top were the Mongols, forming a privileged, military caste of a few hundred thousands, exempt from taxation, and living at the expense of the Chinese peasantry who worked the great estates allocated for their upkeep. The foreign auxiliaries of the Mongols, natives for the most part of Central Asia, formed the second group, the *se-mu jen,* or persons with special status. This class furnished the higher officialdom; and its members, with their worldwide contacts and their privileged status, also formed a new breed of merchants and speculators. Like the Mongols, they were exempt from taxation and enjoyed preferential use of the official postroads and services. The bulk of the population belonged to the third and fourth classes, the Han-jen, or northern Chinese, and the *man-tzu,* or southern barbarians, those people who lived in what had been Sung China. The expenses of state and the support of the privileged bore heavily on these two classes. Kublai's continuing wars meant a heavy and useless burden, as did his showy and extravagant building operations at Ta-tu. Peasants were brought in as labourers, to the neglect of their farms. Food supplies in the north were inadequate for the new labour force and the unproductive Mongols; and large quantities had to be brought by sea, and, when the sea routes proved insecure, along the Grand Canal. The repair and extension of this canal also demanded the diversion of much labour. Kublai, in common with other Mongol rulers, was much preoccupied with religion. His reign was a time of toleration for rival religions and of economic privilege for the favoured religions. Clerics and their communities were exempted from taxation, and Buddhist temples especially were granted generous donations of land and of peasants for their upkeep. The arrogance of the many Tibetan lamas who enjoyed a special status in China was particularly detested.

Such a discriminatory social policy was eventually bound to arouse strong resentment. Moreover, it was only on the surface that Kublai's China, with its intense commercial activity, was economically strong and wealthy. Trade was mainly carried on in the interests of a privileged, foreign merchant class, not those of the community at large. The common people of China were becoming progressively poorer. The old examination system, which admitted to the civil service only men with a proper knowledge of Confucian philosophy, had lapsed; and customary restraints upon absolutism and arbitrary rule, such as would have been imposed by the censorate (a body that scrutinized the conduct of officials) and a professional public service, were lacking. The Chinese literati were excluded from public office and responsibility. As a result, adventurers could attain high positions; and even an emperor of Kublai's unique ability remained for years on end in ignorance of, and unable to check, the depredations of his dishonest foreign financial advisers. The extravagant policies that Kublai had countenanced and the financial ineptitude of later Mongol emperors, provoked, in the 14th century, the economically motivated uprisings that brought the dynasty down.

Kublai is celebrated, mainly because of Marco Polo's account, for his use of paper money. Paper money had, however, been in use in China under the Sung; and Kublai's innovation was merely to make it the sole medium of exchange. Toward the end of the dynasty, an incapable financial administration stimulated inflation by the over-issue of paper money; but in Kublai's time the use of banknotes was essential. The supply of copper was too small to form a metal currency in a period of expanding trade, and in any case large quantities were diverted to the temples to be made into statues and other cult objects.

Assessment. Though celebrated above all as a Chinese emperor, Kublai also helped to form the political traditions of his own Mongol people. To him and to his adviser, the Tibetan grand lama 'Phags-pa, is attributed the development of the political theory known as the "dual principle"; that is, the parity of power and dignity of church and state in political affairs. This theory was turned to practical account on more than one occasion in the subsequent history of Mongolia and, for example, underlay the constitution of the theocratic monarchy proclaimed in 1911, when Mongolia recovered its independence from China.

Kublai's character is difficult to assess. The only personal account of him is by Marco Polo, and this is more of a panegyric than a sober appraisal. Marco presents Kublai as the ideal of a universal sovereign. Yet he does not overlook his human weaknesses, above all, an excessive indulgence in feasting and hunting, a complicated and expensive sexual life. a failure always to exercise proper supervision over his subordinates, and occasional outbursts of cruelty.

BIBLIOGRAPHY. There is no good scholarly biography of Kublai Khan, in spite of his significance as a world figure. The best accounts of his life may be found in standard histories of China and of the Mongols, especially in OTTO FRANKE, *Geschichte des chinesischen Reiches,* vol. 4 (1948). Franke's account, though critical, tends to favour his subject; a contrasting though equally well-founded, viewpoint is put forward in WOLFRAM EBERHARD, *Chinas Geschichte* (1948; Eng. trans., *A History of China,* 1950). The relevant chapters in vol. 2 of M. D'OHSSON, *Histoire des Mongols* (1834, reprinted 1940), are still unsurpassed in spite of the lapse of time. RENE GROUSSET, *L'empire des steppes: Attila, Gengis-Khan, Tamerlan* (1939; Eng. trans., *The Empire of the Steppes: A History of Central Asia,* 1970), gives adequate coverage. A concise, but very competent account of Kublai's reign may be found in J.J. SAUNDERS, *The History of the Mongol Conquests* (1971), which has an annotated bibliography. Marco Polo's book, in any easily available edition, is indispensable reading. LEONARDO OLSCHKI, *L'Asia di Marco Polo* (1957; rev. Eng. trans., 1960), provides the most readable commentary upon it, with rich bibliographical references.

(C.R.B.)

Kunlun Mountains

The Kunlun Mountains (K'un-lun Shan), which extend approximately 1,675 miles from the Pamirs in the Soviet Union on the west to the Sino-Tibetan ranges on the east, constitute the longest mountain system in Asia, uniting dozens of ranges that are among the highest on Earth. Located in the People's Republic of China, within the autonomous regions of Sinkiang Uighur and Tibet and the province of Tsinghai, the Kunlun Mountains form the northern wing of the geologically uplifted region known as High Asia—the highest such region in the world.

The position of the Kunlun Mountains, between Tibet and the northern plains of Central Asia, determines the sharply asymmetrical structure of the system. Although the average elevation of the watershed ridges in the southern ranges is about 21,325 feet, when viewed from the south the ranges rise only from about 3,300 to 4,900 feet above the Plateau of Tibet, which itself has an average height of between about 14,500 and 16,500 feet. As seen from the Tarim and Ala Shan plains to the north, however, which have an average altitude of only about 2,600 to 3,900 feet, the watershed ridges of the northern ranges (the average elevation of which is about 19,650 feet) create the impression of gigantic mountains that tower up to 14,765 feet over the surrounding plains.

General alignment of the mountains

The natural environment. ***Relief and topography.*** General alignment is nearly latitudinal (from east to west), but individual segments change direction significantly, following the outlines of the Tarim Basin, the Ala

Shan Desert, and the Tibetan massifs (mountainous masses). The most significant such deviations occur in the Khotan–Keriya (Ho-t'ien–Yii-t'ien) sector (about 81° E), which faces the Lop Nor plain (about 90" E). Here, the strike of the mountains shifts abruptly from northwest–southeast to southwest–northeast, before resuming its northwest–southeast alig [illegible]

Almost the full length of the Kunlun Mou [illegible] consists of parallel chains of–ranges, the tallest of which are those closest to Tibet, separated by vast depressions and narrow valleys. Because they are higher in relation to the surrounding plains, the northern slopes (the Tarim and Ala Shan) are steeper and more complexly dissected, while the southern slopes (those facing Tibet) are shorter, sometimes taking the form of ledges that are only weakly dissected. Whereas the heights of the major Kunlun peaks are several thousand feet shorter than the famous Himalayan peaks, the average height of the Kunlun and Himalayan ridges are almost equal. The elevations of the Kunlun mountain passes (from 18,700 to 20,340 feet), however, surpass those of the deeply eroded Himalayas.

The western Kunluns. The Kunlun system is not uniform in structure, being subdivided into two unequal sections—the smaller western and the principal eastern part. The western Kunluns (between the Pamirs and the alignment change in the Khotan–Keriya region) form three parallel chains of ranges crowded closely together. The Sha-li-k'o-erh, T'a-shih-k'u-erh-kan (Tashkurgantag), Agyl, and Sugettag ranges form the southern chain, which adjoins the Karakoram Range (*q.v.*); the inner and highest chain is formed by the Mu-ssu-t'a-ko-a-t'e, Tokhtakoram, and Karangutag ranges; the Tiznaf and Sandzhutag ranges make up the northern chain. Because the mountain chains of the western Kunluns are divided only by narrow intermontane depressions, the width of this part of the system usually does not exceed about 60 miles.

The highest groups of peaks in the western Kunluns are found on its flanks—in the Gissar sector, the 24,865-foot (7,579-metre) Kung-ko-erh and the 24,462-foot (7,456-metre) Mu-ssu-t'a-ko-a-t'e massifs; in the Khotan sector, the 23,008-foot (7,013-metre) Karangutag and the 23,891-foot (7,282-metre) Mu-ssu massifs. In the intervening So-ch'e–Yarkand sector, however, all the ranges are lower; even the main peaks rarely reach 19,650 feet. Where the alignment changes in the Khotan–Kariya region, the northern chain of the Kunluns is interrupted, and ranges of the high inner chain border the Tarim Basin, on the side of which they are abruptly bounded by a gigantic ledge.

The eastern Kunluns. The eastern Kunluns are characterized by a complex branching of mountain chains that pass around broad intermontane valleys. The unitary direction characteristic of the western Kunlun ranges is lost here; individual ridges are often situated at an angle to one another. Moreover, the width of the mountain system increases sharply, reaching about 375 miles in places.

The Russian, the A-erh-chin Shan-mo (Astin Tagh), and the group of Nan Shan ranges form the northern chain of the eastern Kunluns, which many consider an independent mountain system. Near the Lop Nor plain these ranges describe an arclike curve in which their alignment changes from southwest–northeast to northwest–southeast. The western branch of the arc (with northeastern alignment) is made up of two ranges with a width of from 19 to 25 miles. The Russian Range, whose crest rises to 21,738 feet (6,626 metres), is the only one of noteworthy height within this branch; A-erh-chin Shan-mo (Astin Tagh) is as much as 11,500 to 13,000 lower, especially in the segment contiguous with the Tsaidam Basin.

The Nan Shan ranges

The eastern branch of the arc, which is formed by the system of Nan Shan ranges, is separated from the principal mountain chains of the eastern Kunluns by the vast Tsaidam depression. The five to seven ranges that constitute the Nan Shan system, which has an overall width of up to 186 miles, include Ch'i-lien Shan-mo (Richthofen), T'o-lai Shan (Khrebet Tkholo-shan'), Zyussa, Wu-lan-ta-pan Shan (Humboldt), Ta-k'en-ta-fan Shan (Ritter), and southern Koko Nor. While the height of their crests varies from about 16,700 to 20,700 feet, the elevation of the longitudinal (north–south) intermontane valley floors between them varies from 10,500 to 11,800 feet. The Zyussa, which rises to altitudes of 20,820 feet (6,346 metres), is the highest of these ranges; but the most developed, as a mountain range, is the Ch'i-lien Shan-mo.

The principal chains of the eastern Kunluns are located between the Tsaidam Basin and the Tibetan uplands. The northernmost of these, the Ch'i-man–Burkhanbudda chain, is the lowest; the level of its series of summits is from about 17,400 to 18,000 feet. It rises massively above the Tsaidam Basin but stands out in only mild relief when seen from the Tibetan side. Forming an extension of the inner chain of the western Kunlun ranges is the Przhevalsky Range (Arkatag), the highest and longest in the eastern Kunluns and the principal structural pivot of this part of the mountain system. It contains the tallest peaks of the entire Kunlun Mountains, the 25,341-foot (7,724-metre) Wu-lu-k'o-mu-shih Ling and the 25,328-foot (7,720-metre) T'ieh-k'o-li-k'o Shan (also called the Chong-Karlyk-Tag [Great Snow Range] or Shapka Monomakha [Hat of Monomakh]). The crest of the range is snow covered and steep walled, rising vertically almost 3,300 feet; its mountain passes (K'a-la-mu-lun Shan-k'ou, Rekviem, and others) have elevations of close to 18,000 feet. The southern chain, formed by the K'u-k'u-shih-li (K'o-k'o-hsi-li) and Pa-yen-k'a-la Shan (Bayan' Kara-shan') ranges, is about 3,300 feet lower than the Arkatag.

The high plains separating the inner mountain chains of the eastern Kunluns from those to the north and south lie at the same elevation as the plateaus in the foothills of the Tibetan uplands and have a similar landscape. The most extensive of these is the Kul'tala Plain, which lies between the Przhevalsky Range and the Ch'i-man chain and which is up to 59 miles wide. Covering its surface next to the mountains are fields of broken stone; in areas of lower elevation there are salt marshes, as well as the A-ya-ko-k'u-mu Hu (Aiag Kum Kul') and A-tz'u-k'o Hu (Achchik Köl) lakes.

Geological history. The principal folded structures and granitic rocks of the Kunluns are of Hercynian age, a period that lasted from about 230,000,000 to 250,000,000 years ago, during which there was much mountain building in the Eastern Hemisphere. The inner depressions of the Kunluns, however, are relatively recent structures in their entirety, being formed by deposits that are no more than 26,000,000 years old; only the largest of them, the Tsaidam depression, contains a thick sedimentary cover of which Jurassic deposits (136,000,000 to 190,000,000 years of age) represent the oldest strata. The Kunluns also represent a region of very recent movements of the Earth's crust, and great seismic (earthquake) activity.

Rivers. The Kunluns form a part of that region in Central Asia in which there is only internal drainage, associated mainly with the Tarim, Ala Shan, Tsaidam, and Kul'talin basins. Only the most easterly spurs of the mountain system, where the sources of the Huang (Yellow) and Yangtze rivers are located, have drainage systems that empty into the ocean.

Major rivers

Two groups of rivers compose the river network of the Kunluns: the large streams that rise in the Karakoram Range and in northern Tibet, cutting through the entire chain of Kunlun ranges by way of gorges, and the small streams that drain the slopes of the peripheral ranges. The major rivers—the Gez, Yarkand, K'a-la-k'a-shih (Kara Kash), Yu-lung-k'a-shih (Yurang Kash), K'o-li-ya (Keriya), Ha-la-mu-lab (Kara Muran), and Ch'e-erh-ch'en (Cherchen)—form lengthy, zigzag valleys. In the broad and open longitudinal valleys between mountain ranges, the rivers flow quietly and calmly for long distances; in the ravines that bisect the ranges, however, short sections of the rivers flow through narrow gorges in violent torrents.

Although they receive some rainwaters, the Kunlun rivers are fed mainly by snows and glaciers. Therefore, the volume of flow varies with the seasons; 60 to 80 percent of it occurs in the summer months, when intensive thawing of snow and ice in the mountains is combined with maximum precipitation. In winter, the discharge of the rivers is extremely insignificant; in spring and autumn it is somewhat greater.

Glaciation. In spite of the great elevation, there is little glaciation in the Kunluns because of the extreme dryness of the climate; external snows persist only along the deep crevices of the highest peaks.

The main centres of glaciation, in which are found dozens of glaciers that are usually not more than six miles long, are the Kung-ko-erh, Mu-ssu-t'a-ko-a-t', Wu-lu-k'o-mu-shih, and Tyumenlik massifs, where elevations approximate about 23,000 feet. All the glaciers are notable for their unusual steepness, dropping 20 to 30 feet in every 100 feet of length.

Soils. Because the surface layer of the Kunluns does not receive moisture during a large part of the year, soil formation proceeds at a very slow rate. In general, the soils have little productive capacity, contain many coarse skeletal soil elements, and are almost devoid of humus. Brown soils appear only in the vicinity of the Pamirs and in the eastern Kunluns, where the moisture levels are better and vegetation richer.

Aridity and extremes of temperature

Climate. Located within the arid region of Central Asia, the Kunluns are almost totally isolated from the climatic influence of the Indian and Pacific Ocean monsoons. Instead, they are under the constant influence of the continental air mass, which causes great annual and daily temperature fluctuations. Desert yields to mountain steppes only near the Pamirs (King Ata Tagh) and the Tibetan mountains (Pa-yen-Fa-la Shan [Bayan' Kara-shan'l and the eastern Nan Shans), where the amount of annual precipitation increases to about 18 inches. In these areas, up to 80 percent of the precipitation falls in summer—an indication of its relationship with the monsoons.

In the high-altitude zone, with its extremely sharp daily fluctuations of temperature, weathering from heat and frost reaches great intensity, accounting for the presence of an enormous quantity of loose material. Wind erosion and accumulations of loose debris are very apparent on the Gobi slope of the peripheral ranges. Maximum aridity occurs in the middle segment of the mountain system, between 78° and 93" E; to the west and east, however, the climate is somewhat moderated. Characteristic of the Kunluns as well as of the entire arid region of Central Asia are the winds; the strongest of which occur in autumn, when they often reach gale intensity.

Scanty cloud cover and prolonged sunshine are also characteristic of the Kunluns. Naturally, the amount of warmth in the Kunluns varies with the altitude: in the lower tier of mountains, (those bordering the northern plains), the average temperature in June is 77° to 82" F (25" to 28° C) and not lower than 16" F (—9° C) in January; in the upper tier of mountains and on the border of Tibet, however, the average temperature in July is less than 50° F (10" C) and often falls to —31" F (—35° C) in winter. Summers in the lower belt are long and hot; in the upper belt, they are short and cold.

In the most arid part of the Kunluns, precipitation is less than two inches annually in the foothills and about four to five inches in the high altitudes. The climate of the lower tier is that of the hot, Gobi-type desert; of the upper belt, it is that of the cold, Tibetan-type desert. Associated with these, in turn, are accumulations of loess —fine, wind-blown material—that forms a cover on the dissected mountain relief and is found at altitudes up to about 13,000 feet.

Soil characteristics

Vegetation. Because of the primitiveness of the soil cover, the extreme deficiency of moisture, and, in the high altitudes, the insufficient warmth, the natural conditions of the Kunluns are not very favourable for plant growth. Plants have a stunted appearance and possess a number of distinctive physiological peculiarities. Most often they are perennial, dwarfish semi-shrubs with stiff leaves and deeply penetrating root systems. The number of species of plants is very limited, and the plant cover itself extremely thin.

In the most arid part of the Kunluns, desert-like conditions prevail at high altitudes. Only two types of landscape are to be seen—the hot desert of the lower part of the mountains and the cold desert of the Alpine region. In both zones, completely barren spaces predominate, alternating with small areas that support a thin plant cover.

In the western and eastern extremities of the mountain system, however, the higher moisture levels and richer vegetation are more conducive to the formation of more fertile soil. In these areas, the vertical zonality of the plant cover is more complex and includes zones that do not occur in those parts of the Kunluns that consist entirely of desert. In the middle-altitude region there is a zone of desert-like steppe (a grassy and almost treeless plain) in which there is a somewhat thicker plant cover as one proceeds upwards. Mountain steppes then emerge, as well as scattered forests, small at first but then larger. A well-developed forest zone, interspersed with mountain steppes and meadow sections, appears in the extreme west and the extreme east of the Kunluns.

Animal life. In the totally arid part of the Kunluns, animal life is meagre and has little variety; it becomes somewhat richer and more varied in the approaches to the Pamirs and in the eastern spurs of the system, where mountain steppe and forest vegetation appears. The predominant animal life in these areas consists of hoofed animals and rodents. Especially characteristic of hoofed animals are the mountain sheep (in the west the ***arkhar*** and in the east the ***kukuyaman*** type); the mountain goat; the wild ass; and the wild yak. The rodents are represented by mouse hare, field vole, and, on the meadowland slopes, marmot. Beasts of prey commonly found include wolf, fox, bear, and, in the west, snow leopard.

The human imprint. Most of the Kunluns is unpopulated; only the large river valleys, up to an altitude of about 10,000 feet, contain any inhabitants. Settlements become fewer deep in the mountains and nonexistent in the high-altitude zone and on the Tibetan slope. The Uigurs, the most numerous population group, are concentrated in large settlements in the foothills bordering the Tarim Basin; Tajiks live in the western and Mogols in the eastern mountains. Agriculture and small-scale, nomadic animal husbandry are the basic occupations of the mountain population. The main agricultural crops are wheat and barley; domestic animals that are bred include sheep, goats, and yaks.

Transport. Throughout their extent the Kunluns are almost impassable, because of their deep and narrow ravines, steep slopes, mountain passes of great height, and torrential streams. In addition, there is an absence of fuel facilities for vehicles and of forage for pack animals. Even the caravan trails are rare and difficult, especially in the highly eroded middle belt of the mountains.

Of the three automobile roads through the Kunluns, one proceeds along the southern edge of the Tarim Basin, partially using the ancient Silk Route that until the 16th century connected China with Central and western Asia. The other two roads, both of which lead into Tibet, cut across the Kunluns: the western road passes along the T'i-shih-yuëh-fu (Tiznaf), Yarkand (Raskem), and K'a-la-k'a-shih (Kara Kash) river valleys and the eastern road reaches Tibet by a route that extends from Ko-erh-mu (Golmo; in the Tsaidam Basin) to the upper reaches of the Yangtze River and then runs through the Ch'i-man Shan, the eastern spur of the Przhevalsky (Marco Polo Range) and the K'o-k'o-hsi-li (Kukushili).

Exploitation of mineral resources. Because the interior of the Kunluns has not been studied extensively, information about the mineral resources of this vast and geologically heterogeneous territory is extremely scant. Evidences of gold-bearing deposits have been found in various parts of the mountain system, and gold was extracted until the beginning of the 20th century, principally along the upper course of the Yu-lung-k'a-shih Ho (Yurung Kash). Nephrite (a type of jade) is widely distributed and has been extracted from rock deposits and river alluvium. There are well-known rock deposits of this mineral in the Karangutag Range, while alluvial deposits are found in the river valleys of the K'a-la-k'a-shih and Yu-lung-k'a-shih Ho (Yurung Kash). Small deposits of lead and zinc have been discovered at a number of points in the northern chain of the western Kunluns, while in the

K'a-la-k'a-shih Ho Valley, above Sai-t'un-la (Shakhidul-la), indications of tin-bearing deposits have been found. Deposits of iron and chromitic ores and evidence of copper mineralization have been located in the Nan Shan and A-erh-chin Shan-mo (Astin Tagh) ranges. Oil is recovered in the Tsaidam Basin, and there are extensive coal-bearing deposits in the intermontane depressions of the western and eastern Kunluns. Although coal is mined in many of these areas, it is on a small scale and solely for local needs.

The exploitation of the mineral resources of the Kunluns is hampered by the harsh natural environment, the great height of the mountains, difficulties of access, lack of water supplies, and scarcity of population. (V.M.S.)

Kurosawa Akira

The Japanese film director Kurosawa Akira has been counted among the world's most prominent directors since the 1950s. His pictures have extremely powerful images and sometimes imply a vigorous moral message. With the immense success of his motion picture *Rashomon* in 1950, Kurosawa attracted a widespread international audience to the Japanese film, which previously had enjoyed little attention outside East Asia despite the high quality and vast number of the industry's products. Although other Japanese film makers subsequently acquired substantial followings, Kurosawa's films continue to command the greatest interest in the West. They represent a unique combination of elements of Japanese art—in the subtlety of their feeling and philosophy, the brilliance of their visual composition, and their frequent use of samurai and other historic Japanese themes—with a distinctly Western feeling for action and drama and a frequent use of stories from Western sources, both literary classics and popular thrillers.

Kurosawa, 1961.

Assistant cinema director and scenario writer

Kurosawa was born in Tokyo March 23, 1910. His father, who had once been an army officer, was a teacher who contributed to the development of gymnastic education in Japan. After leaving secondary school, Kurosawa attended an art school and began painting in the Western style. Although he was awarded important art prizes, he gave up his ambition to become a painter and in 1936 became an assistant director in PCL cinema studio. Until 1943 he worked there mainly as assistant to Yamamoto Kajirō, one of Japan's major directors of World War II films. During this period Kurosawa became known as an excellent scenario writer. Some of his best scenarios were never filmed but only published in journals; yet they were noticed by specialists for their freshness of representation and were awarded prizes.

In 1943 Kurosawa was promoted to director and made his first feature film, *Sanshiro Sugata,* from his own scenario; this story of Japanese judo masters of the 1880s scored a great popular success. In 1944 he made his second film, *The Most Beautiful,* describing an episode of girls at work in an arsenal. Immediately thereafter, he married the actress who had played the leading part in the picture, Yoko Yaguchi; there were two children, a son and a daughter. In August 1945, when Japan offered to surrender in World War II, he was shooting his picture, *They Who Step on the Tiger's Tail,* a parody of a well-known Kabuki drama. The occupation forces, however, prohibited the release of most films dealing with Japan's feudal past, and this outstanding comedy was not distributed till 1952.

Kurosawa's *No Regrets for Our Youth* (1946) portrays the history of Japanese militarism during the period from 1933 through the end of the war in terms of a person executed on suspicion of espionage during the war. Of the many postwar films criticizing Japanese militarism, this was the most successful, both artistically and commercially. It was *Drunken Angel* (1948), however, that made Kurosawa's name famous. This story of a consumptive gangster and a drunken doctor living in the postwar desolation of downtown Tokyo is a melodrama in which desperation and hope, as well as violent action and melancholic atmosphere, are intermingled. The gangster was performed by a new actor, Toshirb Mifune, who became a star through this film and who subsequently appeared in most of Kurosawa's films.

Success of *Rashomon*

Rashomon (1950) was shown at the Venice Film Festival in 1951 and was awarded the Grand Prix. This was the first time a Japanese film had won such high international acclaim, and Japanese films now attracted serious attention all over the world. An adaptation of a short story written in 1915 by Akutagawa Ryūnosuke, the film deals with a samurai, his wife, a bandit, and a woodcutter in the 10th century; a rape and a murder are recollected by the four persons in distinctly different ways. This presentation of the same event as seen by different persons stimulated the imagination of the audience and advanced the idea of cinema as a means of probing a metaphysical problem.

Ikiru (1952) is regarded by many critics as one of the finest works in the history of the cinema. It concerns a petty governmental official who learns he has only half a year until he will die from cancer. He searches for solace in the affection of his family but is betrayed, then seeks enjoyments but becomes disillusioned, and, in the end, is redeemed by using his position to work for the poor. In this film, which abounds in strong moral messages, Kurosawa depicted in an extremely realistic manner the collapse of the family system, as well as the hypocritical aspects of officials in the postwar Japanese society. The picture was an outstanding document of the life and the spiritual situation of Japanese people, who were beginning to recover from the desperation caused by defeat in the war.

Seven Samurai (1954) is the most entertaining of Kurosawa's films and also his greatest commercial success. It depicts a village of peasants and a few leaderless samurai who fight for the village against a band of marauding bandits; although it was inspired by his admiration of Hollywood Western films, it was executed in an entirely Japanese style.

Record of a Living Being (1955) was a deeply honest film portraying the terror of a Japanese dentist of the atomic tests conducted by the United States and the Soviet Union; its pessimistic conclusion, however, made it a commercial failure.

Adaptations of European classics

Kurosawa was also noted for his adaptations of European literary classics into films with Japanese settings. *The Idiot* (1951) is based upon the Dostoyevsky novel of the same title, *The Throne of Blood* (1957) was adapted from Shakespeare's *Macbeth,* and *The Lower Depths* (1957) was from Gorky's drama; each of these films is skillfully Japanized. *The Throne of Blood,* which reflects the style of the sets and acting of the Japanese Nb play and uses not a word of the original, has been called the best film of all the countless cinematized Shakespearean dramas.

Kurosawa's pictures contributed a strong sense of style to the artistic Japanese film, which had been pursuing a naturalistic trend. The violent action of his more commercial works also exerted a powerful influence.

In 1960 he set up Kurosawa Productions, of which he became president, and began to produce his own works. As producer, however, he was continually embarrassed by economic difficulties. Throughout the 1960s, Kurosawa made a number of entertainment films, mainly with samurai as leading characters; Yojirnbo (1961) is a representative work. Red Beard (1965) combines the element of entertainment with a sentimental humanism. In the 1960s, however, Japanese cinema fell into an extreme depression, and Kurosawa's plans, in most cases, were found by film companies to be too expensive. As a result, Kurosawa attempted to work with Hollywood producers, but each of the projects ended in failure. At the Kyoto studio in 1968, for 20th Century Fox, he started shooting Tora, Tora, Tora!, a war spectacle film dealing with the air attack on Pearl Harbor. The work progressed slowly, however, and the producer, fearing an excess in estimated cost, dismissed Kurosawa and replaced him with another director. After a six-year interval, Kurosawa at last managed to present another of his films, Dodesuka*den* (1970); his first work in colour, a fantastic comedy of the poor people living in slums, it recaptured much of the poignancy of his best works.

MAJOR WORKS

Sanshiro *Sugata* (1943); ***Yoidore Tenshi*** (1948; Drunken Angel); ***Rashomon*** (1950); Hakuchi (1951; The Idiot); Ikiru (1952; Living); Shichinin no Samurai (1954; Seven Samurai); *Ikimono* no Kiroky (1955; Record of a Living Being); *Kumonosu-jo* (1957; The Throne of Blood); Donzoko (1957; The Lower Depths); Kakushi *Toride* no *San-akunin* (1958; The Hidden Forfress); Warzti Yafsu Hodo *Yoku* Nemuru (1960; The Bad *Sleep* Well); *Yojimbo* (1961); Tsubaki *Sanjuro* (1962; *Sanjuro*); Tengoku to *Jigoku* (1963; High and Low); Akahige (1965; Red Beard); Dodesukaden (1970).

BIBLIOGRAPHY. TADAO SATO, Kurosawa Akira no sekai (1969), the only book written in Japanese investigating carefully all the works of Kurosawa from the scenarios in his assistant days before he became director to his 1965 work, Red Beard; Complete Works of Akira Kurosawa, 5 vol. (1971), an incomplete compilation of the works of Kurosawa into books with Japanese and English scenarios and stills; DONALD RICHIE, The Films of Akira Kurosawa (1965), an excellent study (in English) written by an acquaintance of Kurosawa who is quite familiar with the language and people of Japan; SACHA EZRATTY, *Kurosawa* (1964), a study (in French) that attempts to place Kurosawa's works in the tradition of Japanese culture.

(T.S.)

Kuwait

Kuwait is an independent Arabian state, lying at the upper corner of the Persian Gulf and having an area of 6,880 square miles (17,818 square kilometres). It is bounded on the west and north by Iraq, on the east by the Persian Gulf, and on the south by Saudi Arabia. Its population in 1972 was estimated at 815,000.

Kuwait is largely a desert, except for al-Jahrah Oasis and a few fertile patches in the southeastern and coastal areas. The largest offshore islands are the uninhabited islands of Būbiyān and al-Warbah. The island of Faylakah, near the entrance of Kuwait Bay, has been populated since prehistoric times. The other islands, Umm an-Naml, Mischan, 'Awhah, al-Kubr, Qārū, and Umm al-Marādim, are small specks of uninviting sand. On some of them, police outposts are stationed; others are occasionally visited by fishermen.

The capital city of Kuwait, a true desert metropolis of 80,000 persons (1970), is located on the southern shore of Kuwait Bay and derives its name from the diminutive of kat, meaning "fort." It is the most important city, even though the suburb of Hawalli is now larger in population, with 107,000 persons (1970). Most of the population of the country is concentrated in the cities. Overall, Kuwait is one of the world's most highly urbanized states.

Oil dominates the economy of the country. Kuwait is the fourth largest oil producer in the world after the United States, the Soviet Union, and Venezuela and the second after Venezuela in the quantity of exported oil. It also ranks first among the producing countries in oil reserves.

Kuwait, Area and Population

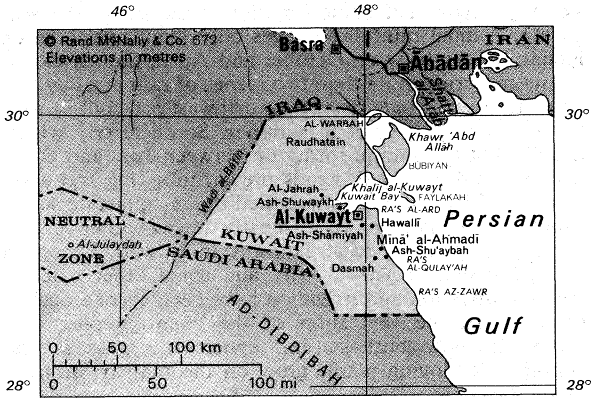
History. The origin of the city of Kuwait—and of the State of Kuwait—is usually placed at about the beginning of the 18th century, when a number of families of the 'Anizah tribe in the interior of the Arabian Peninsula abandoned nomadism and migrated to the shores of the Persian Gulf. The foundation of the autonomous sheikhdom of Kuwait is dated from 1756, when the settlers decided to appoint a sheikh from the aṣ-Ṣabaḥ family.



KUWAIT

British protectorate

Kuwait first came to the attention of the great powers toward the end of the 19th century, at the time that Germany sought to extend the Berlin-Baghdad Railway to the port of Kuwait. Great Britain, eager to frustrate Germany's designs, and Kuwait's ruling sheikh, desirous of protecting himself against the Ottoman Empire's nominal suzerainty, concluded an agreement in 1899 whereby Britain assumed control of Kuwait's foreign affairs. Following the outbreak of war with the Ottomans in 1914, Britain established a protectorate over Kuwait.

Relations with Najd (later Saudi Arabia) were settled by the Treaty of al-'Uqayr (1922), which involved the creation of the compromise Neutral Zone. The northern frontier with Iraq was agreed upon in 1923.

On June 19, 1961, the British government announced its recognition of the full independence of the sheikhdom, and six days later the Iraqi prime minister claimed Kuwait as an integral part of Iraq, his argument being that Kuwait had been a part of the Ottoman Empire and that ethnically, geographically, and socially Kuwait and Iraq were one country that had been arbitrarily divided by Britain. Threatened with invasion, the ruler of Kuwait appealed to Britain for military aid. In early July, British troops landed in Kuwait, and on July 20 the Arab League admitted the sheikhdom to its membership, thus recognizing its independence and refusing to admit the Iraqi claim. Almost two years later, on May 14, 1963, Kuwait was admitted to the United Nations. Relations with Iraq meanwhile improved, and in October 1963 Iraq recognized Kuwait's independence. Today Kuwait is ruled by a sheikh who currently is both head of state and prime minister; under him is a cabinet of 14 ministers (ten appointed and four elected). Under the constitution

Government of independent Kuwait

framed in 1962 the suffrage was extended to all natural-born, literate Kuwaiti males over 21. The ruler promulgates laws and decrees, and the assembly of 50 members also has some legislative power. The state is divided into three governorates: Kuwait, al-Ahmadi, and Hawalli.

The landscape. *Topography and climate.* The topography of Kuwait and the Neutral Zone is generally flat or gently undulating, broken only by occasional low hills and shallow depressions. The elevations range from sea level in the east to nearly 1,000 feet in the southern corner of the country. The Jāl az-Zawr escarpment, one of the main topographic features, borders the northwestern shore of Kuwait Bay and rises to a maximum height of 475 feet above sea level. Elsewhere in coastal areas large patches of salty marshland have developed. Throughout the northern, western, and central sections of Kuwait there are desert basins called playas, which fill with water after winter rains, forming important watering places for the camel herds of the Bedouins.

The climate is semitropical, tempered somewhat in the coastal regions by the warm waters of the gulf. If there is enough rainfall, the desert turns green from the middle of March to the end of April. But during the dry season, between April and September, the heat is severe—the temperature ordinarily reaching 125" F (52" C) during the day and on occasion going as high as 165" F (74" C). The winter is more agreeable (even frost can occasionally occur in the interior, though never on the seacoast). Annual rainfall averages only from one to seven inches, chiefly between October and April, though cloudbursts can bring more than two inches of lain in a day.

The frequent winds from the northwest are cool in winter and spring and hot in summer. Southeasterly winds, usually hot and damp, spring up between July and October; hot and dry south winds prevail in spring and early summer. Fierce dust storms called the *tauz,* lasting sometimes for several days, occur mostly during winter.

True soils scarcely exist naturally in Kuwait. Except in the green belt of Kuwait city and some other patches, where cultivation and irrigation have been carried out for some years, the vegetation of the country consists of scrub and low bushes (and ephemeral grass in the spring). Salt-loving plants grow on the marshy stretches along the coast.

The old city. The old city of Kuwait thus was and is located on one of the harshest spots on the earth's surface. And it is the exploitation of oil that has given rise to an extraordinary metropolis that could never have grown so rapidly under normal conditions.

Nature of the old city

The old city of Kuwait---oriented toward the sea and bounded landward from 1918 to 1954 by a mud wall, with gates that led out only into the endless desert—was compact, only five square miles in area, its typical dwelling a courtyard house. Approaching the city by sea or desert route one could see in the distance a typically Arabian desert city. Although large parts of Kuwait have today changed radically, there are still quarters in old Kuwait that have not been disturbed, giving a true picture of urban conditions before the discovery of oil. The old city, referred to as ad-Dirah in Arabic, was like a huge apartment dwelling, its bazaars a huge department store, its alleys and streets an interesting network of highways. Its courtyards were centres for family socialization, industry, and relaxation. The culture was one of a seafaring, desert-daring, pearl-diving patriarchal society guided by the main driving force of the Arab—his Islāmic religion. Some Kuwaits can still remember the days when drinking water was imported by barge from Iraq.

Modern Kuwait. Today Kuwaitis drink distilled seawater and live and work in air-conditioned surroundings. In and around the city are schools, hospitals, and tall office buildings. There is planning for still further expansion of public and civic facilities. Engineers, doctors, contractors, and merchants from every corner of the earth can be seen busily at work in Kuwait. It is a booming city, a mushrooming city. Behind all this dynamism is oil.

Up to 1951 Kuwait city consisted of little more than the area enclosed within the semicircular city wall built in 1918. With the urban explosion of the years after 1951, the wall was demolished and new suburbs were formally laid out. Within these suburban blocks, building plots of 8,100 and 11,000 square feet were allocated to Kuwaiti citizens who had been displaced from the old city then in process of radical redevelopment. This left the growing non-Kuwaiti population the choice between living within the old city or living in one of the two more freely developing suburbs of Hawalli and as-Siilimiyah.

Urbanization and suburbanization

The results of this sorting process can be witnessed today, two distribution patterns being clearly visible. Kuwaitis are scattered at a relatively low density (16,000–18,000 persons per square mile) throughout the urban area, with minor concentrations in the new suburbs of Dasmah, ash-Shiimiyah, and al-'Idayliyah. On the other hand, non-Kuwaitis, excluded from the restricted suburbs, live at higher densities of between 21,000 and 31,000 persons per square mile in the old city and the suburbs of Hawalli and as-Siilmiyah—mostly in flats and apartments. Strong demographic and geographic contrasts have been introduced by the large-scale influx of migrants in recent years. In Kuwait today there is a veritable cosmopolitan mixture, each ethnic group adding colour and contribution to the fast-changing urban prospects and aspects of the country. A 1961 census of foreigners living in Kuwait showed 27,000 Iraqis, 18,000 Iranians, 31,000 Jordanians, and large numbers of Saudi Arabians, Indians, Pakistanis, and Lebanese. There were approximately 3,000 Britishers and a colony of 400 Americans. The major local firms have lndian or Pakistani clerks and Saudi Arabian, Iraqi, or Iranian workers. The 1970 census indicates a total of about 390,000 foreigners living in Kuwait. Although presumably many of the unskilled foreign construction workers will leave the country as major projects are completed, there are no signs yet of a letup in Kuwait construction programs, and thus there have been few departures of foreign workers. Both working conditions and wages are superior in Kuwait as compared with surrounding countries. Many of the foreign personnel and almost all of the Anglo-Americans are connected with either the oil companies or the government industrial development projects. It is a fair assumption that the population will continue to expand.

Development of oil production

The national economy. In 1934 the Kuwait Oil Company, the ownership of which is divided equally between the British Petroleum Company and the Gulf Oil Corporation (of the United States), obtained a concession covering the whole territory except the Neutral Zone. Oil was struck in 1938, but World War II deferred development until 1946. Thereafter, progress was spectacular. In 1953 the American Independent Oil Company and the Getty Oil Company, which jointly held concessions for the Neutral Zone, struck oil in commercial quantities; and in 1955 oil was discovered in northern Kuwait. European and Japanese companies operate offshore oil concessions. By 1971 total Kuwaiti production was over 1,000,000,000 barrels annually.

More than 90 percent of the income of the government of Kuwait is derived from royalties on the production of oil. Oil production accounts for roughly 57 percent of the country's gross national product—the remainder consisting largely of services dependent upon the flow of income from oil. Employment generated directly by oil production and export, however, accounts for 3.1 percent of the labour force. The government is now planning to spend about 18.5 percent on production sectors (oil and natural gas, industry, agriculture and animal husbandry, and fishing); almost 32 percent on the physical infrastructure (water and irrigation, power, transport, and communications); about 19.5 percent on housing and public buildings; about 22 percent on social, administrative, and commercial services (education, research, information, commerce and tourism, health, religious services, and social welfare); and the balance of about 8 percent on the build-up of commodity stocks.

The low cost of oil production in Kuwait stems from certain unique advantages. First, there are some 50 highly productive wells, whose output can be varied at short notice, thus eliminating the need for large numbers of storage tanks. Most of the storage tanks themselves are placed on a ridge set back a few miles from the seacoast at a height of some 300 feet; this enables loading operations to be carried out by gravity and not through the use of pumps; apart from the obvious savings, this promotes higher loading rates. There are also extensive refineries and bunkers for tankers.

Natural gas and other industries

Massive volumes of natural gas are produced in association with crude oil. Although this natural resource has great potential as a source of foreign exchange, its principal uses so far have been in re-injection in oil fields to maintain pressure, in the generation of electricity (as for water distillation), and in the production (as raw material) of petrochemicals and fertilizers. Other new industries in Kuwait include the production of cement, dry-cell batteries, electric cables, plastic tubes, woollen blankets, confectioneries, paints, liquid gas, and lime bricks. Most of these industries are of small size.

Under construction is ash-Shu'aybah Industrial Area, which is already provided with such facilities as roads, a harbour, gas, power, and water. There is also the National Fisheries seafood packing plant, ammonia and urea plants, a petrochemical complex, and a cement factory. Under consideration by ash-Shu'aybah Industrial Development Board are projects for the construction of a workers' town, a dry dock for the repair of ships, and a plant for liquefaction of natural gas.

Except for oil, there is scarcely any usable natural resource in Kuwait, at least none that is known. There are no other minerals, and even the large expanses of sand, being very solid, are not economically exploitable. The soil is very poor, and fresh water is almost nonexistent. Generally, Kuwait awaits further detailed geologic and stratigraphic studies to determine whether or not anything more fruitful can be extracted.

The government encourages the development of industry by granting land at nominal rent, by subsidizing key inputs like the production of electricity and water, by offering exemptions from customs duty, tariffs, and import controls, by providing loans at low interest rates, by providing capital in exchange for owners' shares, by training labour, and by conducting technical studies designed to devise ways and means of increasing productivity. This all-out government policy to accelerate industrialization has begun to show results. But despite whatever strides in industrialization Kuwait may eventually achieve, it seems unlikely that manufacturing will ever account for more than a small proportion of the total domestic output. The difficulties of a small market and a lack of raw materials and manpower obviously limit the scope for industrialization.

The possibilities of agricultural development, as already intimated, are severely limited. Only about 3 percent of the land is at all arable; and owing to the scarcity of water, deficiencies of soil, and lack of manpower trained in agricultural skills, barely 1 percent of the land area is under actual cultivation. Agriculture in Kuwait has remained a marginal activity. Its contribution to the output of the economy is insignificant at about 0.2 percent.

Fish are plentiful in the Persian Gulf, and in pre-oil days, fishing in Kuwait was a leading and flourishing industry. It is assuming more importance again and is one of the sectors planned to play a significant role in the country's drive for diversification. At present there are four major Kuwaiti fishing companies primarily engaged in exporting shrimp to Europe and the United States.

Water and power

For fresh water, in earlier days, people depended on a few artesian wells and on rainwater collected from the roofs of houses or from cisterns at ground level. Dhows manned by Kuwaiti seamen also brought fresh water from Shatt al-Arab near Basra, Iraq. With the rapid growth of population, however, the government of Kuwait built a seawater distillation plant at ash-Shuwaykh. Its progressive expansion now makes it the largest distillation plant in the world, producing up to 10,000,000 gallons daily.

The expansion of electric facilities has also been remarkable. Production is now concentrated in two large steam-power stations, one at ash-Shuwaykh and the other at ash-Shu'aybah, both fired with natural gas.

Aspects of Kuwaiti society. Unlike most Arab societies, Kuwaiti society was traditionally a compact, united, and virtually classless society. The whole population, to all intents and purposes, constituted one big family. This aspect could be attributed to many factors: (1) the small size of the original city of Kuwait, which made segregated living impossible; (2) the small population, which restricted one's circle of friends and companions; (3) the absence of non-Arab influence in Kuwait, which rendered the class concept incomprehensible; (4) the absence of agriculture and thus of hierarchies based on land ownership; (5) the influence of tribal relations and tribal pride, which tended to deny the importance of the unequal distribution of money and property. For these and other less defined reasons, a definite class system, with all its traditions and conventions, has never developed in Kuwait.

Social welfare services

Today there has arisen a comprehensive scheme of social welfare covering most of the misfortunes that might befall Kuwaiti citizens. For the needy there is financial assistance; for the handicapped there are loans to start a profitable business; for the invalid and deformed there are treatment and training; for the adult illiterates there is education; and for those of limited income there is comfortable housing.

A huge program called the Limited Income Housing Scheme to provide adequate houses, fully equipped with modern facilities, for limited income families has been one of the great cares of the Ministry of Social Affairs and Labour ever since it was entrusted with the task in 1962. About 2,000 new houses every year are contemplated to meet the increasing demand by eligible families.

There are also educational centres, where adults who grew up before the emergence of Kuwait's educational boom are not only taught to read and write but are also prepared for useful careers. General education in Kuwait is entirely free and includes not only tuition but also school meals, books, uniforms, transportation, and medical attention. The educational services provided by the state are arranged in five stages: kindergarten, elementary school, intermediate school, secondary school, and university. Kuwait university was founded in 1962.

The overwhelming majority of the population of Kuwait is Muslim, although there is a large group of Hindus as well as some Christian Arabs and Europeans. Full freedom of religious belief is guaranteed by the constitution.

The native and official language is Arabic. English is the second basic language taught in public schools. Hindi, Urdu, and Persian languages are also prevalent.

The Ministry of Guidance and Information is the principal organ of publicity, enlightenment, and information. It runs the government press and the radio and television broadcasting stations. In 1958 it began to publish *al-'Arab?,* the national and international Arabic monthly, now the largest selling magazine of any sort in the Arab world, with an average monthly circulation of about 125,000. The same ministry has also undertaken the great task of reviving some of the outstanding literary works in Arabic, in the "Arab Heritage" series.

Kwangsi

The Kwangsi Chuang (Guang-xi Zhuang-zu in Pin-yin romanization) Autonomous Region is located in southern China. It is bounded by the Chinese provinces of Yunnan on the west, Kweichow on the north, Hunan on the northeast, and Kwangtung on the southeast, and by North Vietnam and the Gulf of Tonkin on the southwest. It covers an area of 92,700 square miles (240,100 square kilometres), and in the early 1970s had an estimated population of 24,000,000. Nan-ning, the capital, is about 75 miles southwest of the region's geographic centre.

The name Kwangsi dates back to the Sung dynasty (960–1279), when the region was known as Kwang-nan Hsi-lu, or wide south, western route (western half of all territory south of the Nan Ling [Nan Mountains]). The Yuan dynasty (1279–1368) contracted the name to Kwangsi when it created a province out of the western half. In 1958 the People's Republic of China transformed the province into the Kwangsi Chuang Autonomous Region—a step designed to help foster the cultural autonomy of the Chuang people, who constitute the largest minority living in the region.

Under the People's Republic, the region has made considerable progress in its economic development. Dams, canals, and reservoirs have been built to help irrigate dry lands; and hydroelectric stations have been constructed and mineral resources exploited to stimulate modern industry. Rural industries have been developed in an effort to diversify village economy. Kwangsi has become self-sufficient in rice and, in fact, exports surplus rice to Kwangtung. This economic growth has given the region new strength and unity. For a related physical feature see HSI CHIANG (RIVER).

History. *Early history.* Kwangsi was known as the land of Pai Yiieh (the Hundred Yiieh—referring to the aborigines of South China) during the late Chou dynasty from *c.* 453–221 BC. A subgroup of the Tai people, known as the Chuang, inhabited the region and had an economy based on wet (grown under irrigation) rice. Eastern Kwangsi was conquered by the Chinese, or Han, people in 214 BC under the Ch'in dynasty, and the Ling Ch'ü (canal) was dug to link the Hsiang Chiang (Hsiang River) and the Kuei Chiang to form a north–south waterway.

The invasion of the Chinese

An independent state known as Nan Yiieh (South Yiieh), was created by Gen. Chao T'o, with Chuang support, at the end of the Ch'in dynasty and existed until it was annexed in 112–111 BC by the Han dynasty (206 BC–AD 220). The Chinese rulers reduced the power of the Chuang people by consolidating their own control in the areas surrounding the cities of Kuei-lin, Wuchow, and Yü-lin.

In AD 42 an uprising in Tonkin was quelled by an army under Gen. Ma Yüan, who not only sought victory on the battlefield but also showed concern for the well-being of the people. He reorganized Kwangsi's local government, improved public works, dug canals, and reclaimed land to increase production. Temples erected to his memory can still be seen in many places.

From the end of the Han to the beginning of the T'ang dynasty (618–907), the influx of Yao tribes from Kiangsi and Hunan added to racial tensions in Kwangsi. Unlike the Chuang, the Yao resisted Chinese culture. The hill country of Kuei-p'ing, Chin-hsiu, and Hsiu-jen in central eastern Kwangsi (the Ta-yao-shan Yao Autonomous Hsien) where they settled became a centre of chronic unrest. In subsequent dynasties there were further migrations of the Yao from Hunan and Kweichow provinces.

Under the T'ang dynasty, Kwangsi became a part of the Ling-nan Tao (large province). The noted scholar Liu Tsung-yüan was prefectural administrator at Liu-chou. Irked by Chinese expansion, however, the Chuang people moved to support the Tai kingdom of Nanchao in Yunnan. Kwangsi was then divided into an area of Chuang ascendancy west of a line from Kuei-lin to Nan-ning and an area of Chinese ascendancy east of the line. After the fall of the T'ang, an independent Chinese state of Southern Han was created, but it was liquidated by the Sung dynasty in 971.

The Sung dynasty, which lasted until 1279, governed Kwangsi by the alternate use of force and appeasement—a policy that neither satisfied the aspirations of the Chuang nor ended the savage warfare waged by the Yao against the Chinese. In 1052 a Chuang leader, Nung Chih-kao, led a revolt and set up an independent kingdom in the southwest. The revolt was crushed in 1053, but the region continued to seethe with discontent. The Yüan dynasty (1279–1368) imposed direct rule and made Kwangsi a province, but relations between the government and the people did not improve. To further complicate race relations, still another aboriginal people—the Miao—migrated from Kweichow, and additional Chuang also came from Kiangsi and Hunan.

Independent Chuang kingdom

Confronted with a complex situation, the Ming dynasty (1368–1644) actively promoted military colonization in an effort to undermine the tribal way of life. It governed the minority peoples through the hereditary *t'u-ssu* (tribal leaders serving as the agents of Chinese government). This led to some of the bloodiest battles in Kwangsi history—notably, the war with the Yao tribesmen at Giant Rattan Gorge, near Kuei-p'ing, in 1465.

The Chi'ng (Manchu) dynasty (1644–1911) placed the minorities under direct imperial rule in 1726. This, however, did not bring peace. Following a Yao uprising in 1831, the great Taiping Rebellion broke out in 1850—again near Kuei-p'ing and under minority leadership—lasting for over a decade.

Meantime, the execution of a French missionary in western Kwangsi led to an Anglo-French War against China that was concluded by the humiliating treaties of Tientsin in 1858. Then, following the Sino-French War of 1884 to 1885, French supremacy in Vietnam exposed Kwangsi to foreign encroachment. Lung-chou was opened to foreign trade in 1889, Wuchow in 1897, and Nan-ning in 1907; while in 1898 France obtained a sphere of influence which included Kwangsi.

Foreign encroachment

The *revolution.* Together with neighbouring Kwangtung, Kwangsi in the early years of the 20th century became the base of the nationalist revolution led by Sun Yat-sen (*q.v.*). Between 1906 and 1916, the provincial leaders of Kwangsi supported the establishment of a republic, and during the following decade played an active role in the reorganization of the Kuomintang (the Chinese Nationalist Party). Following the rise of Chiang Kai-shek (*q.v.*) to power in 1927, the Kwangsi leaders (notably Li Tsung-jen and Li Chi-sh'en) formed the Kwangsi Clique in opposition to Chiang. The group did much to modernize Kwangsi, but maintained a defiant posture against the central government. Although Chiang crushed their revolt in 1929. he was unable to end the semi-independent status of the region. The Chuang, on their part, formed a string of revolutionary soviets (elected Communist organizational units) between 1927 and 1931 that gave rise to new Communist leaders.

During World War II, Kwangsi was a major target of Japanese attack. The Japanese invaded southern Kwangsi in 1939 and occupied Nan-ning and Lung-chou. In this period, Kuei-lin became the principal base for the Chinese and Allied air forces, as well as the home of the patriotic press, the National Salvation Daily News. In 1944 the Japanese made a determined drive into Kwangsi; although they briefly took Kuei-lin, Liu-chou, and Wuchow, they were unable to maintain their position. Chinese forces subsequently recaptured the major cities. In the civil war that followed World War II, the Chinese Communist forces took Kuei-lin in November 1949 and declared Kwangsi a province of the Chinese People's Republic.

The landscape. *Relief.* Kwangsi forms a tableland that descends in elevation from the north and northwest to the south and southeast. Elevations between 3,000 and 6,000 feet above sea level are reached at the edge of the Yunnan-Kweichow plateau in the northwest, the Chiu-wan Shan (Chiu-wan Mountains) and the Feng-huang Ling (Feng-huang Mountains) in the north, and the Mao-erh Ling in the northeast. The greater part of the region is composed of hilly country lying at a height of between 1,500 to 3,000 feet. In the west, the Tu-yang

Shan rises to 6,500 feet. In the southeast, lowlands are situated at a height of between 300 and 1,500 feet.

The predominance of limestone gives many parts of Kwangsi a spectacular type of landscape, known to geographers as "karst," in which pinnacles and spires, caves and caverns, sinkholes, and subterranean streams abound. Picturesque rocky hills, spires of grotesque proportions, strangely shaped caves, and all manner of stalactites and stalagmites are to be seen in many different parts of this region.

The Hsi Chiang Basin

Drainage and soils. The Ch'in Chiang (Ch'in River) and the Nan-liu (or Lien) Chiang flow into the Gulf of Tonkin. The headwaters of the Hsiang Chiang flow into Hunan Province. The remainder of the region's numerous rivers—including the Hung-shui Ho, the Lui Chiang, Ch'ien Chiang, the You Chiang and Tso Chiang, the Yii Chiang, the Hsiin Chiang, the Meng Chiang, the Jung Chiang, and the Kuei Chiang—follow the general southeastward slant of the terrain. They rise from a profusion of sources and flow into one another in a succession of convergences until they merge into one giant river, the Hsi Chiang (*q.v.*). This mighty river rises in Yunnan Province and cuts across the entire width of Kwangsi before emptying into the South China Sea near Canton in Kwangtung Province.

The hilly areas are composed of red soil, while the lowlands are characterized by alluvial soil brought down by the many rivers.

Climate. Throughout the region, temperatures are warm enough to assure agricultural production throughout the year. The summer, covering a seven-month period from April to October, is marked by enervating heat and high humidity. Winters are mild and snow is rare. July temperatures vary between 80" F (27" C) and 90" F (32" C), while January temperatures range between 40" F (4° C) and 60" F (16" C). The north experiences slightly cooler temperatures than does the south.

Because of the influence of the rain-bearing monsoon wind, which blows from the south and southwest from late April to the end of September, precipitation is abundant; the drier areas are in the northwest, and the wetter areas in the south and east. The average annual rainfall varies from 35 inches in the drier areas to 68 in the wetter zones. Most of the precipitation occurs in the period between May and August. In the extreme south, rain bursts caused by typhoons occur between November and February.

Vegetation and animal life. Stands of fir, red pine, cedar, camphor, and rosewood are found in the north and west; oranges grow in profusion in the south; while the cassia tree, anise, and betel nuts flourish in many parts of the region. In central and south Kwangsi, many denuded hillsides have been taken over by tall coarse grasses, which are used for fuel or as pasturage for young water buffalo. Prominent types of wild life include the bison, boar, bear, gibbon (a kind of ape), hedgehog, and cockatoo.

Population. Demography. The population numbered 19,561,000 in 1953 and reached an estimated 24,000,000 in 1970. The average population density in 1953 was 230 per square mile but was unevenly distributed. Approximately two-thirds inhabit the eastern third of the region, while only one-third occupies the remainder of the territory to the west.

The Chuang, Yao, Miao, and T'ung peoples

Ethnic groups. The population in the early 1970s included over 14,500,000 Han or Chinese, 8,500,000 Chuang, 660,000 Yao, 250,000 Miao, and 200,000 T'ung. The Chuang were found largely in the western two-thirds of the region, while the Chinese were concentrated in the eastern third. Two distinct Chinese linguistic influences are noted—a southwest version of Mandarin is spoken in the Kuei-lin district in the northeast as well as in the north, while Cantonese is spoken throughout the remainder of the region. The Yao, Miao, and T'ung settlements are widely scattered.

The Chuang are a Tai people, who have inhabited Kwangsi since classical antiquity. Living on the plains and in the river valleys of the hilly west, they cultivate wet rice in paddy fields and practice an economy that easily merges with that of the Chinese. They are often referred to as "water dwellers" because their settlements are close to water and their dwellings are constructed on piles or stilts. For two millennia, the Chuang have coexisted with the Chinese; together they constitute the two largest racial groups in Kwangsi. The Chuang have absorbed Chinese culture, speaking both their own dialects and Cantonese. Under the People's Republic, a written Chuang alphabet has been created.

The origins of the T'ung are not clear, but they are generally considered to be a branch of the Chuang. They, too, have absorbed Chinese culture despite the fact that they live in the high mountains close to the Kweichow border to the north. The Miao and the Yao, however, have long resisted the absorption of Chinese culture. They belong to a separate linguistic branch of the vast Sino-Tibetan language family. Their dialects are marked by tribal variations and contain many words borrowed from Chinese and Tai. Neither the Miao nor the Yao dialects were written until alphabets based on adaptations of the Latin script were introduced in the late 1960s.

Upland dwellers who suffer from a scarcity of arable land, the Miao and the Yao practice subsistence agriculture. Characteristically, the Miao–Yao settlements are removed from transportation routes and are walled for defense. Besides farming and lumbering, which form the basis of their economy, the Yao make charcoal and bamboo basketry.

The region's cities

Urbanization. Although urbanization is proceeding slowly throughout Kwangsi, the region has many important cities. The capital city of Nan-ning, situated on the upper Yii Chiang and served by the Hunan–Kwangsi railroad, is the major city and industrial centre of the southwest. Kuei-lin, on the upper Kuei Chiang in the northeast, has a long history as the region's political and cultural centre; it is now a leading educational and commercial centre. In the north, Liu-chou is a hub of water and rail transport as well as the trading centre for the region's lumber and forest products and a burgeoning industrial area. Wuchow, in the southeast, is the gateway to trade along the Hsi Chiang and is also important industrially. Pei-hai (or Pakhoi), on the Gulf of Tonkin, has an excellent harbour; some of its commercial prosperity is attributable to the pearl trade of the nearby town of Ho-p'u. Located near the southern terminus of the Hunan–Kwangsi railroad, P'ing-hsiang guards the Vietnamese frontier and is also a major centre of regional and international trade.

Smaller important cities include Hsing-an, the site of the Ling Ch'ii (canal) connecting the Kuei Chiang and the Hsiang Chiang; Kuei-p'ing (or Hsün-chou), at the confluence of the Ch'ien Chiang and Yü Chiang; Yü-lin, on the Lit'ang–Chan-chiang railroad; Kuei-hsien, situated where the Lit'ang–Chan-chiang railroad crosses the Yii Chiang; and Li-t'ang, a booming town at the junction of the Hunan–Kwangsi and Lit'ang–Chan-chiang railroads. The city of Pai-se, formerly a transshipment point for goods moving to and from Yunnan, is a thriving industrial town.

Administration. Government structure. The region's administration is organized in a series of hierarchical levels. The top is the provincial level, directly under the central government in Peking. Below the top level are the six municipalities (shih) of Nan-ning, Liu-chou, Kuei-lin, Wu-chou, P'ing-hsiang, and Pei-hai, and the eight special districts (*chuan-ch'ü*) of Nan-ning, Pai-se, Liu-chou, Kuei-lin, Ch'in-chou, Wu-chou, Yü-lin, and Ho-ch'ih. Below these are 72 counties (hsien) and eight autonomous counties (tzu-chih-hsien). The lowest administrative units are the communes and towns.

People's congresses and councils

People's congresses are the organs of government authority at all levels. The deputies of the communes and towns are chosen by direct vote, but all other deputies are elected indirectly by the people's congresses to the next higher level. The executive functions of government are performed by people's councils, elected at each level by their respective people's congresses. The chairman of the Region's People's Council (or the Revolutionary Committee since the reorganization of the Council during the Cultural Revolution) is the governor of the region. The Communist Party, with its own congresses and committees at every level, exercises a controlling power over the government. The party supervises the nomination of candidates, and no more than one list of candidates is voted upon. Many positions are held by party members; and party cadres, or trained personnel, are attached to all levels of government.

Minority policy. The People's Republic attaches great importance to the treatment of national minorities and promotes the local autonomy of the Chuang, the Yao, the Miao, and other ethnic groups in an announced effort to assure their equality in an atmosphere of interracial cooperation. At the same time, while minorities enjoy cultural autonomy, minorities are required to participate in the nationwide Socialist transformation, especially at the lower levels of government.

Social conditions. ***Health services.*** Since the 1950s, Kwangsi has made impressive progress in public health and medicine. Such widespread diseases as malaria, smallpox, measles, and schistosomiasis (a parasitic infestation of the bladder or intestines) have been brought under control. The addition of iodine to water has ended the once-frequent occurrences of goitre, and the liver-fluke disease has been overcome by filling in old canals that were sources of infection and digging new ones. There is also a mass program to combat leprosy.

Clinics providing free medical care are available in the communes, but hospitals are found only in the major cities. The policy of "walking on two legs "—*i.e.*, using indigenous drugs and traditionally trained doctors to compensate for the shortage of Western medicine—has been promoted. Acupuncture—the practice of puncturing the body with gold or silver needles—is used extensively for the treatment of tumors, wounds, rheumatism, and arthritis.

Education. The educational system is directed toward raising the cultural level of the people and training technical personnel. Children from three to seven years of age attend nursery schools and kindergartens. Those from the ages of seven to 13 attend primary schools, which are run by production brigades in rural areas and by street committees in the cities. Upon entering the middle schools, all students are required to work and study at the same time; the curriculum stresses proletarian ideology, physical training, and science. The junior and senior middle schools cover three years each. Not all graduates from the junior middle schools enter the senior middle schools; many enter specialized technical schools or teacher training schools. In the 1960s there was a notable expansion in the number of agricultural middle schools and of industrial schools providing vocational-technical education.

Admission to higher education is based on entrance examinations. Since the Cultural Revolution of the late 1960s, students from peasant, worker, or soldier families have been accorded priority in college admissions. The work–study principle is also applied to higher education. Institutions of higher education include the Kwangsi Normal College at Kuei-lin, as well as the Kwangsi Agricultural Institute and the Kwangsi Medical College, both at Nan-ning. The Kwangsi Provincial Museum and the Provincial Library of Kwangsi are located in Kuei-lin.

National minorities education

A special educational feature is the program for the education of national minorities. Minority languages are used for instruction in primary and middle schools, written scripts are developed for spoken minority languages wherever needed, minority teachers are trained, and government subsidies are provided for minority students. The Institute for Minorities in Nan-ning trains both intellectuals and technical specialists of minority descent to work among the minority peoples below the county level.

Social services. A basic minimum of social welfare is available. Welfare funds of the communes guarantee care for the sick, disabled, and aged, and provide relief in times of drought or flood. For industrial workers, there are accident prevention and insurance programs that provide for hospital treatment, sick leave, disability compensation, maternity leave, old-age benefits, and death benefits. The government has been improving housing, expanding recreational facilities, and providing public-health centres.

The economy. ***Agriculture.*** Little more than 12 percent of the region is under cultivation. Agriculture is concentrated in the river valleys and on the limestone plains. The hillsides are terraced wherever feasible. Since the 1950s, the government has been seeking to bring new land under cultivation and to increase the yield of areas already cultivated.

Major food crops include rice, corn or maize, wheat, and sweet potatoes. The leading commercial crop is sugarcane; other important commercial crops include peanuts, sesame, ramie or China grass, tobacco, tea, cotton, and indigo. Kwangsi is also a rich producer of fruits—notably pomelos (a kind of grapefruit), tangerines, mandarin oranges, lemons, litchis (the fruit of a plant of the soapberry family), pears, papayas, bananas, and water chestnuts.

The raising of livestock in Kwangsi is ancillary to farming. Water buffalo are used as draft animals in the paddy fields. Pigs, chickens, and ducks are raised on farms and goats are raised in the hills. In many areas, silkworms are raised on mulberry leaves.

Fishing. Fishing is extensive. Both inshore and deep-sea fishing are carried on in the Gulf of Tonkin. Catches include croaker (a fish that makes a croaking noise), herring, squid, prawns, eels, perch, mackerel, sharks, and sturgeon. The catching of fish fry in the region's many streams is characteristic of the freshwater fishing industry. The fishing season begins in the spring when warm weather raises the water level of the rivers and the fish fry are sufficiently grown. The fry of ***wan yu*** (corvina) hatch first, that of pilchard next, and ***lien yu*** (bream) and others last. The fish-fry industry is heavily concentrated on the Hsün Chiang between Kuei-p'ing and Wuchow. Fish culture and the production of silkworms are complementary; the waste cocoons of silkworms are fed to the fish, and mud from fishponds is used as fertilizer for mulberry bushes.

Forestry. Kwangsi is an important producer of timber and forest products. In the north, large quantities of pine, fir, cedar, and giant bamboo are exploited and marketed at Liu-chou. Red and black sandalwood are also produced in the Yü Chiang Valley. Firewood, mushrooms, *mu-erh* (wood fungus), and bamboo shoots are also sold. More important, however, are sandarac (a resin used in making varnish and incense), star anise (Chinese anise), cassia bark (Chinese cinnamon), nutgall (a swelling on oak trees that produces tannin), and camphor. Tung oil, tea oil, and fennel oil are also produced. Some of these products are vital to traditional Chinese medicine, as are cardamom husks, cassia twigs, plantain seed, the seed of the wax tree, castor-oil seed, mugwort (a perennial herb) powder, dried lizard, mangosteen (a dark-brown fruit), and quinine.

Use of forest products in traditional Chinese medicines

Mining and quarrying. Kwangsi has sufficient coal and iron deposits to support moderate industrial development. Coal is mined in the Hsing-an-Ch'uan-chou region north of Kuei-lin and in the Lai-pin–Li-t'ang region south of Liu-chou. Iron is mined in the Ho-hsien-Chung-shan-Chao-p'ing area to the east, near the Kwangtung-Hunan border, as well as in Kuei-p'ing and Pei-liu. Exploited mineral resources include tin, tungsten, manganese, and antimony. Moderate amounts of bismuth, zinc, and lead are also produced.

Power. Major thermoelectric power stations are located in Nan-ning and Liu-chou. Since the mid-1960s, great emphasis has been placed on the construction of numerous small hydroelectric stations. A 1970 report states, for example, that a project at Tung-shan Commune (in Lu-ch'uan County in Yii-lin Special District) comprises 49 small hydroelectric power stations, each with a capacity of 600 kilowatts.

Industry. Light industries produce textiles, paper, flour, silk, leather, matches, chemicals, and pharmaceuticals as well as sandarac gum, sugar, dyestuffs, and oils and fats. Pine resin is a particularly notable export of

Wuchow. Heavy industries include the iron works and steelworks at Liu-chou and Lu-chai, machinery production at Nan-ning and Wuchow, and the cement works at Liu-chou. Among the numerous handicraft products, special mention may be made of the native cotton cloth of Yii-lin; the ramie cloth of Kuei-lin and Liu-t'an; the bamboo paper and rice paper of Chao-p'ing, Kuei-lin, and Tu-an; and the bamboo combs of Kuei-lin. Pin-yang produces such articles as ceramics, fans, felt caps, copper ware, combs, brushes, and straw bonnets.

Transportation and communications. ***Water transport.*** The elaborate system of waterways provides transportation almost throughout the region. Going north from Wuchow, the Kuei Chiang. is navigable for junks to its source as well as to the Hsiang Chiang via the Ling Ch'ii (canal). Motor launches sail up the Kuei Chiang to Ma-chiang in low water and to Kuei-lin in flood season. Westward from Wuchow, steam boats, motorboats, and junks navigate the hundred miles of the Hsiin Chiang to Kuei-p'ing at all times of the year. Beyond Kuei-p'ing, motor launches and junks navigate the Ch'ien Chiang to Shih-lung, and the Liu Chiang to Liu-chou and the Jung Chiang to Jung-an. The upper reaches of the Jung and Lung Chiang and of the Hung-shui Ho are navigable for junks only.

Conditions are far more favourable on the Yii Chiang, which is navigable by small steamers, motor launches, and junks from Kuei-p'ing to Nan-ning. At high water, the river is navigable to Pai-se on the You Chiang and to Lung-chou on the Tso Chiang. Farther inland, junks ply the headwaters of the You Chiang to Po-i in Yunnan and those of the Tso Chiang to Shui-k'ou-kuan on the North Vietnamese border. The south is served by the Ch'in Chiang and the Nan-liu Chiang (or Lien Chiang). There are proposals to construct a canal connecting the headwaters of the Nan-liu Chiang with those of the Hsiin Chiang, thus linking the south to Wuchow.

Railways. The Hunan–Kwangsi railroad from Heng-yang to Yu-i-kuan (Mu-nan-kuan) runs diagonally across the region from the northeast to the southwest. It forms a vital continental artery that connects with the Canton–Hankow railroad at Heng-yang and with the North Vietnamese railroad at Dong Dang. The Kwangsi–Kweichow railroad links Liu-chou with Kuei-yang, Kweichow Province, and is a great impetus to the development of northern Kwangsi. Another line leads from Li-t'ang on the Hunan–Kwangsi railroad to Chan-chiang, a seaport in southwest Kwangtung Province. It facilitates the trade of southeastern Kwangsi as well as the exploitation of the mineral resources of Hainan Island. Plans for future development include a major line from Nan-ning westward to I-liang, Yunnan Province; another major line from Pai-se northward to Kuei-yang; and a shorter line in the northeast to link Kuei-lin with Lien-hsien, Kwangtung Province.

Roads. The highway system has undergone continuous expansion since the 1950s. First-class highways are paved, and second-class roads have solid rock beds but no surface paving. In the early years of the People's Republic, highways in eastern Kwangsi radiated from Kuei-lin, Liu-chou, Nan-ning, and Yii-lin. The expanded network forms a central rectangle, with Nan-tan, Liu-chou, Nan-ning, and Pai-se at its four corners.

The growing highway system

Running almost due north and south, a trunk road connects Tu-yiin in Kweichow Province, Nan-tan, and Nan-ning with the coast of the Gulf of Tonkin. From Liu-chou, roads lead east to Shao-kuan, Kwangtung Province, north to Kuei-lin and Heng-yang and Yuan-ling in Hunan Province, and south to Nan-ning. From Nan-ning, roads lead south to P'ing-hsiang and Yu-i-kuan, southeast to Pei-hai, and west to Pai-se. From Pai-se roads fan out northeast to Nan-tan; northwest to An-lung, Kweichow Province; west to Wen-shan, Yunnan Province; and south to Cao Bang, North Vietnam. Serving the southeast, one major highway parallels the Lit'ang–Chan-chiang railroad; the coastal highway runs from P'ing-hsiang in the west to the Kwangtung border in the east.

The media. Kwangsi's leading newspapers include the ***Kwangsi Jih-pao*** ("Kwangsi Daily"), the ***Nan-ning Jih-pao*** ("Nan-ning Daily"), and the ***Kuei-lin Jih-pao*** ("Kuei-lin Daily"). The state-controlled New China News Agency is the source of all news. Radio broadcasting, however, is the most powerful means of mass communication, as receiver sets and loud speakers are installed throughout the region. A notable trend in the early 1970s was the use of mobile projection teams to show films and slides in the villages.

Cultural traditions and trends. The cultural traditions of the region are such that the primacy of Chinese culture is widely recognized. Because the minorities in Kwangsi possess neither a unified organization nor support by fraternal groups, their assimilation by the Chinese is far more advanced than in the other autonomous regions. The underlying causes of what appears to be Kwangsi's racial tensions are economic and geographic factors that have exerted a powerful influence on cultural trends.

Like the Chinese, the Chuang and T'ung are agriculturalists. Those who live in the fertile valleys and plains are scarcely distinguishable from the Chinese. They intermarry with the Chinese, speak Chinese in addition to their own dialects, and are at ease with their T'ai background, Before the revolution, many upper-class Chuang were landlords who exploited Yao or Miao tenant farmers. The Chuang and T'ung people in the mountainous regions, however, rarely intermarry, follow their own social customs, and have a definite sense of distinction from the Chinese. The Yao and the Miao, who live in the mountains and mingle even less with the Chinese, have a pronounced feeling of racial differentiation. Until the land reform of the early 1950s, the vast majority of the Miao and Yao were impoverished tenants of Chinese or Chuang landlords.

Under the present regime, a silent but powerful revolution is taking place in the lives of the peoples of Kwangsi. The vigorous development of highways and railroads has broken down transportation barriers and sectional antagonism. Communist authorities have taken steps to move many Yao and Miao to flatlands, to teach them to clear new land, and to allow them to form communes on land confiscated from Chinese or Chuang landlords. In many of the underdeveloped areas of the interior, dams have been built, canals dug, rivers led over arid lands, and reservoirs constructed to expand irrigation. Moreover, workshops for small industries are being set up in all rural communes. It is hoped that the economic measures will erase the racial tensions that have plagued the region for centuries.

BIBLIOGRAPHY. WANG CHUN-HENG, ***A Simple Geography of China*** (1958); and THEODORE SHABAD, ***China's Changing Map*** (1956), contain good introductory chapters on Kwangsi. More up-to-date information may be obtained from ***Nagel's Encyclopedia-Guide to China*** (1968). Maps for general reference may be found in the two CIA publications: ***Communist China Map Folio*** (1967) and ***Communist China: Administrative Atlas*** (1969). Pertinent information on certain periods of the history of Kwangsi may be gleaned from HAROLD WIENS, ***China's March Toward the Tropics*** (1954). For population, economy, and society, see REWI ALLEY, ***China's Hinterland in the Leap Forward*** (1961); and YUAN-LI WU, ***The Spatial Economy of Communist China: A Study on Industrial Location and Transportation*** (1967). Recent developments in the government's policy toward the national minorities are succinctly outlined in C.T. HU, ***The Education of National Minorities in Communist China*** (1970). Current developments can best be traced by following the issues of ***China Reconstructs, Peking Review, Union Research Service Reports,*** and ***Far Eastern Economic Review.***

(P.-c.K.)

Kwangtung

Kwangtung (Guang-dong in Pin-yin romanization), the southernmost of the 21 provinces of the People's Republic of China, also constitutes the region through which South China's trade is primarily channelled. The 12th largest Chinese province in area, it is also the province with the longest coastline—including Hainan, it is about 3,000 miles in length. The province has an area of 81,700 square miles (211,500 square kilometres), which amounts to more than 2 percent of the total area of the People's Republic. The province includes Hainan, which, with an area of 13,124 square miles, is the largest Chinese island except for Taiwan. It is bounded by the Kwangsi Chuang Autonomous Region to the west, and by the provinces of Hunan and Kiangsi to the north, and Fukien to the northeast, and by the South China Sea to the south. At its western extremity on the coast the province borders North Vietnam. Two foreign holdings remain on the coast of Kwangtung—the British crown colony of Hong Kong and the Portuguese territory of Macau. The population of Kwangtung was estimated to be 42,800,000 in 1970, representing a population density of about 525 persons per square mile. The capital is Canton.

Historically Kwangtung and Kwangsi, its neighbouring province to the west, often were jointly governed. Kwangtung was first administered as a separate entity in AD 997 during the Sung dynasty; it was from this time that the term Kwangtung (Chinese ***kuang tung,*** "eastern expanses") began to be used.

Kwangtung has its own characteristics, which manifest themselves in physiography, climate, language, folklore, and products. Its topography separates it somewhat from the rest of China, and this factor, together with its long coastline, its contact with other countries through its overseas emigrants, and its early exposure to Western influence through the port of Canton, has resulted historically in the emergence of a degree of self-sufficiency with which a tendency to separatism has also been associated. Canton dominates the economic, cultural, and political life of the province to an unusual extent. (See CANTON; for associated political units, see HONG KONG; MACAU.)

HISTORY

Physically separated from the early centres of Chinese civilization in North China, Kwangtung was originally occupied by non-Han ethnic groups. It was first incorporated into the Chinese Empire in 222 BC, when Ch'in Shih Huang-ti, first emperor of the Ch'in dynasty, conquered the area along the Hsi Chiang and Pei Chiang valleys down to the Canton Delta. In 111 BC Chinese domination was extended to the whole of what is now Kwangtung, including Hainan, by Emperor Wu of the Han dynasty. The conquest, however, was not followed by successful colonization, and Kwangtung remained part of the empire only politically.

During the five centuries of the Sui, T'ang, and Northern Sung dynasties, from AD 581 to 1126, the military and agricultural colonization of Kwangtung gradually took place. This, combined with increasing overseas trade through Canton, led to an increase of migration into Kwangtung, and to the rise of Canton as a metropolis with a population of hundreds of thousands. At the end of the period, however, Kwangtung was still occupied predominantly by its original ethnic population. The region was viewed as a semicivilized frontier, and disgraced officials often were exiled there as a punishment.

Occupation by the Han Chinese

The southward thrust of the Han Chinese was greatly intensified from 1126, when the Tatars captured the Sung capital. Another major population movement followed a century and a half later, in 1279, as China fell to the Mongols. These migrations marked the beginning of effective Han Chinese occupation and the rapid cultural development of Kwangtung. Especially after the 16th century, with the introduction of sweet potatoes and peanuts into China, the growth of population was so fast that, by the late 17th century, Kwangtung had already become an area from which emigration took place. Migrants from Kwangtung moved first to Kwangsi, Szechwan, and Taiwan and then in the mid-19th century began to pour into Southeast Asia and North America.

As a result of its early contact with modernizing forces, Kwangtung has, since the mid-19th century, produced a number of prominent political and military, as well as intellectual, leaders. Many of the leaders of political movements during this period, such as Hung Hsiu-ch'uan, leader of the Taiping Rebellion (1850–64); K'ang Yu-wei and Liang Ch'i-ch'ao of the Reform Movement (1898), and Sun Yat-sen, who led the Republican Revolution of 1911, had associations with Kwangtung.

PHYSICAL GEOGRAPHY

Physiography. The surface configuration in Kwangtung is diverse, being composed primarily of rounded hills, cut by streams and rivers, and scattered and ribbonlike alluvial valleys. Together with the Kwangsi region, Kwangtung is clearly separated from the Yangtze Basin by the Nan Ling, the southernmost of the three major Chinese mountain ranges running from east to west, which was formed in Late Mesozoic times, between about 70,000,000 and 130,000,000 years ago.

The greater part of eastern Kwangtung consists of the southerly extension of the Southern Uplands, which stretch down from Fukien and Chekiang provinces. Formed at the same time as the Nan Ling, a series of longitudinal valleys running from northeast to southwest extends as far as the vicinity of Canton.

Relief and drainage. Smooth, low hills with slopes of up to 10° cover about 70 percent of the province. Most peaks range in elevation from 1,500 to 2,500 feet, with a few reaching 5,500 feet. Level land of any size is primarily found in the alluvial deltas, formed where rivers empty into the South China Sea.

The Canton Delta

Of great extent and importance, the Canton Delta, measuring about 3,500 square miles, is marked by hilly outliers and by a labyrinth of canalized channels and distributaries totalling some 1,500 miles in length. The delta marks the convergence of the three major rivers of the Chu Chiang system—the Hsi (West), Pei (North), and Tung (East) rivers. The Chu Chiang, or Pearl River, is the name given to the lower course of the Hsi beyond the confluence. Entirely rain-fed, these rivers, which are subject to extreme seasonal fluctuations, collect so much water that, anomalously, the Chu Chiang system discharges annually six and a half times as much water as the Huang Ho (Yellow River), although its basin area of about 173,000 square miles is only about half as large.

Altogether, Kwangtung has 1,343 large and small rivers, with drainage basins covering a total area of about 400,000 square miles. The Han is the most important river outside the Chu Chiang system. Other important rivers and lowlands are located in the southwest and on Hainan.

Hainan

Hainan, separated from the Luichow Peninsula by a shallow channel 15 miles wide, possesses rivers that discharge at least twice as much water as do the rivers in mainland Kwangtung. The discharge rates, moreover, show even greater fluctuations. Alluvial plains on Hainan are largely confined to the narrow coastal margins. A quarter of the island is covered by mountains, the highest of which is the Wuchih Shan, which reaches 6,165 feet.

Soils. In general, soils are poor, as high temperatures and plentiful rainfall result in podzolization (bleaching) and leaching. Almost all of western Kwangtung, together with Hainan, is covered with mature red soils, whereas the rest of the province is covered with a mixture of old and young red soils that have usually been subjected to a high degree of podzolization. In the main, young red soils cover sloping hillsides up to an elevation of over 3,000 feet. In the wettest and hottest parts of Kwangtung, lateritic (heavily leached, iron-bearing) soils are common; like the red soils, they do not resist erosion and require substantial fertilization in their cultivation. The yellow soils are found in the wettest and coolest parts of Kwangtung, occurring in small pockets of flatland with imperfect drainage.

Of more limited distribution, but of evident economic significance, are the alluviums deposited relatively recently in the river valleys and deltas. As a result of the cultivation of rice, the alluviums have developed special morphological characteristics, the most striking of which is the formation of iron hardpans (hard impervious layers composed chiefly of clay) in the zone of the fluctuating water table.

Climate **and** vegetation. Since much of Kwangtung lies south of the Tropic of Cancer, it is the only Chinese province with tropical and subtropical climates. The average July temperature in the Hsi Valley, which is from

82" to 86° F (28° C to 30° C), is little different from temperatures in the lower Yangtze and on the Huang Ho, but the average January temperature is considerably higher, ranging from 55° to 60° F (13° to 16° C). Except on higher elevations, frost is rare, so that almost the whole province lies within the area where two crops of rice can be grown. True winter does not occur in the province, but the hot summer varies in length from ten months in Hainan to six months in northern Kwangtung.

Rainfall. The rainfall regime shows a pronounced summer maximum, with the rainy season lasting from mid-April, when Kwangtung starts to be dominated by moisture-laden tropical air masses from the Equator and the Indian Ocean, until mid-October. Over half of the total precipitation falls between June and August. The months between July and September form the main typhoon season, which ordinarily is accompanied by heavy rains and widespread destruction. From December to February, only 8 percent of the precipitation occurs. Kwangtung's annual rainfall is approximately 60 to 80 inches, decreasing with distance from the coast to the northwest but increasing with altitude and exposure to the prevailing summer monsoon winds.

The typhoon season

Natural vegetation. Abundant moisture and moderate to high temperatures support luxuriant plant growth. Broad-leaved evergreen forests, intermixed with coniferous and deciduous trees, originally covered much of the land, while a more tropical type of vegetation predominates on the south coast and on Hainan. With the exception of the more remote mountainous areas and the interior of Hainan, much of this natural vegetation cover has been stripped by fire and by the use of trees and shrubs for fuel. This circumstance, together with millennia of uninterrupted cultivation, has resulted in much of the natural vegetation now taking the form of secondary forests of hardwoods and horsetail pine. On the more severely eroded hills, coarse grasses and ferns have taken hold. Bamboo groves, varying greatly in height and extent, are widespread, particularly in humid river valleys. The most productive and least disturbed forests cover the mountainous areas. Certain trees, notably camphor, have been revered and protected for centuries, and are found around grave plots and cultivated fields. Since 1949, as a result of massive afforestation programs, the once bare hills of Kwangtung have been reported as resembling "a mist of green."

Plant and animal life. The combination of a propitious climate and a variegated physiography favours considerable diversity in plant and animal life. In the highlands, where coniferous and deciduous species thrive together, the broad-leaved evergreen forests are characterized by tropical oaks, tan oaks (oaks that yield tanin), and chestnut oaks (or chinquapins). The more significant coniferous species of economic value include horsetail pine, Chinese fir, and Chinese hemlock. Some of the species of cypress and pine are little known outside China.

Truly tropical monsoon rain forests are common in the south, particularly in Hainan. In tropical Kwangtung, a number of industrial crops have been introduced and successfully raised. These include rubber, sisal, palm oil, hemp, coffee, and black pepper.

Kwangtung's more traditional agricultural products, however, are rice, sweet potatoes, barley, sugarcane, peanuts, tea, mulberry, tobacco, and no less than 300 types of fruits, among the more representative of which are oranges, tangerines, pomelos (a grapefruit), lychee, longan (a pulpy fruit related to lychee), pineapples, and bananas.

Among the mammals found in Kwangtung are many tropical bats, including fruit-eating bats and several leaf-nosed, insect-eating species. Squirrels, mice, and rats of many species are abundant. Insectivores are generally more diverse than in other regions of China, and carnivores are exemplified by civet cats and small-clawed otters.

Types of birds vary according to their habitat. In the tropical forest, wildfowl, peacocks, and silver pheasants are common. Reptiles are more restricted in distribution. Blind snakes are found on Hainan, while mainland Kwangtung has a number of pit vipers, including the huge and deadly Chinese vipers and bamboo vipers, as well as nonpoisonous pythons which are up to 20 feet long.

Insects of every description—crickets, butterflies, dragonflies, grasshoppers, cicadas, and beetles—are found in profusion. Amphibians include ground burrowers and many types of frogs and toads, some of which rival the American bullfrog in size.

Tigers, rhinoceroses, panthers, wolves, bears, and foxes used to roam the hills of Kwangtung, but their numbers have been decimated by forest fires and persistent deforestation. In the tropical monsoon forest, however, a great number of animals, many of which live in the trees, still remain.

POPULATION

Ethnic composition and distribution. Kwangtung is largely populated by the Han Chinese, the other ethnic minorities totalling less than 2 percent of its population. Numbering around 400,000, the Li are the largest ethnic minority in Kwangtung. They live almost entirely on Hainan, particularly in the mountainous southern portion, designated administratively as the Hainan Li Miao Autonomous District.

Next in importance, the Yao total 41,000. They are concentrated principally near Kwangtung's northwestern border in areas designated as the Lien-shan Chuang Yao Autonomous County (*hsien*), the Lien-nan Yao Autonomous County, and the Ju-yüan Yao Autonomous County. There are 16,000 Miao living with the Li in the autonomous district in Hainan. Some ethnographers, however, maintain that "Miao" is a misnomer on the grounds that, according to their language, customs, and traditions, the Miao are actually the Yao. A heavily Sinicized group, the Chuang live in the Lien-shan Chuang Yao Autonomous County, and there are also about 120,000 Chung in Kwangtung, now redefined as the Ch'in-chou Chuang Autonomous County in Kwangsi.

Other minority groups include the She, who live in the northeast around Ch'ao-an, and the Hui (Chinese Muslims), who are scattered in Hainan. The Ching, roughly 4,500 in number, were transferred to Kwangsi in 1965, when the multinational Tung-hsing Autonomous County in extreme southwestern Kwangtung changed its provincial jurisdiction.

The so-called Tan, or Tanka, the Boat People, are not officially designated as a national minority. Whereas some scholars believe they are descendants of aborigines, others regard them as simply a people who live on boats and speak Cantonese. They generally live along the rivers in the Chu Chiang Basin as well as along the coast.

Linguistic patterns. The relative ethnic homogeneity prevailing in Kwangtung stands in contrast to its linguistic heterogeneity. The Han Chinese speak a wide variety of dialects forming distinct areal patterns. Within the Cantonese-speaking region, however, there exists a great diversity of other dialects.

By far the most important dialect is Cantonese, spoken by about 27,000,000 people in central and western Kwangtung. There is considerable variety among the Cantonese speakers, but the form spoken in Canton is generally regarded as the standard. Hakka is another important dialect; it predominates in the north and northeast of the province; offshoots of Hakka are common in central Kwangtung and northern Hainan. A third major dialect, Fukienese (Southern Min dialect), is spoken mostly along an eastern coastal area centred on Swatow, but Fukienese speakers also are found in northern Hainan. Sometimes Hainanese is treated as a distinct dialect, commonly spoken in the coastal plains of Hainan.

In addition to these Han Chinese dialects, there are the languages and dialects of the ethnic minorities. Notable among these are the dialects of the Li people on Hainan. It should be noted that, although linguistic unity has been the policy orientation of the Chinese Communists, considerable attention has been paid to the popularization of minority languages. New scripts have been created for a number of these languages. They not only are taught in minority-area schools but also are used in conjunction with Chinese in official communications in minority communities.

Patterns of rural and urban settlement. The settlement pattern in Kwangtung is based on a traditional settlement hierarchy ranging from nuclear agglomerated villages, through small and large towns, to county (hsien) capitals and the provincial capital. This basic structure appears to have been little altered since 1949.

Urbanization

Most of the people of the province live in more than 3,000 villages, which remain the basic functional units in the countryside. Population distribution bears almost a one-to-one correlation with agricultural productivity. The greatest numbers of villages are in the fertile river deltas and along the waterways. To an even greater extent, towns and cities are located in the deltas and coastal areas and along major communication lines. The most highly urbanized area within the province is the Canton Delta, where some 60 percent of the population live in urban areas. Kwangtung is a relatively highly urbanized province for China, with about 18 percent of its population being classified as urban.

The urban hierarchy is headed by Canton, with a population of about 3,100,000 (1970). It is far greater in size than the second largest city, Swatow (280,000 in 1959). Other municipalities of over 100,000 inhabitants are Sh'ao-kuan (232,000 in 1965), Chiang-men (180,000 in 1962), Chan-chiang (170,000 in 1959), Fo-shan (120,000 in 1958), Hai-k'ou (110,000 in 1959), and Ch'ao-an (101,000 in 1958). In addition, there are nine cities with populations between 30,000 and 60,000; 46 at the 10,000–30,000 level; and 278 townships of nearly 10,000 persons each.

ADMINISTRATION AND SOCIAL CONDITIONS

Government. The administrative system in Kwangtung has undergone many changes since 1949. "Autonomous" administrative units were established in the early 1950s for areas with large ethnic minority populations. The status of Canton was changed in 1954 from a centrally administered municipality (t'eh-pieh-shih) to a municipality under the jurisdiction of the provincial government. Another important change has been the development of an intermediate layer of administration between the province and the county (hsien), the special districts (chuan-ch'ii), assisting the province in supervising the county.

In addition to the municipality of Canton, Kwangtung is subdivided into seven special districts, one administrative district (hsing-cheng-ch'ii), and one autonomous district (*tzu-chih-chou*). The headquarters of the provincial government is located in Canton. Altogether, there are 94 counties, three autonomous counties, and nine county-level municipalities.

In each special district, there are from seven to 15 counties including the autonomous counties. Every special district also has under its jurisdiction a municipality where its headquarters is situated, except for one having none and two having two municipalities each. The Hainan administrative district includes one municipality and nine counties, while the municipality of Canton administers two counties.

The autonomous district and autonomous county as administrative units are equivalent to the special district and the county, respectively. Though labelled autonomous, they are in fact wholly integrated into the regular administrative hierarchy, possessing no important powers that other administrative units lack. They differ from the other units in the concessions extended to local minority customs and languages. Moreover, special efforts are made to absorb minority cadres into the local administration.

Before the communes were introduced in 1958, the basic administrative units below the county level were the administrative villages (hsiang) or market towns (*chen*) in counties and the districts (ch'ii) in municipalities.

The communes

Rural administration was fully reorganized when communization was implemented in 1958. Especially in Kwangtung and other coastal areas of South China, the communes took over the apparatus and territory of the administrative districts and have become the basic organ of state power. Administrative villages were converted into production brigades under the communes, and the natural villages within administrative villages became the production teams of the brigades. There are 1,500 communes in Kwangtung, integrating the state administration and the economic administration at the subcounty level. A recent development has been greater decentralization of economic management to the production brigades and teams.

Social conditions. Education. Education, health, and other social conditions in Kwangtung have generally been improved since 1949. There are now many more kindergartens and nurseries for preschool education. The number of primary schools in a commune varies from about 15 to more than 50, and, although primary education is not compulsory, over 80 percent of children of primary school age attend these schools. Many communes also have one general middle school, and some have one or two vocational schools. The establishment of many vocational schools, especially the agricultural middle schools, on a part-work, part-study basis, has markedly widened the opportunities for middle school education. There are more than 30 universities and colleges and roughly 20 technical schools.

Special attention has been given to the education of the ethnic minorities. New schools, including one national minority college, have been established in minority communities where none existed before. There are also schools, including one university in Canton, specifically built for returned overseas Chinese students and students from families of overseas Chinese living in Kwangtung. Repeated campaigns have succeeded in reducing illiteracy to well below 50 percent in many areas.

Hospitals, clinics, and medical services

Health. In general, a commune possesses one hospital, up to 15 clinics, and many health stations, including maternity centres. There may be 80 or 90 sickbeds in one hospital, and some hospitals are equipped with X-ray facilities and operating theatres. Better equipped and better staffed hospitals are maintained at the county and provincial levels. All schools and factories, except for the smallest ones, have their own clinics.

Medical education has been greatly expanded. There are eight medical colleges and schools, with one college devoted to Chinese medicine (acupuncture and herbal medicine). Many short-term medical-training classes are organized for health workers who are assigned to rural areas.

Medical services are available to large sections of the population. The cost of a worker's medical treatment is borne by his factory's welfare fund, to which he subscribes. Cooperative medical service resembling the factory's welfare fund is also widely provided in rural communes.

Although epidemics of influenza and liver inflammation struck in 1959 and 1960, the development of medical services, coupled with the general improvement in sanitation and health education, has succeeded in eliminating many previously common diseases such as malaria, schistosomiasis (a waterborne parasitic disease), and filariasis (a parasitic disease infecting the blood and lymph glands).

Welfare. Welfare programs have been organized for children and workers. Nurseries and child-care centres are usually free of charge for children of working mothers. Workers, in addition to the medical funds already mentioned, are provided with maternity benefits, life insurance, and retirement pensions. Their dependents are entitled to partial health benefits.

Economy. Agriculture. The economic foundation of Kwangtung is primarily agriculture. Inasmuch as only about 15 percent of its land is under cultivation, agriculture is of necessity extremely intensive. The limited extent of sown land available is, however, partly offset by repeated uses of it. Two crops of rice a year can be grown on most cultivated land, and in Hainan three crops are not unusual. Thus, although average yields per harvest are below the national average, annual yields resulting from two harvests exceed the national average and are bettered by only four other provinces.

Rice is the leading crop, occupying about 76 percent of the total cultivated area and accounting for over 80 percent of Kwangtung's total food production.

Although food-grain crops (including rice) occupy almost 90 percent of the total cultivated area, the industrial and fruit crops grown on the remaining land are of national importance. Kwangtung annually produces more than 6,720,000 tons of sugarcane—about half of China's total output. Fruit production reaches 6,000,000 piculs (828,000,000 pounds), a significant proportion of which is consumed in north or central China.

Good rice yields depend upon careful water control. Progress in irrigation and flood control has made such water control possible for about 84 percent of the cultivated area. Farming has become increasingly mechanized, and increasing reliance has been placed on the use of chemical fertilizers.

Rural reorganization

Many of these changes have been brought about by rural reorganization since 1949. In a land traditionally plagued by a system of tenant farming that was more widespread than in most other provinces, large-scale agrarian reform was not introduced in Kwangtung until 1952. Rural cooperatives began to be formed in 1954, and by 1958, 98.5 percent of all rural households were organized into people's communes. Each commune has an average population of 30,000, consisting on the average of 7,000 to 8,000 households. Commune production teams are commonly composed of 40 to 50 households each. Small plots of private land are retained for raising vegetables and livestock, particularly hogs.

Since the river valleys and the deltas have been intensively tilled for untold generations, it is in the remote areas that land-reclamation schemes are pursued. In the uplands, for example, efforts have been concentrated on afforestation, fruit growing, and livestock raising.

Reclamation of wasteland in peripheral areas has been largely undertaken by the state farms, which engage in collective farming under the direct control of public authorities.

Fishing. Kwangtung, with its long coastline, produces about one-quarter of China's fish. Fish production accounts for as much as one-third of the income of some communes. Fish farming yields over 110,000 tons of pond fish every year. More than 400 species of saltwater fish, including yellow croaker, white herring, mackerel, golden thread, and pomfret are caught from 57 fishing ports.

Industry. Because of the paucity of its iron deposits, Kwangtung received only scant attention when China's heavy industry was developed during the first five-year plan (1953-57). Light industry, however, has always been of significance in the province. Apart from handicrafts, light industry--especially food processing and the manufacture of textiles—accounts for about three-quarters of industrial production. Almost all of the major light industries are located in the Canton Delta. Sugar refining is centred in Canton, Tung-kuan, Shun-te, Chiang-men, and Swatow, while silk filature (the reeling of silk from cocoons) and weaving are well developed in Canton, Fo-shan, Shun-te, and Fu-shan. The largest and most widespread industry is rice milling, which takes place in nearly every county and municipality.

Existing heavy industries include metal processing, the manufacture of machinery, shipbuilding and ship repairing, the production of hydroelectricity, and mining. A large proportion of these industries is concentrated in Canton, where 85 percent of Kwangtung's machinery-manufacturing and metal-processing industries are located. The province has 32 fertilizer-producing plants.

Despite a shortage of iron in mainland Kwangtung, extensive deposits of high-quality hematite (the principal iron ore) with up to 63 percent iron content, exist in Hainan at Ch'ang-chiang and T'ien-tu. Kwangtung also has nonferrous resources. Coal reserves are estimated at about 4,000,000,000 tons. The province also has about 60 percent of China's manganese deposits, located on the Luichow Peninsula and nearby. Tungsten, which is associated with bismuth, molybdenum, and tin deposits, is mined near the Kiangsi border at Shih-hsing, Lo-ch'ang, and Weng-yüan. Oil-shale deposits have been discovered in quantity on the Luichow Peninsula. Oil refineries have been established in Mao-ming.

Water transport

Transportation and communications. Economically and culturally, the different regions of Kwangtung are linked together by the waterways associated with the Chu Chiang ssytem, which comprises 80 percent of the province's 9,000 miles of navigable inland waterways, of which 2,440 miles are used by motor vessels. In addition, a number of coastwise and international shipping routes are variously linked to more than 100 large and small ports. The leading ports, including Whampoa (Canton's seaport), Chan-chiang, Swatow, and Hai-k'ou, are of national significance. Water transport accounts for approximately 70 percent of Kwangtung's total traffic tonnage. The waterways are maintained by a continual dredging, widening, and clearing of channels.

Connections with other provinces depend principally on land transportation. Kwangtung has developed the best highway network in China, running primarily along river valleys. There are 10,690 miles of highway and 466 miles of railroad. Interprovincial links, both for highways and railroads usually run north–south. The vital Canton–Hankow railroad was double-tracked in the early 1960s. The low priority placed on east–west transport is indicated by the absence of a railroad running parallel to the Hsi Chiang and by the delay in completing the Canton–Chan-chiang line, which was finally opened in 1963.

Kwangtung provides a crucial link in China's domestic and international civil-aviation routes. Air services connect the province to London, Paris, Hanoi, Dacca, Djakarta, Pyongyang, and Dar es Salaam. To cope with the increasing traffic, Canton's White Cloud (Pai-yun) airport was enlarged and modernized in 1964.

Telecommunications, which previously were restricted to the cities, now extend not only to the county capitals but to all communes and to 95 percent of the production brigades as well. Mail from Canton can reach half the province within the same day, while the slowest deliveries do not take more than four days.

Cultural life. Kwangtung has long been noted for the distinctive cultural traits of its people, as evidenced by the variety of dialects spoken. Kwangtung is famous for its two types of local opera: the Yueh Opera and the Ch'ao Opera, which are popular among the Cantonese and Fukienese communities, respectively. Kwangtung also has some characteristic puppet plays. The hand puppets of Canton are distinguished by their size—they are between three and four feet high—and by the beautiful carving of their wooden heads. Many places in Kwangtung have distinctive forms of folk art; the woodcuts of Ch'ao-an and the stone engravings of Shun-te may be mentioned as examples.

Cantonese food is widely recognized as among the best in China. Living in a coastal province, the people are particularly fond of seafood. Especially in winter, the "big-headed fish" (tench) is often served raw in a fish salad—a departure from habitual Chinese culinary practice. Some other food habits, such as the eating of newborn rats, live monkey's brain, and fried snake, are regarded as highly revolting by most Chinese in other provinces. The chewing of betel nut wrapped in ***Celosia*** (cockscomb) leaves has been popularized by Chinese who have returned from Southeast Asia.

Although following essentially the same annual festivals as people in other provinces, many ceremonies in Kwangtung are associated with characteristic celebrations. During the Chinese New Year the performance of lion dances is especially popular. The Dragon Boat Festival in early summer, during which dragon-boat races are held on rivers and lakes, provides another example.

Religions

Ancestor worship, folk religions, and all the institutional religions of Taoism, Buddhism, Christianity, and Islām coexist in the province, as in most places in China. Among these, ancestor worship has the most pervasive influence. Although some folk religions are national in outlook, others are of a more local character, such as the worship of the goddess of fishing and navigation, T'ien-hou Sheng-mu. With the possible exception of Muslims and Christians, people in Kwangtung are polytheistic, visiting temples or priests of different faiths as occasions demand.

Related to folk religions and Taoism are the various folktales and superstitions among the people. There is, for example, a folk belief among the peasants that the work of repairing river dikes should be restricted to men, since the participation of women in the work might cause the dikes to collapse.

Kwangtung is a province where lineage—an important social institution in China—has been particularly emphasized. This is often reflected in the settlement pattern of lineage groups. The inhabitants of many villages belong exclusively to one or two lineages. In such villages, community and lineage organizations are virtually identical. Conflicts between lineages that once were common often took the form of community strife, with bitter fighting sometimes lasting for long periods of time.

Many of these cultural patterns had begun to change long before the founding of the new regime. Since 1949, however, systematic efforts have been made to change them in accordance with governmental ideology and policy. Ancestor worship and folk religions have been repudiated as antisocial and superstitious. The institutional religions, with the possible exception of Islām, have also been ridiculed, criticized, and finally reorganized. The political and economic reorganization of rural areas that culminated in the establishment of communes has deprived the lineage organizations of much of their structural basis and social functions. On the other hand, many aspects of traditional culture, especially the folk arts and the theatre, have been revived and extolled. Provincial songs and popular plays, all in local dialects, are now flourishing as never before.

BIBLIOGRAPHY. Few published sources deal specifically with Kwangtung. One which describes the immediate postwar situation is KWANGTUNG RECONSTRUCTION RESEARCH COMMITTEE, ***Post-War Kwangtung: Reconstruction and Prospects*** (1947). Focussing on the early developments after 1949 is a useful work by LUANG RHIN-CHOY, ***Economic Geography of Kwangtung*** (Eng. trans. 1958).

Books containing sections on Kwangtung include GEORGE B. CRESSEY, ***China's Geographic Foundations*** (1934), and ***Land of the 500 Million: A Geography of China*** (1955); T.R. TREGEAR, ***A Geography of China*** (1965), and ***An Economic Geography of China*** (1970); NORTON S. GINSBURG (ed.), ***The Pattern of Asia*** (1958); THEODORE SHABAD, ***China's Changing Map*** (1956); TUAN YI-FU, ***China*** (1970); and KEITH BUCHANAN, ***The Transformation of the Chinese Earth*** (1970).

(Y.–m.Y./C.-T.C.)

Kweichow

Located in the southwestern part of the People's Republic of China, Kweichow (Gui-jou in Pin-yin romanization) Province is bounded on the north by Szechwan Province, on the west by Yunnan Province, on the east by Hunan Province, and on the south by the Kwangsi Chuang Autonomous Region. The province measures over 350 miles from east to west and about 320 miles from north to south. It has an area of 67,200 square miles (174,000 square kilometres), accounting for some 1.8 percent of China's total land area. The smallest province in the southwest, it had, at the beginning of the 1970s, a reported population of about 20,000,000, or an average density of 298 persons per square mile. The provincial capital, centrally located at Kuei-yang, had an estimated population of more than 530,000 in 1958.

Kweichow shares the frontier character of other southwestern plateau lands. It is characterized by rough topography, poor communication and consequent isolation, and the presence of many ethnic minority groups.

History. Although the area has been known to the Chinese since time immemorial, Kweichow came under large-scale Chinese influence only in the modem era, particularly during the Ming dynasty (1368–1644), when it was made a province. The colonization policy of the Ming and Ch'ing dynasties encouraged a large number of Chinese immigrants from Hunan, Kiangsi, and Szechwan to move into the eastern, northern, and central parts of Kweichow.

Kweichow's history of rebellion

During the Ch'ing dynasty (1644–1911), when the government decided to replace local chiefs by officials appointed by the central government, struggles broke out between the minorities, especially the Miao ethnic group, and the Chinese. Rebellions and suppressions were so common that there was a saying, "a riot every 30 years and a major rebellion every 60 years." In 1726 at the Battle of Lei-kung Shan (Lei-kung Mountain), more than 10,000 Miao people were beheaded and over 400,000 starved to death. The Pan-chiang Riot of 1797 was said to have been started by the Puyi people, and thousands of them were either burned to death or beheaded. The most important popular revolt against the central government was one led by Chang Hsiu-mei, a Miao, in 1854. He and his followers united with the Taiping revolutionaries, and the joint army with a centralized command that was organized soon controlled eastern and southern Kweichow and won numerous victories under the Miao leaders Yen Ta-wu and Pa Ta-tu. When the Miao were eventually defeated in 1871, however, countless numbers of them were massacred. The most recent revolt, known as the Ch'ien Tung (eastern Kweichow) Incident, occurred between 1941 and 1944 as a result of exploitation and suppression by the war-lord Wu T'ing-chang. Bitter struggles between the Miao and Wu's armies went on until 1944.

The landscape. ***Relief, drainage, and soils.*** The Kweichow Province is part of an old eroded plateau, variously known as Kweichow Plateau or Yunkwei Plateau, which connects with plateau areas in Yunnan Province. Situated between the mighty Plateau of Tibet and the hilly regions of Hunan and Kwangsi, the plateau forms part of a continuously ascending profile of the southwest, its altitude increasing from about 2,300 feet in eastern Kweichow to about 6,600 feet in the west. The Szechwan Basin to the north and the Kwangsi Basin to the south are both the results of faulting. The entire terrain of Kweichow thus slopes at a steep angle from the centre toward the north, east, and south. In areas adjacent to Szechwan and Hunan in the north and east, the elevation is about 2,300 feet, while the province's southern slopes descend 1,600–2,000 feet into Kwangsi. Accordingly, rivers in the province flow in three directions, north, east, and south.

Karst features of the landscape

The plateau, which is mostly of limestone and basalt, has undergone complicated and extensive folding, faulting, and stream erosion and consequently has abrupt relief, an example of which is the famous Huang-kuo-shu Waterfall in the southwest. Incised valleys, steep gorges, and cliffs are very common. In the limestone areas, the landscape is karstic (characterized by precipitous slopes, abrupt, protuberant mountains, caverns, and subterranean streams). Only the anticline (upfold of stratified rock) and syncline (downfold of stratified rock) of the plateau in central Kweichow are broad and relatively flat.

Most of the rivers in Kweichow are the upper streams of various large rivers, such as the Yangtze River (Ch'ang Chiang) and the Hsi Chiang. The abrupt change of gradient, the great fluctuation in the flow volumes, and the numerous rapids and reefs make them unsuitable for navigation, though they may have enormous hydroelectric-power potential.

Because of the high humidity, a yellow soil with a yellowish-brown subsoil originated from sandstone, shale, and clay, constitutes the largest area in the province. In the limestone area in the south, there are broad areas of red soil. In the west, the red soils are originated from basalt and sandstone and developed under a relatively drier climate.

Climate. Kweichow enjoys a mild climate with warm summers and mild winters. Kuei-yang has a mean July temperature of about 76" F (24" C), lower than that of any other cities to the east on the same latitude. This is due to its high altitude and the cloudiness of the summer months. In winter, cold air from Siberia cannot easily reach Kweichow because of the barrier effect of the

Tsinling Shan (Ch'in Ling or Tsin Ling in Chinese) to the north of the Szechwan Basin. In spite of its high altitude, Kweichow thus has few snowy days and even fewer freezing days. The mean January temperature at Kuei-yang is about 40° F (4° C).

Rainfall is fairly uniform and plentiful, with an annual average of 31–51 inches, decreasing toward the north and west. The southern and eastern parts of Kweichow are open to the influence of the moist maritime air mass in summer. For the same reason, there is a summer maximum in rainfall, averaging 45 percent of the annual total. About 25 percent falls in spring and 23 percent in autumn. Typically, the province has high relative humidity, lengthy cloudy and rainy days, and little sunshine. The capital, Kuei-yang, has over 260 rainy and cloudy days and the province is said to be without three consecutive rainless days. Most of the precipitation results from frontal activity, though some is a result of convection or condensation.

Forest resources

Vegetation. Partly because of the steep gradient, and partly because of the exposure of limestone, wasteland accounts for nearly 50 percent of the total area. Yet part of the province's natural wealth lies in its forests, The plateau surface is mostly dry and barren, but the peripheral valleys have rich and valuable woodlands. About 9 percent of the land area is under natural forest. There are four main forested areas: the drainage areas of the Ch'ing-shui Chiang in the east, the Jung Chiang in the southeast, the Nan-p'an Chiang and Pei-p'an Chiang in the southwest, and the Ta-lou Shan area in the north.

The forests of the northern valleys, still among the most important in China, consist chiefly of conifers and other trees, such as the tung tree, lacquer tree, camellia, birch, maple, pine, and fir. Forests in the southeast produce camphor, banyan tree, and other broad-leaved varieties. Trees of the southern subtropical valleys typically include willow, cedar, bamboo, and various species of pine and fir. Oak, Yunnan pine, *Hua-shan* pine, and camphor are grown in the west near Yunnan. Cedar, cypress, poplar, and palm trees are also found in the province.

Fauna. In addition to domesticated animals, such as buffalo, horses, donkeys, asses, and pigs, the province's fauna includes leopards, otters, foxes, badgers, tigers, sea otters, and squirrels. In most of the larger rivers such as the Ch'ing-shui Chiang, Tu Chiang, and Wu Chiang, carp and savoury fish are abundant.

Main ethnic groups

Population. Demography. In 1970 the province had a total population of some 20,000,000, of which about 75 percent were Han Chinese. Non-Han Chinese tribesmen account for about 25 percent of the total. An ethnic frontier, Kweichow has a large number of minority peoples. At least 30 different groups have been identified. Of these the most important are the Miao (1,800,000), the Puyi (1,600,000), the Shui (Shui-chia; 200,000), the T'ung (200,000), and the Yi (100,000).

All the minority groups intermingle with Han people. Only at the low hsiang, or village level, can one find any exclusive racial grouping. Generally, very few minority people live in northern Kweichow, particularly in areas north of the Wu Chiang. The Miao are mainly found in southeastern Kweichow, especially in the drainage area of Ch'ing-shui Chiang and in the Miao Ling (mountain range). The Chuang people live near the Kwangsi Chuang Autonomous Region. Most of the Puyi live in south central and southwestern Kweichow in the P'an Chiang drainage area, including the suburbs of Kuei-yang. The T'ung are found mainly in the southeastern areas adjacent to Hunan Province and the Kwangsi Chuang Autonomous Region. The Shui concentrate in southern Kweichow, around San-tu and Li-po, while the Yi, who once were rulers of this frontier region, are scattered in western Kweichow. The Muslim Hui in Kweichow migrated there from Yunnan in the late Ch'ing dynasty after the defeat of a local rebellion. They are found chiefly in towns and cities along the main lines of communication in western and southern Kweichow, especially in Wei-ning.

About 88 percent of the total population is rural, and agriculture is the chief occupation. Rice cultivators dominate the peripheral valleys of the plateau. On the plateau itself, the Miao practice a more primitive form of agriculture, growing subsistence upland crops including wheat, maize, and potatoes. Most of the Puyi live on level lands in the valleys and cultivate rice. While the T'ung are experienced lowland rice cultivators, they are also skillful in forestry and in growing upland crops. The Shui, living together in large families and tribes, are also rice cultivators. Besides growing upland crops, the Yi undertake animal husbandry.

The density of the rural population in general decreases from north to south. It averages 500–800 persons per square mile in the valley lowlands and 250–500 persons per square mile on the lower river courses in northern Kweichow. Further south, the density decreases to an average of only 125 to 250 persons even in the basin areas, and to less than 125 on the southern mountains.

There are few cities in Kweichow. Kuei-yang is the largest (1958 population: 530,000), and Tsun-i (with some 200,000 people in 1958) is a poor second. Only two other cities had populations of more than 50,000 each, namely, Tu-yiin (1959: 80,000) and An-shun (over 50,000), while another six cities had between 20,000 and 50,000 people each (Pi-chieh, Ch'ien-hsi, Ch'ih-shui, T'ung-jen, Kuei-ting, and Tu-shan). Most of these cities are the sites of provincial, special district (chuan-ch'ii) people's councils, and are the economic and, often, communication centres for the various regions of the province.

Linguistic patterns. Chinese is the common language of the Han Chinese and the Muslims in Kweichow, Mandarin being spoken almost exclusively by the former group. Among other minority peoples, only the Miao, the Chuang, the Yi, and the Puyi have their own languages; the newly-created Yi and Chuang scripts are increasingly used by the Yi and the Puyi respectively. The spoken languages of the Puyi, Shui, T'ung, and Chuang are common to the Sai-Chuang group; those of the Miao and the Yao belong to the Miao-Yao group, and that of the Yi to the Tibeto-Burman group.

Administration and social conditions. Government structure. Administratively, Kweichow is divided into one subprovincial municipality (shih), Kuei-yang; five special districts (chuan-ch'ii), An-shun, Hsing-i, Pi-chieh, Tsun-i, and T'ung-jen; and two autonomous districts (tzu-chih-chou), the Southeast Kweichow Miao-T'ung Autonomous District and the South Kweichow Puyi-Miao Autonomous District.

Below the subprovincial level, there are three hsien- (municipal people's congress) level cities (shih) of Tsun-i, Tu-yiin, and An-shun; 69 counties (hsien); and nine autonomous counties (tzu-chih-hsien).

By September 1968, when the turmoil of the Cultural Revolution had subsided, all of the special districts, autonomous districts, subprovincial and hsien-level cities had established Revolutionary Committees. In May 1971, the re-formation of a provincial party committee in Kweichow was announced. The Kweichow Provincial Party Committee was the 21st established in China's 29 administrative regions up to that date.

Health. Since 1949 great strides have been made in the field of public health. Between 1952 and 1955, the province established 118 district health stations, 35 mother-and-child-care centres, and 250 maternity homes. Health-work teams were established, and nearly 3,000 health-work cadres were trained and organized.

Medical education

In 1953 the Hua-ch'i Workers Convalescent Hospital was completed with a capacity of 100 beds. A year later, it was modified to become a preventive medical institution. In addition, the Kuei-yang Medical College turns out doctors and medical workers. Its affiliated hospital not only provides teaching and practical facilities to the college but also takes care of 50,000 outpatients and some 3,000 inmates annually.

Education. In 1954 there were over 879,000 primary school students, 25,800 secondary students, and 2,032 college or university students, representing an 84 to 350 percent increase over the pre-1949 peaks at the three different educational levels.

There are nine institutions of higher learning in

Kweichow. In addition to Kweichow University and the Kuei-yang Medical College, there are the Kweichow Agricultural Institute (which, founded in 1939, is perhaps the oldest of the nine), the Kuei-yang Normal College, the Kuei-yang Nationalities Institute (for training members of ethnic minority groups), Kweichow Chinese Medical College, Kweichow College of Forestry, Kweichow College of Engineering, and the Kuei-yang Part-Study Part-Work Normal College.

Under the Socialist leisure-time education program, winter and other study classes provided some form of education to a total of more than 1,600,000 peasants between 1950 and 1954.

Economy. *Mining.* Kweichow has rich mineral resources. Its metallic minerals include mercury, manganese, zinc, lead, antimony, aluminum, copper, iron, and gold. Its nonmetallic minerals include coal, petroleum, oil shale, phosphate, gypsum, arsenic, limestone, and fluorite.

Extractive industries are consequently very important in Kweichow. Mercury, of which distribution is widespread and reserves are great, is mined at T'ung-jen; manganese at Tsun-i and T'ung-tzu; zinc and lead in many areas (but processed at Ho-chang); antimony at Ch'ing-lung and Tu-shan; coal at Kuei-yang, Shui-ch'eng, Tu-yün, and T'ung-tzu; and iron ore and phosphate at Kuei-yang, Weng-an, and Tsun-i.

Manufacturing. With a sufficient local supply of raw material and fuel and an expanding market in southwestern China, an iron-and-steel industry has been developed in Kuei-yang, Tsun-i, Shui-ch'eng, and, more recently, in Wei-ning and Tu-yun. Machinery manufacturing has been established at Kuei-yang, Pi-chieh, Tsun-i, Cheng-an, and other towns. Mining machinery, agricultural implements, and irrigation equipment are among the main products. Kuei-yang produces steel-rolling machines, steel-smelting converters, and other smelting equipment.

Based on the local supply of phosphate and other raw materials, such as by-products of the iron-and-steel industry, the chemical industry in Kuei-yang and Tsun-i produces chemical fertilizers, soda acid, and other chemicals. Both cities also have a textile industry. Silk textile production is concentrated in Tsun-i; cotton textiles are also produced. Again based on abundant local supply of raw materials, paper mills are found in Kuei-yang, Ch'ih-shui, K'ai-li, and Tu-yiin.

Kuei-yang also has cement, cigarette, glass, battery, and food-processing industries, while Tsun-i produces matches for southwestern China. Tu-yiin produces leather and leather goods, and Hsing-i specializes in sugar refining.

Main food crops

Agriculture. Twelve percent of Kweichow's land area is under cultivation. Over 75 percent of the cultivated area is under grain crops, particularly the rice and corn (maize) which together constitute 90 percent of the total grain output. The rest is under wheat, barley, sweet potato, potato, oat, and broad bean, etc. Due to increases in output, from 6 to 10 percent of the grain production is available for export to other provinces.

Approximately 2,000 square miles and increasingly more of the cultivated area are under industrial crops, of which the most important is rapeseed, followed by cured tobacco, peanuts, cotton, sugarcane, and sesame. Kweichow is the second largest producer of rapeseed in China, and its cured tobacco is well known. In spite of increasing production, Kweichow is never self-sufficient in cotton. Its small production of cotton and other fibres, such as ramie and raw silk, is mainly for local consumption.

Timber and other forestry products are plentiful. Among all the provinces of China, Kweichow ranks first in the production of raw lacquer and third in tung oil. Other important forestry products include camelia oil, cypress oil, gall-nut extract, and lichens.

Kweichow is also known for its production of *mao-tai* liquor—made from wheat and kaoliang—which has won a number of international prizes. Its annual production of about 300 tons is split between domestic consumption and foreign export.

Transportation and communications. *Rivers.* River transportation is of little importance in Kweichow due to the presence of reefs and rapids. The section of Ch'ih-shui Ho between Yu-tang Ho and Erh-lang-t'an is navigable for junks of two to eight tons and the section below Erh-lang-t'an for craft of 50 tons and shallow-water steam tugs. Wu Chiang, the largest river in Kweichow, is another prosperous waterway. The section between Ssu-nan and Kung-t'an, Szechwan Province, is a waterway of 132 miles, navigable for shallow-water steam tugs. The section between Ssu-nan and Shui-k'ou is navigable for junks of 12–40 tons. In addition, the Wu Shui, Chin Chiang, Sung-tao Ho, Ch'ing-shui Chiang, and Tu-Chiang are partially navigable.

Roads. In terms of highway transportation, the province is relatively well-developed. Since 1958 all counties have been connected by roads, the majority of which are all-weather roads. The main interprovincial and intraprovincial arteries are: Kweichow to Kwangsi, Kweichow to Yunnan, Szechwan to Kweichow, Hunan to Kweichow, Ts'e-heng to San-tu, Ch'ing-chen to Pi-chieh, Tsun-i to T'ung-jen, and Kuei-yang to Lo-tien. Prior to the completion of the Kweichow to Kwangsi railway, the Kweichow-Kwangsi highway was the principal freight and passenger route to Kwangtung and Kwangsi and to Central and East China.

Railroads. The Kweichow-Kwangsi railway, opened to traffic in 1959, was built on an old roadbed. Since its completion, it has been responsible for about 40–50 percent of the province's grain shipment. A few years later, railway-transportation service was greatly extended by the completion of the Kweichow–Yunnan railway (about 1963), connecting Kuei-yang with Kunming, and the Kweichow–Szechwan railway (1964 or later), connecting Kuei-yang and Tsun-i with Chungking and Ch'eng-tu. When the Kweichow–Hunan railway is completed, Kweichow will have direct rail links with all of its four neighbouring provinces and will be completely linked up with the national railway network.

Folk dramas and dances

Cultural life. The minority peoples in Kweichow are among the most artistic and musical in China. The Han Chinese also have a long and mixed cultural background. Various types of folk dramas with varying degrees of elaboration, some of which are combined with folk dances, are popular among different nationalities in different areas. Some of the Han Chinese folk dramas, *hua teng* ("Flower Lantern") in northern Kweichow and *ti-hsi* ("Floor Plays") in southern Kweichow, are also popular among the minority groups. Buffalo fighting is part of the festival activity over the New Year, especially among the Miao, Yao, and Chuang peoples. The Miao often sing of their revolutionary history and heroes, and both the Miao and the T'ung folk songs are well known. Embroidery and paper cutting are both important forms of folk art among all minority peoples. The Puyi and Ch'ilao are particularly known for their wax dyeing, the Miao and Puyi for their intricate, coloured cross-stitch work, and the Miao for their heavy silver ornaments.

Since 1949 the Propaganda Bureau of the Provincial Party Committee, the cultural and educational departments of the provincial government, and the Provincial Cultural Workers Union have been responsible for most of the cultural affairs in Kweichow. The Union organizes training classes for artists and publishes literary and art journals. Newspapers and periodicals, such as *Hsin Ch'ien Jih Pao* ("New Kweichow Daily"), *Kuei-chou nung-min* ("Kweichow Peasants"), *Kuei-chou Ching-nien* ("Kweichow Youths") and *Kuei-chou Chiao-yu* ("Kweichow Education"), are published by the Kweichow People's Press.

Since July 1953 a music work team has been established by the provincial cultural department and has maintained contact with some 135 music workers. Kweichow has 50 cultural centres, 36 cultural stations, two public libraries (one at Kuei-yang and one at Tsun-i), and a museum with a collection of over 22,000 articles.

BIBLIOGRAPHY. KWEICHOW PEOPLE'S PRESS, *Tsu kuo ti Kuei-chou* (1955), is an important sourcebook on Kweichow (in Chinese), covering its physiography, nationalities, mineral resources, industries, agriculture, transportation, water conservancy, commerce, and art. The latter part of the book is

devoted to its cities, legends, historical incidents and heroes, and its scenic and historical spots. SUN CHING-CHIH (ed.), *Economic Geography of Southwest China: Szechwan, Kweichow, Yunnan* (1962; orig. pub. in Chinese, 1960), provides an adequate account of the province's economic geography.

(C.K.L.)

Kyōto

For more than 1,000 years—from 794 to 1868—Kybto was the capital of Japan and the place of residence of the Imperial family; and it remains today the principal centre of Japanese culture. It is also the heart of Buddhism in Japan and is a leading manufacturing source of fine textiles and other traditional Japanese products. It is located on the island of Honshu some 29 miles northeast of the great industrial city of Osaka and about the same distance from Nara, which, like Kybto, is another ancient centre of Japanese culture. The capital of the Kyoto Urban Prefecture (Kyoto-fu), in Kinki district, is the city of Kybto, which had a population of about 1,420,000 in 1970.

Plan of the ancient city

History. The history of the city begins in 794, when the Emperor Kammu transferred the capital from Nara to Nagaoka (south of Kyoto) and then to Kybto, where he constructed Heian-kyb ("the capital of peace and tranquillity"; later known simply as Kybto, "the capital"). The plan of the city, like that of its predecessor, was made in imitation of the capital of the T'ang dynasty (618-907) in Ch'ang-an (modern Sian) China. Following the principles of geomancy, or divination by means of landforms and lines of direction, the emperor's palace and court was located in the northern centre of the town, and the central street ran from the north to the south. The city east of the central street was called Sakyb, meaning the left side of the capital, and the west of the same street was called Ukyb, or right side. The plan provided streets and districts for each craft. The central area of the present city of Kybto nearly follows the original street plan, although the city has since developed far to the east and to the north of the old city.

During the Heian period (794–1185), Kybto was the centre of politics and aristocratic culture. At the beginning of the 9th century, its population may have numbered 500,000—which would have made the city larger than any European city of its day. In the 12th century Japan entered into its medieval era, which was characterized by the growth of the samurai class. The first samurai clan to seize the political leadership of Japan was the Taira (Heike), who placed their government in Kybto. But, when Minamoto Yoritomo, chief of the Genji clan, bested the Taira in 1185, he established the shogunate at Kamakura, near Tokyo, after which Kybto experienced a political decline for a time.

After another civil war, at the close of the 14th century, the Ashikaga clan rose to power and placed the government again in Kyoto. During the Ashikaga period the aristocratic culture of the Heian era blended with the culture of Zen Buddhism, which had developed under the samurai and gave birth to a new cultural period called Muromachi (after the site of the Ashikaga government in Kybto). Many of Japan's magnificent architectural landmarks, such as Kinkaku-ji (Golden Pavilion; destroyed by fire in 1950, rebuilt 1955) and Ginkaku-ji (Silver Pavilion), and its famous landscape gardens, paintings, Nb plays (the classical drama of Japan), the arts of the tea ceremony and flower arrangement, and its pottery industry were created here at this time.

The reign of the Ashikaga government ended after the Ōnin War (1467–77), whereupon Japan entered upon a century of civil war fought between powerful daimyos (feudal lords). The warlord Oda Nobunaga and his successor, General Toyotomi Hideyoshi, however, completed the unification of the country, after which Hideyoshi reconstructed Kybto, which had been devastated during these wars. It was at this time—in 1594—that the Momoyama Castle in the southern part of the city was built. Mainly because of Toyotomi's excellent and aristocratic taste, a brilliant civilization called the Momoyama period flourished in his reign (1582–98).

Tokugawa Ieyasu (1542–1616), founder of the third and last military dynasty (shogunate), made Edo (present-day Tokyo) the site of his government in the beginning of the 17th century, but the Kyoto Imperial Palace still remained in Kybto. Throughout the Tokugawa regime, which lasted until 1868, Kyōto remained one of the three main cities of Japan together with Edo and Osaka.

With the beginning of the modern period in Japanese history—*i.e.*, with the Meiji Restoration in 1868—the capital of the country and the residence of the Imperial families was moved to Edo, which was re-named Tokyo.

The contemporary city. City site. Kybto is located in the northern part of the great Kybto (Yamashiro) fault basin and is surrounded on three sides--north, east, and west—by low mountains. The city covers an area of about 236 square miles (611 square kilometres). Its northern edge lies about 290 feet and the south about 41 feet above sea level. The hilly area to the east of the city was called Higashiyama and includes Mt. Hiei (2,782 feet), bordering Shiga Prefecture. To the north extends the Tanba plateau, called Kitayama; it includes Mt. Mikuniga (3,146 feet). To the west is the Nishiyama region, which includes Mt. Atago (3,031 feet).

Many streams flow down from the mountains, including the Kamo, the Katsura, and other rivers, which run through the city to join the Yodo-gawa to the south.

The climate

The climate is typical of inland Japan; it is hot in summer and cold in winter. The yearly mean temperature of Kybto is about 59° F (15" C); the highest monthly mean (80° F, or about 27" C) is in August and the lowest (38° F, or about 3° C) in January. Average yearly rainfall is about 62 inches, with much of the rain arriving in summer (June, July, and August).

The streets of Kybto cross at right angles in a checkerboard pattern, in accordance with the original Heiankyo plan. The centre of the present city, however, has moved northeastward since the time of the original city.

In the centre of the town, Shijb street runs east to west, and Kawaramachi and Karasuma streets run from north to south. The intersection of Shijb and Karasuma streets is the centre of the business district, while the area around the intersection of Shijb and Kawaramachi streets is the shopping and amusement centre. Most of the old city downtown consists of small stores, workshops, and residences, all standing side-by-side. There are many Buddhist temples and Shintb shrines, whose old wood roofs jut through the city's many trees. There are also several parks and small public squares.

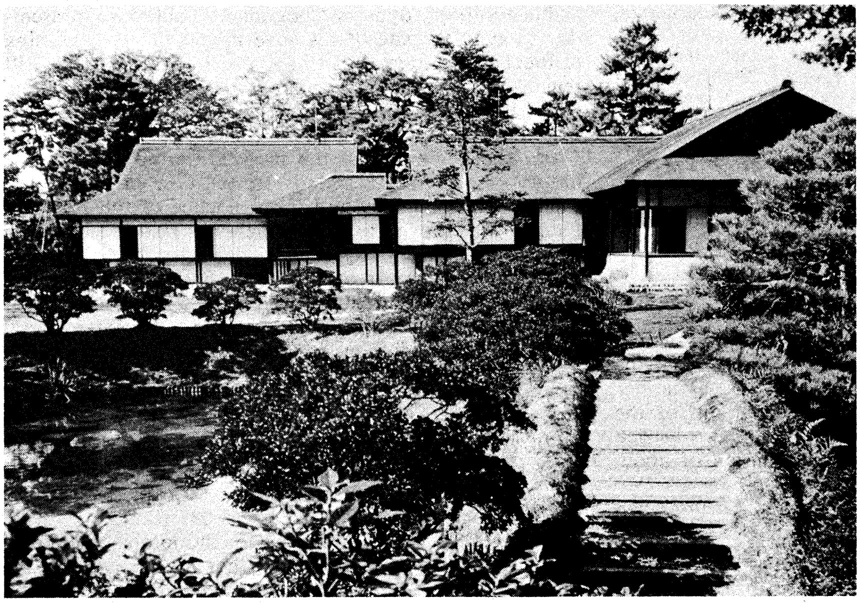
Although the city is divided into nine wards (ku), in popular usage the central part of Kybto is known as the Rakuchu district, the eastern part as Rakuto, the north as Rakuhoku, the west the Rakusei, and the south as the Rakunan district. Suburban communities include Kameoka, a town in a small basin to the west, while to the south the city of Uji lies on the Uji-gawa (a headstream of the Yodo-gawa).

Early transport routes

Transportation. Kybto has always occupied a key position in Japan's transportation system. In the Tokugawa period (1603–1867), it was the terminal of the Tōkaidb Road, which ran westward from Edo, and it was also linked with Osaka by water transport on the Yodo-gawa.

The New Tbkaidb Railway Line runs parallel to the old Tōkaidō Line from Tokyo to Osaka via Kybto. Between Kybto and Osaka there are two tramcar lines. The journey between the two cities takes 40 to 50 minutes, and many who live in Kybto commute to Osaka daily. Kybto is linked to Osaka and Nagoya by the Meishin Expressway, which continues from Nagoya to Tokyo as the Tbmei Expressway. Many national roads also enter the city, including routes running between Osaka, Nagoya, and Tokyo and the main road to Nara. Within the city itself streetcars and buses provide the most serviceable means of transportation.

Demography. In 1970 Kybto had a total population of about 1,420,000 and was the fifth largest city in Japan. The annual rate of population increase was about 1 percent, and the population density was about 6,000 per square mile. The highest density occurs in the central part of the city, where three wards—Kamigyb, Nakagyō, and Shimogyb—each have a density of more



Katsura Imperial Villa, Kyōto.
Camera Tokyo

than 44,000 per square mile. In all other wards, the density is under 18,000.

Economic life. There are about 16,000 factories in Kybto, but 60 percent of them are very small, having under four employees. This reflects the fact that Kybto industry is characterized by the manufacture of traditional products and that its heavy and chemical industries rank relatively low in the scale of importance.

The textile industry accounts for 53 percent of the total number of factories and provides employment for 34 percent of all workers. Its products include silk fabric and embroidery, for which Kybto is famous. They are manufactured in the Nishijin district, the silk-weaving industry of which dates back to the time of the founding of the capital.

The food and drink industry ranks second in importance, principally because of the brewing of sake (rice beer), mainly in Fushimi ward.

The central part of the city is crowded with many small factories or workshops that produce such typical Japanese goods as fans, dolls, Buddhist altar fittings, and lacquered wares. The heart of Kyōto's famed porcelain industry is the Kiyomizu district.

The central business district

In 1971 the city had about 34,000 stores, more than 80 percent of which were retail outlets. The ratio of wholesale stores to retail is lower than that of other cities in Japan, indicating that Kybto is a consuming city. The more expensive stores are concentrated along Shijb street, the business centre, where the main banks and head offices of many companies are located. Wholesale stores, dealing in fine textiles, silk fabrics, and embroidered products, constitute the national centre for the industry.

Machine and chemical industries are developing in the southern part of the city, in the Rakunan industrial area.

Government. Kybto has two main governmental offices; these are the city hall and the prefectural office, both in the central part of the city. The prefectural governor and the mayor are elected by popular vote.

Education. Kybto is also one of Japan's traditional centres for education and for training in arts and sciences. There are 22 national and private universities and colleges in the city, some of which, such as Kyōto University (formerly Kybto Imperial University), founded in 1897, are among the leading educational institutions in Japan. Dbshisha University, founded in cooperation with the American Board of Foreign Missions, has been a centre of Christian higher education since 1875. In addition, as befits the seat of Japanese Buddhism, there are several Buddhist universities.

Culture. As the ancient capital and the former residence of the emperors, Kybto contains many historical and cultural treasures, including paintings, carvings, fine examples of calligraphy and the industrial arts, architecture, and exquisite Japanese-style gardens. Further, there are a number of major cultural institutions, including Kybto Public Hall, Kybto Municipal Museum of Art, Okazaki Zoological Garden, Kyōto Municipal Commercial Museum, and the Kyōto Prefectural Central Library. The Kyōto National Museum, near the Kyōto railway station, is another landmark; it was erected in 1897 by the Imperial family as the Kyōto Imperial Museum. Kyōto also has two important Nō theatres and one Kabuki theatre, as well as many smaller theatres and cinemas and a sports stadium.

Many of the city's houses are built in the Japanese style, characterized by wooden pillars, tiled roofs, mud walls, and sliding inner doors made of wood and paper. And many of the houses also have small Japanese gardens. These characteristics are even more apparent in the examples of historical architecture. Among the most famous examples are Higashi-Hongan-ji, Nishi-Hongan-ji, Saihō-ji, Tenryū-ji, Ninna-ji, and Daitoku-ji (all of which are Buddhist temples); and Heian, Yasaka, and Kitano Tenjin (Shintb shrines).

The old Kybto Imperial Palace, the present buildings of which date from 1855 but which closely resemble the original that they replaced, is one of the most representative examples of Japanese architecture. Nijō Castle, originally built in 1603 by the first Tokugawa shogun, is the most famous castle of that era. The castle itself, which contains many cultural treasures, is one of the 38 buildings in the city registered as national monuments; in 1939 it was given to the-municipality and has since been open to the public.

The facts that the city is the repository for these treasures and that annual festivals and other seasonal events are held there make Kybto the cultural centre of Japan. The city's physical setting also provides another attraction, drawing many tourists to the city. In 1969 alone, some 20,000,000 tourists, including several hundred thousand visitors from abroad, visited Kybto.

(T.O.)

Labour Economics

Labour economics is the study of the labour force as an element in the process of production. The labour force comprises all those who work for gain, whether as employees, employers, or as self-employed, and it includes the unemployed who are seeking work. Labour economics involves the study of the factors affecting the efficiency of these workers, their deployment between different industries and occupations, and the determination of their pay. The article deals with the labour force of contemporary industrialized economies.

Obviously, the economist cannot study the capabilities, jobs, and earnings of men and women without taking account of human nature, social structures, cultures, and the activities of government. These forces, indeed, often play a more conspicuous part in the field of labour than do the market forces with which the economist is ostensibly and chiefly concerned. The difference, for instance, between the rates of pay of a craftsman and the labourer who works alongside him may be governed by custom or determined by an arbitrator or maintained by the bargaining power of a trade union. These determinants may seem to override the forces of supply and demand. but a distinction must be made between the agency by which a given result is brought about and the factors that circumscribe the agency's freedom of action and to that extent determine the outcome. Thus an arbitrator may be very conscious that his award will be effective only if it lies within certain limits. Even when the initial action may be regarded as arbitrary, reactions to it bring market forces into play. The comparative study of wage movements in different periods and countries, moreover, shows similarities and regularities that are more marked than the variety of their settings would ever lead one to expect and that can only be regarded as the product of persistent forces working within an equilibrating system. It is this that justifies speaking of a labour market. Though there is much in labour that can be understood only with the aid of the psychologist, the sociologist, or the political scientist, the forces they study do not supersede the market forces that are the special province of the economist; rather, they provide the setting within which the market forces take effect.

QUANTITY AND QUALITY OF THE LABOUR FORCE

The size of a country's labour force, within a given total population, depends on two factors: the proportion of the total population that is of working age, and the proportion of these who work for gain.

The limits of working age are usually taken to be established by the minimum school-leaving age and the prevailing pensionable age. Allowance must then be made for those persons who continue to work for gain after attaining pensionable age. Typically, some two-thirds of the population of an industrial country lies within these limits.

Activity **rates.** The employed labour force may be analyzed in terms of particular activity rates. An activity rate is the proportion of the whole number in a given age and sex group—for example, females aged 30–34—who work for gain. Among males, activity rates in the earlier years of working age are as a rule low, because so many remain in education and training. Between the ages of 25 and 50, male activity rates approach 100 per cent, but from 50 onward they fall as men begin to retire. The pattern of female activity rates is very different, and has changed greatly in the second half of the 20th century. Formerly, female rates ran higher than male in the earlier years because fewer girls enjoyed extended education, but from the age of 20 onward they fell sharply as women married and withdrew to domestic duties. Women so occupied remain by far the largest contingent of persons of working age but not in the labour force. Since World War II, however, it has been less usual for women to leave paid employment immediately on marriage. A fall in the age of marriage, moreover, together with a smaller size of family, has enabled many women to return to paid work in their 30s, and female activity rates have come to show a second peak between the mid-30s and the mid-40s, after which they decline more steeply than male rates. From these various activity rates there emerges an overall proportion of the gainfully occupied among all of working age that is typically in the region of two-thirds.

Quality of labour. The quality of the labour force depends on education and training, physique, and health. There is evidence that physique has been greatly improved by increases in the standard of living in the 20th century. Because of the reduction in family size, this rise has been even more marked for children than for adults, and the effects have been seen in the greater height and weight attained by children at a given age. The beneficial effects of stronger physique on health have been enhanced by the advance of medical knowledge and the increased availability of medical services. Better health has raised productivity by a reduction in absenteeism and by a prolongation of the working life during which the economy reaps the benefit of the education and training the worker has received.

Education and training

Education and training can be regarded as a kind of investment, and the rate of return it yields can be estimated. The amount of the investment is the value of the student's use of resources—buildings, equipment, and instructors—together with the output that the economy would have enjoyed from his work had he been gainfully occupied rather than studying. The yield, in turn, is calculated by assuming that the average subsequent earnings of those who completed a given course of education, compared with the average earnings of those who stopped just short of it, provide a valuation of the increase in productivity that the course confers. From this difference in earnings there must be deducted the contributions to the sinking fund required to replace the amount of the investment by the end of the student's working life. The net yield so calculated can then be expressed as a rate of return on the investment. Estimates suggest that this rate of return is not less than that generally obtained from investment in physical capital. They also indicate that a great part of the productive resources of the economy consists in the education and training embodied in its labour force.

Though estimates of this kind are subject to some objections in principle, they do serve a useful purpose in stressing the potential of education and technical training in raising productivity and the risk of investing too little in them relative to other forms of investment. There is no less a risk of underinvestment in training in industry. The great obstacle there is that the employer is not assured of retaining the services of workers in whose training he has invested. In traditional apprenticeship, the employer's cost of training was offset by the apprentice's binding himself to stay with the employer at a low wage for a number of years. But apprenticeships persist today only in limited fields. Governments have increasingly exerted themselves to improve the training of non-apprenticed entrants, as well as that of older workers in need of retraining.

DEPLOYMENT OF THE LABOUR FORCE

Shifting patterns of employment

The contribution of education and training to economic development is apparent in the changes that have taken place in the deployment of labour in the developing economies. When the deployment of the labour force is followed over a period of time, certain patterns appear. One of these arises from changes in methods of production. In farming, improvements in technique and equipment have made possible an increasing output from a declining labour force. In industry, the extension of research and development, the increased complexity of products and equipment, and new methods of collecting, storing, and processing information, along with other developments of management procedures, have all acted to increase the numbers of administrative, clerical, and technical workers relative to manual workers. A second course of change has affected occupations linked with particular industries, when those industries have contracted or expanded as compared with others. Coal mining and cotton textiles are examples of contraction. The service industries, on the other hand, have expanded: a greater proportion of household expenditure is devoted to services; education has extended; governments have provided more social services. A third course of change has its origins in relation to supply. Domestic services, for instance, have contracted because improved education and the opening up of other occupations to women has enabled many to take up work that they prefer. The aggregate effect of these changes has been to decrease the relative number of manual workers in the labour force and increase that of the administrative, clerical, and technical. One general tendency is that as standards of living rise the service industries absorb a greater proportion of the labour force, because the extension of the demand for their output is not generally offset, as in manufacturing, by a progressive reduction in the amount of labour required to produce a given output.

The many far-reaching changes that have come about in the relative numbers in different occupations and industries have called for corresponding changes in the training and allocation of young entrants to employment and for the movement of workers already in employment to other kinds of work and, often, other places. Though part of this adaptation has been unplanned and undirected, a number of governments have undertaken to foster the process of adaptation by a labour-market policy. One means of applying this policy is the provision of information to job seekers as to vacancies immediately available, and to workers at large as to the prospects and requirements of particular occupations. Labour-market policy also tries to guide entrants toward those occupations for which an expansion of demand is expected. One way of doing this is by promoting the training and retraining of selected persons for selected occupations. The function of retraining may be extended, as in Sweden, to offer all workers opportunities to qualify themselves for better-paid jobs throughout their working lives.

FIXING RATES OF PAY

Customary rates

Wages may be fixed by collective bargaining between unions and management or by individual bargaining between worker and employer or simply by custom. When the status of wage earner became distinguished from other forms of labour, it was marked by the existence of an individual agreement about the rate of pay between each wage earner and his employer. The law still recognizes the individual contract of service even where the rate of pay has been fixed collectively. In earlier days there was often not even individual bargaining, because customary rates of pay prevailed that might be unchanged for many years at a time. In southern England, for instance, the prevailing rate for building craftsmen remained at sixpence a day for 120 years after 1412; for most of the 500 years after 1412, the building craftsman's rate was half again as great as the labourer's, or nearly so. After industrialization had set in, custom continued in some measure to regulate rates of pay and to protect workers who entered into individual agreements. But its sway was much less extensive: from time to time rates changed. Though there was at first no reference to the cost of living, when price increases were general and sustained, there must have been informal understandings among the wage earners of a locality that each in making his own agreement would hold out for a higher rate. At times of increased demand for labour, moreover, the employer would have to offer a rate sufficient to attract and retain the wage-earners against the competition of other employers. The necessity of holding needed labour is today the governing factor for employers who have workers with whom they do not negotiate either collectively or individually—generally clerical and administrative workers. Individual bargaining also persists in those higher appointments in which the worker has access to a number of potential employers, and the employer will have to pay more if he is to secure a worker of higher quality.

But frequently, where the safeguards of both custom and of competition for workers have been missing, workers have felt the need to combine in order to bargain collectively. The force of custom declined as industrialization created new jobs and moved workers into new localities. Business fluctuations brought unemployment so that instead of employers competing for labour, workers were often competing for jobs. Thus industrialization has been universally associated with the rise of trade unions.

Forces making for uniformity

Trade unions and bargaining areas. A main purpose of the trade union was to maintain a minimum rate of pay for its members, a purpose that led unions to extend or delimit both their membership and the number of employers with whom they bargained. The starting point was typically the club of craftsmen in a certain locality, concerned to ensure that none of its members worked for less than the rate it recognized from time to time as a minimum and to raise that rate when opportunity offered. By bringing all who worked in the same craft and district into membership, the club could reduce the risk of their bidding against each other; and if it could also limit the number entering the craft—by controlling the number of apprentices—it would be more likely to be able to raise the rates. But since it was still likely to be subject to the competition of members of the same craft coming in from other places, and some of its own members might move in search of work; it had an interest in extending its coverage over all members of the craft throughout the labour market. If the labour market was not coextensive with the product market, however, the union might still find itself exposed to the competition of workers at a distance if these worked at lower rates and so enabled their products to be sold at lower prices. Thus there was reason to extend the coverage of the union up to the boundary of the market for the product, though it was not practicable to organize workers in other countries. But the union would see no advantage in bringing men of other occupations into membership: on the contrary, it was felt that one could expect employers to concede a rise more readily if it would have to be paid to only a restricted membership. What has been said here of the craft union applies to all unions insofar as their aim is to maintain and raise the pay of members of a given occupation: the pursuit of that aim will lead them to embrace all the members of the occupation throughout the market for their product and to establish a basic rate throughout this bargaining area.

The reactions of employers both reinforce and modify this tendency. The ability of any one employer to pay a given rate will depend largely on what rates are being paid by other employers who compete with him in the product market. When competition is close and labour costs are a substantial proportion of total costs, all employers selling in a given product market have a strong inducement to negotiate only through an employers' association that embraces them all. Most employers' associations are in fact industry-wide, though some are limited to particular regions or sectors of an industry. Employers also know that what is conceded to employees in one occupation will commonly be demanded by those in others, unless they are divided by such a gulf as used to separate the manual from the clerical workers. Employers therefore commonly prefer to reach an agreement with all their workers in common, and may make this a condition of negotiation. They thereby put pressure on occupational unions either to extend, amalgamate, and divide up until they form industrial unions each embracing all the manual workers in a given industry, as the Swedish unions have done, or to enter into confederations that provide all the unions having members in a given industry with a common front for the purpose of bargaining—the course followed by British unions.

Many semiskilled and unskilled workers are unable to seek bargaining advantage by restricting the membership of their unions to one defined occupation: they have to seek it rather through the accumulation of funds and the force of numbers—for them, "unity is strength." Some unions have therefore adopted the principle of industrial unionism from the outset, in accordance with the tendency noted above toward establishing industry-wide bargaining areas. Others, the general unions, have set out to recruit workers from every occupation and industry; but for bargaining purposes they have commonly had to act on behalf of their members in each industry separately. In any clash between the forces delimiting the bargaining area and those delimiting the trade union, the former generally prove the stronger.

Effects of collective bargaining. Collective bargaining developed with the growth of trade unionism, especially from 1890 onward. It impinged upon labour markets in which the trend of money wages was upward: in years of good business, money wages generally rose, and though in the years of falling or low activity they were often cut, the cuts were generally smaller than the preceding rises had been.

Levelling of pay rates. A first effect of the extension of collective bargaining was to reduce pay differences, which had been large, between the wages a given grade of labour received at any one time in different regions and in different firms in the same region, and even between one man and another under the same employer. The unions at first had to accept the prevailing regional differences, but their pressure to bring up the lower-paid regions has reinforced the effect of improved communications and information in reducing these differences greatly, especially since World War II. Assurance of "the rate for the job" raised the wages of particular groups or individuals who lacked access to alternative employers, either spatially or because of their lack of information and mobility. In general, the extension of collective bargaining brought about greater uniformity in the rates of pay received by workers of a given grade, and it did so by raising the lower rates.

"The rate for the job"

Collective bargaining has also affected the forms in which improvements in pay are realized. It has borne particularly on those parts of the terms and conditions of employment that of their nature require to be regulated collectively. Chief among these are the hours of work. The extension of fringe benefits, such as insurance and pensions paid for by the employer, has also reflected trade union pressure.

Other effects. Studies of differences between the movements of wages in unionized and non-unionized sectors of employment, especially in the United States, have brought out three other effects of the extension of collective bargaining. One is an impact and once-for-all effect: the introduction of collective bargaining has raised the wages of the workers concerned, relative to the general level prevailing around them, by some 10–15 percent. A second effect has been in the timing of changes: when wage rises were the order of the day, unionized workers achieved them earlier than non-unionized; and when the market was moving the other way, cuts of unionized workers were put off longer. When the cost of living has risen rapidly, as in wartime, the unionists' ability to secure compensatory rises in money wages more promptly promoted the extension of unionism, especially among white-collar workers who had previously stood aloof from it. The third effect has been in the ability not only to defer wage cuts in depression but also to reduce their amount. In the United States, for example, the differential between wages in the unionized and non-unionized sectors was at its highest in the 1932 depression trough. A major effect on the general level of pay in terms of purchasing power and on its share in the product of industry seems to have stemmed from the resistance to pay cuts in the world economic depression of 1921: though pay was cut severely, often after protracted struggles, it could not be brought down as far as product prices had fallen, and in more than one country the distribution of the product of industry between pay and profit seems to have been permanently shifted.

Impact of the union on pay rates

In these ways, by raising the pay of particular workers and by modifying fluctuations in the workers' favour, over a period of time collective bargaining has made the total of pay higher than it would have been otherwise in the same conditions of the market. But the effect has been limited. Before World War II, the movements of the general level of pay continued to depend mainly on market conditions, and the points at which the effects of collective bargaining can be distinguished clearly are fewer than might be expected. Collective bargaining provided the arena in which market forces took their effect, rather than a shelter from or alternative to them. Full employment after World War II, however, greatly modified the bearing of those forces on the collective bargain by engendering the expectation among employers that if they agree to rises in pay that exceed the rise in productivity and so raise unit costs, they will still be able to preserve profit margins by raising the prices of their products, and do this without loss of business, provided only that the initial rise in pay is not greater than what is generally being conceded at the time by other employers. In these circumstances of cost inflation, the rate of rise of money wages depends in great part on the policies of the trade union.

A second limitation is that even where collective bargaining has affected the movement of money wages, it has had only transient effect on the division of the national income between pay and profits. Whatever the course from time to time of rates of pay in money, the pay per man in real terms (*i.e.*, in terms of purchasing power) has risen with remarkable regularity in much the same proportion as output per man, save for the one major exception of the displacement in favour of pay in the early 1920s. This fact is well-established. The reasons for it will be touched on in the last section of this article. Here an explanation may be offered of its consistency with what will seem, especially to the trade unionist, to be equally well established facts—that in a particular case a trade union is able to obtain a rise in pay that would not have come about at that time had the union not entered a claim and backed it with the threat of a strike; that when the rise begins to be paid, it comes out of current profits; and that at that time also the real wage (*i.e.*, the wage in terms of what it will buy) is raised in the same proportion as the wage in money. It is necessary to look beyond these immediate effects. As time goes on, firms will take the opportunity to restore profit margins either by maintaining their selling prices while productivity rises or by raising those prices. The statistical record makes it clear that firms have generally been able to do this, except during phases of downward pressure by the market upon prices, and it is in these phases that the successful prosecution of pay claims is least likely. When market conditions favour such prosecution, moreover, many unions are likely to be moving at much the same time, and insofar as higher rates of pay are followed by price rises, these rises will be general. What holds of one pay rise in isolation does not hold of a number occurring together: the rise in real pay initially conferred by any one rise in money pay will be reduced as the cost of living rises.

Restoration of profit margins

Theory of bargaining. Limitations on the scope of bargaining are also suggested by theory. Collective bargaining can be seen as the reduction of two risks to which the worker is exposed if he bargains individually. There is first the risk that he will find himself merely one of a number of applicants for a single vacancy and that competition between them will force the pay down. Even if he is the sole applicant for the vacancy, there remains the second risk that the job will be offered to him only on terms that he is not willing to accept; in the event of failure to agree, going without the job will inflict more hardship on him than not filling the vacancy will on the firm. Bargaining through a trade union removes the first risk by ensuring that whichever applicant the firm engages it must pay not less than the union rate: in this sense the union exercises monopoly power. Membership in a trade union reduces the second risk by increasing the workers' relative power to change proffered terms by withholding consent: in this sense the union confers bargaining power.

Constraints. The scope of the monopoly power that the union exercises by maintaining the rate for the job may be seen by supposing that this rate is simply announced by the union, which leaves firms to hire as many or as few men as they choose at that rate. In deciding how high it can set the rate, the union must have regard for the consequences for employment. Firms may be able to alter the design of the product and the method of production so as to use less labour. To the extent that they cannot economize in the use of labour and that the pay of this labour enters into the total cost of production, a higher cost arises that firms may be obliged to pass on to their customers through higher product prices; the customers are then likely to buy less from them, especially if there is international competition in the markets for the product, and again employment will suffer. Thus a union that dictates its own terms is still subject to the constraint of the demand curve for the labour concerned. Equally, if the employers dictate the rate of pay, they could not set it so low as to make it impossible to attract and retain the required labour force: they would be subject to the constraint of the supply curve of the labour concerned.

Work stoppages. When neither side dictates the terms and an agreement must be negotiated, failure to agree results in a stoppage that causes losses to both parties. Attempts have been made to develop the pluses and minuses of these losses into a theory of bargaining. If, for example, it is assumed simply that the continuance of a stoppage progressively increases the wish of the parties to end it, and so causes firms to raise and the union to lower the rate at which each is prepared to settle, then the stoppage will end on the day when the two rates have been brought into equality. Further, if the parties agree in their forecasts of how the wish to settle will be affected by the continuance of the strike, they will find it in their interests to reach agreement on what would be the terms of the ultimate settlement without resorting to coercion by stoppage. A more elaborate theory has been developed in which each party is seen as weighing the cost to itself of a stoppage of given length, the benefit to it of a given concession by the other party, and its estimate of the effect of a given extension of the stoppage on the willingness of the other party to make a concession.

When stoppages are unlikely

In practice much more is involved—internal political pressures, for instance, personal prestige, or the tactic of involving the government and public opinion. Many of the costs of a stoppage, moreover, are hard to express in terms of money. But the above three variables must always figure prominently in the parties' consideration. A stoppage is unlikely when on a consideration of these variables it appears that there will be no net gain; this situation will exist when bargaining power is evenly balanced or when negotiation has already brought the parties' positions close together. One party is likely to see a clear advantage in a stoppage only when market forces are working in its favour, and these will have told already in the course of negotiation. In particular the cost of a stoppage will be high to employers when they are busiest, whereas in a recession a stoppage may be a positive benefit to them. Insofar as bargaining power is thus conferred by market forces, it injects no distinct factor into the determination of rates of pay. But bargaining power may also be conferred by determination, loyalty, and leadership on either side. It has also been conferred on trade unions by the expectation, engendered among employers by the experience of sustained full employment, that rises in pay can be covered by higher prices so as to maintain profit margins without loss of business.

Methods of rate setting. Industrialization has greatly increased the variety of the jobs performed, even among workers who work alongside one another. Rates of pay have been adjusted to particular jobs and to the performance of particular workers by a combination of procedures initiated by management and of bargaining pressures exerted by the workers.

Job evaluation. One such procedure is job evaluation, the aim of which is to measure the aggregate requirements of different jobs on a common scale and to use these measurements to adjust the relative rates of pay for particular jobs, always within the range of prevailing rates. The requirements considered include the amount of previous experience and of training that constitute the threshold for entry to the job, the demands the job makes on mental and bodily faculties, the responsibilities it imposes, and any unpleasant working conditions or risks of accident associated with it. Of the various ways of measuring these requirements, the simplest and most common procedure is to begin by allotting a maximum number of points to each requirement, and then assigning each job a number of points within that maximum according as the intensity of the requirement appears in a given job in comparison with others. The totals of the points awarded in this way to the various jobs are then compared with the jobs' rates of pay, and a formula for turning points into money is derived and applied to the total of points for each job in order to obtain the appropriate rate of pay for it. There may thus be as many rates as there are jobs, but it is often found more convenient to draw up a wage structure of, say, seven or eight grades and to put into each grade, at a common rate of pay, all the jobs whose evaluated requirements fall within a certain range.

Graded structure of wages

Merit rating and the "straight piece rate." The adjustment of rates of pay to the performance of individual workers may be made by merit rating, that is, by the payment of higher rates to those whose personal conduct and capabilities are adjudged to be superior to the general run. The most widely applied and far-reaching method, however, adjusts the worker's earnings to the output he achieves week by week. Such payment by results can be applied only where output is measurable, and this may require applying it to all the members of a working group in common and not individually. Where output cannot be measured in physical units at all, indicators of performance such as economy of materials or the running hours achieved by machines for whose maintenance the worker is responsible, may be used as the basis of bonus payments. The simplest connection between output and earnings is provided by the "straight piece rate," under which the worker receives the same payment for each piece or unit he produces; but the connection may also be provided by a formula under which earnings vary less, or in some instances more, than in proportion to output. The common aim of methods of payment by results is to give the worker an incentive to reach and maintain higher levels of output, and experience shows that workers moved from hourly rates to payment by results are likely to raise their output by from 15 to 30 percent.

The piece rate is commonly arrived at after time study, in which the time actually taken to achieve a unit of output is measured by stopwatch, and the observed time is adjusted according to the observer's judgment of whether the worker studied was working faster or more slowly than the average worker might be expected to when habituated to the job. If the adjusted time in a given case was three minutes, the worker on a straight piece rate would be credited with three minutes' pay, at his hourly rate, for each unit produced, even if he produced it in less than three minutes. Obviously there is room for argument here; rates are often the subject of dispute, and many are in practice negotiated rather than fixed by the rate setter alone. A rate that is appropriate when first installed is apt to become less so as minor improvements in materials and methods cumulate. Some firms that looked to methods of payments by results to lower their costs have thus found them increasingly costly as well as vexatious as time goes on, and some have moved back to hourly rates with reliance on supervision or the payment of a high hourly rate subject to the maintenance of a certain output in order to maintain productivity.

Single-plant contracts and pay adjustments. The rates paid in a given plant or firm may be the subject of collective bargaining when the bargaining area is not wider than the firm; negotiations over a wider area can deal with them only when they are relatively few or are capable of being classified in a limited number of grades. One of the advantages of the plant contract prevalent in United States manufacturing is that it enables the wage structure of the plant to be specified and negotiated in detail. United States trade unionism lends itself to this procedure in that in manufacturing the unions are predominantly industrial in scope, so that most of the manual workers in a plant are members of the same union; and the local, or branch, of the union coincides with the plant. In the absence of such arrangements, bargaining over particular rates is likely to go on nonetheless, but in a piecemeal and unregulated way. A leading part in the negotiation of particular rates will be played by the shop steward. When a number of unions have members in the same firm, the committee of shop stewards provides a common front, and its convener may be heavily engaged as a negotiator; such a committee acts in considerable independence of the parent unions.

The wage drift phenomenon

A number of possible ways have been indicated in which the effective rates of pay obtaining at the place of work may be raised during the intervals between rises negotiated by recognized procedures: employers may voluntarily extend payments over and above the negotiated rates; the standards applied in fixing rates under payment by results may become looser; any single rate once fixed may become looser as time goes on; and pressures exerted by workers individually or in small groups may enforce claims for higher rates for particular jobs. The outcome of these processes is known as wage drift. It has been fostered by conditions of full employment, which have given the individual worker the indispensability that enables him to press his claim under threat of withdrawing his labour, and has made management more anxious to maintain and raise output than to keep costs down. In a number of countries wage drift has accounted for a sixth or more of the total increase in the payment made for the hour of work. Wage drift is precluded where rates are specified in detail in a collective agreement such as the plant contract and will not be varied until that agreement is renegotiated.

Public regulation of rates of pay. Governments have intervened in three ways to enforce minimum rates for workers who lacked both the protection of trade unions and competition between employers for their services and whose wages in consequence were regarded as needlessly low. One way has been to provide by law that "recognized terms and conditions of employment," such as those reached by collective bargaining for workers of a particular description, shall be applied to all others engaged in the same kind of work. A second way, followed by the United Kingdom since the Trade Boards Act of 1909, and by a number of state legislatures in the United States, has been to set up boards of representatives of the workers concerned and their employers, together with independent members, charged with determining rates of pay and hours of work that will be legally binding as minima on all employers within the scope of the board. The board discusses and negotiates wage claims in much the same way as in collective bargaining, albeit if the parties cannot reach agreement, the independent members have a deciding vote. A third way, followed notably by the United States in its Fair Labor Standards Act since 1938, has been to specify by statute the actual minimum wage applicable to wide categories of employment—the amount set being such that only a relatively small number of workers, namely the lowest paid, are immediately affected.

When such third-way measures were first proposed, critics argued that they would only result in the workers they were intended to protect losing their jobs. In some cases this has happened, as when the United States minimum wage was applied to the needleworkers of Puerto Rico. More often, however, the workers concerned were receiving lower pay than a competitive market would have afforded them—that is, if they had had more access to alternative employers. The first two forms of intervention were calculated to raise the pay of particular groups of unorganized workers only to the extent that it would have been raised by the extension of collective bargaining to cover them. It is a disadvantage of the third method that the pay of all workers below the statutory minimum is raised irrespective of the effect it may have on their continued employment.

Practice in Australia and New Zealand

Arbitration. Another way of regulating rates of pay is a by-product of arbitration systems set up originally as a means of avoiding strikes and lock-outs. In Australia and New Zealand it has become the practice, accepted by both employers and trade unions, to have the main proportions of the wage structure and the movements of the general level of wages determined by the awards of arbitrators to whom these issues are submitted in the form of disputes. In setting rates for particular occupations or industries relatively to others, arbitrators must in practice have regard to what is acceptable to the parties; for even where arbitration is compulsory, its awards would cease to be observed if either party had cause to believe that the terms of the awards were persistently less favourable than it could obtain by its own bargaining power. In regulating the movement of the general level of pay, the arbitrators have more discretion; but the government, and the employers in so far as they meet international competition at home and abroad, will make them aware of the effects of the awards on the level of domestic costs and prices and on the balance of payments.

National incomes policy. Under full employment the rise in effective rates of pay, whether through negotiation or through wage drift, has generally been inflationary in that it has exceeded the rise of productivity. The consequent rise in costs and prices has been disturbing domestically and has been particularly embarrassing to governments that face difficulties in balancing their external payments. Governments in general have been unwilling to check the rise of inflation by applying fiscal and monetary restraints to the degree that unemployment would be substantially raised. In the belief that at least part of the rise is due not to excess purchasing power but to the pushing up of costs and prices, governments have appealed to those who make decisions affecting labour costs and product prices to moderate the rise in pay and profits. Some governments have formulated norms that would in theory keep the general level of prices constant, and would keep the general level of pay rising only at the rate of the expected rise in productivity, allowing, of course, for specific exceptions. Agencies have been set up to apply these principles, but usually only by way of investigation, assessment, and advice. Governments have preferred to rely on the acceptance of the policy in principle by employers and trade unions, and on their efforts to secure its observance by their affiliates. Even where statutory powers of control exist, they have usually been kept in reserve. When the experience of sustained full employment has made employers generally expect that they can raise pay by an inflationary amount without harm to their own businesses, it is hard to persuade workers to accept smaller rises in pay than employers are willing to give. Whatever moderating effect incomes policy may have had upon cost inflation, it has not stopped it. The policy remains in the stage of improvisation and experiment.

THE STRUCTURE OF PAY

Factors in pay, variations

Systematic differences are found in the average earnings obtained in different regions, industries, and occupations. The average earnings prevailing in different regions of a country show a considerable range between the highest and the lowest, even when the same procedures for fixing rates apply everywhere. Much of the dispersion is due to differences in the localization of industry: if the relatively high-paying iron and steel industry, for instance, is concentrated in a particular region, then the average pay of the region will be raised to that extent. But regional differences also exist because work of the same kind frequently commands different rates of pay in different regions.

Such differences may correspond to regional differences in the quality of workers, so that there is no real difference in what is being paid per unit of work. But there may be real differences as well. Such differences are sometimes necessary to maintain the balance of payments between regions; they may also be in some measure a legacy of history and are likely to be reduced as communications improve and labour becomes more mobile. As noted above, this process of reduction has been expedited by trade-union pressures.

Average earnings also vary from industry to industry, and the considerable range that appears can again be attributed largely to differences in the composition of the labour force: such an industry as printing that by the nature of its processes employs a high proportion of skilled workers will on that account alone show higher average earnings than, say, the textile industry, which employs a higher proportion of the semiskilled. The similarity between the structure of earnings by industry in different countries—with printing, iron and steel, and engineering near the top, and textiles and food processing low down—is thus attributable to common processes requiring similar compositions of the labour force (assuming, of course, that the structure of rates of pay by occupation in the given countries is also similar).

Occupational pay theories. This occupational structure, therefore, presents the main object of economic analysis. International comparisons show that the ranking order of the rates of pay prevailing in different occupations is similar in different countries, but that the range, whether between professional and manual occupations or, within the manual, between the skilled and unskilled, is much wider in economies at an early stage of development and diminishes in the course of development. These are the principal observations to be accounted for by any theory of the differences in the rates of pay that different kinds of work command. Several such theories have been propounded.

Relation between esteem and pay

Status. One theory stresses the link between occupations and their status in the community, some having higher status than others. The community believes, according to this theory, that pay should correspond to status; and the rate of pay for each occupation is assigned to it by common consent, reflecting the place it occupies in the hierarchy of esteem. The implications are that the community's discretion is not as a rule subject to other factors such as the market forces of supply and demand and that, if people came to make less distinction of status between occupations, then the rates of pay for different jobs could be more nearly equal. Doubtless, many people do think in the way the theory supposes, feeling it anomalous, for example, when an occupation that is commonly accorded a higher status than another ceases to command a higher rate of pay; and arguments appealing to this habit of thought are sometimes used in support of claims. But the correspondence between status and pay is ambiguous; it is not clear to what extent pay is made to fit the status and to what extent status follows from pay, if not today's pay then yesterday's. Moreover, the occupational pay structures of different countries show more similarity than do their social values. Nor does the theory explain why the pay structure has generally become compressed in the course of development, and the ranking order sometimes inverted, as when some clerical occupations drop below some manual ones: changes that can otherwise be explained as the effect of extended education in increasing the relative supply of more qualified labour.

But if the theory is not acceptable as an explanation of the pay structure as a whole, it does call attention to a factor that appears to affect parts of that structure. One of these parts is that of the higher administrative posts. It is generally accepted that any such post must carry a higher salary than any post below it in the chain of command; and when this chain is long, as it is in a big corporation, the salaries set for the posts in it, and the high level reached at the top, are to be accounted for by this principle. The same theory also suggests a cause of prevailing differences between men's and women's rates of pay. Most women's work is different in kind from men's, irrespective of the fact that it is done by women; and where men and women both do work of the same description, some disabilities attaching to women as employees, in particular the likelihood that they will not stay in the job as long as men, may make them worth less to the employer. But there are some jobs in which these considerations do not apply and in which there is no difference in the productivity of men and women adequate to account for the actual difference between men's and women's rates. The difference seems attributable rather to customary attitudes and valuations: in particular, the assumption that women's productivity is lower in all jobs and also the belief that pay should be proportioned to need (women workers generally needing less than the man who has a family to support). If such factors as these account for differences in pay between men and women where there is no corresponding difference in the work they do or the efficiency with which they do it, one may speculate that the same factors account for some part of the pay differential where the two kinds of job are distinct.

Control of the labour supply

Power. A second theory lays its stress on power: the ways in which organized groups can protect and advance the pay of their members. Any group that restricts entry into its occupation can keep its labour relatively scarce and thereby support the rate of pay that that kind of labour commands. The discussion above of the economic effects of the trade union indicated the circumstances in which a trade union would be able to raise the relative pay of its members by the exercise of monopoly and bargaining power. The general increase in the pay of the less skilled relative to that of the skilled manual worker has been attributed in part at least to the increased unionization of the unskilled. Evidently, policies of organized groups will account for some part at least of the position of particular occupations in the pay structure, but they cannot alone account for the main proportions of that structure: it cannot be supposed that the hierarchy of pay corresponds with and is due to a hierarchy of the power of organized groups.

Value. A third theory treats the differences in pay for different jobs as corresponding to differences in their content or requirements. The simplest form of this theory was embodied in the labour theory of value, whether in the system of Adam Smith or of Karl Marx, by the assumption that different kinds of labour can be reduced to different quantities of "homogeneous labour time," and that rates of pay are then simply proportional to those quantities. Job evaluation, discussed above, purports to condense the varied requirements of each job to a single figure in a common scale in order that the ranking order of the rates of pay of the jobs may be brought into conformity with that of those figures. But the assumption that if two articles are priced in the same currency they must contain quantities of a common substance is gratuitous. The impossibility of establishing the existence of such a substance and measuring the amount of it in any article drives both the labour theory of value and job evaluation into the circular argument of inferring the job content from the rate of pay and then explaining the rate of pay by the job content. That job evaluation is nonetheless useful in practice may be accounted for by its ability to arrive at an estimate of the extent to which the requirements of each job tend to raise the rate of pay it commands in the present state of the market.

Costs and benefits to workers

The supply price of labour. The foregoing directs attention to the supply price of labour to the job—the rate that must be paid if employers are to be able to attract and retain the quantity of labour that they wish to employ at that rate. Entry into an occupation generally imposes certain monetary costs; there may also be subjective costs; for example, in the effort of concentration required by preparation for examinations. The exercise of any occupation may be attended by disadvantages that require monetary compensation or may provide satisfactions and amenities that make workers willing to accept lower pay. For each occupation the various costs and benefits can be set off against the pay, and entrants will choose the one in which the prospective balance of advantage seems greatest. If more workers are to be attracted to and retained in a given occupation with unchanged conditions on the side of supply, the rate of pay in that occupation must be raised relative to others. An extension of supply will work to the opposite effect: for instance, if there is more public provision for secondary and tertiary education, and if rising standards of living enable more families to hear the costs of training, then a given number of workers will come to be available in a given occupation at a lower relative rate of pay. Here is to be found the reason for the occupational pay structure extending over a smaller range in developed than in poor countries and for the reduction in the margins for skill and the relative rate of pay for clerical work in the developed economies during the present century.

A number of considerations thus indicate that the rate of pay in any occupation tends to equality with the long-run supply price of labour to that occupation. In the absence of an extension of supply, a fall in the relative rate of pay of an occupation will bring a check to recruitment, followed by some withdrawal to other jobs of those already in the occupation. A rise in the relative rate of pay needs longer to take effect where proficiency takes long to acquire. Some types of proficiency may be limited by nature, and the rise in the rate of pay that follows on an extension of demand for them constitutes an economic rent; *i.e.*, a payment that is not required to maintain supply. In general, however, given time, the number of proficient workers available to follow a given occupation will be increased by a rise in the relative rate of pay it offers.

It is, then, to differences in the long-run supply price of labour to different occupations that the differences between the rates of pay they offer appear to be mainly attributable; though considerations of status and the power of organized groups set their mark upon the occupational pay structure at particular points.

Marginal productivity and **the** demand for labour. The above statement is incomplete, because the supply price of labour in a given occupation generally varies with the number of workers supplied, and what that number will be depends in turn on the demand for labour in that occupation. The rate of pay must not only be such as will maintain the supply of a given number of workers but such also as will lead employers to employ that number. The theory of marginal productivity analyzes the demand for labour in a given employment in the same way that it derives the demand for any factor of production from the demand for the product and from technical conditions of production that determine how much output will be increased by using one more unit of the factor in the presence of given inputs of the other factors; that is, what the marginal product of the factor in the given setting will be. If the employer seeks to maximize his profit, he will presumably adjust the input of each factor so as to bring the value of its marginal product into equality with its price (see DISTRIBUTION, THEORY OF).

Reality versus theory

The theory of marginal productivity has been challenged on the ground that it is unrealistic. The marginal product can be measured, it is pointed out, only for direct labour; that is, for work in which physical output varies directly with labour input; but here the number of workers required is determined simply by the size of current output. Yet though this holds at any one time, a rise in the relative pay of a given kind of labour puts managers under pressure to change equipment, processes, or the design of the product as opportunity offers, so as to use less of that labour relatively to other factors of production. Insofar as this cannot be done, moreover, the rise in pay will result in a higher relative price for the product, which will tend to reduce sales and hence the number of workers.

With indirect labour, on the other hand, the marginal product is not measurable. It is the function of management, however, to assess the contribution made by such workers, so as to decide whether employing one more at a given rate of pay would yield a balance of advantage to the business, and managers are efficient in proportion as they make such assessments rightly. In general, insofar as managers are concerned to produce a given output at the lowest possible cost, they will avoid paying for a unit of labour if the same payment used to hire more of another factor would result in a greater increment of output; and insofar as they are concerned to increase profit, they will not fail to engage a unit of labour whose contribution to proceeds would exceed its pay. While, therefore, the adjustment supposed by the marginal productivity theory of the demand for labour is seldom capable of being effected exactly, there is no reason to doubt that market forces do operate to check deviations from that adjustment and retain them within a zone of tolerance.

MOVEMENT OF THE GENERAL LEVEL OF PAY

A wage is a price, and the rise of the general level of wages or rates of pay in the course of time has, to some extent, been part of the long-term rise in the general level of prices; that is, of the cumulative depreciation of the purchasing power of money, largely attributable to increases in its quantity. In another way, however, the movements of rates of pay have been an independent cause of the rising trend of prices. At times those rates rose in common with prices under the pull of monetary demand (in times of inflation, during war, or in the rising phase of the trade cycle), but when the demand fell off they were resistant to cuts; and though they were cut somewhat, they commonly remained at a higher level than when the preceding rise began. A graph of product prices shows big falls as well as big rises, and sometimes a falling trend persisting for many years together; but a graph of money wage rates is more like a flight of steps. This characteristic of wage movements puts a floor under prices and provides a higher starting point for the next upward movement, so that the fluctuations of monetary demand impose a rising trend on prices. In addition, the analysis of cost inflation under full employment, noted above, has shown that when employers generally expect demand to be sustained, rises in pay may occur in the absence of excess demand and so initiate rises in prices; and it is possible that the same process may have played some part in the rising phase of the trade cycles of earlier years.

The level of real earnings

The rise of real earnings may be traced by comparing the movements of earnings in money with those of an index number of the prices of the articles on which pay is typically expended. Such comparisons indicate that between 1860 and 1960 the real earnings of manual workers rose fourfold in France, Germany, and the United Kingdom; more than fivefold in the United States; and more than sevenfold in Sweden. In considering the standard of living attendant on these movements, it is necessary also to take account of the prevailing reduction in the size of the family, the complex effects of urbanization on the amenities of life, the effects of changed techniques and deployment between occupations on the strains and satisfactions experienced in work, and the reduction of hours of work. The last element has been extensive: it appears that down to World War II the wage earners of the five countries mentioned, save the United States, gave up from a third to a half of the potential increase in annual purchasing power in favour of a shorter working week and longer vacations.

To the extent that real earnings are measured simply by the quantity of consumables that money earnings will buy, their rise has depended on three factors: productivity, or the output per worker in terms of his own product; the share of this product that accrues to the worker; and the rate of exchange between the worker's own product and the goods and services he buys. In the industrialized countries, the last factor has presented itself largely in the form of the terms of trade between manufactured products and primary products, especially foodstuffs: real earnings have risen faster or slower according as a representative consignment of manufacturers may be exchanged, at the prices of the day, for a greater or smaller quantity of foodstuffs and raw materials. There have also been variations from time to time in the second factor: the share of the product accruing to the worker. The effect of the last two factors, however, has been small in comparison with that of the first, the rise of productivity. The salient finding from the statistical record of the last hundred years is that real earnings per worker have risen very nearly in the same proportion as output per worker.

How this can have come about is a question for the theory of distribution (*q.v.*). Here the comparative stability of the share of the product accruing to the worker may be noted. The statistical record shows this stability in its relation with the behaviour of two other factors: the rate of return on capital, and the amount of capital employed per unit of output. The stability of any two of the three factors implies that of the third.

BIBLIOGRAPHY. Some textbooks that apply economic analysis to labour in the particular circumstances of labour markets are: G.F. BLOOM and H.R. NORTHRUP, *The Economics of Labor Relations,* 6th ed. (1969); A.M. CARTTER and F.R. MARSHALL, *Labor Economics: Wages, Employment and Trade Unionism* (1966); L.C. HUNTER and D.J. ROBERTSON, *Economics of Wages and Labour* (1969); L.G. REYNOLDS, *Labor Economics and Labor Relations,* 5th ed. (1970); and E.H. PHELPS BROWN, *The Economics of Labor* (1962).

The relation of the labour force to the population of a number of countries is surveyed in UNITED NATIONS, *Sex and Age*

Patterns of Participation in Economic Activities, Population Studies no. 33, rept. 1 (1962); and in C.D. LONG, *The Labor Force Under Changing Income and Employment* (1958). Education is treated as a form of investment in G.S. BECKER, *Human Capital* (1964).

The deployment of the labour force is traced historically in S. LEBERGOTT, *Manpower in Economic Growth: The American Record Since 1800* (1964). The mechanism of recent changes is discussed in two OECD reports: P. de WOLFF *et al., Wages and Labour Mobility* (July 1965); and L.C. HUNTER and G.L. REID, *Urban Worker Mobility* (1968).

For trade union structure and bargaining areas, see A.R. WEBER (ed.), *The Structure of Collective Bargaining* (1962). Numerous studies of the effects of collective bargaining are digested in: L.G. REYNOLDS and C.H. TAFT, *The Evolution of Wage Structure* (1956); and in the papers by C. KERR and L.G. REYNOLDS, in *The Theory of Wage Determination,* ed. by J.T. DUNLOP (1957). Theories of collective bargaining are surveyed in A. CODDINGTON, *Theories of the Bargaining Process* (1968); see also R.E. WALTON and R.B. MCKERSIE, A *Behavioral Theory of Labor Negotiations* (1965).

Forms of minimum wage regulation are surveyed in S.B.L. NIGAM, *State Regulation of Minimum Wages* (1955). The experience of a number of countries with incomes policy is reported by D.C. SMITH, *Incomes Policies: Some Foreign Experiences and their Relevance for Canada* (1966); and by H.A. TURNER and H. ZOETEWEIJ, *Prices, Wages, and Incomes Policies in Industrialized Market Economies* (1966). Regional, industrial, and occupational structures are treated in L.G. REYNOLDS and C.H. TAFT, *The Evolution of Wage Structure* (1956); and E.M. HUGH-JONES (ed.), *Wage-Structure in Theory and Practice* (1966). Theories of differences in the rates of pay for different jobs are developed in B.F. WOOTTON, *The Social Foundations of Wage Policy: A Study of Contemporary British Wage and Salary Structure* (1955); and H.F. LYDALL, *The Structure of Earnings* (1968). The movement of the general level of pay, in money and real terms, is recorded and analyzed in France, Germany, Sweden, the United Kingdom, and the U.S. since 1860 in E.H. PHELPS BROWN and M.H. BROWNE, *A Century of Pay* (1968).

(E.H.P.B.)

Labour Law

Labour law is the term used to describe the varied body of law applied to such matters as employment, remuneration, conditions of work, trade unions, and labour management relations. In its most comprehensive sense it also includes old age and disability insurance. Unlike the laws of contract, tort, or property. the elements of labour law are less homogeneous than the rules governing a particular legal relationship. In addition to the individual contractual relationships growing out of the traditional employment situation, labour law deals with the statutory requirements and collective contractual relationships that are increasingly important in mass-production societies, the legal relationships between organized economic interests and the state, and the various rights and obligations related to some types of social services.

Labour law has now won recognition as a distinctive branch of the law within the academic legal community, but the extent to which it is recognized as a separate branch of legal practice varies widely depending partly on the extent to which there is a labour code or other distinctive body of labour legislation in the country concerned, partly on the extent to which there are separate labour tribunals, partly on the extent to which an influential group of the legal profession practice specifically as labour lawyers.

In the early phases of development the scope of labour law is often limited to the most developed and important industries, to undertakings above a certain size, and to wage earners; as a general rule, these limitations are gradually eliminated and the scope of the law extended to include handicrafts, rural industries and agriculture, small undertakings, the self-employed, and office workers. Thus a body of law originally intended for the protection of the working class is gradually transformed into broader welfare legislation.

Statute
versus
contract

The general tendency in the modern development of labour law has been the strengthening of statutory requirements and collective contractual relations at the expense of individual employment relationships. How important these latter remain depends, of course, on the degree of personal freedom in the given society as well as the autonomy of both employer and worker allowed by the actual operation of the economy. In such matters as hours of work, health and safety conditions, or labour-management relations, the statutory or collective elements may define most of the substance of the rights and obligations of the individual worker, while with respect to such things as the duration of his appointment, his level and extent of responsibility, or his place in the scale of remuneration, these elements may provide what is essentially a framework for individual agreement.

The scope of labour law also grows beyond the employment relationship as important parts of it are increasingly made applicable to the self-employed. This has been done partly, as in the case of laws regulating business hours, to prevent the undercutting by the self-employed of fair labour standards for employed persons and partly, as in the case of the extension of old age and disability insurance to the self-employed and the protection of the tenancy rights of small farmers and sharecroppers, to improve the living and working conditions of disadvantaged groups who need such protection as much as employed persons.

HISTORICAL DEVELOPMENT

The origins of labour law can be traced back to the remote past and the most varied parts of the world. While European writers often attach importance to the guilds and apprenticeship systems of the medieval world, some Asian scholars have identified labour standards as far back as the Laws of Hammurabi and rules for labour-management relations in the Laws of Manu; Latin American authors point to the Laws of the Indies of the conquistadors. None of these can be regarded as more than anticipations with no influence on subsequent developments. Labour law as it is known is essentially the child of successive industrial revolutions from the 18th century onward. It became necessary when customary restraints and the intimacy of employment relationships in small communities ceased to provide adequate protection against the abuses incidental to new forms of mining and manufacture on a rapidly increasing scale at precisely the time when the 18th-century Enlightenment, the French Revolution, and the political forces that they set in motion were creating the elements of the modern social conscience. It developed rather slowly, chiefly in the more industrialized countries of western Europe, during the 19th century and has attained its present importance, relative maturity, and worldwide acceptance only during the present century.

Impact of
the
Industrial
Revolution

The first landmark of modern labour law was the British Health and Morals of Apprentices Act of 1802, sponsored by the elder Sir Robert Peel. Similar legislation for the protection of the young was adopted in Ziirich in 1815 and in France in 1841. By 1848, the first legal limitation of the working hours of adults was adopted by the Landsgemeinde (citizens' assembly) of the Swiss canton of Glarus. Sickness insurance and workmen's compensation were pioneered by Germany in 1883 and 1884, and compulsory arbitration in industrial disputes was introduced in New Zealand in the 1890s. The progress of labour legislation outside western Europe, Australia, and New Zealand was slow until after the First World War. The more industrialized states of the United States began to enact such legislation toward the end of the 19th century, but the bulk of the present labour legislation of the United States was not adopted until after the 1929 depression. There was virtually no labour legislation in Russia prior to the October Revolution of 1917. In India the hours of work of children between 7 and 12 were limited to nine per day in 1881 and the hours of adult males in textile mills to ten per day in 1911, but the first major advance was the amendment of the Factory Act in 1922 to give effect to conventions adopted at the first session of the International Labour Conference at Washington in 1919. In Japan rudimentary regulation? on work in mines were introduced in 1890, but a proposed factory act was controversial for 30 years before it was adopted in 1911, and the decisive step was the revision of this act in 1923 to give effect to the Washington Convention. Labour legislation in Latin America began in Argentina in the early years of the century and received a powerful impetus from the Mexican Revolution, which ended in 1917, but, as in the North, the trend became general only with the impact of the world depression. In Africa the progress of labour legislation became significant only from the 1940s onward.

The legal recognition of the right of association for trade union purposes has a distinctive history. There is no other aspect of labour law in which successive phases of progress and regression have been more decisively influenced by political changes and considerations. The legal prohibition of such association was repealed in the United Kingdom in 1824 and in France in 1884; there have been many subsequent changes in the law and may well be further changes, but these have related to matters of detail rather than to fundamental principles. In the United States freedom of association for trade union purposes remained precarious and subject to the unpredictable scope of the labour injunction, by means of which the courts helped restrain trade-union activity until the 1930s. In many other countries the record of progress and regression with respect to freedom of association falls into clearly distinguished periods separated by decisive political changes. This has certainly been the case with Germany, Italy, Spain, Japan, and much of eastern Europe; there have been many illustrations of it, and there may well be more, in the developing world.

Labour codes and ministries of labour were not introduced until the 20th century. The first labour code (which, like many of its successors, was a consolidation rather than a codification) was projected in France in 1901 and promulgated in stages from 1910 to 1927. Among the more advanced formulations affecting the general condition of labour were the Mexican Constitution of 1917 and the Weimar Constitution of Germany of 1919, both of which gave constitutional status to certain general principles of social policy regarding economic rights. Provisions of this kind have become increasingly common and are now widespread in all parts of the world.

Departments or ministries of labour responsible for the effective administration of labour legislation and for promoting its future development were established in Canada in 1900, in France in 1906, in the United States in 1913, in the United Kingdom in 1916, and in Germany in 1918. They became general in Europe and were established in India and Japan during the following years and became common in Latin America in the '30s. A labour office was established in Egypt in 1930, but only in the '40s and '50s did similar arrangements begin to take root elsewhere in Asia and Africa. Under differing political circumstances there continue, of course, to be wide variations in the authority and effectiveness of such administrative machinery and in the extent of its influence in matters of general economic policy and labour conditions.

THE ELEMENTS OF LABOUR LAW

The basic subject matter of labour law can be considered under nine broad heads: employment; individual employment relationships; wages and remuneration; conditions of work; health, safety, and welfare; social security; trade unions and labour management relations; the administration of labour law; and special provisions for particular occupational or other groups.

The worker in new economic thought

Employment. Employment considered as a basic concept and category of labour law is a relatively recent development. Prior to the Great Depression and World War II the emphasis was upon the prevention or reduction of excessive unemployment rather than upon long-term employment policy as part of a comprehensive scheme to promote economic stability and growth. The new approach, arising from changes in political outlook and contemporary economic thought, has increasingly found expression in legal provisions that establish the creation of employment opportunities as a general objective of policy. To this end, legislation has established the necessary legal framework for the forecasting of manpower needs and availability and the provision of employment services including recruitment, vocational training, and apprenticeship. Freedom from forced labour, equality of treatment in employment and occupation, and even unemployment compensation may, in a broad sense. be regarded as part of the same general subject.

Individual employment relationships. This includes the making, modification, and termination of such relationships and the resulting obligations for the parties. It may also involve certain aspects of promotion, transfer, and dismissal procedures and compensation. The law on the matter was at one time often described as the law of master and servant. It implied a contractual relation in which one party agreed to be under the control of the other in the sense that he was bound to obey orders not only as to the work that he would execute but also as to the details of the work and the manner of its execution. As the law developed, the implied terms and statutory incidents attached to this relationship concerning such matters as termination of employment, dismissal procedures and compensation, minimum wages, conditions of work, and social security rights began to limit freedom of contract. The individual employment relationship continues, however, to be the subject matter of labour law to which general legal principles, as opposed to statutes and collective agreements, still have the greatest application.

Wages and remuneration. The substantive law here covers such elements as forms of wages and methods of payment, the protection of wages against unlawful deductions and other abuses, minimum wage arrangements, the determination of wages, fringe benefits in relation to wages, and, in highly sophisticated economies, incomes policies designed to protect the real value of wages against the erosion of inflation. The concept of wage regulation as a restraint upon extreme social evils has gradually been superseded by wage policies as deliberate instruments of positive management designed to promote economic stability and growth.

Wage protection and abuse

Legal requirements concerning the forms of wages and methods of wage payment deal with such matters as the proper notification of wage conditions, the payment of wages in legal tender or by check, the limitation and proper valuation of payments in kind, the freedom of the worker to dispose of his wages, regularity in wage payments, the treatment of wages as a privileged debt, and restrictions upon the attachment or assignment of wages.

The protection of wages against deductions and related abuses covers such topics as placement fees, payments at company stores or for tools or other supplies, and fines for alleged breaches of discipline. Minimum-wage regulation takes varied forms; it may, following the pattern originally set by the British Trades Boards Acts from 1909 onward, provide for wages councils or similar bodies to fix wages in trades that have no arrangements for collective agreements and where wages are exceptionally low; it may consist, as in Australia and New Zealand, essentially of arbitration arrangements; or it may, as in the United States under the Fair Labor Standards acts, provide a comprehensive statutory rate or criteria for determining such a rate. Statutory provisions and collective agreements for determining wages may embrace such varied matters as skill differentials, the elimination of race and sex differentials, payment according to results and the relationship of wages to productivity, and wage guarantees for agreed periods of time. Fringe benefits, such as bonuses payable in varying contingencies, are typically a matter for collective agreements. Incomes policies remain the subject of much controversy. Their general purpose, sometimes embodied in legislation and sometimes expressed in collective agreements or statements of government policy, is to restrain inflationary pressures resulting from wage increases unrelated to increased productivity and to do this in a manner that promotes a fairer distribution of income.

Conditions of work. The conditions of work involve hours, rest periods, and vacations; the prohibition of child labour and regulation of the employment of young persons; and some special provisions concerning the employment of women. This part of the law originated in legislation for the protection of children, young persons, and women against the worse evils of the Industrial Revolution. It originally dealt particularly with such matters as admission to employment, night work, and excessive hours, but the elements of its content and their relative importance have been wholly transformed during the present century.

As economic and educational progress and changed social habits have limited recourse to child labour in the advanced countries, and to an increasing extent in the modernized sectors of developing economies, the special concern of labour law with regard to the young has shifted from the prohibition of child labour to such areas as vocational guidance and training, career planning and advancement, and medical protection.

As employment opportunities for women have become more varied and responsible, there has been a similar shift of emphasis from protective legislation, which has now come to be regarded as discriminatory since it tends to limit such opportunities, to legal guarantees of equal pay and equal employment, coupled with adequate maternity protection and the provision of facilities to enable women with family responsibilities to continue to be employed.

Another, but no less important, change has taken place in the gradual slackening of the so-called morality of work. Whereas previously any statutory limitation of the hours of work of adult males was regarded as being highly questionable, except in mines where it had been introduced on safety grounds, in a society of much increased leisure it has now become a general practice to fix hours of work by statute or collective agreement. In many countries the eight-hour day has been superseded by the forty-hour week as the statutory maximum for a wide range of occupations, and collective agreements providing for substantially shorter working hours are not uncommon. The details of hours regulation, whether by statute or collective agreement, include such matters as exceptions allowed for managerial and supervisory personnel and adjustments necessary for continuous shift working. In addition, such regulations cover the extensions permitted for preparatory, complementary, and intermittent work; the special rules for *force majeure* (work of absolute necessity), accident, maintenance, and repair work; and the limitation, authorization, and remuneration of overtime.

The principle of resting one day of the week, sanctioned as it is by religious practice in many places, was widely incorporated in legislation at an early date; the lengthening of this weekly rest through the creation of the five-day week has been strongly influenced by statutory requirements and collective agreements.

Holidays

Legislation granting annual holidays with pay and comprehensive collective agreements providing for such holidays are almost entirely a development of the last half-century but are increasingly common; moreover, there is a marked tendency for the minimum annual holiday to be increased and for collective agreements to provide holidays longer than the statutory minimum. Complex questions may arise concerning the qualifying period of service required for entitlement, breaks in the continuity of service, the calculation of average or normal remuneration for the purpose of the holidays, the extent to which holidays may be divided, and the liability for holidays where there has been a change of employer. The question of educational leave is receiving increasing attention.

Health, safety, and welfare. This is a category that includes such general matters as occupational health and accident prevention regulations and services; special regulations for particularly hazardous occupations such as mining, building and dock work; and provisions concerning such health and safety risks as poisons, dangerous machinery, dust, noise, vibration, and radiation. The law on the subject began with elementary safety rules for mines and other undertakings with particularly high accident rates and with the precautions taken against a number of dramatic poisonings and infections brought on by such agents as phosphorus, lead, and anthrax germs. The efforts of organized safety movements and the progress of occupational medicine have produced comprehensive occupational health and accident-prevention services and regulations no longer limited to a few specially acute risks but covering the full range of dangers arising from modern industrial processes. A major recent development has been the increased concern with health and safety regulations for agriculture and forestry made necessary by mechanization and the widespread use of chemicals. Welfare benefits, in the sense of communal services and special schemes and facilities for disadvantaged groups of society, go well beyond the scope of labour law; but there is increasing provision by law or collective agreement for welfare facilities related to employment, including feeding, rest, recreation, and transport facilities.

Social security. In the present stage of development of labour law, social security ranges from relatively straightforward employers' liability for occupational accidents to the most comprehensive schemes of payment, including income security in the form of sickness, unemployment, old age, employment injury, maternity, family, invalidity, and survivors benefits and medical care. As with other aspects of labour law, a progression from the particular to the general has been characteristic of the development of social security legislation. By the time of World War I, workmen's compensation schemes were general in industrialized and industrializing countries, but they still tended to define restrictively the cases regarded as occupational accidents and they were highly restrictive in their provisions for occupational diseases. Pension insurance was part of Otto von Bismarck's legacy to Germany, but elsewhere there was little more to be found than pension funds for the privileged and in some countries noncontributory pensions for the aged. Great Britain, as befitted its early entry into industrialization, had been the pioneer in health and unemployment insurance. But social insurance remained a pragmatic experiment limited to a few countries advanced in both economic development and social policies. Such coverage as there was in these countries was limited to specific risks for certain categories of protected persons. Its object was to protect the worker against the sort of hazards of life for which preindustrial societies provide by some form of community or family responsibility, but the approach was piecemeal and was limited to the most manageable cases of acute hardship. Eventually, the impact of the world economic depression of the '30s and World War II in the industrial nations and the increasingly apparent inadequacy of earlier forms of community responsibility in developing countries transformed the position. The concept of social security, first given statutory expression in the United States in 1935 and in New Zealand in 1938, superseded that of social insurance, and the Beveridge Report of 1943 developed it even further to provide a basic income for all in need of such protection, along with comprehensive medical care. The concept has continued to broaden since that time and has found increasing acceptance, with varying degrees of practical application, in countries in the most varied stages of economic development. Acute problems, particularly cost and efficiency of administrative organization and medical care, remain almost everywhere and sometimes become highly controversial, but far-reaching progress has been made in many countries in developing higher standards of medical care available as a legal right and in converting the guarantee of a basic income as a protection against want into provision for effective income maintenance in the event of the loss of employment or breadwinner. The idea has not yet reached the end of its development. The current trend is to broaden it to the point at which it includes all the varied hazards of life in industrialized societies, including accidents of any kind, with the idea of facilitating economic growth by reducing the human cost of structural change. Some attempt is being made to adapt these same ideas to the needs and practical possibilities of developing societies and rural communities. The pattern varies widely in different countries, partly as a reflection of different relationships between social security and private life, retirement and health insurance, partly because of differences in economic and social conditions.

The right to security

Trade unions and labour-management relations. A number of complex legal relationships fall under this heading, including the legal status, rights, and obligations of trade unions and employers' organizations, collective bargaining and collective agreements, the representation of employees at plant and enterprise level (including joint consultation and, where it exists, co-determination and other forms of worker's participation in management), work rules and labour discipline, the prevention and settlement of labour disputes in general, and strikes and lockouts in particular. As might be expected, there are wide variations both in the extent to which such matters as the representative character and capacity of trade unions, their legal status, the obligation to recognize and bargain with them, the enforceability of collective agreements, the scope of activities permitted to trade unions, and their obligations in contract and tort are subject to legal rules and in the content of such rules. In the United States, for instance, there is a considerable body of law on these subjects, the most important enactments being the National Labor Relations Act of 1935 (the Wagner Act) and the Labor Management Relations Act of 1947 (the Taft-Hartley Act); in the United Kingdom the law has hitherto remained marginal to most of these trade union issues, though changes may be in prospect. In general, the trend is to expand the role of law in labour-management relations to reduce the increasing disruption caused by industrial conflict in a more complex society. How to reconcile freedom of association with the stability and growth of the economy remains the most challenging and difficult problem of labour law.

The administration of labour law. This is an area involving the organization and functioning of administrative authorities concerned with labour problems, including labour inspection services and other organs of enforcement. Administration of the law also encompasses the organization, jurisdiction, composition, and procedure of labour courts and other bodies for the settlement of grievances arising from existing contracts or collective agreements.

Labour law and the economic goal

The principal problem in many countries is to relate the process of labour administration and its special intimacy with labour and management to overall economic and social planning in a manner that gives proper weight to social considerations in economic policy. This problem falls mostly outside the scope of labour law, but its solution does depend in part on the extent to which labour law provides for and secures effective standards of administration.

Special categories of workers. Labour law includes a wide range of special provisions for particular occupational or other groups. These sometimes appear as special parts of a general code or as special legislation; sometimes they take the form of provisions that limit the applicability, or vary the mode of application, of specific legislative provisions with regard to particular groups. The broad sectors of the economy for which such special provisions are particularly common and important include mines, transport (and in particular maritime transport), commercial occupations, and agriculture. Cutting across these broad sectors of economic activity are the traditional legal distinctions made in some countries between workers and salaried employees and certain newer distinctions, such as that between employees who earn annual salaries and have rights of tenure and persons with no such rights engaged and remunerated on a monthly or weekly basis, or that between white collar and manual workers—the latter often resting on a factual rather than a legal basis.

LABOUR LAW IN DIFFERENT LEGAL SYSTEMS

Among the distinctive elements of labour law that reflect the political, socio-economic, and legal differences from country to country are variations in the relative importance of statutory regulation and collective agreements, the prevalence of national or industrial collective agreements as opposed to company or plant agreements, the exceptional importance in certain countries of arbitral awards, and the extent to which the labour law of certain countries has been affected by the constitutional structure, especially with regard to judicial review of constitutionality of legislation and judicial interpretation of constitutional powers, limitations, and guarantees. How significant these distinctive elements will remain is uncertain.

In the United Kingdom and Scandinavia, for instance, the tradition has been to allow a maximum of initiative and freedom to employers' and workers' organizations in the regulation of their mutual relations and the determination of conditions of work.

In the United Kingdom, however, the reluctance to legislate is becoming less marked; there is now legislation concerning industrial training and discrimination in employment, until recently essentially matters for collective agreement, and legislation concerning collective bargaining and safeguards against unfair dismissal is under consideration. It is anticipated that membership in or closer association with the European Economic Community will accentuate this tendency. In virtually all of the developing countries the absence of an established tradition of responsible collective bargaining and the importance of the part played by the state in economic development have placed a premium on legislative action.

Variations in collective agreements

The coverage and scope, term of validity and legal effect of collective agreements varies widely. In Sweden there has been a practice of national negotiations covering the whole of industry; in the United Kingdom agreements generally cover an industry or occupation in the country as a whole or a particular industrial area; in the United States the unit of negotiation is generally the company or plant. The contrast may be less significant in practice than in principle, since an important company or plant agreement tends to set an industry-wide pattern of negotiation; nevertheless, the difference is important. The future trend may well be toward mutually complementary and interlocking national or industrial and company or plant agreements, but uniformity in this matter among countries with widely varying traditions and problems seems unlikely, and there remain many uncertainties. Still more important is the distinction between a collective agreement that is accepted as binding for an agreed term and one that has no such agreed term. There may well be a far-reaching tendency to prefer agreements for agreed terms during the coming years, but this also is by no means a certainty.

In Australia and New Zealand conciliation and arbitration tribunals determine by awards matters normally dealt with in other countries by legislation or collective agreement, such as wages, hours, and conditions of work. The example has had some influence on systems of arbitration courts established in developing countries, notably in Singapore and East Africa, but with this exception there is no tendency for it to be widely imitated elsewhere except as a device for avoiding deadlocks in negotiation, especially in essential public services.

Constitutional impediments

The United States and Canada are examples of the development of labour law being affected by questions of constitutionality, which, in this instance, not only influenced its ultimate form but also retarded its development. In the United States the constitutionality of workmen's compensation laws was a much debated issue until it was favourably settled by the Supreme Court in 1917, and child-labour and minimum-wage regulation was retarded for a generation by judicial decisions holding them to be outside federal competence and, in some cases, inconsistent with the constitutional guarantee against deprivation by the state of life, liberty, and property without due process of law (the guarantee conceived of here as applying to the factory owner). The first attempt of Pres. Franklin Roosevelt's administration to regulate hours and wages by codes of fair competition during the Great Depression was also held to be unconstitutional as an improper delegation of legislative power by Congress to the executive branch of the government. But thereafter the temper of judicial review changed and the validity of federal legislation guaranteeing free collective bargaining, regulating wages and hours, and establishing social security was upheld. In Canada, a pioneer in establishing a labour department, restrictive judicial interpretations of the powers of the federal government had a somewhat similar effect, and only after World War II did federal-provincial cooperation afford a basis for achieving greater uniformity and more rapid progress. In both cases the impress of constitutional law upon labour law remains but is perhaps less significant than a generation ago.

UNIFYING TENDENCIES

It is no less true in labour law than in other branches of the law that the possible solutions for identical or similar problems are not infinite in number. Indeed, the range of possible solutions often consists of variations of detail on a limited number of options. It is therefore natural that many common elements, often expressed in identical or almost identical texts, should recur in the law of different countries. These elements derive partly from the legislation of other nations but increasingly from the influence on the law of the international standards evolved by the International Labour Organisation.

From the beginnings of modern labour legislation in the early 19th century, the law of certain countries has been extensively used as a model. A full picture of this pattern would require a detailed account of the interplay of external influences in the law of many countries, but, by way of illustration, it may be pointed out that United Kingdom factory legislation was widely copied at an early date and German social-insurance legislation provided a prototype dating back to the time of Bismarck's reforms. United Kingdom legislation has continued to serve as a model in the contemporary period for the basic legislation of many states that were formerly British dependencies and remains in force subject to modifications made since independence. Much of the French Labour Code became applicable through the 1952 Labour Code for Overseas Territories to the states that were formerly French dependencies and remains the basis of their labour law. The United States legislation of the period from the 1930s onward has been taken as a model in Japan, the Philippines, Liberia, and other countries. The Mexican Labour Law of 1917, varied by elements derived primarily from European models, had considerable influence on the early development of labour law in a number of Latin American countries. Through quite another process, the labour law of the U.S.S.R. has reshaped without replacing the earlier elements in the labour law of the other Communist states. But on the whole these national influences of particular countries and legal systems are declining.

The ILO: international standards

During the last half-century the standards evolved by the International Labour Organisation (ILO) have gradually become the leading external influence upon the labour law of many countries. They have had a far-reaching impact in virtually all of the advanced countries except the U.S. and the U.S.S.R., where external influences have been secondary. In much of the developing world they were of great importance even before independence, since a large part of the legislation sponsored there by the metropolitan powers was based essentially on ILO standards; in more recent years they have become a main source of new legislation in these countries. The ILO, created in 1919 as an autonomous partner of the League of Nations, and since 1946 a specialized agency associated with the United Nations, adopts international standards in the form of conventions and recommendations that each member state has an obligation to submit for consideration to the national legislative authority. Conventions when ratified become binding obligations of the member states ratifying them; recommendations are designed as guides for legislation, collective agreements, administrative measures, etc. Elaborate follow-up arrangements, including examination of regular reports and commissions of enquiry into complaints, are provided for to ensure that the obligations assumed are fulfilled. These standards, which already cover, in varying degrees of detail and at varied stages of development, virtually all the more important branches of labour law, are constantly amplified and revised at the annual sessions of the International Labour Conference. By 1970, 130 conventions and 134 recommendations had been adopted. The conventions dealing with such fundamental human rights as freedom from forced labour, freedom of association, and freedom from discrimination have been ratified by from over 70 to over 100 countries. The conventions and recommendations are supplemented by regional and technical standards, approved in the form of resolutions but often given effect by law, regulation, or collective agreement. In the field of health and safety model codes, codes of practice, manuals, and guides have become particularly important; in social security matters the technical resolutions adopted by the International Social Security Association, which was created on the initiative of ILO, play a comparable role.

Unification of labour law is one of the professed purposes of a number of regional economic organizations in different parts of the world, but only in the Council of Europe, the European Communities, and the Organization of American States have tangible measures been taken, and these have been largely based on ILO standards and framed with its technical cooperation and assistance. The more important instruments adopted are the European Social Charter, the European Social Security Code, the Social Security Regulations of the European Economic Community, and the Central American Convention on Social Security for Migrant Workers. The Conferences of American and African Labour Ministers, sponsored by the Organization of American States and the Organization of African Unity respectively, and the Conference of Asian Labour Ministers, which has developed without any comparable sponsorship, discuss matters of general policy and the coordination of action in the ILO rather than the formulation of specific standards. An Arab Labour Organization was created in 1970.

FUTURE OF LABOUR LAW

Labour law differs from the older branches of the law in that its history has been in some cases so much influenced by the ebb and flow of political change, its development so rapid, and its expansion on a world scale so recent, that it is exceptionally difficult to predict its future. But the general trend is clear.

Nowhere is labour law becoming less important. While some types of protective legislation, notably special provision for the protection of women workers, are losing their importance, the general tendency continues to be toward more comprehensive legislation embracing a wider range of subjects and often dealing with matters previously left to collective agreement, individual contract, or the discretion of the employer.

Irrespective of ideology or economic or social structure, the transition everywhere has been from a class law protecting the weakest segment of society to a community law designed to serve the common interest. This is a development that can be seen not only in the elimination of limitations and exceptions to the law but in the increasing emphasis being given to matters of general interest, including full employment, equitable distribution of wealth, and community responsibility for the incidence of misfortune in individual lives.

The place of labour law in legal evolution

Labour law must also be said to serve the social interest in promoting civilized labour-management relations. This evolution of labour law is an important contribution to the evolution of the law as a whole, from a law for the propertied and trading classes with a special chapter for the working class to a common law for the entire community.

The importance of a body of law that has a dynamic and progressive impact rather than a restrictive influence is now widely understood, and the need for legal flexibility to facilitate economic development and change is increasingly appreciated. In addition, the value of delegated powers and procedures of consultation with interested groups and organizations to achieve such flexibility is more generally recognized. Social objectives remain the test of the validity of economic policy, and labour law plays a major part in defining these objectives and ensuring that economic policy respects them in the interest of the whole community.

BIBLIOGRAPHY. The more important labour laws from all countries are reproduced in the *International Labour Office Legislative Series* (1920–), continuing the *Bulletin of the International Labour Office* (1906–19). The international standards are collected in ILO, *The International Labour Code,* 2 vol. (1951), supplemented for the more recent period by *Conventions and Recommendations, 1919–1966.* For the impact of ILO standards see C.W. JENKS, *International Protection of Trade Union Freedom* (1957), *Human Rights and International Labour Standards* (1960), and *Social Justice in the Law of Nations* (1970). For the wide range of comparative international studies available at any particular time see the current *Catalogue of Publications* of the Inter-

national Labour Office. The *International Encyclopaedia of Comparative Law* (in prep.), sponsored by the International Association of Legal Science, is to contain a volume on labour law. The following are some of the more important works on this subject.

Introductions: K.W. WEDDERBURN, *The Worker and the Law,* new ed. (1966); A. ROUAST and P. DURAND, *Précis de droit du travail,* 2nd ed. (1961); F. SANTORO-PASSARELLI, *Nozioni di diritto del lavoro,* 19th ed. (1967); M. ALONSO OLEA, *Introducción al derecho del trabajo* (1963).

(C.W.J.)

Lacquerwork

Lacquerwork is a general term for certain metallic and wood objects to which coloured and frequently opaque varnishes called lacquer are applied. The term lacquer is derived from lac, which is the basis of some lacquers. This article deals with artistic lacquer ware; for a discussion of lacquers used as protective coatings, see PAINTS, VARNISHES, AND ALLIED PRODUCTS.

The lacquer of East Asia, China, Japan, and Korea must not be confused with other substances to which the term is generally applied; for instance, the lac of Burma, which is the gummy deposit of an insect, *Coccus lacca,* and the various solutions of gums or resin in turpentine of which European imitations of Eastern lacquer have been and are concocted.

TECHNIQUES

Obtaining and preparing lac. Lacquer, as used in China and Japan, is a natural product, the sap of a tree, *Rhus vernicifera;* subject to the removal of impurities and excess water, it can be used in its natural state, though it was frequently adulterated. The tree, which is indigenous to China and has certainly been cultivated in Japan at least since the 6th century AD, is tapped at about the age of ten years, when lateral incisions are made in the bark and the running sap is collected during the months of June to September. Branches of a diameter of one inch (about three centimetres) or more are also tapped, the bark having first been removed. Smaller branches are cut off and soaked in water for ten days, and the sap is collected, producing a lacquer *(seskime)* of particular quality, used for special purposes. These processes kill the tree, but the wood, when of sufficient size, is of some use for carpentry. From the roots five or six shoots spring up, which become available for the production of lacquer after about six years, and the operation can be thus continued for a considerable length of time before the growth is exhausted. The Chinese and Japanese methods are practically identical in this respect, but the cultivation of the tree does not seem to have been as systematic in China as in Japan.

Collecting
the sap

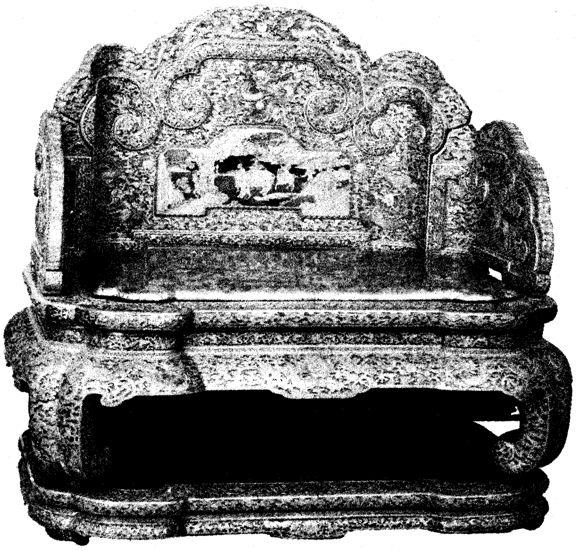
The sap is white or grayish in colour and about the consistency of molasses. On exposure to the air it turns yellow-brown and then black. It is strained through hempen cloth to remove physical impurities, after being pounded and stirred in shallow wooden tubs to give it uniform liquidity. It is then slightly heated over a slow fire or in hot sunshine, and stirred again to evaporate excess moisture, and stored in airtight vessels.

The basis of lacquer ware, both in Japan and in China, is almost always wood, although it was also occasionally applied to porcelain, brass, and white metal alloys. In some instances, objects were carved out of solid lacquer. The wood used, generally a sort of pine having a soft and even grain, was worked to an astonishing thinness. The processes that follow are the result of extraordinary qualities of lacquer itself, which, on exposure to air, takes on an extreme but not brittle hardness and is capable of receiving a brilliant polish of such a nature as to rival even the surface of highly glazed porcelain. Moreover, it has the peculiar characteristic of attaining its maximum hardness in the presence of moisture. To secure this result, the Japanese place the object in a damp box or chamber after each application of lacquer to the basic material (wood, etc.). The Chinese are said (in an account of the industry dating from 1621–28) to use a cave in the ground for this purpose and to place the objects therein at night in order to take advantage of the cool night air. It may, indeed, be said that lacquer dries in a moist atmosphere.

Hardening
with
moisture

Application. The joiner's work having been completed and all knots or projections having been most carefully smoothed away, cracks and joints are sealed with a mixture of rice paste and *seshime* lacquer, until an absolutely even surface is obtained. It is then given a thin coat of *seshime* lacquer to fill up the pores of the wood and to provide a basis for succeeding operations, which may number as many as **20** or **30** or even more, of which any one of the following may be taken as typical. On the basis, as above described, is laid a coat of lacquer composition which is allowed to harden and is then ground smooth with whetstone. Next comes a further coat of finer composition, in which is mixed some burnt clay, which is again ground and laid aside to harden for at least 12 hours. On this is fixed a coat of hempen cloth (or, rarely in Japan but more often in China, paper) by means of an adhesive paste of wheat or rice flour and lacquer, which needs **24** hours at least to dry. The cloth is smoothed with a knife and then receives several successive coats of lacquer composition, each demanding the delay necessary for hardening. On this is laid very hard lacquer, requiring a much longer drying interval, afterward being ground to a fine surface. Succeeding coats of lacquer of varying quality are now laid on, dried, and polished.

This preliminary work, requiring for artistic lacquer at least 18 days, produces the surface on which the artist in lacquer begins his task of decoration. **A** large number of processes have been at his command, especially in Japan, but the design was first generally made on paper with lacquer and transferred to the object while still wet or drawn on it direct with a thin paste of white lead or colour. In carrying it out the artist used gold or silver dust applied through a quill, a bamboo tube, or, for equal distribution, a sieve. Larger fragments of the precious metals were applied separately by hand, with the aid of a small, pointed tool. In one typical instance approximately 500 squares of thin gold foil were thus inserted within one square inch (six square centimetres). These decorative processes each entailed prolonged hardening periods and meticulous polishing. Relief was obtained by model-



Imperial Chinese throne of the Ch'ien-ling emperor (1736-96), red lacquer carved in dragons and floral scrolls, Ch'ing dynasty. In the Victoria and Albert Museum, London. 1.19 m X 1.26 m X 91 cm.

ling with a putty consisting of a mixture of laquer with fine charcoal, white lead, lampblack, etc., camphor being added to make it work easily. Lacquer was sometimes engraved, both in China and Japan.

Chinese carved lacquer. The carved lacquer of China (tiao-ch'i), which was imitated but never equalled in Japan (as the Chinese have never reached the perfection of the Japanese gold lacquer ware), needs particular notice. In this the lacquer was built up in the method described above, but to a considerable thickness; when several colours were used, successive layers of each colour of uniform thickness were arranged in the order in which they were to predominate. When the whole mass was complete and homogeneous, it was cut back from the surface to expose each colour as required by the design. When the lacquer was cold and hard, the carving was done with a V-shaped tool kept very sharp. The cutting was done with amazing precision—no correction of faults was possible, for each layer had to be exactly and accurately reached and the final result precisely foreseen and allowed for from the beginning of the work. The red lacquer (t'i-hung), so well known and justly appreciated, was coloured with cinnabar (red mercuric sulfide). Other colours which were employed include a deep and a lighter olive-green, buff, brown, black, and purple (aubergine).

Use of successive layers of different coloured lacquer

Japanese processes. In Japanese lacquer, the following are the chief processes used: nashiji (pear skin), small flakes of gold or silver sunk to various depths in the lacquer; *fundame*, fine gold or silver powder worked to a flat, dull surface; *hirame*, small, irregularly shaped pieces of sheet gold or silver placed on the surface; togidashi, the design built up to the surface in gold, silver, and colours with many coats of lacquer and then polished down to show them; *taka-makie*, decoration in bold relief; hiramaki-e, decoration in low relief: *rō-iro*, polished black; chinkin-bori, engraved lacquer; kirikane, square dice of sheet gold or silver, inserted separately on the surface; and *raden*, inlaid shell and metal. From the earliest recorded times shell was used in the adornment of lacquer in China as well as in Japan, being inlaid on the surface in patterns as well as in small squares like *kiri*kane and dust. For this purpose various shells were used, mother-of-pearl (for larger work), nautilus, pear shell, sea-ear (Haliotes, Japanese Awabi) and Turbo *cornutus* (Japanese Sazae). For a very charming form, called laque *burgauté*, the iridescent blue and green shell of the sea-ear was delicately engraved with gold and silver as early as the Ming period (1368–1644) and also in Japan. Chinese lacquer was also inlaid with jade, malachite, coral, soapstone, ivory, porcelain, and other substances.

Laque burgautk

HISTORICAL DEVELOPMENTS

China. The use of lacquer in China goes back traditionally to legendary times. A late Ming manuscript, the Hsui *shih lu*, states that it was first employed for writing on bamboo slips, then for utensils for food, made of black lacquer, and subsequently for vessels for ceremonial use, of black with red interiors. During the Chou dynasty (1122–249 BC) it served for the decoration of carriages, harnesses, bows and arrows, etc., and was the subject of official regulations. At this time, gold and colours are said to have come into use. About the 2nd century BC buildings were decorated with lacquer, as were musical instruments. Under the Han dynasty (206 BC–AD 220) further development took place. Pot covers of paper, covered with lacquer and found near Port Arthur, are attributed to this period.

Of the lacquer of the T'ang dynasty (618–907) more reliable information is available, for the collections still preserved in the Hōryū-ji in Japan, founded AD 607, and those collected by the Japanese emperor Shōmu (724–748), deposited after his death in the Imperial treasury (Shdsd-in) at Nara, contain many objects of Chinese origin; in particular, musical instruments with inlay of cutout figures of gold and silver inserted on the surface, covered with lacquer, which was then rubbed down until the metal ornaments were again visible.

Wood bowl decorated in red and black lacquer with stylized birds and animals, from Ch'ang Sha, China, late Chou dynasty, 3rd century BC. In the Seattle Art Museum, Washington. Diameter 25 cm.

Under the Sung dynasty (960–1279) the industry further developed, and the use of gold and silver lacquer in the utensils made for the palace is particularly recorded. The chief seat of manufacture was Chia-hsing, between Hangchow and Su-chou, the latter city being also an important centre of the industry. A lacquer box of the early Sung period, probably once of rhinoceros-horn colour, black and red, with gold dust and silver wire, is one of the very few known examples of the period. Toward the close of the period (c. 1220) it is stated that lacquer wares were exported from Ch'uan-chou, Fukien to Java, India, Persia, Japan, Mecca, and other places. Chinese writers record the existence of carved red lacquer during the time of the Yüan dynasty (1279–1368) as well as of pierced ware and that inlaid with shell.

Ming lacquerwork

Of the state of the industry under the Ming dynasty (1368–1644) there are contemporary Chinese descriptions; for instance, in the *Ko* ku yao lun, published in 1388, the Ch'ing pi-ts'ang, published in 1595, and the Hsiu *shih lu*, which has been handed down in manuscript. This last work was written by a celebrated lacquerer, Huang Ch'eng, and bears a preface by Yang Ming, another lacquerer, dated 1625. The work itself was probably written towards the end of the 16th century. From these works one can ascertain the excellence of the carved lacquer made during the reigns of the Yung-lo (1403–24) and Hsiian-te (1426–35) emperors. Examples of carved lacquer that can be attributed to both these reigns are extant. They are bold in design and free from the superabundance of small detail that characterized later productions; the colour also is generally deeper and richer than that of the 18th-century pieces. In the 16th century there were special factories for carved lacquer at Ta-Li in Yünnan, which also produced spurious imitations. Lacquer with designs painted in gold outlines were made, early in the Ming dynasty, at Nanking and afterward at Peking, and lacquer inlaid with mother-of-pearl was made at Chi-chou in Kiangsi. In the reign of Hsiian-te, lacquer decorated in sprinkled gold was introduced from Japan and excellent copies were made by Chinese lacquerers. Toward the end of the Ming dynasty there was a decline in lacquer manufacture as a result of the troubles accompanying the fall of the last Ming emperor.

Importation into Europe

The first and perhaps the greatest of the Manchu emperors, K'ang-hsi (1654–1722), revived the lacquerwork industry in 1680, when he established a series of 27 workshops for artistic handicrafts in the precincts of the palace at Peking. Carved lacquer was, however, also made at Canton, Su-chou, and Foo-chow; and the Jesuit Louis le Comte, who arrived in China in 1687, gave a good account of the flourishing state of the industry at that time. In this connection it is worth noting that the period of K'ang-hsi was that which saw the first considerable importation of lacquer ware (and other objects of industrial art) into Europe. This led to the development of imitation lacquer applied to furniture and other objects, which were conspicuous features of the chinoiserie craze of the late 17th and 18th centuries. A screen, c. 1700 in the collections of Earl Spencer and R. Freemer Smith, Esq., for example, was made by command of K'ang-hsi for presentation to the Holy Roman emperor Leopold I, whose badge, the double-headed eagle, is incorporated in the design. Carved lacquer of this period, though far from negligible, hardly attains to the rich colour, breadth, and simplicity of that of the Ming period.

In technique the K'ang-hsi ware shows an advance and is generally free from the small cracks too often found to have developed in the Ming products. The perfection of this quality, apart from other considerations, is found in the lacquer ware of Emperor Ch'ien-lung (1736–96), a devoted admirer of this art, who employed it on a large scale for the furniture and fittings of his palaces, as well as for ceremonial and commemorative gifts. The workmanship of objects made under his auspices is brilliant in the extreme, but the colour is hard as compared to earlier work, and the design tends to a somewhat stereotyped formalism.

Still, the 18th century can hardly be called a period of decadence in the decorative arts of China: the superb execution of its productions, a characteristic that commands admiration, redeems it from adverse criticism. The downward course began in the 19th century, with loss of originality and a falling off, due to adulteration, in the quality of the material. What was left of the Imperial factories was burnt in 1869, and, though carved red lacquer was made after that date, the industry had already ceased to have artistic importance.

Japan. Although the earliest reference to the manufacture of lacquer accepted by all Japanese authorities is a code of law (known as Taihō code) dated 701, there can be no doubt that the manufacture was brought to Japan from China via Korea at the time of the introduction of Buddhism in the middle of the 6th century. At the same time, according to tradition, the Chinese lacquer tree was introduced. The earliest piece of lacquer known today that is accepted as having been made in Japan is the Tamamushi Shrine in the Hōryū-ji, which is attributed to the 7th century. This piece shows strong Korean influence. Many fine pieces of the late 7th and the 8th centuries, inlaid in gold, silver, or mother-of-pearl, of Chinese origin, have been preserved in the Shōsō-in, as already mentioned in the section above on Chinese lacquer. But there is one piece in the Shōsō-in, a sword-scabbard of black lacquer decorated in gold, formerly belonging to the emperor Shōmu (724–748), that is undoubtedly Japanese. This is listed in an old catalog dated 756. There are also two arrows in the Tokyo National Museum that belong to the same period. These can be regarded as the real beginnings of a Japanese style in lacquer.

The emperor Kammu (781–806) removed the capital from Nara to a new city, Heian-kyō—the modern Kydto; and an increased luxury in the style of living brought about further developments in the art, especially in the use of gold lacquer, largely because of the spread of Buddhistic influence. This period, however, saw the beginnings of a Japanese national style as distinct from the Chinese methods and manner, imported by Buddhist missionaries. Lacquer was used at this time in the decoration of important buildings, and inlay of shell also became popular. The organization of the industry was extended, and, as early as 905, sumptuary edicts began to be issued regulating the dimensions and quantities of material to be used in the domestic utensils—chiefly of black or red polished lacquer—which now began to come into general use. From this time, it is no exaggeration to say that, to a considerable extent, lacquer filled the place occupied in China by ceramic wares. A remarkable development of this period that must not be overlooked was the production of statuary of considerable merit, made with lacquer composition (kanshitsu), a process derived from China but carried to a high standard in Japan for a brief period, until it was superseded by wood sculpture. Some few authentic examples remain of the fine lacquer of the Heian period, notably a case for Buddhist scriptures in the Ninna-ji at Kyōto, made at the beginning of the 10th century, which bears an inscription dated 919. The case is in black lacquer, sprinkled with gold dust and with a pattern of flowers, clouds, birds, and Buddhist winged genii in gold and silver togidashi.

Production of statuary

During the Kamakura period (1192–1333), in spite of the disturbance caused by the famous struggle between the Minamoto and Taira clans and the establishment of the feudal shogunate at Kamakura, which gives its name to the period, the art of making fine lacquer continued to progress under the patronage of the Fujiwara family, who maintained the Imperial court at Kydto with ever increasing luxury. Marked features of this time are improved methods of inlay of precious metals and shell and, especially, an attractive form of design in which beautifully written poems are interwoven with the pattern (*ashide*). The process called Kamakura-bori, carved wood thickly lacquered with red or black, also dates from this period and continued to flourish for another two centuries or so. During this epoch occurred the beginnings of the characteristic Japanese treatment of landscape and flower subjects in design, generally in flat gold lacquer with nashiji and pewter inlay.

"Priest Ganjin," hollow dry lacquer (*kanshitsu*) statue, Late Nara period (724–794 AD). In the Tōshōdai-ji, Nara, Japan. Height 80 cm.

Muromachi lacquerwork

The Muromachi period (1338–1573) saw a further technical and artistic development, largely under the patronage of the shogun Ashikaga Yoshimasa (reigned 1443–73). He gave great impetus to the tea and incense ceremonies, the latter of which brought about a whole series of new applications of the art because of the exquisitely wrought small utensils required by that ritual. The ostentatious simplicity of the Zen sect of Buddhists was displayed in the use of black lacquer of the first quality with little or no ornament. Excellent work in shell inlay was also a characteristic of the time. The gold lacquer of the Muromachi craftsmen gained so great a reputation in China that artisans from that country went to Japan to learn the methods by which it was produced, though they seem to have had little success in introducing it into their own country. Among the leading Japanese craftsmen of the period may be mentioned Kbami Dbchb, Taiami, Seiami, and Igarashi Shinsai, but attribution of specific works to them is largely a matter of conjecture.

The civil wars which continuously infested Japan during the later Middle Ages checked the growth of the industry for a while, but the short Azuchi-Momoyama period (1574–1600) that followed saw at least the work of one of the greatest of Japanese artists in lacquer, Hon'ami Kbetsu. He was the founder of a striking and original style of ornament, essentially national in character. His designs were bold and simple in detail, generally executed in high relief with masses of shell or metal inlay. The great shogun Toyotomi Hideyoshi (died 1598), who secured the peace of the country with a strong hand, was an enthusiastic patron of the arts, and under his patronage a real revival took place. When he died, his widow erected the Kbdai-ji at Kybto, in which distinctive lacquer decoration called tata maki-e (Koda-ji maki-e) was used. This temple still contains examples of this ware that were presented by her.

The Edo school

In 1603 began the rule of the Tokugawa shogunate, which continued without a break until the restoration of the Imperial family to actual power in 1867. The first of the line, Ieyasu, established at Edo (the modern Tokyo) the great school of lacquer artists that is responsible for almost the whole of the artistic ware known outside Japan. Technical processes were still further developed with additions such as engraved lacquer (chinkinbori) derived from China, carved red and black lacquer from the same source, and the so-called somada ware of shell inlay of black, different in character from the Chinese *laque burgauté* already mentioned above.

This period also saw the introduction of the now well-known inrd, or portable medicine case, worn on the girdle and an indispensable addition to the national costume so long as the latter was uncontaminated by Western influence. An inrd consisted, as a rule, of from two to five compartments, beautifully fitted into each other and held together by silken cords running along each side, secured by a bead (ojime) and kept in place on the sash by a kind of toggle (netsuke), sometimes of lacquer but more often of cunningly carved wood, ivory, bone, or other material. On this class of work was lavished some of the finest artistry of the Japanese craftsmen, and the convenient size and intrinsic charm of these dainty utensils (originally, perhaps, made for seals) have caused them to be much favoured by collectors.

Chinese influence on Tokugawa lacquerware

The earlier years of the Tokugawa period saw a considerable Chinese influence in the design of lacquer, especially in inrd; but the work of the greatest Japanese lacquer artists, Ogata Kbrin (*c.* 1658–1716), followed and extended in the late 17th century the style originated by his master, Kbetsu. Ritsuō and Hanzan in the 18th century maintained this tradition, and a considerable revival of the style took place in the early years of the 19th century, when memorial volumes of the designs of the great master were published. To the latter period belong not a few objects which have been accepted as the original work of Kbrin himself. The more formal school of lacquerers included Kbami Chbgen (1572–1607) and Komo Kitb-ye, who was appointed court lacquer artist to the shogun Iemitsu in 1636 and died in 1674. One of the most important lacquerers of the Kbami family was Kbami Nagashige, whose masterpiece, consisting of three connected cabinets with numerous writing cases, paper cases, and toilet cases, a mirror stand, and other accessories, was completed in 1639. It was made for the dowry of Tokugawa, Iemitsu's eldest daughter, on her marriage to Mitsumoto, prince of Bitchū, whose coat of arms is affixed to all the pieces. The lacquer is now in the Tokugawa Art Museum, Nagoya. As did other craftsmen in Japan, lacquer artists followed the practice of transmitting their names to sons or selected pupils. Thus, there were ten generations of the family of Yamamoto Shunshō, who died in 1682, aged 63. The Kajikawa family continued the tradition of its founder well into the 19th century, and the same must be said of Shiomi Masanari in the 18th century, whose work was notable for the quality of the rubbed-down gold and colour lacquer called togidashi.

The Genroku period (1688–1703) saw, perhaps, the ultimate perfection of style and technique; but the work of the later 18th and, to some extent, of the early 19th centuries has many exquisite qualities. The later periods were characterized by more elaborate detail, but adulteration of the gold with bronze and other metallic powders was often prevalent. A fiery brown tint of the nashiji is a certain mark of quite late date. Nevertheless, there is plenty of good work of the 19th century, and to this period belongs the last of the great artists of the industry,

Shibata Zeshin, whose work bears comparison even with some of the greatest of his predecessors, both in technique and in design.

Modern industrial conditions, however, have practically killed this ancient and beautiful art. It would not have survived so long had not the country been closed to alien influences for two and a half centuries. (E.F.S.)

Europe. Although East Asian objects of art were taken to Europe in considerable quantity during the 16th century, it was not until after 1600 that a real trade with China grew up, fostered by the East India companies of the Netherlands, England, and France. Porcelain and lacquerwork then became so fashionable that European craftsmen undertook to make their own. The secret of porcelain manufacture was discovered shortly after 1700, and by that time the imitation of lacquer had become established in various parts of Europe. Jesuit missionaries had cooperated with scientists and master craftsmen to create formulas, and a small body of writing had appeared, which was to be augmented in the 18th century —the golden age of European lacquer.

Origins of the European lacquer-work industry

Among the earliest surviving examples of this art is the ballot box of the Saddlers Company (1619; Saddlers Company, London). Information on the lacquer process seems first to have been published by the Italian Jesuit Martin Martinius (*Novus Atlas Sinensis*, 1655). John Stalker and George Parker's *Treatise of Japanning and Varnishing* (London, 1688) was the first text with pattern illustrations. The English term japanning was inspired by the superiority of Japanese lacquer, which Stalker found ". . . in fineness of Black, and neatness of draught . . . more beautiful, more rich, or Majestick" than the lacquer of other places, which came to be known as "Indian" or "Bantam" work.

In France, on the other hand, *ouvrage à la **Chine*** was the term for the imitation of lacquer practiced at the Gobelins factory in Paris from 1672. By the end of the century Berlin had become another centre of experimentation, from which a Fleming, Jacques Dagly, brought secrets that were to lead to the 18th-century innovations of the Martin brothers: Guillaume, Simon, Étienne, Julien, and Robert. They created the lustrous *vernis Martin,* which was praised by Voltaire. The Martins decorated rooms at Versailles, and Robert's son Jean Alexandre worked for Frederick the Great II at Potsdam. French lacquer was further improved through new information provided by the *Mémoire sur le vernis de la Chine*, which the French missionary Pierre d'Incarville wrote in 1760 and which appeared as an appendix to *L'Art du peintre, doreur, vernisseur* of the Sieur Jean-Felix Watin (1772), the most precise account of lacquerwork that appeared in the 18th century. In this book Watin examined the recipes of his predecessors and recommended the best formulas for lacquering objects to be used indoors, such as furniture, and outdoors, such as carriages. Although nothing could equal the excellence of Oriental resins, he found sandarac from Western juniper trees the best substitute. This, together with various gums dissolved in alcohol and turpentine and mixed with bitumens, produced the different varnishes Watin relied upon. His book gives detailed instruction for preparing the wood, covering it with cloth, varnishing this with from eight to 20 coats, polishing the surface, drawing and painting the designs, and making relief decorations. The best results of this process (*e.g.*, an 18th-century commode attributed to René Dubois in the Wallace Collection, London) were never as hard and brilliant as real Oriental lacquer, but they provided an admirable substitute; on occasions it is not easy to distinguish them, especially when East Asian designs were imitated.

Introduction of European motifs

The chief interest of European lacquer of the 18th century lies, however, in the fact that it was not a purely imitative art, as it had been at its beginning. Until about 1720, European craftsmen sought to reproduce exactly the figures, the architectural settings, and the stylized vegetable forms of the imported lacquers. Then, in keeping with the playful spirit of the rococo, they modified these designs by introducing European figures, exotic animals such as monkeys, draperies and arabesques, and cartouches and ribbon compositions. Along with this transformation, in place of the conventional black and gold of the Oriental products, came a wide choice of background colours, including scarlet, yellow, white, blue, and green, sometimes flecked with gold. Particularly in Venice, where craftsmen followed the rules of a treatise by Filippo Buonanni (1720), a great originality was achieved by the informal spacing of bouquets of flowers around gracefully posed figures set against delicate hues of yellow and bluish green.

The uses of lacquer in Europe reflect the changing tastes of the 17th and 18th centuries. In the late 17th century it was principally employed for decorating the cases of cabinets set upon carved baroque bases or for ornamenting leather wall coverings. In the 18th century, bookcase desks, tall clocks, and tea tables became the most fashionable articles of lacquered furniture in England and Germany, while in France and Italy the chest of drawers and corner cabinet were preferred. Whole sets of furniture with Orientalizing lacquer decoration were made in England by Giles Grendey and other cabinetmakers of the Chippendale era (1754–68). Rooms with lacquered walls have survived at the palaces of Nymphenburg outside Munich, Bamberg, and other German cities. Small lacquered boxes called ***Boite de Spa*** became a specialty of that Belgian town and the nearby centres of Liège and Aachen, where a member of the Dagly family was active.

Lacquered armoire belonging to David Garrick; by Giles Grendey (1693–1780). In the Victoria and Albert Museum, London. 1.4 m × 1.68 m × 62 cm.

In the early 19th century the solemn grandeur of the international Classical style with its insistence on plain wood or gilt surfaces almost eliminated the taste for lacquered furnishings. It survived in Victorian times in the vogue for painted tin or toleware (as in Pontypool, England) and the decoration of small tables and chairs of papier-maché inlaid with mother-of-pearl. The making of this furniture, dominated by the London firm of Jennens and Bettridge, rapidly declined after reaching the height of its popularity about the time of the Great Exhibition held in London in 1851. In the period 1925–30, two European sculptors, the Belgian Marcel Wolfers and the Franco-Swiss Jean Dunand, successfully approximated the true Oriental lacquer techniques in a few art objects of clay, wood, and bronze. By this time, however, the making of lacquer surfaces had become a part of the chemical industry, which today produces effects of depth and hard translucence surpassing the finest products of the European lacquer masters of the past. (R.C.Sm.)

Lacrosse

Lacrosse is the oldest organized sport in North America and, inasmuch as baseball and U.S. and Canadian football were developed respectively from pre-existing rounders and rugby prototypes, is the only modern team sport, except for basketball, that originated on that continent. The game resembles the Irish national game of hurling and the hockey games (and thus also the football games, especially soccer) in the flow of play, in which two sides or teams each attempt to propel an object (ball) into a goal defined by uprights and a crossbar framing a loose net and to prevent the other side from doing so.

The crosse

The distinctive feature of the game is the crosse, the implement used by the players to carry, catch, and pass the ball. The crosse is a staff of wood, usually hickory, the top being sharply bent to form a hook from the end of which a thong is drawn and fastened to the shaft about two or three feet (0.6 or 0.9 metres) from the end of the handle, forming an oval triangle that is woven with a loose network of leather, nylon, or gut to form the pocket with which the ball is handled.

The following discussion traces the history and development of the game and describes the playing field and equipment and the principles of play and points out the distinctive features of the women's game.

History. Lacrosse was played by The Six Nations of the Iroquois in upper New York State and lower Ontario long before Columbus landed in the New World. The sport was then played in a much rougher form than it is today. Among some tribes as many as a thousand players took part on each side, goals were miles apart, and a game could last as long as three days (thus somewhat reminiscent of the Romans' *harpastum* and the *mêlées* or mellays indigenous to ancient Briton, battle-like pastimes held to be ancestral to modern football). The strategy of each player was to disable as many opponents as possible with the stick he carried and afterward concentrate on scoring a goal. The Cherokees called their version of the game "little brother of war." Because of the endurance required and the injuries that had to be borne with fortitude it was considered excellent training for combat. Among many tribes the game was as much a mystic ceremony as a sport and was preceded by complex rituals and a solemn dance. Indians on government reservations in the United States and Canada still field strong teams.

Origin of the name

To the first French settlers in Canada who saw the game, called "baggataway" by the Indians, the shape of the implement used to catch, carry, and throw the ball suggested a bishop's crozier *(la crosse)*, giving the sport its name; the stick itself becoming known as a crosse.

Europeans in Canada started playing the game in about 1840, and the first lacrosse organization, the Olympic Club, was founded in Montreal in 1842. In playing Indian teams, white players lost so frequently they were allowed to field extra men. Members of the Montreal Lacrosse Club, founded in 1856, modified the rules somewhat, and four years later George Beers of Montreal, called "the father of lacrosse," made further changes that included replacing the Indian ball of deerskin stuffed with hair by a hard rubber ball, limiting the number of players on a team to 12, and improving the stick for easier catching and throwing of the ball. The 12 players were designated at that time as goal, point, cover point, first defense, second defense, third defense, centre, third attack, second attack, first attack, out home, and in home. The year 1867 was an important one for the sport: Parliament declared it Canada's national game, the National Lacrosse Association was formed, and the game was introduced to England. Capt. W.B. Johnson of Montreal toured with a team of Caughnawaga Indians, appearing before Queen Victoria at Windsor Castle, who found the game "very pretty to watch." The English took to the sport and the game achieved popularity in various parts of the country—notably in Lancashire, Cheshire, Yorkshire, Manchester, Bristol, and London. The English Lacrosse Union was founded in 1892. English teams have exchanged visits with teams from the United States and Canada from time to time, and combined Oxford–Cambridge teams have frequently exchanged visits with college or all-star teams from the United States. The game is also popular in Ireland, Australia, New Zealand, and the Republic of South Africa. In both Canada and the United States it has grown with extreme rapidity since the mid-1950s, being played at the high-school and elementary-school levels, as well as by colleges and club teams. Lacrosse was included in the Olympic Games in 1904 and 1908 with teams representing Canada, the U.S., and Great Britain. Teams from those countries also demonstrated the sport in exhibitions at the Games in 1928, 1932, and 1948, but lacrosse did not attract international interest and is no longer recognized as an Olympic sport.

Arrival of the game in England

Although preoccupied with baseball in its embryo form in the late 1800s, the United States was not long in developing an interest in the game. A team of Indians introduced it to Troy, New York, in about 1868, and a few years later teams were started in that city, New York City, and Brooklyn. In the 1880s Eastern colleges including New York University, Princeton, Yale, and Harvard took up the sport. In 1884 a successful tour of Europe was made by a team of American collegians and in 1906 the U.S. Intercollegiate Lacrosse League was formed. The game received its greatest impetus, however, when it was introduced to Baltimore, Maryland, by some track men from that city who were intrigued when they saw the game being played by some Canadians on Long Island. Returning, they actively promoted the sport, aiming at all age levels, with the result that Baltimore is the main U.S. centre of lacrosse. Strong teams are invariably fielded by Johns Hopkins University and St. John's of that city and by the nearby University of Maryland and the U.S. Naval Academy at Annapolis. Two other colleges with fine records are the U.S. Military Academy at West Point, New York, and the University of Virginia. The Mt. Washington Club of Baltimore and the Long Island Athletic Club in Wantagh, Long Island, are perennial winners of annual national club championships sponsored by the U.S. Lacrosse Club Association. The Intercollegiate Lacrosse League was reorganized in 1926 to become the U.S. Intercollegiate Lacrosse Association, which had about 120 member colleges. In 1970 the National Collegiate Athletic Association (NCAA), with more than 500 member colleges, undertook sponsorship of intercollegiate lacrosse competition and championships, reflecting the growth of the sport in the country outside its traditional Eastern Seaboard stronghold. The college team considered the best in the country is awarded the Wingate Trophy, Johns Hopkins being its most frequent recipient.

The field and equipment. The basic elements and dimensions of the field are shown on the accompanying diagram. The field is 110 yards (about 100 metres) long and 60 yd (55 m) wide. The goals are 80 yd (73 m) apart, the goal posts being 6 feet (1.83 m) high and the same distance apart, surmounted by a crossbar. The posts are fitted with a pyramid-shaped netting fastened to the ground behind the goal to stop passage of the ball after a successful shot. The goal-area lines, wing lines, and centre line serve to act as restraints on certain players during play; *i.e.*, their range of movement is limited. Passing over a line into a prohibited area results in a penalty.

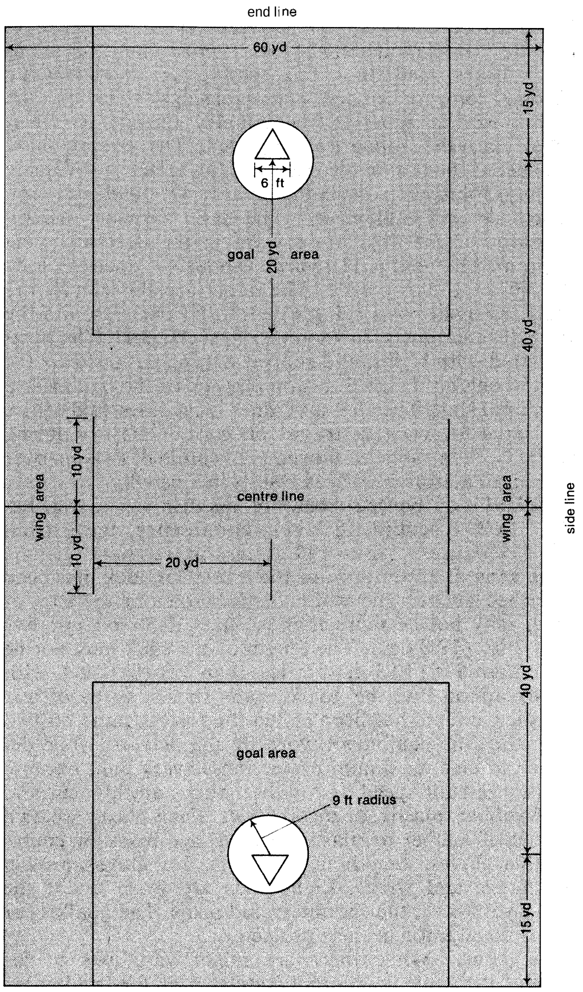
The ball is of sponge rubber, not less than 7% to 8 inches (19.7 to 20.3 centimetres) in circumference, and is from 5 to 5% ounces (142 to 149 grams) in weight.

The general appearance of the crosse, or stick, has been described above. The width of the crosse at the top, or head, may not be more than 12 in. (30.5 cm) nor less than 7 in. (17.8 cm). The length of the stick may not be more than 6 ft (1.83 m) nor less than 3 ft (0.91 m), with the exception that the goalkeeper's stick may be of any length. Lacrosse has been called the fastest game on two feet: thus the equipment worn by the players, while designed to give maximum protection, is very light because of the need for speed and agility. Shoes are low cut and have rubber, plastic, or metal cleats. Each player wears a helmet of leather or plastic, with a face mask or guard. Leather gloves, something like ice-hockey gloves, protect the hands and wrists. Light pads are worn under the jersey to protect the shoulders and arms. The goalkeeper wears, in addition, a chest protector.

Use of lightweight equipment to enhance speed of play

"Cradling" the ball

The game. While there are minor variations in the rules of the game in different countries, all are fundamentally similar. The object of the game is to send the ball through the opponents' goal as many times as possible and to prevent one's opponents from scoring. A goal counts one point. Under most rules for men, there are ten players per team. They are designated as the goalkeeper or goaltender, three defensemen, three midfielders (one of whom is the centre), and three attackmen. During play each team must have at least four players in its defensive half of the field and no fewer than three in its offensive half of the field. The purpose of this rule is to prevent excessive crowding around a goal when it is under attack. Conventionally, the goalkeeper and the three defensemen stay in the defensive half, while the three attackmen stay in the offensive half. The midfielders are permitted to roam the field, reinforcing the attack or defense as needed. There are two officials, a referee and a judge. The game is divided into four periods of 15 minutes each, with intervals of one minute between the first and second quarters and between the third and fourth quarters and a ten-minute rest at half time. If the score is tied at the end of regulation time, play is resumed after an intermission of five minutes for two four-minute periods, with a one-minute rest in between. Free substitution is allowed. A player may run with the ball, pass it in any direction, and catch it, but—with the exception of the goalkeeper—he may not touch it with his hand. A player may kick the ball or bat it, but not into the opponents' goal. A unique feature of the game is "cradling," in which the player rapidly rotates the stick in half-turns while holding it nearly upright as he runs. The centrifugal force developed keeps the ball in the pocket of the crosse and also puts it in position for accurate throwing. Defensive players are allowed to poke the ballcarrier in the body with their sticks or slap at his stick to dislodge the ball. Blocking the ballcarrier—*i.e.*, hitting him with the shoulder in an attempt to throw him off-balance or knock him down—is legal. For minor infractions of the rules the penalty is either suspension



Playing field for men's lacrosse

from the game for 30 seconds or an exchange of the ball. In the case of personal fouls of a more serious nature—for example, an illegal block (as below the knees from the rear)—the offender is suspended from the game for one, two, or three minutes, and his team plays one man short for that period of time. Other serious fouls in the game of lacrosse include tripping, slashing, and unnecessary roughness.

Play is started at the beginning of each quarter and after the scoring of a goal with a face-off at midfield, as in hockey. The two centres face each other, the heads of their sticks touching the ground. The referee places the ball between the two crosses, and at his signal each player tries to gain control of the ball. He may keep it himself or bat it to a teammate. The player with the ball tries to advance it toward the opposing goal by running or passing to a teammate in the open. The defenders try to force him into making a poor pass, intercept the ball when it is thrown, knock the ball from his stick, or occasionally knock it loose with a block. The game is lively since the players are in constant movement: dodging, hurling, or flipping the ball to a teammate; scooping up the ball while running at full speed; or making quick, deceptive shots at the goal. A unique ceremony at the beginning of the game consists of the teams lining up in the centre of the field opposite each other. Each player introduces himself to his particular opponent, shakes hands, and wishes him luck.

Women's lacrosse. This version of the game, popular in the British Isles, Australia, Canada, New Zealand, South Africa, Switzerland, and the United States, was first played in Scottish and English private schools in the early 1900s. It was introduced to schools and colleges in the eastern United States by English women educators. Frequent exchange visits have been made by American and English women's teams, the latter showing themselves to be the best in the world. British-Irish touring teams have continued to maintain excellent records against American teams.

The game is one of speed and skill in passing, no body contact or rough play with the stick being permitted. With the exception of the goalkeeper, who wears a chest pad and leg guards, the players do not wear protective equipment. There are 12 players on each side. The goals are 90 to 110 yards (82 to 100 metres) apart, and there are no sidelines or end lines, the goal creases and centre circle being the only ground markings. A game consists of 25-minute halves, with a 10-minute intermission. There is no overtime in the case of a tie. The rules established by the All-England Ladies' Lacrosse Association are universally accepted by other nations. In the United States, the Philadelphia, Baltimore, and Boston areas traditionally have had strong teams, while the main English centres of women's lacrosse are Hertfordshire, Kent, Norfolk, Essex, and Suffolk.

Lactation, Human

Lactation, the secreting and yielding of milk, normally occurs in human beings and other mammals after the birth of an offspring. The secreting organs are the mammary glands, contained within the breasts. The structure and diseases of these glands, and of the breasts, are discussed in the article MAMMARY GLANDS, HUMAN. Breast development begins at puberty, though the rudiments of the mammary glands are present much earlier and can manufacture a secretion in the first few days after birth. The mammary glands of boys and girls are similar before puberty, and most of the increase in size evident in girls upon sexual maturation is due to the accumulation of fat and connective tissue within which the secretory elements, called alveoli, and the duct system of the mammary glands are embedded. The ovarian hormones, estrogen and progesterone, are necessary for mammary gland growth, and in their absence, as in girls with malfunction of the pituitary gland or whose ovaries have been lost before puberty, breast development is minimal. Rhythmic changes in the microscopic structure of the breasts are detectable during the menstrual cycle, and many women describe a feeling of heaviness, fullness, and tenderness in the breasts just before menstruation (see MENSTRUATION). These changes increase during pregnancy, when each mammary gland may increase in weight by a pound or more, largely because of the development and elaboration of the milk-secreting apparatus.

Development of the breasts and the mammary glands

Enlargement of the breasts during pregnancy. The growth of the breasts during pregnancy is controlled by the hormones prolactin, from the hypophysis, or pituitary gland, and estrogen and progesterone, from the ovaries and the placenta (the temporary organ whose prime purpose is to provide nourishment for the fetus and to eliminate its wastes). The placenta also produces a substance that acts like prolactin. Estrogen promotes development of the ducts of the mammary glands, whereas alveolar growth is most greatly influenced by progesterone; both hormones are secreted in increased amount during pregnancy. Milk formation follows from the action of prolactin. Experiments on rats have shown that additional hormones aid in maintaining and augmenting mammary growth and lactation. These include thyroid hormone, adrenal hormone, insulin, and growth hormone. Because of the dual supply of estrogen and progesterone, from the ovaries and the placenta, the ovaries can be removed between the first and second months of pregnancy without causing loss of the fetus or arresting breast growth. Sufficient prolactin-like hormone for mammary development can also be produced by the placenta, as was shown in cases in which the removal of the pituitary gland during pregnancy did not stop mammary growth and development in monkeys or in a woman, and milk secretion occurred after delivery.

Initiation of lactation. A hormonal change that initiates lactation occurs during pregnancy. (It is no longer possible to believe, as did the ancient Greeks, that milk is produced in the uterus and carried to the mammary glands by special vessels, so that the uterine milk that has nourished the fetus can continue to be utilized after birth.) Although mammary growth occurs during pregnancy under the influence of ovarian and placental hormones and some milk is formed, copious milk secretion sets in only after delivery. Since lactation ensues after a premature birth, it would appear that milk production is held back during pregnancy. The mechanism by which this inhibitory effect is brought about, or by which lactation is initiated at delivery, has long been the subject of an argument that revolves around the opposing actions of estrogen, progesterone, and prolactin, as studied in laboratory animals, goats, and cattle. During pregnancy the combination of estrogen and progesterone circulating in the blood appears to inhibit milk secretion by blocking the release of prolactin from the pituitary gland and by making the mammary gland cells unresponsive to this pituitary hormone. The blockade is removed at the end of pregnancy by the expulsion of the placenta and the loss of its supply of hormones, as well as by the decline in hormone production by the ovaries, while sufficient estrogen remains in circulation to promote the secretion of prolactin by the pituitary gland and so favour lactation. It is also possible that a relative increase in the blood level of adrenal hormones favours the production of milk.

Milk-producing complex of hormones

Continuation of lactation. For lactation to continue, necessary patterns of hormone secretion must be maintained; and disturbances of the equilibrium by the experimental removal of the pituitary gland, in animals, or by comparable diseased conditions in human beings, quickly arrest milk production. Several pituitary hormones seem to be involved in the formation of milk, so that it is customary to speak of a lactogenic ("milk-producing") complex of hormones. To some degree, the role of the pituitary hormones adrenocorticotropin, thyrotropin, and growth hormone in supporting lactation in women is inferred from the results of studies done on animals and from clinical observations that are in agreement with the results of animal studies. Prolactin, growth hormone, and adrenal hormone seem of greatest value in restoring lactation after removal of the pituitary, although the precise response varies from species to species. The greatest difficulty with respect to the observations on women has been experienced in separating the actions of prolactin and growth hormone, for highly purified samples of growth hormone prepared from human pituitary glands still possess prolactin-like activity and can greatly enhance milk production.

The release of prolactin and of other hormones from the pituitary is controlled by the brain through its hypothalamic area. In the case of prolactin, however, the control consists in holding back output; whereas brain activity serves to stimulate the secretion of the other pituitary hormones. Thus, surgical separation of the connections between the pituitary gland and the brain, or depression of the functioning of the hypothalamus by drug treatment, favours the release of prolactin and the secretion of milk while it reduces the secretion of the other pituitary hormones. Tranquillizing agents, such as chlorpromazine and reserpine, can cause breast enlargement and lactation, probably by increasing the output of prolactin. In the condition known as pseudocyesis, or false pregnancy, the affected person firmly believes that she is pregnant and shows many of the signs of pregnancy such as breast enlargement, milk secretion, and abdominal swelling, although the uterus is empty. This effect of a psychological disturbance is an excellent example of the influence of the mind on the secretion of hormones.

Suckling and the release of oxytocin

The stimulus of nursing or suckling supports continued lactation in two ways: it promotes the secretion of prolactin (and possibly other pituitary hormones of value in milk formation), and it triggers the release of yet another hormone from the pituitary gland—oxytocin, which causes contraction of special muscle cells around the alveoli in the breast and ensures the expulsion of milk. It is in this way that a baby's sucking at one breast may cause an increase in milk flow from both, so that milk may drip from the unsuckled nipple. About 30 seconds elapse between the beginning of active suckling and the initiation of milk flow.

The nerve supply to the mammary glands is not of great significance in lactation, for milk production is normal after the experimental severing of nerves to the normal mammary glands in animals or in an udder transplanted to the neck of a goat. Milk ejection, or "the draught," in women is readily conditioned and can be precipitated by the preparations for nursing. Conversely, embarrassment or fright can inhibit milk ejection by interfering with the release of oxytocin; alcohol, also, is known to block milk ejection in women, again by an action on the brain. Beyond its action on the mammary glands, oxytocin affects uterine muscle, so that suckling can cause contractions of the uterus and may sometimes result in cramp. Since oxytocin release occurs during sexual intercourse, milk ejection in lactating women has been observed on such occasions. Disturbance of oxytocin secretion, or of the milk-ejection reflex, stops lactation just as readily as a lack of the hormones necessary for milk production, for the milk in the breast is then not extractable by the infant. Many instances of nursing failure are due to a lack of milk ejection in stressful circumstances; fortunately, treatment with oxytocin, coupled with the reassurance gained from a successful nursing, is ordinarily successful in overcoming the difficulty.

Suckling can initiate lactation in nonpregnant women. This has been seen most often in women of child-bearing age but also has been observed in older persons. A baby who had lost his mother was suckled by his 60-year-old grandmother, who had borne her last child 18 years before. The grandmother produced milk after a few days and continued to nurse the baby until he was a year old and could walk. Rarely, lactation has been reported to set in after operations on the chest; in such instances it is attributed to injury or irritation of the nerves in this region. Such observations argue against the possibility that lactation continues simply as a consequence of emptying the breasts.

The production of milk during lactation seems to decline with age, regardless of the number of previous pregnancies. Some correlation exists between the size of the breasts and milk secretion, but women with small breasts secrete milk normally, so that output could probably be raised by increasing the frequency of nursing. Drinking water beyond the demands of thirst impairs lactation and has been advocated as a means of suppressing this process.

Varying customs with respect to weaning

Weaning and the cessation of lactation. There is no typical age at which human infants are weaned, for this varies from country to country and among the social classes of a nation. In the United States in 1946 only 38 percent of babies were totally breast-fed at the time of discharge from the hospital. By 1958 the figure had fallen to 21 percent, but by the early 1970s had risen to about 23 percent. Breast-feeding rates vary with region and culture and may be higher in Arizona, Colorado, and Georgia than in Connecticut, Maine, and Massachusetts. In India women in the higher socioeconomic groups tend to use artificial feeding, while the reverse relationship holds in Britain and the United States. Most commonly, weaning is a gradual process, with a gradual increase in the proportion of solid food supplied to the infant together with breast milk. Pediatricians in general have concluded that, on the basis of present knowledge, no nutritional superiority or psychological benefits result from the introduction of solid foods into the infant diet earlier than 2% to 3½ months and that normal full-term infants can be expected to thrive for the first three months of life on a diet consisting exclusively of milk, either normal human milk or properly modified milk from other sources.

With the reduced demand of the baby, lactation slowly declines and stops. Estrogen treatment is often used to suppress lactation, and the high doses used may accomplish this; but there is often a rebound effect at the end of treatment. Lactation may be slightly depressed when oral contraceptives are being taken in high dosage.

Nursing as a contraceptive technique

Apart from providing nourishment for the infant, nursing may be continued as a means of contraception. In a recent study in which the subjects were women of European stock, menstruation was found to return in a high proportion of the women who had lactated for three months or more, while nearly all women who had discontinued lactation some two months after delivery resumed menstruation within six weeks. Different results emerged from studies on Punjabi women, for whom the mean duration of lactation was 21 months and the median length of time from the date of giving birth to the return of menstruation was 11 months. The lesser effect of lactation in delaying menstruation in women of European stock may have been due to the provision of supplementary food in addition to the breast milk so that the suckling stimulus was reduced in intensity.

Composition and properties of milk. Milk can be regarded as an emulsion of fat globules in a colloidal solution of protein together with other substances in true solution. Two constituents of milk, the protein casein and milk sugar, or lactose, are not found elsewhere in the body. The general assumption that breast milk provides the ideal food for human babies, in that it contains all the elements required in a good diet and in the most appropriate proportions, though entirely reasonable, is extremely difficult to prove, for controlled experiments are hardly possible with human infants. It is also extremely difficult to disprove, for the faster growth that may occur with supplemented diets is not necessarily optimal growth. While supplying an excellent infant diet, breast feeding confers other benefits, for the milk is normally delivered from a sterile container, and the feelings of well-being and the emotional bond generated between mother and child are important in the psychological welfare of both.

Colostrum

The milk released from the breast when lactation starts differs in composition from the mature milk produced when lactation is well established. The early milk, or colostrum, is rich in essential amino acids, the protein building blocks essential for growth; it also contains the proteins that convey immunity to some infections from mother to young, although not in such quantity as among domestic animals. The human infant gains this type of immunity largely within the uterus by the transfer of these antibody proteins through the placenta; the young baby seldom falls victim to mumps, measles, diphtheria, or scarlet fever. For a short time after birth, proteins can be absorbed from the intestine without digestion, so that the acquisition of further immunity is facilitated. The growth of viruses and bacteria in the intestines is probably inhibited by immune factors in human milk. After childbirth the composition of milk gradually changes; within four or five days the colostrum has become transitional milk; mature milk is secreted some ten days after delivery.

Some Constituents of Human Colostrum, Transitional, and Mature Milk and of Cow's Milk
(average values per 100 millilitres whole milk)

	colostrum (1–5 days)	transitional (6–10 days)	mature (after 30 day?)	cow's milk

***Kilocalorie; sufficient energy to raise the temperature of one kilogram of water one degree Centigrade.**

Some variations between human colostrum, transitional milk, and mature milk and cow's milk are shown in the accompanying table. The greater amount of protein in unmodified cow's milk is largely responsible for its dense, hard curd, which the infant cannot digest; the difficulty can be avoided by heat treatment or dilution of the milk. Ordinarily, when cow's milk is fed to young infants, it is modified so as to match its composition as far as possible to breast milk.

Ladoga, Lake

Lake Ladoga (Ladozhskoye Ozero in Russian; Ladozhskoje Ozero in the transliteration system of the Akademiya Nauk), in the northwest European part of the Union of Soviet Socialist Republics, is the largest lake in Europe. Located about 25 miles east of Leningrad in the Russian Soviet Federated Socialist Republic and in the Karelian Autonomous Soviet Socialist Republic, it is 6,826 square miles (17,678 square kilometres) in area --exclusive of islands—and 136 miles (219 kilometres) long, with an average width of 51 miles and an average depth of 167 feet. Its greatest depth is 754 feet.

The lake basin

Lake Ladoga's basin has a total area of about 100,000 square miles. The northern part of its basin and depression lies within the Baltic crystalline shield, and the southern part lies within the so-called Russian Platform of Precambrian rocks (more than 570,000,000 years old). The depression of the lake was produced by the action of glaciers. The northern shores are mostly high and craggy and are broken by deep, ice-covered, fjord-like inlets. There are numerous, mostly wooded islands here, with cliffs. The southern shores, which have many sandy or rocky beaches, are primarily low, slightly indented, and overgrown with willows and alders. In some places there are ancient coastal embankments overgrown with pines. The contour of the northern part of the lake bottom is complex, with deep depressions alternating with shallower areas. Depths of more than 300 feet predominate. The greatest depth, 754 feet, is located west of Valaam Island (Ostrov). In the southern section of the lake the bottom is more uniform, with depths decreasing from 300 to 30 feet and less; there are also many sandy and rocky slopes and sandbanks. In the deep areas of the northern and central sections of the lake, the bottom is muddy, whereas in the south it is mainly sandy and covered with detritus. In many areas there are boulders near the shore.

The lake also contains approximately 660 islands of more than 2½ acres in extent, occupying a total of 176 square miles. About 500 of the islands are located near the northwestern shore. In the central section of the lake, approximately 65 islands make up the Valaam and Western archipelagoes. The largest islands are Riyekkalan-Sari, Mantsinsari, Kilpola, Tulolansari, and Valaam.

The climate in the Lake Ladoga region is moderately cold, with a mean air temperature of 14° to 18" F (–10° to –8" C) in February and 61" to 64" F (16" to 18° C) in July. The absolute minimum temperature is –65" F (–54" C) and the absolute maximum 90" F (32" C). Mean annual precipitation is 24 inches.

There are approximately 50,000 lakes and 3,500 rivers of more than six miles length in the Lake Ladoga Basin. The largest tributaries are the Volkhov from the south, the Svir from the southeast, and the Vuoksa from the west. The discharge of river waters into the lake, mainly from the Volkhov, Svir, and Vuoksa, accounts for 85 percent of its incoming water balance (an average of 16.3 cubic miles per year), with 13 percent coming from precipitation and 2 percent from groundwater. Of the outgoing water balance, 92 percent flows into the Neva River (an average of 17.8 cubic miles per year), and the remaining 8 percent is accounted for by evaporation from the water surface. The lake is highest in June and July and lowest in December and January, with the average annual range of variation being 2.6 feet and the absolute maximum being about 9.8 feet. Taken together, the northern section has variations from about two to four inches, and, less frequently, up to a range of seven to 15 inches, with the southern section having level variations of up to 35 inches. Seiches, or changes in the water level, can be observed; in the north and centre of the lake, the seiches average ten to 11.5 feet and occasionally rise to 16 or 20 feet; in the south, they measure about eight feet. During the fall there are frequent storms.

Water temperatures

Thermal conditions differ from the deep central to the shallow coastal regions of the lake. The coastal regions and inlets usually freeze at the beginning of December, and the open central area freezes in January or February; the average ice thickness is 20–23 inches, with a maximum of 35–39 inches. The central part of the lake opens in late March or early April and the northern part not until the beginning of May. The temperature of the bottom layers varies from 35.5" to 36.5" F (2° to 2.5" C) in the winter and from 39" to 41° F (4° to 5° C) in the summer. In August the mean temperature of the surface is about 61° F (16" C), with a maximum of 77" F (25" C).

The water of Lake Ladoga is yellow brown in colour. Its transparency averages 15 feet in the centre, 6.5 to eight feet near the western shore, three to 6.5 feet near the eastern shore, and one to three feet in the estuarine areas. The greatest transparency east of Valaam Island is from 26 to 33 feet. Lake Ladoga's water is fresh, with an average mineralization of 56 milligrams (0.002 ounce) of calcium hydrocarbonate per litre. Its dissolved oxygen content is 14 to 15 milligrams per litre in winter and in summer from ten to 11 milligrams per litre in the surface layers and from 12 to 13 milligrams per litre in the depths. The lake abounds in fish; of commercial importance are salmon, trout, bull trout, whitefish, pike perch, golden shiner, bass, roach, pickerel, and frostfish.

Water transportation and fishing are the principal commercial uses of Lake Ladoga. The lake is part of the Volga–Baltic water route and of the Baltic–White Sea Waterway system, through which freight is carried, without the need for transshipment, to points within the U.S.S.R. and to Finland, the German Democratic Republic, and other countries. A bypass canal was cut along its southern shore to protect shipping against storms.

During World War II, when Leningrad was under siege from September 1941 to March 1943, Lake Ladoga was the lifeline connecting it with the rest of the country. Supplies and military equipment were brought to the city across the water and ice, and the sick and wounded were evacuated over the same route.

The cities of Priozyorsk, Petrokrepost, and Sortavala are located on its shores. (B.B.Bo.)

La Follette, Robert M.

A congressman, governor, and senator from Wisconsin, Robert Marion La Follette was a prominent leader of the United States Progressive movement. A major critic from the left of five piesidents, La Follette was most famous for his courage and eloquence as a speaker and writer. He championed progressive legislation in Wisconsin and Washington and was the first United States politician to rely heavily on the help of university professors to draft and administer reform laws.

La Follette's progressivism developed slowly. Born on a farm in Primrose, Wisconsin, on June 14, 1855, he did not advocate progressive measures until 1897. In the meantime, as a boy growing up in moderately prosperous rural areas, as a student at the University of Wisconsin (1875–79), as a county district attorney (1880–84) and congressman from southwestern Wisconsin, La Follette developed the personality and style that made him a popular leader. He combined an unusually outgoing personality, which made it natural for him to absorb the ideas and prejudices of his constituents, with an extraordinary flair for zealous oratory. As an eloquent spokesman for popular causes, La Follette exalted his constituents' wishes—even when those wishes ran counter to the desires of party leaders. His principal concerns in his three terms as congressman were economical government and protection for his district's farmers. He married his college sweetheart, Belle Case, on December 31, 1881, after his first year as district attorney.

La Follette, 1906.

Defeated for re-election to Congress in a Democratic landslide of 1890, La Follette returned to Madison to practice law and develop the political organization that within ten years would elect him governor and allow him to dominate Wisconsin politics until his death. His reputation as an enemy of political bosses began in 1891 when he announced that the state Republican boss, Sen. Philetus Sawyer, had offered him a bribe. For the next six years La Follette built a competing Republican faction on the support of other party members (Scandinavians, dairy farmers, young men, disgruntled politicians) with grievances against the dominant "stalwart" faction. His oratorical talents, combined with his natural charm, organizational skill, and driving ambition to become governor made him the leader of his new group of Republicans.

Campaign for governor

In 1897 La Follette began to advocate programs that local-level progressives had popularized during the legislative session a few months earlier. Following their lead, he demanded tax reform, corporation regulation, and political democracy. In particular, he promoted steeper railroad taxes and a direct primary. Elected governor on this platform in 1900, he was re-elected in 1902 and 1904.

As governor he developed new political techniques, which he later took to the Senate. The first, which received national attention as the "Wisconsin Idea," was the use of professors from the University of Wisconsin—57 at one point—to draft bills and administer the state regulatory apparatus created by the new laws. The second innovation was his public reading of the "roll call" in districts in which legislators had opposed his reform proposals.

With these new methods he secured the passage of several progressive laws. Believing that the railroads were the principal subverters of the political process, he persuaded the legislature to tax them on the basis of their property (1903) and to regulate them by commission (1905). The legislature enacted the direct primary in 1903 and state civil service reform in 1905. His appointees to the Tax Commission, given new power by the legislature, equalized tax assessments. Wisconsin's leadership in these areas gave La Follette his reputation as a pioneering progressive.

United States senator

Resigning as governor in 1906, he was elected to the Senate at a time when that institution was widely believed to be a refuge for millionaires. La Follette acquired instant fame as a new type of senator, one who was not controlled by "the interests," and in his first three years there La Follette achieved the passage of laws aimed against the freight rates, labour policies, and financing practices of the railroads.

These laws reflected an emerging ideology that dominated La Follette's Senate activities thereafter. Politics, he believed, was a never-ending struggle between "the people," all men and women in their common roles as consumers and taxpayers, and the "selfish interests" for control of government; law-given privileges allowed "selfish interests" to dominate all facets of American life. He supported labour legislation because unions were battling the same enemies that menaced consumers, and because consumers benefitted directly from improvements in working conditions. He believed, for example, that his most famous achievement, the La Follette Seaman's Act of 1915, would increase the safety of passengers while it also improved working conditions for sailors. Beginning in 1908, with elaborate documentation during debate on the Aldrich–Vreeland Currency Act, La Follette argued that the nation's entire economy was dominated by fewer than 100 men who were, in turn, controlled by the J.P. Morgan and Standard Oil investment banking groups. Thereafter, he shifted his concern from the power of railroads to the power of their "owners," namely the large banks.

In 1909 La Follette founded *La Follette's Weekly,* later a monthly, and, much later called *The Progressive.* The highpoint of his national popularity came in 1909–11 when he emerged as the leader of newly elected and newly converted progressives in Congress. Directing Republican opposition to the tariff, conservation, and railroad policies of Pres. William Howard Taft, La Follette was widely boomed for the presidency in 1912. Most progressives backed La Follette because their first choice, Theodore Roosevelt, had refused to run; later, when Roosevelt entered the race early in 1912, they deserted La Follette. The bitterness of La Follette's attacks on Roosevelt cost him his reputation as a leader and left him an independent figure in the Senate. Although he had backed Woodrow Wilson in 1912 for the presidency, he was disgusted that the new president ignored the ideas of progressive Republicans and shaped most legislation in the Democratic caucus. While applauding the social justice laws, he believed that most of Wilson's regulatory acts—particularly the Federal Reserve Board—constituted government sponsorship of big business.

Anti-war position

Foreign affairs catapulted La Follette back into a leadership position in 1917, this time of the anti-war movement. Since 1910 he had argued that U.S. interventions in the problems of foreign governments were intended to protect the investments of U.S. corporations and to smash revolutions. Now he believed that the U.S. entered World War I in 1917 because U.S. businessmen needed protection for their investments and because Wilson had become isolated from public opinion. Confident that the majority opposed U.S. involvement, La Follette led the campaign for a popular referendum on war in 1916–17. He led the 1917 Senate filibuster against arming U.S. merchant ships and voted against the war declaration. Once war was declared, he opposed the draft, defended the civil liberties of the war's opponents, and insisted that wealthy individuals and corporations pay the costs of a war that mainly benefitted them. Pro-war groups demanded his expulsion from the Senate for treason, but a Senate investigating committee exonerated him. As a martyr to the war hysteria, La Follette once again became a popular hero to millions of Americans.

Believing that the war had given large corporations nearly complete control over the federal government, La Follette concentrated on exposing the most flagrant corruption of the postwar years. His most significant contribution was his major role in publicizing the oil scandals of the Warren Harding administration.

As disillusionment with the war deepened and as labour and farm groups despaired of the conservatism of Democrats and Republicans alike, La Follette was frequently mentioned as a presidential candidate for a third party. Declining the pleas of the Farmer–Labor convention that he run in 1920, La Follette accepted the Progressive Party's nomination in 1924. His 1924 candidacy was supported by several farm groups, by organized labour (particularly the railroad brotherhoods, La Follette's oldest friends in the labour movement), by many old Progressives, by the Socialist Party, and by the Scripps–Howard newspaper chain. In the end La Follette carried only the state of Wisconsin, although he placed second in 11 states, and polled about one-sixth of the national total. He died in office, in Washington D.C., on June 18, 1925.

BIBLIOGRAPHY. The most detailed biography is BELLE CASE LA FOLLETTE and FOLA LA FOLLETTE, *Robert M. La Follette, June 14, 1855–June 18, 1925,* 2 vol. (1953). His *Autobiography* (1913), a campaign document for 1912, reveals his ideology. DAVID P. THELEN, *The Early Life of Robert M. La Follette, 1855–1884* (1966); ROBERT S. MAXWELL, *La Follette and the Rise of the Progressives in Wisconsin* (1956), on the governorship; HERBERT F. MARGULIES, *The Decline of the Progressive Movement in Wisconsin, 1890–1920* (1968), on Wisconsin politics; and KENNETH C. MACKAY, *The Progressive Movement of 1924* (1947), are useful monographs.

(D.P.T.)

La Fontaine, Jean de

The 17th-century poet Jean de La Fontaine is remembered chiefly for his *Fables,* which rank among the greatest masterpieces in French literature. Too wise to suppose that moral truths can ever be simple, he wrote stories that offer no rudimentary illustration of a certain moral but a subtle commentary on it, sometimes amending it and hinting that only the naïve would take it at face value. Thus, what the *Fables* teach is trivial in comparison with what they suggest: a view of life that, although incomplete (for it takes little account of man's metaphysical anguish or his highest aspirations), is mature, profound, and wise. Enjoyed at many different levels, the *Fables* continue to form part of the culture of every Frenchman, from schoolchildren to such men of letters as André Gide, Paul Valéry, and Jean Giraudoux, who have given fresh luster to La Fontaine's reputation in the 20th century.

He was born in 1621, probably on July 8, at Château-Thierry in Champagne into a bourgeois family. There, in 1647, he married an heiress, Marie Héricart, but they separated in 1658. From 1652 to 1671 he held office as an inspector of forests and waterways, an office inherited from his father. It was in Paris, however, that he made his most important contacts and spent his most productive years as a writer. An outstanding feature of his existence was his ability to attract the goodwill of patrons prepared to relieve him of the responsibility of providing for his livelihood. In 1657 he became one of the protégés of Nicolas Fouquet, the wealthy superintendent of finance. From 1664 to 1672 he served as gentleman-in-waiting to the dowager duchess of Orléans in Luxembourg. For 20 years, from 1673, he was a member of the household of Mme de La Sablière, whose salon was a celebrated meeting place of scholars, philosophers, and writers. In 1683 he was elected to the Académie Française after some opposition by the King to his unconventional and irreligious character.

The Fables. La Fontaine did not invent the basic material of his ***Fables;*** he took it chiefly from the Aesopic tradition and, in the case of the "second collection," from the Oriental. He enriched immeasurably the simple stories that earlier fabulists had in general been content to tell perfunctorily, subordinating them to their narrowly didactic intention. He contrived delightful miniature comedies and dramas, excelling in the rapid characterization of his actors, sometimes by deft sketches of their appearance or indications of their gestures and always by the expressive discourse he invented for them. In settings usually rustic, he evoked the perennial charm of the countryside. Within the compass of about 240 poems, the range and the diversity of subject and of treatment are astonishing. Often he held up the mirror to the social hierarchy of his day. Intermittently he seems inspired to satire; but, sharp though his thrusts are, he had not enough of the true satirist's indignation to press them home. The ***Fables*** occasionally reflect contemporary political issues and intellectual preoccupations. Some of them, fables only in name, are really elegies, idylls, epistles, or poetic meditations. But his chief and most comprehensive theme remains that of the traditional fable: the fundamental, everyday moral experience of mankind throughout the ages, exhibited in a profusion of typical characters, emotions, attitudes, and situations.

Diverse themes of the ***Fables***

Countless critics have listed and classified the morals of La Fontaine's ***Fables*** and have correctly concluded that they amount simply to an epitome of more or less proverbial wisdom, generally prudential but tinged in the "second collection" with a more genial epicureanism. Simple countryfolk and heroes of Greek mythology and legend, as well as familiar animals of the fable, all play their parts in this comedy; and the poetic resonance of the ***Fables*** owes much to these actors who, belonging to no century and to every century, speak with timeless voices.

What disconcerts many non-French readers and critics is that in the ***Fables*** profundity is expressed lightly. La Fontaine's animal characters illustrate the point. They are serious representations of human types, so presented as to hint that human nature and animal nature have much in common. But they are also creatures of fantasy, bearing only a distant resemblance to the animals the naturalist observes; and they are amusing because the poet skillfully exploits the incongruities between the animal and the human elements they embody. Moreover—as in his ***Contes,*** but with far more delicate and lyrical modulations—the voice of La Fontaine himself can constantly be heard, always controlled and discreet, even when most charged with emotion. Its tones change swiftly, almost imperceptibly: they are in turn ironical, impertinent, brusque, laconic, eloquent, compassionate, melancholy, or reflective. But the predominant note is that of ***la gaietk,*** which, as he says in the preface to the "first collection," he deliberately sought to introduce into his ***Fables;*** and "Gaiety," he explains, is not that which provokes laughter but is "a certain charm . . . that can be given to any kind of subject, even the most serious." No one reads the ***Fables*** rightly who does not read them with a smile—not only of amusement but also of complicity with the poet in the understanding of the human comedy and in the enjoyment of his art.

Verse and metre

To the grace, ease, and delicate perfection of the best of the ***Fables,*** even close textual commentary cannot hope to do full justice. They represent the quintessence of a century of experiments in prosody and poetic diction in France. The great majority of the ***Fables*** are composed of lines of varying metre and, from the unpredictable interplay of their rhymes and of their changing rhythms, La Fontaine derived the most exquisite and diverse effects of tone and movement. His vocabulary harmonizes widely different elements: the archaic, the precious and the burlesque, the refined, the familiar and the rustic, the language of professions and trades and the language of philosophy and mythology. But for all this richness, economy and understatement are the chief characteristics of his style, and its full appreciation calls for keener sensitivity to the overtones of 17th-century French than most foreign readers can hope to possess.

Miscellaneous writings. La Fontaine's many miscellaneous writings include much occasional verse in a great variety of poetic forms and dramatic or pseudodramatic pieces such as his first published work, ***L'Eunuque*** (1654), and ***Climène*** (1671), as well as poems on subjects as different as ***Adonis*** (1658, revised 1669), ***La Captivitk de saint Malc*** (1673), and ***Le Quinquina*** (1682). All these are, at best, works of uneven quality. In relation to the perfection of the ***Fables,*** they are no more than poetic exercises or experiments. The exception is the leisurely narrative of ***Les Amours de Psiché et de Cupidon*** (1669), notable for the lucid elegance of its prose, its skillful blend of delicate feeling and witty banter, and some sly studies of feminine psychology.

The Contes. Like his miscellaneous works, La Fontaine's ***Contes*** ("Short Tales") considerably exceed the ***Fables*** in bulk. The first of them was published in 1664, the last posthumously. He borrowed them mostly from Italian sources, in particular Boccaccio, but he preserved none of the 14th-century poet's rich sense of reality. The essence of nearly all his ***Contes*** lies in their licentiousness, which is not presented with frank Rabelaisian verve but is transparently and flippantly disguised. Characters and situations are not meant to be taken seriously; they are meant to amuse and are too monotonous to amuse for long. The ***Contes*** are the work far less of a poet than of an ingenious stylist and versifier. The accent of La Fontaine the narrator enlivens the story with playfully capricious comments, explanations, and digressions.

Personality and reputation. Though he never secured the favour of Louis XIV, La Fontaine had many well-wishers close to the throne and among the nobility. He moved among churchmen, doctors, artists, musicians, and actors. But it was literary circles that he especially frequented. Legend has exaggerated the closeness of his ties with Molière, Nicholas Boileau, and Jean Racine; but he certainly numbered them among his friends and acquaintances, as well as La Rochefoucauld, Mme de Sévigné, Mme de La Fayette, and many less well-remembered writers.

Friendships with Molière, Boileau, and Racine

The true nature of the man remains enigmatic. He was intensely and naïvely selfish, unconventional in behaviour, and impatient of all constraint; yet he charmed countless friends—perhaps by a naturalness of manner and a sincerity in social relationships that were rare in his age—and made apparently only one enemy (a fellow academician, Antoine Furetière). He was a parasite without servility, a sycophant without baseness, a shrewd schemer who was also a blunderer, and a sinner whose errors were, as one close to him observed, "full of wisdom." He was accommodating, sometimes to the detriment of proper self-respect; but he was certainly not the lazy, absent-minded simpleton that superficial observers took him for. The quantity and the quality of his work show that this legendary description of him cannot be accurate: for at least 40 years La Fontaine, in spite of his apparent aimlessness, was an ambitious and diligent literary craftsman of subtle intelligence and meticulous conscientiousness.

He was an assiduous and discriminating reader whose works abound in judicious imitations of both the matter and the manner of his favourite authors. He was influenced by so many 16th- and 17-century French writers that it is almost invidious to mention only **François Rabelais**, **Clément Marot**, Franfois de Malherbe, Honor6 **d'Urfe**, and Vincent Voiture. The authors of classical antiquity that he knew best were Homer, Plato, Plutarch —these he almost certainly read in translation—Terence, Virgil, Horace, and Ovid. Boccaccio, **Machiavelli**, Ariosto, and Tasso were his favourites among the Italians. La Fontaine was no romantic; his work derives its substance and its savour less from his experience of life than from this rich and complex literary heritage, affectionately received and patiently exploited. He died in Paris on April 13, 1695.

MAJOR WORKS

Les Amours de Psiché et de Cupidon (1669; *The Loves of Cupid and Psyche.* 1744); *Contes et nouvelles en vers* (the first published 1664, the last posthumously; *Tales and Novels in Verse,* 2 vol., 1884); *Fables choisies, mises en vers,* in verse ("premier recueil," first six books, 1668; "second recueil," the next five, 1678–79; the twelfth book 1692–94); *La Fontaine's Fables,* verse trans. by Sir Edward Marsh, 1952; and *The Fables of La Fontaine,* 1954, abridged Eng. ed., *Selected Fables,* 1955, free trans. by M. Moore.

BIBLIOGRAPHY

Editions and translations: The standard edition of the complete works is still that of HENRI REGNIER, *Oeuvres,* 11 vol. (1883–92); the best edition of the *Fables* is by FERDINAND GOHIN, 2 vol. (1934); and of the *Contes* by PIERRE CLARAC, 2 vol. (1933); the best edition of the miscellaneous works (*i.e.*, all the works except the *Fables* and the *Contes)* is *Oeuvres diverses* by PIERRE CLARAC (1942 and 1958). *La Fontaine's Fables* were translated into English verse by SIR EDWARD MARSH (1931; Everyman's Library, 1952); also by the U.S. poet MARIANNE MOORE (1954; new ed., 1964), whose versions may, however, seem to some readers to be adaptations rather than translations of the original text.

Biography and .criticism: All of the studies listed below, with the exception of John C. Lapp's, are written in French. LOUIS ROCHE, *La Vie de Jean de La Fontaine* (1913); GUSTAVE MICHAUT, *La Forttaine,* 2 vol. (1913–14), mainly biographical; PIERRE CLARAC, *La Fontaine* (1947; rev. ed., 1959), a basic reference book; ODETTE DE MOURGUES, *O Muse, fuyante proie: essai sur la poésie de La Fontaine* (1962); RENEE KOHN, *Le Goût de La Fontaine* (1962); and J.-P. COLLINET, *Le Monde littéraire de La Fontaine* (1970), three general appraisals of La Fontaine's works; FERDINAND GOHIN, *L'Art de La Fontaine dans ses Fables* (1929); and JOHN C. LAPP, *The Esthetics of Negligence: La Fontaine's Contes* (1971), deal more specifically with the *Fables* and the *Contes.*

Lagomorpha

The terrestrial mammals of the order Lagomorpha include the relatively well known rabbits and hares and also the less frequently encountered pikas, or mouse-hares. Rabbits and hares characteristically have long ears, a short tail, and strong hindlimbs that provide a bounding locomotion. In contrast, pikas have shorter, rounded ears, no external tail, and less well developed hindlimbs associated with scampering locomotion.

GENERAL FEATURES

Wild lagomorphs are small to small-medium sized, ranging from the smallest pikas, about 150 millimetres (about 6 inches) in length and 100 grams (3% ounces) in weight, to the largest hares, 700 millimetres (about 28 inches) and 4.5 kilograms (10 pounds). Wild rabbits range between pikas and hares in size, while some varieties of domestic rabbit may reach up to seven kilograms in weight.

Economic importance of lagomorphs

Nearly worldwide in distribution, lagomorphs are absent only from most of Southeast Asian islands, Australia, New Zealand, Madagascar, southern South America, and Antarctica. Man has introduced rabbits and hares into areas outside their original ranges for purposes of sport and to provide a readily available food supply. The natural range of the Old World or European rabbit, *Oryctolagus cuniculus,* appears to have been southwestern Europe and North Africa, but in Roman times this species was often introduced to islands, where it flourished, and spread north and east, partly following man's agricultural activities, reaching Britain in Norman times. More recently *Oryctolagus* was introduced for sport and food into New Zealand and Australia, where the absence of native predators and other factors soon led to its becoming an agricultural pest and a threat to some of the native fauna. In North America several species of the cottontail rabbit, *Sylvilagus,* have shown an increase in abundance and a broadening of range in areas disturbed by man.

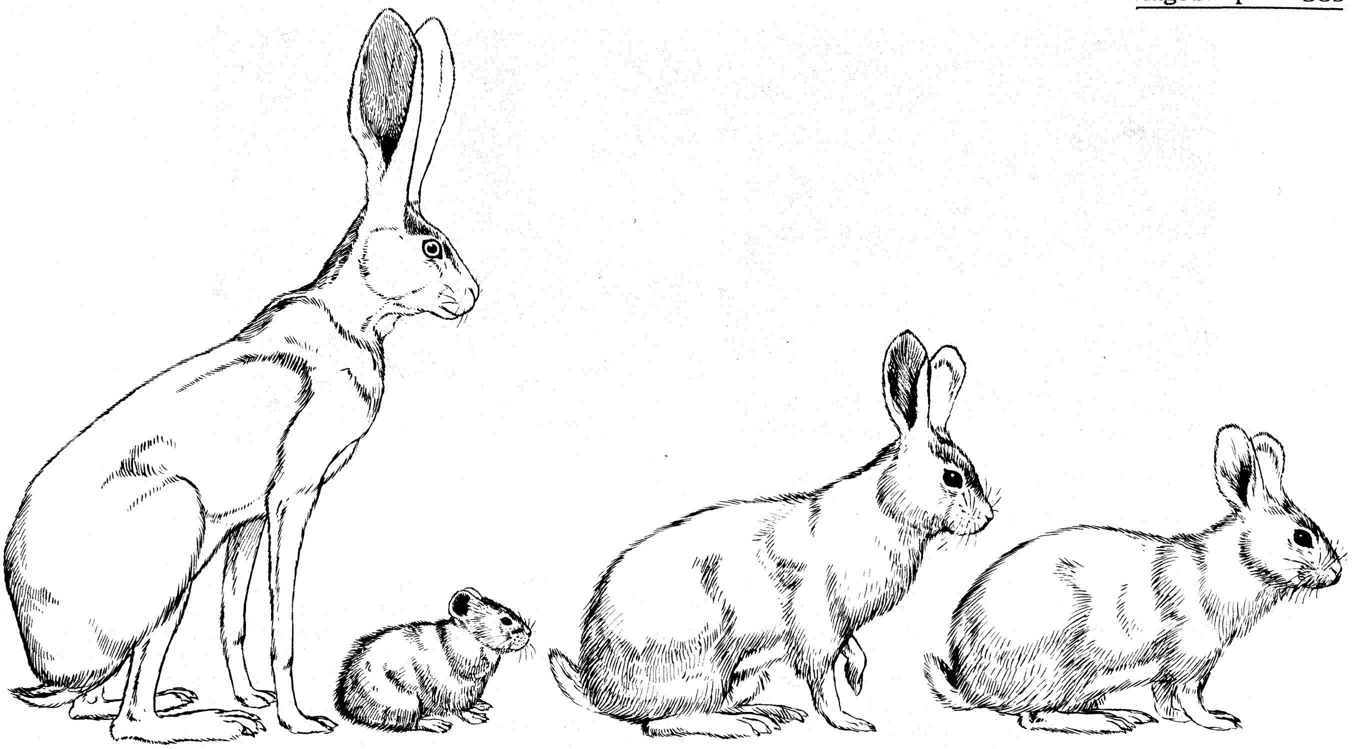
Wild lagomorphs are popular with hunters for sport as well as for food and fur. Domestic rabbits, all descendants of the Old World rabbit, O. *cuniculus,* are raised for meat and skins, the latter of which are used both as pelts and for making felt. In addition, these rabbits are important laboratory animals for biological and medical research. They make good and relatively undemanding pets. Their attractive appearance and quiet manners have made them favourite characters with children's storytellers. On the other hand, wild rabbits and hares locally may become pests, depleting vegetation available to domestic grazers or damaging young trees and orchards, especially in winter. The problem becomes especially acute in areas where man has removed the natural predators of lagomorphs. Attempts have been made to control Old World rabbit populations in western Europe and Australia by introducing the virus disease **myxomatosis**, which exists naturally in populations of certain South American rabbits of the genus *Sylvilagus,* but in some areas the rabbits have developed a certain amount of resistance to the disease. Use of this virus in controlling rabbit numbers has been fought by some humane organizations because of the distressing symptoms of the disease. Pikas, usually found in areas remote from human activity, have little economic importance for man.

NATURAL HISTORY

Rabbits and hares occupy a wide variety of habitats, including grassland, desert, forest, marsh, brushland, and tundra. They are found in mountains up to 4,900 metres above sea level. Rabbits frequent areas where cover is readily accessible and do not venture far from it. Some rabbits dig their own burrows; others use burrows dug by other mammals. Although most rabbits are solitary, some live in pairs. The Old World rabbit, *O. cuniculus*, usually is gregarious, forming breeding colonies called warrens, with extensive burrow systems. The Mexican volcano rabbit, *Romerolagus,* maintains runways through dense vegetation. Although rabbits are typically terrestrial, two North American species of *Sylvilagus,* the marsh rabbit and the swamp rabbit, take readily to water when necessary. Hares tend to live in more open areas than do rabbits. They are solitary and do not use burrows but rest and take shelter in shallow depressions made in soil or vegetation. Pikas occur in northern steppes, semideserts, some forests and scrub thickets of Asia, and in rocky terrain, especially on rock debris on slopes; they range in mountainous areas to 6,000 metres in the southeastern U.S.S.R., northern and central Asia, and western North America. Steppe-dwelling pikas construct and inhabit burrows in flat areas. Rock-dwelling pikas usually seek shelter among rocks and boulders. Some pikas are colonial, whereas others are solitary and may exhibit some degree of territorial behaviour.

Vocalizations

Rabbits and hares are customarily nonvocal, making cries or screams only when frightened or injured. One rabbit, the South African red "hare" *Pronolagus,* is known to utter a warning call. Pikas are highly vocal, having a whistle or bark and a chattering call, reflected in



antelope jackrabbit (*Lepus* alleni) pika (Ochotona princeps) European rabbit (*Oryctolagus cuniculus*) eastern cottontail rabbit (*Sylvilagus floridanus*)

Diversity among lagomorphs.

such common names as whistling hare and piping hare. The voice is used in giving alarm signals and in maintaining territorial boundaries. Mountain hikers or climbers frequently hear their calls and may see these attractive little creatures sunning themselves on rocks and going about their daily activities.

Rabbits and hares are active mainly from dusk to after dawn, whereas most pikas are active during the day. All lagomorphs are plant eaters, grasses and soft vegetation being their dietary staples, but they may also eat twigs and bark, especially in winter. Arctic hares are known to break through crusted snow with their forelimbs to feed on the buried vegetation. Rabbits and hares are not known to store food, but pikas store and cure piles of vegetation for use during the winter. Some pikas cut grasses, carry them to the pile, and allow the vegetation to dry before adding more, whereas other pikas actually turn the contents of a pile to aid in the curing. Pikas that live among rocks first pile the vegetation in the sun and open air before moving it under the shelter of rocks for the winter. Steppe-dwelling pikas pile their hay in the open. Other pikas may store hay not in piles in the open but in crevices in trees, stumps, and among rocks. Some of the Asian pikas unwittingly supply hay for domestic livestock during the winter.

Some lagomorphs regularly reingest fecal pellets (coprophagy). Two kinds of pellets are produced: dry and hard, and soft and moist. The latter kind, which appear to contain vitamins and metabolic products, are eaten, often directly from the anus. The nutritional effect of this practice has been compared to that of rumination among cows.

Rabbits and hares differ from one another in the condition of their young at birth. Young rabbits are born and cared for in a nest; they are naked, blind, and relatively helpless at birth. Hares are born in the open; they are furred, have open eyes, and can run shortly after birth. Confusion of the terms "rabbit" and "hare" in common parlance is shown by such popular names as "jack rabbit" for a hare and "Belgian hare" for a variety of domestic rabbit.

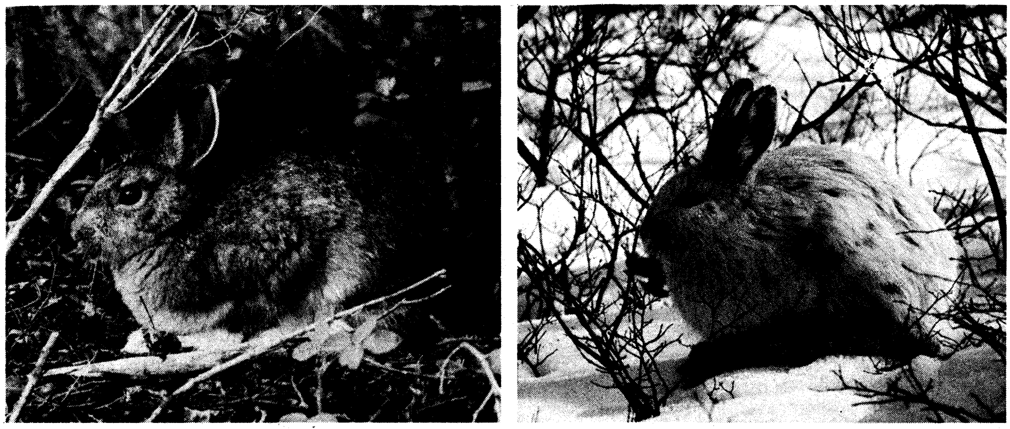
Reproductive potential

The reproductive abilities of rabbits are proverbial. Rabbits and hares usually produce several litters during each breeding season, two or three litters being common among hares and three to six among rabbits. The gestation period ranges from about 28 days in rabbits to 47 in hares, and litter size is usually between two and eight. A female cottontail rabbit from an early spring litter can produce offspring by the end of the summer at age ten weeks. In contrast to most mammals, female rabbits and hares are usually larger than males. Reproductive cycles of pikas are less well known than those of rabbits and hares. Their breeding season occurs in late spring and summer, with a gestation period of approximately 30 days. Litter size normally ranges from two to six, and two or three litters may be born each year. In some pikas, the newborn young are only lightly furred, have eyes and ears closed, but can move about after about eight days.

Lagomorphs, especially hares and rabbits, are important elements in many food chains. They are preyed upon by a variety of carnivores, both mammals and birds, who rely upon them as dietary staples. Wolves, foxes, bobcats, weasels, predatory hawks, and owls all take their toll. More northerly species of rabbits and hares frequently exhibit cyclic fluctuations in numbers, which are reflected in the cycles of the carnivores dependent upon them. The snowshoe hare–snowy owl cycle is one of the prominent ones (see PERIODICITY, BIOLOGICAL). Pikas are preyed upon by various carnivores, among which weasels and birds of prey are probably most important.

Externally most rabbits and hares are not dissimilar from one another, the main variation occurring in length of ear and strength of hindlimb. The coat is usually brownish or reddish brown above and lighter to white below. An exception to this coloration is found in the Arctic hare, in which the winter coat is pure white with only the eartips dark. In more northerly representatives of the Arctic hare, individuals retain this colour pattern all year, whereas more southerly forms of it may become grayish or buff-coloured. In other northern hares, the varying hare (Lepus *timidus*) of Eurasia and the snowshoe hare (L. *americanus*) of North America, the winter coat is white and the summer coat brown. Some varying hares in Ireland and snowshoe hares from the Pacific Coast do not become white in winter. The most unusual coloration in a modern rabbit occurs in the Sumatran rabbit ***Nesolagus***, which has brown stripes on its buff-gray pelage and a bright red rump and tail. Pikas are usually brownish to reddish above and somewhat lighter below.

Lagomorphs illustrate adaptation to particular habitats in an interesting gradational series of features for detection of, and escape from, enemies. At one end of the series



The summer fur (left) of the snowshoe hare (Lepus *americanus*) blends with the browns of woodland and prairie. A mottled effect, created by white hairs gradually replacing the brown, is similar to patches of new snow, while the white winter coat (right) is completely camouflaged in a snowy landscape.
National Audubon Society, (left) Charlie J. Ott, (right) Leonard Lee Rue

are the long-eared, wary, and alert hares, inhabitants of open country, which detect enemies at considerable distance and rely for escape on their strengthened hindlimbs and bounding locomotion that takes them up to 80 kilometres per hour. Rabbits, shorter eared and with weaker hindlimbs, do not react to such distant threats and are scamperers or bounders who do not venture far from cover. They are quick over short distances but lack the endurance of hares. With still shorter ears and relatively weaker hindlimbs, pikas live in areas in which a quick scamper takes them the short distance that usually separates them from secure cover.

FORM AND FUNCTION

Dentition

Lagomorphs are well adapted to a herbivorous diet. Like rodents, they have well-developed incisors that grow continuously from the roots, while they are worn down at the cutting edges. These teeth are extremely effective for severing plant stems and for gnawing on bark. The very mobile lips each consist of two lobes, which meet behind the chisel-like incisors when the mouth is closed. There are no canine teeth, a gap (diastema) showing where they might have been. Cheek teeth farther back in the jaw are also ever growing, wearing away as they grind abrasive vegetation. The upper tooth rows are more widely separated than the lower rows, and chewing is done with a transverse movement. The chewing muscles of the jaws, though strong, are less well developed than in rodents.

Vegetation passes through the long small intestine, which has a spiral valve (like a wood screw), providing a much greater surface area for digestion of food and absorption of nutriment. A large pouch, or cecum, located at the point of attachment of the large intestine contains bacteria that aid digestion and that produce the nutritional soft fecal pellets.

Skeletal adaptations for speed and agility are evident and are discussed as taxonomic characters in the *Annotated Classifications* section, below. The bones of the hindlimb are fused where they move against the anklebone (calcaneum), affording strength and leverage employed in bounding or scampering locomotion. Lagomorphs move about as if they walked on their toes (digitigrade locomotion). There are five digits on the forefoot and four or five on the hindfoot.

EVOLUTION, PALEONTOLOGY, AND CLASSIFICATION

The order Lagomorpha appears to have originated in northern Asia, probably by the end of the Paleocene (about 55,000,000 years ago), and has been relatively stable morphologically throughout the approximately 40,000,000 years since the end of the Eocene, when its fossil record first becomes well documented. Lagomorphs seem to have established early in their history the patterns of dental and skeletal development that were to change, for the most part, only by gradual advances in the basic pattern. Within the order several trends can be observed from more primitive to more advanced lagomorphs: development of ever-growing cheek teeth, simplification of the pattern of the occlusal surfaces of the upper cheek teeth, and shortening of the shaft of the lower incisor where it passes back into the jaw. When dealing with fossil forms, often known only from fragments of jaws and teeth, the most useful characters that differentiate taxa are ordinarily found in the structure of the anterior two upper, and anterior lower, premolars. Presence or absence of the last upper molar may also be important, as may the pattern of the upper cheek teeth. When preserved in fossils, structure of palate and of lower jaw also provide characters that assist in determining affinities.

Evolutionary trends

The family of rabbits and hares (Leporidae) entered North America by the end of the Eocene and underwent most of its Middle Tertiary development there. By the Pliocene (about 7,000,000 years ago) it had become reestablished in Asia and had moved also into Europe. The leporids now extend throughout those ranges and down to the tip of South Africa and as far south as northern Argentina in South America.

The pika family (Ochotonidae) spread from Asia to Europe, where they developed into a number of types in the Middle Tertiary. One of these lines persisted until the late Pleistocene or early modern times (about 1,000,000 years ago) on Corsica and Sardinia. Other ochotonid branches reached Africa and North America in the Middle Tertiary. The extant genus *Ochotona* appeared in Asia in the Pliocene and spread from there, reaching western Europe and eastern North America in the Pleistocene. The current range of the genus represents a considerable reduction from that during the Pleistocene.

Distinguishing taxonomic features. Within the order Lagomorpha living members of its two extant families are clearly separable on morphological grounds, the differences being in skull, jaw, and dental structures, as well as in postcranial morphology.

Morphological trends in the rabbits and hares include increase in arching of the skull, correlated with the development of bounding locomotion and of a relatively upright posture of the head; reduction in the ability to perform lateral movements, caused partly by fusion of bones and partly by modifications related to specialization for anteroposterior movements; strengthening of the hindlimbs and pelvic girdle; and elongation of the limbs distally. Pikas lack these skeletal modifications and are adapted rather for a scampering locomotion.

Annotated classification. In older classifications lagomorphs were usually placed in the order Rodentia. Both rodents and lagomorphs are gliriform mammals; that is, they have enlarged, ever-growing incisor teeth that function as effective tools for gnawing. Under this scheme, the lagomorphs were the suborder Duplicidentata, and the true rodents the suborder Simplicidentata. Early workers, however, recognized many features separating these suborders. For one, there are two pairs of upper incisors in lagomorphs (thus the name Duplicidentata) as opposed to one pair of upper incisors in rodents (Simplicidentata). It is now known that lagomorphs and rodents have long separate histories and that even their earliest representatives did not closely resemble one another. Accordingly, it is more accurate and currently generally accepted to classify the two groups as distinct orders, Lagomorpha and Rodentia. The following classification is the one in general use.

ORDER LAGOMORPHA

Small to medium-sized mammals with two pairs of upper incisor teeth, one pair large, ever-growing, and grooved, in front of a pair of small, peglike incisors, and one pair ever-growing lower incisors. In skull the jawbone, or maxilla, pierced or with open lacework laterally; palatal bone with large, deep-cut openings and relatively short bridge. Of muscles used in chewing, masseter muscles not greatly enlarged, temporalis muscle reduced, pterygoid muscles well developed. Twelve extant and approximately 35 known extinct genera are included in three families, one extinct (†).

†**Family** Eurymylidae

Late Paleocene and (?) Eocene. This extinct family of two genera known only from northern Asia may or may not be closely allied to the other two families of lagomorph. Several anatomical features, such as the presence of only two pairs of upper premolars, show that it was not directly ancestral to later lagomorphs, but it may have been near a group from which later lagomorphs originated.

Family Leporidae (rabbits and hares)

Late Eocene to Recent. Almost worldwide. Distinguished by elongated ears, hindlegs much longer and stronger than forelimbs, often greatly strengthened, and short external tail. Most anterior premolars unlike others in pattern, the following two premolars similar; usually three upper and three lower molars in each jaw, reduced to two upper molars in *Pentalagus;* shafts of upper cheek teeth extend upward into socket in bony capsule (orbit) surrounding eye. Skull with jawbone having open lacework of bone laterally; bony process present over orbit. The palate has one pair of large deep-cut holes; bony palate with longer maxillary and shorter palatine components. Tendency toward arching of skull in profile, related to increasingly upright posture of head. Clavicle rudimentary. Strong, well-developed lumbar region of back, and strong pelvic girdle for articulation with hindlimb and attachment of limb muscles. Five digits on forefoot and on hindfoot.

The subfamily Palaeolaginae is an extinct group that includes primitive Old and New World forms. Descendants of the Palaeolaginae were the extinct Archaeolaginae, including most North American Middle Tertiary forms as well as a group that reached Eurasia in the Pliocene. The most advanced leporids are in the subfamily Leporinae, which includes all living leporids (11 genera), including the American *Sylvilagus*, the Old World *Oryctolagus, Lepus* of the Northern Hemisphere, *Romerolagus* of central Mexico, *Pentalagus* of the Ryukyu Islands south of Japan, *Bunolagus* and *Pronolagus* of South Africa. Other leporids showing some relatively primitive characters are *Nesolagus* of Sumatra and *Brachylagus* of the western United States. The subfamilial divisions are based partly on the pattern of the most anterior upper and lower premolars, which seem to be valid indicators of leporid relationships. Size 25 to 70 centimetres.

Family Ochotonidae (pikas)

Oligocene to Recent. Asia and western North America. Distinguished by short, rounded ears, hindlegs slightly longer than forelimbs, no external tail. Three upper premolars exhibit three different patterns; two upper and three lower molars in each jaw in modern forms, ranges from three upper and lower molars in each jaw to two in each jaw in fossil forms. Shafts of upper teeth curve outward into arch of the zygomatic bone beneath eye socket. Skull with single large opening in each jawbone, other holes present in some fossil forms. Bony process over orbit absent in modern ochotonids but present in some fossils. On palate one or two pairs of deep-cut holes; bony palate with larger palatine component and smaller maxillary component. Skull typically more flattened than in leporids. Well-developed clavicle. Five digits on forefoot and four on hindfoot. One extant genus, *Ochotona,* and 14 or 15 extinct genera. Size 15 to 28.5 centimetres.

Critical appraisal. Perhaps the most important unanswered question in lagomorph classification is that of affinities to other mammals. Part of the difficulty is that the fossil record from the Early Tertiary of Asia is incomplete for large parts of the Paleocene and Eocene. The Eurymylidae, known from some Paleocene and possibly Eocene deposits in Asia, have some characters similar to those later lagomorphs but other characters showing that they were not the direct ancestors of later forms. Other fossil mammals now known from the Paleocene of Asia may represent forms related to eurymylids. The evidence is incomplete, but perhaps eurymylids and these possibly allied forms were in a generally ancestral position to leporids and ochotonids. The wider affinities of this possibly ancestral group to other mammals are not yet clear. No transitional forms are known between the eurymylids and later lagomorphs, which had attained their distinctive characters by the late Eocene. Earlier attempts to arrive at the solution to the problem of lagomorph affinities often emphasized similarities between various primitive herbivorous animals, such as the condylarths, and primitive lagomorphs. These similarities, however, are probably due to the presence, in both groups, of morphological characters common to primitive mammals in general.

Relationships with other mammals

A further point causing some difficulty in studies on fossil leporids and ochotonids is the assignment of various primitive forms to one family or the other. The problem is especially acute when the fossil record is based only on a few teeth or jaw fragments. Morphologically these primitive forms seem to be intermediate between the two families.

Some differences of opinion exist in regard to the subfamilial classification of leporids. Some students of these animals have taken the step of subdividing leporids into several families. Other problems in the classification of modern leporids are matters of specific assignment of various populations. A sound subfamilial arrangement for the ochotonids has not yet been established.

Lagoons

Lagoons are areas of relatively shallow water situated in a coastal environment and having access to the sea but separated from the open marine conditions by a barrier. The barrier may be either a sandy or shingly wave-built feature, or it may be a coral reef. Thus, there are two main types of lagoons, namely, elongated or irregular stretches of water that lie between coastal barrier islands and the shoreline, and circular or irregular stretches of water surrounded by coral atoll reefs or protected by barrier coral reefs from direct wave action. Lagoons of the first type are characterized by quiet water conditions, fine grained sedimentation, and, frequently, brackish salt marshes. Water movements are related to discharge of river flow through the lagoon and to the regular influx and egress of tidal waters through the inlets that normally separate the barrier islands. Lagoons of the second type are best exemplified by the roughly circular quiet waters that are surrounded by coral atoll reefs. Lagoon depths are maintained at a moderate level by sedimentation, and

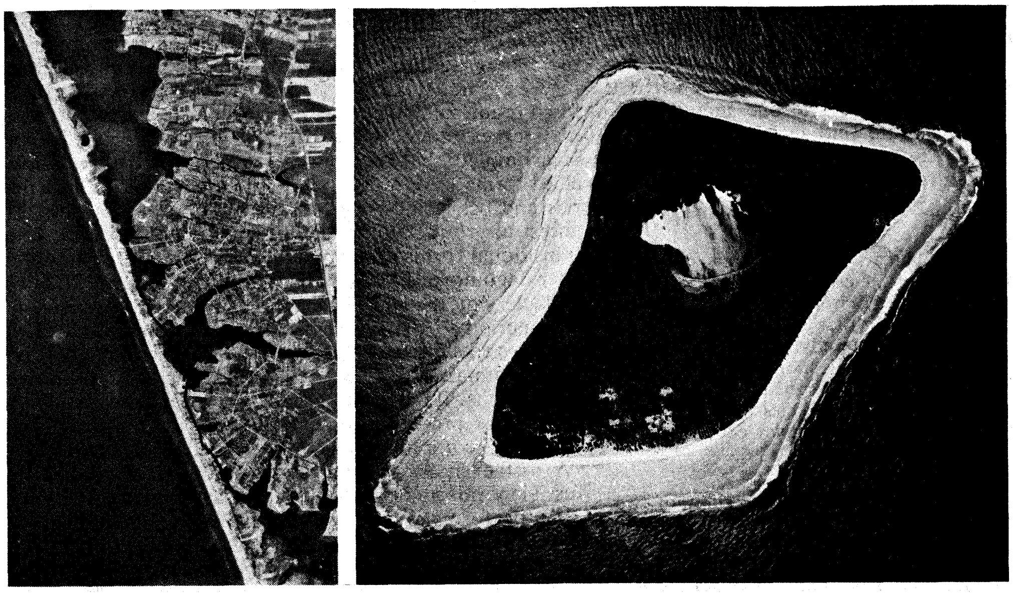

Figure 1: Two *main* types of lagoon.

this compensates for the subsidence that commonly attends reef formation (see CORAL ISLANDS, CORAL REEFS, AND ATOLLS). Because the reef is an organic structure, the lagoonal sediments contain much calcareous material. The sheltered waters support a distinctive flora and fauna. Lagoons also can occur in lakes, where transport of sediment from deltas or other sources creates barrier bars.

Coastal lagoons

Coastal lagoons are widely distributed throughout the world and have been estimated to constitute about 13 percent of the total world coastline. Lagoons are more common on coasts with moderate to low tidal ranges; for example, they occur widely on low coasts of the southern Baltic, southeast North Sea, Black Sea, Caspian Sea, and Mediterranean Sea, and of the southeastern United States, and the Gulf of Mexico. Lagoon coasts also occur along the southeastern coast of South America; the east coast of Madagascar; northeastern U.S.S.R.; Japan; and isolated parts of Africa, India, Australia, and New Zealand.

Lagoons are generally characteristic of coasts of low or moderate energy, occurring especially on the east coasts of continents where the swells are less violent and in high latitudes where offshore ice provides some protection. They also are associated with low coasts and rarely occur where high cliffs form the coast. They can form only where there is abundant sediment for construction of the protective barrier islands. Too much sediment from the mainland, however, can lead to delta formation rather than lagoons, although lagoons frequently occur along the outer delta margin and between delta distributaries (see also RIVER DELTAS).

Coral lagoons

Coral lagoons are restricted to tropical open seas that provide the conditions necessary for coral growth: the water temperature must equal or exceed 20" C (68" F), and it must be clear, moving, and not deeper than seven metres. Coral lagoons occur widely in the western Pacific, in parts of the Indian Ocean, and in isolated places in the Caribbean, mainly within 25° latitude of the Equator. Coral lagoons are of great importance to many island communities in the Pacific, particularly where they provide the only quiet water for use as harbours, although the passage through the reef into the lagoon is often perilous.

The clarity of the water of the coral lagoon contrasts with the considerable amount of fine sediment in barrier island lagoon water. The extensive growth of salt marsh in such lagoons often detracts from their use as harbours, but where the water is deep enough they provide sheltered anchorage and good conditions for small-boat sailing in quiet water (see also CORAL ISLANDS, CORAL REEFS, AND ATOLLS; SWAMPS, MARSHES, AND BOGS).

THE NATURE OF THE LAGOON ENVIRONMENT

Dimensions. Coral lagoon dimensions range from small atolls to those so wide that the coral reefs on the far side cannot be seen across the lagoon. Atoll widths range from about 2.5 kilometres to nearly 100 km, but the mean value is about 20 km. Depths rarely exceed 60 metres and many are shallower, usually less than 20 m deep. The lagoon of Mayotte Island in the Comoro Archipelago in the Indian Ocean attains a maximum depth of about 92 m but generally is shallower, and it is about 16 km in width at its widest point; this lagoon lies behind a barrier reef.

Barrier island lagoons are typically elongated, although irregular ones may occur where river estuaries are flooded behind the barriers. This pattern occurs on the east coast of the U.S., where lagoons extend intermittently for nearly 1,500 km along the coast. The Gippsland Lakes in Victoria exemplify a complex lagoon system formed behind the 90-mile beach (Figure 2). Elongated lagoons up to 64 km (40 miles) long lie behind the beach barrier, and larger lagoons, such as Lake Wellington, which is 50 km wide, lie behind the northern end of the barrier. Postglacial subsidence has flooded the lowland in this area. The lagoons are shallow; Lake Wellington is less than 3.5 m deep and much of King Lake is less than 6 m deep. Scour holes as deep as 16.5 m do occur, however. The elongated lagoon behind the barrier is only 1 to 1% m deep, typical of barrier island lagoons.

Current velocities

Water circulation. The degree of water circulation depends on the width of the tidal inlets, the tidal range, and on the amount of runoff from adjacent land areas. Maximum velocities are attained at the points where the water passes through the barriers. In the entrance to the Gippsland lagoons, tidal currents reach three knots, but river floods that escape to the sea can raise the velocity to seven knots. Water may be blown into the lagoon by strong winds, which raise its level and cause an outflowing current when the wind drops. Seiches can be created in this way. Small waves can be generated within lagoons when the wind blows along their maximum dimension. These may reach 1% m (4 ft) in height and 1½ to 9 m in length in the Gippsland lagoons. In coral atoll lagoons there is little or no runoff; and seawater moves in and out through the passes, where tidal currents reach their maxima. Velocities of 10 to 12 knots have been recorded in the Hao Channel of the Tuamotu Island.

Water temperature and salinity. In the Mayotte Lagoon the water has the same properties as the upper layers of the open sea; the salinity is close to 35 parts per 1,000 (‰), and the temperature varies between 27° and 24° C. This is typical of coral lagoons, but the temperature

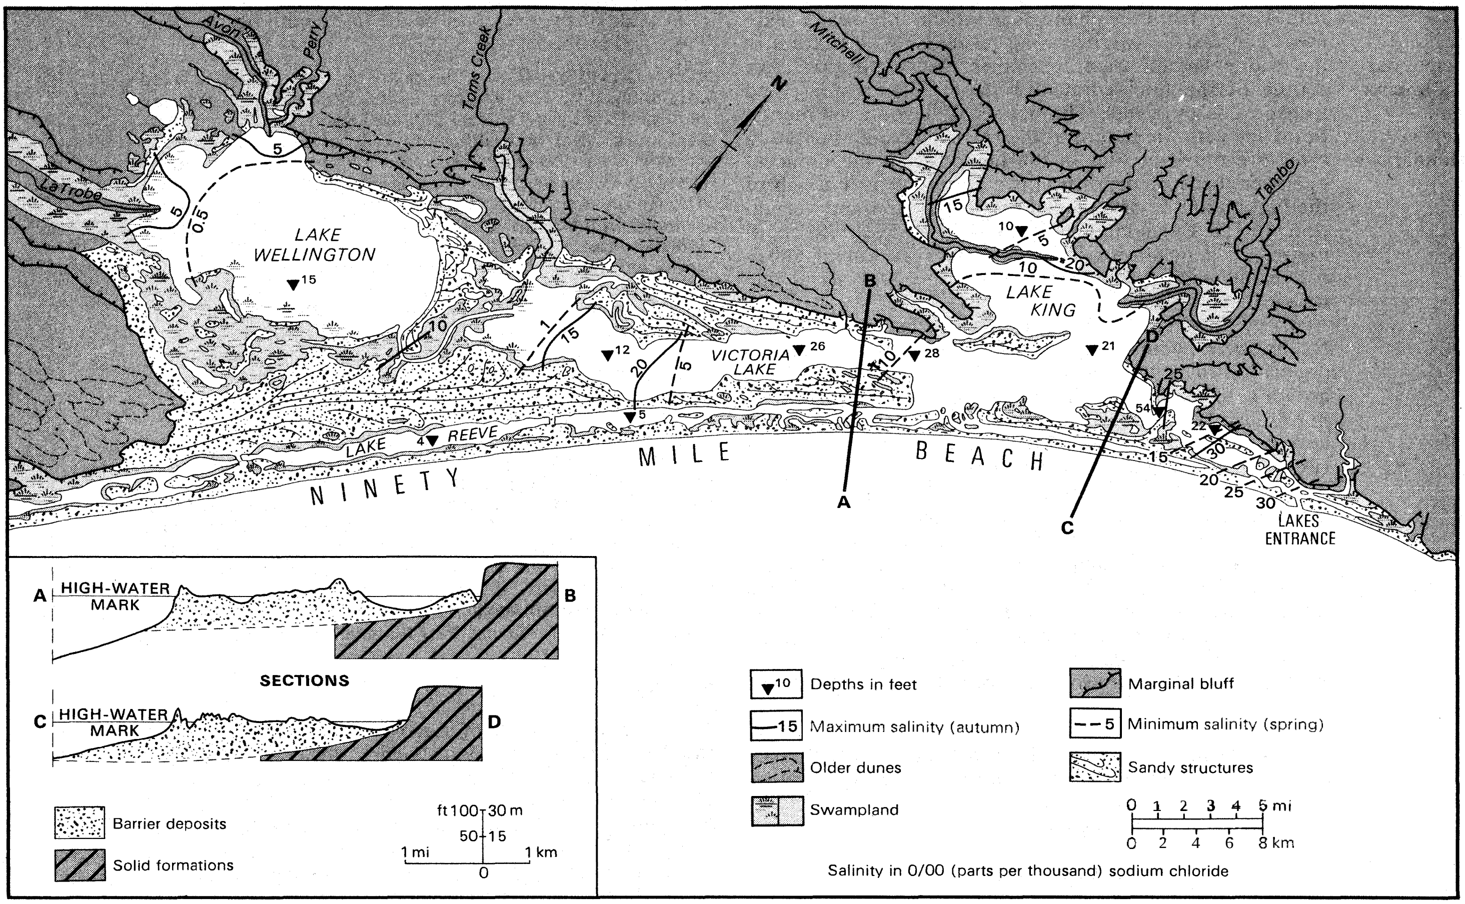

Figure 2: Sandy coastal barriers enclose the Gippsland Lakes, a lagoon region in Victoria, Australia.

and salinity of barrier island lagoons are more variable because of their wider climatic range. Because they are shallow, lagoon waters approximate the air temperature: colder than the open sea in winter, warmer in summer.

Salinities decrease as a function of the amount of runoff entering the lagoon in relation to the tidal influx. Lagoons may be considered brackish, marine, or hypersaline. Brackish lagoons receive much runoff, and salinity increases toward the tidal inlets. The Gippsland lagoons exemplify this type. The salinity at the inner end varies from 0.5‰ to 5‰ according to season, and central values vary between 5‰ and 20‰. Hypersaline lagoons occur where evaporation exceeds inflow. Lagune Madre in Texas and Sivash Lagoon in the Black Sea have salinities of 65 and 132‰, respectively. Salt deposits may form in these conditions. The denser saline water tends to lie beneath the fresher water where mixing is not severe.

Equilibrium bottom profiles. Lagoons behind coastal barriers normally are zones of fine sedimentation. Their bottom profiles, therefore, build up gradually with time. Typical depths of the Texas lagoons vary between 1¼ and 3½ m, and their floors are flat. Early theories that attempted to relate the form of the offshore and lagoon profile are no longer held; and because the lagoon profile changes with continued deposition, it cannot be used to establish the process of lagoon formation. The profile is usually gently undulating, but it may contain deeper channels, especially near the tidal inlets. Profiles across coral lagoons are either smooth and flat from calcareous sedimentation, or they contain knolls of growing or dead coral. There are 2,300 such knobs in the Eniwetok Lagoon in the Marshall Islands.

Flora and fauna. The flora depends on the climate of the area and the salinity of the lagoon waters. In tropical areas mangroves colonize the quiet lagoons, whereas in temperate latitudes salt marsh vegetation is common. The species depend on their salt tolerance and the bottom conditions. In less saline conditions *Phragmites,* or reed swamp, may be dominant but, where salinity approaches that of the open sea, halophytes are found. The plants accelerate the deposition of sediment on the lagoon floor, resulting in a decrease in area and water volume.

The fauna of the barrier-type lagoon are those that can live in soft mud or sandy sediment. Oysters and mollusks, such as *Scrobicularia,* can flourish in lagoon conditions. Organisms must be able to withstand a greater range of conditions than those of the open sea.

Corals and algae

In coral lagoons fauna are fundamental to the formation of the reefs. Coral polyps live in symbiosis with the unicellular algae *Zooxanthellae,* hence they require light and are restricted to the upper layers of water. Calcareous algae, *Lithothamnion,* normally grow in coral reefs. Corals and algae grow in the lagoons, often forming knolls. Sediment may prevent coral growth, although various species of *Acropora* may grow in this zone.

FACTORS INVOLVED IN LAGOON FORMATION

The essential feature that causes the lagoon to exist is the barrier that separates it from the sea. In the coral lagoon the formation of the reef depends upon the existence of suitable conditions for reef growth, which have already been mentioned briefly.

Barrier bars and sediment sources. The barrier island lagoons, on the other hand, depend not on organic processes but on waves, which act in a suitable environment on an adequate supply of bottom material, most commonly sand. Barrier islands are formed in those areas where the coastal slope is flatter than the equilibrium slope required by the long constructive swells, the waves that build up the foreshore in front of their breakpoint. They are, therefore, found on low coasts. They may occur in areas of subsidence, stability, or emergence, wherever sufficient sand exists.

The barrier islands that form the lagoons are made of sand, but the sediments of the lagoon are usually finer, as conditions are quieter. The lagoonal muds differ from shelf muds. Glauconite is rare in lagoon muds, but oyster reefs may occur as along the Texas coast. The muds are

Lagoonal sediments and depositional rates

found away from the channels in which only coarse sediment can rest, owing to strong currents. Flocculation in the saline lagoon water expedites clay deposition. The source of the fine sediment is from inland areas, and transport is by rivers. The details of lagoon sedimentation vary with the nature of the river load. Sedimentation rates are much greater in the lagoon than the adjacent open sea, because deposition is continuous over much of the lagoon and is often aided by flocculation and vegetation. In the Texas lagoons from 1875 to 1936, 20 centimetres of deposition occurred, despite 30 cm of subsidence; the sedimentation rate, therefore, was about one metre in 100 years.

Waves, tides, and surf. The barrier islands are formed by the waves, which build up their equilibrium profile by deposition on a gradient that is too flat. The level of the growing accumulation may be raised by the wind, forming dunes. Where the land behind the growing barrier is low, it will become flooded to form a lagoon if sea level rises slowly. Such a rise of sea level has occurred during the last 20,000 years. As long as the barrier island can maintain its level above the sea, as sea level rises, the lagoon will exist until it is filled with sediment. Not all lagoons and barrier island complexes have formed during rising sea-level conditions, but where there is evidence that no open sea foreshore sediments lie on the land side of the barrier this hypothesis seems likely. In some barriers, however, outbuilding of material by glacial outwash streams or rivers may provide a suitably low gradient and enough sediment to form a barrier, as along the south coast of Iceland. In other areas material carried alongshore to form a spit may develop into a bay-mouth barrier, enclosing a lagoon. Such features can be of sand or shingle. The Fleet behind Chesil Bank in southern England is an example of the latter type.

Waves within the lagoon may develop cuspate spits along the land side of the barrier and the inner edge of the lagoon. These features may eventually break the lagoon into almost circular or oval water bodies. Examples occur on the Chukchi Sea lagoons in the U.S.S.R. and elsewhere where vegetation does not form marshland.

Storms and catastrophic events. Storms or tsunami exert an effect on lagoons when they breach or overtop the barriers around the lagoon by raising the water level temporarily. Major changes in configuration can occur in a short time. Hurricanes, for instance, can cause serious effects on the coast of Texas, along which lagoons are common. Padre Island was lowered to below mean low tide at its southern end by one storm in 1919, and several washover channels were cut. The mainland shore also suffered erosion. Deposition may also occur; saline marls have been laid down on freshwater marsh, and small beach ridges may be built inside the lagoon where the high water level drives sand inland over mud. Coral reefs are more resistant to storms than are mobile sandy barriers.

Darwin's hypothesis

The effect of time. Lagoons of both types change with time. In both a relative rise of sea level with time is important in the development of the lagoon. In coral atolls there is evidence from deep boring that Charles Darwin's original subsidence hypothesis of atoll formation, via barrier reefs from fringing reefs around a subsiding volcanic peak, is substantially correct in many cases. As long as the coral can maintain its growth at a suitable level as its foundation subsides, the atoll will continue to enclose a lagoon, which is floored by coral or calcareous sediment, derived from the reef, and that maintains its depth by deposition or growth.

The postglacial rise of sea level also has influenced barrier island formation in many instances. When sea level rises too fast a barrier may be drowned, and its lagoon will cease to exist.

Experimental studies include work on the closing of tidal inlets into lagoons across barrier beaches. Such experimental work has shown the importance of storm tides in maintaining the openings through barriers, where longshore movement of material is great and runoff from land areas is not abundant. These experiments show that the deepest water occurs where the channel cuts through the barrier. Lobate shoals form areas of shallow water on either side of the deep part of the inlet, both on the open shore and in the lagoon.

BIBLIOGRAPHY. There are relatively few works devoted only to lagoons. The literature is widely spread in biological, geological, and geographical publications. The following classical works deal with different types of lagoons: CHARLES DARWIN, *The Structure and Distribution of Coral Reefs* (1842); W.M. DAVIS, "The Coral Reef Problem," *Spec. Publs. Am. Geogr. Soc.*, no. 9 (1928); E. DE BEAUMONT, *Leçons de geologie pratique,* pp. 223–252 (1845), and D.W. JOHNSON, *Shore Processes and Shoreline Development* (1919), two works on coastal barrier island lagoons. A recent study of coral lagoons and their ecology is D.R. STODDART, "Ecology and Morphology of Recent Coral Reefs," *Biol. Rev.*, 44:433–498 (1969), with an extensive bibliography. Useful references on barrier island lagoons include: K.O. EMERY, R.E. STEVENSON, and J.W. HEDGPETH, "Estuaries and Lagoons," in *Treatise on Marine Ecology and Paleoecology,* ch. 23, pp. 673–749 (1957); A. GUILCHER, *Coastal and Submarine Morphology* (1958; orig. pub. in French, 1954); F.P. SHEPARD, *Submarine Geology,* 2nd ed. (1963); and V.P. ZENKOVICH, *Processes of Coastal Development* (1967; orig. pub. in Russian, 1962). H.G. GIERLOFF-EMDEN, "Nehrungen und Lagunen," *Petermanns Geogr. Mitt.,* 105:81–92, 161–176 (1961), deals in detail with early theories of lagoon formation and includes a map of lagoon and barrier shorelines of the world. A more detailed study of one lagoon is E.C.F. BIRD, "Coastal Lagoons of Southeastern Australia," in J.N. JENNINGS and J.A. MABBUTT (eds.), *Landform Studies from Australia and New Guinea,* pp. 365–385 (1967).

(C.A.M.K.)

Lagos

The Federal Territory of Lagos, the national capital of the West African country of Nigeria, located at the western end of its Atlantic coastline, covers 27 square miles (70 square kilometres); and, at the start of the 1970s had a population of 945,000 in the city proper and about 1,600,000 in the metropolitan area. The territory is also the administrative centre for Lagos State and is the country's industrial and commercial centre, as well as its most important port. Originally known to the conquering Bini people as Eko (War Camp), it was successively designated by the Portuguese as Lago de Curamo and Onin, before finally being named Lagos, after a harbour in southern Portugal.

The city itself is the second largest—after Kinshasa—in tropical Africa. It is afflicted with industrial pollution, slums, and traffic congestion. It is also a thriving centre of economic and social activity that has an aura of progress. Its cultural life is cosmopolitan; tourists are attracted to its sandy beaches, and foreign capital investment is encouraged. The basic character of the city, however, remains African.

The city's origins

History. Some 300 years ago, the first Yoruba fishermen and hunters settled on Lagos Island, where the lagoon, swamps, and forests helped to protect the settlement from the neighbouring kingdoms of Dahomey to the west, Benin to the east, and the Yoruba states to the north. The area was, however, under Benin's domination from the late 16th to the mid-19th century, during which time it was governed as a part of the kingdom's westernmost province. It was during this period that power over land in Lagos was exercised by the Idejo, or White Cap Chiefs, who wore white hats as a symbol of their office. When lesser functionaries were later given the privilege of wearing the caps, two classes of chiefs were created. Their conflicting claims to power are still part of the city's political life.

The Portuguese first landed on Lagos in 1472; trade developed slowly, however, until the Portuguese were granted a slaving monopoly a century later. The city's position on the main lagoon of the West African coast and its proximity to the Yoruba states that were then ravaged by war contributed to its emergence as a major slaving centre, and this in turn attracted British interest in Lagos when British policy was to favour suppression of the slave trade. In about 1841, Kosoko became ***oba*** (king) of Lagos. Ten years later his support of the slave trade led to a clash with the British, who deposed him in favour of his rival, Akitoye. The slave trade continued to grow under Docemo, successor to Akitoye, and in 1861 he was forced to cede Lagos to the United Kingdom.

Under British administration. Lagos continued to thrive as a trade and administrative centre. Much of the population increase of the period was due to the repatriation of emancipated Yoruba slaves from Brazil, the West Indies, and Sierra Leone. Originally governed as a crown colony, Lagos was part of the United Kingdom's West African Settlements from 1866 to 1874, when it became part of the Gold Coast Colony (then the coastal region of modern Ghana). In 1886 it again achieved separate status under a British governor, and in 1906 it was amalgamated with the Protectorate of Southern Nigeria. When Southern and Northern Nigeria were amalgamated as the Protectorate of Nigeria in 1914, Lagos was made the capital of the Colony and Protectorate of Nigeria. In 1954 most of the hinterland was incorporated into the region of Western Nigeria, while the city itself was designated as federal territory. In 1960 it became the capital of independent Nigeria. In 1967, control of its hinterland was returned to the city with the creation of Lagos State which has an area of 1,381 square miles.

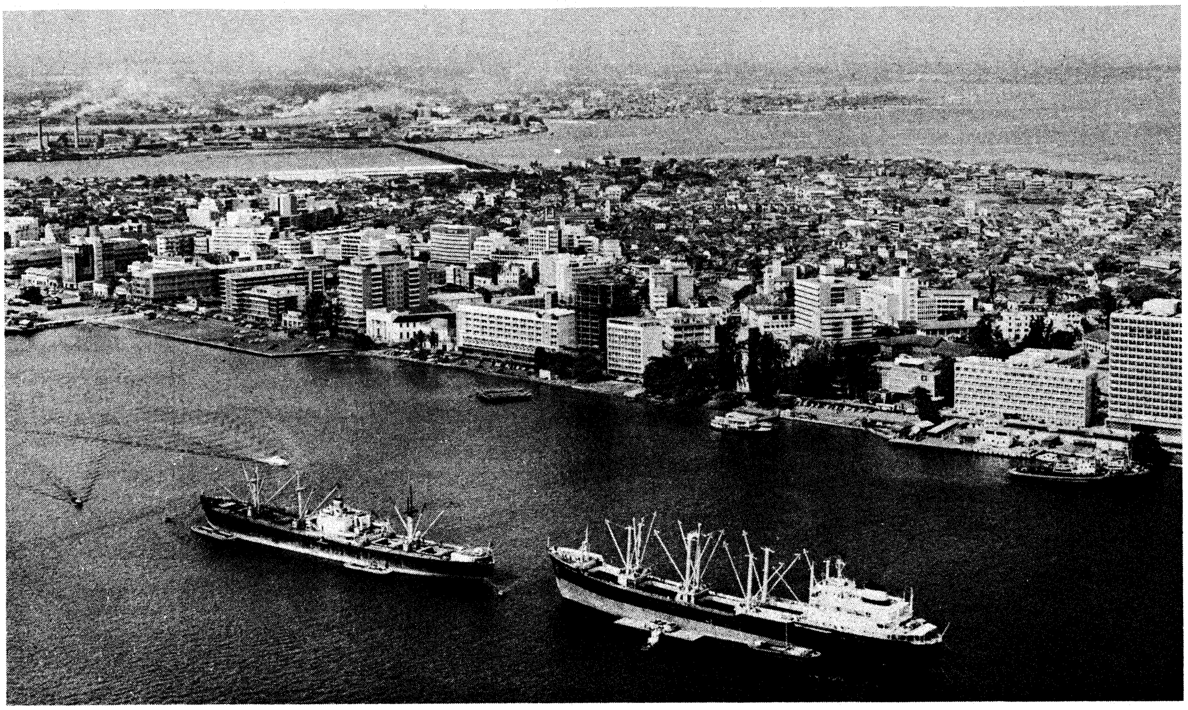
The contemporary city. ***The environment.*** The Lagos landscape is dominated by its system of islands. sandbars. and lagoons. During the latter part of the Pleistocene Epoch (about 10,000 years ago), the level of the Atlantic Ocean rose and submerged parts of the Nigerian coast, drowning river mouths and creating islands and bays. The tidal drift of sands along the coast eventually built up the sandbar that now encloses Lagos Lagoon itself.

Topography

The federal territory includes a strip of the mainland on the western shore of the lagoon, several islands and marshes, and the western end of the sandbar. The main islands of Iddo, Lagos, Ikoyi, and Victoria are connected to each other and to the mainland by a system of bridges. They are subject to flooding after heavy rains, but the installation of a series of drainage canals has alleviated much of the problem. The smaller islands at the western entrance to Lagos Lagoon are, however, swampy and only sparsely inhabited. All of the territory is low-lying, and the highest point on Lagos Island is only 22 feet above sea level.

Lagos has a tropical climate with an average temperature of 80° F (27" C) and an annual rainfall average of 72 inches. There are two seasons; the rainy season lasts from May to September, with the largest amount of precipitation falling in July, and the dry season lasts from October to April. The dusty, dry, and cold harmattan wind blows from the northeast from December to February. The original vegetation and animal life of the area have virtually disappeared. There are, however, scattered palm trees and green tropical vegetation on the mainland, and the Lagos Zoo is popular.

Because the surrounding swamps and smaller lagoons were long used as refuse dumps, water pollution is a serious problem. Reclamation projects have added about 1,000 acres of land to the city area, reduced the offensive stench of the swamps, and decreased mosquito breeding



The harbour, business section, and old town, Lagos Island. In the background, Carter Bridge, which connects with Iddo Island on the northwest.

Marc and Evelyne Bernheirn—Rapho Guillumette

grounds. Though atmospheric pollution was not a problem in the early 1970s, it was feared that the rapid industrialization would make clean air a matter for concern.

Settlement pattern. Lagos developed from traditional Yoruba settlements on the north of the island and later from communities established by Europeans, as well as by repatriated people from the Americas and Sierra Leone, on the southern coast. With the industrial development and population increase of the 20th century, the land between these areas was built up, and residential suburbs were founded to the north on the mainland.

The original settlement on the northwestern tip of Lagos Island now forms the core area of Lagos City. A slum area, it is characterized by narrow streets, poor housing, overcrowding, and a lack of sanitation facilities. Its traditional-minded inhabitants strongly resisted the slum clearance program of the late 1960s. Other slum areas include the mainland suburbs of Shomolu, Mushin, and Ajegunle. Newer sections of Lagos, such as Victoria Island, Ikoyi, Ebute Metta, Yaba, Apapa, and Surulere, are well planned, with wide streets, open spaces, and adequate sanitation facilities.

Pre-eminent among the neighbourhoods of Lagos is Isale Eko, site of the palace of the *oba* of Lagos, the Iga Idungaran, which occupies about ten acres. Close to it are the Obun Edo and Ebute Ero markets.

The business district

The main business district, occupying Lagos Island's southwestern shore, contains an increasing number of multistoried buildings. Its restricted land area is intensively utilized, for this is the heart of the city, where its primary activities—commerce, finance, administration, and education—are performed. Slum clearance in the district made provisions for some expansion, but some businesses were relocating to the outskirts of the city. Industry is located on the mainland in the city areas of Apapa, Ijora, and Yaba, and in the suburbs of Ikeja and Mushin.

Transportation. Transportation problems have beset Lagos throughout the 20th century. A railway, with its headquarters in Ebute Metta and its terminal at Iddo, connects the mainland's residential and industrial centres during the morning and afternoon rush hours. Bus services operating throughout the city carry about 100,000 persons daily. The city is also well served by taxis, and there are so many private automobiles, motorcycles, and bicycles that traffic jams are constant. Bridges to the islands from the mainland are unable to handle the growing volume of traffic, and slow-moving rush hour traffic is further frustrated by a lack of sufficient parking facilities on Lagos Island. It is anticipated that by the mid-1970s motorists may be forced to leave their cars on the mainland and take buses to the islands.

The city is the terminus for the nation's road network. An airport at Ikeja receives most of Nigeria's visitors from overseas, is served by 18 international airlines, and is used by the Nigerian Air Force. Lagos is the headquarters of the Nigerian Airways Corporation and the focus for flights from the country's 28 other airports.

The port of Lagos

The port of Lagos consists of two quays—Customs Quay, on Lagos Island, and the more important Apapa Quay, on the mainland. Both are served by a channel that is protected by breakwaters to the east and west. Apapa, the main outlet for Nigeria's exports, is served by a railway and also has a small floating dock. The creeks and lagoons are plied by numerous canoes, engaged in fishing and carrying goods between Lagos and other coastal cities in Nigeria or in Dahomey. The port is administered and maintained by the Nigerian Ports Authority.

The people. With a metropolitan population of about 1,600,000 and a city proper of 945,000 inhabitants, Lagos is tropical Africa's second-largest city. Its size is attributable to its position as a leading industrial centre; the relative youth of the population—70 percent are between 20 and 29 years of age—is an indication of its attraction to labour. The crowded conditions of the city are at their worst in central Lagos, where densities were reported to exceed 14,000 persons per square mile in 1961. Over 80 percent of the population are Yorubas, but the city attracts goodly numbers of immigrants from other parts of the country and from abroad. Among other Nigerian ethnic groups the Hausa and Ibo are the largest; there are also Edo and Ijaw communities. Among those from other African countries, the largest number come from Dahomey. There are about 10,000 Europeans, Americans, and Asians in the city. The largest white groups originate from the United Kingdom, the United States, France, and Germany. Over half of the population are Christian, 42 percent are Muslim, and about 3 percent practice traditional religions.

Housing. The city's most pressing problem is housing. The severe overcrowding and lack of sanitation in central Lagos prompted the slum-clearance scheme that led to the redevelopment of 70 acres by the early 1970s. In the poor districts, houses lack piped water, toilets, and electricity. The buildings are composed of cement or mud and are roofed with corrugated iron. In the wealthier areas, relatively new houses are equipped with modern conveniences; they range in architecture from Brazilian-style storied buildings to English country and colonial styles. Population density is low because of the predominance of single-family dwellings. Population pressure in the rertricted metropolitan area was potentially relieved in 1967 by the creation of Lagos State; the extension of the city's political control on the mainland will permit the establishment of new industrial and residential suburbs to the north and west.

Manufacturing

The economy. ***Industry.*** Industrial development has been promoted by the tax concessions accorded to investors, by the large reserve of labour, and by the availability of transport facilities. Most establishments are small, the largest employing fewer than 1,000 persons. Apapa contains the largest industrial area, while the suburb of Ikeja is also growing in industrial importance. Manufacturing and processing operations include automobile and radio assembly, food and beverage processing, metalworks, and the production of paints and soap. Textile, cosmetic, and pharmaceutical manufacture is also important. The fishing industry possesses trawlers, laboratory facilities, and a research library.

Commerce. There are 16 licensed banks, owned by Nigerians, Europeans, Americans, or Asians. The Central Bank of Nigeria is the sole bank of issue for Nigerian currency. The city is the national centre for insurance, as well as the seat of the Lagos Stock Exchange.

Public utilities. The federal government is responsible for the daily supply of about 24,000,000 gallons of water to the city; the piped water supply is of good quality, is filtered, and is chlorinated. Electricity is provided by the Electricity Corporation of Nigeria, with the main generating station, powered by coal and diesel oil, located on Iddo Island.

Administration and social conditions. ***Governmental institutions.*** As a federal territory, Lagos is independent of the other regions and is the direct responsibility of the national government. Since 1967 it has been governed by the Lagos State government and by a City Council Caretaker Committee appointed by the military government of Lagos State. The city is also the seat of the Nigerian House of Representatives and of the Federal Supreme Court and the location of a number of foreign embassies and consulates.

Health and safety. Medical and health facilities—ranging from large specialized hospitals to small maternity clinics—include a teaching hospital of the University of Lagos, an orthopedic hospital, a tuberculosis sanatorium, and a mental institution. The most common diseases in the city are malaria, bronchitis, pneumonia, and dysentery. The narrow and crowded streets cause a large number of accidents, which lead to more hospital admissions than do major illnesses. The Municipal Board of Health has reduced the incidence of malaria through swamp reclamation and conducts periodic inspections of residences. Detachments of the Nigerian Police are stationed in Lagos, and there is a fire brigade. The city contains the headquarters of the Nigerian Red Cross.

Education. The Lagos State government is responsible for education in the federal territory. Most of the schools are run by religious organizations with governmental assistance. There are about 450 free primary schools, almost 80 secondary schools, five teacher-training colleges, and four technical and vocational colleges. Of the total student enrollment of more than 227,000, the overwhelming preponderance attend primary schools, where there are more male than female students. The University of Lagos, founded in 1962, has an enrollment of over 2,000.

Cultural life. Religious institutions include churches and mosques. Cultural associations, clubs, debating societies, and ethnic unions form an integral part of Lagos life, and the performing arts are popular. The National Museum houses excellent historical examples of Nigerian arts and crafts. Organizations include the Nigerian Institute of International Affairs and the Nigerian Institute of Management, as well as British, German, Italian, and American institutes. There are several city libraries, the National Library of Nigeria, and the library of the University of Lagos. There are many bookshops, and numerous cinemas offer varied programs that include American Westerns and Indian films on mystical themes.

Museums and cultural institutions

The media. Lagos is the centre of the country's international telecommunications system and has good postal services. Radio Nigeria and the Nigerian Television Service broadcast from Lagos in English and 15 or more African languages. Leading daily newspapers include ***The Daily Times, The Sunday Times, The Morning Post, The West African Pilot,*** and ***The Daily Sketch.*** There are also a large number of weeklies, monthlies, and specialized quarterly journals; most are published in English, but a few are in Yoruba.

Recreation. Popular sports include association football (soccer), boxing, wrestling, tennis, and horse racing. The lagoons are dotted with sailboats, and Victoria Island has a beautiful sand beach. There are walkways lined with coconut groves along the Marina, and the open spaces throughout the city are used for recreational purposes. At the many nightclubs, the music includes high life (a form of West African dance music), waltzes, rumbas, rock, soul, and rhythm and blues.

The future. Lagos faces such general urban problems as air and water pollution, traffic congestion, and the need for expansion. Suburban development on the mainland is being promoted, and continued land reclamation and slum clearance will add space for new construction. The creation of Lagos State will allow for the planning of new industrial districts that may reduce pollution dangers. To ameliorate the transportation problem, a monorail has been proposed that would link Lagos Island with the mainland.

BIBLIOGRAPHY. The most recent authoritative study of Lagos is contained in A.L. MABOGUNJE, ***Urbanization of Nigeria*** (1968). J.B. LOSI, ***History of Lagos*** (1914, reprinted 1967); and J.B. WOOD, ***Historical Notices of Lagos,*** 2nd ed. (1933), are valuable for the early history of Lagos before it became the hub of Nigerian life. Conventional works that touch on the history of Lagos include A.C. BURNS, ***History of Nigeria,*** 7th ed. (1969); MICHAEL CROWDER, ***The Story of Nigeria*** (1962); and T.F. HALLIGEY, ***The Yoruba Country: Abeokuta and Lagos*** (1893). ROBERT S. SMITH, ***Kingdoms of the Yoruba*** (1969), contains valuable sections on Lagos. On the British occupation of Lagos, the best accounts are those by J.F.A. AJAYI, "The British Occupation of Lagos," ***Nigeria Magazine*** (1961); and W.D. McINTYRE, "Commander Glover and the Colony of Lagos, 1861–71," ***Journal of African History,*** 4:57–79 (1963). P.T. BAUER, ***West African Trade*** (1954); and B.W. HODDER, "The Growth of Trade at Lagos, Nigeria," ***Tijdschrift voor Economische en Sociale Geografie,*** 50:197–202 (1959), give a good picture of the economic life of Lagos. On the port of Lagos, the most reliable works are ***Lagos: The Federal Capital*** (Government Printer, 1955); "The Port of Lagos, Nigeria: Description of Apapa Wharf Extension," ***The Dock and Harbour Authority*** (1956); ***Metropolitan Lagos,*** United Nations Report (1964); and the official ***History of Lagos Harbour*** (Federal Ministry of Transport, 1956). PETER MARRIS, ***Family and Social Change in an African City: A Study of Rehousing in Lagos*** (1961), and "Slum Clearance and Family Life in Lagos," ***Human Organization,*** 19:123–128 (1960), are excellent studies. Demographic information is contained in some of the works mentioned above, but the ***Population Census of Lagos, 1950*** (1951), is a solid source; on architecture, A.L. MABOGUNJE (*op. cit.*) is the best account; see also G.J. AFOLABI OJO, ***Yoruba Palaces*** (1967); ***The Iga Idunganran: Palace of the Oba of Lagos*** (Federal Ministry of Information, 1966); and PIERRE VERGER, ***Flux et reflux de la traite des Negres entre le Golfe de Benin et Bahia de Todos os Santos du XVII***^{e} ***au XIX***^{e} ***siècle*** (1968), which contains many photographs illustrative of Lagos architecture over the years.

(B.I.O.)

Lagrange, Joseph-Louis, Comte de

A French–Italian mathematician, Joseph-Louis Lagrange was the intellectual disciple of Leonhard Euler, the leading 18th-century mathematician. He excelled in all fields of analysis and number theory, as well as in analytical and celestial mechanics. His most important book is ***Mkcanique analytique*** **(1788)**, the textbook on which all later work in this field is based.

Lagrange, engraving by Robert Hart.

Early achievements

He was born January 25, 1736, in the Italian city of Turin, of a well-to-do family of French origin on his father's side. His father was treasurer to the King of Sardinia and lost his fortune in speculation. Lagrange later said, "If I had been rich, I probably would not have devoted myself to mathematics." His interest in mathematics was aroused by the chance reading of a memoir by the English astronomer Edmond Halley. At 19 (some say 16) he was teaching mathematics at the artillery school of Turin. He was to be instrumental in founding the Turin Academy of Sciences. His early publications, on the propagation of sound and on the concept of maxima and minima, were well received; Leonhard Euler, in Berlin, praised Lagrange's version of his theory of variations. The young mathematician continued to surprise his contemporaries with his discoveries.

By 1761 he was already recognized as one of the greatest living mathematicians. In 1764 he was awarded a prize offered by the Paris Academy of Sciences for an essay on the libration of the Moon, the apparent oscillation that causes the slight changes in position of lunar features on the face that the Moon presents to the Earth. In this essay he used the equations that now bear his name. His success encouraged the Academy in 1766 to propose, as a problem, the theory of the motions of the satellites of Jupiter. The prize was again awarded to Lagrange; and he won the same distinction in 1772, 1774, and 1778. In 1776, on the recommendation of Euler and the French mathematician Jean d'Alembert, Lagrange went to Berlin to fill a post at the academy vacated by Euler, at the invitation of Frederick the Great, who expressed the wish of "the greatest king in Europe" to have "the greatest mathematician in Europe" at his court.

Life in Berlin

Lagrange stayed in Berlin until 1787. His productivity in those years was prodigious: he published papers on the three-body problem, which concerns the evolution of three particles mutually attracted according to Newton's law of gravity; differential equations; prime number theory; the fundamentally important number-theoretic equation that has been identified (incorrectly by Euler) with John Pell's name; probability; mechanics; and the stability of the solar system. In his long paper "Réflexions sur la resolution algébrique des équations" (1770), he opened a new period in algebra and inspired Galois to his group theory.

A kind and quiet man, living only for science, Lagrange had little to do with the parties and intrigues around the King. When Frederick died, Lagrange preferred to accept Louis XVI's invitation to Paris. He was given apartments in the Louvre, was continually honoured, and was treated with respect throughout the Revolution. From the Louvre, he published his classical ***Mécanique analytique*** **(1788)**, a lucid synthesis of the hundred years of research in mechanics since Newton, based on his own calculus of variations, in which certain properties of a mechanistic system are inferred by considering the changes in a sum (or integral) that are due to conceptually possible (or virtual) displacements from the path that describes the actual history of the system. This led to independent coordinates that are necessary for the specifications of a system of a finite number of particles, or "generalized coordinates." It also led to the so-called Lagrangean equations for a classical mechanical system in which the kinetic energy of the system is related to the generalized coordinates, the corresponding generalized forces, and the time. The book was typically analytic; he stated in his preface that "one cannot find any figures in this work."

Work after the Revolution

The revolution that began in 1789 pressed Lagrange into work on the committee to reform the metric system and then into teaching. When the great chemist Antoine-Laurent Lavoisier was guillotined, Lagrange commented: "It required only a moment to sever that head, and perhaps a century will not be sufficient to produce another like it." When the École Polytechnique was opened in 1795, he became, with Gaspard Monge, the leading professor of mathematics. His lectures were published as ***Théorie des fonctions analytiques*** (1797) and ***Leçons sur le calcul des fonctions*** (1804) and were the first textbooks on real analytical functions. In them Lagrange, worried about the weak foundation of the calculus having to do with the ratios of small quantities and the limits of such ratios, namely, the differential calculus, tried to base it on algebra and thus eliminate the infinitesimal—a gallant but unsuccessful attempt. He also continued to work on his ***Mkcaniaue analvtique,*** but the new edition appeared only after his death.

Napoleon honoured the aging mathematician, making him a ***senateur*** and a *comte de l'Empire*, but he remained the quiet, unobtrusive academician, a venerable figure wrapped in his thoughts. He married twice. His second wife, the daughter of the astronomer Pierre-Charles Le Monnier, was much younger than he. When he died on April 10, 1813, he was interred in the Panthéon. The funeral orations were given by the astronomer Pierre-Simon Laplace and the naturalist Bernard Lacépède.

BIBLIOGRAPHY. A recent biography of Lagrange is F. BURZIO, *Lagrange* (1942), in Italian. The only other extensive biography is by Lagrange's friend, the astronomer J.B. DELAMBRE, ***Notice sur*** *Lagrange* (1816). E.T. BELL, ***Men of Mathematics*** (1953), devotes a chapter to Lagrange. An interesting essay is G. SARTON, "Lagrange's Personality," in ***Proceedings of the American Philosophical Society,*** 88:457–496 (1944). See also histories of mathematics such as C.B. BOYER, ***A History of Mathematics*** (1968). Lagrange's works have been published in 14 volumes, ***Oeuvres*** (1867–92); Delambre's biography is included in the first volume.

(D.J.S.)

Lahore

Lahore, the second largest city of Pakistan after Karāchi, is situated in a flourishing region of fertile alluvial soil in the upper Indus plain. It lies on the historic routes at the bridgehead over the Rāvi, a tributary of the Indus. It is important as an administrative, industrial, commercial, agricultural-marketing, and educational centre and as a military cantonment and also gives its name to a district and a division.

The city of Lahore was the capital of the Punjab for over 900 years; in 1955 it was selected as the capital of West Pakistan. After the dismemberment of the province of West Pakistan into four provinces in 1970, Lahore became the capital of a new province of the Punjab.

History. Information about the history of the settlement prior to the Muslim period is fragmentary and dubious. Hindu legend attributes the founding of Lahore to Lava, or Loh, son of Rāma, after whom it is said to have been named Lohawar. A Chinese traveller, Hsüan Tsang, however, made no mention of it in connection with his journey from Taki (northern Punjab) to Jullunder in 630.

Lahore figured prominently in the historical annals of Punjab from 1152 to 1849. It was the seat of government of the Ghaznavid dynasty from 1152 to 1186, during which time it was put to ransom by the Ghūrid Muʿizz-ud-Din Muhammad, in 1181, and later taken in 1186. From this time to 1238, Lahore was the centre of opposition to the authority at Delhi, while itself subject to incursions of the turbulent Khokhars. During the following century, the city lay at the mercy of recurrent Mongol incursions. In 1301 it was raided by Dua the Chagatai and in 1398 was destroyed by a detachment of the Central Asian conqueror Timur's army. It was rebuilt by Mubārak Shāh in 1422, and in 1451 came under Bahlūl Khān Lodī. The city seems to have enjoyed a period of peace under him and his lineage.

Mughal period

The city was captured by the Mughal Bābur's troops in 1524, and there ensued the golden period of Lahore's history under Mughal rule. Under the Mughals it occasionally became the place of royal residence. The city underwent an unprecedented expansion during the reign of Shāh Jahān (1628–57) but declined in importance during the reign of Aurangzeb.

From the death of Aurangzeb (1707) to the accession of Ranjit Singh (1798), the fate of Lahore was singularly unfortunate, since it was subjected to Sikh insurrections. With the invasion of Nāder Shāh, Lahore for some time became an outpost of his empire, but its history thereafter was associated with the rise of the Sikhs. Under the Sikh ruler Ranjit Singh (1799–1839) it once more became the seat of a powerful government but declined again under his successors. At the time of the British occupation in 1849, the "environs of Lahore were a mere expanse of crumbling ruins."

The contemporary city. The urban centre of Lahore comprises an area of 128 square miles (332 square kilometres). The city is sited on the left bank of the Rāvi on gently sloping terrain about 700 feet above sea level. The environs of Lahore contain three distinct alluvial landforms: active floodplain, a meander floodplain, and a "cover" floodplain inundated only occasionally. Most of the city spreads over the cover floodplain, the surface materials of which consist of deposits from repeated sheetflooding accompanied by vertical accretion.

Lahore has a subtropical continental type of climate, with hot summers and cool winters. The mean annual temperature and rainfall, respectively, are 74" F (23" C) and 20 inches (500 millimetres). June is the hottest month, with mean maximum and minimum temperatures of 106" F (41° C) and 79" F (26" C). January, the coldest month, registers a mean maximum temperature of 69" F (21" C) and a mean minimum of 40° F (4° C). July is the rainiest month (mean rainfall 5.5 inches, or 140 millimetres), and November the driest (mean rainfall 0.10 inches, or three millimetres). From July to September the weather, owing to a combination of high temperatures and humidity, is oppressive.

In terms of vegetation, Lahore is often eulogized as the "city of gardens," for, in comparison with other big urban centres of Pakistan, it contains much greenery in the form of roadside ornamental trees and sizable gardens.

Air pollution is increasing in the city because of an expanding number of automobiles and increasing industrialization. Water pollution is in evidence in ill-drained low-lying peripheral areas with high water tables.

Lahore presents a diversity of urban landscape and street patterns, resulting from its long and checkered history. Three main elements stand out:

Major sections of the city

1. An old walled city of amorphous growth, with narrow streets of uncertain width and direction, high intensity of development, great vertical expansion, inappropriate admixture of urban functions, and a congested appearance. This forms the hard core, or the inner region, of the city.

2. Anglicized districts and the cantonment, containing modern marketing areas and fashionable residential quarters. These districts, excluding the cantonment, form the intermediary zone of the city and were added during the late 19th and early 20th centuries. They manifest a lesser admixture of urban functions and moderately wide roads forming a loose rectangular pattern. The main functions are administrative, educational, commercial, and residential.

3. Postindependence residential localities, exhibiting some of the important traits of contemporary urban planning. These, together with the cantonment, encircle the inner city. This is quite extensive and contains planned residential localities, industrial sites, educational institutions, and agricultural land. The intensity of development here is least. The cantonment is a distinctive area because of its specialized function and the strict gridiron pattern of its streets. (Ed.)

The old city was formerly surrounded by a 30-foot-high brick wall and a moat, but these have been replaced, except in the north, by a garden. A circular road around the rampart gives access to the city by 13 gates. The architecture of Lahore cannot compare with that of Delhi, although there are some beautiful buildings in the fort dating from the time of Jahiingir and Shāh Jahān. The mosque of Wazīr Khān (1634) and the northern wall of the fort display magnificent examples of kashi or encaustic tile work. The Bādshāhī (Imperial) Mosque, built by Aurangzeb, is a lofty structure of red sandstone ornamented with marble tracing. The buildings of Ranjit Singh and his mausoleum are common and meretricious in style. He was, moreover, responsible for much of the despoiling of the earlier buildings, having stripped the Muslim tombs of their ornaments and sent them to Amritsar. Two of the chief features of the city lie outside its wall—Shāhdara and Shālīmār gardens. Shāhdara, about three miles to the north across the Rāvi, contains the tomb of the Mughal emperor Jahāngīr (1569–1627), surrounded by a garden. The tomb itself is a splendid marble monument in a building largely of red sandstone, with a profusion of marble ornaments arranged in elegant mosaics representing flowers, and inscriptions in Arabic and Persian. The Shālīmār gardens six miles to the east, which were laid out in 1641 by Shāh Jahān, are among the most magnificent in the world. (K.S.-U.A.)

The intracity road pattern is an irregular one with no defined geometrical design, except in some parts where it is dominantly rectangular. The pattern has resulted in a number of focal points in various parts of the city, the two most important of which are the Anārkalī-Mall Road area and the railway station. The road pattern is ill adapted to modern traffic needs, and the overall land-use pattern of the city is haphazard and poorly defined, except in the recently developed areas.

Railways link Lahore with all the important urban centres of Pakistan. The city lies on the Peshāwar–Karachi railway line and has, apart from the city railway station, several outer stations. Some 10,000,000 rail passengers are handled annually.

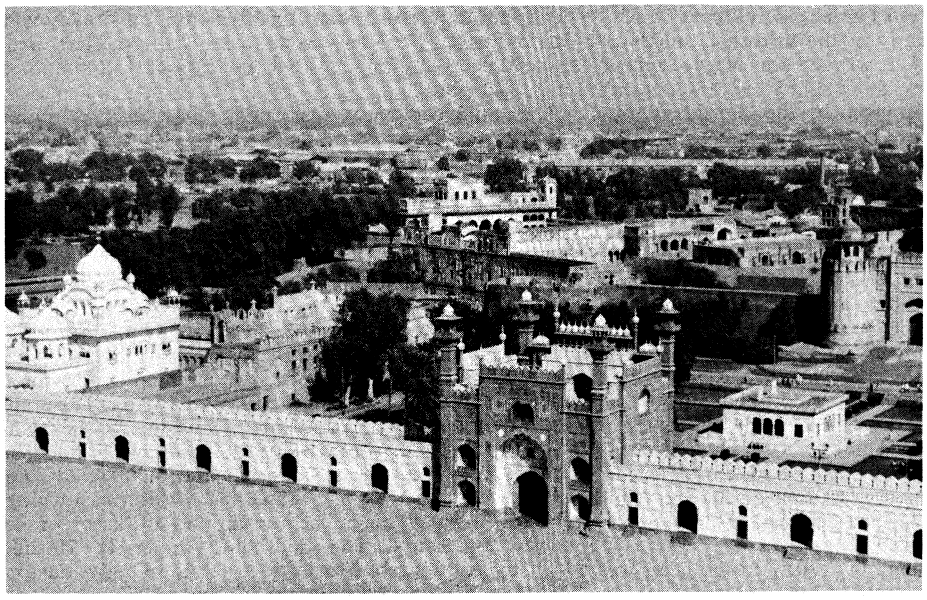
Motor transport of goods and passengers is also very important: the number of passengers carried on incoming and outgoing buses exceeds 2,000 per day, and a large number of trucks, exceeding 3,500, handle goods traffic to and from Lahore. By air, Lahore is directly connected with Rāwalpindi, Peshāwar, Lyallpur, Multān, Karāchi, and Quetta. Air traffic is increasing.

Demographic statistics

The estimated population of the city in 1971 was 1,985,800. The enumerated population (1961) was 1,296,477 (males 723,199; females 573,278). The overall density of population of the urban area works out to 10,129 persons per square mile. At the beginning of the 20th century, the population of Lahore was 202,964 (1901).

Like several other large urban agglomerations of Pakistan, Lahore suffers from overcrowding, with an average of 3.2 occupants per habitable room, which compares unfavourably with the statutory overcrowding limits of about two persons per room in countries such as Great Britain. In the poorer residential areas of the city, overcrowding is a serious menace.

Lahore presents a diversity of architectural features. The walled-city area and its outskirts contain a large number of buildings of the Mughal period, and a large number of government and public buildings, erected during the British period, particularly in the later part of the



Tomb of Ranjit Singh (left) and Lahore Fort (right) as seen from the turret of the Bādshāhī Mosque, Lahore.
Frederic Ohringer—Nancy Palmer Agency

19th century, are to be found. These generally suggest a blending of the Oriental and Western structural traits. The postindependence upper class residential colonies abound in beautiful modern structures.

Economic activity

Lahore contains 18 percent of the total industrial establishments of Pakistan. Manufacturing occupies some 30 percent of the total labour force of Lahore, textiles being the single most important industry. Trade and commerce provide employment for about 25 percent of the total labour force, and services (government, community, and personal) provide employment for about 26 percent. Lahore is the second largest centre, after Karāchi, of banking and insurance.

Public utilities include water supply, electricity, and sewerage. Water-supply arrangements, though quite elaborate, are inadequate. It is estimated that there is a deficiency of about 30 percent, or 7,000,000 to 10,000,000 gallons, per day.

The sewerage system is a semicombined one, designed to convey the domestic sewage and only a relatively small part of storm water. Overflows are provided to divert excessive storm water into drainage channels. Newly developed areas such as Gulberg have a waterborne sewage system, while older parts have open drains for sullage and conservancy crews for the collection of night soil.

Health facilities in the city include 18 hospitals, a large number of dispensaries and privately owned clinics, and over 700 private medical practitioners. It is estimated that there are only three hospital beds per 1,000 persons, a deficiency made more acute by the high incidence of disease. Being the provincial metropolis, Lahore also provides specialized medical services for its hinterland.

Lahore is an important educational centre, with two universities and numerous colleges and schools. The number of primary schools exceeds 360. According to the 1961 census, the city had a literacy rate of 32.7 percent of the total population.

Lahore has numerous and diversified cultural centres, ranging from city libraries to museums, theatres, clubs, and cultural societies. It is very deficient in public auditoriums, however, having only seven of limited capacity. Numerous English and Urdu newspapers and periodicals are published. The city has both radio and television stations.

Ranking high in the administrative hierarchy, Lahore has numerous political, governmental, and semi-governmental institutions.

The proportion of open recreational lands, including parks and playgrounds, is low in the urban centres of Pakistan. In Lahore, open recreational land accounts only for 4.6 percent of the total area, or 0.63 acre per 1,000 persons—while, according to generally accepted British and U.S. standards, it should be between five and ten acres.

Except in the planned residential districts, there is a paucity of neighbourhood parks and children's playgrounds. Lahore has, however, a few famous and large town parks.

BIBLIOGRAPHY. Published literature on Lahore consists mainly of archaeological and historical accounts. Such works include: ALEXANDER CUNNINGHAM, *Ancient Geography of India*, ed. by S.N. MAJUMDAR (1924); T.H. THORNTON, *Lahore: A Historical and Descriptive Note, Written in 1860* (1924); S.M. LATIF, *Lahore: Its History, Architectural Remains and Antiquities* (1892); H.K. TREVASKIS, *The Land of Five Rivers* (1928); R.E.M. WHEELER, *Five Thousand Years of Pakistan* (1950); and M. BAQIR, *Lahore: Past and Present* (1952).

(Ed.)

Lakes and Lake System

Definition and general occurrence

Lakes are bodies of slowly moving or standing water that occupy inland basins. Definitions that precisely distinguish lakes, ponds, swamps, and even rivers and other bodies of nonoceanic water are not well established. It may be said, however, that rivers and streams are relatively fast moving; marshes and swamps contain relatively large quantities of grasses, trees, or shrubs; and ponds are relatively small in comparison to lakes. Geologically defined, lakes are temporary bodies of water.

Within the global hydrologic cycle, freshwater lakes play a very small quantitative role, constituting only about 0.009 percent of all free water, which amounts to less than 0.4 percent of all continental freshwater. Saline lakes and inland seas contain another 0.0075 percent of all free water. Freshwater lakes, however, contain well over 98 percent of the important surface waters available for use. Apart from that contained in saline bodies, most other continental waters are tied up in glaciers and ice sheets and the remainder in groundwater.

Four-fifths of the 125,000 cubic kilometres (30,000 cubic miles) of lake waters occur in a small number of lakes, perhaps 40 in all. Lake Baikal, in central Asia, contains about 22,000 cubic kilometres (5,000 cubic miles) of water, and Lake Tanganyika (19,000 cubic kilometres [4,500 cubic miles]) and Lake Superior (12,000 cubic kilometres [3,000 cubic miles]) are the next largest. The Great Lakes of North America contain a total of about 25,000 cubic kilometres (6,000 cubic miles) of water and, together with other North American lakes larger than ten cubic kilometres (two cubic miles), constitute about one-fourth of the world's lake waters.

Although lakes are to be found throughout the world, the continents of North America, Africa, and Asia contain about 70 percent of the total lake water, the other continents being less generously endowed. A fourth of the total volume of lake water is spread throughout the world in uncounted numbers of small lakes. Anyone who has flown over much of the Canadian plains area cannot help but be struck by the seemingly endless skein of lakes and ponds covering the landscape below. Though the total volume of water involved is comparatively small, the surface area of lake water is substantial. The total surface area of all Canadian lakes has been estimated to exceed the total surface area of the province of Alberta. The state of Alaska has over 3,000,000 lakes with surface areas greater than eight hectares (20 acres).

The larger, deeper lakes are a significant factor within the cycle of water—from rain to surface water, ice, soil moisture, or groundwater and thence to water vapour. These lakes receive the drainage from vast tracts of land, store it, pass it on seaward, or lose it to the atmosphere by evaporation. On a local basis, even the smaller lakes play an important hydrologic role. The relatively high ratio of exposed surface area to the total water volume of these lakes accentuates their effectiveness as evaporators. In some cases the efficiency of lakes in losing water to the atmosphere is locally undesirable, because of demands for it by public and industrial requirements. In some basins, lakes are the terrestrial end point of the hydrologic cycle. With no outflow downstream toward the oceans, these closed lakes swell or recede according to the balance of local hydrologic conditions.

Importance to man

In today's industrial societies, requirements for water—much of which is derived from lakes—include its use for dilution and removal of municipal and industrial wastes, for cooling purposes, for irrigation, for power generation, and for local recreation and aesthetic displays. On a national level, in 1965 the United States used 160,000,000,000 gallons per day for industrial purposes, 22,000,000,000 gallons per day for all municipal reasons, and 141,000,000,000 gallons per day for irrigation. Obviously, these requirements vary considerably among regions, climates, and countries.

In another vein, it is convenient to use water to dilute liquid and some solid wastes to concentrations that are not intolerable to the elements of society that must be exposed to the effluent or wish to use it. The degree of dilution that may be acceptable varies from situation to situation and is often in dispute. In some cases, dilution is used purely to facilitate transport of the wastes to purification facilities. The water may then be made available for reuse.

Lake water is also used extensively for cooling purposes. Although this water may not be affected chemically, its change in thermal quality may be detrimental to the environment into which it is disposed, either directly, by affecting fish health or functions, or indirectly, by causing an excessive plant production and ultimate deoxygenation due to biological decay. Both fossil- and nuclear-fuelled power plants are major users of cooling water. Steel mills and various chemical plants also require large quantities. In Sweden an estimated 3.5 percent of the total national surface-water flow is presently required for cooling purposes, and it is estimated that this requirement will increase to 80 percent by the year 2000. For the United States these estimates are 10 and 50 percent.

Concern with thermal pollution of surface waters is concentrated principally on rivers and small lakes. With power requirements in modern societies increasing by about 7 percent per year, however, some apprehension has been expressed about the future thermal loading of even the largest lakes. It has been predicted that thermal inputs to each of the North American Great Lakes will increase by nearly 11 times by the year 2000. In terms of energy to be disposed in this fashion, the numbers are staggeringly large. These lakes have such large volumes, however, and such large surface areas (from which much of the heat goes into the atmosphere) that there is some question about the nature and magnitude of the actual effects.

The economic importance of waterways as communication links is enormous. In the earliest times, when travel by many societies was substantially by water, travel routes became established that resulted in relationships between cultural factors and surface hydrology networks. Today, river and lake systems serve as communication links and play an important role in shipping because of the large cargo capacities of merchant vessels and the still fairly uncongested condition of inland waterways. Oceanic shipping lanes play the major role, but river and lake systems, which link inland ports with the oceans, have been key factors in the rates of economic growth of many large inland ports.

In the Northern Hemisphere, icing on lakes precludes normal shipping commerce. Despite the limited shipping season, however, cargo tonnage on the Great Lakes for 1966 was about equal to Suez Canal tonnage and was more than twice the Panama Canal tonnage.

Commercial fisheries and other food industries reap great harvests from the major lakes of the world. The quality of the fish catch has steadily decreased in many lakes, however, with the more desirable species becoming less plentiful and the less desirable species gradually dominating the total wherever pollution and contamination of waters have occurred. Other commercial harvesting from lakes includes waterfowl, fur-bearing mammals, and some plant material, such as rice.

Abuse of lakes

Each of the uses described has associated with it the means for abuse of the very characteristics of lakes that make them desirable. Wise management of natural resources has never been man's forte. Municipalities and industries have polluted lakes chemically and thermally, the shipping that plies large inland water bodies leaves oil and other refuse in its wake, water used for irrigation often contains chemical residues from fertilizers and biocides when it is returned to lakes, and the populace that so desperately demands clean bodies of water for its recreation often ignores basic sanitary and antipollution practices, to the ultimate detriment of the waters enjoyed.

Among the major problems affecting the optimum utilization and conservation of lake waters are eutrophication (decay processes), chemical and biological poisoning, and decreases in water volumes. In the former case, discussed in more detail later, the enrichment of lakes with various nutrients supports biological productivity to an extent in which the ultimate death and decay of biological material places an excessive demand on the oxygen content, resulting in oxygen depletion in the worst cases. Phosphates and nitrates are two of the types of nutrients that are most important in this connection, particularly since they are often introduced in critical quantities in waste effluents from human sources. Other examples of chemical pollution of lakes include the introduction of DDT and other pesticides and heavy metals such as mercury. Bacteriological contamination of lake waters resulting in levels that constitute a hazard to health is another common result of man's inhumanity to his natural environment.

Water-quantity problems are complex, being related to natural vagaries of supply and levels of consumptive utilization of water. In the latter case, the percentage of water returned to the source after utilization varies with the use. The largest losses are due to actual water diversions and processes that result in evaporative losses. The use of large quantities of lake water for cooling purposes by industry and utilities, for example, may raise lake temperatures near the effluents sufficiently to cause increased evaporation. The use of certain types of cooling towers results in even larger losses. Some of the water evaporated will stay within the lake basin, but some will be lost from it.

Influence on local climate

Another example of this type of loss is connected with the possible application of weather-modification techniques to alleviate the heavy lake-effect snowfalls experienced along the lee shores of large lakes in intermediate latitudes. Redistribution of precipitation always raises the possibility of redistribution of water among various basins.

Lake-effect snowfall is just one example of the influence of lakes on local climate. The ability of large bodies of water to store heat during heating periods and to lose it more gradually than the adjacent landmasses during cooling periods results in a modifying influence on the climate. Because of this propensity, air passing over a lake's surface is cooled during summer and heated during winter. Consequently, the predominantly downwind side of a lake is more influenced by the ameliorating effects of a lake.

In most instances, moisture is also passed to the atmosphere. In summer, lake cooling serves to stabilize the air mass, but winter heating tends to decrease stability. The moisture-laden, unstable winter flows off lakes therefore produce so-called snow belts, which significantly affect downwind cities. The snow belts are usually of limited extent, often within a mile of the lake shore.

This article treats lake basins and sedimentation; the physical and chemical properties of lake waters; lake currents, waves, and tides; the hydrologic balance of lakes; and life in lakes and lake systems. For further information on related systems and environments, see SWAMPS, MARSHES, AND BOGS; RIVERS AND RIVER SYSTEMS; PLAYAS, PANS, AND SALINE FLATS; and ESTUARIES. The place of lakes within the hydrologic cycle is further dealt with in the article HYDROLOGIC CYCLE, and some aspects of lake sedimentation and water chemistry are treated in the articles SEDIMENT YIELD OF DRAINAGE SYSTEMS; RIVER DELTAS; and FRESHWATER, GEOCHEMICAL PROPERTIES OF. See also WATER WAVES; WATER RESOURCES; ICE IN RIVERS AND LAKES; and AQUATIC ECOSYSTEM for further detail on these topics, as they relate to lakes.

This article is divided into the following sections:

I. Lake basins

CLASSIFICATION OF BASINS

The name given to the study of lakes is limnology. Limnologists have used several criteria for the development of systems for classifying lakes and lake basins but have resorted particularly to the mechanisms that have produced lake basins. These have been summarized and examined in *A Treatise on Limnology*, by the American limnologist G.E. Hutchinson, which includes treatment of tectonism, volcanism, landslides, glaciation, solution, river action, wind action, coastline building, organic accumulation, animal activity, meteoritic impact, and human activity.

Basins formed by tectonism, volcanism, and landslides. Tectonism—or movements of the Earth's crust—have been responsible for the formation of very large basins. During the late Miocene (the Miocene Epoch includes the time interval from 26,000,000 to 7,000,000 years ago), broad, gentle earth movements resulted in the isolation of a vast inland sea across southern Asia and southeastern Europe. Through most of the Tertiary Period (from 65,000,000 to 2,500,000 years ago), subbasins developed that gradually were characterized by a great range of salinities. Resumption of communication with the oceans occurred later, and there is evidence of considerable variation in water levels. The present remnants of these inland bodies of water include the Caspian Sea and the Aral Sea, along with numerous smaller lakes. The Black Sea, which was also once part of this large inland basin, is now in direct communication with the oceans.

In some cases, elevated land areas may already contain depressions that eventually form lake basins. Lake Okeechobee, Florida, is cited as being such a basin, formed by uplift of the ocean floor.

Tectonic uplift may interfere with natural land-drainage patterns in such a way as to produce lake basins. The Great Basin of South Australia, some of the lakes in Central Africa (*e.g.*, Lakes Kioga and Kwania), and to some extent Lake Champlain, in the northeastern United States, are examples of this mechanism. Land subsidence, due to earthquake activity, also has resulted in the development of depressions in which lakes have evolved. Many such cases have been reported within the past 300 years.

The damming of valleys as a result of various tectonic phenomena has resulted in the formation of a few lake basins, but faulting, in its great variety of forms, has been responsible for the formation of many important lake basins. Abert Lake, in Oregon, lies in the depression formed by a tilted fault block against the higher block. Indeed, many lakes in the western United States are located in depressions formed through faulting, including Lake Tahoe, in the Sierra Nevada, California. Great Salt Lake, Utah, and other nearby salt lakes are remnants of a large Pleistocene lake, Lake Bonneville, which was formed at least partly by faulting activity (the Pleistocene Epoch includes the interval from about 2,500,000 to about 10,000 years ago).

In other parts of the world, faulting has also played an important role in basin formation. Lake Baikal and Lake Tanganyika, the two deepest lakes in the world, occupy basins formed by complexes of grabens (down-dropped faulted blocks). These lakes are among the oldest of modern lakes, as are other graben lakes, particularly those within the East African rift system which extends through the East African lake system and includes the Red Sea (see further RIFT VALLEYS).

Crater lakes and lava damming

Basins formed from volcanic activity are also greatly varied in type. The emanation of volcanic material from beneath the surface can be explosive, or it can issue in a gentle and regular manner. This range of activity and the variation of types of material which may be involved result in the possible development of many different types of basins.

One broad category includes those occupying the actual volcanic craters or their remnants. Crater lakes may occupy completely unmodified cinder cones, but these are rare. Craters caused by explosions or by the collapse of the roofs of underground magma (molten silica) chambers and those caused by explosion of new volcanic sources and that are built of nonvolcanic material are other examples. The latter are termed maars, following the local name for such forms in Germany. They are found, however, in several locations, including Iceland, Italy, and New Zealand. The maars of the volcanic district of Eifel, West Germany, are the most well-known of these formations.

The collapse of magma chambers and the development of very large surface craters called calderas is an important source of lake basins. Crater Lake, Oregon, is a typical example, exhibiting characteristically great depth and a high encircling rim. Some caldera basins evolved with gently sloping sides, however, due to the deposition of material from a series of explosions and a more gentle collapse of the structure. Secondary cones may develop within calderas, as shown by Wizard Island, in Crater Lake. The largest caldera in the world, which contains Lake Toba, in Sumatra, was formed through a combination of volcanic action and tectonic activity. Lake Toba's basin is contained in a strike-slip fault belt along the entire length of the Barisan Mountains of Sumatra. A vast, initial eruption of lava under gas pressure collapsed the magma reservoir, forming a depression that filled with water, producing the lake. Renewed volcanic activity subsequently led to the formation of an island in the centre, but a second collapse later cut it in two. Additional tectonic activity has further modified the lake's configuration.

Lake basins may also arise from the action of lava flows that emanate from volcanic fissures or craters. Lake Mývatyn, in Iceland, was formed in a basin arising from the collapse of the interior part of a large lava flow. Other basins have formed as the result of volcanic damming. This usually happens where a lava flow interrupts the existing drainage pattern.

Lake basins also may form following the blockage of a drainage depression by landslides. These may be temporary in nature because of the eroding action of the lake on the damming material. Lake Sārez in the Pamirs is stable, being dammed by a rockslide.

Basins formed by glaciation. The basin-forming mechanism responsible for the most abundant production of lakes, particularly in the Northern Hemisphere, is glaciation. The Pleistocene glaciers, which seem to have affected every continent, were especially effective in North America, Europe, and Asia. The retreat of ice sheets produced basins through mechanical action and through the damming effect of their ice masses at their boundaries (see further GLACIATION, LANDFORMS PRODUCED BY).

In some cases, lakes actually exist in basins made of ice. In other cases, water masses may form within ice masses. Such occurrences are rare and are not very stable. Damming by ice masses is a more common phenomenon but is also likely to be relatively temporary. Glacial moraine (heterogeneous sedimentary deposits at glacier margins) is also responsible for the occurrence of dammed lake basins. The Finger Lakes of New York State are dammed by an end-moraine.

Ice-scour lakes, cirque lakes, and fjords

Ice sheets moving over relatively level surfaces have produced large numbers of small lake basins through scouring in many areas. This type of glacial rock basin contains what are known as ice-scour lakes and is represented in North America by basins in parts of the high Sierras and in west central Canada (*e.g.*, near Great Slave Lake). Tens of thousands of these lakes are found in the ice-scoured regions of the world. Many of them are interconnected with short streams and may contain narrow inlets. Characteristically, they may be dotted with numerous islands and sprawling bays. Many are comparatively shallow. Where they are particularly abundant, they may cover up to 75 percent of the total surface, as in Quetico canoe country of Minnesota.

Glacier scouring associated with the freezing and thawing of névé (granular snow adjacent to glacier ice) at the head of a glaciated valley may produce a deepened circular basin termed a cirque. These are found in widely scattered mountain locations. The action of glaciers in valleys can produce a similar type of basin, often occurring in series and resembling a valley staircase. Ice movement from valleys through narrow openings has produced another type of rock basin, known as glint lake basins, particularly in Scandinavian regions.

Piedmont and fjord (*i.e.*, a river valley that has been "drowned" by a rise of sea level) lakes are found in basins formed by glacial action in long mountain valleys. Excellent examples are found in Norway, the English Lake District, the European Alps, and the Andes. In North America, several regions contain this type of lake basin. In British Columbia, many good examples exist, the largest of which are the Okanagan and Kootenay systems. These are long, narrow lakes of substantial depth. In northwestern Canada, some of the largest lakes, including Lake Athabaska, Great Slave Lake, and Great Bear Lake, are of this type, although they are not found in the same type of mountainous terrain. These lakes, as well as the North American Great Lakes, resulted from the movements of large ice sheets that deepened existing valleys.

The Wisconsin (latest stage of Pleistocene glaciation) ice sheet was responsible for shaping the present Great Lakes system, which drains mainly eastward to the Atlantic through the St. Lawrence River, during its retreat. The principal stages in the history of these lakes have received much study, and several stages of retreat and advance of the ice sheet have been identified. Behind the lobes of the ice sheet, ice lakes developed that drained according to the modifications of pre-existing valleys for glacial action. As the mass of ice retreated far to the north, glacial rebound (uplift of the Earth's crust in response to removal of the loading by ice) caused a general tilting of the land surface; the new lake basins also contributed to the subsequent changes through their own erosional action.

The material comprising glacial moraines or glacial outwash may provide dams that confine postglacial waters. The Finger Lakes, in New York State, constitute one interesting group of this type. These lakes were formed through glacial scouring of existing valleys, which were blocked at both the northern and southern ends by morainic deposits.

A variety of basin types have been formed in the different types of glacial drift-deposits, including basins in morainic material, kettle lakes, channels formed by water movement in tunnels beneath the ice masses, and lake basins formed by thawing in permafrost. An interesting example of glacial action is the formation of giant's kettles; these are glacial potholes in the form of deep cylindrical holes. Their origin is still uncertain. Sand gravel, or boulders, are sometimes found in their bottom. The kettles vary from a few inches to several feet in diameter. Good examples are found in the Alps, Germany, Norway, and in the United States.

Formation of natural dams

Basins formed by fluvial and marine processes. Fluvial action in several forms can produce lake basins; the most important processes include waterfall action, damming by sediment deposition from a tributary (fluviatile dams), sediment deposition in river deltas, damming by tidal transport of sediments upstream, changes in the configuration of river channels (*e.g.*, oxbow lakes and levee lakes), and solution of subsurface rocks by groundwater.

This last mechanism has produced the well-known formations in the Karst region, in Yugoslavia, which include subterranean and surface cavities and basins in limestone. The term karstic phenomena is applied to similar cases in many parts of the world (see further CAVES AND CAVE SYSTEMS). Solution lakes in Florida (*e.g.*, Deep Lake) are also of this origin, as are Liinersee and Seewlisee, in the Alps. Other rock types susceptible to solution basin formation include gypsum and halite. Mansfeldersee in Saxony formed in this manner.

In some coastal areas, longshore marine currents may deposit sufficient sediment to block river outflows. This damming action may be of varying intensity, and it may also occur in lake regions, where such current action causes sediment deposition that leads to the formation of multiple lakes. Accumulation of organic plant material can also result in structures that produce lake basins; Silver Lake, Nova Scotia, evolved from damming by plant material. Structural formations of coral are another potential cause of damming.

Basins formed by wind action, animal activity, and meteorites. Wind action may lead to dam or dune construction or erosion and thus can play a role in lake-basin formation. The latter case has been demonstrated in North America; a number of basins in Texas and northward, on the plains east from the Rocky Mountains, are thought to have originated from wind erosion—at least in part. Moses Lake in Washington state was formed by windblown sand that dammed the basin.

Mammals have constructed lake-forming dams: the American beaver is highly skilled at this, and his activities in this connection have established him as a symbol of industriousness. Man has also been busy in this regard and is fully capable of producing lakes that would rival the largest of the more natural variety. Plans once proposed for the damming of the Yukon River in Alaska would, if carried through, result in the formation of a lake larger than Lake Erie in surface area. Other human activities, such as quarrying and mining, also have produced cavities suitable for lake formation.

The last major mechanism of basin formation is that due to meteoritic impact. Meteorite craters (*q.v.*) are best preserved in arid climates and are often dry for this reason. A few lakes are known in craters, however, including Ungava Lake, in Quebec. In many other cases, it has not been possible to definitely confirm that basins that have the appearance of meteorite craters have, indeed, been produced by meteorite impact. Controversial ones include the bay lakes of southeast North America.

TOPOGRAPHY OF BASINS

Lakes meet with both the atmosphere and the underlying material of their terrestrial basins and interact with each. The topography and configuration of the lake bottom and the nature of the bottom materials vary considerably. They are of sufficient importance to most lake processes to warrant recognition as basic lake characteristics.

The surface area of a lake can easily be determined by cartographic techniques, but lake-volume determinations require knowledge of lake depths. Throughout the world, lakes important enough to warrant study have been sounded, and many nations have completed comprehensive programs to determine the bathymetry of large numbers of lakes. Lake sounding involves traversing a lake to collect either point or continuous measurements of depth until an accurate survey is made. Modern sounding devices measure the time taken for emitted sound to return after reflection from the bottom, relying on a knowledge of the speed of sound in water. The more sophisticated of these also provide for detection of the depths of stratification in sedimentary materials on the lake bottom. The employment of laser devices from aircraft is a recent development that is based on the transmission of light beams with wavelengths that will penetrate water.

For more practical purposes, lake morphology is a stable characteristic. Shore erosion, sediment deposition and transfer, and other processes, however, including dredging by man, may significantly alter a lake's bottom topography and thus affect navigation, currents, and ecological factors, such as fish spawning grounds.

SEDIMENTS AND SEDIMENTATION

Lake sediments are comprised mainly of clastic material (sediment of clay, silt, and sand sizes), organic debris, chemical precipitates, or combinations of these. The relative abundance of each depends upon the nature of the local drainage basin, the climate, and the relative age of a lake. The sediments of a lake in a glaciated basin, for example, will first receive coarse clastics, then finer clastics, chemical precipitates, and then increasingly large amounts of biological material, including peats and sedges.

Clues to lake history

Geologists can deduce much about a lake's history and the history of the lake basin and climate from the sedimentary records on its bottom. A sediment core contains such clues as ripple marks caused by current or wave action, carbonaceous layers, and alternations of strata that include cold- and warm-water species of fossils, pollen, and traces of chemicals of human derivation. These data provide the basis for extensive documentation of lake history (paleolimnology). Some well-known historical events, such as major volcanic eruptions, the clearing of North American forests by early settlers as revealed by pollen concentrations, the first extensive use of certain heavy metals by industry, and nuclear explosions, provide reference points in the sediment record.

Many of the materials that are detrimental to the ecology of a lake—*e.g.*, excessive quantities of nutrients, heavy metals, pesticides, oil, and certain bacteria—are deposited in lake sediments by chemical precipitation or the settling of particulate matter. These materials are potentially available for regeneration into the lake water and must be considered in any planning for measures to abate lake pollution. Within the uppermost lake sediments, large volumes of interstitial water are often present. This water may have high concentrations of nutrients and other constituents and enhance the exchange potential with the lake proper.

Clastic sediments. Waters draining into a lake carry with them much of the suspended sediment that is transported by rivers and streams from the local drainage basin. Current and wave action along the shoreline is responsible for additional erosion and sediment deposition, and some material may be introduced as a result of wind action. Rivers and streams transport material of many different sizes, the largest being rolled along the riverbed (the bed load). When river water enters a lake, its speed diminishes rapidly, bed-load transport ceases, and the suspended load begins to settle to the bottom, the largest sizes first. Lake outlets carry with them only those materials that are too small to have settled out from the inflows or those that have been introduced adjacent to the outflow. Because dynamic processes that keep materials suspended are generally more active near the shore, lake sediments are usually sorted by size; the rocks, pebbles, and coarse sands occur near shore, whereas the finer sands, silts, and muds are, in most cases, found offshore.

Clastic material over most of a lake basin consists principally of silts and clays, especially away from shores and river mouths, where larger material is deposited. Clays exist in a variety of colours, black clays containing large concentrations of organic matter or sulfides and whiter clays usually containing high calcium carbonate concentrations. Other colours, including reds and greens, are known to reflect particular chemical and biological influences.

Organic sediments are derived from plant and animal matter, Forna is recognizable plant and animal remains, *äfja* finely divided remains in colloidal suspension, and *gyttja* is a deposit formed from *äfja* that has been oxidized. Rapid accumulation of organic matter in still lakes is not uncommon; in the English Lake District, five metres (15 feet) of lake sediment of organic origin accumulated in 8,000 years. Pollen analysis has been used to accurately decipher climatic conditions of the lake in the past.

Varved deposits (*q.v.*) are the product of an annual cycle of sedimentation; seasonal changes are responsible for the information. Varves are a common feature in many areas and especially so where the land has received meltwaters from ice sheets and glaciers. The deposits consist of alternating layers of fine and coarse sediments.

Coarse clastic materials seldom are larger than boulders (25 centimetres [ten inches]), and the type of material in sizes larger than silt and clay often reveals its source. Materials along lakeshores can usually be traced back to a particular eroded source within the local drainage basin, and the distribution of this material provides evidence of the predominant current or wave patterns in the lake.

Volcanic ash is deposited downwind from its source. Ash from volcanic activity during the Pleistocene Epoch can often be dated and used as a stratigraphic marker. Lakes throughout the northwestern United States contain some of the best examples (the Mazama ash), and one deposit in the central United States, called the Pearlette ash deposit, occurs in beds as thick as three metres (ten feet).

Deposition of salts

Chemical precipitates. The major chemical precipitates in lake systems are calcium, sodium, and magnesium carbonates and dolomite, gypsum, halite, and sulfate salts. Calcium carbonate is deposited as either calcite or aragonite when a lake becomes saturated with calcium and bicarbonate ions. Photosynthesis can also generate precipitation of calcium carbonate, when plant material takes up carbon dioxide and bicarbonate and raises the pH above about 9 (the term pH is a measure of the acidity or alkalinity of water; acid waters have a pH of less than 7, and the pH of alkaline waters range from 7 to 14).

Dolomite deposition occurs in very alkaline lakes when calcium carbonate and magnesium carbonate combine. Recent dolomites have been found in Lake Balkhash, in the Soviet Union. In many saline lakes, gypsum deposition has occurred; Lake Eyre, Australia, is estimated to contain more than 4,000,000,000 tons of gypsum. For gypsum to be deposited, sulfate, calcium, and hydrogen sulfide must be present in particular concentrations. Hydrogen sulfide occurs in deoxygenated portions of lakes, usually following the depletion of oxygen resulting from decomposition of biological material. Bottom-dwelling organisms are usually absent.

Lakes that contain high concentrations of sodium sulfate are called bitter lakes, and those containing sodium carbonate are called alkali lakes. Soda Lake, California, is estimated to contain nearly 1,000,000 tons of anhydrous sulfate. Magnesium salts of these types are also quite common and can be found in the same sediments as the sodium salts. Other salts of importance occurring in lake sediments include borates, nitrates, and potash. Small quantities of borax are found in various lakes throughout the world. Mono Lake, in California, due to its high alkalinity is devoid of any life.

The gradual increase of sediment thickness through time may threaten the very existence of a lake. When a lake becomes shallow enough to support the growth of bottom-attached plants, these may accelerate the extinction of a lake. In several European countries, steps are being taken to restore lakes threatened by choking plant growth. Lake Hornborgesjon, Sweden, which has been prized as a national wildlife refuge, became the subject of an investigation in 1967 that may lead to a program involving the cutting and removal of plants that have seriously reduced the area of exposed water. It is expected that the lake level may be raised at least one metre above the present mean summer level. Lake Trummen, also in Sweden, has been treated by dredging its upper sediments. In Switzerland, Lake Wiler (Wilersee) has been treated by the removal of water just above the sediments during stagnation periods.

II. Lake waters

CHEMICAL COMPOSITION

Although the chemical composition of lakes varies considerably throughout the world, due to the varying chemistry of the erosion products of different lake basins, in most cases the principal constituents are similar. Human influences have also contributed greatly to the chemical makeup of lakes, and, although industrial effluents vary from lake to lake, many of the chemical effects of human activities are similar throughout the world. Another source in the chemical balance of lakes is the dissolved and suspended material contained in precipitation. Again, human activities have been responsible for steadily increasing concentrations of this input.

Concentration of salts in lake water

Salinity, nutrients, and oxygen. Salinity is the total concentration of the ions present in lake water and is usually computed from the sodium, potassium, magnesium, calcium, carbonate, silicate, and halide concentrations. Several important bodies of inland waters, often called inland seas, have very high salinities. Great Salt Lake, in Utah, has a salinity of about 200,000 milligrams per litre, as compared to Lake Superior's value of about 75 and an estimated mean for all rivers of 100 to 150. These ions are steadily introduced to lakes from rivers and rainwater, where they concentrate because of the evaporative loss of relatively pure water.

Where inflowing rivers erode igneous rocks, lake salinity values are relatively low, but, where soluble salts are available for erosion, salinities are relatively high. In general, it has been found that, of the cations (positively charged ions), calcium concentrations are highest, followed by magnesium, sodium, and potassium, in that order. Of the major anions (negatively charged ions), carbonate is usually the most abundant, followed by sulfate and chloride.

Other inorganic ions, though present in smaller concentrations, are of great importance. In particular, the nutrients (especially phosphate, nitrate, and silicate), heavy metals (*e.g.*, mercury, manganese, copper, lead), and polychlorinated hydrocarbons (DDT, for example) have attracted recent interest because of their role in ecological problems. Although sources of nutrients and mercury exist that are not directly related to human activities, budget studies and studies of the historical records available in sediment cores clearly reveal the great impact of human disposal of these constituents in lakes. Rainfall and dry fallout are small but significant chemical inputs to lakes. The release of gases and particulate matter into the atmosphere from factories and similar sources has increased dramatically in recent years, with consequent alterations in the chemistry of rainwater. It has been estimated, for example, that 16,000 tons of nitrogen, about 8 percent of the total from all sources, is introduced annually to Lake Erie from atmospheric action.

The substance of most interest in lakes is oxygen; once introduced to the lake water, its concentration is subject to factors within the water. Biological production (photosynthesis) releases oxygen into the water, while biological decay consumes it. Various chemical reactions within the lake system also affect the concentration of dissolved oxygen. The main source is the passage of oxygen through the air–water interface, which is affected principally by the lake temperatures; at low temperatures the partial pressure of dissolved oxygen in water is reduced. Consequently, during cold seasons, especially when vertical mixing is greatly enhanced due to lack of thermal structure and increased wind stirring, lakes are replenished with oxygen. In the warmer seasons, although surface waters may remain more or less saturated and even supersaturated, the concentrations are lower. Beneath the surface, oxygen consumption due to biological decay may cause serious depletion. Oxygen depletion also occurs near the bottom due to processes at the mud–water interface, many of which are still inadequately explained.

In winter months, a rapid formation of ice or the establishment of strong winter thermal stratification may significantly inhibit the replenishment of oxygen. Where ice cover lasts for long periods, a loss of oxygen at the mud–water interface may have repercussions for the whole lake, particularly if density currents cause significant vertical transport.

In tropical regions, where the winter replenishment mechanism (turnover) is absent, there is great reliance on the occasional occurrence of cold spells or on significant nighttime cooling to promote oxygen replenishment. Deep lakes in these regions are often anoxic (lacking in oxygen) in the deeper portions.

At any particular time, lake waters or waters entering a lake may have a biological or chemical potential for oxygen utilization. Measurements of this are termed BOD (biological oxygen demand) or COD (chemical oxygen demand). These concepts are used as partial indicators of the quality of waters being introduced to a lake.

Lakes that have a vertical salinity gradient strong enough to prevent winter turnover will usually be deoxygenated at depths where the vertical diffusion of oxygen is less than the oxygen demand. Such lakes are termed meromictic.

Carbon dioxide. Another gaseous substance of great

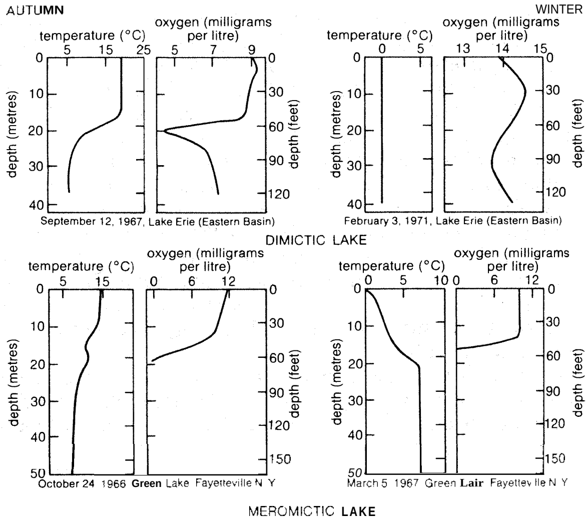


Figure 1: Seasonal variation of temperature and dissolved oxygen in dimictic (having two circulation periods annually) and meromictic (undergoing incomplete circulation at the fall overturn) lakes (see text).

importance that is exchanged with the atmosphere at the surface is carbon dioxide. Photosynthesis requires the presence of carbon dioxide, and it is released during biological breakdown.

Relation of carbon dioxide to pH and carbonate solubility

Carbon dioxide is very soluble in lake water; it forms carbonic acid, which dissociates and raises the concentration of hydrogen ions (lowering the pH). The relative proportions of bicarbonate, carbonate, and free carbon dioxide depend upon the pH. At high values of pH, carbonate ions will predominate; at low values, free carbon dioxide and carbonic acid will predominate.

Various carbonates (particularly sodium, calcium, potassium, and magnesium) are important to the carbon dioxide system. Increased pressure of carbon dioxide in the system increases the solubilities of these carbonates. In some cases, photosynthetic activity results in precipitation of certain carbonates. The entire carbon dioxide system and its behaviour at various pH values is very complex but can be interpreted from historical knowledge of lake sediments.

In waters that are neither very acidic (pH much less than 7) nor very basic (pH much greater than 7 but less than 14), the carbon dioxide system serves as a buffer, because, within limits, a change in pH will cause a shift within the system that ultimately serves to offset the pH change. Consequently, most lakes have a pH between 6 and 8. Some volcanic lakes are extremely acid, however, with pH values below 4, and some lakes with very high pH values, such as Lake Nakuru, Kenya, also occur in nature.

Sulfates, nitrates, and phosphates. Sulfate usually occurs as a principal ion in lake waters. Under anaerobic conditions in which bacteria persist in the oxidation of biological material, hydrogen sulfide is produced. When anoxic conditions exist in the deep waters just above the sediments, and the water is acidic enough to precipitate the iron present, hydrogen sulfide occurs. The characteristic and unpleasant odour of this gas is often popularly identified with the "death" of a lake. Big Soda Lake, Nevada, is extremely rich in this substance.

Nitrogen and its various compounds form another complex system in lakes, appearing as free nitrogen in solution, organic compounds, ammonia, nitrite, and nitrate. Sources of nitrogen compounds include influents to the lake (the most important source), fixation in the lake, and precipitation. Losses are experienced mainly through effluents but also by denitrification, sediment formation, and loss to the atmosphere.

Orthophosphate and various organic phosphates are the most important phosphorous compounds in lakes. Phosphates and nitrates are heavily consumed in the upper portion of lakes during periods of high productivity of phytoplankton. Increased concentrations occur in deeper portions due to decay of falling biological material and regeneration from the sediments, especially during anoxic conditions or stormy periods in shallow lakes. As limiting nutrients in many lake productivity cycles, phosphates and nitrates are often identified as controllable elements in situations where abatement is necessary to control eutrophication. Carbon is also a necessary constituent for production and in some cases can be the limiting component. Because carbon is less easily controlled and not often limiting, however, phosphates are most frequently named as substances to be reduced in effluents from industry and municipalities.

Silica also is present in lake waters, and, as with the other nutrients, it is introduced in influents and to some extent from the sediments. The production of diatom blooms is a major process for reducing silicate concentrations. Within this context, silica can also be regarded as a limiting nutrient.

THERMAL PROPERTIES

Basic physical data

Pure water freezes at 0° C (32" F), boils at 100" C (212" F), and has a latent heat of evaporation of 539.55 calories per gram, a latent heat of sublimation (ice) of 679 calories per gram, and a specific heat of 1.01 calories per gram, per ° C, at 0° C. The temperature of maximum density at atmospheric pressure occurs at 3.94" C (39.09" F). At the freezing point, ice has a lower density than water. For natural waters with high salinities, such as the oceans and inland seas, each of the values above is significantly altered. In most lakes, however, they are quite representative.

The density of water increases at pressures above one atmosphere (the pressure at sea level). Thus, pure water at 10" C (50" F) has a density of 0.9995 at one atmosphere and 1.0037 at the pressure existing at a lake depth of 1,000 metres (3,000 feet). Water raised from great depths to conditions of lower pressure experiences adiabatic cooling (without significant heat exchange with surrounding water), but there are very few lakes in which this factor can be of much significance.

Vertical mixing and overturn. It is useful to know how the temperature of maximum density changes with depth (*e.g.*, from 3.94" C at the surface to 3.39" C at 500 metres depth [38.10° F at 1,500 feet]). The fact that the temperature of maximum density of most lake waters is close to 4° C (39" F), whereas ice forms at temperatures close to 0° C, is of considerable importance. As lakes cool down to 4° C in response to surface cooling, vertical mixing takes place. When density increases with depth, the lake is said to be stable. Unstable conditions exist when density decreases with depth. Cooling at the surface to temperatures below 4° C establishes stability based on a negative thermocline (a positive thermocline is a vertical decrease in temperature with depth), because density will increase with depth. Ice then forms at the surface, enabling liquid water to exist beneath the ice in lakes, unless they are shallow enough to freeze to the bottom.

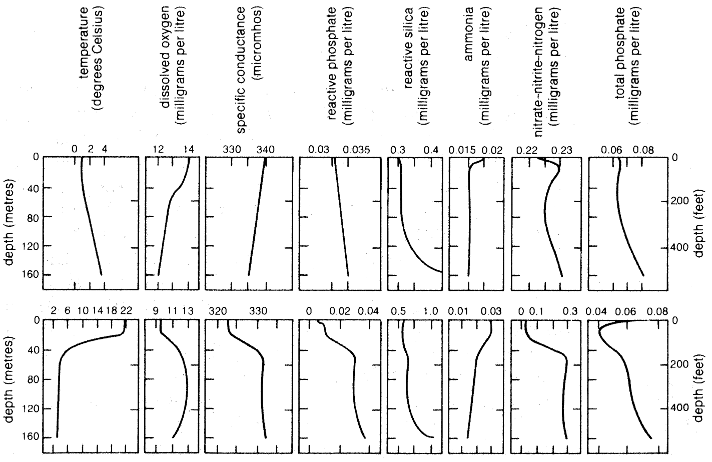

Figure 2: Distribution of some physical and chemical variables in central Lake Ontario in (bottom) July 1969 and (top) June 1970.

During the warming season, after ice has melted, heating increases the density of the surface waters, causing them to sink until stability is achieved. When surface heating proceeds above the temperature of maximum density, this process ceases, and the vertical thermal structure maintains and strengthens its stable condition, based on a positive thermocline. Turnovers tend to be seasonal.

Dimictic, monomictic, holomictic, and meromictic lakes

Mixing due to cooling or warming processes that increase the density of surface waters sufficiently to cause them to sink results in what is termed circulation, or overturn, of lake waters. Lakes that cool to below 4" C in winter experience two turnover periods, as just described, and are called dimictic lakes. Most lakes in temperate regions fall into this category. Lakes that do not cool to below 4" C undergo overturn only once per year and are called warm monomictic. Lakes that do not warm to above 4° C also experience only one overturn period per year and are called cold monomictic. There are many examples of the former, including lakes in the tropical regions and generally as far north as about 40". The cold monomictic type, however, is less common but can be found at high latitudes and at high aititudes (in the Alps, for example).

All the types described that circulate at least once throughout are called holomictic. It is possible, however, for lakes to be stable despite the thermal processes that normally induce overturn due to the existence of a positive salinity gradient with depth (chemocline). This type is called meromictic, and, in those cases where stability is permanent in at least part of the lake, the deep waters do not experience overturn and consequently are deoxygenated. Three principal origins of meromixis have been recognized. Ectogenic meromixis results from either the intrusion of seawater into a lake, as in the case of flooding from an unusually high sea level (*e.g.*, Hemmelsdorfersee, in Germany), or the introduction of freshwater through land drainage and precipitation to a saline lake (*e.g.*, Soda Lake, Nevada). Crenogenic meromixis is due to the introduction of saline water by springs, and biogenic meromixis is due to the uptake of salts from the lake sediments. North American examples include Lake Mary, Wisconsin. and Sodon Lake, Michigan.

A strong vertical salinity gradient that exists in the upper portion of a lake will affect the thermal structure by inhibiting the downward mixing of heat. In holomictic lakes, however, the downward mixing of heat due primarily to wind action usually compresses or concentrates the thermocline until it essentially separates an upper layer (epilimnion) from a lower layer (hypolimnion), each possessing weak or nonexistent vertical thermal gradients. The thermocline normally begins to grow at the beginning of the warming season. As summer passes and autumn commences, it intensifies and deepens. The onset of the cooling sees the beginning of the decay of the thermocline from above, although it usually continues to deepen until it is completely destroyed. The process just described is commonly found in lakes in temperate regions and is a seasonal phenomenon. During any period of strong warming, one or more shallower thermoclines may be observed to develop and move downward to the seasonal thermocline.

The heat budget of lakes. The heat budget of a lake includes several major factors: net incoming solar radiation, net exchange of long-wave radiation emitted by the lake surface and the atmosphere, transfer of sensible heat at the surface interface, and latent-heat processes. Those processes that are usually of much smaller importance include net inflow and outflow of heat advected by streamflow, precipitation, and groundwater flow, conduction from terrestrial heat flow, and dissipation of kinetic energy. In some cases, however, river inflow may be of more importance, such as where flow is from a nearby glacier or where the volume inflow is a significant fraction of the lake volume. Within a large lake the heat-budget considerations for a particular location must also take into account the local advection of heat within the lake by currents.

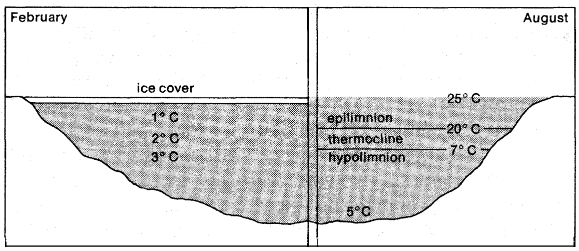

Figure 3: Temperature distribution in lakes in the middle latitudes of North America in winter and summer.

Incoming solar energy varies seasonally and with the latitude and is greatly influenced by cloud cover. The fraction that is reflected away from the lake surface depends upon the solar angle, the turbidity of the atmosphere, and the wave state, or surface roughness. In middle latitudes this ranges from about 6 percent in summer months to about 14 percent in winter.

The amount of radiation emitted by the lake surface is proportional to the fourth power of the surface temperature, whereas the radiation emitted by the clouds and atmosphere overlying the lake depends primarily upon the amount and height of the clouds and the temperature and moisture content of the atmosphere near the lake surface.

The fluxes of sensible heat and moisture at the lake surface are of great importance yet are still poorly understood. They depend upon the vertical gradients of temperature and vapour pressure above the water, respectively, and upon the factors that influence the transfer processes, such as wind and atmospheric stability. The transfer of sensible heat may be either into or out of the lake surface, usually on a seasonal basis but also sometimes on a diurnal basis. It is also possible but less likely for condensation to occur on a lake surface.

Heat flow through the bottom of lakes is normally of small significance, but exceptions exist. In a very deep lake where low rates of heating are important, such as Lake Baikal, Soviet Union, the results may be detectable. In some ice-covered lakes where other sources of heating are small, heat flux through sediments also has been shown to be significant.

The dissipation of wind energy that has been transferred to water movements is quite insignificant, as is the effect of heat transfer due to chemical and photosynthetic processes.

In latitudes and altitudes where ice is a factor, the latent heats of fusion and of evaporation of ice must also be considered within any heat-budget considerations. Heat-balance studies have been performed for lakes that are always ice covered. Solar radiation is often an important factor where ice thickness and consistency permits penetration. The heat balance of the ice is often difficult to assess, as long-wave radiation and evaporation factors are not easily measured and are very important. The exchange of sensible heat may not be large during summer months in these cases but is likely to be significant in the colder months. Several lakes that are ice covered have been shown to be meromictic; two examples are Lake Tuborg, Ellesmere Island and Lake Bonney, Antarctica.

Heat balance of two representative lakes

Heat-balance measurements or estimates have been made for many lakes throughout the world. Results show that the difference between the highest and lowest heat content for each lake varies from around 5,000 calories for high and low latitudes to around 45,000 calories for some midlatitude lakes.

The relative importance of each of the major terms of the heat budget is shown by data for two North American lakes: Lake Ontario, a large, deep, middle-latitude lake; and Lake Hefner, a relatively small, shallow lake in Oklahoma. The energy unit frequently employed is the langley (one gram calorie per square centimetre), and the figures given are approximate monthly means of langleys per day. Net solar radiation input to Lake Ontario varies from 80 to 600 (Lake Hefner varies from 200 to 600), midwinter to midsummer. Net losses due to long-wave radiation from Lake Ontario are nearly 100 throughout the year (Lake Hefner varies from **100** to **200).** Evaporation losses for Lake Ontario vary from **250** in midwinter to slightly negative values in early summer (Lake Hefner varies from **450** in late summer to **150** in spring). Conduction of heat from the surface of Lake Ontario varies from **250** in winter to about minus **100** in summer (Lake Hefner varies considerably from 80 to **—80** for the same time interval).

Heat added to a lake at the surface is usually mixed mechanically downward as a result of wind action. This process keeps the upper portion of a lake relatively uniform thermally. Consequently, a thermal gradient (thermocline) becomes established between the upper mixed layer (epilimnion) and the deep portion of the lake (hypolimnion). In shallow lakes or shallow portions of large lakes, the thermocline will eventually intercept the lake bottom so that no hypolimnion exists. Normally, as the heating season progresses, the thermocline intensifies and deepens. Secondary thermoclines may develop in the epilimnion, and these will migrate downward to the main seasonal thermocline. On very warm, still days, a thin surface layer may store heat before a mixing episode transfers heat downward. When the cooling season commences, the mixing that tends to destroy the thermocline is enhanced by vertical convection. If the cooling continues until the entire thermocline is eliminated, the lake becomes essentially isothermal and no longer exhibits the characteristics of a two-layered system.

When a lake is stratified, the most important process for downward transfer of heat to the hypolimnion is through eddy conduction. The coefficient of eddy conductivity is determined empirically and varies substantially from lake to lake. Mixing processes are generally more active in coastal areas, so that isotherms can be expected to slope downward toward shore. In large, relatively unprotected lakes, wind stress at the surface causes convergence or divergence or both of shallow waters along coastlines. Isotherms will slant upward toward the shore, and hypolimnion water may even become exposed at the surface. These occurrences are of great importance with regard to the distribution of heat within stratified lakes.

Thermal pollution in lakes

Heat introduced to lakes in large quantities, as a waste product of cooling processes in power-generating plants and other industrial concerns, is presently viewed with some concern as a pollutant, especially in small lakes. If the heat is injected at the surface it will spread initially according to the momentum of the influent and the speed and direction of ambient surface currents. When the initial momentum is sufficiently dissipated, the heat will spread mainly as a consequence of turbulent mixing processes. Throughout these events, substantial losses of heat to the atmosphere may occur, so that the full effects of the thermal input are not borne solely by the lake. Temperature values at the surface, adjacent to the influent-heat source, may be raised to a very high level—as much as several centigrade degrees. Under certain conditions fish-activity tolerances may be exceeded, and undesirable algae and plankton production may be stimulated.

If waste heat is not released at the surface but is diffused over a large depth range or injected at depth, the large local-surface-temperature problem is avoided. Losses to the atmosphere in this case, however, are also greatly reduced, and the net heat input to the lake as a whole is much greater. Over a long period, this may prove to be more detrimental to the general ecology than near-surface injection.

III. Lake hydraulics

CURRENTS

The principal forces acting to initiate water movements in lakes are those due to hydraulic gradients, wind stress, and factors that cause horizontal or vertical density gradients. Lakewater movement is usually classified as being turbulent.

Hydraulic effects are frequently the result of inflows and outflows of water. These may be substantial and continuous or weak and sporadic; in terms of the ratio of the volume of the inflow or outflow to the lake volume, the latter is the most frequently observed situation.

The stress of wind moving over the lake surface causes a transport of water within the lake, as well as the movement of energy downwind through the mechanism of surface waves. The wind is therefore one of the most important external forces on a lake. It can be relatively consistent in speed and direction, or it can be highly variable in either or both.

Pressure **gradients.** Water movements can occur as a result of internal pressure gradients and from density gradients caused by variations in temperature, sediment concentration, or the concentration of dissolved substances. Surface water in lakes can become more dense than underlying water either by cooling or heating, because the temperature of maximum density for pure lake water is about 4° C **(39" F).** Water entering a lake from rivers with a high concentration of dissolved substances will sink to a lake level of similar density. These movements are both horizontal and vertical, but the net effect is downward, if not vertical, motion.

Horizontal pressure gradients can result from many different processes that act to produce density gradients. One example is the situation of solar heating in a shallow nearshore region, where the heat is committed to the warming of a relatively small volume of water. This produces a water of lower density than the near-surface water of an adjacent deep region, where the heat is spread throughout a greater volume. Consequently, the pressure gradient force will act to move the warmer water offshore and to replace it from below with cooler water.

Influence of the Coriolis effect

Lake currents are the result of complex interactions of forces, but in many cases a small number of particular forces dominate. In the case of horizontal flow in the absence of horizontal pressure gradients, assuming no friction, water set in motion will curve to the right in the Northern Hemisphere because the Earth rotates from west to east. This effect is called the Coriolis force, and it will continue to influence water motion until there is a balance with the centrifugal force. This movement causes free-floating markers to move in an elliptical manner with a period that depends upon the latitude. In Lake Ontario, for example, it is about **17** hours. Where a dominating pressure gradient exists, the balance of the pressure-gradient force with the Coriolis force results in the so-called geostrophic flow, at right angles to the pressure gradient, with low pressure on the left (Northern Hemisphere). These conditions are most nearly realized only in very large lakes and in the oceans.

In those small lakes where hydraulic effects dominate, steady flow conditions may be achieved through balance with friction. This situation is commonly encountered in rivers, and relationships exist between mean current speed and the slope and mean depth of the river or narrow lake. These are called gradient currents and occur following situations where the wind or atmosphere pressure gradient causes a tilting of the lake surface (denivellation). In cases where the Coriolis force is a significant factor, the flow down a lake will tend to move toward the right (in the Northern Hemisphere). The development of a deeper countercurrent to the left will occur to compensate for the piling up of water on the right side.

Horizontal pressure gradients will be important in lakes where there are significant inflows of water with markedly different density from ambient lake density or where significant differential surface heating occurs.

Wind stress. Currents resulting from wind stress are the most common in lakes. Considerable research is still underway into the mechanism of transfer of wind momentum to water momentum. The stress on the lake is proportional to some power of wind speed, usually taken to be **2,** although it evidently varies with wind speed, wave conditions, and atmospheric stability. In large, deep lakes, away from the boundaries, where wind-stress effects may be balanced by Coriolis-force effects, theory suggests that the surface current will move in a direction **45°** to the right of the wind and that deeper currents are progressively weaker and directed further to the right. The depth at which flow is opposite to the wind direction is effectively the depth below which there is no influence from the wind. This depth, designated D, can theoretically occur at about 100 metres (300 feet) in large, deep, midlatitude lakes. Observations show varying degrees of fidelity to theory because of complications from coastal effects and thermal stratification.

In coastal regions, if water depth is a significant fraction of or greater than D, winds blowing parallel to the shore will transport water either onshore or offshore. In the latter case, where the coast is to the left of the wind flow (Northern Hemisphere), the water driven offshore is replaced by cooler, deeper water (upwelling).

Internal waves and Langmuir circulation. Under stratified conditions a strong thermocline will essentially separate a lake into two layers. Shearing forces that develop between these layers cause a motion, termed internal waves, that may serve to directly dissipate a substantial portion of a lake's kinetic energy and act as a coupling between motion in the epilimnion and hypolimnion. A great range of periodicities is observed in the oscillations of the thermoclines, particularly in large lakes. Internal seiches, which are responsible for relatively long-period internal waves, are discussed later.

A small-scale circulation phenomenon that has aroused considerable attention on lakes is Langmuir circulation. On windy days, parallel "streaks" can be observed to develop on the water surface and exhibit continuity for some distance.. These streaks may be caused by convergence zones where surface froth and debris collect. Langmuir circulation thus appears to be a relatively organized mixing mechanism wherein sinking occurs at the streaks and upwelling occurs between the streaks. Under favourable circumstances, this appears to be a key process for mixing heat downward in lakes.

SURFACE WAVES

Wind blowing over a calm lake surface first produces an effect that may appear as a widely varying and fluctuating ruffling of the surface. The first wave motion to develop is relatively regular, consisting of small, uniformly developed waves called capillary waves. These are quite transient, dissipating rapidly if the wind dies away or developing to the more commonly observed and more persistent gravity waves.

Energy will be continually fed to the waves by the frictional drag of the air moving over the water and by the direct force of the wind on the upwind face of the waves. The latter effect occurs only while the waves move more slowly than the wind. Pressure differences at the air–water interface also contribute energy to surface waves. Energy losses occur due mainly to turbulence in the water and, to a smaller extent, to the effects of viscosity.

Growth and movement of waves

Waves will continue to grow as long as there is a net addition of energy to them. Their height will increase as a function of wind speed and duration and the distance over which it blows (fetch). Most lakes are so small that fetch considerations are unimportant. Studies in larger lakes, however, have shown that the height of the highest waves are related to the fetch. In these lakes, waves as high as several metres are common, although waves of about seven metres (23 feet) are the highest to be expected. Wave heights in a given portion of a lake may vary considerably, due to interactions that suppress some waves and amplify others. As waves develop, their lengths increase, even after their height has stopped increasing. The phenomenon of swell, commonly observed in the oceans, is not truly realized, even in the largest lakes.

Waves travel in the same direction as the wind that generated them and at right angles to their crests. If they meet a solid object rather than a sloping beach, much of their energy will be reflected. If they enter shallow water obliquely, they are refracted. Wave speed, for waves longer than four times the depth of the water, is approximately equal to the square root of the product of the depth and the gravitational acceleration. For waves in relatively deep water, the wave speed is proportional to the square root of the wavelength.

As wave height increases, the sharpening of the wave crest may result in instability and a breaking off of the crest, a process hastened by the wind. This results in the familiar whitecaps. Waves that run ashore break up in surf. The wave height first decreases slightly, then increases, and the speed decreases, and eventually the wave form disappears as it crumbles into breakers. These can be plunging forms, in which the top curls right over the forward face, or of the spilling type, in which the crest spills down the forward face. A particular wave may break several times before reaching shore.

SEICHES

Cause and characteristics. If a denivellation, or tilting of a lake's surface, occurs as a result of a persistent wind stress or atmospheric pressure gradient, the cessation of the external forcing mechanism will result in a flow of water to restore the lake level. The flow would be periodic and uniform with depth, except for the damping effects of the lake-bottom friction and internal turbulence. Because of this, each successive tilt of the lake surface in the opposite direction occurs at a level slightly less than the previous one. The oscillation proceeds, moving the water back and forth until damping levels the water or until wind and pressure effect another tilt. This process is seiching; the lake oscillation is a seiche. The basic seiche has a single node, but harmonics of the oscillation occur, with several nodes being possible.

Seiche periods

The period of the uninodal seiche can be estimated from a formula that equates it to twice the length in the direction of the tilt, divided by the square root of the product of the mean lake depth and the gravitational acceleration.

Seiches have been noted, recorded, and studied for hundreds of years. Lake Geneva, Switzerland, was one of the first lakes to be studied in connection with seiching; it

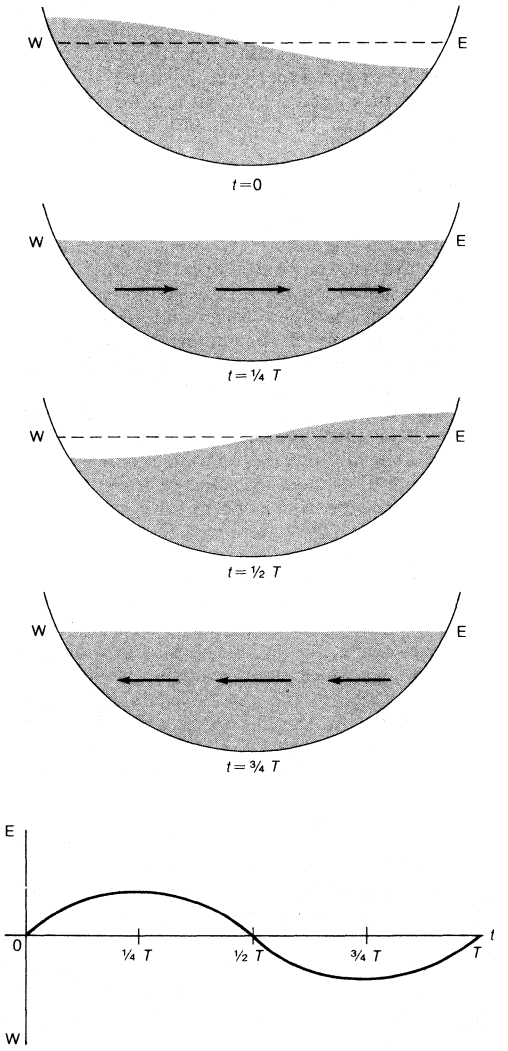

Figure 4: Four phases of elevations and currents. Below, time graph of current at centre of lake (*t* is time and T is seiche period; see text).

has an observed uninodal period of about 74 minutes and a binodal period of about 35 minutes. The observed uninodal periods of Loch Treig and Loch Earn, Scotland; Lago di Garda, Italy; Lake Vetter, Sweden; and Lake Erie, North America, are approximately nine, 14.5, 43, 179, and 880 minutes, respectively.

Long, relatively narrow lakes that are exposed to a predominance of wind flow along their major axes are most likely to exhibit so-called longitudinal seiches. Transverse seiching can occur across the narrower dimension of a lake; that observed in Lake Geneva, for example, has a period of about ten minutes.

The height of the denivellation depends upon the strength and duration of the forcing mechanism, as well as on the lake size and dimensions. In small lakes, level changes of a few centimetres are common, whereas, in the Great Lakes, intense storms can produce changes as great as two metres (seven feet). If the disturbance causing the tilting moves across the lake at close to the speed of the shallow-water wave speed, a profound amplification can occur, with possible disastrous consequences.

True tides that result from the gravitational effects of the Moon and Sun are rarely measurable in lakes, but small values of tidal components occasionally have been discerned.

Internal seiches. Internal seiching results from thermal stratification. The layers separated by the thermoclines oscillate relative to one another. Observed uninodal periods for Loch Earn, Lake Geneva, Lake Baikal, and Lake Cayuga (New York) are approximately 16, 96, 900 (binodal), and 65 hours, respectively.

Because hypolimnion water is very different from epilimnion water with regard to both thermal and biological characteristics, the massive movements of water and the turbulent exchanges that can occur during internal seiching are very important. Substantial portions of the bottom of shallow lakes can experience periodic alternation of exposure to hypolimnetic and epilimnetic water, and hypolimnetic water can be periodically exposed to the surface.

EFFECTS OF WAVE AND CURRENT ACTION

Changes in the coastline

Shore erosion and coastal features. In a lake's early stages of existence, its shore is most susceptible to changes from wave and current action. As these changes occur, there is a tendency over time to an equilibrium condition—a balance between form and processes that depends upon the nature of the materials present (*e.g.*, the size of sand and gravel present). The effectiveness of waves in the erosion process depends in part upon the depth and slope of the lake bottom. Where the shore consists of a shear cliff adjacent to deep water, wave energy will be reflected away without much erosional effect. The refraction of waves in zones of irregular coastline tends to concentrate wave energy at some locations and dilute it in others. Thus, features extended out into the lake will receive more wave energy, and the tendency is to smooth out an irregular coastline. Other net effects of shore erosion are an increase in the surface area of a lake and a reduction in its mean depth.

As erosion takes place, the distribution of erosion products results in transport of finer material offshore. The resulting terrace is called the beach in its above-water manifestation and the littoral shelf where it is below water. Landward, beyond the beach, a wave-cut cliff is usually found. The steeper slope that often separates the littoral shelf from the benthos (bottom) zone in the central part of the lake is called the step-off by some limnologists.

Water movement directed at an angle to the coastline will result in the generation of currents along the shore. Erosion products will then be transported down the coast and may be deposited in locations where transport energy is dissipated due to movement around a bend or past an obstruction. A buildup of such material is called a spit. If a bay becomes completely enclosed in this way, the spit is called a bar.

Water in very shallow lakes that are subjected to strong winds may be piled against the lee shore to such an extent that counter currents will develop from along the lee shore around each side of the lake. The cutting effects of these currents are known as end-current erosion and may characteristically alter the shape of a lake frequently subjected to winds from a particular direction.

Bottom morphology. The bottom morphology of a lake can be greatly influenced by deposition of sediment carried by inflowing rivers and streams. Although this process can be modified by wave and current action, most lakes are sufficiently quiet to permit the formation of substantial deltas. In very old lake basins the relief may become so extensively decreased due to the great buildup of deltaic deposits and the long-term effects of river widening, that deposition on the outer portions of a delta will fail to balance the effects of wave erosion. A delta, in these circumstances, will begin to shrink in size (see further RIVER DELTAS).

Problems with artificial lakes

It is very important to understand lake processes that affect the basin morphology and to be able to predict their trends and their impact on human activities. Increasingly, man is imposing his ability to change natural events in lakes, and he has often encountered problems by not anticipating a lake's reaction to his projects. The actual creation of a lake by damming a river is a major undertaking of this type. One recent example is Lake Diefenbaker, in Saskatchewan. In this region of prairie farmland, the banks of the new lake are extremely vulnerable to erosion, and planners have had to contend with the consequences of bank cutting and infilling of the basin. There are many examples of lesser engineering undertakings that have had to face the consequences of a lake's reaction. The building of jetties or breakwaters, for example, may interfere with natural circulation features. In some cases this has resulted in the reduction of flow past a harbour and increase in flow past a previously stable shoreline, with the result that the harbour has filled in or been blocked by sediment deposition, while the stable shoreline has become badly eroded (see further BEACHES).

IV. The hydrologic balance of the lakes

THE WATER BUDGET

Importance of water-budget studies

The role of lakes within the global hydrologic cycle has been described earlier. Lakes depend for their very existence upon a balance between their many sources of water and the losses that they experience. This so-called water budget of lakes is important enough to have warranted considerable study throughout the world, with each lake or lake system possessing its own hydrologic idiosyncracies. Aside from being of scientific interest, water-budget studies serve to reveal the dependence of each lake on particular hydrologic factors, thus enabling better management practices. These may include restrictions on water utilization during drought conditions, dike construction and evacuations prior to flooding, control of water levels to ensure efficient power production, and major decisions associated with diversions of watercourses in order to enhance water-quantity- and water-quality-management activities.

Often, man is able to react to predicted imbalances in the hydrologic budget, although he is usually unable to influence the basic natural factors that cause the imbalances. Precipitation and evaporation, for the most part, are uncontrollable, although some advances have been made in evaporation suppression from small lakes through the use of monomolecular surface films. Groundwater flow is not controllable, except where highly restricted flow can be tapped. Rivers and streams, however, can be subjected to regulation by well-established practices through the use of dams, storage reservoirs, and diversions. It is mainly through these controls that efforts are made to make the most efficient usage of water as a resource.

When man takes steps to alter elements of a basin's water budget, careful consideration must be given to the consequences of the hydrology and ecology of the entire watershed. Dredging operations for the purpose of harbour clearance or improvements to a navigable channel, for example, may increase the outflow from an upstream lake, increase shore erosion, or regenerate undesirable sedimentary constituents into the lake or river water. The damming of a river or a lake outlet to increase local water storage may also result in undesirable effects, such as an increased evaporation from the larger surface area, the restriction of fish movement, or changes in the thermal climate of the downstream flow. Diversions and dam-site construction may also result in flooding of important bird-breeding areas or a lowering of other lakes in the system, resulting in undesirable consequences.

Water input. The usual major input of water to a lake derives from streams and rivers, precipitation, and groundwater. In some cases inflow may come directly from glacier melt. The relative importance of each of the major sources varies from lake to lake.

Stream and river flow are usually seasonally variable, depending upon precipitation cycles and snowmelt. At low altitudes some rivers exhibit a peak during a high precipitation period in winter and then a second peak associated with a subsequent spring snowmelt that feeds the nearby high-altitude tributaries. In regions where precipitation can occur in great quantities at high rates, streams swell quickly, and water is delivered in relatively large volumes to downstream lakes.

A great deal of work has been done to improve the ability to measure and record streamflow. Consequently, it is usually the most accurately known of the inflow terms in the water budget. Most frequently, the height of the river level (stage) correlates well with the water discharge. In other cases, direct river-flow measurements are taken periodically with flow meters.

Precipitation over lake basins

Precipitation reaching a lake's surface directly may be the major input; this is true of Lake Victoria, Kenya–Tanganyika. In other cases, where the lake basin is large with well-developed drainage to a deep lake of small surface area, precipitation may be a small component. Precipitation that falls elsewhere in the lake basin may reach the lake through either surface or groundwater flow, or it may be lost due to evapotranspiration.

Measurements or estimates of precipitation for a basin are difficult to achieve. Even where elaborate networks of rain gauges exist or where these are supplemented by meteorological radar installations, total basin-precipitation data are still considered to be poor. Measurements of direct precipitation over lakes are exceedingly rare; this situation is especially serious in the case of a large lake for which nearby land data are not necessarily representative of conditions over the lake. Each climatic region throughout the world has its typical precipitation pattern, and the lakes within the regions are affected accordingly.

Groundwater controls on lake level

Groundwater reaches lakes either through general seepage or through fissures (springs). Groundwater is taken to be water in that zone of saturation that has as its surface the water table. The depth of the water table can be determined by digging a well into the saturated zone and noting the level of water—unless the water is under pressure, in which case it will rise in the well to a level above the water table. Clearly, it is possible for a lake level to coincide with the water table. In fact, unless impermeable material intervenes, the water table will drop to, rise to, or lie level with a lake surface. Groundwater that is lost from the saturated zone to a lake is termed groundwater discharge. Groundwater introduced to the saturated zone from a lake is termed recharge. The rate at which groundwater is exchanged between a lake and the saturated zone depends mainly upon the level of the water table and the pressure conditions within the saturated zone.

In permeable materials the zone above the water table is called the zone of aeration, and water within it is called soil moisture. Soil moisture is classified into three types: hygroscopic water adsorbed on the surface of soil particles; water held by surface tension in capillary spaces in the soil and moving in response to capillary forces; and water that drains through the soil under gravitational influence. The latter will most significantly contribute to groundwater recharge and to the water balance of a lake. The second category will generally be subject to loss due to transpiration by plants.

Water output. Lakes that have no outlets, either above or below surface, are termed closed lakes, whereas those from which water is lost through surface or groundwater flows are called open lakes. Closed lakes, therefore, lose water only through evaporation. In these cases, the loss of water that is less saline than the source water results in an increasing lake salinity.

Evaporation losses from lake surfaces

The process of evaporation results from a vertical gradient of vapour pressure over the water surface. Next to the water surface, saturation conditions exist that are a function of the temperature at the interface. The vapour pressure in the air above the surface is calculated from the temperature of the air and the wet-bulb temperature. The rate at which evaporation occurs also depends upon the factors that affect the removal of the saturated air above the surface (for example, wind speed and thermal convection).

Studies of evaporation must surely constitute a sizable proportion of all hydrological and oceanographic work. The principal categories of evaporation studies are water budget, energy budget, bulk aerodynamic techniqnes, and direct measurements of vapour flux (see further HYDROLOGIC CYCLE).

The so-called aerodynamic technique is based upon Dalton's formula, which correlates evaporation with the product of the vapour pressure gradient and the wind speed. Studies during the past 20 years have produced a host of variations of this equation, determined empirically using independent measurements of evaporation. One of the most often used of these was developed in a study of Lake Hefner, and even this work has been subsequently modified to suit other climates and conditions. Few workers are satisfied with the present state of the art in the use of the aerodynamic equations. Nevertheless, once an equation of this type is satisfactorily developed for a particular lake, having been checked with independent methods, it is attractive because it usually employs data that can be routinely observed.

The direct measurement of vapour fluxes is an extremely intricate proposition, as motions over a water surface are usually turbulent, and instruments capable of measuring rapidly changing vertical motions and humidities are required. Not the least of the difficulties is the likelihood that the kind of turbulence over large bodies far from land is significantly different from that over land. Recent advances in theoretical developments and instrumentation continue to encourage this type of study. In turn, successes in this field offer the opportunity for the refinement of empirical techniques more practically suited for general lake investigators.

In many lake studies, data from evaporation pans have been used to determine lake evaporation. Pans have even been developed for flotation on lakes. Pans cannot truly simulate lakes, however, as they constitute a different type of system (they are not exposed to the atmosphere in the same way, they exchange heat through their sides, and they do not store heat in the same way as lakes).

Some examples of evaporation estimates include annual totals of between 60 and 90 centimetres (two and three feet) for Lake Ontario (using different techniques and for different years); about 75 centimetres (2.5 feet) for Lake Mendota, Wisconsin; over 210 centimetres (seven feet) for Lake Mead, Arizona and Nevada; about 140 centimetres (4.5 feet) for Lake Hefner; about 660 millimetres for Lake Ijsselmeer, The Netherlands; and about 109 millimetres for Lake Baikal.

Water output from a lake in the form of surface-water outflow generally depends upon the lake level and the capacity of the effluent channel. Although lakes often have many surface inflows or at least several incoming streams or rivers, they generally have but one surface effluent.

Water-level fluctuations. The net water balance for a particular lake will vary according to the periodic and nonperiodic variations of the inputs and outputs and is reflected in the fluctuations of the lake level. Because the prime influencing factors are meteorological, the periodicity of seasonal events are often seen in water-level records.

Seasonal variations of level

Lake-level rises generally coincide with or closely follow seasons of high precipitation, and falls of level generally coincide with seasons of high evaporation. Complications are introduced by a variety of factors, however. The storage of heavy winter precipitation as snowpack is one example. The release of this water during the spring thaw may also be hampered by the presence of river ice, resulting in late-spring or summer peaks. In large drainage basins the full effects of heavy precipitation may not be immediately realized in the lake-water balance because of the time required for basin drainage. Where glacier melt is a major input to a lake, the level changes respond to seasonal heating as well as seasonal precipitation.

Although artificial controls, in the form of diversions, river dredging, and dams, affect the levels of the Great Lakes, the latter provide good examples of seasonal variations because of the lengthy record of levels available. The rivers draining to these large lakes are relatively stable; that is, the ratio of maximum to minimum flow is about 2 or 3 to 1, compared to 30 to 1 for the Mississippi River and 35 to 1 for the Columbia River. A 67-year average of lake levels by month shows that high water occurs, on the average, in September for Lake Superior and in June for Lake Ontario. Lows occur in March and December–January, respectively. The mean range in seasonal levels, for this period, is about 30 centimetres (one foot) for Lake Superior and about 45 centimetres (1.5 feet) for Lake Ontario. The pattern varies considerably from year to year, however, and periods of exceptional precipitation and drought are shown in the records. These events ultimately affect the downstream lakes, but, because of their relatively small discharge volumes, it takes 3.5 years for 60 percent of the full effect of a supply change to Lake Huron–Michigan to appear in the outflow from Lake Ontario.

The seasonal changes in a lake's level may be superimposed on longer term trends, which in some cases dominate. Several of the large lakes of the world have lengthy water-level records that illustrate long-term periods of relative abundance of water and drought. In Central Africa, Lakes Victoria, Albert, Tanganyika, and Nyasa exhibit substantial long-term features, some of which are consistent, suggesting that a common climatological factor is responsible for their existence (see further CLIMATIC CHANGE). Nevertheless, others of these features are not consistent within the lakes and have not been adequately explained.

The principal climatological factors that would most affect long-term lake-level variations have not been recorded for long periods at many locations. Regular precipitation observations were not made before about 1850. Some useful evidence is found in such natural records as tree rings and peat-bog stratigraphy.

On a worldwide basis, there is evidence of a period of low levels in the middle 19th century and near the end of the first quarter of the 20th century. Lake George, in Australia, the Caspian Sea, several lakes in western North America, and Pangong Lake, in Tibet, are examples that have exhibited these features.

LAKE EXTINCTION

Possible causes of lake extinction

The life history of a lake may take place over just a few days, in the case of one formed by a beaver dam, or, for the largest lakes, it may cover geological time periods. A lake may come to its end physically through loss of its water or through infilling by sediments and other materials. Reference has previously been made to the chemical–biological death of a lake, which is not necessarily the end of it as a physical entity but may in fact be its termination as a desirable body of water.

Geological processes involving the uplift and subsequent erosion of mountains and the advance and retreat of glaciers, establish lake basins and then proceed to destroy them through infilling. Lake basins may also lose their water through drought or through changes in the drainage pattern that result in depletion of water inflows or enhancement of outflows.

The chemical–biological changes within a lake's history offer a fine example of ecological succession. In the early stages a lake contains little organic material and has a poorly developed littoral zone. Particularly in temperate zones, such conditions favour a plentiful oxygen content, and the lake is said to be oligotrophic. As erosion progresses and as lake enrichment and organic content increase, the lake may become sufficiently productive to place an excessive demand upon the oxygen content. When periods of oxygen depletion occur, a lake is said to be eutrophic. An intermediate stage in this course of events is called mesotrophy. In the case of oligotrophy the vertical oxygen distribution is essentially uniform, or orthograde. Under eutrophic conditions, oxygen values decrease with depth, and the vertical distribution is called clinograde.

The limits of oligotrophic and eutrophic conditions have been set in terms of the rate at which oxygen is depleted from the hypolimnion. These limits are arbitrary but are approximately 0.03 and 0.05 milligrams per square centimetre per day as the upper limit of oligotrophy and the lower limit of eutrophy, respectively.

As eutrophic conditions develop, bottom sediments become enriched in organic material, and bottom plants spread throughout the littoral zone. As infilling proceeds, the plant-choked littoral zone spreads lakeward. Eventually, the littoral zone becomes a marsh, and the central part of the lake diminishes to a pond. When the lake finally ceases to exist, terrestrial vegetation may flourish, even to the extent of forestation.

(R.K.L.)

V. Life in standing water

STANDING WATER AS A BIOLOGICAL ENVIRONMENT

Standing waters—ranging from days-old ponds to million-year-old lakes—despite differences in size and in age, share certain factors in common; these determine the kind of organisms that can live in such communities. Among the most important of these factors are light, temperature, and dissolved nutrients; wind waves are important in large lakes.

The influence of light. If a lake is turbid, photosynthesis is possible only in the uppermost lighted layers. In fact, when the sun is high in the sky, the illumination in the upper few centimetres of even a murky lake is likely to be too high, rather than too low, for optimum photosynthesis. Deep in the lake, however, light is scarce. Attenuation of light is a logarithmic process; for example, if one-half of the incident sunlight reaches a depth of one metre (about three feet), only a quarter of it will reach two metres, an eighth of it three metres, and so on. Accordingly, the illumination and the amount of photosynthesis drop off extremely rapidly with increasing depth.

The food requirements of organisms, however, are nearly constant. Respiration of both plants and animals continues in the dark, so in the deeper levels of a lake respiration is likely to exceed photosynthesis. If the depth is great enough, plants will not be able to manufacture enough organic material to keep themselves alive, and the animals must depend upon food falling from the illuminated surface layers of the lake.

Lake stratification

It is convenient to think of a deep lake as divided into two layers, a food-generating, or trophogenic, zone, in which there is enough light for photosynthesis to exceed respiration over a 24-hour period, and a food-consuming, or tropholytic, zone, in which respiration exceeds photosynthesis. The boundary between trophogenic and tropholytic zones (the compensation level) commonly moves up and down with the seasons, particularly in polar lakes with their very pronounced seasonal pulse of incident sunlight.

Temperature effects. Temperature is also very important to life in lakes. It acts directly, of course; fluctuations in temperature are gradual and less extreme than they are in air. In the temperate zone during spring and summer and in the tropics during the dry season, solar heat is commonly delivered to the surface of a lake faster than the wind can stir it into the depths. Unless the lake is very shallow relative to its size, the warm surface water, being lighter, rides over the cool water beneath, and the lake is effectively divided into two compartments until either autumn or a rainy season cools the surface enough for complete mixing to occur.

The surface layer of a stratified lake is called the **epilimnion** and the deep layer the hypolimnion, and the boundary zone between them, where temperature changes rapidly with depth, is usually known as the thermocline. Epilimnion and hypolimnion are not completely sealed off from each other. There is a continual rain of debris, largely corpses and feces, through the thermocline and some upward movement of gas bubbles, mostly methane produced by bacterial decomposition of organic sediment. Organisms with a broad enough range of temperature tolerance may move freely through the thermocline in either direction. In general, however, movement through the thermocline is slight.

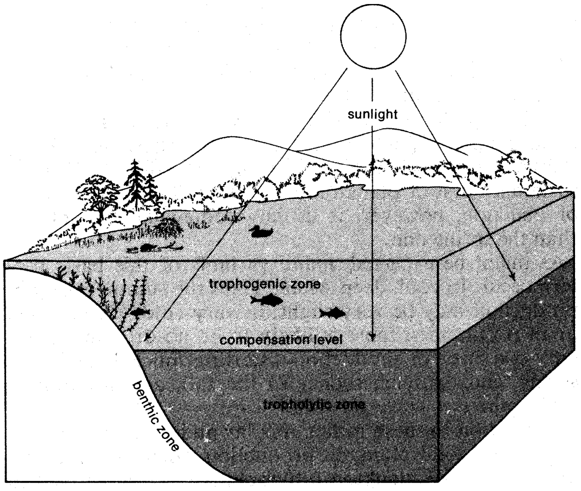

Figure 5: A lake in midsummer, showing zones of food production and consumption.

The relative extent of the **epilimnion** and the **trophogenic** (food-generating) zone and of the hypolimnion and the tropholytic (food-consuming) zone depends upon both the transparency of the water and the interplay of wind mixing and solar heating: but, in general the **epilimnion** (surface layer) tends to be strongly trophogenic, the hypolimnion (deep layer) tropholytic. During stagnation, respiration by organisms in the deep water may use a large part of the hypolimnetic store of dissolved oxygen, so that only animals capable of respiring without oxygen can survive there. If the hypolimnetic volume is very large or if it includes an appreciable part of the trophogenic zone, then an adequate supply of oxygen will be available throughout the period of stagnation, and the hypolimnion may provide a refuge for oxygen-demanding animals, such as lake trout or whitefish, which cannot tolerate summer surface temperatures.

Chemical stratification

In most lakes temperature differences are the most important cause of stratification; of special interest, however, is the minority that are stratified because of chemical differences between deep and shallow water. In this condition, called meromixis, a pocket of dense water (the monimolimnion), rich in dissolved salts, lies under the fresher upper water of the lake.

The warmest lakes known are meromictic ones of such high transparency that an appreciable amount of solar heat penetrates to the monimolimnion, where it accumulates. The density changes in such chemically stratified lakes are much greater than those resulting from temperature changes in freshwaters and occasionally lead to the formation of a lake—such as Soap Lake, in Washington—that, in wintertime may have a surface layer of ice although its hypolimnion is almost hot enough to poach eggs.

Mineral factors. Life in calcium bicarbonate lake waters is determined less by changes in the major constituents—calcium, magnesium, sodium, potassium, bicarbonate, sulfate, chloride, and silica—than by variations in biologically important substances that are commonly present in much smaller concentrations. The production of a lake commonly can be increased by adding phosphorus or compounds containing nitrogen; the addition of both increases production more than the addition of either alone. Changes in silica content have serious consequences for diatoms, algae with a siliceous cell wall; iron affects plant life directly and also because it chemically controls the availability of phosphorus.

In laboratory experiments it is possible to show that lake algae require numerous elements—nitrogen, phosphorus, sulfur, potassium, magnesium, silicon, sodium, calcium, iron, manganese, zinc, copper, boron, molybdenum, cobalt, and vanadium—and three vitamins. In most lakes, however, most of these materials are generally present in such adequate supply that it is usually difficult to demonstrate a deficiency.

Wind waves and seiche effects. Lunar tides are insignificant to life in lakes, being barely detectable on only a few of the world's largest lakes. Progressive wind waves, however, are a dominant influence on the plants and animals of the shore zone. In locales where the winds are strong and act over considerable surface area, waves

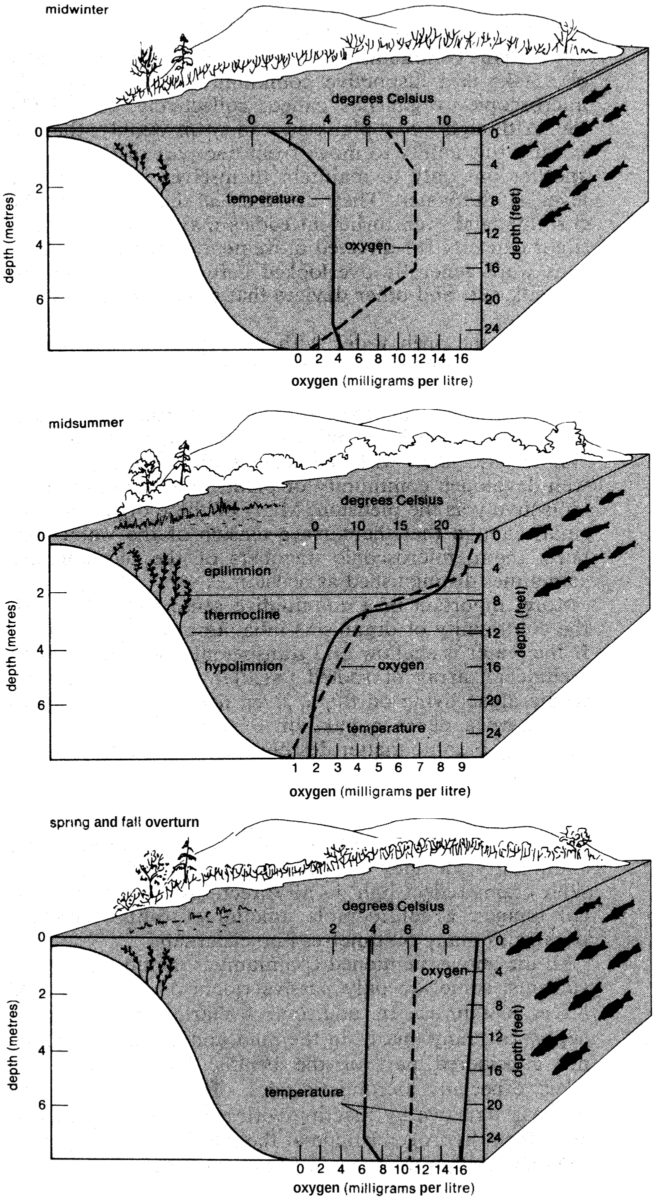

Figure 6: The influences of the seasons on lake stratification. The oxygen and temperature curves of the superimposed graphs are related to the depth of the water, as shown.

more than five metres (about 16 feet) high can be produced—high enough to be a hazard to navigation and to remove mud, clay, silt, and many organisms from beaches. Waves are probably the dominant influence on the distribution of shore plants and of the many smaller organisms of all sizes adapted to life among them.

The effect of an internal seiche

Less evident most of the time, though perhaps even more significant to life in many lakes, are standing waves called seiches, which are usually produced by the wind or by abrupt pressure disturbances. The initial disturbance tends to pile the water against one shore of the lake, leaving the opposite shore more exposed than normal. After the disturbance passes the lake, water rocks back and forth like soup in a bowl. Seiches only occasionally exceed a metre (three feet) in height, at which times they can cause considerable damage to shore structures and can sweep persons off low piers and docks. Biological significance is attached not so much to the surface seiche, however, as to the corresponding displacement of the thermocline, set up at the same time. Such an internal seiche is usually of greater amplitude than the surface seiche; in fact, all of the epilimnion may rock toward one shore, leaving hypolimnetic water exposed at the other. These large displacements of water are the main mechanism for generating turbulence in the hypolimnion of a stratified lake, and they play a vital role in the biological and chemical economy of such a lake.

CHARACTER OF LACUSTRINE POPULATIONS

Lacustrine communities. Suspended in the open water of a lake is a distinctive community of small—mostly microscopic—organisms called, collectively, the plankton. Although many plankters can swim weakly, they do not use this ability to move from one part of the lake to another but only to maintain themselves at a desirable level in the water. They are thus at the mercy of the currents, and even turbulent eddies may overpower their slight capacity for directed movement; planktonic organisms were generally overlooked before the invention of fine silk nets and other devices that separated them from the water.

Sharing the open water with the plankton are animals known collectively as the nekton; they are large, active swimmers able to move under their own power from one part of a lake to another. Fish, seals, turtles, hippopotamuses, and other large animals of lakes are all nektonic.

Often associated with the surface film of the lake is a well-developed community of plants and animals known collectively as the pleuston. Many of these organisms are small enough that the surface tension of the water supports them; microscopic members of the pleuston are sometimes distinguished as neuston.

More important in a quantitative sense is the benthos, the community of organisms inhabiting the lake bottom. If the water is shallow and transparent, the benthos may include an array of rooted vascular plants with microscopic algae living on them. Even deep or opaque lakes may have a dense population of benthic animals, sustained by organic matter descending from the trophogenic zone.

Lakes with waves adequate to maintain sand beaches are ringed with a psammon community, tiny organisms adapted to grow or move through the grains of sand. This community includes both plants and animals. Although sand grains reflect light in all directions and destroy visual images, a considerable amount of diffuse sunlight penetrates many centimetres into clean sand.

All the above-mentioned communities include micro-organisms; some are only passive riders on the bodies of larger creatures. In addition, bacteria are found to depths of many metres in the mud under a lake—depths not considered part of the benthic habitat. Stratified lakes, especially meromictic ones, often have a layer of bacteria that live by reacting with sulfate compounds so as to form hydrogen sulfide at the interface between oxygenated and nonoxygenated (reduced) zones.

Changing lake populations. In the Arctic and in the temperate zone the abundance of plants of both major producing communities, the plankton and the shallow-water benthos, fluctuates with the seasons. This presents no problem as far as the higher plants ringing the shore are concerned: like the land vegetation, they sprout in the spring, grow more slowly during the summer, and die back in the fall in response to the same climatic controls that influence trees or grasses.

Planktonic cycles

The fluctuation in abundance and activity of the planktonic algae, however, is more complex. A common pattern consists of two peaks of abundance and activity each year, one in the spring and one in the fall, with a period of relative quiescence during the summer. It appears that during the winter, when solar energy is scarce, photosynthesis is reduced, and many planktonic organisms die, releasing the nutrient salts of which they are composed. If the lake is covered with ice and snow, this process is so enhanced by the intensification of the darkness that oxygen may be sufficiently depleted to kill fish.

In spring the ice melts and freely circulating water, rich in nutrients, is exposed to bright sunlight. The result, predictably, is a spurt of photosynthetic activity and an increase in plankton abundance. During summer, thermal stratification occurs and with it a gradual depletion of nutrients in surface layers.

With the autumn overturn, however, nutrient-rich water is once again exposed to surface light intensities, which, though lower than those of spring, are still sufficient to sustain a burst of plankton production. The fall "bloom" of plankton, however, is usually somewhat less intense than the spring one.

As might be expected, many variants of this basic pattern occur. In cool, deep Alpine lakes the summer drop in production may be very slight; in very cold Alpine lakes or in Arctic ones. there is likely to be no drop at all but only one burst of production—starting much later in the spring, ending much sooner in the fall, and peaking in midsummer.

In addition to these rather regular and predictable fluctuations in total plankton production, there are changes in the plantlike plankton (phytoplankton), with first one species, then another, appearing in a fairly regular seasonal succession, repeated with minor variations from year to year. There is also a succession in the animal-like plankton (zooplankton), with some species remaining throughout the year but others appearing only during the winter or only during the summer.

These changes probably could be understood in terms of seasonally changing chemical and physical conditions, but the exact way in which the environment acts to control a single species throughout the year has not been worked out in a single lake as yet.

It seems likely that the appearance of blue-green algae in many lakes during midsummer, when dissolved nutrients are at their lowest ebb, has to do with their capacity to utilize atmospheric nitrogen, giving them an advantage over spring and fall species that must have their nitrogen presented to them in the form of nitrates or ammonia. It is also possible that biochemical factors may be important: perhaps the blue-greens require organic growth factors released by the dominant algae of spring.

ADAPTATIONS TO THE LACUSTRINE ENVIRONMENT

Compared with rivers and oceans, lakes are rather transitory features of the Earth. A lake is likely to fill in or be drained, to evaporate or freeze solid, in a time that is short compared to the rate of evolution. Many ponds are seasonal, some desert lakes (playas) hold water for only a few weeks after each rain, and Lake Eyre, in Australia, contains water so seldom that its flooding is usually recorded in the scientific literature.

Responses to the changes in lakes

Dormancy and emigration. Because of the ephemeral nature of lakes, many aquatic organisms have mechanisms of resting in a dormant state or for moving from one lake to another. Aquatic vascular plants are commonly provided with large, thick-coated seeds, with underground storage rhizomes (underground stems), or with overwintering buds that will keep the population alive while most of the active individuals succumb to drought or cold. *Daphnia*, the water flea, normally reproduces parthenogenetically (without the need of mating), but, when food gets scarce or the pond begins to dry up or some other unfavourable circumstances develop, males appear in the population and fertilize the females. The offspring of this sexual union develop inside a thick-walled resting egg, which is shed into the environment at molting, instead of being placed in the mother's brood pouch. The resting egg is capable of withstanding adverse conditions of cold or drought and does not hatch until favourable circumstances have returned. Similar resting eggs are produced by many other planktonic crustaceans and by bryozoans. In the fall, in temperate-zone lakes, large, globular, jelly-filled colonies of bryozoans are blackened by thousands of small, round resting eggs, each armed with a ring of anchor-like hooks that increase the egg's chances of being carried to a surface suitable for growth.

Many planktonic algae produce resistant spores capable of withstanding drought, and the larvae of bivalve mollusks are adapted to cling for dispersal to the gills of fish or to the feet of ducks. The short adult phase in the life of aquatic insects is also a device for moving from lake to lake. A very large part of the lacustrine (lake) biota seems to consist of species well-adapted to flee to more favourable areas should the lake in which they live become unsuitable. This is true even of such large, self-sufficient animals as the hippopotamus and the crocodile.

Planktonic adaptations. Plankters must stay suspended in the light water to survive. If they sink into the tropholytic zone, they die, either by poisoning or by starvation. Many plankters have overcome this threat by moving enough to keep themselves suspended. A few have developed gas bubbles or oil droplets to aid buoyancy. Other plankters have adapted by becoming as small as possible; thus, they sink very slowly through the water, relying on normal turbulence to hinder sinking further. If the growth of the population is greater than the slow loss to the depths, then the species can survive. This is probably the commonest way out of the dilemma and may explain why so many plankters are microscopic in size, especially in freshwater. In the sea, with its higher salinity, the sinking problem is less acute, and larger plankters are found.

Many of the planktonic organisms in lakes are surrounded either with a jelly coat or with long spines sticking out in all directions. Both are probably adaptations for increasing effective diameter without greatly increasing mass, thus reducing the sinking rate. Many diatoms are slightly asymmetrical—sigmoid or S-shaped, for example—a physical advantage that also reduces the rate of sinking.

Many species of lake plankton show one or another of two bizarre phenomena that may adapt them to open-water existence, although just how is still obscure. The first phenomenon is daily vertical migration: the plankters move up and down in the water, often considerable distances, according to the daily cycle of solar illumination. The second phenomenon is cyclic change of form. This occurs in animals such as ***Daphnia*** and in some plants, all of which reproduce asexually as they change in form from one generation to another. Some populations show only slight change during the course of each year; others go through such variation that the extremes in form would certainly be taken for different species if the intermediate types were not known. These form changes are induced largely by changes in temperature during development, although turbulence also plays a role. Of the many ideas that have been advanced for the adaptive value of the changes—that they are adjustments to the properties of warm water, that they keep the animals swimming in strata in which food is densest, that they are defense mechanisms against seasonal predators—none seems a convincing explanation for the general phenomenon.

Water-balance problems

Physiological adaptations. The ancestors of most animals that live in lakes were either terrestrial or marine. Adapted to a situation in which water was scarce, these ancestors had to be able to conserve water and to excrete extra salts and waste products with minimal water loss. The water in most lakes is much more dilute than is the body fluid of the animals; there is thus a strong tendency for the animals to gain water. This problem has been solved in two fundamentally different ways. One is typified by the freshwater mussels, which have an enormous area of mantle (an extension of the body wall) and gill exposed to the water; it might seem that they would take up water at a very high rate. The mussel, however, has developed extremely dilute body fluid—thus minimizing the tendency for water to cross its membranes—and a kidney that, because it is able to excrete very dilute urine, can excrete the excess water that does happen to enter the body. The problem has been solved in a different way by most insects in freshwater, which have a hard outer skeleton (or exoskeleton), covering as much as possible of the body; because the exoskeleton does not allow water to pass through (*i.e.*, it is impermeable), water uptake is reduced and can be handled adequately by an excretory apparatus designed for terrestrial performance.

Not all lake dwellers face the problem of an excess of water. The problem of those who live in waters many times more concentrated than the sea is to conserve water and get rid of excess salts. Relatively little is known about the excretory mechanisms of animals in such environments, however.

Water and salt balance are more easily studied in large nektonic and benthic animals than in microscopic organisms, but the latter, with their relatively thin walls and enormous surface-to-volume ratio, are exposed to severe stresses. In the case of single-celled protozoans, the problem is met by a structure called a contractile vacuole, by which dilute fluids are excreted.

Lake animals such as mussels, which have a large permeable surface exposed to the environment, are able to obtain their oxygen by diffusion from the water. Many insects, however, exploit the natural advantages of air as their respiratory medium.

Lake plants are commonly well provided with hollow tissues in their stems, through which they are able to pump oxygen down to roots and tubers buried deeply in mud. Mosquito larvae of the genus *Mansonia* have learned to tap into this gas supply with their respiratory organs and so free themselves from the usual repeated journeys to the surface to replenish their air.

Species interactions. Probably because most lakes are young and transitory, they have few of the elaborate and subtle interactions between species that are so conspicuous a part of the marine or terrestrial scene. A few cases are reminiscent of sea corals and the algae that live in them (zooxanthellae). Freshwater sponges, for example, are green because of the algae within them when they grow in the light; the same sponges are white when they grow in darkness. Some salamander eggs are usually green as a result of algae growing in the jelly masses.

Among the fishes of the oldest lakes are some interesting cases of egg predation; in one, a species of cichlid fish feeds exclusively on the eggs of mouth-brooding cichlids of other species. The predatory cichlid mimics the prey cichlid very closely in colour pattern and general appearance, persuading the mouth brooder to spit out its incubating eggs.

Parasitic relations between lake dwellers are elaborate, probably because the cycle has evolved in rivers and been secondarily extended to lakes. Many parasitic life cycles involve both lakes and terrestrial organisms; for example, the schistosomes, a group of blood flukes that are widely distributed in the lakes of the world, pass several larval stages in freshwater snails but spend their adult lives in the bloodstream of a terrestrial vertebrate. In most of the temperate zone the vertebrate host is usually a duck. Occasionally, certain of the larvae may penetrate the skin of humans, where they die, producing an annoying but usually short-lived dermatitis called swimmer's itch. In Japan and much of the tropics, however, the larvae of several species complete their development in man and cause a serious human disease.

BIOLOGICAL PRODUCTIVITY

Generally, the productivity of lakes is lowest in the Arctic, intermediate in the temperate zone, and highest in the

Correlations with latitude

tropics. The dark Arctic winter provides little solar energy for photosynthesis, and most of the springtime period of bright sunshine and long days occurs when the lakes are still covered by a thick layer of ice. In the tropics, on the other hand, where there is an adequate supply of solar energy all year and no ice cover to absorb it, high temperatures speed decomposition of plants and animals, so that nutrients of which they are composed are returned rapidly to the water and support new growth.

A second important influence on the productivity of lakes is the nature of the underlying bedrock. Rocks that are readily soluble and rich in nutrient elements, such as calcium, potassium, silica, and phosphorous, provide for a high and sustained rate of photosynthesis. Lakes resting on insoluble rocks, even though located in the favourable light and temperature environment of the tropics, have a productivity so low as to be unmeasurable by standard methods. It is in tropical regions of internal drainage, with much volcanic ash in the rocks—such as the rift valleys of tropical East Africa—that the most productive lakes in the world are found.

Presumably, an estimate of the total amount of each nutrient in the water and organisms of a lake would show a clear relation with productivity, but such an estimate is difficult to make. Even for phosphorus, which can be detected easily by radioisotope-tracer methods, the estimate is too cumbersome to be used on a widespread comparative basis.

There is, however, a fairly strong correlation between the bicarbonate–carbonate content of lakes and their primary productivity. This is likely to be at least partly the result of a correlation between bicarbonates and the generally unknown and unmeasurable total supply of nutrient salts, but it also may mean that plants in most lakes are chronically short of a convenient carbon source for photosynthesis.

If a lake is deep and transparent, it can sustain a respectable productivity per unit surface area while at the same time exhibiting a low productivity per unit volume of water. In a shallow lake, on the other hand, all the primary production takes place in a short water column, so that its effects, such as the production of algal blooms, are much more pronounced. This concentration of such growth is beneficial to organisms higher up on the food chain, such as zooplankton and fish, because large volumes of water are not required to obtain food. This is probably one reason the shore zone of a lake normally supports much denser populations of fish than does the open water.

The depth of mixing is important to the phytoplankton in another way. If it is so great that the phytoplankters spend an appreciable part of their time in the tropholytic zone, they may use up a very large part of the food they manufacture in their own respiration. This is probably why the very dense perennial blooms of highly productive tropical lakes develop only in shallow lakes or in meromictic ones, in which mixing is shallow and contained largely in the zone of trophogenesis.

Lake food chains

In general, only about 10 percent of the energy passing through one level in any food chain is consumed by the next trophic level above, which places a severe limit on the possible length of lake food chains. Few, if any, consist of more than six links, and in small lakes they may be only three links long. A high-level predator can increase its population by shortening the food chain on which it is dependent, just as human populations can (and do) by shifting from a diet rich in meat to one that is largely cereal. The resulting increase of food from a short food chain, however, is obtained at a considerable increase in the energy used to gather the food.

(D.A.L.)

BIBLIOGRAPHY. G.E. HUTCHINSON, *A Treatise on Limnology*, vol. 1, *Geography, Physics, and Chemistry* (1957) and vol. 2, *Introduction to Lake Biology and the Limnoplankton* (1967), contains a comprehensive treatment of the physical, chemical, and biological aspects of lakes and includes excellent bibliographies of previous work; basic books that contain useful bibliographies are F. RUTTNER, *Grundriss der Limnologie*, 2nd ed. (1952; Eng. trans., *Fundamentals of Limnology*, 3rd ed., 1963), a short introduction to lakes, with main emphasis on their biology; and D.G. FREY, *Limnology in North America* (1966). R.E. COKER, *Streams, Lakes, Ponds* (1954), is often used as a textbook on limnology; but for physical, hydrologic, and geologic aspects of lakes, the interested reader should see: J. PROUDMAN, *Dynamical Oceanography* (1953); B. KINSMAN, *Wind Waves: Their Generation and Propagation on the Ocean Surface* (1965); R.L. WIEGEL, *Oceanographical Engineering* (1964); and S.N. DAVIS and R.J.M. DEWEIST, *Hydrogeology* (1966). The subject of water use and planning is covered in R.J. CHORLEY (ed.), *Water, Earth and Man* (1969); J.G. NELSON and M.J. CHAMBERS (eds.), *Water* (1969); W.R.D. LEWELL and B.T. BOWER, *Forecasting the Demands for Water* (1968); UNITED STATES WATER RESOURCES COUNCIL, *The Nation's Water Resources: The First National Assessment* (1968); and F.E. MOSS, *The Water Crisis* (1967). Journals of particular interest include: *Limnology and Oceanography* (bimonthly), *Journal of the Fisheries Research Board of Canada* (monthly), *Proceedings* of the International Association for Great Lakes Research, and several oceanographic and meteorological journals. See also M.M. KOZHOV, *Lake Baikal and Its Life* (1963), a general account of the world's oldest lake and its rich biota; J.G. and P.R. NEEDHAM, *A Guide to the Study of Fresh-Water Biology*, 5th rev. ed. (1962), an introductory manual for the identification of lake and stream life; and W.R. EDMONDSON, *Fresh-Water Biology*, 2nd ed. (1959), a thorough and rather technical guide to the identification of most groups of lacustrine organisms.

(R.K.L./D.A.L.)

Lamarck, Jean-Baptiste de Monet, chevalier de

Jean-Baptiste de Lamarck, pioneer biologist in the formative era of that science, is remembered for bold speculations that all animals had evolved from primitive corpuscles through progressive improvements. His notion that evolution occurred as new characteristics were acquired through interaction with the environment and passed on to progeny is at odds with the Darwinian theory—now accepted without major qualification as the leading principle of evolutionary biology—of genetically determined variations selected by competition. Controversies generated by conflicts between these beliefs have tended to obscure Lamarck's substantial contributions to comparative anatomy and the study of the principles of classification and nomenclature of the invertebrates.

By courtesy of the Museum National D'Histoire Naturelle, Paris

Lamarck, engraving by W.H. Lizars (1788–1859).

Lamarck was born on August 1, 1744, in Picardy in northern France, the youngest of 11 children of a baron and lieutenant of infantry. Intended for the priesthood, he was sent to a Jesuit school at Amiens, but after his father died he took the opportunity to enlist in an infantry regiment, serving several years (1761–68). He became interested in plants while stationed on the Riviera and, following his resignation from the army, embarked upon the study first of medicine and then of botany, to which he soon devoted himself entirely under the French botanist Bernard de Jussieu at the Jardin du Roi (the royal botanical gardens) in Paris. Drawing on nine years of field study and collecting, Lamarck published a three-volume flora of France in 1778. Botany had become universally popular, and a wide public greeted his *Flore françoise* as a useful manual of identification. It did not adhere slavishly to the methods of the Swedish botanist Carolus Linnaeus and won for Lamarck appointment to the Académie des Sciences, which at that time was restricted to 42 members. Comte Georges de Buffon, the leading naturalist of the day, engaged him as tutor to his son during two years of travel in central Europe visiting botanical gardens and other learned institutions. He devoted the years following to voluminous botanical writings for the ***Encyclopédie me'thodique,*** successor of the famous ***Encyclope'die*** founded by Diderot, and to working as curator of the royal herbarium.

The revolution of 1789 was devoted to remaking institutions of intellect as well as of politics, and so the royal collection of natural history was discontinued. Lamarck addressed a memoir to the National Assembly condemning the random cabinets for display of curiosities built up by well-meaning amateurs and urged instead that collections be applied to the progress of science through the establishment of a great museum of natural history. Within such a collection objects "ought to be arranged in methodical or properly systematic order," not for display at random: each division of nature (animal, vegetable, and mineral) should be subdivided by classes, and those in turn by orders, and so to genera, with a written catalogue that would be the basis for systematic knowledge. Lamarck was one of the originators of the modern concept of the museum collection, an array of objects whose arrangement constitutes a classification under institutional sponsorship, maintained and kept up to date by knowledgeable specialists. When the Muséum National d'Histoire Naturelle was founded in 1793, Lamarck was placed in charge of the invertebrates, of which he had already made an important collection. He seems to have been the first to relate fossils to the living organisms to which they corresponded most closely, evincing a remarkable awareness of the great unities underlying the diverse external appearances of organisms.

Systematic order established in museum collections

By the end of the 18th century, enough had been learned in the sciences of chemistry and physiology to persuade the most acute inquirers that new understandings of great consequence might be attained through patient search for clues to fundamental relationships. Lamarck had been satisfied with and indeed excited by the looser, less critical notions of natural rhythm and the sense of cosmic unities entertained by 18th-century writers. It seemed to him that the new chemistry of Antoine Lavoisier led away from grand facts into a labyrinth of details. He feared that science would cease to be a coherent system whereby all men might understand the world and their place in it, becoming instead the confined domain of a few specialists. So he conceived a plan for a series of treatises, elaborating a unified view of physical processes and chemistry, geology, climate, and life. The first of these was a two-volume speculative treatment of matter and energy, ***Recherche~sur les causes des principaux faits physiques, et particulihrement sur celles de la combustion*** (1794), followed in 1796 by ***Réfutation de la the'orie pneumatique, ou de la nouvelle doctrine des chimistes modernes,*** in which he opposed his own theory of combustion to the views of Lavoisier and the French chemist Comte Antoine de Fourcroy. Neither of Lamarck's works was calculated to appeal to the mood of caution then coming to govern most serious scientific work, and Lamarck did not know how to dramatize his views for a wider public.

His ***Hydroge'ologie*** (1802) offered a history of the earth interpreted as a series of inundations by a global sea, each accompanied by organic deposits building up the continents. Among the insights that were highly advanced for his day was Lamarck's recognition that the type of fossil occurring in a deposit would permit inferences as to whether the deposit had been built up as deep marine sediments or coastal deposits. The book also revealed an extraordinary perception of the vastness of geologic time. "Time is insignificant and never a difficulty for Nature. It is always at her disposal and represents an unlimited power with which she accomplishes her greatest and smallest tasks." This treatise was also neglected, to Lamarck's deepening sorrow. Increasingly, science was being conducted through networks of mutual criticism in which evidence and data were employed to secure wide acceptance of essential facts before general theories were attempted. Scorning these procedures, Lamarck was transformed into a scientific outcast and gradually became an embittered solitary.

In 1800 he announced a revision of the classification of lower animals that had been left in a confused state by Linnaeus. He was able to penetrate superficial resemblances in form, as between certain worms and mollusks, through discriminating analysis of the functions and complexity of essential organs. This work he placed on an empirical foundation, "having at my disposal the magnificent collections of the Museum and another fairly rich, which I have myself made in the course of nearly thirty years' work." Published as ***Système des animaux sans vertèbres, ou table général des classes*** in 1801, Lamarck's first major work on the invertebrates reflected current research, most notably the anatomical studies of Cuvier, and established the basic arrangement for these animals that served as a guide to inquiry throughout the 19th century and is still largely accepted. These systematic studies of invertebrates were climaxed by the publication of his life's work, ***Histoire naturelle des animaux sans vertèbres,*** from 1815 to 1822, a complete vindication of his proposal to establish museum collections as the basis for revisionary work in systematic biology.

Guide to invertebrates

Lamarck imagined a vast sequence of life forms extending like a series of staircases from the simplest to the most complex. Impelled by "excitations" and "subtle and ever-moving fluids," the organs of animals became more complex and took their place on successively higher levels. This was the summary view of the relationship between physical energy and the overall organization of life set forth in ***Recherches sur l'Organisation des Corps vivans*** (1802) and the ***Philosophie Zoologique*** (1809). In the latter work he stated two "laws" that he held to govern the ascent of life to higher stages: first, that organs are improved with repeated use and weakened by disuse; second, that such environmentally determined acquisitions or losses of organs "are preserved by reproduction to the new individuals which arise." Thus, in a celebrated example, the forelegs and neck of giraffes have become lengthened through their habit of browsing. With the publication of Charles Darwin's ***Origin of Species*** 50 years later, these views of Lamarck became the centre of interest and controversy. As originally formulated, however, they were part of an elaborate surmise about processes for whose operation Lamarck had no direct evidence. To apply excerpts from so general a course of speculation to questions made much more precise through the application of Darwinian theory a century or more later—especially within the field of genetics, of which Lamarck had no conception—necessarily entails radical alterations of his meaning. From a lifelong, direct exposure to plants and animals Lamarck gained an intuitive sense of the dynamic quality of life, the close interdependence of physical and vital processes upon which the modern science of biology rests. Indeed Lamarck was the first to use the word biology, in 1802. But in the history of that science he may best be considered a forerunner rather than a founder, except in the systematic biology of the invertebrates, for which he established not only the best procedures of inquiry but also the kind of institution within which these inquiries have since been most successfully pursued.

Lamarck versus Darwin

Lamarck died blind and in poverty in Paris on December 18, 1829.

BIBLIOGRAPHY. There is no modern biography of Lamarck. Information on his work may be found in MARCEL LANDRIEU, "Lamarck, le fondateur du transformisme," ***Mémoires de la Société Zoologique de France,* vol.** *21* (1908), a

richly detailed chronological account of his major interests; H. BENTLEY GLASS, O. TEMKIN, and W.L. STRAUS (eds.), *Forerunners of Darwin: 1745–1859* (1959), an appraisal of Lamarck's contribution to evolutionary thought; and PHILIP C. RITTERBUSH, *Overtures to Biology: The Speculations of Eighteenth-Century Naturalists* (1964), a general account of speculative themes in 18th-century natural history. Two important translations of Lamarck's writings are by HUGH ELLIOTT, *Zoological Philosophy* (1914, reprinted 1963), his major speculative work; and by ALBERT V. CAROZZI, *Hydrogeology* (1964), an excellent modern edition of his work on the physical globe.

(P.C.R.)

Lamartine, Alphonse de

The earliest of the French Romantic poets, Alphonse de Lamartine also played a prominent, though less well-known, political role in the early 19th century. His spontaneous response to nature and his emotional sincerity rescued French verse from the abstractions and rigid structures of an exhausted classicism.

Giraudon

Lamartine, oil painting by François Gerard (1770–1837). In the Musée National de Versailles et des Trianons.

He was born at Mâcon on October 21, 1790. His father, an aristocrat, was imprisoned during the culminating phase of the French Revolution known as the Reign of Terror but was fortunate enough to escape the guillotine. Alphonse was educated at the college at Belley, which was maintained by the Jesuits though they were suppressed in France at this time.

Early military career

Lamartine had wanted to enter the army or the diplomatic corps, but because France was ruled by Napoleon, whom his faithful royalist parents regarded as the usurper, they would not allow him to serve. Thus, lacking a settled occupation. he remained idle until the Bourbon monarchy was restored in 1814, when he served in Louis XVIII's bodyguard. The following year, however, Napoleon returned from exile and attempted to rebuild his empire during the Hundred Days. Lamartine emigrated to Switzerland. After Napoleon's defeat at Waterloo and the Second Bourbon Restoration, he abandoned the military profession.

Attracted to literature, he wrote some tragedies in verse and a few elegies. By this time his health was not good, and he left for the spa of Aix-les-Bains, where, in October of 1816, on the shore of Lake Bourget, he met the brilliant but desperately ill Mme Julie Charles. Early in 1812 Lamartine had fallen deeply in love with a young working girl named Antoniella. In 1815 he had learned of her death, and later he was to recast her as Graziella in his prose "anecdote" of that name. He now became passionately attached to Madame Charles, who, because of her vast connections in Paris, was able to help him find a position. After her death in December 1817, Lamartine, who had already dedicated many strophes to her (notably "Le Lac"), devoted new verses to her memory (particularly "Le Crucifix").

In 1820 Lamartine married Maria Ann Birch, a young Englishwoman connected by marriage to the Churchills. The same year he published his first collection of poetry, *Méditations poétiques*, and finally joined the diplomatic corps, as secretary to the French embassy at Naples. *Meditations* was immensely successful because of its new romantic tone and sincerity of feeling. It brought to French poetry a new music; the themes were at the same time intimate and religious. If the vocabulary remained that of the somewhat faded rhetoric of the preceding century, the resonance of the sentences, the power of the rhythm, and the passion for life sharply contrasted with the often-withered poetry of the 18th century. The book was so successful that Lamartine attempted to extend it two years later with his *Nouvelles méditations poétiques* and his *Mort de Socrates*, in which his preoccupation with metaphysics first became evident. *Le Dernier Chant du pèlerinage d'Harold*, published in 1825, revealed the charm that the English poet Lord Byron exerted over him. Lamartine was elected to the French Academy in 1829, and the following year he published the two volumes of *Harmonies poétiques et religieuses*, a sort of alleluia, filled with deist—and even occasionally Christian ("L'Hymne au Christ")--enthusiasm.

Political career

That same year (1830), when Louis-Philippe acceded to the throne as constitutional monarch after the July Revolution, Lamartine abandoned his diplomatic career to enter politics. He refused to commit himself to the July Monarchy, however, and preserving his independence, he set out to draw attention to the social problem. After two unsuccessful attempts he was elected deputy in 1833. Yet he still wanted to write a poem, *Les Visions*, that he had been thinking about since 1821 and that he had conceived of as an "epoch of the soul." The symbolic theme was that of a fallen angel cast out of heaven for having chosen the love of a woman and condemned to successive reincarnations until the day on which he realized that he "preferred God." Lamartine wrote the last fragment of this immense adventure first, and it appeared in 1836 as *Jocelyn*. It is the story of a young man who intended to take up the religious life but, instead, when cast out of the seminary by the Revolution, falls in love with a young girl; recalled to the order by his dying bishop, he renounces his love and becomes a "man of God," a parish priest, consecrating his life to the service of his fellow men. In 1838 Lamartine published the first fragment of this vast metaphysical poem under the appropriate title *La Chute d'un ange* ("The Fall of an Angel"). In 1832–33 he travelled to Lebanon, Syria, and the Holy Land. He had by then definitively lost the Catholic faith he had tried to recover in 1820; a further blow was the death in Beirut, on December 7, 1832, of his only remaining child, Julia. A son born in Rome in 1821 had not survived infancy.

After a collection published in 1839 under the title *Recueillements poétiques* ("Poetic Recollections"), Lamartine interrupted his literary endeavours to become more active as a politician. He was convinced that the social question, which he himself called "the question of the proletariat," was the principal issue of his time; he deplored the inhumanity of the worker's plight; he denounced the trusts and their dominant influence on governmental politics, directing against them two discourses, one in 1838, another in 1846; he held that a working class revolution was inevitable and did not hesitate to hasten the hour, promising the authorities, in July 1847, a "revolution of scorn." In the same year he published his *Histoire des Girondins*, a history of the right, or moderate, Girondin Party during and after the French Revolution, which earned him immense popularity with the left-wing parties.

After the revolution of February 24, 1848, the Second Republic was proclaimed in Paris, and Lamartine became, in effect, head of the provisional government. The propertied classes, who were at first startled, pretended to accept the new circumstances, but they were unable to tolerate the fact that the working class possessed arms with which to defend themselves. In April, 1848, Lamartine was elected to the National Assembly by ten *départements*. The bourgeoisie, represented by the right-wing parties, thought they had elected in Lamartine a clever manipulator who could placate the proletariat, while military forces capable of establishing order, such as they conceived of it, were being reconstituted. The bourgeoisie was enraged to discover, however, that Lamartine was, indeed, as he had proclaimed himself to be, the spokesman of the working class. On June 24, 1848, he was thrown out of office and the revolt crushed.

Publications of last years

A broken man, Lamartine entered the "twilight" of his life. He was 60 years old in 1850, and his debts were enormous, not because he had been personally extravagant but because of the allowances he gave his sisters to compensate for the total property inheritance he had received as the only male in the Lamartine family. For 20 years he struggled desperately, though in vain, against bankruptcy, publishing book after book: *Raphael,* a transposed account of his love for Julie Charles, *Les Confidences* and *Nouvelles Confidences*, wherein he intermingled real and imaginary elements *(Graziella* is a fragment of it); novels: *Genevieve, Antoniella, Mémoires politiques,* the last work being of great historical interest; a periodical titled *Cours familiers de littérature* (1856–68/69), in which he published such poems as "La Vigne et la maison" and "Le Désert"; some historical works that remained unequalled, including *Histoire des Constituants, Histoire de la Restauration, Histoire de la Russie, Histoire de la Turquie*.

He died February 28, 1869, in Paris, nearly forgotten by his contemporaries and pursued by the hate of the bourgeoisie whom he had frightened in 1848. His stature remains that of a great poet, "a *voyant,* a seer, who was still inhibited by the old style of prosody" as the 19th-century symbolist poet Arthur Rimbaud would later say, a man haunted by the problem of God, and a courageous and lucid political combatant.

MAJOR WORKS

POETRY: *Méditations podtiques* (1820; *Mdditations,* 1920); *Nouvelles méditations poe'tiques* (1823); *La Mort de Socrates* (1823; *The Death of Socrates,* 1829); *Le Dernier Chant du pèlerinage d'Harold* (1825; *The Last Canto of Childe Harold's Pilgrimage,* 1827); *Les Visions* (critical edition by H. Guillemin, 1936); *Harmonies poe'tiques et religieuses* (1830); *Jocelyn,* 2 vol. (1836; Eng. trans., 1837); *La Chute d'un ange* (1838); *Recueillements poe'tiques* (1839).

HISTORICAL AND POLITICAL WRITINGS: *Histoire des Girondins,* 8 vol. (1847; *History of the Girondists,* 1847–48); *Histoire de la Re'volution de* 1848, 2 vol. (1849); *Histoire de la Restauration* (1851–52; *History of the Restoration of Monarchy in France,* trans. by the author and Capt. Rafter, 1851–53); *Histoire des Constituants* (1854; *History of the Constituant Assembly,* 1858); *Me'moires politiques* (1863); *La France parlementaire (1834–1851), oeuvres oratoires et e'crits politiques* (1864–65).

STORIES: *Raphael, pages de la vingtième année* (1849; *Raphael; or, Pages of the Book of Life at Twenty,* 1849); *Graziella* (1852; *Graziella; or, My First Sorrow,* 1871); *Geneviève* (1851; *Genevieve; or, the History of a Servant Girl,* 1851); *Le Tailleur de pierres de Saint-Point* (1851; *The Stonecutter of St. Point: A Village Tale* and *The Stonemason of Saint-Point: A Village Tale,* both 1851).

OTHER WORKS: *Souvenirs, impressions, pensées et paysages, pendant un voyage en Orient,* 1832–1833 (1835; *A Pilgrimage to the Holy Land, Comprising Recollections, Sketches, etc. Made During a Tour in the East in* 1832–3, 1835); *Les Confidences* (1849; *Confidential Disclosures* and *Memoirs of My Youth,* both 1849); *Nouvelles Confidences* (1851; *The Wanderer and His Home,* 1851); *Me'moires inédits* (1790–1813), published by his niece from 1870. Also general correspondence and numerous volumes of biography.

BIBLIOGRAPHY. A critical edition of the *Oeuvres poe'tiques complètes de Lamartine* now exists in the "Pléiade" collection (1963). For the prose works, it is necessary to refer to the edition furnished in 1863 by Lamartine himself, which includes neither *Antoniella* (1867) nor the *Me'rnoires posthumes* (1871). *Le Cours familier de litte'rature* (1856–69) has never been republished in full. The *Correspondence* is only complete—and imperfectly-for the years 1830–34 and the whole, very fragmentary, appears only in the volumes published in 1881 by the poet's niece. JEAN DES COGNETS, *La Vie intérieure de Lamartine* (1913), remains excellent; it was supplemented in 1916 by *Lamartine orateur by* LOUIS BARTHOU, and in 1925 by C. LATREILLE, *Les Dernières années de Lamartine,* 1852–1869. A book by H. GUILLEMIN, intended for students, *Lamartine, l'homme et l'oeuvre,* was published in 1940. By the same author are *Jocelyn, étude historique et critique* (1936), *Connaissance de Larnartine* (1942), and *Lamartine et la question sociale* (1946). Another important work is *Les Travaux et les jours d'Alphonse de Lamartine* by the MARQUIS DE LUPPE (1942); a popularized study (in French) is *Lnmartine* by MAURICE TOESCA (1969). *Le Livre du centerwire: etudes rec. et présentées par Paul Viallaneix* (1971) and *Actes du Congrès lamartinien* 111 (1971), should be consulted as well. Two English-language studies are A. PIRAZZINI, *The Influence of Italy on the Literary Career of Alphonse de Lamartine* (1917); and H.R. WHITEHOUSE, *Life of Lamartine, 2* vol. (1918, reprinted 1969).

(He.Gu.)

Lamiales

The order Lamiales includes four families of flowering plants: Verbenaceae (verbena family); Lamiaceae, sometimes called Labiatae (mint family); Phrymaceae (*Phryma*, or lopseed, family); and Callitrichaceae (water-starwort family). The family Lamiaceae, with over 3,500 species, is the largest, and is among the ten largest families of flowering plants.

GENERALFEATURES

Size range and diversity of structure. The order Lamiales shows a considerable diversity in size and habit, ranging from the slender, weak-stemmed aquatic and semiaquatic herbs of the Callitrichaceae to large trees of tropical forests in some genera of the Verbenaceae.

The teak tree

Of the many trees in the family Verbenaceae, the best known is teak *(Tectona grandis),* which ranges in height from 80 to 150 feet (20 to 50 metres) and has large leaves 18 to 24 inches (46 to 61 centimetres) long. Several genera of the family are entirely shrubby, a few are woody climbers, and others are annual and perennial herbs, small nonwoody plants that either complete their development and die within a single growth season, overwintering by means of seeds, or that live and produce seed from year to year, surviving winter or dry seasons by means of underground parts. Plants in the family Lamiaceae are mostly annual and perennial herbs, less often shrubs. Trees are rare and of small stature, generally not more than about 30 feet (nine metres) tall.

Distribution and abundance. The closely-related families Verbenaceae and Lamiaceae, when considered together, form one of the large natural alliances of flowering plants, worldwide in distribution. The Verbenaceae tends to be tropical and to occur in low-lying regions, in contrast to the Lamiaceae, which is predominantly temperate to subtropical and more often occurs in mountain or foothill regions.

The family Verbenaceae, with about 100 genera and 2,600 species, has its greatest concentration of genera and species in the warm parts of South America, Africa, and Madagascar. Lesser concentrations occur in continental Asia, Japan, and the islands of the Indian Ocean and the Pacific Ocean. The smallest concentrations are found in Europe, Asia Minor, and North America. In the family Lamiaceae, which has about 160 genera and 3,500 species, the primary centre of concentration is in the Old World from the Canary Islands to the Himalayas, with secondary outlying centres in Ethiopia, Madagascar, the Cape region of southern Africa, southern India, Sri Lanka (Ceylon), the Malaysian region, southern Australia, and Hawaii. In the New World a second principal centre of concentration lies in the mountain region extending from central Mexico southward to Bolivia and central Argentina; seondary centres include the northern plateau of Mexico, southwestern and southeastern United States, the highlands of Brazil and Guyana, the Caribbean region, and Chile.

Phryma leptostachya, the single species of the family Phrymaceae, has a distribution discontinuous between eastern North America and eastern Asia, a distributional phenomenon common to many plants and one that illustrates the floristic relationships between these two regions. This pattern is seen in such woody genera as *Mag-*

Split-distribution pattern

nolia (order Magnoliales), *Hamamelis* (Hamamelidales), and Wisteria (Fabales) but not in any other member of the Lamiales. In Callitriche, the single genus of the family Callitrichaceae, there are 25 or more species, which occur around the world, always associated with water.

Economic importance. The families Verbenaceae and Lamiaceae are of considerable economic importance, particularly the Lamiaceae.

From the Verbenaceae are obtained several useful wood products and some beautiful garden plants. Teak (from *Tectona* grandis), one of the most valuable of all known timbers, is native to India and Burma but is also cultivated for its timber in the Asiatic tropics. Other useful timbers are obtained from the genera Vitex, *Citharexylum*, *Peronema*, and *Premna*. The family Lamiaceae is an important source of oils, which are used in the manufacture of perfumes, deodorants, and toilet preparations and as flavourings for foods and beverages. Perfume oils are obtained commercially from basil (Ocimum), lavender (Lavandula), marjoram (*Origanum*), rosemary (*Rosmarinus*), thyme (*Thymus*), and sage (Salvia). Horehound (Marrubium vulgare) yields an essential oil used medicinally. Spices and flavouring oils are obtained from spearmint (Mentha spicata), peppermint (*Mentha piperata*), and balm, or melissa (Melissa *officinalis*). Spices are obtained from sage (Salvia *officinalis*); savory (*Satureja hortensis*); origanum, or European oregano (Origanum vulgare); thyme (*Thymus* vulgaris); Creten dittany (*Amaracus dictamnus*); sweet marjoram (*Majorana hortensis*); and basil (*Ocimum basilicum*).

Ornamental plants

Both the Lamiaceae and the Verbenaceae have many attractive ornamental plants. In the Lamiaceae most of the plants used as seasoning herbs are also used as garden ornamentals. Border and bedding plants come from several herbaceous (nonwoody) genera with brightly coloured and showy flowers, such as *Monarda*, Mentha, *Colquhounia*, *Phlomis*, Physostegia, and *Lavandula*. The shellflower (Molucella laevis) with large, saucer-like green calyxes (sepals—the outer series of petallike, usually green, structures in a flower) is popular for flower arrangements. *Coleus*, which has brightly coloured leaves, is one of the most popular houseplants. Shrubby ornamentals in the family Verbenaceae include the Chinese hat plant (Holmskioldia *sanguinea*), pigeonberry (*Duranta* erecta), the beauty-berries (Callicarpa species), the glory-bowers (Clerodendrum), the chaste tree (Vitex *agnus-castus*), lemon verbena (Aloysia *triphylla*), and the lantanas (*Lantana camara* and L. *montevidensis*).

Several of the mangroves of the genus *Avicennia* (Verbenaceae) have astringent bark that is used for tanning.

There are a few edible plants in the Verbenaceae and the Lamiaceae. The beauty-berry (Callicarpa *americana*) of the southeastern United States has juicy, slightly aromatic, sweet, fleshy fruits that are sometimes eaten. Several species of *Stachys* and Lycopus, in the eastern United States, and Coleus *esculentus*, of southern Africa, have tuberous roots that are used as root vegetables. The seeds of chia (Salvia *columbariae*), one of the sages widespread in the dry parts of the western United States, were once used extensively as food by the Indians. Members of both families have been used for various medicinal purposes. Bugleweed (*Ajuga reptans*) of the Lamiaceae, for example, has been used in treatment of bleeding of the lungs and as a safe and mild narcotic.

NATURAL HISTORY

Life cycle. *Pollination* and seed dispersal. Most of the Lamiales have brightly coloured, often bilaterally symmetrical flowers, which usually occur in showy clusters. These flowers are pollinated by insects and birds. Flowers with short corolla tubes are usually pollinated by bees; those with longer tubes, by butterflies and moths. The lobes of the corolla serve as a landing place or platform for the insect visitor, but in bird-pollinated flowers a platform is not usually present.

Pollination in the family Callitrichaceae takes place either on the surface of the water or in the water.

Mechanisms ensuring cross-pollination

The unisexual flowers of Callitriche are of necessity cross-pollinated, but cross-pollination is the rule in the order. The families with bisexual flowers are adapted to cross-pollination through the agency of insects and birds. In addition, there are several floral devices that further ensure cross-pollination. One is a time difference in the maturation of the stamens and stigmas. Flowers of the families Lamiaceae and Verbenaceae are largely protandrous; that is, the anthers (pollen sacs) mature earlier than the stigmas on a particular flower. This differential maturation time is sometimes accompanied by a change in position of the stamens, relative to the stigmas, during the life of the flower. In the large genus Clerodendrum (Verbenaceae), for example, the long stamens and style are at first parallel to each other; then the style bends down, away from the stamens as the anthers open. Following this the stamens curve downward, and the style returns to its original position before the stigmas become receptive to pollen.

In some genera of the Lamiaceae, there is a change from the bisexual condition to one in which there are two kinds of plants: some bisexual; others only female. This is called gynodioecy and occurs in Origanum, Salvia, *Mentha*, *Glechoma*, and Ziziphora. Sometimes, when this occurs, the plants with the female flowers are smaller than those with bisexual flowers. In a few instances size and sexual differences have not been recognized, and the two forms of one species have been described as separate species.

Fruits and seeds of the Lamiales show little diversity in structure in relation to their dispersal. The calyxes (sepals), except in *Callitriche*, remain attached much longer than in most flowers, usually enclose the fruits or seeds, and act as the vehicle for disseminating them.

Vivipary. *Avicennia*, a mangrove, is one of the remarkable genera of the Verbenaceae. It is a small genus of about 14 species found in coastal mud flats, tidal estuaries, or salt marshes of tropical or subtropical Africa, Asia, Australia, the Philippines, and North and South America. In these restricted habitats it occurs with *Rhizophora* and *Bruguiera* (family Rhizophoraceae) and *Sonneratia* (Sonneratiaceae) to form the vegetation type called mangrove forest. Mangrove plants are all similar in appearance in having prop roots or sucker shoots, and their seedlings are viviparous—that is, they germinate while still attached to the parent plant. In Avicennia, the seedling, when ready to be released from the parent plant, has a protruding rudimentary root and shoot that enable it to become embedded as soon as it falls into the mud. Vivipary is regarded as an adaptation to a saline environment. While growing on the parent plant, the seedlings store chloride, and their cell sap contains a very high salt content. Later, when the seedlings fall, they are able, because of their internal salt content, to take up water from the salty mud.

Root adaptations to obtain oxygen

Ecology. Some members of the Lamiales are adapted to specialized growth requirements. One of the most outstanding of these is seen in plants of the genus Avicennia. These plants have long cable-like roots that run horizontally through the mud and send up numerous erect suckers, or pneumatophores, the ends of which stand above the surface of the water and supply the underground roots with needed oxygen.

In the South American genus *Junellia* (Verbenaceae) are plants adapted to dry conditions that occur at high elevations from 10,000 to 14,000 feet (3,000 to 4,000 metres) in the Andes mountains and others adapted to dry desert regions of lower elevations. In the family Lamiaceae a number of species of *Scutellaria*, *Pogogyne*, *Stachys*, Lycopus, and *Mentha* grow in wet marshy ground. Several species of Salvia, which occur in the arid southwestern United States, are hard-leaved evergreen shrubs that are resistant to long dry spells.

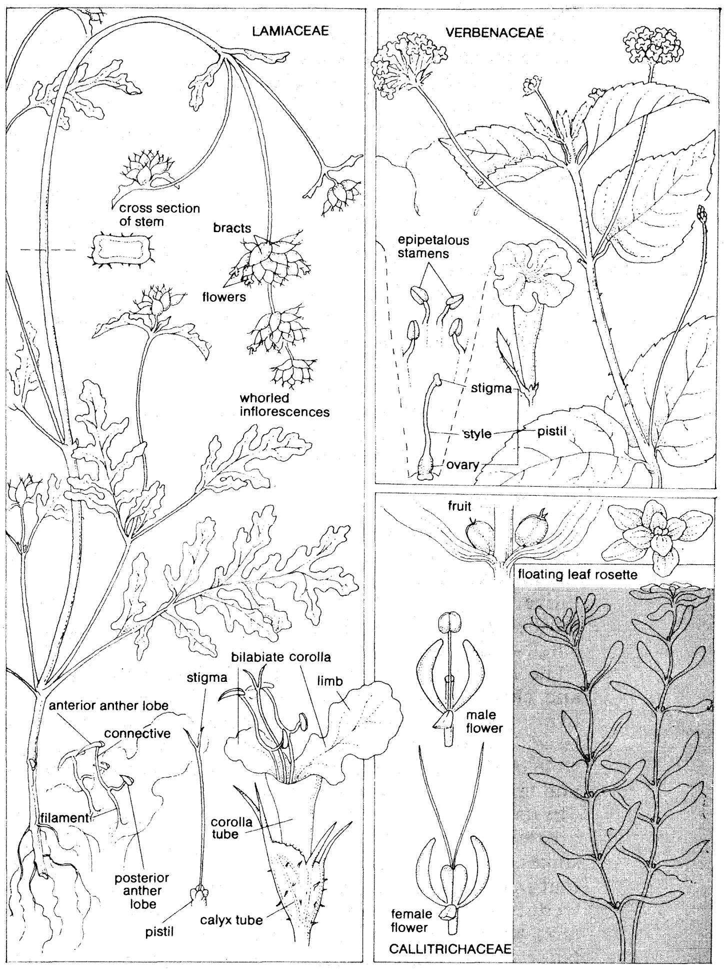
FORM AND FUNCTION

Vegetative characteristics. Members of the order Lamiales characteristically have opposite or whorled evergreen leaves. Square stems, popularly associated with the Lamiaceae, are lacking in some members of the family, particularly those with a shrubby habit. Square stems also occur in a few herbaceous members of the family Verbenaceae. The leaf blades of many of the Lamiaceae and the Verbenaceae and the single species of the Phrymaceae are entire—smooth margined—but in others the margins show all possible variations from smooth to variously toothed or cut; occasionally they are lobed. Compound leaves are uncommon. In some members of the family Lamiaceae, the stems, leaves, and inflorescences (flower clusters) are more or less hairy, sometimes with glandular hairs that secrete an aroma characteristic of the particular plant. In addition, there are frequently oil-secreting glands on the surfaces of the leaves and flowers. Except for the well-known lemon verbena (Aloysia *triphylla*; also called Lippia citriodora), scented foliage in the Verbenaceae is rare.

Aquatic plants

The family Callitrichaceae, well adapted to an aquatic or semi-aquatic habitat, is characterized by extreme reduction in its vegetative parts. The delicate and slender stem, which is either supported by water or lies prostrate, consists of a much-reduced vascular bundle and pith composed—in cross section—of only two or three cells.

Flower and fruit characteristics. The plants of the order Lamiales, with the exception of the family Callitrichaceae, have attractive, often brightly coloured flowers. They usually are not individually large but are generally clustered in various showy and often conspicuous inflorescences. These are usually racemes—flower clusters with a central axis and short side branches bearing flowers that mature from the bottom of the cluster upward—or whorls, and they have bracts (leaflike appendages below flowers) that are occasionally colourful or enlarged. The flowers are almost always bisexual (*i.e.*, structures of both sexes are found in one flower), with the basic parts, sepals and petals, five in number and more or less irregular or zygomorphic (bilaterally symmetrical). It is usually the corolla, the collection of petals, that is brightly coloured, mostly in shades of red or blue; white and yellow are rare. The calyx, or collection of sepals, is mostly tubular and five-parted or two-lipped at the apex and is usually green, smaller, and less conspicuous than the corolla. The corolla consists of a tube (the basal part) and a limb (the terminal showy part). The tube may be short or long in relation to the limb and is usually straight with parallel sides; it is rarely pouched. The limb shows variation in shape and size. It may be divided into five more or less irregular parts or into two unequal parts to form a two-lipped corolla. The five-parted corolla is more often seen in the family Verbenaceae, and the two-lipped one is typical of the Lamiaceae. The flowers in the family Phrymaceae have a tubular calyx and a two-lipped corolla. There may be four stamens (male pollen-producing structures) usually in two pairs of unequal length, sometimes two, or rarely five. They are attached to the inner side of the corolla tube and are contained within or sometimes extended beyond it. The ovary is superior; *i.e.*, it is located above the point where the sepals, petals, and stamens arise. It is composed of two carpels—simple ovaries or segments of a compound ovary—that usually appear to be four because of the division of each into two parts. Within each carpel are two ovules, seed precursors, which are usually erect but with the micropyles, tiny openings through which fertilization takes place, directed downward. The single style, the narrow upper part of the compound ovary or pistil, may or may not extend beyond the end of the corolla tube along with the stamens. The stigmatic surface, the pollen-receiving portion of the style tip, usually matures after the pollen is shed from the stamens of the same flower. The fruit in the family Lamiaceae usually consists of two to four hard, dry, one-seeded nutlets, each containing one seed. Sometimes, in the Verbenaceae, the fruit is a drupe, a stone-seeded fleshy fruit, which breaks up into one-seeded pyrenes, nutlet-like fruit segments.



Representative members of the order Lamiales.

Drawing by M. Pahl; from A. Enaler and K. Prantl, *Die Naturlichen Pflanzenfamilien, 2nd ed.*, vol. 19c (1931); Duncker & Humblot

Reduced flowers of Callitriche

The tiny flowers of Callitriche are lacking in showy parts—*i.e.*, sepals and petals—and are as much reduced as a flower can be and still function. They consist of only their essential organs, each flower having but one stamen and one pistil (female complex with stigma, style, and ovary). Each flower is solitary in a leaf axil—the upper angle between a leafstalk and the plant stem or branch—and is usually subtended by a pair of tiny, delicate bracts. Both staminate (male) and pistillate (female) flowers are on the same plant, so that the plants are monoecious, a condition not found elsewhere in the order Lamiales. The ovary of the female flower is two-celled and two-lobed; each cell is further divided into two parts as in the Lamiaceae and the Verbenaceae, but unlike them there are two separate styles. The small solitary fruits break up into four tiny one-seeded nutlets.

EVOLUTION

Fossil record. Fossil records show occasional occurrences of modern genera of both Lamiaceae and Verbenaceae. Perhaps the earliest record is that of *Vitex pentadactyla* (Verbenaceae) in the Cretaceous Period (65,000,000 to 136,000,000 years ago) of Bohemia. Nutlets of *Hancea* (Lamiaceae), a genus that now occurs in eastern Asia, have been found in the London clay flora of the Eocene Epoch (38,000,000 to 54,000,000 years ago). Records also have been found of a few present-day species. *Verbena officinalis*, now widespread in Europe, has been found in deposits of the Pliocene Epoch (2,500,000 to 7,000,000 years ago) of Belgium.

The fossil record, although small, indicates that some modern genera have been in existence since the Cretaceous and early Tertiary and suggests that during these times groups similar to those of the present day were being differentiated.

Phylogeny. The meagre fossil record is of no help in explaining relationships of the Lamiales to closely related families in other orders. Nor does it explain relationships among the families within the order. The characters most generally useful for establishing relationships among the flowering plants are in the flowers and fruits, and these seldom are found in the fossil record. As a result, the living members of these groups must provide the clues to relationships. In their floral structures, for example, the plants of the order Lamiales are considered to be among the most highly evolved groups of dicotyledons, the group of flowering plants with two "seed leaves" and net-veined leaves.

Relationship between mint and verbena families

The similarity between the families Lamiaceae and Verbenaceae has been evident for many years. The four-lobed ovary and gynobasic style—a style arising from near the base of the ovary—of the Lamiaceae separate it from the Verbenaceae in which the entire, rarely shallow, four-lobed ovary has a terminal style. Several genera of the Verbenaceae, however, have a nearly gynobasic style partially sunk between the four shallow lobes of the ovary. This and other intergrading characters make it difficult to separate all the members of one family from the other, but at the same time they emphasize the closeness of the relationship between the two families.

CLASSIFICATION

Distinguishing taxonomic features. Of the four families here comprising the Lamiales, the Callitrichaceae is the most easily distinguished by its greatly reduced vegetative and floral structure. The Phrymaceae is distinguished from the Lamiaceae and the Verbenaceae by its single-celled ovary.

The most useful characters for distinguishing the large and closely related Lamiaceae and Verbenaceae are the ovary and fruit structure, type of inflorescence, and, to a lesser extent, habit. The four-lobed ovary and gynobasic style of the Lamiaceae contrasts with the nonlobed ovary and terminal style of the Verbenaceae.

In its inflorescence types, the family Verbenaceae shows greater diversity than the Lamiaceae, with racemes, spikes, and compound cymes, complex-branched clusters that mature from the apex downward. The Lamiaceae infrequently has racemes and frequently has whorled clusters, which may be separated or crowded. In fact, the latter inflorescence occurs widely enough in the family to be considered characteristic of it.

In the Verbenaceae the woody habit predominates, but in the Lamiaceae the plants are mostly herbaceous and, less often, somewhat shrubby.

Annotated classification. The descriptions of the four families presented here are generalized to include most of their genera. In the large families there may be exceptions. Thus, the Lamiaceae is said to be bisexual, yet the family includes at least one genus, *Iboza*, with male and female flowers on separate plants and other genera with separate female flowers besides the bisexual ones. Exceptions to the characteristic two-lipped flowers are seen in Ajuga and *Teucrium* in which the upper lip of the corolla is lacking. In the Verbenaceae are several genera so unlike most of the family that from time to time they have been placed in separate families. One of these is *Avicennia*, which some botanists place in its own family, the Avicenniaceae, on the basis of its ovary structure.

ORDER LAMIALES

Herbs, shrubs, or trees; leaves nearly always opposite and simple; 5-parted flowers usually bisexual and with a gamopetalous (1-piece, of fused petals), irregular, or bilaterally symmetrical corolla; stamens 2, 4, or 5, arising from the inner surface of the tubular corolla; ovary superior (positioned above the attachment point of the calyx and corolla), usually with 2 carpels (ovule-bearing segments of the ovary) and 4 locules (chambers), ovules usually 1 in each locule; usually 1 style, forked at the apex, terminal on the ovary or arising from its base; fruit of 4 nutlets, a drupe that separates into 4 pyrenes, or rarely a capsule. Four families, about 260 genera, and over 6,000 species, worldwide distribution.

Family Callitrichaceae (water-starwort family)

Annual or perennial monoecious herbs with slender delicate stems; leaves opposite, entire; flowers solitary in leaf axils, subtended by two bracteoles (small leaflike appendages), unisexual, radially symmetrical; sepals and petals lacking; male flower consisting of 1 stamen with a 2-celled anther; female flower consisting of 1 pistil; ovary superior with 2 carpels and 4 locules, 1 ovule in each locule, pendulous, anatropous (reversed (the micropyle opening is close to the point of the funiculus, or stalk, attachment); styles 2, separate to the base; fruit composed of 4 nutlets, variously keeled or winged. One genus, Callitriche, with 25 or more aquatic or semi-aquatic species distributed on all continents.

Family Phrymaceae (lopseed family)

Perennial herbs; leaves opposite, entire; flowers solitary, in opposing axils, arranged in terminal elongated slender racemes, bilaterally symmetrical; calyx tubular, 2-lipped; corolla 2-lipped, lower lip 3-lobed, larger than upper lip; stamens 4 in 2 pairs, attached to corolla tube; ovary superior, 1-chambered with free central placentation; ovule 1, erect, orthotropous (straight—the micropyle opening is at the apex opposite the point of attachment); fruit a 1-seeded nutlet, enclosed in the persistent calyx. One genus and species (*Phryma* leptostachya), in damp woods of eastern North America and eastern Asia.

Family Verbenaceae (verbena family)

Herbs, shrubs, trees, or climbers; stems occasionally square in cross section; leaves usually opposite, sometimes whorled, mostly simple, rarely compound, without stipules; inflorescence variable, often large and showy; flowers irregular or bilaterally symmetrical, calyx mostly 5-lobed or 5-toothed, persistent; corolla of fused petals, irregularly 5-lobed or occasionally 2-lipped; stamens 4 in 2 pairs, rarely 5, attached to petals; ovary superior, sometimes shallowly 4-lobed, with 2 carpels, 4 locules, and ovule attachment along the central axis; 1 ovule in each locule, mostly erect, anatropous; 1 terminal style; stigma divided into 2 equal lobes; fruit generally a drupe separating into *2* to 4 pyrenes, or nutlets, or rarely (in *Avicennia*) a capsule; seed with a thin seed coat and straight embryo, lacking endosperm (nutritive tissue) except in *Avicennia*, *Stilbe*, and Chloanthes. About 100 genera and 2,600 species, predominantly in tropics and subtropics around the world.

Family Lamiaceae (mint family)

Mostly herbs, shrubs, or subshrubs, rarely trees or climbers; stems usually square in cross section; leaves opposite, simple, rarely pinnately compound (*i.e.*, with leaflets arranged on both sides of a central axis) or lobed, without stipules; flowers usually in a series of successive whorls, the whorls scattered or contiguous and spikelike, or flowers solitary at each axil; bracts usually present, sometimes showy and colourful; flowers bilaterally symmetrical or nearly so; calyx tubular, persistent, 5-lobed, often 2-lipped, usually with 5, 10, 13, or 15 conspicuous ribs; corolla 5-lobed, usually 2-lipped, typically the upper lip 2-lobed and erect and the lower 3-lobed, concave or spreading; stamens 2 or 4 in 2 pairs, attached to the petals, 1 pair usually longer, a staminode (sterile stamen) rarely present; anthers 2-celled, opening longitudinally, the connective tissues between the anther sacs sometimes well-developed and the anterior cell reduced or absent; nectar-secreting disk present at base of ovary; ovary superior, 4-lobed, with 2 carpels and 4 locules, ovule attachment basal, 4 ovules, anntropous, erect; style 1, forked at apex, usually arising from base of ovary; fruit typically of 4 nutlets, dry, rarely fleshy, separate or cohering in pairs, enclosed in persistent calyx. About 160 genera and 3,500 species distributed in temperate regions around the world.

Critical appraisal. The family Callitrichaceae with its tiny unisexual flowers may seem out of place in the Lamiales. Because of its flowers its relationship has been placed from time to time with other families that are largely unisexual and without flower petals, such as the Haloragaceae or the Euphorbiaceae. Recent embryological studies of the ovule, however, have shown features that are characteristic of the Verbenaceae, which tends to place the relationship of the Callitrichaceae with the Lamiales. Placing it in this order might still be questioned, however, since its well-developed endosperm and separate styles are not generally found in the Lamiales.

The families of the Lamiales were formerly placed in the large order Tubiflorae. This order contained about 20 families with bisexual flowers having tubular corollas. In their floral structures these families are among the highly evolved groups of dicotyledons.

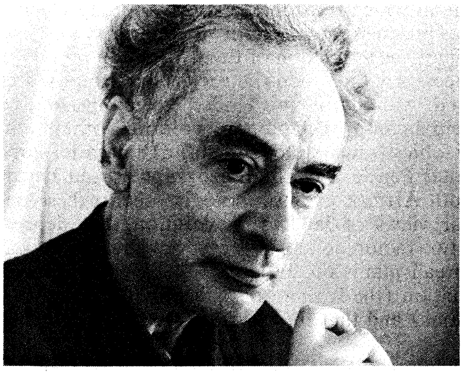
Landau, Lev Davidovich

Lev Davidovich Landau, one of the greatest theoretical physicists of the 20th century, made an outstanding contribution to the development of that subject in the U.S.S.R.

USSR Magazine—Sovfoto



Landau.

Education

Landau was born on January 22, 1908, in Baku, Azerbaijan, Russia. His father was an engineer working in the Baku oil industry and his mother a doctor who had at one time done physiological research. Landau graduated at 13 from the gymnasium and, because he was too young to go to the university, attended the Baku Economical Technical School. He matriculated in 1922 at Baku University, studying physics and chemistry, and transferred in 1924 to the Leningrad State University, which at that time was the centre of Soviet physics. Graduating in 1927, he continued research at the Leningrad Physico-Technical Institute. At that time there were practically no outstanding senior theoretical physicists in the Soviet Union, and since the younger men had to teach themselves and each other, it was important for them to go abroad and be in touch with the Western theoretical physics schools that were flourishing in such centres as Copenhagen and Munich. Landau got his first chance to go abroad in 1929, on a Soviet government travelling fellowship supplemented by a Rockefeller Fellowship. After brief stays in Gottingen and Leipzig, he went to Copenhagen to work in Niels Bohr's Institute for Theoretical Physics. It is probably no exaggeration to say that the development of present-day theoretical physics owes more to Bohr's Institute than to any other place in the world. Almost all of the leading theoretical physicists of the 1920s and 1930s spent some period at this institute. Landau always considered himself a pupil of Bohr's, and his attitude to physics was greatly influenced by Bohr's example. After his stay in Copenhagen he visited Cambridge and Ziirich before returning to the U.S.S.R. Apart from short visits to Copenhagen in 1933 and 1934, Landau spent the remainder of his life in his own country.

In 1932 Landau went to Kharkov to become the head of the Theoretical Division of the Ukrainian Physico-Technical Institute, which position he combined in 1935 with that of head of the Department of General Physics at the Kharkov A.M. Gorky State University. In Kharkov Landau began to build a Soviet school of theoretical physics, so that Kharkov soon became the centre of theoretical physics in the U.S.S.R. It was also in Kharkov that, with his friend and former student, E.M. Lifshits, he started to write the well-known *Course of Theoretical Physics*, a set of nine volumes that together span the whole of the subject. His great interest in the teaching of physics is also shown in his plans for a "Course of General Physics" and even a series "Physics for Everybody."

Landau required that his students master all necessary mathematical techniques before coming to him. After that he expected them to master the so-called theoretical minimum, which included a basic knowledge of all the domains of theoretical physics. Only the ablest of the students were able to pass this minimum. In this way his students became proper physicists, rather than narrow specialists.

Work on liquid helium

In 1937 Pyotr Leonidovich Kapitsa, a low-temperature experimentalist, persuaded Landau to move to Moscow and to head the Theory Division of the S.I. Vavilov Institute of Physical Problems, which had been created by the U.S.S.R. Academy of Sciences. There, Landau's close interest in experimental physics led to his development of the theory of liquid helium, the last of the elements to be liquefied and the most remarkable of all liquids. Kapitsa had found that liquid helium was superfluid—that is, that it had less resistance against moving through a tube than any other known liquid. Landau's theory to explain this peculiar behaviour was the work for which he was awarded the Nobel Prize for Physics for 1962.

Landau's attitude to physics and physicists was critical; he did not suffer fools gladly. While always willing to help anybody, he hated pomposity. People either adored him or were his bitter enemies, and he was imprisoned during the Stalin era, in 1938, and only a personal intervention by Kapitsa freed him.

In 1937 Landau married K.T. Drobanzeva, and in 1946 they had a son, Igor, who became an experimental physicist.

In Moscow Landau continued to make significant contributions to almost all parts of physics. The topics he covered range from low-temperature to nuclear physics, from the theory of metals to stellar energy, from cosmic rays to plasmas, from hydrodynamics to atomic physics. Landau's contributions are partly reflected in such terms as Landau diamagnetism and Landau levels in solid-state physics, Landau damping in plasma physics, the Landau energy spectrum in low-temperature physics, or Landau cuts in high-energy physics.

On January 7, 1962, Landau was involved in a car accident. He was unconscious for six weeks and was several times declared clinically dead, but he somehow revived. Distinguished specialists from several countries helped to save his life. After Landau had regained consciousness his faculties slowly returned to him, but he was no longer able to perform creative work. His physical condition never returned to normal, and he died April 1, 1968.

Apart from the Nobel Prize, Landau received many other honours. In the U.S.S.R. he was directly elected a member of the Academy of Sciences, was given the title of Hero of Socialist Effort, and was awarded three State Prizes, as well as a Lenin Prize. He was a foreign member of the Royal Society of London and of the academies of The Netherlands, Denmark, and the United States, as well as a recipient of the Max Planck Medal and the Fritz London Prize.

BIBLIOGRAPHY. A popular account of Landau's life, and especially of his last six years after his accident, may be found in A. DOROZYNSKI, *The Man They Wouldn't Let Die* (1966). His scientific papers were published in D. TER HAAR (ed.), *Collected Papers of L.D. Landau* (1965). *All* his books have been published in English translation.

(D.t.H.)

Landform Evolution

Landform evolution is a descriptive term that may be applied to all changes in the earth's surface features throughout time. In the broad sense, such changes are a consequence of the interaction of two basic processes: relative uplift on the earth's surface and downwearing by weathering and erosion. The eternal struggle between these opposing processes is reflected at any particular point in time by the landforms, or scenery, that appear on earth. The casual visitor to Victoria Falls, the Alps, Lake Baikal, or elsewhere is, in effect, a witness to this contest, for no landform or feature on the earth's surface is unchanging. At some point in the geological past it did not exist, and at some future date it will have vanished once again.

The transient character of landforms is both inescapable and obvious when time spans of great duration are involved. But when the focus is on a somewhat shorter time period, and when landform evolution is examined more closely, a number of difficult questions arise. In a general way, it might be asked how a given landform originated, how it changed in the past, and how it will change in the future. In more precise terms, however, the inquiry really centres on whether the processes of uplift or downwearing dominate at a given point in time and throughout time, on the precise nature of the interaction between these processes, and on the effect of this interaction on the configuration of landforms at the earth's surface. The latter question involves a host of physical, chemical, and biological factors and processes, many of which are imperfectly understood. In one sense it is adding the query **why** to the previously asked *how*; in another, it is asking the ultimate question, namely, whether landform evolution accords with some natural law that causes change to occur in a predictable manner.

Early theories of landform evolution

These questions have long been of interest to man and many views have been set forth. The Greek authors Herodotus and Strabo and the Persian Avicenna perceived correctly that the landforms about them were acted upon and molded by physical processes. Cogent arguments along these lines were provided in the 15th and 16th centuries by Leonardo da Vinci, Agricola, and others who recognized that stream erosion and fluvial processes were responsible for the creation of mountain valleys and the transportation of sediment.

This promising beginning toward understanding was halted abruptly by theological constraints on the time available for the occurrence of landform evolution. Archbishop Ussher of Ireland, for example, concluded from biblical studies in 1654 that earth and man had been created in 4004 BC, on October 26, at 9:00 A.M. His pronouncement, accepted literally, forced the conclusion that all aspects of the earth's surface features must have developed in less than 6,000 years. There thus arose a catastrophic school of thought, so called because its adherents interpreted the evolution of all landforms in terms of catastrophic events that presumably had occurred during extremely brief periods of time.

Abraham Werner (1750–1817), German mineralogist, was one of the chief proponents of this view. During a long tenure in Germany he produced an entire generation of student disciples who went so far as to champion the notion that all rocks of the earth's crust had been rapidly precipitated from a single "universal sea." At that time there was no knowledge of the several advances and retreats of glacial ice during the Pleistocene Epoch, and the enormity of geological time was still unsuspected. Combined with the theological constraints imposed on the earth's age, it is not surprising that the valleys of the Swiss Alps and the glacially derived debris on their floors commonly were explained by recourse to the advance and retreat of the biblical flood. Georges Cuvier (1769–1832) the French paleontologist, gave the same explanation for disrupted strata and unconformities in sedimentary deposits in France. As recently as the early part of the 19th century, in fact, there was conflict between supporters of a relatively modern view of nature and those who wished to interpret landforms in terms of the universal deluge that had raised the Ark.

Present theories of landform evolution

Controversy about the nature of landform evolution has persisted to the present day. There are, presumably, no advocates of Ussher's chronology or of a universal rush of waters. Moreover, since quantitative data for the retreat of the chalk cliffs of England, the canyon walls along the Colorado River, the escarpment at Niagara Falls, and similar features, became available, none has doubted that landforms tend to change gradually, at observable rates in most instances. With the replacement of the theory of catastrophism by that of gradualism, several distinct concepts of landform evolution have emerged. They are uniformitarianism, the cycle of erosion, regional morphogenesis, dynamic equilibrium, and entropy-probability. Briefly, these ideas may be described as follows.

Uniformitarianism. According to uniformitarianism, the processes operative on the earth's surface today are similar in kind to those that were operative in the past. Hence, if runoff from a storm is seen to produce gullies in hillslopes today, it is argued that knowledge of this modern hillslope erosion, and of the transportation and deposition of the removed sediment, can be extrapolated in time to interpret hillslopes and sedimentary accumulations of the past.

Cycle of erosion. The cycle of erosion, also called the geographic cycle by some, is a quasi-anthropomorphic explanation of landform evolution set forth by William Morris Davis (1850–1934), the American geographer, in the latter part of the 19th century and the early part of the 20th century. Its proponents assumed that landforms traverse a cycle in which hillslopes, valleys, mountains, and river systems progress from "youth" to "maturity" to "old age," principally as a function of time, although rock type and the processes acting upon the rocks were supposed to be considered. Although Davis tended to emphasize time as the principal causative factor in evolution, others emphasized tectonics (crustal movements) and parallel slope retreat. Walter Penck, a German geographer, and Lester King, a South African geomorphologist, set forth somewhat similar views of landform evolution that depend upon these two factors. King, in fact, drew the conclusion that widespread plains on the continents were produced by pediplanation (the formation of pediments under humid conditions) and that they are correlative surfaces of denudation.

Morphogeneric regions. According to the concept of regional morphogenesis, similarities of landforms are thought to result primarily from similarities of climatic regimes in the regions involved. Thus, in a gross way, the angularity of desert landscapes and the gentler expression of temperate and humid landscapes are taken as examples of morphogenetic regions. Considered in detail, this concept, like that of the cycle of erosion, falters because it requires too much dependence on a single factor, or single group of factors, and the denigration of others of equal importance.

Interestingly, the predominant Russian view of landform evolution tends to parallel the regional morphogenetic system, though instead of emphasizing climate Soviet workers emphasize tectonics and speak of "morphostructural units" as a basic conceptual framework. Simply stated, this means that a relationship between form and uplift is thought to exist, such that the genesis or history of a given landform or region can be deduced from its geographic aspect.

Dynamic equilibrium. The idea of dynamic equilibrium can best be explained in terms of high school chemistry: If reversible reactions of substances A and B yield substances C and D and if any of these four substances is added after equilibrium has been attained, there will then occur a reaction in a direction that will tend to minimize the changed conditions, and a new balance point or state of equilibrium will be established. Analagous examples from the elementary laws of motion in physics and from other disciplines can be given. In terms of landform evolution, the conception of dynamic equilibrium means that a balance tends to be established between the resistance of the rocks on the one hand and the processes of downwearing and erosion on the other. This "balance" may be expressed as a particular hillslope or stream bed profile.

Concept of balance between rock resistance and erosion

Any change in conditions, such as renewed uplift or climatic change, will, like the addition of one of the substances in the chemical example, cause a concomitant change in the hillslope or stream bed profile toward a new state of equilibrium. Because landform systems are not static, equilibrium is called dynamic to indicate its constant change or fluctuation about a mean position that is termed the steady state. An important consequence of the equilibrium concept is that landforms in equilibrium must be considered timeless.

The idea of dynamic equilibrium is in direct contrast to that of the erosion cycle, which is the notion that the history of a landform is revealed by its stage or aspect within some fixed development sequence. Dynamic equilibrium is, in fact, in contrast to nearly all other views of landform evolution because they set forth *chronologies* of denudation regardless of the procedural element (for example, tectonics, climate) that is being emphasized. Thus, landforms are time bound within other frameworks of thought.

Entropy-probability. The last concept to be considered, entropy-probability, is not applied to landforms solely in terms of its inverse thermodynamic relation to free energy but, rather, in terms of probabilities. Entropy in landform evolution is related to the most probable distribution of energy and to the most probable configurations of stream profiles, drainage networks, and the like. It has been found, for example, that the plans and profiles of river systems and the distribution of branches and other aspects of drainage networks accord well with comparable features that have been deduced theoretically or that have been generated by random-walk statistical procedures. The body of knowledge that has accrued in this area suggests that hillslopes, river systems, and other features of the surface of the earth generally accord with the most probable configuration of their class or type, unless physically constrained in some manner. This most probable configuration represents both the most probable distribution of energy within a given system and the most probable point of fluctuation of dynamic equilibrium. The entropy-probability concept is in one sense, therefore, an extension of that of dynamic equilibrium. The additional notion of randomness in nature is important, however, because it suggests that certain aspects of landform evolution may be indeterminate. If drainage networks evolve according to the laws of chance, for example, and if their aspect in nature reflects only a distribution about the most probable network configuration, then it is clear that although a great deal can be said about networks as a class, treatment of a single, specific drainage network rests upon ground of far lesser strength.

Because landform evolution is a subject that is intimately associated with the concepts outlined above, this article will treat these concepts in detail, and classes or kinds of specific landforms only incidentally. The interested reader should refer to such articles as COASTAL FEATURES; DESERTS; PEDIMENTS; SAND SHEETS AND SAND DUNES; JUNGLES AND RAIN FORESTS; GLACIATION, LANDFORMS PRODUCED BY; and RIVER DELTAS for treatment of landforms as such. For more detailed treatment of some of the components of landform systems that are germane here see HILLSLOPES; SOILS; SEDIMENT YIELD OF DRAINAGE SYSTEMS; ROCKS, PHYSICAL PROPERTIES OF; RIVERS AND RIVER SYSTEMS; FLUVIAL PROCESSES: WEATHERING; CLIMATE; CLIMATIC CHANGE; and PHYSIOGRAPHIC EFFECTS OF TECTONISM. For further information about geomorphology, the discipline concerned with landform evolution, see GEOLOGICAL SCIENCES and EARTH SCIENCES; for the relevance of the topic to aspects of earth history, see EARTH, GEOLOGICAL HISTORY OF; and for information on the geological time periods of greatest pertinence to this article, see PLEISTOCENE EPOCH and HOLOCENE EPOCH.

UNIFORMITARIANISM

The concept of uniformitarianism is often equated to the phrase "the present is the key to the past." The allusion made is to present and past processes that are operative upon and within the earth. James Hutton (1726–97), a Scottish naturalist, was the first to recognize this truth; and his views were expanded by his friend John Playfair (1748–1819), a mathematician at Edinburgh, and ensconced in geological thought for all time by Sir Charles Lyell, the English geologist, in his *Principles of Geology*, published between 1830 and 1832.

Methodological and substantive uniformitarianism

Uniformity in nature is undoubted, and it is a commonplace that rocks weather today as they did in the past, that coasts are beaten by waves and tides as in the past, and that the dunes that move in response to wind action today must also have migrated under this impetus in the past. These are the dictates of common sense, and their denial would appear to be akin to repeal of the fundamental laws of nature, but the concept of uniformitarianism has not been viewed with unity by all observers. The rub involves the question of whether past processes are similar to modern processes when magnitudes, intensities, and rates are considered. In the light of modern data, most authorities today would probably agree that uniformitarianism is a dual concept: substantive uniformitarianism, representative of the original view, holds that present and past processes are similar in kind and rate, whereas methodological uniformitarianism asserts that although process rates may have varied throughout time, the concept of uniformitarianism properly pertains only to the principle of invariance of natural laws in space and time. The truth of this proposition is manifest from plotted graphs of mountain building, petroleum and coal reserves, extinctions of life forms, extent of glacial ice, and many other variables against time. In each case the frequency of occurrence of processes, or their magnitude, or both, fails to accord with a uniform distribution throughout time. This demonstrates that although present and past processes are similar in kind, process rates must have been variable.

This is a fact of considerable importance with respect to landform evolution. Central to the controversy between the adherents of Davis' anthropomorphic theory and proponents of dynamic equilibrium, for example, is the question of whether a given landform reflects the historical imprint of time; that is, whether the effects of former processes are discernible, or whether the landform is fully adjusted to present processes. Though the main question will be discussed later, some aspects of methodological uniformitarianism are worthy of mention at this point.

Earth-Moon relationships

Earth-Moon relationships serve as an excellent example because the laws of motion that apply to these bodies are representative of invariant natural laws. Despite this fact, their relationship through time has been such that certain process rates have changed.

Both observational and theoretical data, for example, indicate that the Moon has accelerated in its orbit through time. Because the angular momentum of the two-boldy system must be conserved, the increase in the angular velocity of the Moon has to he associated with an increase of the Earth-Moon separation distance and a decrease in the rate of rotation of the Earth. A number of models can be postulated to account for this situation; but these are only speculative because neither the initial separation distance nor the initial time involved is known. The physical limitation on this point, regardless of the origin of the Moon, is the Roche limit, named for its discoverer Edouard Roche in 1850, which posits a minimum possible separation distance for the Earth and its satellite at 2.89 Earth radii. Closer proximity would result in destruction of the Moon.

Within the context of methodological uniformitarianism two points, above others, need to be stressed. First, the tide-generating potential on Earth is proportional to M/R^3, in which M is the mass of the Moon and R the Earth-Moon separation distance. This means that, aside from the host of complexities that enter tidal computations, it is beyond dispute that greater tides were experienced on Earth in the geological past because the separation distance was less than it is today. This may be related to such problems as the uneven distribution of blanket sands (sand-size sediments of great areal extent), cyclothems (rhythmic and alternating strata that include sandstones, limestones, and coal beds), or other features in the geological record, but the basic point is that past tidal processes must have differed in magnitude and frequency from those of today. Second, because the rate of rotation of the Earth has decreased, so fundamental a quantity as the length of day has also varied through time.

Based on a calculation of tidal dissipation in shallow seas and in the form of bodily or earth tides, it has been proposed that the length of the day on earth has increased by 1.8 milliseconds per century for about 1.5×10^9 years. Corroboration from a fascinating and independent source was provided in 1963 by the discovery of banding in Devonian (345 to 395,000,000 years ago) corals that represent increments of growth. A simple counting of fine bands within the annual bands provides the number of days per year. Counts from several specimens yielded an average of approximately 400 days per year, in middle Devonian time. These results differ from tidal-dissipation calculations of the increase in the length of day by only 0.7×10^{-10} sec per day (see also DATING, RELATIVE AND ABSOLUTE).

Changes in the length of day and the Earth's rotation rate through time bear upon a considerable number of processes and factors of interest. These include the duration and frequency of incoming solar radiation at a given point on Earth, oceanic current systems, and a wide variety of atmospheric phenomena that affect the weather and climate.

Effects on climate and erosion rates

The climate, in turn, is of considerable importance because it has both indirect and direct influence on the erosion of the earth's surface. Indirectly, climate tends to control the type and density of vegetation as well as the development of soils. The presence or absence of soils and vegetation will in turn cause considerable variation of the sediment yield from given areas, under identical precipitation conditions. The relation between annual sediment yield and effective precipitation that was developed in 1958 is still generally valid. Basically, the relationship shows that maximum yields are correlative with semi-arid conditions. As precipitation decreases, the sediment yield diminishes drastically because the lack of sufficient runoff under increasingly arid conditions compensates for the absence of vegetation. As precipitation increases above semi-arid levels, sediment yield again diminishes. In this instance, however, it is because greater abundance of vegetation inhibits erosion despite the greater amounts of runoff. When effective precipitation attains a value of 1,000 millimetres (about 40 inches) per year, the curve of relation flattens; higher annual values do not produce greater sediment yields.

With respect to the role of vegetation in inhibiting erosion rates, it is necessary to bear in mind that the earth's present plant cover has not always existed. Plants as ground cover were totally absent during Precambrian and early Paleozoic time, and on these grounds alone it is clear that erosion rates must have varied through geologic time. Present rates have been computed by a number of authorities, but the values vary because bed-load transport (coarse material in transit along the bed of a stream), for example, is unmeasured in most streams and because few data on the dissolved loads of rivers are available. The computation involves converting the annual tonnage of suspended sediment in streams into denudation rates, which are expressed as rates of uniform lowering of the land surface over large areas. The present rate for the continental United States has been given as 2.5–7.5 centimetres per 1,000 years, which is considered by many to be abnormally high when geological time is considered.

Magnitude and frequency of geomorphic processes

It is well established that climate has changed through geologic time and that, in a general way, this can be linked to changes in rates of denudation. The precise relationship between the magnitude and frequency of natural geomorphic processes, such as fluvial runoff, and the rate of accomplishment of work (*e.g.*, erosion) is still elusive. It has been argued that it is the natural event of moderate magnitude and relatively frequent occurrence that accomplishes most of the work on the surface of the earth. It must be noted, however, that this view applies best to depositional landforms in temperate regions.

The retreat of cliffs, for example, tends to be a process characterized by great magnitude (*e.g.*, landslides, avalanches) and infrequent occurrence; it can be termed a step-function process for this reason. The same is true of stream-channel erosion in many situations; the largest boulders will be transported only by extreme events (*e.g.*, the thousand-year flood). An examination of Coffee Creek, California, following such an extreme event, for example, has suggested that the role of infrequent events of large magnitude deserves renewed consideration in landform evolution. And an analysis of high mountain streams in the Sangre de Cristo Mountains of New Mexico by J.P. Miller (1923–62), the American geomorphologist, led him to conclude that a certain fraction of the bed material present today may have moved frequently only under Pleistocene runoff conditions that would have been extreme in terms of modern phenomena. Runoff events under arid conditions clearly belong to this same category. As the mean annual precipitation falls below 250 mm (about ten inches) per year, the variability of its distribution increases markedly, and the relatively infrequent flash flood becomes the most significant event in terms of work performed.

Thus, with respect to the uniformitarian view, the present is the key to the past; but at every hand there is abundant evidence of diverse nature which indicates that the magnitudes, intensities, and rates of processes have varied throughout time. The fact that the kinds of operative processes have been similar throughout time, however, permits rational examination of the relative merits of the several concepts of landform evolution. And the fact that process rates have varied throughout time provides an avenue for investigation of the extent to which the imprint of time is present on a given landform and under a given climatic regime.

CYCLE OF EROSION

The concept that landforms are subjected to a cycle of erosion, also called by some the geographic or geomorphic cycle, was set forth in more than 500 published works of William Morris Davis between 1884 and 1934. Particularly important among these works was a paper on the rivers and valleys of Pennsylvania, the features that he interpreted in terms of the concept. Following its publication in 1889, an entire generation of geographers and geomorphologists devoted the bulk of their productive years to the expansion, elaboration, or further illustration of the cycle of erosion. Despite the advent of quantitative methods in the 1950s and of alternative general syntheses of landform evolution, the views expressed by Davis are still accepted by some geologists as a correct conceptual framework of reference. Clearly they must, therefore, be considered in any general discussion of landforms and their change through time.

The Davisian concept of stage and age:

Davis believed that landforms evolve from an initial state to an ultimate state, and that this is accomplished by progressing through definite and characteristic stages after the initial regional uplift has occurred. The initial state may be represented by a relatively flat plain, perhaps one that has emerged from the sea. Uplift transforms such an area into fold mountains or block mountains, leading to the stage which Davis termed youth. Next, dissection of these massifs by fluvial processes causes the establishment of drainage systems and maximum relief during the stage termed maturity. Ultimately, and in Davis' view, inexorably, the streams then continue to transport debris to the sea until the entire region is reduced to sea level, or nearly so. This is the stage of "old age"; the surface is termed a peneplain, and the anthropomorphic cycle of erosion, which was to some extent inspired by debate about organic evolution in the 19th century, has run its course.

This easily grasped deductive scheme is depicted in Figure 1. The last stage shown, namely rejuvenation, was thought to occur when uplift again raised the peneplain of old age. Davis argued that the streams of such a region would cut downward with renewed vigour, essentially starting a second cycle of erosion. His interpretation of the folded mountain region of the Appalachians in terms of multiple erosion cycles was hailed as a triumph of geomorphic analysis at that time. Because it is still praised today, its possible flaws are worthy of some analysis.

First, it should be noted that the stage names of the stages adopted by Davis lack the degree of precision that is generally required of a definition. Second, the invocation and widespread employment of the stage names is symptomatic of the fact that among the several important factors in landform evolution, time was vastly overemphasized. Davis was fond of using the notation

$$\text{landforms} = f\ (\text{structure} + \text{process} + \text{stage}).$$

He did so for pedagogic reasons and although this pseudo-quantitative expression is quite correct (landforms are, in general, a function of rock type, the processes that are operative upon the rocks, and time), Davis basically ignored structure (rock type) and processes. He emphasized stage, or time, and because of this literally thousands of papers have been devoted to the "matching" of landscapes from all parts of the world to block diagrams such as those depicted in Figure 1. Once a "stage" within the cycle of erosion was established, the history of the region could be written directly by using block diagrams.

Drainage systems and peneplains

Aside from these points, there is considerable difficulty involving drainage systems and peneplains. Davis thought that like the landforms, and, in fact, with them the streams of a region progressed, through an evolutionary sequence of stages. Wildly dashing rivers in steep mountain areas were "youthful"; meandering rivers that flowed across gently sloping plains, on the other hand, were "sluggish," "tired," and representative of the final stages of old age. This remarkable view flies in the face of present knowledge of the velocity of flow and stream discharge near the mouth of the Congo, the Amazon, the Mississippi, or any other great river of the world. The velocity of flow of most rivers tends to remain the same or to increase slightly in a downstream direction; discharge will increase greatly between headwaters and mouth. Meandering bears no relation to time, and it is ludicrous to discuss the "age" of the average river. Moreover, the assignment of stage names to entire river systems was basically incorrect on other grounds. Even in Davis' terms it can be said that along its course, between the divide area and the river mouth, any single river system in any large region exhibits most of the supposed attributes of each of the successive stages.

With respect to peneplains, it can be argued that, like river systems, no large area of perhaps subcontinental dimensions can truly represent a single stage or point in time It seems likely that the interior portion of anv such surface will be somewhat higher in-elevation than the peripheral parts. This alone might ultimately lead to an interpretation of the occurrence of two cycles of erosion, in the classical or Davisian view. Also, the degree of departure from a planar surface that can be tolerated or expected has not been specified; relativelv flat surfaces can be attributed to causes other than erosion cycles; and unequivocable examples of undissected "peneplains" do not readily come to mind. Finally, and most important, the evidence of peneplanation that was offered by Davis in support of his Appalachian interpretation consisted principally of: (1) the statement that accordant summit elevations occurred in areas of discordant (dissimilar) structure (rock type) and (2) that the courses of certain streams that flowed across the northeastward-trending regional structure could best be explained in terms of superposition from a pre-existing peneplain.

Inter-pretation of Appala-chian history

These two points are most instructive, because the search for supporting evidence has led to the contradictory view that the principle of dynamic equilibrium best explains the landscape in Davis' classical study area. This will be discussed later, but the general thrust may be indicated here. First, the advent of modern mapping and quantitative observation have shown that the "accordant summits" were, in part, a mirage; a plane cannot be well fitted to the ridge-top remnants. In addition, the work in the Appalachian area suggests that the "restored" peneplain would necessarily be as irregular as is the present landscape. In other words, it would seem that ridges and valleys were in existence in this region at the time when the erosion cycle concept dictates the presence of a nearly featureless plain. The close relationship of topography and structure is shown in Figure 2.

Still more telling, however, is the argument that even if accordant summit levels on hills of different rock type did exist today, these hilltops would not represent erosional remnants of a former peneplain but, rather, remnants of hills of different age. This follows directly from knowledge that different rock types weather at different rates: if a hill of sandstone and another of shale exist side by side today and exhibit the same summit elevation, then their original elevations (or time of landform formation) must have been quite different. This is clearly borne out by studies of the relationship between altitudes and rock types in Connecticut (Figure 3).

The course of streams in the Appalachian area has also been explained without recourse to the cycle of erosion concept. Available evidence strongly suggests that most river-course attributes are a function of differences in the resistance of existing rock types. There is no need to postulate the lowering of rivers by thousands of feet from hypothetical planar surfaces. A map of part of the Shenandoah Valley (Figure **8**) clearly shows, for example, the accentuated meanders of the North Fork where it flows over the Martinsburg Shale. The structure of this rock formation is such that the path of least resistance is to the northwest, and for this reason extreme sinuosity of river path exists. Hence on a larger scale it may be reasonable to suppose that stream trends across the major ridges can be accounted for by such preferred orientation or structural controls.

The cycle of erosion was challenged during Davis' lifetime, notably by Walter Penck, who believed that landform configuration was a function of the balance, or lack of balance, between rates of uplift and rates of denudation through time. In this view, greater rates of uplift would yield convex hillslopes, whereas greater rates of denudation would produce concave slopes. Straight slopes were said to reflect equality of the two rates. Most authorities today believe that Penck was more nearly correct than Davis, with respect to hillslope aspects, but that he too based his argument on deductive reasoning in the face of a dearth of data. Also, he ignored the effects of rock type and climate in his evolutionary scheme.

Open versus closed systems

In summary, the cycle of erosion as the first great synthesis of landform evolution theory, was widely accepted as the explanation of landforms and their origins in the past. Its chief virtue was its simplicity; once the inherent assumptions were accepted, any region of the earth's surface could be compared to some suitable block diagram and the history of the region set forth straightaway. The chief question that has arisen in the minds of modern geologists is whether this history is correct. Although dispute on the point continues, the dominant view today is that landform evolution should be considered within the framework of general systems theory. Within this framework, the Davisian cycle of erosion reflects a closed system in which the initial conditions of the system suffice to determine the final conditions and end products. The factor of overriding importance in the erosion cycle scheme is initial uplift; once this occurs, the outcome or ultimate fate of the region is fixed. It must become a peneplain after intermediate stages are traversed; rock type and processes are largely irrelevant. No allowance is truly made for the possible addition and subtraction of materials and energy, which is characteristic of an open system, the other type of general system. Likewise, the concept of attainment of equilibrium, after the initial state but prior to the ultimate state, was not envisaged by Davis and is not permitted in a closed-system framework of reference. Each of these conclusions seems erroneous in the light of modern knowledge.

Before turning to the evidence that appears to support dynamic equilibrium and the view that landforms are best considered with reference to open systems, some views on the role of climate in landform evolution must be considered. Like the time factor emphasized by Davis, climate is of undoubted significance—but it is not of overriding significance.

MORPHOGENETIC REGIONS

Climatic factor in landform evolution

The role of climate in landform evolution was acknowledged only indirectly by Davis and his many adherents. In their view, the cycle of erosion, or some modification of it, explained landforms everywhere; but largely because Davis' initial investigations were in Pennsylvania and New England, the temperate-humid regions were taken as "normal," and, in fact, the impress of glaciation or aridity was termed a climatic accident by C.A. Cotton, the New Zealand geographer, years ago, and only recently, A.L. Bloom, a coastal specialist, has discussed the ways in which such accidents alter the orderly rate of progression of the erosion cycle. From the meteorological vantage, of course, the term accident is most unfortunate. In general it is argued by all proponents of the concept that different landforms result from different climatic regimes and, as a consequence, that there are regions of the Earth that can be defined on morphological grounds because these regions are distinctive on climatic grounds. Such regions are termed morphogenetic, meaning essentially that the morphology of the forms present supposedly has a common genesis—which is climatic. In turn, the geomorphic processes will yield characteristics distinguishing the landscape from other areas developed under other climatic conditions.

In a gross way, it is generally agreed that climate is extremely important in the weathering of rocks and that it exerts an influence on the dynamics of processes that, in turn, will leave their own impress on the landforms of a region. Julius Biidel, the German geographer, has argued that for such reasons climatic variance must take prece-

dence over all structural factors. This is another way of saying that climate and climatic differences overshadow rock type as a controlling variable in landform configuration. The morphogenetic regions of the earth according to Biidel are shown in Figure 4. Considered in detail this map offers a few surprises, because maps showing the world distribution of deserts, for example, would reveal that at least two of Büdel's zones, and in some instances three, coincide with these arid areas; one would anticipate the existence of uniformity of forms in these regions according to the thesis as presented. Moreover, R. Common, who has studied slopes and processes in Ireland, Greece, and elsewhere, has indicated that there are ten zones in which temperature differences are likely to be of geomorphic significance and six zones in which important precipitation distinctions can be made. This difference in the number of zones of climatic distinction and, hence, of zones of supposed morphological distinction, varies as a function of the investigator involved. The fact that any variation exists demonstrates that the determination of morphogenetic regions is somewhat subjective; the qualitative criteria for recognition of such regions lead to disparate numbers, kinds, and locations of regions. The regions are primarily structural, topographical, and erosional and depositional. All are influenced by climatic controls.

Climate versus rock type

Proponents of the concept would say that climatic controls outweigh rock type as a landform factor because the significance of a given rock type and its resistance to the forces of erosion is to some extent a function of the climate in which it exists. Granite, for example, is a relatively hard rock that comprises many mountain ranges in temperate and other regions. In tropical zones, however, where intense chemical weathering has occurred, granites are weathered to great depths and commonly underlie plains and pediment-like areas. With respect to carbonate rocks, it is argued that these are "soft" in areas of frost action where they are readily shattered, and "hard" (in the sense of being cliff-forming rocks) in more humid regions. This is because the high degree of solubility and gross structure of carbonate rocks tend to permit cavern formation and the development of subterranean channels and does not lead to surficial erosion of any magnitude.

It is also true that processes such as frost wedging, wind action, oxidation, reduction, and others are indeed climatically linked. Despite this there is some reason to question the general thesis of the concept of morphogenetic regions. What has best been distinguished to date are the extreme "regional types." Opponents of the theory ask first if any of the supporters of regional morphogenesis have in fact gone much beyond the notion that tropical, glacial, arid, and temperate environments are generally recognizable. All protagonists would acknowledge that Arabia is inherently distinctive when compared to equatorial Africa or that Iceland and Florida are in some ways quite different, but they would insist that even this degree of acquiescence is deceptive because the real question is not whether the climates of these contrasting areas differ but whether their landforms differ. They would conclude that the answer may seem to be affirmative at a distance —but only at a distance.

It is commonly said, for example, that desert landforms are distinctive by reason of their high degree of angularity, particularly if such terrain is compared to the "rolling forms" of an area such as New England, where the climatic regime is quite different. The impression of rolling forms is, of course, largely conveyed by the soil cover or by the structure (*e.g.*, folded mountains) of certain areas. Where the Hudson River flows along the Palisades diabase sill (a tabular body of intrusive crystalline rock), however, this igneous rock type clearly serves as an angular cliff former. The hillslopes to be found in basaltic terrane along the Columbia River plateau, or in any temperate humid region, will differ hardly at all from hillslopes of the Black Haruj or similar volcanic terranes of the Sahara; many analyses of hillslopes in the U.S., Africa, Australia, and elsewhere have indicated that there is a basic interdependence of slope angle and particle-size distribution, which is governed by the lithology (or rock type) in question. This relationship is nearly ubiquitous and may suggest that, contrary to the claims of adherents of the morphogenetic regions concept, climatic controls have complemented but not transcended the basic importance of lithology in landform evolution. Aridity, however, has a great effect on the rate of erosion and evolution of landforms.

In the light of present knowledge on the subject, it would appear that climate is an important variable in landform evolution for the following reasons: first, climate determines those regions in which mechanical or chemical weathering and the action of wind or water will be important. Second, climate determines the intensities and frequencies of processes and, consequently, the rates of erosion or deposition in different regions. Finally, climate determines whether soils or vegetation will be present and, if so, their kinds and extent. This indeed has much to do with the general impression one receives of the morphology of an area. The available evidence also indicates, however, that hillslopes are strongly influenced by rock type. If this is true, then it would appear that the concept of morphogenetic regions is somewhat overblown. In the final analysis, landforms must be considered to be a response to multivariate controls; it is an error to assume that one factor subsumes the others, regardless of whether one wishes to make the case for time, for climate, or for rock type. Landforms tend to reflect the interaction of the materials of which they are composed and the applied stresses of processes that act upon them. As indicated by the Soviet geographer I.S. Shchukin in a recent critique, climate, rock properties, and physical processes are intimately intertwined in landform formation, and there is but little basis for the creation of a "climatic geomorphology" (which is essentially synonymous with morphogenetic regions as used here).

DYNAMIC EQUILIBRIUM

Gilbert's view of the relation between form and process

The concept of dynamic equilibrium in landform evolution was introduced by G.K. Gilbert, the American geologist, in his classic reports on the geology of the Henry Mountains, Utah, in 1877 and 1880. To explain the assemblage of landforms in this area, Gilbert applied several fundamental principles of fluvial erosion which today seem to have been intuitive and self-evident but which reflect his relatively sophisticated grasp of fluid mechanics and hydraulics at that time. Gilbert recognized that steep slopes erode more rapidly than gentle ones, that erosion is most rapid where rocks are least resistant, and that both the steepness of slope and water discharge affect sediment transport to a disproportionate degree. These principles led him to two important conclusions, namely, a stream tends to equalize the work done over each part of its course, and when the ratio of erosion as a function of slope becomes equal to resistance as a function of rock character, there is an "equality of action."

Gilbert did not give a name to his conceptual views, and his conclusions were not truly measured against the assumptions of the cycle of erosion. The Davisian bandwagon gathered momentum, and not for a generation was Gilbert recognized widely as a founder of this field of inquiry. It seems clear today, however, that Gilbert's conclusions are basic to, if not indeed synonymous with, the concept of dynamic equilibrium. This is the concept that landforms tend toward and attain a configuration that reflects a balance between rock resistance and the erosive action of natural processes upon them. Stated differently, landforms can be considered as part of an open system in a steady state of balance, in which every slope element is adjusted to its neighbours.

Both definitions imply an anticipation that changes in climate and relief, or, in general, changes in materials and energy, will affect the steady state and will produce new equilibriums between landform configurations and the environment. It is for this reason that equilibrium is termed dynamic. Topographic change is acknowledged to occur in response to changed conditions; therefore, the landscape will tend to shift toward some new equilibrium condition.

It should be noted again that the concept of dynamic equilibrium differs drastically from that of the cycle of erosion. No definite and inevitable sequence of landforms through time is postulated. Equilibrium states and configurations are recognized as highly probable and frequent conditions in nature, whereas only the old-age peneplain at base level is viewed as an equilibrium form in the Davisian scheme. And finally, a landform that is in a steady state of balance is considered timeless from the viewpoint of equilibrium; its history cannot be deduced from its configuration or other outward manifestations.

If the cycle of erosion is accepted as a correct conceptual framework, however, then landform configuration is at once indicative of history, or the effects of time, because any landform is assigned to a specific part of an evolutionary scale that ranges from youth to old age.

The answer to whether or not the historical imprint of time can be discerned from landform configuration can best be considered in terms of an example. If it be supposed that a steep cliff consisting of jointed sandstone is acted upon by weathering, gravity, and fluvial processes in such a manner that each year a certain number of fragments and small blocks are dislodged and tumble to the base of the cliff, then as long as the nature of the rock and the intensity of the processes acting upon it do not change, the rate of addition of material to this talus pile will remain fairly constant. Some material will, however, be removed from the talus pile by processes acting upon it, and ultimately the rate of removal will equal the rate of addition. At that time the talus pile will be in a state of dynamic equilibrium. Its volume will not change unless some factors that can alter the rates of addition or removal are changed.

C.C. Nikiforoff, the soils scientist, discussed soil formation in terms of dynamic equilibrium in 1942 and his work was adapted to landform evolution by J.T. Hack, the American geomorphologist, in a basic series of papers in the 1960s. The general equation describing the talus-pile case, from these sources, is as follows:

$$S_n = A\left[\frac{(1-r).[1-(1-r)^n]}{r}\right] + A,$$

in which S_n is the total volume of talus after n years, A is the amount of talus that accumulates in one year, and r is the rate of removal, expressed as a decimal proportion of the amount present. In the limit, with the passage of time, the equation reduces to:

$$S_n = A\left(\frac{1-r}{r}\right) + A, \text{ or } = \frac{A}{r}.$$

This equation shows that when the rate of removal r produces an absolute amount equal to the accumulation A, the volume of talus S_n will be a constant. A graphical expression of this relationship is shown in Figure 5, assuming that A = 1 and r = 0.3, or that for each unit increment of talus derived from the cliff, 30 percent of the amount present is removed from the pile. The limiting value in this case is 3⅓ times the amount added per unit of time, and it can be seen from the above graph that the limit is asymptotically approached after approximately 12 units of time.

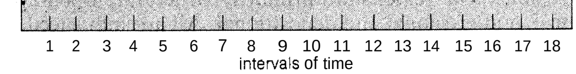

Figure 5: Nikiforoff's equation for growth of a deposit toward steady state in which two opposing processes are involved in formation of deposit.

Assuming that the talus pile attains a steady state, that S_n is constant, and that an investigator approaches the base of the cliff at any future time, it is interesting to ask what history of the talus-cliff configuration could be deduced? To question whether the system is at the stage of maturity or what might be concluded about the initial conditions, whether the volume of talus was larger, smaller, or zero 1,000,000 years earlier, would be somewhat specious. It seems evident from the example given, and from what has been said thus far, that the eradication of initial systemic conditions is a by-product of the attainment of steady-state conditions. This would lead to speculation as to whether all landforms are in fact at or near steady-state conditions today. Before turning to this question, field evidence for dynamic equilibrium must be considered. This is of three principal kinds: the equilibrium of slopes, the equilibrium of river systems, and the equilibrium of regions.

Altitudes, rock type, and slope equilibria

The equilibrium of slopes is well established in the sense that the logic of Gilbert's observations is overwhelming and that detailed field observations sustain expected relationships between slopes and rock character, other factors being equal. The histograms of altitude and rock type in Connecticut (Figure 3, bottom) serve as one example of differential erosion that is attributable solely to rock type. The Stockbridge Marble would be predicted to be the most easily erodible rock type because of its high solubility, whereas quartz-rich rocks would be expected to be at the other end of the erosional spectrum. This is the relationship found; lowest mean altitudes occur on terrain underlain by marble, and the greatest average altitudes coincide with outcrops of quartzose rocks.

The relationship of channel slope and stream length in rocks of different lithology is known for some streams in Virginia and Maryland. There is a clear distinction between relationships in sandstone and those in shale; for a given stream length, streams in sandstone areas flow over channel beds that are seven times steeper than those in shale areas. A curve of relationship for carbonate rocks has not been constructed because of the relatively great degree of scatter of the data. This scatter is caused by the chert content of the limestone, which is abundant in some stream channels and tends to produce increased gradients.

Profiles of hillslopes on similar rock types, as shown from Hack's studies in the same area, also show unsurprising relationships. The steepest profile prevails in terrain that predominantly consists of sandstone, the gentlest on hills composed of shale beds, and intermediate profiles are associated with carbonate rocks.

Hydraulic geometry of river systems

Other examples could be cited from all parts of the world, as mentioned above in the discussion of morphogenetic regions, but still more telling are the available data on equilibriums in river systems. The hydraulic geometry of stream channels, as it was termed by Luna Bergere Leopold and Thomas Maddock, Jr., both hydrologists with the U.S. Geological Survey, in a basic exposition of the subject in 1953, is based on the observation that fundamental relationships exist between water discharge and the width, depth, and velocity of flow, among other variables. At a given river cross section, for example:

$$
\begin{aligned}
w &= a\,Q^{b},\\
d &= c\,Q\text{, and}\\
v &= k\,Q^{m},
\end{aligned}
$$

in which w, d, and v are width of water surface, depth of flow, and velocity of flow, respectively; Q is water discharge of a given frequency of occurrence; and a, c, k and b, f, m are numerical constants and exponents in the power-function relationships shown. From the law of continuity (water input along a given river reach equals water output):

$$Q = Av,$$

in which Q is again water discharge, A is cross sectional area, and v is velocity of flow. Because area is equal to the product of width and depth,

$$Q = wdv,$$

and substituting from above:

$$Q = a\,Q^{b} \times c\,Q \;\times k\,Q^{m} = ackQ^{b+f+m}$$

This identity indicates that:

$$a \times c \times k = 1\text{, and } b + f + m = 1$$

The last is an important result of this analysis because b, f, and m are the slopes of lines that relate water discharge and width, depth, and velocity, and the average values of these exponents provide a means of characterizing and comparing river systems. The at-a-station (a given cross section of observation) relationships vary for different rivers and for different sections along their courses; but in a downstream direction it has been shown that $b = 0.5$, $f = 0.4$, and $m = 0.1$ for many rivers. This indicates that width, depth, and velocity of flow all tend to increase regularly with water discharge in a downstream direction and that channel width adjusts most rapidly.

Similarly, there are relationships between water discharge and suspended sediment load, channel roughness, and channel slope, and each of these can be expressed as power functions. For example:

$$l = p\,Q^{j}$$

in which l is suspended sediment load, Q is water discharge, p is a numerical constant, and j is the characterizing exponent, equal to about 0.8 in a downstream direction for many streams.

Generalized graphs of each of these relationships are shown in Figure 6; the solid lines give changes in a downstream direction with discharge, and the dashed lines show at-a-station results. Only channel roughness (a measure of particle size, among other factors) and channel slope decrease in a downstream direction, as would be expected. The block sections on the right half of the diagram permit visualization of the at-a-station and downstream relationships for different magnitudes of discharge; these correspond to different frequencies of occurrence of water discharge.

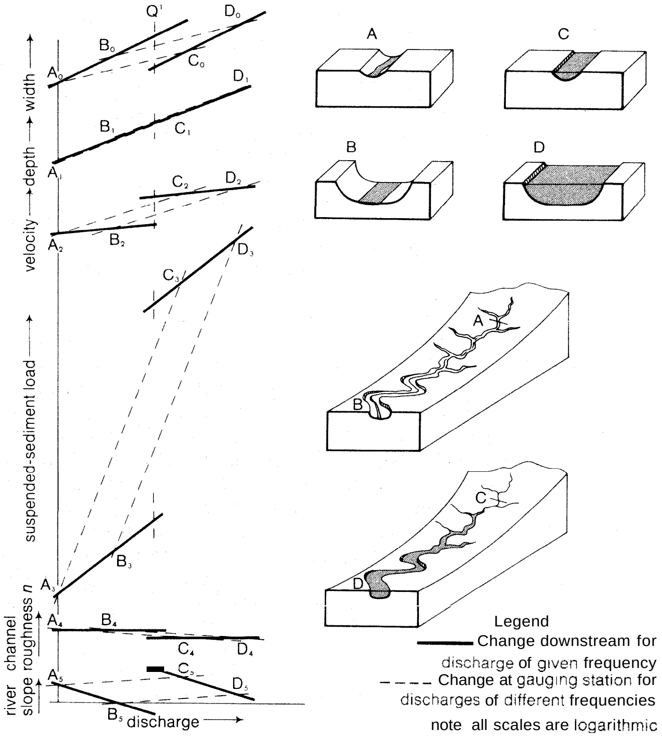

Figure 6: Average hydraulic geometry of river channels expressed by relations of width, depth, velocity, suspended-sediment load, roughness, and slope to discharge at a gauging station and downstream.

River systems and dynamic equilibrium

With respect to the magnitude and frequency of water discharge, it has been found that the channel-forming discharge, or that magnitude of flow that best relates to the dimensions and characteristics of a given channel, is the bankfull discharge. As implied by the name, bankfull discharge is a magnitude of flow that fills a channel; it has a recurrence interval (frequency of occurrence) of one to two years in humid temperate regions and an interval of as much as hundreds of years in extremely arid areas.

Typical relationships in humid-temperate regions are indicated by the map and cross section of Stevens Creek, South Carolina (Figure 7). This stream was studied in conjunction with long-term records of water discharge in an attempt to learn whether some physical aspects of a channel did in fact correspond to the **bankfull** stage. They found, in general, that water discharge with a recurrence interval of one to two years was related to the bench level adjacent to channel levees (predominant bench **3** in the cross section of Figure 7). The highest benches bordering the channel were correlative with a magnitude of discharge that occurred as infrequently as once in 25 to once in 90 years.

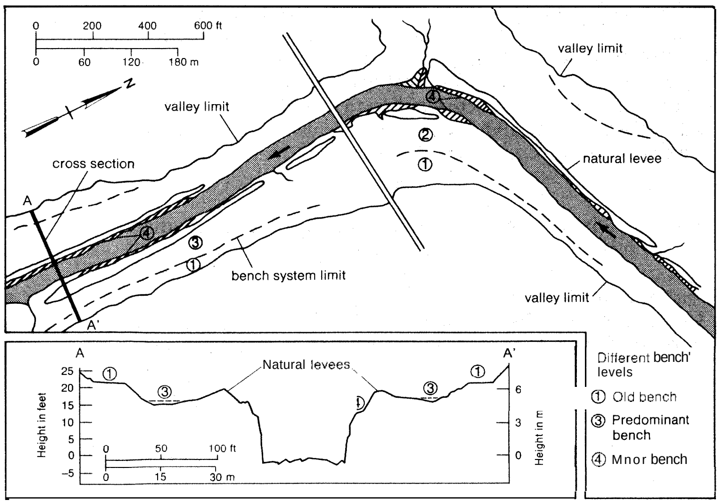

Figure 7: Map and cross section of Stevens Creek, South Carolina, showing the several benches associated with flow stages of different frequency of occurrence.

With respect to landform evolution and the merits of the dynamic equilibrium view, it must be concluded that evidence derived from study of river systems is both pervasive and persuasive. **A** river adjusts its profile and cross section to accord with its bankfull discharge and the requirements of its sediment load. In alluvial channels this adjustment is rapidly accomplished and the hydraulic geometry has been demonstrated to hold in a wide variety of physical environments and for rivers of all sizes. If climatic change occurs, or if uplift alters channel slope, then a river will adjust its channel geometry and load to correspond. In other words, most river systems are in a state of dynamic equilibrium. Rivers provide an example of the adjustment of forms to process and although a stratigraphic record is available in certain alluvial deposits, it is absurd to speak of the age of a river; once again, time and adjustment have obscured initial systemic conditions. These conditions change as the river goes through a series of stages in its life history.

The third line of evidence supporting the concept of dynamic equilibrium is evidence of the equilibrium condition of regions. In a sense this line of argument is somewhat superfluous; if hillslopes are in equilibrium and if drainage systems are in equilibrium, then it follows that many regions must also be in a state of equilibrium because they consist of these two elements. Nevertheless, Hack's intensive study of the Shenandoah Valley (Figure 8) is worthy of mention because similar work has not yet been done elsewhere and because it is part of an area long interpreted in terms of the erosion cycle. In this region the streams accord with the general hydraulic geometry; their longitudinal profiles are adjusted to differential rock resistance; the meanders of the North Fork are confined principally to the Martinsburg Shale, in which they parallel the rock structure; and the Potomac River enters and leaves the valley where narrow outcrops of weaker rock occur. **As** indicated by Hack, it is extremely unlikely that such close relationships between drainage and rock resistance and structure would prevail in this region if the streams were superposed.

Similarly, hillslopes reflect rock resistance to erosive stresses, and major topographic features accord with the generalization that lowlands and valleys are correlative with soft rocks (carbonates and shales), whereas the greatest altitudes and most persistent ridges are correlative with the most resistant rocks. Climatic conditions also modify the hillslope erosion.

Interpretation of landform history

Granting that equilibrium can and does exist in nature, it is fair to ask what can be said of landform evolution; is there some historical imprint of time that will yield upon analysis? It must be emphasized that the concept of dynamic equilibrium is a framework of thought that provides a rational basis for the study of landforms. It is a standard against which landscape features can be tested; studies of process intensities and rates of change can, in many instances, lead to conclusions about those features that are not in equilibrium. This narrows the search for time-dependent landforms and can lead to important conclusions.

For example, G.H. Dury, a British geomorphologist, observed that the wavelength of valley meanders clearly differed from the wavelength of stream meanders. The plots of wavelength for the Dnestr and Don rivers, and for rivers in France, England, and the U.S., sustain this view. Because it was known that the wavelength of stream meanders bears a consistent relationship to water discharge (or drainage area, which is closely correlative), it was possible for Dury to argue that the valley meanders represented misfit or nonequilibrium forms, which were related to water discharge during more humid, Pleistocene time.

There are many landforms that reflect the historical imprint of time in some way. Most of these are Pleistocene relicts: large cirques and V-shaped valleys in formerly glaciated areas; beach ridges around modern playas (dry lakes); and solution caverns and stream channels that reflect adjustment to moister hydrologic regimes in modern deserts. These and other landforms consequently reflect equilibriums with past processes rather than present processes. Given sufficient time, they will attain new steady-state conditions and their history will be erased. In the interim, however, interpretation is possible, and it can be said that one of the chief virtues of the equilibrium concept is that it permits discrimination between the time-independent and relict landforms in nature.

By courtesy of the U.S. Geological Survey

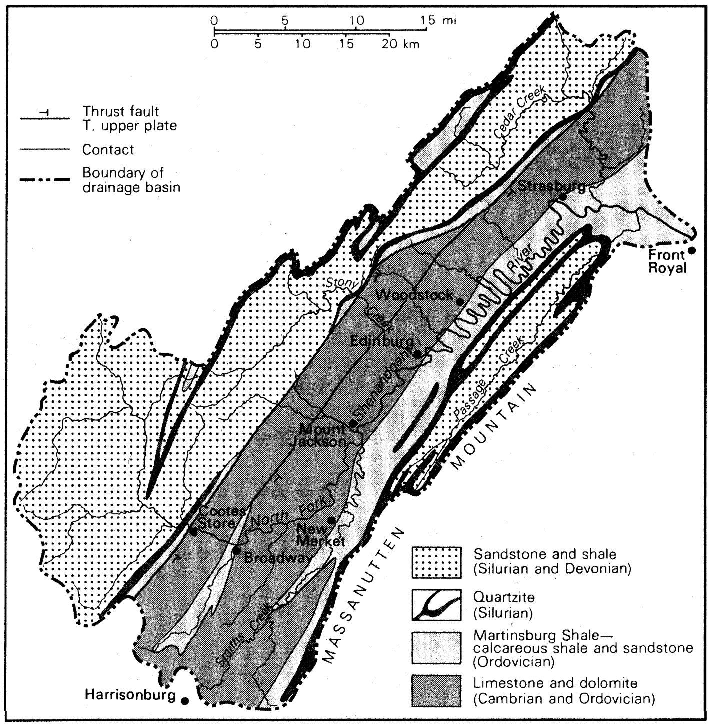

Figure 8: Geological map of the North Fork, Shenandoah River drainage area.

In addition, as summarized so well by Richard J. Chorley, the British geomorphologist, the equilibrium concept fosters recognition of the multivariate nature of geomorphic phenomena and directs attention to the entire landscape rather than only to those elements of supposed cyclic significance.

ENTROPY—PROBABILITY

Entropy and the work of river systems

The entropy-probability concept in landform evolution is a logical outgrowth of the dynamic equilibrium known to prevail in river systems. The hydraulic geometry of stream channels concerns the interrelationship and adjustment of channel morphology and the several hydraulic variables. In discussing this adjustment, however, nothing was said of the distribution of work done and energy available in relation to fluvial processes or of whether river systems reflect some basic natural law as they follow a course from highlands to the sea. These questions will be considered here, but a brief exposition of the thermodynamic and probabilistic connotations of entropy is required first.

In thermodynamics, entropy is an expression of the reduction of free energy in a system and, therefore, of a reduction in the ability of a system to perform work. This relationship can be expressed simply as:

$$\Delta F = \Delta H - T \Delta S,$$

in which ΔF, ΔH, and ΔS represent the changes of free energy, enthalpy (heat content), and entropy of a system that passes from one state to another, and T is absolute temperature. The essential point is that an increase of entropy (ΔS) must be associated with a decrease in free energy (ΔF). The second law of thermodynamics specifies this relationship for natural processes and provides as well the explanation for the lack of success of any perpetual motion apparatus.

A river system obviously involves natural processes; each droplet of water in the headwaters of the system contains a certain amount of potential energy that is a function of its elevation above sea level. With the passage of time, as the stream transports sediment to the sea and the landmass is reduced, if no other changes affect the system then it must suffer an energy decrease and a corresponding rise of entropy. Therefore, overall entropy will increase as work is done by the river system under these conditions.

But entropy also relates to states of order-disorder and to probability. A mass of gas in a container at room temperature consists of individual gas molecules, each of which follows random paths and engages in random collisions with its fellows. This may be contrasted with a situation in which the same amount of gas is compressed into a small volume so that the motions of the molecules are greatly restricted. The first state could be designated as one of great disorder and high entropy, whereas the second would be characterized by a high degree of order and low entropy.

In this example, work would need to be done in order to produce the second state, but there is some finite probability that all the gas molecules in a given closed container will cluster at one end through chance alone. The probability that this will occur through chance alone is small indeed, but it does serve to illustrate the basic point, namely, that there are several possible alternate states in all natural systems and that each such state is able to be characterized by a certain probability of occurrence, a certain degree of order or disorder, and a certain potential for work. In this statistical sense the entropy of a system can be defined as:

$$S = \sum_{i=1}^{i=n} \log pi$$

in which S is the entropy of the system and p_i represents the probabilities of each of the possible alternate states ($p_1, p_2, p_3, \ldots p_n$).

When the sum of the logarithms of the probabilities of all possible states is a maximum, the most probable energy distribution in the system will be achieved. This will occur when the probabilities of all alternative states are equal ($p_1 = p_2 = p_3 \ldots = p_n$). It has been argued that river systems are open systems in which the hydraulic geometry adjusts to achieve the most probable energy distribution and, further, that there is a tendency toward minimization of work along a stream's course. It can be shown on theoretical grounds that the most probable series of energy losses along a river's course is coincident with a series of entropy increases that are equal in magnitude for each unit length of river. Most important is the fact that when this occurs the longitudinal profile of a river will be best represented by an exponential curve. The basic relationship is:

$$\frac{dS}{dt} \cdot \frac{1}{Q} = \frac{dh}{dx} \cdot \frac{1}{h},$$

in which the left side of the equation is the rate of change of entropy (S) per unit discharge (Q) and the right side is the loss of elevation (h = head) with distance of flow (x) along a river's course. This fact is important because available data on the natural channels of streams in all types of environments have indicated that the preferred profile in nature is indeed an exponential, concave-upward path.

Stream profiles and the most probable path

If the exponential profile of streams is theoretically predicted to be the most probable flow path, then it follows that it should be reproducible by chance alone. For this reason random-walk procedures, generated by manual or computer methods, can be employed to test the theory. Figure 9 shows the mean longitudinal profile generated by two random-walk trials, the condition of the trials being that no constraints be imposed on length of path. It can be seen that the resulting curve is exponential in form and is asymptotic at base level (elevation = 0). A much greater number of trials yields the same result. If constraints on length are imposed upon the model, then a variety of curves is obtained, but these are of the same general form.

By courtesy of the U.S. Geological Survey

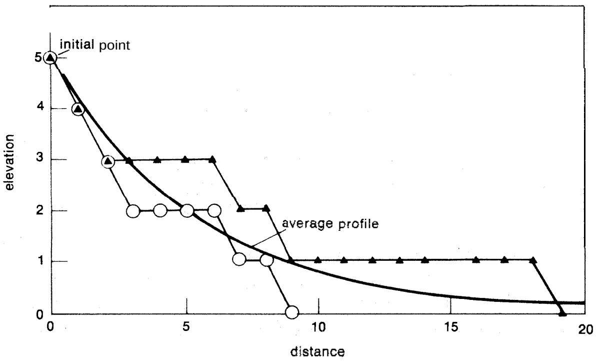

Figure 9: Stream profile generated by two random-walk trials.

The resulting form is related to the rate of work done by a given stream. Least work expenditure is required of streams with profiles of maximum concavity because the greatest fall or head loss in such cases is in the headwaters, where the water discharge is least. The general relationship of least-work, equal-work-distribution, and natural-river profiles is shown in Figure 10, which is based on the relationship

$$s \propto Q^z,$$

in which s is slope of channel, Q is water discharge, and z is the characterizing exponent.

The plan views of rivers have not been neglected in the search for underlying principles. Typical drainage nets have been generated by random-walk procedures. Aside from their obvious superficial resemblance to natural drainage nets, it has been shown that such random, and therefore most probable, drainage nets accord with the laws of stream order, stream number, bifurcation, and other empirical properties of networks set forth by R.E. Horton, an American hydraulic engineer, in a basic paper on this topic. A test of Horton's laws, as they are termed, was devised by R.L. Shreve who concluded that randomly generated channel networks exhibited all the properties required by Horton's laws and that the population of such networks conformed statistically to the attributes of 172 published sets of data on natural networks. The general conclusion that can be drawn from all such work must be that drainage networks, like channel profiles, can be reproduced by random-generating methods. This means that they too reflect the most probable network patterns, tend toward least-work paths, and are associated with an entropy distribution that leads to these results.

From *American Journal of Science*, vol. 262 (1964)

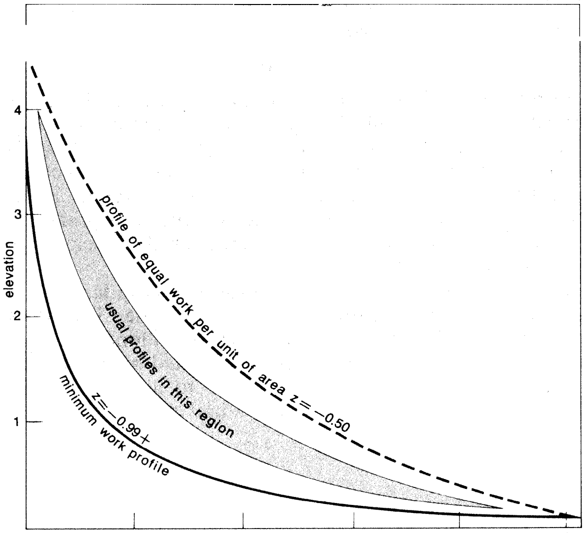

Figure 10: River profiles for a given relief in relative units.

Randomness in nature as a factor in landform configuration

Stochastic models, or those involving the element of randomness, are applicable to a wide variety of natural phenomena. These range from patterns of sedimentation revealed by the stratigraphic record, to the branching nature of rivers, trees, and lightning, and include the landform configurations in all natural environments. From the vantage of the entropy-probability concept it can be said that nature tends to produce the most probable patterns and configurations unless constrained in some way in specific cases. It may be noted that the logic of the position that hillslopes, drainage networks, and river channels in nature present the aspects they do simply because these aspects are most probable has much to commend it. Clearly, one would not wish to attempt to sustain the alternative proposition that these aspects are most improbable.

In summary, the entropy-probability concept serves to explain why dynamic equilibrium holds for most landforms in nature, that is, because the equilibrium condition reflects a nice distribution of available energy relative to work done, which is the most probable distribution. The previously indicated virtue of the equilibrium concept, namely that it served to segregate the time-independent from the time-bound landforms, still holds true. With respect to the entropy-probability view, this might be altered to say that the study of landform evolution must be considered a search for constraints, these constraints being the conditions that lead to departure from equilibrium forms. In this sense, however, modern studies of landform evolution still can treat the interpretation of landforms in terms of the historical imprint of time, but such studies must be entirely restricted to the nonequilibrium landforms.

In addition, the element of indeterminacy in landform evolution must be recognized. It is clear that individual landforms, like individual stream profiles, are members of populations that statistically cluster about mean values. Because these are the most probable values in nature, and commonly reflect steady-state values, studies of individual forms that fluctuate about the mean cannot provide a valid basis for extrapolation of class attributes. Given a thousand hypothetical talus piles it is possible that nearly half of these would exhibit slight increases of volume through time, whereas the remainder would exhibit diminution of volume. This possibility implies that general rules governing talus piles as a class may be indeterminate if the rules are derived from data based on the study of only one or a few members of that class. Stated differently, the principle of indeterminacy in nature is a logical consequence of the operation of randomness. The latter forces consideration of landforms and their evolution into the statistical realm.

BIBLIOGRAPHY. There are few books that treat all aspects of landform evolution, and the interested reader will need to investigate some specialized literature and journals to pursue this topic. Several books that are worthy of citation include R.W. FAIRBRIDGE (ed.), *The Encyclopedia of Geomorphology* (1968), articles on specific landforms and their presumed evolution; G.H. DURY (ed.), *Essays in Geomorphology* (1966), several articles of relevance on morphogenetic regions, the concept of grade or equilibrium, and statistical methods; L.B. LEOPOLD, M.G. WOLMAN, and J.P. MILLER, *Fluvial Processes in Geomorphology* (1964), a basic coverage of the principles of geomorphology that is derived from much of the specialized and fundamental literature on landform evolution; H.F. GARNER, *The Origin of Landscapes* (1974), and C.H. CRICKMAY, *The Work of the River* (1974), both of which treat fluvial processes in geomorphology; L.C. KING, *Morphology of the Earth,* 2nd ed. (1967), an exhaustive summary of the author's views on intercontinental denudation chronology (resulting from pediplain formation and parallel slope retreat on a vast scale); W.M. DAVIS, *Geographical Essays* (1909; reprinted 1954, ed. by D.W. JOHNSON), a reissue of some of Davis' basic writings on the cycle of erosion, including the article on the rivers and valleys of Pennsylvania; R.J. CHORLEY, A.J. DUNN, and R.P. BECKINSALE, *The History of the Study of Landforms,* vol. 1 (1964), lively and enjoyable account of ideas on earth history (from antiquity to 1893), can be read with profit by any curious lay reader; C.C. ALBRITTON, JR. (ed.), *The Fabric of Geology* (1963), a collection of essays designed to probe the philosophical aspects of geology. Of particular interest, with respect to landform evolution, are articles on rational and empirical methods of investigation and on association and indeterminacy in geomorphology: WALTHER PENCK, *Die morphologische Analyse* (1924; Eng. trans., *Morphological Analysis of Land Forms,* 1953), summarizes Penck's views on parallel slope retreat and landform evolution, largely ignored or overlooked by Davis and his adherents; Y. ABUL-HAGGAG, A *Contribution to the Physiography of Northern Ethiopia* (1961), and E.H. BROWN, *The Relief and Drainage of Wales* (1960), two relatively modern examples of the interpretation of regions within the framework of the cycle of erosion.

The specialized literature on landforms and their evolution is vast, and reference cannot be made here to the many fundamental contributions on the development of ideas. The serial publications involved would include minimally, however, the *Zeitschrift für Geomorphologie* (papers are in French, German, and English), *Revue de Géomorphologie Dynamique* (papers are in French), *Soviet Geography: Review and Translation* (occasionally contains useful surveys of ideas on landform evolution in the Soviet Union), and *Geographical Abstracts A: Geomorphology* (contains abstracts of world literature). Additionally, journals that principally treat geology may contain important papers on this topic (*e.g., Journal of Geology, American Journal of Science,* and *Geological Magazine).* The *U.S. Geological Survey Professional Paper* series includes papers on the hydraulic geometry of stream channels in several environments, on dynamic equilibrium and the entropy-probability concept, and on general systems theory in geomorphology. In this same vein, see *Benchmark Papers in Geology* (1971–), which present results of geomorphology symposia held at the State University of New York, Binghamton.

(L.K.L.)

Land Reform and Tenure

Land reform, in its many historical manifestations, has varied according to the functions performed by land itself. Land serves as a factor of production, a store of value or wealth, a status symbol, and a source of social and political influence. Land values reflect the relative scarcity of land, which usually depends on the ratio between the area of usable land and the size of the population dependent on it. As the per capita land area declines, the relative value of land rises; and land becomes increasingly a source of conflict among economic and social groups in the community.

The patterns of wealth and income distribution, and of social and political influence, that arise from land ownership are determined by the laws governing land tenure. These laws specify which forms of tenure are acceptable, and the privileges and responsibilities that go with them. They define the right to the land: whether the owner has full power to dispose of it as he wishes or whether it must be kept within the same family. For example, if private ownership is permitted, class differentiation is unavoidable; if only public or collective ownership is permitted, distinctions based on land ownership will be eliminated. Similarly, if land is held in hereditary tenure, the benefits will accrue only in the form of income; in contrast, absolute ownership may confer social and political advantages in addition to income.

The purposes of land reform

Historically and until very recent decades, land reform meant reform of the tenure system, or a plan for rapid improvements in the pattern of distribution of rights to the land and of the benefits and responsibilities derived from ownership of it. This idea of reform has been modified in recent years in response to the growing interest in guiding or planning national economic development and a recognition of the strategic role land and agriculture can play in economic development. It has therefore become more accurate to speak of land reform in terms of such things as planned, rapid improvement of the land tenure system; the pattern of cultivation; the scale of operation of farms; terms of tenancy, rural credit, marketing, and education; the state of technology; or any combination of these. This broader concept has characterized all recent reform movements, regardless of the political or ideological orientation of the reformers.

OBJECTIVES OF REFORM

Reform is usually introduced by governments, at their own initiative or in response to internal and external pressures, to resolve or avoid an economic, social, or political crisis. The objectives of reform may be only indirectly associated with the crisis, since reform programs may be introduced for their apparent merits, quite apart from the impending crisis.

The distinction between the real motives for reform and the objectives proclaimed by the reformers may be especially significant if the proclaimed objectives are imposed upon the reformers by political circumstances and do not have their full support. For example, the reformers may proclaim certain objectives (without any intention of enforcing them) to appease the peasants, to undermine the opposition, to gain international good will, or to comply with instructions from outside forces. Given the difficulty of isolating the real from the proclaimed purposes of land reform, the latter will be taken as a point of departure in this article.

Political objectives. The most common objective of land reform is to abolish feudal forms, which, in practice, usually means overthrowing the landlord class controlling the land and depriving it of power in favour of a reforming elite. If "foreigners" happen to be among the landlord class, the objectives are reformulated to call for the defeat of imperialism, and the end of foreign exploitation.

Another objective is to free the peasants and make them active citizens by ending their subjugation to and dependence on the exploiters. This objective assumes a moral and humanitarian character as a means of restoring to the peasants what assertedly had been taken away from them.

A third objective is to create democracy—a stated purpose of both non-Communist and Communist reformers. Most non-Communist reforms are based on the assumption that individual private ownership in the form of family farms will promote and sustain democratic institutions by increasing the number of independent family farmers.

Communist reformers have usually aimed at overthrowing both feudalism and capitalism on the assumption that private ownership of the means of production, including land, inherently breeds exploitation. In practice they have favoured radical land reforms with the stated goal of "returning land to the tillers" and creating a classless, democratic society. One of the more or less open political aims of Communist reformers is to rally the peasants in support of the new order. Once this has been done they seek to move the peasants toward the next step of socialized farming.

Finally, reform may be undertaken as a pragmatic step to resolve a crisis or avoid a revolution when the peasants become restless enough to threaten the government or the political order in general. Under these circumstances, the regime in power or a new one introduces and implements just enough reform to appease the peasants and contain the conflict, especially when the reformers are in sympathy with the landlord class or with the established order or when they do not feel strong enough to undertake a more radical reform.

These political objectives overlap and are frequently proclaimed in different combinations. All of them, however, are subject to two conditions: they tend to undergo change during the period of implementation, and they are usually kept vague enough to permit flexibility and modification as conditions change.

All land reforms tend to emphasize improvements of the peasants' social conditions and status through such measures as the alleviation of poverty and the redistribution of income and wealth in their favour.

Reformers attempt to raise the social level of the community by improving the conditions of the individual. In addition to the creation of employment opportunities, they focus attention on social improvements such as expansion of education and health services, the benefits of which accrue to the community at large. Given the long-term and lasting nature of social objectives, reformers usually aim at the younger generations.

Economic objectives. Economic development has become a major objective of governments and parties in recent decades. In pursuit of this, efforts have been made to encourage agricultural progress. The peasant who does not own his land or whose share of the crop is relatively small may have little incentive to invest capital or expend effort to improve the land and raise productivity. Agrarian reform is presented as a correction of such defects.

Another objective is to encourage more intensive cultivation, that is, the application of more labour and other resources to a given unit of land. This assumes that large landowners often use their land wastefully, even when abundant labour is available to farm it more intensively.

An equally important economic objective is to promote optimum-scale operation of the farm. Both excessively large farms (latifundia) and excessively small farms (minifundia) tend to be inefficient in the sense that output per unit of input is less than it can be under more favourable circumstances. Reform aims at creating farms of the correct size for full and efficient utilization of resources under given technological conditions.

Finally, reform aims at coordinating agricultural production with the rest of the economy. In their quest for economic development and industrialization, reformers hope to make the rural sector more responsive in various ways to the needs of the industrial sector—to use it as a source of new labour, of expanded food supplies, or of industrial raw materials. The rural sector may also be seen as a source of funds to invest in industry or of commodities that can be exported to strengthen the balance of payments. These functions are often expected to be performed simultaneously.

TYPES OF REFORM

The variety of reform objectives implies different types and measures of reform. They can be classed in five main categories according to whether they deal with land title and terms of holding, with land distribution, with the scale of operation, with the pattern of cultivation, or with the supplementary measures necessary for success of the reform.

Reforms that are concerned with the title to land and the terms upon which it is held mainly represent a transition from tradition-bound to contractual systems of landholding. Their implementation involves property surveys, re-

Title settlement and terms of holding land

cording of titles, and provisions freeing the landholder from restrictions or obligations imposed by tradition. Property surveys are introduced where land is held by a tribe or clan or where reallocation of cultivable land still follows tradition. The landholder in these situations lacks security of tenure and frequently does not even know the boundaries of his holdings. Though he cultivates the land, the right of disposal belongs to the tribe, clan, or feudal lord, as in medieval Europe and in modern Africa and the South Pacific islands. Reform therefore involves surveying the land area, devising a formula for its redistribution among the occupants, and recording the titles accordingly. In most cases this kind of reform tends toward establishment of private ownership or some form of individual family holding. Title settlement touches on at least three aspects of landholding: it may increase security of tenure and hence incentives; it may reorganize the system of inheritance in favour of offspring; and it tends to bring land onto the market so that land transactions become possible. Reform of this kind has little effect on the scale of operation until some land concentration or fragmentation takes place.

In areas of the world where the terms of holding and tenancy are regulated by tradition, frequently to the advantage of the landlord, reform may involve seeking to convert tenancy into a contractual agreement that offers some protection to the tenant, as has been the case in India and Pakistan. The terms of tenancy are made flexible and the tenant is given more incentive to improve the land and advance technology.

The redistribution of land

The most common type of reform involves the redistribution of titles from one individual to another, from individuals to a group or community at large, or from a group to individuals, regardless of how the land is finally held for purposes of cultivation. For example, the land of one landlord may be redistributed to many individuals as in Egypt, Iran, or Ireland. Or the land of individuals may be reallocated in favour of the community at large by abolishing private ownership as in Soviet Russia and China. Or, again, public land may be distributed to individuals as in various parts of Latin America.

The impact of redistribution on the scale of operation and on marketability of the land depends on the form it takes and the restrictions attached to it. Ownership may change hands without affecting the scale of operation. For example, if the redistributed farm was previously operated as a unit, its division means fragmentation and reduction of scale; however, if it was operated in smaller segments by individual tenants, transfer of title to these tenants would not affect the scale of operation. The final results depend on the measures taken to prevent adverse effects.

Efforts to improve the scale of operation

Land reform is, of course, able to improve the scale of farm operations by enlarging the farm unit or by reducing it. Enlargement applies when the holding is increased in size either by adding to it or by consolidating its fragmented parts into one intact unit. Farm consolidation involves reallocation of the total farm land within a region among holders through a system of land evaluation and exchange, possibly including compensation so that no one loses and all gain by increasing efficiency. The scale of operations may also be increased by pooling resources as in farm cooperatives that offer facilities otherwise inaccessible at the level of the relatively small farm. Collectives aim at the same objective, although overexpansion has often led to negative rather than to positive economic effects.

An equally common approach is to divide large, extensively cultivated farms into smaller and more intensively cultivable units. Reduction of the scale, however, has potential problems since it may be confused with redistribution of income and employment. In such cases, it is not uncommon that extra weight may be given to the social impact so that the division may result in excessively small units or in the break up of efficiently run farms. Reduction of the scale may also inhibit changes in technology, capital investment, and diversification, all of which require relatively large units.

Changing the pattern of cultivation

Changes in the pattern of cultivation relate directly to the important question of increasing productivity in agriculture. While other types of reform may influence productivity indirectly by their influence on security of tenure, or scale of operation, improvement of the pattern of cultivation affects productivity directly: through advances in technology, improved irrigation, and the application of fertilizers and pesticides.

Technological advance usually implies mechanization, although this need not always be the case since it may be possible to improve agricultural techniques by introducing crop rotation, investigating the quality of the soil, or by better use of available technology. Such changes, however, have limited effects unless new technology has been introduced. The state of technology largely determines the level of productivity or the ratio between outputs and inputs, with more advanced technology permitting the cultivation of more land per unit of labour. It also makes possible deeper plowing, more timely cultivation and harvesting, reclamation of areas previously inaccessible, and possibly wider diversification of the crops than previously attainable. By easing the physical burden of farm work, it helps to conserve human energy; and it may even be the most direct way to modify tradition without an open confrontation with traditional forces. Mechanization may also have some adverse effects, such as the release of labour that may be difficult to employ elsewhere or the consumption of capital badly needed in other sectors.

Improvements in irrigation include not only increasing the water supply but draining swampy land and regulating the quantity and quality of water flow. This enables more intensive cultivation and expands the variety of crops that can be raised. Irrigation has commonly been a public responsibility since it often involves large investments and infringes on tenure rights.

Both irrigation and technology are closely related to the use of fertilizer and other chemicals to restore fertility, improve the crops, and eliminate weeds and pests. Chemicals may be difficult to apply without irrigation, and neither may be practical unless technology has advanced beyond relatively primitive methods. Despite the potential benefits, improvement of the pattern of cultivation may be delayed by traditional attitudes in rural areas, or by the lack of skills to operate more advanced technology, or by scarcity of capital. Another difficulty is that changes in the pattern of cultivation are usually long-term investments that may be too slow to satisfy immediate pressures for reform.

Measures that supplement land reform

Many things need to be done outside the immediate sphere of agriculture if reform is to be successful. Probably the most important involve credit, marketing, and education. Unless the farmer is able and ready to take advantage of new opportunities and unless his product can be marketed profitably, reform efforts may be of no use. Costly or inaccessible credit, and the excessive charges of middlemen, increase the relative costs of farming. Supervised credit, subsidies, and low interest loans help to remove the need for traditional sources of credit; credit cooperatives help to ease the problems of financing. Similarly, marketing cooperatives and public supervision that reallocate the middleman's share back to the farmer help him realize greater benefits from the market.

Finally, improvements in general education are essential in any reform that involves the modernization of agriculture. These include literacy programs, the teaching of home economics, and vocational training, which is especially important in helping the young and unemployed and in providing skilled labour for industry.

EVALUATION AND CRITERIA OF SUCCESS

The difficulties of appraising agricultural reforms

Agricultural reform is a complex process of directed change, and its effects touch society in many ways. Any specific reform program may be difficult to evaluate because its various social, political, and economic objectives may be inconsistent; even its supporters may have different ideas about it. Moreover, there are no generally accepted criteria for determining the success of such a program, nor adequate tools for measuring its progress.

Economic criteria. Economic indicators are the easiest to use since the conditions of economic development are more readily identified than the conditions of social and political development. Economic development may be defined as a sustained increase in per capita real income. To be sustained, the rise of per capita real income must be accompanied by changes in the economic and social structures of society. From an economic standpoint, development requires an increase in total investment (capital formation), higher productivity, and full employment.

Capital formation, or investment, in agriculture implies that more resources will be put at the disposal of the farmer in the form of technology, fertilizers, and irrigation facilities, all of which contribute to his productive capacity and productivity. Since capital formation depends greatly on domestic saving and income, however, a higher rate of capital formation may thus be an indicator of the success of the reform in aiding economic development.

Another indicator is change in agricultural productivity. A rise in productivity implies higher efficiency, better use of resources, and an advance in the state of technology. It also suggests an increase in the level of income and a higher potential for saving and investment. In the final analysis, change in productivity may be the most important single indicator of the contribution made by reform to economic development. Change in the level of rural employment or unemployment provides another indicator.

Finally, an important indicator may be the change in agriculture's responsiveness to the demands of the nonagricultural sectors. The ability of agriculture to provide labour, food, industrial crops, and a market for industrial products is a significant measure of its contribution to industrialization.

Social criteria. Social and political accomplishments are more difficult to measure. One of the important indicators may be the degree of peasant participation in society, relative to other groups, in matters such as voting, representation, and decision-making. Change in social and political stability is another indicator. Stability is defined in this context as the ability of a government to change by constitutional and nonviolent means and to maintain peace and continuity of the social and political order without resort to force.

Attempts to measure changes

But these various indicators can only suggest that change has taken place. Evaluation of the results depends on the measurement and interpretation of change. Although it is usually tempting to describe a reform as successful or unsuccessful in general terms, it is more realistic to evaluate it according to each indicator separately, since the results are not necessarily additive. A negative impact on economic development may or may not be offset by higher stability, depending on the system of evaluation. Nor is it easy to measure change; some results may be intangible, and in some cases data on prereform conditions may not be accessible and hence the change not measurable. Assuming that measurement is feasible, however, evaluation of the results may follow one of two approaches: that of maximization or that of relative gain.

The maximization approach considers reform successful only if maximum benefits have been derived in the area under consideration. For example, a reform would be successful in increasing capital formation if any further effort would result in a decline of net investment. This approach has been applied to political and social results as well, such as the maximization of votes, equality, and social participation. The maximum is achieved when the cost of additional results is equal to the additional benefits derived.

The alternative approach is to measure success by the amount of gain or improvement over the prereform conditions. Thus, while the maximization approach asks how close to the ideal the results have been, the relative gain approach asks how much improvement has taken place. By this approach a reform would be successful to the extent to which capital formation has been encouraged and net investment increased. This is difficult to apply because of differences in underlying conditions. A 20 percent rise in capital formation in a capital-poor economy may be more significant than a 30 percent rise in a capital intensive economy. Similarly a 20 percent decline in the number of dissatisfied peasants in a peaceful or democratic society may be more conducive to stability and harmony than a 30 percent decline in a radical or violent society. For this reason the relative gain approach can be meaningful only if a critical minimum achievement is specified as a criterion of success in each specific situation. For instance, if the critical minimum is a 20 percent increase in per capita income in one economy and 30 percent in another, an increase of 20 percent in the first and 30 percent in the second would have equal significance as measures of success.

Whichever of these approaches is applied, it is still necessary to consider the subjective evaluation of reform programs. The degree to which the actual results approximate the expectations of the parties concerned will determine the success of a reform in promoting political stability. The reform may be considered successful if the peasants are satisfied that they achieved as much as possible and the landlords that they did not lose more than they had to. Thus, political stability may be another indicator of the success of a reform.

Paradoxes of reform

Inadequacies of the indicators. Whether the criteria used to measure the success of reform are the objective economic indicators or the more problematical social and political effects, there are inherent contradictions that tend to render the indicators vague and inconclusive. Several of these paradoxes are worth noting.

First, land redistribution often implies withdrawal of the landlord's contribution to the functioning of the farm. His managerial ability is no longer available, and his contributions to investment, credit, and general farm security are lost. Therefore, unless substitute sources of credit and investment capital are provided, land redistribution may retard rather than advance economic development. Further, while redistribution creates security, it may inhibit mobility of the new owners. A stake in the land tends to reduce the incentive to seek opportunity elsewhere, even though the new farm may be below optimum size and the farm family underemployed.

Second, reformers often must choose between breaking up efficiently run farms or reducing the land available for redistribution. Some efficiently run farms are exempted from redistribution; in other cases they are taken over as state farms, and the landless farmers are hired permanently as wage workers. Or the estate is broken up and the smaller units are pooled together in the form of a cooperative. Each of the alternatives has its own weaknesses—*e.g.*, the problem of how to weigh the economic gains of cooperative or state farming against loss of independence and freedom of decision making or the hope of becoming an owner.

Third, redistribution is often accompanied by compensation of landlords for expropriated property. Compensation tends to reduce the equalizing effects of reform since the relative position of the compensated landlord is little affected. Compensation payments may be lower than the market value or their real value may be depreciated by inflation, but these are uncertain results and may be difficult to account for in evaluating the reform.

Fourth, though it is usually hoped that reform will encourage saving, it is a fact that the farmers tend to spend the extra income on consumption, which may be unavoidable so long as farmers' incomes are relatively low and they prefer consumption to saving.

Fifth, reform tends to invite social and political participation prematurely. Participation, particularly after many years of backwardness, requires a degree of readiness and awareness that is slow in developing. Yet the farmers are placed in a position where immediate participation is expected. Hence the dilemma: delayed participation could be interpreted as reform failure, and premature participation could spell chaos. Shortcut measures to speed up participation often aggravate the problem.

Finally, land redistribution without preventive measures to preclude future concentration of ownership might simply prepare the way for future crises. Yet, preventive measures such as restrictions of land division, a ceiling on holding size, or regulation of land transfer infringe on the rights of ownership and may also inhibit the efficient owner from expanding his operations. These paradoxes have sometimes been resolved by subjecting private interests to public interest. But this depends on the ideology of the reformers and their ability to enforce the regulations.

HISTORY OF LAND REFORM

The ideas and principles discussed so far may be illustrated by a selective survey of the history of land reform movements, emphasizing the objectives and processes of reform, the difficulty of evaluating it, and the evolution of reform.

Ancient reforms. The recorded history of reform begins with the Greeks of the 6th century BC. Land in ancient Athens was held in perpetuity by the tribe or clan, with individual holdings periodically reallocated according to family size and soil fertility. Population increase, expansion of trade, growth of a money economy, and the opening up of new business opportunities eventually made financial transactions in land an economic necessity. Land itself continued to be inalienable, but the right to use the land could be mortgaged. Thus, peasants could secure loans by surrendering their rights to the product of the land, as "sale with the option of redemption." Lacking other employment, the debtor continued to cultivate the land as *hektdmor*, or sixth parter, delivering five-sixths of the product to the creditor and retaining the rest for himself. Mortgaged land was marked by *horoi*, or mortgage stones, which served as symbols of land enserfment. When Solon was elected archon or chief magistrate, *c.* 594 BC, his main objective was to free the land and destroy the *horoi*. His reform law, known as the *seisachtheia* or "shaking-off the burdens," cancelled all the debts, freed the *hektēmoroi*, destroyed the *horoi*, and restored land to its constitutional holders. Solon also prohibited the mortgaging of land or of personal freedom on account of debt.

The impact of the reform was extensive but of short duration. The *hektēmoroi* were freed, but since no alternative sources of support or credit were provided and creditors were uncompensated, dissatisfaction and instability continued to prevail. Two decades of anarchy were followed by a revolution, *c.* 561 BC, that brought Peisistratus to power, who enforced the reform and distributed lands of his adversaries (who were killed or in exile) among the small holders. He also extended loans to aid cultivation and prevent migration to the city and expanded silver mining to create employment. Although the amount of land redistributed is unknown, Peisistratus was apparently able to satisfy the peasantry, secure their loyalty, and stay in power for life. The reform seems to have been an effective mechanism to sustain tyranny or nonconstitutional rule, but the economic effects are too vague to evaluate.

The reforms of the Gracchi

The Roman reform by Tiberius and Gaius Gracchus came between 133 and 121 BC. The land reform law, or *lex agraria*, of Tiberius was passed by popular support against serious resistance by the nobility. It applied only to former public land, *ager publicus*, which had been usurped and concentrated in the hands of large landholders. Land concentration reduced the number of owners and hence the number of citizens and those eligible to serve in the army. In addition, such concentration was accompanied by a shift from cultivation to grazing, which reduced employment and increased the poverty of the peasants, producing a crisis. The motives of the reformers have been debated, but it would appear that sympathy with the poor and concern for political stability were the factors that led the Gracchi to attack usurpation and return the public domain to small cultivators.

The *lex agraria* specified minimum and maximum individual land holdings, with an allowance for male children of the family. Excess land would be expropriated and compensation paid for improvements. A standing *collegium*, or commission, was to enforce the law, but implementation was delayed because Tiberius was killed the same year of its passage. When Gaius was elected tribune about a decade later, he revived the reform and went even farther. He colonized new land and abolished rent on small holdings to put them in the same position as large holdings on which rent had been suspended as compensation for expropriation. However, Gaius was killed in 121 BC and within a decade the reform was reversed: private acquisition of public land was legalized, the land commission dissolved, rent on public land abolished, all holdings declared private property, and squatting on public land prohibited. Even colonization was ended and colonies established by Gaius were broken up. The era of reform came to an end and another period of land concentration was inaugurated.

Modern European reforms. The French Revolution brought a new era in the history of land reform. Reform meant dealing with survivals of the medieval tenures that had left a common heritage in most European countries and, through them, in the colonies. The measures and approaches varied from place to place and period to period.

The French Revolution and after

On the eve of the Revolution, French society was polarized, with the nobility and clergy on one side and the rising business class on the other. The middle class was relatively small, especially in the rural areas. The majority of the peasants were hereditary tenants, either *censiers*, who paid a fixed money rent, or *mainmortables*, or serfs, who paid rent in the form of labour services, *corvée*, of about three days a week. The peasants paid various other burdensome feudal dues and taxes, from which the nobility and clergy were exempted. Peasant poverty, which was intolerable enough, was exacerbated by their servile status. The Revolution overthrew the *ancien régime* and the feudal order, and introduced land reform.

The reform repealed feudal tenures, freed all persons from serfdom, abolished feudal courts, and cancelled all payments not based on real property, including tithes. Rents based on real property were redeemable. Once the law had been passed, however, the peasants seized the land and refused to pay any rents or redemption, and in 1792 all payments were finally cancelled. Land of the clergy and political emigrants was confiscated and sold at auction, together with common land. The terms of sale, however, often favoured the wealthy, which may explain the rise of a new class of large landowners among the supporters of Napoleon.

The social and political objectives of the reformers were fully realized. The *censiers* and serfs became owners. Feudalism was destroyed, and the new regime won peasant support. The economic effects, however, were limited. Incentives could not be increased substantially since the peasants already had full security of tenure prior to the reform. The scale of operations was not changed; and no facilities for credit, marketing, or capital formation were created. The major achievement was perpetuation of the small family farm as a basis of democracy, a contribution of the Enlightenment and the *Code Napoléon*. The small family farm has characterized French agriculture ever since.

There were other reforms in most European countries. England resolved its land problems by the enclosure movement that drove the small peasants into the towns, the consolidation of holdings, large scale operation, and private ownership. Sweden and Denmark pioneered between 1827 and*1830 by peacefully abolishing village compulsion, or imposed labour service, and the strip system of cultivation and by consolidating the land and dividing the commons among the peasants. Though influenced by the French Revolution, only after the 1848 revolutions did Germany, Italy, and Spain free the peasants and redistribute the land. Reform in Ireland took a whole century before substantive results were achieved, in the mid-1930s, after Ireland was divided into Northern Ireland and the Irish Free State. The tenants were converted into owners by subsidized purchase of the land.

Russian reforms

The first major Russian reform was the emancipation of the serfs in 1861. At the time of emancipation about 45 percent of the land was private property and the remainder was held as allotment land, cultivated in units averaging 9.5 acres by the peasant serfs against rent in kind and labour, payable to feudal lords. In contrast, fewer than 1,000 noble families owned about 175,000,000 acres and received rent therefrom. Conflict between such extremes of poverty and wealth, the expansion of trade and commerce, and the pressure of population caused restlessness among the peasants and rendered reform inevitable. As Tsar Alexander II put it: "It is better to abolish serfdom from above than to await the day when it will begin to abolish itself from below."

The Emancipation Act of 1861 abolished serfdom and distributed allotment land among the peasants. The homestead became hereditary property of the individual; but the field land was vested in the village *mir* as a whole. The peasant paid redemption through the village authority, while the landlord received state bonds as compensation equal to 75–80 percent of the land market value. Though legally freed, the private serf had to ransom his freedom by surrendering a part of the allotment land. In contrast, serfs belonging to the royal family were emancipated in 1863 and received the maximum amount of land fixed by law. Serfs belonging to the state were emancipated in 1866 and allowed to keep the land they occupied in perpetual tenure against money rent. The Cossacks received two thirds of the land, to be held in common, but instead of redemption they had to serve 20 years in the army. The serfs in mines and households were freed but received no economic assets.

Redemption payments, however. soon proved too burdensome, village restrictions were tight, and the allotment land area declined; all of which led to renewed restlessness and disturbances. Following the revolt of 1905, the government, under Pyotr Stolypin, tried to create middle class, independent farmers by replacing the village tenure with private ownership, consolidating holdings, and encouraging land purchase by individuals; but the time was too short for effective implementation. The Soviet Revolution overthrew the tsarist regime and introduced the concepts of public ownership and collectivization.

By decree in 1918, the Soviets abolished private ownership of land, made farming the sole basis of landholding, and declared collectivization a major objective of policy. Marketing of agricultural products became a state monopoly. In 1929 Stalin was able to embark on a full course of collectivization, which he pursued by various means and at high cost. By 1938 collective farms occupied 85.6 percent of the land and state farms 9.1 percent. Credit facilities and tractor stations supplemented collectivization, while agricultural production was integrated in the national plan for industrialization and development.

The costs of Soviet reform included the destruction of capital and the death of large numbers of peasants. Nevertheless, farm operation was enlarged, sometimes to the point of inefficiency; agriculture was coordinated with nonagricultural sectors; and mechanization was advanced sufficiently to release labour for the industrial sector. Total output and productivity increased; and capital formation was made possible through forced saving, taxes, and regulated prices. The peasant received health care, education, and better labour conditions. The objectives of the decree of 1918 have been fully realized.

Reform in eastern Europe

Reform in eastern Europe was complicated by the fact that most of the east European countries remained under foreign rule until the middle of the 19th century or later. In Hungary, the Decree of 1853 abolished the *robot,* or forced labour and feudal dues, freed the serfs, liberalized land transaction, and encouraged consolidation. The Romanian reform of 1864 freed the serfs and distributed both the land and the redemption payments in proportion to the number of cows or oxen each peasant had. Formal emancipation in Bulgaria was introduced by the Turkish government in the 1850s; but actual reform came in 1880, after independence. Each peasant, including sharecroppers and wage workers, who had worked the land for ten years without interruption, was entitled to the land he had cultivated. With the exception of Bulgaria, the distribution of ownership throughout most of eastern Europe remained highly uneven. Political instability reached a dangerous point between the two world wars. Following World War II, the east European countries acquired Communist governments with a strong tendency toward collectivized and mechanized agriculture.

Mexico. The Mexican reform of 1915 followed a revolution and dealt mainly with lands of Indian villages that had been illegally absorbed by neighbouring *haciendas* ("plantations"). Legally there was no serfdom; but the Indian wage workers, *peones,* were reduced to virtual serfdom through indebtedness. Thus, the landlords were masters of the land and of the *peones.* The immediate aim of reform was to restore the land to its legal owners, settle the title, and use public land to reconstruct Indian villages. The motives were mainly to reduce poverty and inequality and to secure political stability, which was then in the balance. A decree of 1915 voided all land alienations that had taken place illegally since 1856 and provided for extracting land from *haciendas* to re-establish the collective Indian villages, ejidos. The 1917 constitution reaffirmed those provisions but also guaranteed protection of private property, including *haciendas.* Nevertheless, a combination of loopholes, litigation, and reactionary forces slowed implementation; and effective reform came only after passage of the Agrarian Code of 1934 and the sympathetic efforts of President Lázaro Cárdenas.

The reform restored many villages and freed the *peones,* but land concentration and poverty continued. In 1950, more than 31 percent of the private cropland was owned by fewer than half of one percent of the owners. Small-scale operation was retained or encouraged, a fact explaining the decline of output in the early years. More recently, efficiently run farms have been exempted from distribution.

The social and political impact was more positive. The peasants acquired more land and liberty, and control by landlords was reduced, although it was replaced by village restrictions. At least legally, farming became the basis of landholding. Some have seen in land reform the reason for Mexico's political stability, although there have been sporadic peasant uprisings as recently as the mid-1960s.

REFORMS SINCE WORLD WAR II

Reforms for the purpose of economic development

Recent decades have witnessed widespread, comprehensive land reform programs in a number of countries. Reforms have been oriented toward economic development, with guidance and aid from the United Nations and various outside countries. The trend can be only selectively illustrated.

Japan. The Japanese reform came after the war at the insistence of the Allied Occupation Army. The reform was designed by experts to suit the uniquely high literacy rate and advanced industrialization of the country. Although the Meiji government had formally abolished feudalism and declared the land to be the property of the peasants, usurpation of land by the rich and by moneylenders had created classes of perpetual tenants and absentee landlords. In 1943, 66 percent of the land was operated by tenants against rent in kind that averaged 48 percent of the farmers' product. The trend was strengthened by population pressure on scarce land resources, which also resulted in fragmentation of holdings. The social class structure was closely tied to tenure, the owners in each village being at the top of the structure. Conflict between landlords and peasants was widespread.

After the war, the crisis was revived by food shortages, the breakdown of the urban economy, and the return of absentee landlords to the land. The Occupation Army insisted on reform, presumably to democratize the society and rehabilitate the economy. The reform law of 1946 established a ceiling on individual holdings and provided for expropriation and resale of excess land to the tenants against long-term payments. The government compensated the landlords in cash and bonds redeemable in 30 years. Tenants who remained were protected by contract, and rents were reduced to a maximum of 25 percent of the product. The redistributed land was made inalienable, though this restriction was relaxed four years later. The program also provided for marketing and credit cooperatives. An important supplementary measure was the Local Autonomy Law of 1947; this reform law decentralized the power structure and put village affairs in the hands of the villagers.

Within two years tenancy declined by more than 80 percent. Rent control and land distribution helped to equalize incomes in the villages and restore the sociopolitical status of the peasants. Crop yields per unit of land increased, but despite improved techniques the yields per man declined. In general the reform seemed to realize the objectives of the reformers and the peasants, although smallness of scale, low per capita incomes, underemployment, and insufficient mechanization have persisted. Even black market rents have developed. These problems were tolerable in view of the upsurge of the urban economy and the ability of the Japanese farmer to supplement his income from nonagricultural employment.

Egypt. The Egyptian reform of 1952 followed the revolution that overthrew the monarchy and brought young middleclass leaders to the helm. It was the most comprehensive reform outside the Communist countries. Though affecting only about 12 percent of the arable land, it was applied thoroughly and touched all aspects of rural life. Egypt had two main forms of tenure: private ownership and *waqf* or land held in trust under a special ministry and dedicated to charitable or educational purposes. *Waqf* land was inalienable, but private land was subject to speculation and concentration. In 1950, 1 percent of the owners had more than 20 percent of the private land, and seven percent had more than two-thirds. The operating unit was small, with 77 percent of all the holdings occupying less than one acre each. Tenancy was widespread and rents exorbitant. The peasants were exploited by middlemen who sublet the land to tenants, mediated between them and the market, and extended credit at high rates of interest.

The revolutionary reformers aimed at abolishing feudalism, recruiting peasant support, promoting economic development, and bringing the villagers back into the stream of national life. The Agrarian Reform Law of 1952 put a ceiling on individual holdings at 200 *faddān* (1 *faddān* = 1.038 acres), later reduced to 100 *faddān*, with special allowance for male children. The excess land was expropriated and distributed to the peasants in parcels not exceeding five *faddān*. Compensation was given in bonds, while land recipients had to repay in annual installments. The new owners were obligated to join cooperatives for production, marketing, and credit. Tenancy conditions were also regulated, with contract replacing traditional terms; rent could not exceed 50 percent of the product nor could a tenant hold more than 50 acres, to avoid subletting. An interesting feature of the reform was the special attention given to college graduates by allowing them up to 20 *faddān* parcels.

The Reform Law of 1952

The reform was enforced quickly and had a great impact on the morale of the peasants. The economic effects, however, were minor since agriculture had already been intensive and land yield high. Producer cooperatives served only to offset the impact of distribution on the scale of operation. Some increases in yield have been claimed, but the evidence is insufficient. Furthermore, little capital was redirected into productive investment since the compensation bonds were not negotiable. Peasant savings remained limited, income increments being spent mostly on consumption. Finally, underemployment in agriculture has remained widespread.

The social and political effects, however, were far reaching. Redistribution and regulation of rent raised the incomes of small owners and tenants. Cooperatives replaced the middleman and captured his share for the farmer. The peasant gained social status and enjoyed a higher level of political participation, mostly in support of the revolutionary regime. These effects, however, can be easily exaggerated. The peasants became dependent on the cooperatives whether they liked them or not. Great differences in landholding continued to exist, and peasant incomes remained low relative to urban incomes. Black market rents appeared. The example of Egypt suggests that successful land reform requires an upsurge in the industrial sector of the economy.

Southeast Asia. The model of Japan's reform has been followed in Southeast Asia, especially in Taiwan and South Vietnam. Both were influenced by American experts and by the anti-Communism of the governments. The objectives in both have been to sustain the political order, raise living standards, and promote some degree of economic development. Both reforms began with regulation of tenancy, restriction of rent, and the institution of written contract for leases, following which tenants were to be-transformed into owners. Taiwan's reform was implemented between 1949 and 1953, in three stages. First, rents, which had sometimes reached 70 percent of the product, were reduced to 37.5 percent. Next, tenant-farmed public land was sold to the tenants. When this was done, tenant-farmed private land was bought by the government and resold to the tenants.

Vietnamese reform

The Vietnamese reform was introduced in 1955. Rents were reduced to a maximum of 25 percent of the product. However, a ceiling of 100 hectares was put on individual holdings, and only the excess land was subject to redistribution in parcels of three to five hectares to the tenants. Reforms in both Taiwan and South Vietnam have been formally supplemented by other measures described as community development (more thoroughly implemented in Taiwan), including adult education, credit facilities, improved technology, and other social services. Some consolidation was attempted in Taiwan, but in both countries the scale of operation was little affected. The main effect seems to have been the regulation of tenancy and the redistribution of rent incomes. An innovation of Taiwan's reform was the partial compensation of landlords with industrial shares in public enterprises.

Taiwan's reform has been hailed as a major success, both in economic and political terms. Some observers, however, are unwilling to reach such a conclusion until the peasants have a free choice of tenure and farm organization. As in Vietnam, however, such a choice may be a long way off, given the political conflict in the region.

The Philippines introduced a reform program in 1963 with emphasis on economic development. The reform aimed primarily at replacing share tenancy with lease contracts and eventually with ownership, and at revitalizing agriculture through extension services. The reform was intended to increase credit facilities, create cooperatives, and establish social service clubs. The main effects initially were seed improvement, greater use of fertilizers, and an increase in contractual tenancy.

Various other reforms have been introduced in Southeast Asia. In Malaysia, Thailand, and Indonesia the emphasis has been on settlement of landless people on virgin public land. In Indonesia attempts have been made to shift people from relatively crowded to sparsely populated islands. In Thailand various approaches to settlement have been attempted, including cooperative and government-sponsored programs, although self-help has been emphasized. Fewer than 25,000 persons were settled between 1956 and 1965.

Reform in Malaysia

In contrast, the program in Malaysia has been highly organized and oriented toward economic development. It combines social and economic objectives with emphasis on the production of rubber and palm oil for export. The program gradually transforms the landless into hereditary tenants. A typical project covers 4,500 to 5,000 acres of jungle land and absorbs about 400 families. The land is cleared and planted by contract, and a village is constructed, with all the necessary services, before the settlers arrive. Each house has a quarter of an acre for a household garden. Crop land is divided in blocks of 120 to 200 acres, to be worked by a team of 15 to 25 people until the plants have matured. Upon maturation, each settler receives a share by lottery and a lease title for 99 years. This tenure arrangement precludes alienation, subdivision, or subleasing; it thus sidesteps the Islamic laws of inheritance and opens the door for institutional change in society at large.

The settler is responsible for the cost of clearing and planting, but the government pays the administrative costs. The settler is guaranteed supplementary employment to earn subsistence income pending maturity of the plants, and cultivation is supervised and guided by experts. The rate of settlement is determined by the overall economic plan. During the First Five Year Plan, 1957–60, 3,300 families were settled. During the second, 1961–5, 9,500 families, or 57,000 people, were settled. Although it is too early to measure the success or failure of the reform, it is already clear that land holding has become tied to cultivation; fragmentation and diseconomies of scale have been avoided, and cultivation has become a rational economic operation. The Malaysian program has much in common with the cooperative settlements of Israel, and also resembles the Gezira Scheme in Sudan.

Latin America. Except for the early example of Mexico, reform in Latin America has been recent, and appears to have come only in response to the threat of social and political instability and mounting international pressures. It must be seen against a background of rapidly increasing population; extreme contrasts between plantation economies and small units; high concentration of land ownership, income, and power; relatively backward cultivation methods; and extensive foreign ownership of land. Latin American society is also complicated by its ethnic mixtures and its high dependence on staple trade items such as sugar, tobacco, cocoa, coffee, and beef cattle.

As reform in Latin America has come in one country after another, each program has reflected the differing ideologies and objectives of the national leaders. Brazil has had several attempts at reform, the latest and most comprehensive of which was initiated in 1964. The measures have been indirect and relatively mild, the most important being taxation of idle land and large plantations. The rates of tax are progressively higher as the size of the farm increases, on the assumption that wealth redistribution will follow. Actual redistribution of land has received a low priority. Provisions for credit, tenancy protection, and colonization were made; but as of 1970 they had not been strongly implemented.

Reform in Cuba

At the other end of the Latin-American spectrum is the Cuban reform that followed the revolution of 1958. Cuba retained private ownership, but reduced it effectively in favour of the public sector. As proclaimed a few months before the overthrow of the old regime, the reform aimed at the elimination of *latifundia* tenure, expropriation of land owned by foreign companies, higher standards of living for the peasantry, and national economic development. It began by setting a ceiling of 30 *caballerias* (1 *caballaria* = 13.4 hectares) on individual holdings, with a maximum of 100 *caballerias* if economic operations required such a scale. All foreign-owned land was nationalized. Public land on which rice and cattle were raised was converted into state farms, and the peasants became permanent wage workers on these farms. Sugar plantations were converted into cooperatives to avoid their subdivision into small uneconomical units. Before long the ceiling on individual holdings was lowered to five *caballerias* and all such holdings became private family farms. The rest were nationalized, and the expropriated owners compensated with a pension for life. The reform was supplemented by the organization of national farmer associations; people's stores; credit, housing, and educational facilities; and the supply of machinery and fertilizers. In 1963 a major reorganization of state farms took place; they were subdivided on the basis of crop specialization into smaller operational units of about 469 *caballerias.*

Effects of the reform were comprehensive and immediate. The tenure institutions were radically changed in favour of public ownership, while *minifundia* and tenancies were abolished. Socially and politically, the reform realized the objectives of the reformers. Economically, the government claimed higher yields of sugar cane, vegetables, and fruit; but this was disputed by foreign observers.

Other Latin American reforms have fallen in a range between those of Brazil and Cuba. For example, that of Costa Rica has overlooked land concentration and income inequality and concentrated on the squatters or *parasitos,* who in 1961 numbered between 12,000 and 16,000 people. The reform aimed at legalizing existing squatter holdings, preventing further squatting, and conserving virgin land. Even this modest program was implemented very slowly. Colombia has had reform programs for at least 30 years; but concentration of ownership, fragmented small holdings, and backward methods of cultivation are still the rule rather than the exception.

Chile

Chile undertook various reform programs before achieving concrete results. In 1962 a program was enacted to encourage settlement of new land, but only about 1,000 families were settled. A comprehensive agrarian reform was introduced in 1965 with three main objectives: to make the agricultural workers owners of the land they had cultivated previously, to increase agricultural and livestock production, and to facilitate social mobility and peasant participation in political life. The Chilean reform is unique in its method of implementation. Once the plantation has been designated for expropriation and the prospective owners selected, they are organized into ***asentamientos,*** or settlement groups. The group elects a committee to take charge of settlement. The members cultivate the land as a team for three to five years. Meanwhile they receive training and guidance in social participation, decision making, and modern farming. Upon completion of the transition period, the land is divided among those who have shown promise, to be held outright and without restriction. All new owners are obligated to join cooperatives, the form of these being determined by the members. Between 1965 and 1969 more than 15,000 families were settled on 2,000,000 hectares expropriated by the reformers.

Observers of the Latin American scene have been pessimistic regarding the adequacy of these land reform programs. With the exception of Cuba, capital formation in agriculture has not substantially increased; the pattern of land distribution has undergone little change; and social and political stability has remained in question. The agrarian structure is still considered defective both from the point of view of the peasants and for purposes of economic development.

India and Pakistan

Other recent reforms. The tendency to reform the agrarian structure has been manifest in nearly all countries. India and Pakistan have concentrated on abolishing intermediaries who existed as survivals of traditional and feudal tenures. In India the tenants have become hereditary holders, with the title vested in the state. India has left reform to the individual states and emphasized peaceful and compensatory methods; hence the results have varied from one state to another. Pakistan, following the revolution of 1958, enacted a reform that made most of the tenants owners. In both countries, however, small-scale farming has persisted, and Pakistan has tolerated and protected owners of up to 500 acres. In neither country has fragmentation been effectively reduced or capital formation and modern cultivation methods significantly advanced.

China has eliminated private ownership and organized the peasants in village communes. Extensive supplementary measures have been spoken of, but the role and organization of the commune have varied according to the pressures upon the economy. Iran's reform made owners of most of the former sharecroppers. The scale of operation and the methods of cultivation, however, were not affected. Capital formation among the Iranian peasants has been limited since the small increases in their incomes have been spent mainly on consumption. Iran's reform has apparently succeeded in sustaining the existing social order.

Reform was introduced in Syria and Iraq following their revolutions, but the status of these reforms remains indeterminate. Reforms in Africa have been concerned mainly with title settlement and colonization of new land. Many African countries have tended toward some form of socialism in tenure arrangements. In most countries where partial reforms have been carried out the agrarian structure still suffers from defects that obstruct economic development and nourish social and political instability.

Language

Many definitions of language have been proposed. Henry Sweet, an English phonetician and language scholar, stated: "Language is the expression of ideas by means of speech-sounds combined into words. Words are combined into sentences, this combination answering to that of ideas into thoughts." The U.S. linguists Bernard Bloch and George L. Trager formulated the following definition in their *Outline of Linguistic Analysis* (1942): "A language is a system of arbitrary vocal symbols by means of which a social group cooperates." Definitions like these and, indeed, any succinct definition make a number of presuppositions and beg a number of questions. The first, for example, puts excessive weight on "thought," and the second uses "arbitrary" in a specialized, though legitimate, way (see below).

A number of considerations enter into a proper understanding of language as a subject:

1. Every physiologically and mentally normal person acquires in childhood the ability to make use, as both speaker and hearer, of a system of vocal communication that comprises a circumscribed set of noises resulting from movements of certain organs within his throat and mouth. By means of these he is able to impart information, to express feelings and emotions, to influence the activities of others, and to comport himself with varying degrees of friendliness or hostility toward persons who make use of substantially the same set of noises.

2. Different systems of vocal communication constitute different languages; the degree of difference needed to establish a different language cannot be stated exactly. No two people speak exactly alike; hence, one is able to recognize the voices of friends over the telephone and to keep distinct a number of different unseen speakers in a radio broadcast. Yet, clearly, no one would say that, for that reason, they speak different languages. Generally, systems of vocal communication are recognized as different languages if they cannot be understood without specific learning by both parties, though the precise limits of mutual intelligibility are hard to draw and belong on a scale rather than on either side of a definite dividing line. Substantially different systems of communication that may impede but do not prevent mutual comprehension are referred to as dialects of a language. In order to describe in detail the actual different speech patterns of individuals, the term idiolect, meaning the speech habits of a single person, has been coined.

Languages, dialects, and idiolects

3. Normally, people acquire a single language initially—their first language, or mother tongue, the language spoken by their parents or by those with whom they are brought up from infancy. Subsequent "second" languages are learned to different degrees of competence under various conditions, but the majority of the world's population remains largely monolingual. Complete mastery of two languages is designated as bilingualism; in a few special cases—such as upbringing by parents speaking different languages at home—speakers grow up as bilinguals, but ordinarily the learning, to any extent, of a second or other language is an activity superimposed on the prior mastery of one's first language and is a different process intellectually.

4. Language, as described above, is species-specific to man. Other members of the animal kingdom have the ability to communicate, through vocal noises or by other means, but the most important single feature characterizing human language (that is, every individual language), against every known mode of animal communication, is its infinite productivity and creativity. Human beings are unrestricted in what they can talk about; no area of experience is accepted as necessarily incommunicable, though it may be necessary to adapt one's language in order to cope with new discoveries or new modes of thought.

Animal communication systems are by contrast very tightly circumscribed in what may be communicated. Indeed, displaced reference, the ability to communicate about things outside immediate temporal and spatial contiguity, which is fundamental to speech, is found elsewhere only in the so-called language of bees. Bees are able, by carrying out various conventionalized movements (referred to as bee dances) in or near the hive, to indicate to others the locations and strengths of nectar sources. But nectar sources are the only known theme of this communication system. Surprisingly, however, this system, nearest to human language in function, belongs to a species remote from man in the animal kingdom and is achieved by very different physiological activities from those involved in speech. On the other hand, the animal performance superficially most like human speech, the mimicry of parrots and of some other birds that have been kept in the company of humans, is wholly derivative and serves no independent communicative function. Man's nearest relatives among the primates, though possessing a vocal physiology very similar to that of humans, have not developed anything like a spoken language.

Interaction of language with society

Language interacts with every other aspect of human life in society, and it can be understood only if it is considered in relation to society. This article attempts to survey language (both spoken and written) in this light and to consider its various functions and the purposes it can and has been made to serve. Because each language is both a working system of communication in the period and in the community wherein it is used and also the product of its past history and the source of its future development, any account of language must consider it from both these points of view.

The science of language is known as linguistics. It includes what are generally distinguished as descriptive linguistics and historical linguistics. Linguistics is now a highly technical subject; it embraces, both descriptively and historically, such major divisions as phonetics, grammar, and semantics, dealing in detail with these various aspects of language.

For a full account of the theory and methods of linguistic science, see the article LINGUISTICS. The articles PHONETICS; GRAMMAR; and SEMANTICS provide further information. For a general survey of known living and dead languages, consult the article LANGUAGES OF THE WORLD. Treatments of language families and individual languages, such as ROMANCE LANGUAGES; GERMANIC LANGUAGES; and BASQUE LANGUAGE, are also provided.

This article is divided into the following sections:

ATTITUDES TOWARD LANGUAGE

The practice of naming

As is evident from the introduction above, human life in its present form would be impossible and inconceivable without the use of language. People have long recognized the force and significance of language. Naming—applying a word to pick out and refer to a fellow human being, an animal, an object, or a class of such beings or objects—is only one part of the use of language, but it is an essential and prominent part. In many cultures men have seen in the ability to name an ability to control or to possess; this explains the reluctance, in several primitive and other communities, with which names are revealed to strangers and the taboo restrictions found in several parts of the world on using the names of persons recently dead. Lest it be thought that attitudes like this have died out in modern civilized communities, it is instructive to consider the widespread and perhaps universal taboos on naming directly things considered obscene, blasphemous, or very fearful. Indeed, use of euphemistic substitutes for words referring to death and to certain diseases actually seems to be increasing in some civilized areas.

Not surprisingly, therefore, several independent traditions ascribe a divine or at least a supernatural origin to language or to the language of a particular community. The biblical account, representing ancient Jewish beliefs, of Adam's naming the creatures of the Earth under God's guidance is well-known:

> So out of the ground the Lord God formed every beast of the field and every bird of the air, and brought them to the man to see what he would call them; and whatever the man called every living creature, that was its name (Gen. 2:19).

Norse mythology preserves a similar story of divine participation in the creation of language, and in India the god Indra is said to have invented articulate speech. In the much more sophisticated debate on the nature and origin of language given in Plato's Socratic dialogue *Cratylus,* Socrates is made to speak of the gods as those responsible for first fixing the names of things in the proper way.

A similar divine aura pervades early accounts of the origin of writing. The Norse god Odin was held responsible for the invention of the runic alphabet. The inspired stroke of genius whereby the ancient Greeks adapted a variety of the Phoenician consonantal script so as to represent the distinctive consonant and vowel sounds of Greek, thus producing the first alphabet such as is known today, was linked with the mythological figure Cadmus, who, coming from Phoenicia, was said to have founded Thebes and introduced writing into Greece. The Arabs had a traditional account of their script, together with the language itself, being given to Adam by God.

Biblical traditions concerning language

The later biblical tradition of the Tower of Babel (Gen. 11:1–9), whatever its exact place in ancient Near Eastern history, exemplifies three aspects of early thought about language: (1) divine interest in and control over its use and development, (2) a recognition of the power it gives to man in relation to his environment, and (3) an explanation of linguistic diversity, of the fact that people in adjacent communities speak different and mutually unintelligible languages, together with a survey of the various speech communities of the world known at the time to the Hebrews.

The origin of language has never failed to provide a subject for speculation, and its inaccessibility adds to its fascination. Informed investigations of the probable conditions under which language might have originated and developed are seen in the late-18th-century essay of the German philosopher Johann Gottfried von Herder, "Abhandlung über den Ursprung der Sprache" ("Essay on the Origin of Language"), and in numerous other treatments. But people have tried to go further, to discover or to reconstruct something like the actual forms and structure of man's first language. This lies forever beyond the reach of science, in that spoken language in some form is almost certainly coeval with *Homo* sapiens. The earliest records of written language, the only linguistic fossils man can hope to have, go back no more than about 4,000 or 5,000 years. Attempts to derive human speech from imitations of the cries of animals and birds or from mere ejaculations of joy and grief, as if onomatopoeia were the essence of language, were ridiculed for their inadequacy by the Oxford philologist F. Max Miiller in the 19th century and have been dubbed the bowwow and pooh-pooh theories.

On several occasions attempts have been made to identify one particular existing language as representing the original or oldest tongue of mankind, but, in fact, the universal process of linguistic change rules out any such hopes from the start. The Greek historian Herodotus told a story that King Psammetichus of Egypt caused a child to be brought up without ever hearing a word spoken in its presence. On one occasion it ran up to its guardian as he brought it some bread, calling out "bekos, bekos"; this, being said to be the Phrygian word for bread, proved that Phrygian was the oldest language of mankind. The naïveté and absurdity of such an account have not prevented its repetition elsewhere and at other times.

In Christian Europe the position of Hebrew as the language of the Old Testament gave valid grounds through many centuries for regarding Hebrew, the language in which God addressed Adam, as the parent language of all mankind. Such a view continued to be expressed even well into the 19th century. Only since the mid-1800s has linguistic science made sufficient progress finally to clarify the impracticability of speculation along these lines.

Language and thinking

When people have begun to reflect on language, its relation to thinking becomes a central concern. Several cultures have independently viewed the main function of language as the expression of thought. Ancient Indian grammarians speak of the soul apprehending things with the intellect and inspiring the mind with a desire to speak; and in the Greek intellectual tradition Aristotle declared, "Speech is the representation of the experiences of the mind" (*On Interpretation*). Such an attitude passed into Latin theory and thence into medieval doctrine. Medieval grammarians envisaged three stages in the speaking process: things in the world exhibit properties; these properties are understood by the mind of man; and, in the manner in which they have been understood, so they are communicated to others by the resources of language.

Rationalist writers on language in the 17th century gave essentially a similar account: speaking is expressing thoughts by signs invented for the purpose, and words of different classes (the different parts of speech) came into being to correspond to the different aspects of thinking.

Such a view of language continued to be accepted as generally adequate and gave rise to the sort of definition proposed by Henry Sweet and quoted above. The main objection to it is that it either gives so wide an interpretation to thought as virtually to empty the word of any specific content or gives such a narrow interpretation of language as to exclude a great deal of normal usage. A recognition of the part played by speaking and writing in social cooperation in everyday life has highlighted the many and varied functions of language in all cultures, apart from the functions strictly involved in the communication of thought, which had been the main focus of attention for those who approached language from the standpoint of the philosopher. To allow for the full range of language used by speakers, more comprehensive definitions of language have been proposed in recent years on the lines of the second one quoted above (*i.e.*, "A language is a system of arbitrary vocal symbols by means of which a social group cooperates").

A rather different criticism of accepted views on language began to be made in the 18th century, most notably by the French philosopher Étienne Bonnot de Condillac in "Essai sur l'origine des connaissances humaines" (1746; "Essay on the Origin of Human Knowledge") and by Johann Gottfried von Herder. These men were concerned with the origin and development of language in relation to thought in a way that earlier students had not been. The medieval and rationalist views implied that man as a rational, thinking creature invented language to express his thoughts, fitting words to an already developed structure of intellectual competence. With the examination of the actual and the probable historical relations between thinking and speaking, it became more plausible to say that language emerged not as the means of expressing already formulated judgments, questions, and the like but as the means of thought itself, and that man's rationality developed together with the development of his capacity for speaking.

Language as a means of thought itself

The relations between thought and speech are certainly not fully explained today, and it is clear that it is a great oversimplification to define thought as subvocal speech, in the manner of some behaviourists. But it is no less clear that propositions and other alleged logical structures cannot be wholly separated from the language structures said to express them. Even the symbolizations of modern formal logic are ultimately derived from statements made in some natural language and are interpreted in that light.

The intimate connection between language and thought, as opposed to the earlier assumed unilateral dependence of language on thought, opened the way to a recognition of the possibility that different language structures might in part favour or even determine different ways of understanding and thinking about the world. Obviously, all people inhabit a broadly similar world, or they would be unable to translate from one language to another; but, equally obviously, they do not all inhabit a world exactly the same in all particulars, and translation is not merely a matter of substituting different but equivalent labels for the contents of the same inventory. From this stem the notorious difficulties in translation, especially when the systematizations of science, law, morals, social structure, and so on are involved. The extent of the interdependence of language and thought—linguistic relativity, as it has been termed—is still a matter of debate, but the fact of such interdependence can hardly fail to be acknowledged.

THE STRUCTURE AND COMPOSITION OF LANGUAGE

Languages are immensely complicated structures. One soon realizes how complicated any language is when trying to learn it as a second language. If one tries to frame an exhaustive description of all the rules embodied in one's language—the rules by means of which a native speaker is able to produce and to understand an infinite number of correct, well-formed sentences—one can easily appreciate the complexity of the knowledge acquired by a child in mastering his mother tongue. The descriptions of languages written so far are in most cases excellent as far as they go, but they still omit more than they contain of an explicit account of a native speaker's competence in his language, by virtue of which one calls him a speaker of English, French, Swedish, or Swahili. The most recent developments in the study of language have served to reveal just how much more there is to do to bring palpable fact within systematic statement.

A detailed treatment of the science of linguistics is found elsewhere (see LINGUISTICS). Here it is proposed simply to give a brief outline of the way language or languages can be considered and described from different points of view, or at different levels, each contributing something essential and unique to a full understanding of the subject.

Phonetics and phonology. The most obvious aspect of language is speech. Speech is not essential to the definition of an infinitely productive communication system, such as is constituted by a language. But, in fact, speech is the universal material of human language, and the conditions of speaking and hearing have, throughout human history, shaped and determined its development. The study of speech sounds and of the physiology of speaking is called phonetics; this subject is dealt with further below, as well as in the article PHONETICS. Articulatory phonetics relates to the physiology of speech and acoustic phonetics to the physics of sound waves, their transmission and reception.

Speech, the universal material of human language

Phonetics covers much of the ground loosely referred to in language study as pronunciation. But, from a rather different point of view, speech sounds are also studied in phonology. Every language makes use of a very wide range of the articulations and resultant sounds that are available within the human vocal and auditory resources. Each language uses a somewhat different range, and this is partly responsible for the difficulty of learning to speak a foreign language and for speaking it "with an accent." But mere repertoires of sounds are not all that is involved. Far fewer general classes of sounds are distinctive (carry meaning differences) in any language than the number of sounds that are actually phonetically different. The English *t* sounds at the beginning and end of "tot" and in the two places in "stouter" are all different, though these differences are not readily noticed by English speakers; and, rightly, the same letter is used for them all. Similar statements could be made about most or all of the other consonant and vowel sounds in English.

What is distinctive in one language may not be distinctive in another or may be used in a different way; this is an additional difficulty to be overcome in learning to speak and understand a foreign language. In Chinese and in several other languages loosely called tone languages, the pitch, or tone, on which a syllable is said helps to distinguish one word from another: ma in northern Chinese on a level tone means "mother," on a rising tone means "hemp," and on a falling tone means "to curse." In English and in most of the languages of Europe (though not all—Swedish and Norwegian are exceptions) pitch differences do not distinguish one word from another, but form part of the intonation tunes that contribute to the structure and structural meaning of spoken sentences.

Languages differ in the ways in which consonant and vowel sounds can be grouped into syllables in words. English and German tolerate several consonants before and after a single vowel: "strengths" has three consonant sounds before and three after a single vowel sound (*ng* and *th* stand for one sound each). Italian does not have such complex syllables, and in Japanese and Swahili, for example, the ratio of consonant and vowel sounds in syllables and in words is much more even. Speakers of such languages find English words of the sort just mentioned very hard to pronounce, though to an Englishman they are perfectly "natural," "natural" in this context meaning "within the sounds and sound sequences whose mastery is acquired in early childhood as part of one's mother tongue."

All these considerations relating to the use of speech sounds in particular languages fall under the general heading of phonology; phonology is often regarded as one component of language structure.

Relations between words in sentences

Grammar. The other component is grammar. There is more to language than sounds, and words are not to be regarded as merely sequences of syllables. The concept of the word is a grammatical concept; in speech, words are not separated by pauses, but they are recognized as recurrent units that make up sentences. Very generally, grammar is concerned with the relations between words in sentences. Classes of words, or parts of speech, as they are often called, are distinguished because they occupy different places in sentence structure, and in most languages some of them appear in different forms according to their function (English "man," "men"; "walk," "walked"; "I," "me"; and so on). Languages differ in the extent to which word-form variation is used in their grammar; Classical Chinese had almost none, English does not have much, and Latin and Greek had quite a lot. Conversely, English makes much more use of word order in grammar than did Latin or Greek.

Traditionally, grammar has been divided into syntax and morphology, syntax dealing with the relations between words in sentence structure, morphology with the internal grammatical structure of words. The relation between "boy" and "boys" and the relationship (irregular) between "man" and "men" would be part of morphology; the relation of concord between "the boy [or "man"] is here" and "the boys [or "men"] are here" would be part of syntax. It must, however, be emphasized that the distinction between the two is not as clear-cut as this brief illustration might suggest. This is a matter for debate among linguists of different persuasions; some would deny the relevance of distinguishing morphology from syntax at all, referring to grammatical structure as a whole under the term syntax.

Grammar is different from phonology, though the word grammar is often used comprehensively to cover both aspects of language structure. Categories such as plural, past tense, and genitive case are not phonological categories. In spoken language they are, like everything else, expressed in speech sounds, but within a language these may be very different for one and the same category. In English noun plurals, the added *-s* in "cats," the vowel changes in "man, men" and in "goose, geese," and the *-en* in "oxen" are quite different phonologically; so are the past-tense formatives such as *-ed* in "guarded," *-t* in "burnt," vowel change in "take, took," and vowel and consonant change in "bring, brought." In Latin the genitive case can be represented in singular nouns by *-ī*, *-is*, *-ae*, *-ūs*, and *-eī*. The phonological difference does not matter, provided only that the category distinction is somehow expressed.

The same is true of the orthographic representation of grammatical differences, and the examples just given illustrate both cases. This is why the grammar of written language can be dealt with separately. In the case of dead languages, known with certainty only in their written forms, this must necessarily be done; insofar as the somewhat different grammar of their spoken forms made use of sound features not represented in writing (*e.g.*, stress differences), this can, at best, only be inferred or reconstructed.

Meaning expressed by grammatical forms, vocabulary, and intonation

Grammatical forms and grammatical structures are part of the communicative apparatus of languages, and along with vocabulary, or lexicon (the stock of individual words in a language), they serve to express all the meanings required. Spoken language has, in addition, resources such as emphatic stressing and intonation (see below). This is not to say, however, that grammatical categories can be everywhere directly related to specific meanings. Plural and past tense are fairly clear as regards meaning in English, but even here there are difficulties; in "if I knew his address I would tell you," the past-tense form "knew" refers not to the past but to an unfulfilled condition in the present. In some other languages greater problems arise. The gender distinctions of French, German, and Latin are very much part of the grammar of these languages, but only in a small number of words do masculine, feminine, and neuter genders correspond with differences of sex, or with any other category of meaning in relation to the external world (see also GRAMMAR).

Semantics. Language exists to be meaningful; the study of meaning, both in general theoretical terms and in reference to a specific language, is known as semantics. It embraces the meaningful functions of phonological features, such as intonation, and of grammatical structures and the meanings of individual words. Once again, it must be stressed that questions arising from the relations between grammar and meaning and between grammar and phonology are the subjects of continuing controversy today (see also SEMANTICS).

VARIETIES OF LANGUAGE

The word language contains a multiplicity of different designations. Two senses have already been distinguished: language as a universal species-specific capability of mankind, and languages as the various manifestations of that capability, as with English, French, Latin, Swahili, Malay, and so on. There is, of course, no observable universal language over and above the various languages that have been or are spoken or written; but one may choose to concentrate on the general and even the universal features, characteristics, and components of different languages and on the ways in which the same sets of descriptive procedures and explanatory theories may be applied to different languages. In so doing one may refer to language (in general) as one's object of study. This is what is done by linguists, or linguistic scientists, persons devoting themselves to the scientific study of languages (as opposed to the popular sense of polyglots, persons having a command of several different languages).

Intercomprehensibility of dialects

Languages and dialects. It has already been pointed out that no two persons speak exactly alike, and within the area of all but the smallest speech communities (groups of people speaking the same language) there are subdivisions of recognizably different types of language, called dialects, that do not, however, render intercommunication impossible nor markedly difficult. Because intercomprehensibility lies along a scale, the degree required for two or more forms of speech to qualify as dialects of a single language, instead of being regarded as separate languages, is not easy to quantify or to lay down in advance, and the actual cutoff point must in the last resort be arbitrary. In practice, however, the terms dialect and language can be used with reasonable agreement. One speaks of different dialects of English (Southern British English, Northern British English, Scottish English, Midwest American English, New England American English, Australian English, and so on, with, of course, many more delicately distinguished subdialects within these very general categories), but no one would speak of Welsh and English or of Irish and English as dialects of a single language, although they are spoken within the same areas and often by people living in the same villages as each other.

Certain problems arise over the use of the term dialect. The criterion of intercomprehensibility may link a chain of adjacent dialects together, such that at either end of the chain no intercomprehensibility is found. Thus, in a territorial sequence A, B, C, D, E, F, G . . . , speakers of A and B, B and C, C and D, and so on may be able to understand each other and, to a lesser extent, speakers of A and C, B and D, and so on, but a speaker of A and a speaker of F or a speaker of B and a speaker of G may find each other virtually unintelligible. Some such situation is said to obtain in the chain of spoken dialects extending across the French–Italian frontier, between the extremes of Parisian French and Roman Italian. In cases such as this the decision to allot one set to one language and the other to another may have to be taken on different grounds, such as political divisions.

Dialects and political boundaries

Because the frontiers of the modern nation-states of Europe tend to correspond more or less to language areas, with certain notable exceptions, such as Switzerland and Belgium, there is a general tendency to group European dialects within political frontiers as dialects of the national language of the country. This practice is reinforced under modern social conditions, as children of most countries in Europe are taught literacy in the "standard language," or standard dialect, of the country they live in. Swedish, Norwegian, and Danish are, in varying degrees, intercomprehensible for many speakers of any one of the three, and it is quite possible that without the political division of Scandinavia the existing dialects of each would be regarded as dialects of a single language or at any rate that the grouping of them within separate languages would be different.

A converse of the situation just referred to is the peculiar use of the term dialect in relation to Chinese, whereby all varieties of Chinese are loosely called dialects. In fact, several major divisions of Chinese speech—*e.g.*, Pekingese (Mandarin) in the north and Cantonese in the south—are mutually unintelligible as spoken languages. They do, however, employ the same writing system (the so-called Chinese characters), and in general the same written texts can be read and understood by speakers of either, though they would pronounce them differently. By the usual criterion of mutual intelligibility, there are several Chinese languages, each in turn subdivided into a number of dialects.

Yet a third use or, rather, misuse of the term would separate "the language" from "the dialects," as if a particular form of a language was in some way more representative of the language as a whole. Thus, Classical Arabic is sometimes contrasted with the spoken Arabic "dialects" of the contemporary Arabic-speaking world, and "standard English," at least in some parts of Great Britain, is contrasted with "the English dialects."

This leads to a further important observation about variations within a language. Speakers often differ in their dialect not only regionally but also socially, though these divisions are less easily represented graphically on the dialect maps of linguistic geographers. Sometimes, socially preferred dialects are themselves regional; for example, Parisian French, as the form of the language used in the capital, is regarded as standard. In most cases, however, nonregional differences are also involved: standard French is the French of educated Parisians, and standard has been loosely defined in this context as the speech of educated inhabitants of the capital city.

Prestige dialects and literary dialects

In a socially stratified community, the speech habits, like the other habits, of a group that enjoys general respect, political and social prestige, and economic power (or, at any rate, is thought to do so) tend to be preferred as models to imitate in the interests of social advancement. When literacy is the privilege of such a group, as was the case in most of Europe before the middle of the 19th century, such a dialect comes to be regarded as the language of education and of the educated and becomes the variety of the language directly represented in the writing system. Such dialects (for that is what they are) often correspond to the type of language in which national literatures are written. In English literature, though recognized authors of prose and poetry may speak regional varieties of the language (as the poet Alfred, Lord Tennyson is reported to have spoken Lincolnshire English), there are only a few pieces specifically written to be read in a nonstandard dialect. In Britain the poems of William Barnes of Dorset, the few Lincolnshire poems of Tennyson (*e.g.*, "Northern Farmer"), and above all the Scottish English poetry of Robert Burns are notable examples. In American literature one may cite the Uncle Remus tales of Joel Chandler Harris. The social prestige enjoyed by some Scottish dialects as compared with the nonstandard dialects of English spoken in England and Wales may have derived in part from the educational and literary reputation of Edinburgh, especially in the 18th century, but it was probably the eminence of Burns's Scottish English poetry that played the major role.

Standard British English is historically derived from a variety of southern English, the language of the Tudor court and of court circles. Though regional in origin and still having the largest concentration of speakers in London and the southeast of England, it is less locally rooted than other dialects, in part as the result of the greater mobility of well-educated and economically successful people. It is the type of English that foreign speakers are taught and are expected to aim at. The same holds true in large measure for educated Parisian French, which represents the French language as taught in other countries.

Influence of Dante on Italian language

In some languages the importance of literature or of a particular author in the development and emergence of the recognized standard language (*i.e.*, the standard dialect) has been considerable. Particularly in linguistic areas in which political unity came late—and, as a consequence, a court or capital city influence was not a strong factor—a widely read and respected body of literature has been found to have promoted one dialect above others as the representative of the language for literary and didactic purposes. Martin Luther's translation of the Bible into German in 1534 is regarded as having been a main influence in establishing Modern High German as the literary standard for the unified Germany of a later century and as the standard for teaching abroad. In Italy, like Germany a country that achieved political unity only in the 19th century, Dante's influence in the formation of a recognized Italian literary language, based on his native Florentine Tuscan, was overwhelming. This result, indeed, was deliberate; in his essay "De vulgari eloquentia" ("On the Vernacular Tongue"), Dante pleaded for the cultivation of some one dialect to represent Italian as a whole and to supply a focus of loyalty comparable to that exercised by the court in other countries.

Within an already recognized standard language and as part of its development, the effects of major works of literature may be very extensive. The number of expressions regularly used in English today that have their origin in Shakespeare or in the King James Bible is far greater than is often realized, and many such expressions are used without further reference to their Shakespearean or biblical source: "There's the rub" (*Hamlet*, Act III, scene 1), "A rose by any other name" (*Romeo and* Juliet, Act II, scene 2), "The time is out of joint" (Hamlet, Act I, scene 5), "Screw your courage to the sticking-place" (*Macbeth*, Act I, scene 7); "Jacob's ladder" (Gen. 28:12), "Noah's Ark" (Gen. 6:14), "A land flowing with milk and honey" (Ex. 3:8), "The shadow of death (Psalms 23:4), "The patience of Job" (James 5:11), and so on. Other authors have contributed to the English language in similar ways, but none are so significant in this respect as Shakespeare and the translators of the King James Bible.

It must be emphasized that, considered simply as modes of communication, nonstandard dialects are neither less "correct" nor more "correct" than standard dialects. There may be social reasons for preferring the use of standard dialects, but these do not involve inherent merits or demerits of a linguistic sort. Dialects differ at all levels of structure—in phonetics, in grammar, and in vocabulary—but there are no grounds for saying that one dialect is more orderly, systematic, or expressive than another. Each is capable of meeting the requirements that its speakers need to impose on it. Nor is it true, as is sometimes maintained, that nonstandard dialects are later degenerations of the original "purer" language. In British English, in fact, several nonstandard dialects preserve older features now lost in the standard; for example, a postvocalic *r* sound exists in the West-Country pronunciation of words such as "farm" and "cart," and a distinct 2nd-person singular pronoun is used in parts of the northern English counties, taking various phonetic forms and corresponding to "thou" and "thee" of earlier written English (see also DIALECTS).

Specialized language forms: slang, argot, and others. The above-mentioned social and regional dialect variations within languages are more or less natural; that is, they arise largely from the conditions of language use and language transmission: without deliberate intent on the part of speakers. There are, however, some deliberately created variations within languages. The socially unifying force of a single language or dialect and the divisive force of language and dialect differences have always been apparent. Language was a main inspiration in 19th-century European nationalism and is one of the factors in nationalist movements in the world today. Not surprisingly, groups within a society that set a special value on group identity and group consciousness deliberately develop and foster private dialects that are known to insiders but are mysterious and baffling to those not belonging to the group. The various underworld jargons and special trade argots can be cited, such as Loucherbème in Paris (from *boucher* "butcher," by systematic deformation), the private slang vocabulary of many schools and colleges, and the systematic and regular alteration of certain words in some private languages of schoolboys and students—American "pig Latin" and the former "Oxford and British public-school "-agger" talk ("nogger," meaning agnostic; "wagger pagger bagger," meaning wastepaper basket), developed from universally recognized forms such as "rugger," Rugby football. From all over the world the transient but zealously cherished speech styles of teen-agers can be noted, whereby, along with particular fashions in clothes, they maintain and assert their identity over against the childhood they have left and the adult world they do not yet recognize (see also SLANG).

Group identity and private dialects

Sometimes, as in the case of criminal argots, part of the function of special languages is deliberately to mislead and obstruct the rest of society and the authorities in particular; they may even become wholly impenetrable to outsiders. But this is not the sole or main purpose of most specialized varieties of language. Professions whose members value their standing in society and are eager to render their services to the public foster their own vocabulary and usage, partly to enhance the dignity of their profession and the skills they represent but partly also to increase their efficiency. An example of this is the language of the law and of lawyers.

The cultivation and maintenance of specialized types of language by certain professions should not be regarded as trivially or superficially motivated. In general usage, languages are necessarily imprecise, or they would lack the flexibility and infinite extensibility demanded of them. But for certain purposes in restricted situations much greater precision is required, and part of the function of the particular style and vocabulary of legal language is the avoidance, so far as may be possible, of all ambiguity and the explicit statement of all necessary distinctions. This is why legal texts, when read out of their context, seem so absurdly pedantic and are an easy target for ridicule. Similar provision for detail and clarity characterizes the specialist jargons of medicine and of the sciences in general and also of philosophy. Indeed, one might regard the formulas of modern symbolic logic as the result of a consciously developed and specialized written language for making precise the relations of implication and inference between statements that, when couched in everyday language, are inexact and open to misinterpretation. Some would go as far as to say that traditional metaphysics is no more than the result of misunderstanding everyday discourse and that the main purpose of philosophy is to resolve the puzzles that arise from such misunderstandings.

Stereotyped language of games

The use of specialized types of language in fostering unity is also evidenced in the stereotyped forms of vocabulary employed in the playing of certain games. Tennis scores use the sequence "love, 15, 30, 40, and game"; cricketers verbally appeal to the umpire when a batsman may be out by calling "How's that?" and the ways of being out are designated by stereotypes, "run out," "leg before wicket," "stumped," and so forth. The esoteric language of horse racing and its associated wagering of money is well-known, though not readily understood by outsiders.

The ancient but persistent recognition of the power of language is apparent in the respect for correctness in the use of language in any sphere of life having supernatural connections. Those credited with such connections employ special formulas and rigidly prescribed modes of diction; examples of the language of magic and of magicians are widespread, ranging from the usages of shamans and witch doctors to the ritual "abracadabra" of the mock magic displayed by conjurors at children's parties.

The efficacy of religious worship and of prayers is frequently associated with the strict maintenance of correct forms of language, taught by priests to their successors, lest the ritual become invalid. In ancient India the preservation in all its supposed purity of the language used in the performance of certain religious rituals (Sanskrit) gave rise to one of the world's most important schools of linguistics and phonetics. In the Christian churches one can observe the value placed by Roman Catholics on the Latin of the mass and by Church of England and Episcopalian churchmen on the formal English of the Authorized Version of the Bible and of *The* Book of *Common* Prayer, despite recent attempts at replacing these ritual forms of language by forms taken from modern spoken vernaculars.

Pidgins and creoles. Some specialized languages were developed to keep the outsider at bay. In other circumstances, languages have been deliberately created to facilitate communication with outsiders. This happens when people speaking two different languages have to work together, usually in some form of trade relation or administrative routine. In such situations the so-called pidgins arise, more or less purposively made up of vocabulary items from each language, with mutual abandonment of grammatical complexities that would cause confusion to either party. Pidgins have been particularly associated with areas settled by European traders; examples have been Chinook Jargon, a lingua franca based on an American Indian language and English and formerly used in Washington and Oregon, and Beach-la-mar, an English-based pidgin of parts of the South Seas.

Sometimes, as the result of relatively permanent settlement and the intermixture of two speech communities, a pidgin becomes the first language, or mother tongue, of later generations, ultimately displacing both the original languages. First languages arising in this way from artificially created pidgins are called creoles. Notable among creoles is the language of Haiti, Haitian Creole, built up from the French of the settlers and the African language of the former slaves; it shows lexical and grammatical features of both sources.

Creolization of a pidgin language

Creoles differ from pidgins in that, as first languages, they are subject to the natural processes of change like any other language (see below *Linguistic* change); and, despite the deliberately simplified form of the original pidgin, in the course of generations creoles develop their own complexities. The reason is plain to see. The restricted uses to which pidgins were first put and for which they were devised did not require any great flexibility. Once such a language becomes the first or only language of many people, it must perforce acquire the resources (*i.e.*, the complexity) to respond adequately to all the requirements of a natural language (see also PIDGIN).

Nonverbal language. Speech and writing are, indeed, the fundamental faculties and activities referred to by the term language. There are, however, areas of human behaviour for which the term is used in a peripheral and derivative sense.

When individuals speak, they do not normally confine themselves to the mere emission of speech sounds. Because speaking usually involves at least two parties in sight of each other, a great deal of meaning is conveyed by facial expression, tone of voice, and movements and postures of the whole body but especially of the hands; these are collectively known as gestures. The contribution of bodily gestures to the total meaning of a conversation is in part culturally determined and differs in different communities. Just how important these visual symbols are may be seen when one considers how much less effective telephone conversation is as compared with conversation face to face; the experience of involuntarily smiling at the telephone receiver and immediately realizing that this will convey nothing to the hearer at the other end of the line is common. Again, the part played in emotional contact and in the expression of feelings by facial expressions and tone of voice, quite independently of the words used, has been shown in tests in which subjects have been asked to react to sentences that appear as friendly and inviting when read but are spoken angrily and, conversely, to sentences that appear as hostile but are spoken with friendly facial expressions. It is found that it is the visual accompaniments and tone of voice that elicit the main emotional response. A good deal of what goes under the heading of sarcasm exploits these contrasts.

Expression by vocal, non-linguistic utterances

Just as there are paralinguistic activities such as facial expressions and bodily gestures integrated with and assisting the communicative function of spoken language, so there are vocally produced noises that cannot be regarded as part of any language, though they help in communication and in the expression of feeling. These include laughter, shouts and screams of joy, fear, pain, and so forth, and conventional expressions of disgust, triumph, and so on, traditionally spelled "ugh!," "ha ha!," etc., in English. Such nonlexical ejaculations differ in important respects from language: they are much more similar in form and meaning throughout mankind as a whole, in contrast to the great diversity of languages; they are far less arbitrary than most of the lexical components of language; and they are much nearer the cries of animals produced under similar circumstances and, as far as is known, serve similar expressive and communicative purposes. As noted above, some people have tried to trace the origin of language itself to them.

A language is a symbol system. It may be regarded, because of its infinite flexibility and productivity, as the symbol system ***par excellence.*** But there are other symbol systems recognized and institutionalized in the different cultures of mankind. Examples of these exist on maps and blueprints and in the conventions of representational art (*e.g.*, the golden halos around the heads of saints in religious paintings). Other symbol systems are musical notation and dance notation, wherein graphic symbols designate musical pitches and other features of musical performance and the movements of formalized dances. More loosely, because music itself can convey and arouse emotions and certain musical forms and structures are often associated with certain types of feeling, one frequently reads of the "language of music" or even of "the grammar of music." The terms language and grammar are here being used metaphorically, however, if only because no symbol system other than language has the same potential of infinite productivity, extension, and precision.

Languages are used by human beings to talk and write to other human beings. Derivatively, bits of languages may be used by humans to control machinery, as when different buttons and switches are marked with words or phrases designating their functions. A recent and specialized development of man–machine language is seen in the various "computer languages" now in use; *e.g.*, Cobol, Algol, and Fortran. These are referred to as programming languages, and they provide the means whereby sets of "instructions" and data of various kinds can be supplied to computers in forms acceptable to these machines. Various types of such languages are in use for different purposes. The development and use of computer languages must now be regarded as a distinct science in itself (for more information, see COMPUTERS).

PHYSIOLOGICAL AND PHYSICAL BASIS OF SPEECH

Primacy of speech in language

For an adequate understanding of human language it is necessary to keep in mind the absolute primacy of speech. In societies in which literacy is all but universal and language teaching at school begins with reading and writing in the mother tongue, one is apt to think of language as a writing system that may be pronounced. In point of fact, language is a system of spoken communication that may be represented in various ways in writing.

Man has almost certainly been in some sense a speaking animal from early in the emergence of Homo *sapiens* as a recognizably distinct species. The earliest known systems of writing go back perhaps some 5,000 years. This means that for many hundreds of thousands of years human languages were transmitted from generation to generation and were developed entirely as spoken means of communication. Moreover, in the world as it is today, literacy is still the privilege of a minority in many language communities. Even when literacy is widespread, some languages remain unwritten if they are not economically or culturally important enough to justify creating an alphabet for them and teaching them; then literacy is acquired in a second language learned at school. Such is the case with many speakers of South American Indian languages, who become literate in Spanish or Portuguese. A similar situation prevails in some parts of Africa, where reading and writing are taught in languages spoken over relatively wide areas. In all communities, speaking is learned by children before writing, and all people act as speakers and hearers much more than as writers and readers.

It is, moreover, a total fallacy to suppose that the languages of illiterate or so-called primitive peoples are less structured, less rich in vocabulary, and less efficient than the languages of literate civilizations. The lexical content of languages varies, of course, according to the culture and the needs of their speakers, but observation bears out the statement of the U.S. anthropological linguist Edward Sapir made in 1921: "When it comes to linguistic form, Plato walks with the Macedonian swineherd, Confucius with the head-hunting savage of Assam."

All this means that the structure and composition of language and of all languages have been conditioned by the requirements of speech, not those of writing. Languages are what they are by virtue of their spoken, not their written, manifestations. The study of language must be based on a knowledge of the physiological and physical nature of speaking and hearing. The details of these aspects of language are covered in other articles, especially PHONETICS and SPEECH, PHYSIOLOGY OF; only the essentials are given here.

Speech production. Speaking is in essence the by-product of a necessary bodily process, the expulsion from the lungs of air charged with carbon dioxide after it has fulfilled its function in respiration. Most of the time one breathes out silently; but it is possible, by adopting various postures and by making various movements within the vocal tract, to interfere with the egressive airstream so as to generate noises of different sorts. This is what speech is made of.

Vocal tract and speech organs

The vocal tract comprises the passage from the trachea (windpipe) to the orifices of the mouth and nose; all the organs used in speaking lie in this passage. Conventionally, these are called the organs of speech, and the use in several languages of the same word for the tongue as a part of the body and for language shows the awareness people have of the role played by this part of the mouth in speaking. But few if any of the major organs of speech are exclusively or even mainly concerned with speaking. The lips, the tongue, and the teeth all have essential functions in man's bodily economy, quite apart from talking; to think, for example, of the tongue as an organ of speech in the same way that the stomach is regarded as the organ of digestion is fallacious. Speaking is a function superimposed on these organs, and the material of speech is a waste product, spent air, exploited to produce perhaps the most wonderful by-product ever created.

Relatively few types of speech sounds are produced by other sources of air movement; the clicks in some South African languages are examples, and so is the fringe linguistic sound used in English to express disapproval, conventionally spelled "tut." In all languages, however, the great majority of speech sounds have their origin in air expelled through the contraction of the lungs. Air forced through a narrow passage or momentarily blocked and then released creates noise, and characteristic components of speech sounds are types of noise produced by blockage or narrowing of the passage at different places.

If the vocal cords (really more like two curtains) are held taut as the air passes through them, the resultant regular vibrations in the larynx produce what is technically called voice, or voicing. These vibrations can be readily observed by contrasting the sounds of f and v or of *s* and *z* as usually pronounced; "five" and "size" each begin and end with voiceless and voiced sounds, respectively, which are otherwise formed alike, with the tongue and the lips in the same position. Most consonant sounds and all vowel sounds in English and in the majority of languages are voiced, and voice, in this sense, is the basis of singing and of the rise and fall in speaking that is called intonation, as well as of the tone distinctions in tone languages. The vocal cords may be drawn together more or less tightly, and the vibrations will be correspondingly more or less frequent. A rise in frequency causes a rise in perceived vocal pitch. Speech in which voice is completely excluded is called whispering.

Formation of vowels

Above the larynx, places of articulation in frequent use are between the back of the tongue and the soft palate, between the blade of the tongue and the ridge just behind the upper front teeth, and between the lips. Stoppage and release (technically, plosion) at these places form the k (often written as *c*, "cat"), *t*, and *p* sounds in English and, when voicing is also present, the g (as in "gay"), d, and b sounds. Obstruction at these and other places sufficient to cause noise gives rise to what are called fricative sounds; in English these include the normal pronunciations of *s*, z, f, and v and the *th* sounds in "thin" and "then." A vowel is characterized as the product of the shape of the entire tract between the lips and larynx, without local obstruction though usually with voicing from the vocal cords. It is contrasted with a consonant, though the exact division between these two categories of speech sound is not always easy to draw. Different shaping of the tract produces the different vowel sounds of languages.

The soft palate may be raised or lowered. It is lowered in normal breathing and allows air to pass in and out through the nose. In the utterance of most speech sounds it is raised, so that air passing through the mouth alone forms the sound; if it is lowered, air passes additionally or alternately through the nose, thus producing the nasal sounds. All but a very few languages have nasal consonants (the English sounds m, n, and *ng* as in "sing") and some, such as French, have nasalized vowels as well. A few speakers regularly allow air to pass through their nasal passages all the time while they are speaking; such persons are said to "speak through the nose."

All articulatory movements, including the initial expulsion of air from the lungs, may be made with greater or less vigour, giving rise to louder or softer speech as a whole or to greater loudness on one part of what is said, for emphasis or contrast.

Every different configuration and movement of the vocal tract creates corresponding differences in the air vibrations that comprise and transmit sound. These vibrations, like those of all noises, extend outward in all directions from the source, gradually decreasing to zero or to below the threshold of audibility. They are called sound waves, and they consist of rapid rises and falls in air pressure. The speed at which pressure rises and falls is the frequency. Speech sounds involve complex waves containing vibrations at a number of different frequencies, the lowest being the voice pitch of singing and intonation, produced by the vocal cords in voiced sounds.

The eardrum responds to the different frequencies of speech, provided they retain enough energy, or amplitude (*i.e.*, are still audible). The perceptibly different speech sounds that comprise the spoken utterances of any language are the result of the different impacts on one's ears made by the different complexes of frequencies in the waves produced by different articulatory processes. As the result of careful and detailed observation of the movements of the vocal organs in speaking, aided by various instruments to supplement the naked eye, a great deal is now known about the processes of articulation. In recent years an array of other instruments has provided much information about the nature of the sound waves produced by articulation. Speech sounds may be and have been described and classified both from an articulatory viewpoint, in terms of how they are produced, and from an acoustic viewpoint, by reference to the resulting sound waves (their frequencies, amplitudes, and so forth). Articulatory descriptions are more readily understood, being couched in terms such as nasal, bilabial, lip-rounded, and so on. Acoustic terminology requires a knowledge of the technicalities involved for its comprehension. In that almost every person is a speaker and a hearer, it is clear that both sorts of description and classification are important, and each has its particular value for certain parts of the scientific study of language.

Articulatory and acoustic descriptions of speech

Language acquisition. As far as the production of speech sounds is concerned, all human beings are physiologically alike. People have differently shaped faces, as much as they differ in other aspects of bodily build, but it has been shown time and again that a child learns to speak the language of those who bring him up from infancy. In most cases these are his biological parents, especially his mother, but one's first language is acquired from environment and learning, not from physiological inheritance. Adopted infants, whatever their race or physical type and whatever the language of their actual parents, acquire the language of the adoptive parents who raise them just as if they had been their own children.

Different shapes of lips, throat, and other parts of the vocal tract have an effect on the voice quality of people's speech, and this is part of the individuality of each person's voice referred to above. Physiological differences, including size of throat and larynx, both overall and in relation to the rest of the vocal tract, are largely responsible for the different pitch ranges characteristic of men's, women's, and children's speech. But these individual differences do not affect one's ability or aptitude to acquire and speak any particular language.

Speech is species-specific to mankind. Physiologically, animal communications systems are of all sorts. The type that is in some ways functionally the nearest to human language, the system of bee dances, is entirely remote from human speech and does not make use of sound at all. The animal sounds superficially most resembling speech, the imitative cries of parrots and some other birds, are produced by very different physiological means: birds have no teeth or lips but vocalize by means of the syrinx, a modification of the windpipe above the lungs. Almost all mammals and many other animal species make vocal noises and evince feelings thereby and keep in contact with each other through a rudimentary sort of communication, but those members of the animal kingdom nearest to man genetically, the primates, have proved highly resistant to the acquisition of speech.

Advantages of speech as a means of communication

Man's development of speech has been linked to his upright posture and the freeing of his vocal cords from the frequent need to "hold one's breath in using the arms for locomotion. Certainly, speaking and hearing—as man's primary means of communication—have a number of striking advantages: speech does not depend on daylight or on mutual visibility, it can operate in all directions over reasonably wide areas, and it can be adjusted in loudness to cope with distance. As is seen in crowded rooms, it is possible to pick out some one person's voice despite a good deal of other noise and in the midst of other voices speaking the same language. In addition, the physical energy required in speaking is extremely small in relation to the immense power wielded by speech in man's life, and scarcely any other activity, such as running, walking, or tool using, interferes seriously with the process (even eating and drinking can be carried on simultaneously with talking, and the reluctance one may feel for "speaking with one's mouth full" is more a matter of cultural convention and good manners than of physiological difficulty).

The characteristics just outlined pertain to all of the world's languages, including those of the allegedly primitive peoples. What is more a matter of controversy is the extent to which man's biological inheritance is involved in language acquisition and language use. The fact that language is species-specific to man argues an essential cerebral or mental component, and in the last century certain aspects of speech control and use were located in a particular part of the human brain (Broca's convolution).

No one inherits the ability to speak a particular language, but every normal human child is born with the ability and the drive to acquire a language, namely, the one to which he is predominantly exposed from infancy. He brings to this task a very considerable innate ability, because his exposure is largely to a random selection of utterances (apart from any attempts at systematic teaching that he may encounter) occuring within his earshot or addressed to him. Yet by late childhood he has, through progressive stages, acquired the central or basic vocabulary of the language, together with its phonological and grammatical structure. Observation shows that this is substantially the same situation the world over, among literate and illiterate communities, and that much the same number of years of childhood is taken up by the process. Thus, it would appear that, objectively considered, all languages are roughly equal in complexity and in difficulty of mastery.

Innate human capacity for language acquisition

It is, therefore, clear that all normal humans bring into the world an innate faculty for language acquisition, language use, and grammar construction. The last phrase refers to the internalization of the rules of the grammar of one's first language from a more or less random exposure to utterances in it. The human child is very soon able to construct new, grammatically acceptable sentences from material he has already heard; unlike the parrot in human society, he is not limited to the mere repetition of whole utterances.

What is currently under debate is the part played by this innate ability and its exact nature. Until the 1950s scholars considered language acquisition to be carried out largely by analogical creation from observed patterns of sentences occurring in utterances heard and understood by the child. Such a view, much favoured by persons inclined to a behaviourist interpretation of human learning processes (*e.g.*, the U.S. linguist Leonard Bloomfield), stressed the very evident differences between the structures of different languages, particularly on the surface. Since the late 1950s, a number of linguists have been placing much more emphasis on the inherent grammar-building disposition and competence of the human brain, which is activated by exposure to utterances in a language, especially during childhood, in such a way that it fits the utterances into predetermined general categories and structures. Such linguists, inheritors of the 17th- and 18th-century interest in "universal grammar," put their stress on the underlying similarities of all languages, more especially in the deeper areas of grammatical analysis (for the distinction between deep structure and surface structure in grammar, see the article LINGUISTICS).

MEANING, VOCABULARY, AND STYLE IN LANGUAGE

The whole object and purpose of language is to be meaningful. Languages have developed and are constituted in their present forms in order to meet the needs of communication in all its aspects.

It is because the needs of human communication are so various and so multifarious that the study of meaning is probably the most difficult and baffling part of the serious study of language. Traditionally, language has been defined, as in the definition quoted above, as the expression of thought, but, as was seen, this involves far too narrow an interpretation of language or far too wide a view of thought to be serviceable. The expression of thought is just one among the many functions performed by language in certain contexts.

Distinguishing meaning by word order or grammatical form

Structural and lexical meaning. First, one must recognize that the meaning of any sentence comprises two parts, the meanings of the words it contains and the structural or grammatical meaning carried by the sentence itself. In English "the dog chased the cat" and "the boy chased the cat" differ in meaning because "dog" and "boy" are different words with different word meanings; the same applies to equivalent sentences in other languages. The two sentences "the dog chased the cat" and "the cat chased the dog," though containing exactly the same words, are different in meaning because the different word orders distinguish what are conventionally called subject and object. In Latin the two corresponding sentences would be distinguished not by word order, which is grammatically indifferent and largely a matter of style, but by different shapes in the lexical equivalents of "dog" and "cat." In Japanese the grammatical distinction of subject and object, normally marked by the word order subject–object–verb, can be reinforced by a subject particle after the first word and an object particle after the second.

The formal resources of any language for making distinctions in the structural meanings of sentences are limited by two things: the linear (time) dimension of speaking and the limited memory span of the human brain. Writing copies the time stream of speech with the linear flow of scripts. Diagrams and pictures employ two dimensions, and models employ three; but writing is partially relieved of memory-span restrictions by the permanence of visual marks. Because written texts are almost entirely divorced from oral pronunciation, sentence length and sentence complexity can be carried to extremes, as may be observed in some legal and legislative documents that are virtually unintelligible if read aloud.

Within these linear restrictions, distinctions corresponding to the main uses of language can be made. All languages can employ different sentence structures to state facts (declarative), to ask questions (interrogative), and to enjoin or forbid some course of action (imperative). More delicate means exist to soften or modify these basic distinctions: *e.g.*, "It's cold today, isn't it?"; "Isn't it still raining?"; "Shut the door, would you mind"; "Don't be long, will you?" Languages use their resources differently for these purposes, but, generally speaking, each seems to be equally flexible structurally. The principal resources are word order, word form, syntactic structure, and, in speech, pitch and stress placement. In English, as an example, a word or phrase can be highlighted by being placed first in the sentence when it would not normally occur there: compare "he can't bear loud noises" with "loud noises he can't bear" or "loud noises, he can't bear them." The object noun or noun phrase can also be put first by making the sentence passive; this allows the original subject to be omitted if one does not know or does not want to refer to an agent: "the town was destroyed (by the revolutionaries)." Within and together with all these possibilities, almost any word can be made contrastively prominent by being stressed (spoken more loudly) or by being uttered on a higher pitch, and very often these two are combined: "I asked you for red roses (not yellow)"; "I meant it for you (not her)"; "I know nothing about it (someone else may)." Prominence is especially associated with intonation, itself an important carrier of structural meaning in speech. One may state facts, ask questions, and give instructions with a variety of intonations indicating, along with visible gestures, different attitudes, feelings, and social and personal relations between speaker and hearer.

The possibilities of expressing structural meanings are a most important part of any language. They are acquired along with the rest of one's first language in childhood and are learned more slowly and with more difficulty in mastering a second or later language. Scholars are still only at the beginning of a full formal analysis of these resources, as far as most languages are concerned, and are still further from an adequate understanding of all the semantic functions performed by means of these resources.

Meanings of words

The other component of sentence meaning is word meaning, the individual meanings of the words in a sentence, as lexical items. The concept of word meaning is a familiar one. Dictionaries list words and in one way or another state their meanings. It is regarded as a sensible question to ask of any word in a language, "What does it mean?" This question, like many others about language, is easier to ask than to answer.

It is through lexical resources that languages maintain the flexibility their open-ended commitments demand. Every language has a vocabulary of many thousands of words, though not all are in active use, and some are known only to relatively few speakers. Perhaps the commonest delusion in considering vocabularies is the assumption that the words of different languages, or at least their nouns, verbs, and adjectives, label the same inventory of things, processes, and qualities in the world but unfortunately label them with different labels from language to language. If this were so, translation would be easier than it is; but the fact that translation, though often difficult, is possible indicates that people are talking about similar worlds of experience in their various languages.

Languages in part create the world in which men live. Of course, many words do name existing bits and pieces of earth and heaven: "stone," "tree," "dog," "woman," "star," "cloud," and so on. Others, however, do not so much pick out what is there as classify it and organize one's relations with it and with each other with regard to it. A range of living creatures are mammals or are vertebrates, because people classify them in these ways, among others, by applying selected criteria and so determining the denotation of the words mammal and vertebrate. Plants are vegetables or weeds according as groups of people classify them, and different plants are included and excluded by such classifications in different languages and different cultures.

Time and its associated vocabulary ("year." "month," "day," "hour," "minute," "yesterday," "tomorrow," and so on) do not refer to discrete sections of reality but enable people to impose some sort of order, in agreement with others, on the processes of change observed in the world. Personal pronouns pick out the persons speaking, spoken to, and spoken about; but some languages make different distinctions in their pronouns from those made in English. For example, in Malay, *kita*, which means "we," including the person addressed, is distinct from *kami*, a form for "we" that includes the speaker and a third person or persons but excludes the person addressed. In Japanese and in several other languages, a variety of words denoting the 1st and 2nd persons indicate additionally the observed or intended social relationship of those involved.

Other word meanings are even more language and culture bound, and in consequence harder to translate. "Right" and "wrong," "theft," "inheritance," "property," "debt," "sin," and "crime" (as different sorts of wrongdoing) are just a few of the words regulating one's conduct and relations with one's fellows in a particular culture. Translation becomes progressively harder as one moves to languages of more remote cultures, and it has been said that it requires "a unification of cultural context." Insofar as a person's understanding of the universe and of the relations between himself and other people is closely linked with the language he speaks, it must be assumed, and the evidence confirms this assumption, that the child progressively acquires such understanding along with his language.

Onomatopoeic words

The great majority of word shapes bear no direct relation to their lexical meanings. If they did, languages would be more alike. What are called onomatopoeic words are rather similar in shape through different languages: French *coucou*, English "cuckoo," and German *Kuckuck* directly mimic the call of the bird. English "dingdong" and German *bim-bam* share several sound features in common that partially resemble the clanging of bells. More abstractly, some direct "sound symbolism" has been seen between certain sound types and visual or tactile shapes. Most people agree that the made-up word "oomboolu" would better designate a round, bulbous object than a spiky one. In addition, the appropriateness of the vowel sound represented by *ee* in English "wee" and *i* in French *petit* "small" and Italian *piccolo* "small" for expressing things of small size has been traced in several languages.

Vocabulary. All this, however, is a very small part of the vocabulary of any language. For by far the largest number of words in a language there is no direct association between sound and meaning. English "horse," German Pferd, French *cheval,* Latin *equus,* and Greek *hippos* are all unrelated to the animal so named, except that these words are so used in the languages concerned. This is what is meant by the term arbitrary in the second definition of language quoted at the beginning of this article. Vocabulary has to be largely arbitrary, because the greater part of the world and of man's experience is not directly associated with any kind of noise, and it is a contingent, though universal, fact of history and biology that sound and not the material of some other sense is the basis of human language.

The relations between sentence structure and structural meanings are also largely arbitrary and tacitly conventional. Though loudness and stress for emphasis and certain linguistic indications of anger, excitement, and the like are more closely akin to nonlinguistic ejaculations and are somewhat similar across language divisions, actual intonations and features such as word order, word inflection, and grammatical particles, used in maintaining distinctions in structural meaning, differ markedly in different languages.

Not only are word meanings somewhat different in different languages; they are not fixed for all time in any one language. Semantic changes take place all along (see below), and at any moment the semantic area covered by a word is indeterminately bordered and differs from context to context. This is a further aspect and condition of the inherent and necessary flexibility of language. A person can be as precise or as imprecise as he needs or wishes lo be. In general, words are fairly imprecise; yet for particular purposes their meanings can be tightened up, usually by bringing in more words or phrases to divide up a given field in more detail. "Good" contrasts generally with "bad"; but one can, for example, grade students as "first-class," "excellent," "very good," "good," "fair," "poor," and "failed" (or "bad"). In this case, "good" now covers a restricted and relatively low place in a field of associated terms. Colour words get their meanings from their mutual contrasts. The field of visually discriminable hues is very large and goes far beyond the resources of any vocabulary as it is normally used. Children learn the central or basic colour words of their language fairly early and at the same time; such terms as red and green are normally learned before subdivisions such as crimson and scarlet or chartreuse. It is well-known that languages make their primary divisions of the spectrum of colours in different places; Japanese ***aoi*** covers many of the hues referred to in English by "green" and "blue," while "blue" covers much of the range of the two Russian words *goluboy* and *siny.* While the actual colour vocabularies of languages differ, however, recent research by Brent Berlin and Paul Kay has tried to show that "there exist universally for humans eleven basic perceptual color categories" that serve as reference points for the colour words of a language, whatever number may be regularly employed at any time.

Precision and imprecision of words

Ordinarily, considerable areas of indeterminate designation in colour vocabulary and in other fields are tolerated; between "red" and "purple" and between "purple" and "blue" there are hues that one would hesitate to assign firmly to one or the other and on which there would be considerable personal disagreement. When greater precision than normal is required—as, for example, in listing paint or textile colours—all kinds of additional terms can be brought into service to supplement the usual vocabulary: "off-white," "light cream," "lemon," "blush pink," and so on.

The vocabulary of kinship terms varies from language to language, reflecting cultural differences. English distinguishes the nearer kinsfolk by sex: "mother, father"; "sister, brother"; "aunt, uncle"; and others. Other languages, such as Malay, make a lexical distinction of age the primary one, with separate words for elder brother or sister and younger brother or sister. Still other languages—for example, some American Indian ones—use different words for the sister of a man and for the sister of a woman. But beyond this any language can be as precise as the situation demands in kin designation. When it is necessary, English speakers can specify "elder sister" and "female cousin," and within the overall category it is possible to distinguish "first and second cousins" and "cousins once removed," distinctions that it is ordinarily pedantic to make.

The best example of infinite precision available from a

Vocabulary of mathematics

strictly limited lexical stock is in the field of arithmetic. Between any two whole numbers a further fractional or decimal number may always be inserted, and this may go on indefinitely: between 10 and 11, 10% (10.5), 10¼ (10.25), 10% (10.125), and so on. Thus, the mathematician or the physical scientist is able to achieve any desired degree of quantitative precision appropriate to his purposes; hence the importance of quantitative statements in the sciences—any thermometric scale contains far more distinctions of temperature than are reasonably available in the vocabulary of a language ("hot," "warm," "cool," "tepid," "cold," and so on). For this reason mathematics has been described as the ideal use of language, but for many purposes in everyday life the very imprecision of natural languages is the source of their strength and adaptability.

Every living language can readily be adapted to meet changes occurring in the life and culture of its speakers, and the main weight of such changes falls on vocabulary. Grammatical and phonological structures are relatively stable and change noticeably over centuries rather than decades (see below); but vocabularies can change very quickly both in word stock and in word meanings. Consider as an example the changes wrought by modern technology in the vocabularies of all European languages since 1945. Before that date "transistor" and "cosmonaut" did not exist, and "nuclear disarmament" would scarcely have had any clear meaning.

Every language can alter its vocabulary very easily, which means that every speaker can without effort adopt new words, accept or invent new meanings for existing words, and of course, cease to use some words or cease to use them in certain meanings. Dictionaries list some words and some meanings as "obsolete" or "obsolescent" to indicate this process. No two speakers share precisely the same vocabulary of words readily used and readily understood, though they may speak the same dialect. They will, however, naturally have the great majority of words in their vocabularies in common.

Languages have various resources for effecting changes in vocabulary. Meanings of existing words may change. With the virtual disappearance of falconry as a sport in England, "lure" has lost its original meaning of a bunch of feathers on a string by which hawks were recalled to their handler and is used now mainly in its metaphorical sense of enticement. The additional meaning of "nuclear" has already been mentioned; one may list it with words such as computer and jet, which acquired new ranges of meaning in the mid-20th century.

Creation of new words

All languages have the means of creating new words to bear new meanings. These can be new creations; "Kodak" is one such, invented at the end of the 19th century by George Eastman; "chortle," now in general use, was a jocular creation of the English writer and mathematician Lewis Carroll (creator of *Alice in Wonderland),* and "gas" was formed in the 17th century by the Belgian chemist and physician Jan Baptist van Helmont as a technical term in chemistry, loosely modelled on the Greek *chaos* ("formless void"). But mostly languages follow definite patterns in their innovations. Words can be made up without limit from existing words or from parts of words; the sources of "railroad," "railway," and "aircraft" are obvious, and so are the sources of "disestablishment," first cited in 1806 and thereafter used with particular reference to the status of the Church of England. The controversy over the relations between church and state in the 19th and early 20th centuries gave rise to a chain of new words as the debate proceeded: "disestablishmentarian," "antidisestablishmentarian," "antidisestablishmentarianism." Usually, the bits and pieces of words used in this way are those found in other such combinations, but this is not always so. The technical term permafrost (terrain that never thaws, as in the Arctic) contains a bit of "permanent" probably not hitherto found in any other word.

A particular source of technical neologisms in European languages has been the words and word elements of Latin and Greek. This is part of the cultural history of western Europe, in so many ways the continuation of Greco-Roman civilization. "Microbiology" and "dolichocephalic" are words well formed according to the rules of Greek as they would be taken over into English, but no records survive of *mikrobiologia* and *dolichokephalikos* ever having been used in Ancient Greek. The same is true of Latinate creations such as "reinvestment" and "longiverbosity." The long tradition of looking to Latin and, since the Renaissance, to Greek also as the languages of European civilization, keeps alive the continuing formation of learned and scientific vocabulary in English and other European languages from these sources. The dependence on the classical languages in Europe is matched by a similar use of Sanskrit words for certain parts of learned vocabulary in some modern Indian languages (Sanskrit being the classical language of India). Such phenomena are examples of loanwords, one of the readiest sources for vocabulary extension.

Transmission of loanwords

Loanwords are words taken into a language from another language (the term borrowing is used for the process). Most obviously, this occurs when new things come into speakers' experiences as the result of contacts with speakers of other languages. This is part of the history of every language, except for one spoken by an impossibly isolated community. "Tea" from Chinese, "coffee" from Arabic, and "tomato," "potato," and "tobacco" from American Indian languages are familiar examples of loanwords designating new products that have been added to the vocabulary of English. In more abstract areas, several modern languages of India and Pakistan contain many words that relate to government, industry, and current technology taken in from English. This is the result of British role in these countries up to independence and the worldwide use of English as a language of international science since then.

In general, loanwords are rapidly and completely assimilated to the prevailing grammatical and phonological patterns of the borrowing language. The German word *Kindergarten,* literally "children's garden," was borrowed into English in the middle of the 19th century to designate an informal school for young children. It is now regularly pronounced as an English word, and the plural is kindergartens (not *Kindergarten,* as in German). Occasionally, however, some loanwords retain marks of their foreign origin: examples include Latin plurals such as cacti and narcissi (as contrasted with native patterns such as cactuses and narcissuses).

Languages differ in their acceptance of loanwords. An alternative way of extending vocabulary to cope with new products is to create a descriptive compound from within one's own language. English "aircraft" and "aeroplane" are, respectively, examples of a native compound and a Greek loan creation for the same thing. English "potato" is a loan; French *pomme de terre* (literally, "apple of the earth") is a descriptive compound. Chinese is particularly resistant to loans; "aircraft," "railway," and "telephone" are translated by newly formed compounds meaning literally "fly machine," "fire vehicle," and "lightning (electricity) language."

Language and conceptualization. The ability to speak and the ability to conceptualize are very closely linked, and the child learns both these skills together at the same time. This is not to say that thinking is no more than subvocal speech, as some behaviourists have proposed; most people can think pictorially and in simple diagrams, some to a greater degree than others, and one has the experience of responding rationally to external stimuli without intervening verbalization. But, as 18th-century thinkers saw, man's rationality developed and still goes hand in hand with his use of language, and a good deal of the flexibility of languages has been exploited in man's progressive understanding and conceptualizing of the world he lives in and of his relations with other men. Different cultures and different periods have seen this process differently developed. The anthropological linguist Edward Sapir put it well: "The 'real world' is to a large extent unconsciously built up on the language habits of the group."

Much of this lies in the irrecoverable prehistory of languages. The idea that there are still some primitive, al-

Language and thought patterns

most "fossil" languages, embodying a very low level of conceptualization, is a vain one. All that can be said is that languages are different and that, in part, the world is seen differently through the eyes of speakers of different languages. But, in some cases, part of the lexical adaptation of a language to developing thought patterns can be followed through. Ancient Greece saw a wholly unique growth and flowering of civilization in the 1st millennium BC, which has put virtually the entire civilized world in its debt ever since. In Greek, along with the emergence of certain abstract concepts and ways of thinking, one can follow some of the changes of word meanings and the coining of new words that accompanied this. As an example, the word *dikē* originally meant “way” or "manner"; thereafter, it acquired the meaning of the right way of doing something, the right way of behaving, and finally abstract right. Its derivative *dikaiosynē*, traditionally translated "justice," became the subject of philosophical debate and analysis by the Greek philosophers and covered almost the whole range of moral obligation involved in the relations of one person with others in society. Similar debate and refinement of key terms in the various branches of thought covered by Greek philosophy can be followed through; indeed, the term philosophy is directly taken from Greek *philosophia*, a compound formed not later than the 5th century BC from *philo-* (compare ***philein*** "to love") and ***sophia*** "wisdom" to refer to abstract speculation and debate of a fundamental nature about the world and man's place in it.

More recently, the development of the lexical resources of the languages of civilization can be observed, in one way or another, as they keep up with the scientific progress that dominates contemporary life.

An examination of the lexical structure of languages throws some light on the relations among various aspects of man's conceptualization. Spatial relations and their expression seem to lie very deep in the content of vocabulary. Words referring to time are drawn metaphorically from spatial words with great frequency: "a long/short time," "the near future," "far ahead/separated in time." Although time is a continuum, people readily divide it up into bits and record it rather as they do materials extended in space: "five years," "three months," “six seconds." This last use of vocabulary may be a particular trait of European languages and some others. An American Indian language is reported not to do this nearly so readily; it uses cardinal numbers only for discrete, countable objects. A separate class of words aligns the vocabulary of sequential time with that of intensity, so that repetition of the same activity again and again (to a European) is rather the intensification of a single activity. Certain differences in cultural attitudes and world outlook are said to accompany this kind of linguistic difference.

Expression of abstract relationships

Spatial terms are also freely used in the expression of other, more abstract relationships: "higher temperature," "higher quality," "lower expectations," “summit of a career," "far removed from any sensible course of action," "a distant relationship," "close friends," "over and above what had been said." It has been theorized that the linguistic forms most closely associated semantically with the expression of relations—case inflections in languages exhibiting this category—are originally and basically spatial in meaning. This “localist” theory, as it has been called, has been debated since the beginning of the 19th century and probably cannot be accepted as it stands, but the fact that it can be proposed and argued shows the dominant position that spatial relations hold in the conceptualization and verbalization of relations in other realms of thought.

It has been maintained that the human brain has a preference for binary oppositions, or polarities. If this is so, it will help explain the numerous pairs of related antonyms that are found: "good, bad"; "hot, cold"; "high, low"; "right, wrong"; "dark, light"; and so on. For finer discriminations, these terms can be put into more narrowly specified fields containing more than two terms taken together, but their most general use is in binary contrasts. Here, however, one term seems to represent the fundamental semantic category in question. In asking about size, one asks "How big is it?"; about weight, "How heavy is it?"; and about evaluation, "How good is it?" It is possible to ask how small, how light, or how bad something is, but such questions presuppose that the thing in mind has already been graded on the small side, on the light side, or on the bad side.

Style. The capacity for conceptualization possessed and developed by languages is by no means the only purpose language serves. A person's speech, supplemented by facial expression and gesture when speaker and hearer are mutually in sight, indicates and is intended to indicate a great deal more than factual information, inquiries, and requests. The fact that some of these other functions are performed by parts of a language usually mastered later by foreign learners gives rise to misinterpretation and often makes foreign speakers appear rude or insensitive when they are, in actuality, simply deploying fewer resources in the language.

Expression of emotional attitudes

Within the range of the structural and lexical possibilities of a language, speakers are able to convey their emotional attitudes and feelings toward the person or persons they are addressing and toward the subject matter of what they are saying. They are also able to conceal such feelings as one form of linguistic deception, though this is usually a harder task. These same resources are also exploited to arouse appropriate feelings and responses in others, again independently of any factual content. This is the chosen field of the propagandist, the preacher, the orator, the barrister, and the advertiser. All languages make use of intonation and voice qualities in these different ways; a person can produce and recognize the intonation and type of voice employed in coaxing, in pleading, in browbeating, and in threatening, in pleasure, and in anger, as well as those appropriate for matter-of-fact statements and the exposition of details about which the speaker has little or no emotional involvement. To describe exactly which phonetic features are brought into play is quite another matter, involving advanced competence in phonetic discrimination and analysis. This is one of the areas of speech about which all too little is currently known. Grammar and vocabulary are equally involved, though differently in each language. English speakers know the difference between "Come and give me a hand!" and "Could you possibly come and help me?'; "He's got the gift of gab” and "He is undoubtedly a fluent and persuasive speaker" are each appropriate for different occasions. By greetings and leave-takings a great deal of intended interpretation of the social relations between individuals can be expressed. Much of this is the “good manners" taught to children and expected of adults; these aspects of language behaviour vary from culture to culture, but in none are they wholly absent. It is, of course, equally possible to be deliberately bad mannered or deliberately to flout a linguistic convention or expectation, but this can be done only by knowing what is expected in the situation. The refinements of rudeness, like the refinements of politeness, insofar as the use of language is involved, require a very good knowledge of a language if it is other than one's mother tongue.

Written language is no less adapted to conveying more than just factual information, asking factual questions, and giving instructions. Intonation and tone of voice are clearly not reproducible in existing orthographic systems, but part of the skill of a novelist or a reporter is to convey these features of speech in his descriptions. Additionally, grammatical and lexical choices are available to the writer, as reading the examples above will show, and everyone knows the special artistry and techniques involved in composing written memorandums or letters if they are to achieve precisely the purpose for which they are intended.

Styles: variations within a language

These variations, written and spoken, within a language or within any dialect of a language, may be referred to as styles. Each time a person speaks or writes he does so in one or another style, deliberately chosen with the sort of considerations in mind that have just been mentioned, even though in speech the choice may often be routine. Sometimes style, especially in literature, is contrasted with "plain, everyday language." In using such plain, unmarked types of speaking or writing, however, one is no less choosing a particular style, even though it is the most commonly used one and the most neutral in that it conveys and arouses the least emotional involvement or personal feelings.

Stylistic differences are available to all mature native speakers and in literate communities to all writers, as well as to foreigners who know a second language really well. But there is undoubtedly a considerable range of skills in exploiting all the resources of a language, and, whereas all normal adults are expected to speak correctly and, if literate, to write correctly, communities have always recognized and usually respected certain individuals as preeminently skilled in particular styles, as orators, storytellers, preachers, poets, scribes, belletrists, and so forth. This is the material of literature. Once it is realized that oral literature is just as much literature as the more familiar written literature, it can be understood that there is no language devoid of its own literature.

In all languages certain forms of utterance have been considered worthy of preservation, study, and cultivation. In writing, the nature of written surfaces makes this fairly easy, though not all written material is deliberately preserved; much of it is deliberately destroyed, and, although the chance survival of inscriptions on stone or clay is of the greatest value to the archaeologist and historian, a good deal of such material was never intended to survive. Literature, on the other hand, is essentially regarded as of permanent worth. Printing and, in earlier days, the copying of manuscripts are the means of preserving written literature. In illiterate communities certain persons memorize narratives, poems, songs, prayers, ritual texts, and the like, and these are passed on, with new creations in such styles, to succeeding generations. Such skills, preservative as well as creative, are likely to be lost along with much of the surrounding culture under the impact of literacy. Here, modern technology in the guise of the tape recorder has come to the rescue, and many workers in the field of unwritten languages are recording specimens of oral literatures with transcriptions and translations while speakers having the requisite knowledge and skills are still available. A great amount of such material, however, must have been irretrievably lost from illiterate cultures before the 20th century.

Culture and literature

All languages have a literature, but different types of literature flourish in different languages and in different cultures. A warrior caste or a general respect for martial prowess fosters heroic verse or prose tales; strongly developed magical and mystery cults favour ritualistic types of oral or written literature; urban yearnings for the supposed joys of country life encourage the development of pastoral poetry, itself an outgrowth of the songs of shepherds and rural workers; and the same sense of the jadedness of city life is the best ground for the cultivation of satirical verse and prose, a form of literature probably confined largely to urban civilizations. Every language has the resources to meet these and other cultural requirements in its literature as the occasions arise, but some literary forms are more deeply involved in the structure of the language itself; this is made clear by the relative difficulty of translating certain types of literature and literary styles from one language to another. Poetry, in particular, is closely bound to the structure of the language in which it is composed, and poetry is notoriously difficult to translate from one language into another.

The special vocabularies and linguistic forms used in several games have already been mentioned. Here one may point to the widespread existence of verbal games themselves, based on the accidental features of a particular language. English-speaking children are accustomed to riddles, puns, and spelling games: "I spy with my little eye something beginning with *p*" (notice the regular formula with which this opens). These and similar word games have been found all over the world. Homer records the punning use by Odysseus of No-man (Greek *Outis*) as his name when he was about to attack Cyclops, who then roared out "No-man is killing me!" and so failed to attract any help (Odyssey 9:366–408). In some languages that make use of lexically distinctive tones, tone puns (words alike but for having different tones) are a form of word play.

As an intellectual challenge, the crossword puzzle in all its varieties, originally an American development early in the 20th century, has maintained and indeed greatly increased its popularity over much of the literate world that employs the Latin (Roman) alphabet. Crossword-puzzle solvers rely heavily on the relative probabilities of letter sequences in written words to suggest an answer to a partly filled line; and, depending on the particular style of the originator, crossword clues make use of many sorts of formal features in the language, among them spelling puns, spoken puns, and accidental letter sequences in words and phrases. To be able to solve a crossword puzzle in a second language shows a high degree of skill and knowledge therein.

LANGUAGE AND CULTURE

It has been seen that language is much more than the external expression and communication of internal thoughts formulated independently of their verbalization. In demonstrating the inadequacy and inappropriateness of such a view of language, attention has already been drawn to the ways in which one's mother tongue is intimately and in all sorts of details related to the rest of one's life in a community and to smaller groups within that community. This is true of all peoples and all languages; it is a universal fact about language.

Language as a part of culture

Anthropologists speak of the relations between language and culture. It is, indeed, more in accordance with reality to consider language as a part of culture. "Culture" is here being used, as it is throughout this article, in the anthropological sense, to refer to all aspects of human life insofar as they are determined or conditioned by membership in a society. The fact that a man eats or drinks is not in itself cultural; it is a biological necessity that he does so for the preservation of life. That he eats particular foods and refrains from eating other substances, though they may be perfectly edible and nourishing, and that he eats and drinks at particular times of day and in certain places are matters of culture, something "acquired by man as a member of society," according to the now-classic definition of culture by the English anthropologist Sir Edward Burnett Tylor. As thus defined and envisaged, culture covers a very wide area of human life and behaviour; and language is manifestly a part, probably the most important part, of it.

Although the faculty of language acquisition and language use is innate and inherited, and there is legitimate debate over the extent of this innateness, every individual's language is "acquired by man as a member of society," along with and at the same time as other aspects of that society's culture in which he is brought up. Society and language are mutually indispensable. Language can have developed only in a social setting, however this may have been structured, and human society in any form even remotely resembling what is known today or is recorded in history could be maintained only among people speaking and understanding a language in common use.

Transmission of language. Language is transmitted culturally; that is, it is learned. To a lesser extent it is taught, when parents deliberately encourage their children to talk and to respond to talk, correct their mistakes, and enlarge their vocabulary. But it must be emphasized that children very largely acquire their mother tongue (*i.e.*, their first language) by "grammar construction" from exposure to a random collection of utterances that they encounter. What is classed as language teaching in school either relates to second-language acquisition or, insofar as it concerns the pupils' first language, is in the main directed at reading and writing, the study of literature, formal grammar, and alleged standards of correctness, which may not be those of all the pupils' regional or social dialects. All of what goes under the title of language teaching at school presupposes and relies on the prior knowledge of a first language in its basic vocabulary and essential structure, acquired before school age.

Transmission of culture through language

If language is transmitted as part of culture, it is no less true that culture as a whole is transmitted very largely through language, insofar as it is explicitly taught. The fact that mankind has a history in the sense that animals do not is entirely the result of language. So far as researchers can tell, animals learn through spontaneous imitation or through imitation taught by other animals. This does not exclude the performance of quite complex and substantial pieces of cooperative physical work, such as a beaver's dam or an ants' nest, nor does it preclude the intricate social organization of some species, such as bees. But it does mean that changes in organization and work will be the gradual result of mutation cumulatively reinforced by survival value; those groups whose behaviour altered in any way that increased their security from predators or from famine would survive in greater numbers than others. This would be an extremely slow process, comparable to the evolution of the different species themselves.

There is no reason to believe that animal behaviour has materially altered during the period available for the study of human history, say the last 5,000 years or so, except, of course, when man's intervention by domestication or other forms of interference has itself brought about such alterations. Nor do members of the same species differ markedly in behaviour over widely scattered areas, again apart from differences resulting from human interference. Bird songs are reported to differ somewhat from place to place within species, but there is little other evidence for areal divergence. By contrast with this unity of animal behaviour, human cultures are as divergent as are human languages over the world, and they can and do change all the time, sometimes with great rapidity, as among the industrialized nations of the 20th century.

The processes of linguistic change and its consequences will be treated below. Here, cultural change in general and its relation to language will be considered. By far the greatest part of learned behaviour, which is what culture involves, is transmitted by vocal instruction, not by imitation. Some imitation is clearly involved, especially in infancy, in the learning process, but proportionately this is hardly significant.

Diffusion of knowledge through writing and printing

Through the use of language, any skills, techniques, products, modes of social control, and so on can be explained, and the end results of anyone's inventiveness can be made available to anyone else with the intellectual ability to grasp what is being said. Spoken language alone would thus vastly extend the amount of usable information in any human community and speed up the acquisition of new skills and the adaptation of techniques to changed circumstances or new environments. With the invention and diffusion of writing, this process widened immediately, and the relative permanence of writing made the diffusion of information still easier. Printing and the increase in literacy only further intensified this process. Modern techniques for almost instantaneous transmission of the written and spoken word all over the globe, together with the rapid translation services now available between the major languages of the world, have made it possible for usable knowledge of all sorts to be made accessible to people almost anywhere in the world in a very short time. This accounts for the great rapidity of scientific, technological, political, and social change in the contemporary world. All of this, whether ultimately for the good or ill of mankind, must be attributed to the dominant role of language in the transmission of culture.

Variations within languages. The part played by variations within a language in differentiating social and occupational groups in a society has already been referred to above. In language transmission this tends to be self-perpetuating unless deliberately interfered with. Children are in general brought up within the social group to which their parents and immediate family circle belong, and they learn the dialect and speaking styles of that group along with the rest of the subculture and behavioral traits and attitudes that are characteristic of it. This is a largely unconscious and involuntary process of acculturation, but the importance of the linguistic manifestations of social status and of social hierarchies is not lost on aspirants for personal advancement in stratified societies. The deliberate cultivation of an appropriate dialect, in its lexical, grammatical, and phonetic features, has been the self-imposed task of many persons wishing "to better themselves" and the butt of unkind ridicule on the part of persons already feeling themselves secure in their social status or unwilling to attempt any change in it. Much of the comedy in George Bernard Shaw's *Pygmalion* turns on Eliza's need to unlearn her native Cockney if she is to rise in the social scale. Conversely, it is readily apparent today that middle class people, mostly adolescents, who for some reason want to "opt out" of the social group of their parents make every effort to abandon the distinctive aspects of the social dialect that would mark them, along with dress and general behaviour, as members of a group whose mores they are, at least temporarily, affecting to reject. Culturally and subculturally determined taboos play a part in all this, and persons desirous of moving up or down in the social scale have to learn what words to use and what words to avoid if they are to be accepted and to "belong" in their new position. All through the ages, a good part of the material for "comedies of manners" has come from the social role of language variation within a society.

The same considerations apply to changing one's language as to changing one's dialect. Language changing is harder for the individual and is generally a rarer occurrence, but it is likely to be widespread in any mass immigration movement. In the 19th and early 20th centuries, the eagerness with which immigrants and the children of immigrants from continental Europe living in the United States learned and insisted on speaking English is an illustration of their realization that English was the linguistic badge of full membership in their new homeland, at the time when the country was proud to consider itself as the melting pot in which people of diverse linguistic and cultural origins would become citizens of a unified community.

Special vocabularies of games, trades, professions

The same sort of self-perpetuation, in the absence of deliberate rejection, operates in the special languages of games and of trades and professions (these are in the main concerned with special vocabularies). Game learners, apprentices, and professional students learn the locutions together with the rest of the game or the job. The specific words and phrases occur in the teaching process and are observed in use, and the novice is only too eager to display an easy competence with such phraseology as a mark of his full membership of the group; *e.g.*, golfers are keen to talk of birdies, fairways, and slicing.

Languages and variations within languages play both a unifying and a diversifying role in human society as a whole. Language is a part of culture, but culture is a complex totality containing many different features, and the boundaries between cultural features are not clear-cut, nor do they all coincide. Physical barriers such as oceans, high mountains, and wide rivers constitute impediments to human intercourse and to culture contacts, though modern technology in the fields of travel and communications make such geographical factors of less and less account. More potent today are political restrictions on the movement of people and of ideas, such as divide western Europe from Communist eastern Europe; the frontiers between these two political blocs represent much more of a cultural dividing line than any other European frontiers.

The distribution of the various components of cultures differs, and the distribution of languages may differ from that of nonlinguistic cultural features. This results from the varying ease and rapidity with which changes may be acquired or enforced and from the historical circumstances responsible for these changes. In contemporary Europe, as the result of World War II, a major political and cultural division cuts across an area of relative linguistic unity in East and West Germany. It is significant, however, that differences of vocabulary and usage are already noticeable in the German speech from each side, overlying earlier differences attributed to regional dialects; one may surmise that, if the present political situation endures for several more generations, the East–West frontier will come to mark a definite dialect boundary within the German language as well.

Language distribution. Language, no less than other aspects of human behaviour, is subject to purposive interference. When people with different languages need to communicate, various expedients are open to them, the most obvious being second-language learning and teaching. This takes time, effort, and organization, and, when more than two languages are involved, the time and effort are that much greater. Most people are monolingual, and those with a working knowledge of three or four languages are much fewer than those with a competence in just one second language. Other expedients may also be applied. Ad hoc pidgins for the restricted purposes of trade and administration were mentioned above. Tacit or deliberate agreements have been reached whereby one language is chosen for international purposes when speakers of several different languages are involved. In the Roman Empire, broadly, the western half used Latin as a lingua franca, and the eastern half used Greek. In western Europe during the Middle Ages, Latin continued as the international language of educated people, and Latin was the second language taught in schools. Later, the cultural, diplomatic, and military reputation of France made French the language of European diplomacy. This use of French as the language of international relations persisted until the present century. At important conferences among representatives of different nations, it is usually agreed which languages shall be officially recognized for registering the decisions reached; and the provisions of treaties are interpreted in the light of texts in a limited number of languages, those of the major participants.

International and diplomatic languages

Since World War II the dominance of the English-speaking peoples in science and technology and in international commerce has led to the recognition of English as the major international language in the world of practical affairs, with more and more countries making English the first foreign language to be taught and thus producing a vast expansion of English-language-teaching programs all over the world. Those whose native language is English do not sufficiently realize the amount of effort, by teacher and learner alike, that is put into the acquisition of a working knowledge of English by educated first speakers of other languages.

As an alternative to the recognition of particular natural languages as international in status, attempts have been made to invent and propagate new and genuinely international languages, devised for the purpose. Of these, Esperanto, invented by the Polish–Russian doctor L.L. Zamenhof in the 19th century, is the best known. Such languages are generally built up from parts of the vocabulary and grammatical apparatus of the better known existing languages of the world. The relationship between the written letter and its pronunciation is more systematic than with many existing orthographies (English spelling is notoriously unreliable as an indication of pronunciation), and care is taken to avoid the grammatical irregularities to which all natural languages are subject and also to avoid sounds found difficult by many speakers (*e.g.*, the English ***th*** sounds, which most Europeans, apart from English speakers, dislike). Despite the high hopes of their inventors, these artificial languages have not made much progress, though an international society of Esperanto speakers does exist (for more information, see also INTERNATIONAL LANGUAGE).

Deliberate interference with the natural course of linguistic changes and the distribution of languages is not confined to the facilitating of international intercourse and cooperation. Language as a cohesive force for nation-states and for linguistic groups within nation-states has for long been manipulated for political ends. Multilingual states can exist and prosper; Switzerland is a good example. But linguistic rivalry and strife can be disruptive. Language riots have occurred in Belgium between French and Flemish speakers and in parts of India between rival vernacular communities. A language can become or be made a focus of loyalty for a minority community that thinks itself suppressed, persecuted, or subjected to discrimination. The French language in Canada in the mid-20th century is an example. In the 19th and early 20th centuries Irish Gaelic came to symbolize Irish patriotism and Irish independence from Great Britain. Since independence, government policy continues to insist on the equal status of English and Irish in public notices and official documents, but, despite such encouragement and the official teaching of Irish in the state schools, a main motivation for its use and study has disappeared, and the language is giving ground to English under the international pressures referred to above.

Language as a cohesive political force

For the same reasons, a language may be a target for attack or suppression, if the authorities associate it with what they consider a disaffected or rebellious group or even just a culturally inferior one. There have been periods when American Indian children were forbidden to speak a language other than English at school and when pupils were not allowed to speak Welsh in British state schools in Wales. Both these prohibitions have been abandoned. Since the Spanish Civil War of the 1930s Basque speakers have been discouraged from using their language in public, as a consequence of the strong support given by the Basques to the republican forces. Interestingly, on the other side of the Franco-Spanish frontier, French Basques are positively encouraged to keep their language in use, if only as an object of touristic interest and consequent economic benefit to the area.

Translation. So far, some of the relatively large-scale effects of culture contacts on languages and on dialects within languages have been surveyed. A continuous concomitant of contact between two mutually incomprehensible tongues and one that does not lead either to suppression or extension of either is translation. As soon as two speakers of different languages need to converse, translation is necessary, either through a third party or directly.

Before the invention and diffusion of writing, translation was instantaneous and oral; persons professionally specializing in such work were called interpreters. In predominantly or wholly literate communities, translation is thought of as the conversion of a written text in one language into a written text in another, though the modern emergence of the simultaneous translator or professional interpreter at international conferences keeps the oral side of translation very much alive.

Oral and written translation

The tasks of the translator are the same whether the material is oral or written, but, of course, translation between written texts allows more time for stylistic adjustment and technical expertise. The main problems have been recognized since antiquity and were expressed by St. Jerome, translator of the famed Latin Bible, the Vulgate, from the Hebrew and Greek originals. Semantically, these problems relate to the adjustment of the literal and the literary and the conflicts that so often occur between an exact translation of each word, as far as this is possible, and the production of a whole sentence or even a whole text that conveys as much of the meaning of the original as can be managed. These problems and conflicts arise because of factors already noticed in the use and functioning of language: languages do not operate in isolation but within and as part of cultures, and cultures differ from each other in various ways. Even between the languages of communities whose cultures are fairly closely allied, there is by no means a one-to-one relation of exact lexical equivalence between the items of their vocabularies.

In their lexical meanings, words acquire various overtones and associations that are not shared by the nearest corresponding words in other languages; this may vitiate a literal translation. The English author and theologian Ronald Knox has pointed to the historical connections of the Greek ***skandalon*** "stumbling block, trap, or snare," inadequately rendered by "offense," its usual New Testament translation. In modern times translators of the Bible into the languages of peoples culturally remote from Europe are well aware of the difficulties of finding a lexical equivalent for "lamb," when the intended readers, even if they have seen sheep and lambs, have no tradition of blood sacrifice for expiation nor long-hallowed associations of lambs with lovableness, innocence, and apparent helplessness. The English word uncle has, for various reasons, a cozy and slightly comic set of associations. The Latin poet Virgil uses the words *avunculus Hector* in a solemn heroic passage of the Aeneid (Book III, line 343); to translate this by "uncle Hector" gives an entirely unsuitable flavour to the text.

Poetry translation

The translation of poetry, especially into poetry, presents very special difficulties, and the better the original poem, the harder the translator's task. This is because poetry is, in the first instance, carefully contrived to express exactly what the poet wants to say. Second, to achieve this end, the poet calls forth all the resources of the language in which he is writing, matching the choice of words, the order of words, and grammatical constructions, as well as phonological features peculiar to the language in metre, perhaps supplemented by rhyme, assonance, and alliteration. The available resources differ from language to language; English and German rely on stress-marked metres, but Latin and Greek used quantitative metres, contrasting long and short syllables, while French places approximately equal stress and length on each syllable. The translator must try to match the stylistic exploitation of the particular resources in the original language with comparable resources from his own. Because lexical, grammatical, and metrical considerations are all interrelated and interwoven in poetry, a satisfactory literary translation is usually very far from a literal word for word rendering. The more the poet relies on language form, the more embedded his verses are in that particular language, and the harder they are to translate adequately. This is especially true with lyrical poetry in several languages, with its wordplay, complex rhymes, and frequent assonances.

At the other end of the translator's spectrum, technical prose dealing with internationally agreed scientific subjects is probably the easiest type of material to translate, because cultural unification (in this respect), lexical correspondences, and stylistic similarity already exist in this type of usage in the languages most commonly involved, to a higher degree than in other fields of discourse.

Significantly, it is this last aspect of translation to which mechanical and computerized techniques are being applied with some prospects of limited success. Machine translation, whereby, ultimately, a text in one language could be fed into a machine to produce an accurate translation in another language without further human intervention, has been largely concentrated on the language of science and technology, with its restricted vocabulary and overall likeness of style, for both linguistic and economic reasons. Attempts at machine translation of literature have been made, but success in this field, more especially in the translation of poetry, seems very remote at present.

Translation as an art

Translation on the whole is an art, not a science. Guidance can be given and general principles can be taught, but after that it must be left to the individual's own feeling for the two languages concerned. Almost inevitably, in a translation of a work of literature something of the author's original intent must be lost; in those cases in which the translation is said to be a better work than the original, an opinion sometimes expressed about the English writer Edward Fitzgerald's "translation" of The *Rubdiydt of Omar Khayyám*, one is dealing with a new, though derived, work, not just a translation. The Italian epigram remains justified: *Traduttore traditore* "The translator is a traitor."

Messages and codes. Translation serves to extend the communicative value of a text. Sometimes people want to restrict it. Confidential messages, spoken and written, require for their efficacy that they be known to and understood by only the single person or the few persons to whom they are addressed. Such are diplomatic exchanges, operational messages in wartime, and some transmissions of commercial information. Protection of written messages from interception has been practiced for many centuries. Recent developments in telegraphy and telephony have made protection against unauthorized reception more urgent, whether of texts transmitted as speech or as series of letters of the alphabet. Scrambling of telephony is a common expedient; the wave frequencies through which the sounds are to be transmitted are altered at the source so as to be unrecognizable and then reconverted by the intended recipient's receiver. Codes and ciphers (cryptography) are of much longer standing in the concealment of written messages, though their techniques are being constantly developed. Such gains are, of course, countered by developments in the techniques of decipherment and decoding (as distinct from getting hold of the key to the system in use). An important by-product of such techniques has been the reading and interpretation of inscriptions written in otherwise unknown languages or unknown writing systems for which no translation exists. The recent, very significant decipherment of the Linear B script and its recognition as Mycenaean Greek, an early Greek dialect written in a form of orthography quite distinct from the later classical Greek alphabet, was first achieved by the application of cryptographic "code cracking" methods (see also CRYPTOLOGY).

LANGUAGE LEARNING: BILINGUALISM AND LITERACY

Role of the brain in language learning

Every physiologically and mentally normal person has learned the main structure and basic vocabulary of his mother tongue by the end of childhood. It has been pointed out that the process of first-language acquisition as a spoken medium of communication is largely achieved from random exposure. There is legitimate controversy, however, over the nature and extent of the positive contribution that the human brain brings to the activity of grammar construction, the activity by which the child develops an indefinitely creative competence from the finite data that make up his actual experience of the language. Creativity is what must be stressed as the product of first-language acquisition. By far the greater number of all the sentences anyone hears and utters during his lifetime are new; that is, they have not occurred before in his personal experience. But individuals find no difficulty at all in understanding at once almost everything they hear nor for the most part in producing sentences to suit the requirements of every situation. This very ease of creativity in man's linguistic competence makes it hard to realize its extent. The only regularly reproduced sentences in most speakers' experience are the stereotyped forms of greeting and leave-taking and certain formalized responses to recurrent situations, such as shopping, cooperative activities in repetitive jobs, the stylized parts of church services, and the like.

Yet, despite this really immense achievement that the progressive mastery of one's first language constitutes, it arouses no comment and attracts no credit. It is simply part of what is expected of one in growing up. Different people may be singled out for praise in certain uses of their language, as good public speakers, authors, poets, tellers of tales, and solvers of puzzles, but not just as speakers. The credit that some individuals acquire in certain communities for "speaking correctly" is a different matter, usually the result of speaking as one's mother tongue a prestigious standard dialect among people most of whom speak another, less favoured one.

Bilingualism. The learning of a second and of any subsequently acquired language is quite a different matter. Except for one form of bilingualism (see below), it is a deliberate activity undertaken when one has already nearly or fully acquired the basic structure and vocabulary of one's first language. Of course, many people never do master significantly more than their own first language. It is only in encountering a second language that one realizes how complex language is and how much effort must be devoted to subsequent acquisition. It has been said that the principal obstacle to learning a language is knowing one already, and it may also be that the faculty of grammar construction exhibited in childhood is one that is gradually lost as childhood recedes.

Whereas every normal person masters his mother tongue with unconscious ease, people vary in their ability to learn additional languages, just as they vary in other intellectual activities. Situational motivation, however, Ability to learn additional languages

appears to be by far the strongest influence on the speed and apparent ease of this learning. The greatest difficulty is experienced by those who learn because they are told to or are expected to, without supporting reasons that they can justify. Given a motive other than external compulsion or expectation, the task is achieved much more easily (this, of course, is an observation in no way confined to language learning). In Welsh schools it is found that English children make slower progress in Welsh when their only apparent reason for learning Welsh is that there are Welsh classes. Welsh children, on the other hand, make rapid progress in English, the language of most further education, the newspapers, most television and radio, most of the better paid jobs, and of any job outside Welsh-speaking areas. Similar differences in motivation have accounted for the excellent standard of English, French, and German acquired by educated persons in the Scandinavian countries and in Holland, small countries whose languages, being spoken by relatively few foreigners, are of little use in international communication. This attainment may be compared with the much poorer showing in second-language acquisition among comparably educated persons in England and America, who have for long been able to rely on foreigners accommodating to their ignorance by speaking and understanding English.

It is often held that children brought up bilingually in places in which two languages are regularly in use are slower in schoolwork than comparable monolingual children, as a greater amount of mental effort has to be expended in the mastery of two languages. This is by no means proved; and, because much of a child's language acquisition takes place in infancy and in the preschool years, it does not represent an effort in the way that consciously learning a language in school does, and indeed it probably occupies a separate part of the child's mental equipment. The question of speed of general learning by bilinguals and monolinguals must be left open. It is quite a separate matter from the job of learning, by teaching at home or in school, to read and write in two languages; this undoubtedly is more of a labour than the acquisition of monolingual literacy.

Types of bilingualism

Two types of bilingualism have been distinguished, according to whether the two languages were acquired from the simultaneous experience of the use of both in the same circumstances and settings or from exposure to each language used in different settings (an example of the latter is the experience of English children living in India during the period of British ascendancy there, learning English from their parents and an Indian language from their nurses and family servants). However acquired, bilingualism leads to mutual interference between the two languages; extensive bilingualism within a community is sometimes held partly responsible for linguistic change (see below). Interference may take place in pronunciation, in grammar, and in the meanings of words. Bilinguals often speak their two languages each with "an accent"; *i.e.*, they carry into each certain pronunciation features from the other. The German word order in "He comes tomorrow home" has been reported as an example of grammatical interference; and in Canadian French the verb introduire has acquired from English the additional meaning "introduce, make acquainted" (which in metropolitan French is *présenter*).

Literacy. The acquisition of literacy is something very different from the acquisition of one's spoken mother tongue, even when the same language is involved, as it usually is. Both skills, speaking and writing, are learned skills, but there the resemblance ends. The child learns his first language at the start involuntarily and mostly unconsciously from random exposure, even if no attempts at teaching are made. Literacy is deliberately taught and consciously and deliberately learned. There is current debate on the best methods and techniques for teaching literacy in various social and linguistic settings. Literacy is learned through speech, by a person already possessed of the basic structure and vocabulary of his language.

Such facts should be very obvious, but the now-accepted, though fairly recent, standard of near-universal literacy in technologically advanced countries, along with the fact that in second-language learning one usually acquires speech and writing skills at the same time, tends to bring these two parts of language learning under one head. Literacy is manifestly a desirable attainment for all communities, though not necessarily in all languages. It must be borne in mind that there are many distinct languages spoken in the world today by fewer than 1,000 or 500 or even 50 persons. The capital investment in literacy, including teaching resources, teacher time and training, printing, publications, and so forth, is vast, and it can be economically and socially justified only when applied to languages spoken and likely to continue to be spoken by substantial numbers over a wide area.

Effects of literacy

Literacy is in no way necessary for the maintenance of linguistic structure or vocabulary, though it does enable people to add words from the common written stock in dictionaries to their personal vocabulary very easily. It is worth emphasizing that until relatively recently in human history all languages were spoken by illiterate speakers and that there is no essential difference as regards pronunciation, structure, and complexity of vocabulary between spoken languages that have writing systems used by all or nearly all their speakers and the languages of illiterate communities.

Literacy has many effects on the uses to which language may be put; storage, retrieval, and dissemination of information are greatly facilitated, and some uses of language, such as philosophical system building and the keeping of detailed historical records, would scarcely be possible in a totally illiterate community. In these respects the lexical content of a language is affected, for example, by the creation of sets of technical terms for philosophical writing and debate. Because the permanence of writing overcomes the limitations of auditory memory span imposed on speech, sentences of greater length can easily occur in writing, especially in types of written language that are not normally read aloud and that do not directly represent what would be spoken. An examination of some kinds of oral literature, however, reveals the ability of the human brain to receive and interpret spoken sentences of considerable grammatical complexity.

In relation to pronunciation, writing does not prevent the historical changes that occur in all languages. Part of the apparent irrationality of English spelling, such as is found also in some other orthographies, lies just in the fact that letter sequences have remained constant while the sounds represented by them have changed. For example, the *gh* of "light" once stood for a consonant sound, as it still does in the word as pronounced in some Scots dialects; and the k of "knave" and "knight" likewise stood for an initial k sound (compare the related German words *Knabe* and *Knecht*). A few relatively uncommon words, including some proper names, are reformed phonetically, specifically to bring their pronunciation more in line with their spelling. Spelling pronunciations, as these are called, are a product of general literacy. In London, the pronunciation of "St. Mary Axe" as if it were spelled "Simmery Axe" is now decidedly old-fashioned. "St. John" and "St. Clair" survive as proper names with their old pronunciations, in the latter case helped by the presence of the alternative spelling "Sinclair."

WRITTEN LANGUAGE

Historically, culturally, and in the individual's life, writing is subsequent to speech and presupposes it. Aristotle expressed the relation thus: "Speech is the representation of the experiences of the mind, and writing is the representation of speech" (On Interpretation). But it is not as simple as this would suggest. Alphabetic writing, in which, broadly, consonant and vowel sounds are indicated by letters in sequence, is the most widespread system in use today, and it is the means by which literacy will be disseminated, but it is not the only system, nor is it the earliest.

Evolution of writing systems. Writing appears to have been evolved from an extension of picture signs: signs that directly and iconically represented some thing or action and then the word that bore that meaning. Other

Character scripts

words or word elements not readily represented pictorially could be assigned picture signs already standing for a word of the same or nearly the same pronunciation, perhaps with some additional mark to keep the two signs apart. This sort of device is used in children's word puzzles, as when the picture of a berry is used to represent, say, the second half of the name Canterbury. This opens the way for what is called a character script, such as that of Chinese, in which each word is graphically represented by a separate individual symbol or character or by a sequence of two or more such characters. Writing systems of this sort have appeared independently in different parts of the world.

Chinese character writing has for many centuries been stylized, but it still bears marks of the pictorial origin of some characters. Chinese characters and the characters of similar writing systems are sometimes called ideograms, as if they directly represented thoughts or ideas. This is not so. Chinese characters stand for Chinese words or, particularly as in modern Chinese, bits of words; they are the symbolization of a particular language, not a potentially universal representation of thought. The & sign, standing for "and in English printing, is a good isolated example of a character used in an alphabetic writing system.

Character writing is laborious to learn and imposes a burden on the memory. Alternatives to it, in addition to alphabetic writing, include scripts that employ separate symbols for the syllable sequences of consonants and vowels in a language, with graphic devices to indicate consonants not followed by a vowel. The Devanagari script, in which classical Sanskrit and modern Hindi are written, is of this type, and the Mycenaean writing system, a form of Greek writing in use in the 2nd millennium BC and quite independent of the later Greek alphabet, was syllabic in structure. Japanese employs a mixed system, broadly representing the roots of words by Chinese characters (the Japanese learned writing from the Chinese in and after the 5th century AD) and the inflectional endings by syllable signs. These syllable signs are an illustration of the way in which a syllabic script can develop from a character script: certain Chinese characters were selected for their sound values alone and, reduced in size and complexity, have been standardized as signs of a particular consonant and vowel sequence or of a single vowel sound.

Greek alphabet

The Greek alphabet came from the Phoenician script, a syllabic-type writing system that indicated the consonant sounds. By a stroke of genius, a Greek community decided to employ certain consonantal signs to which no consonant sound corresponded in Greek as independent vowel signs, thus producing an alphabet, a set of letters standing for consonants and vowels. The Greek alphabet spread over the ancient Greek world, undergoing minor changes. From a Western version sprang the Latin (Roman) alphabet. Also derived from the Greek alphabet, the Cyrillic alphabet was devised in the 9th century AD by a Greek missionary, St. Cyril, for writing the Slavic languages.

Spelling. Alphabetic writing is not and cannot be an exact representation of the sequence of sounds or even of the sequence of distinctive sounds in the spoken forms of words and sentences. "Consonant" and "vowel" mean different things when applied to letters and to sounds, though there is, of course, much overlap. The y at the beginning of "yet" stands for a consonant sound; at the end of "jetty" it stands for a vowel sound. In “thick” and "thin" the sequence *th* represents a single sound, not a *t* sound followed by an h sound. In "kite" the *e* represents no sound directly but distinguishes the vowel between k and *t* from the vowel in “kit.” These disharmonies arise from a number of causes. Economy in the use of letters is one factor. In addition, spoken forms are always changing over the centuries, whereas writing, particularly since the invention of printing, is very conservative. At one time the *e* at the end of words such as "kite" did stand for a vowel sound. This sound was lost between the 14th and 16th centuries, a time when other changes in the pronunciation of such words also occurred. The notorious *ough* spellings in English, standing for different sounds and sound sequences in "rough," "cough," "dough," "plough," "ought," and other such words, have arisen from historical changes that have driven spelling and pronunciation further apart.

This, of course, does not mean that spelling reforms are out of the question. Spelling reform has been talked of in relation to English for many centuries without much effect; but in some countries—for example, Norway and Holland—official action has prescribed certain reforms to be made, and these have then been taught in school and have gradually found their way into printed works. The sheer volume of printed matter preserved for use and consultation in the modern world adds much weight against the convenience otherwise accruing from reforms designed to correct the historically produced disharmonies between spelling and pronunciation.

Representing grammatical distinctions in spelling

Moreover, it is not always most useful for spellings to represent exactly the sound sequences in a word and nothing else; this is the task for which phoneticians have devised transcriptions. As far as the sounds themselves are concerned, the plural signs of "cats," "dogs," and "horses" are different: the final sound of "cats" is like the initial sound of "sink," that of "dogs" like the initial sound of “zinc,” and the plural of "horse" is indicated by a sound sequence rather like that in "is." But they are all indicated in writing by one and the same letter and always have been, because only one grammatical distinction, that of singular as against plural, is involved, and at this point in the language the actual differences in the sounds, important elsewhere, are irrelevant.

Letters, insofar as they stand for sounds, stand for consonants and vowels. But other sound features are involved in languages. In English words the location of the stress is important, and the words "import" as a noun and "import" as a verb are distinguished by this alone. All languages make use of sequences of rises and falls in pitch, called intonation, as part of spoken communication. These phenomena are unrepresented in orthography except for certain punctuation marks such as ? and ! and sometimes by italicization and underlining.

This is not a weakness in orthography. Writing is normally intended to be read and when necessary read aloud by people who already know the language and are therefore able to supply from their own competence the required detail. For specific purposes such as foreign-language teaching, as well as for the specific study of pronunciation and speech sounds in phonetics and phonology, various forms of transcription have been devised to indicate unambiguously by written signs the precise form of the spoken utterance, without regard to other considerations.

Written versus spoken languages. For these reasons one should distinguish the grammar of a written language (*e.g.*, written English) from the grammar of the corresponding spoken language (spoken English). The two grammars will be very similar, and they will overlap in most places; but the description of spoken English will have to take into account the grammatical uses of features such as intonation, largely unrepresented in writing, and the description of written English must deal adequately with the greater average length of sentences and some different syntactic constructions and word forms characterizing certain written styles but almost unknown in ordinary speech (*e.g.*, "whom" as the objective form of "who").

Ancient, or dead, languages

In studying ancient (dead) languages one is, of course, limited to studying the grammar of their written forms and styles, as their written records alone survive. Such is the case with Latin, Ancient Greek, and Sanskrit (Latin lives as a spoken language in very restricted situations, such as Roman Catholic services and as the official language of some closed religious communities, but this is not the same sort of Latin as that studied in classical Latin literature; Sanskrit survives also as a spoken language in similarly restricted situations in a few places in India). Scholars may be able to reconstruct something of the pronunciation of a dead language from historical inferences and from descriptions of its pronunciation by authors writing when the language was still spoken. They know a good deal about the pronunciation of Greek and Latin and a great deal about the pronunciation of Sanskrit, because ancient Indian scholars left a collection of extremely detailed and systematic literature on its pronunciation. But this does not alter the fact that when one teaches and learns dead languages today, largely for their literary value and because of the place of the communities formerly speaking them in our own cultural history, one is teaching and learning the grammar of their written forms. Indeed, despite what is known about the actual pronunciation of Greek and Latin, Europeans on the whole pronounce what they read in terms of the pronunciation patterns of their own languages.

Under present conditions, with universal literacy either an accepted fact or an accepted target, it is assumed that, wherever it is convenient or useful, writing may be employed for any purpose for which speech might have been used and by all sections of the community. This has not always been so. Literacy was until the 19th century the privilege of the few. In other periods and cultures, writing was the preserve of certain defined groups, such as the priesthood and the official class, and it was restricted to certain purposes, such as the annals of important events, genealogical tables, and records of inventories of things and persons. It is highly probable that writing first developed for particular types of use by particular groups of specialists within communities and subsequently, because of its obvious utility, spread outside these limits.

For further accounts of writing systems in greater detail, see WRITING, FORMS OF; ALPHABETS.

LINGUISTIC CHANGE

Every language has a history; and, as in the rest of human culture, changes are constantly taking place in the course of the learned transmission of a language from one generation to another. This is just part of the differences between human culture and animal behaviour. Languages change in all their aspects, in their pronunciation, word forms, syntax, and word meanings (semantic change). These changes are mostly very gradual in their operation, becoming noticeable only cumulatively over the course of several generations. But, in some areas of vocabulary, particular words closely related to rapid cultural change are subject to equally rapid and therefore noticeable changes within a generation or even within a decade. In the 20th century the vocabulary of science and technology is an outstanding example. The same is also true of those parts of vocabulary that are involved in fashionable slangs and jargons, whose raison d'être in promoting group, particularly age-group, solidarity depends on their being always fresh and distinctive. Old slangs date, as any reading of a novel or visit to a film more than ten years old is apt to show. The rapid obsolescence of young people's slangs is equally to be seen in the unsuccessful efforts of some well-intentioned older persons who vainly attempt to cultivate the speech styles of present-day youth groups in a misdirected attempt to bridge "the generation gap" (this last phrase is an example of mid-20th-century pseudoscientific slang).

Changes in vocabulary

Development of language families. In the structural aspects of language, their pronunciation and grammar, and in vocabulary less closely involved in rapid cultural movement, the processes of linguistic change are best observed by comparing written records of a language over extended periods. This is most readily seen by English speakers through setting side by side present-day English texts with 18th-century English, the English of the Authorized Version of the Bible, Shakespearean English, Chaucer's English, and the varieties of Old English (Anglo-Saxon) that survive in written form. Noticeably, as one goes back in time, the effort required in understanding increases, and, while people do not hesitate to speak of "Shakespearean English," they are more doubtful about Chaucer, and for the most part Old English texts are as unintelligible to a modern English speaker as, for example, texts in German. It is clear that the differences involved include word meanings, grammar, and, so far as this can be reconstructed, pronunciation.

Similar evidence, together with what is known of the cultural history of the peoples concerned, makes clear the continuous historical connections linking French, Spanish, Portuguese, Italian, and Romanian with the spoken ("vulgar") Latin of the western Roman Empire. This group constitutes the Romance subfamily of languages and is an example of how, as the result of linguistic change over a wide area, a group of distinct, though historically related, languages comes into being.

In the transmission of a language from parent to child, slight deviations in all aspects of language use occur all the time, and as the child's speech contacts widen he confronts a growing range of slight differences in personal speech forms, some of them correlating with social or regional differences within a community, these speech differences themselves being the results of the transmission process. As a consequence, the child's speech comes to differ slightly from that of his parents' generation. In urbanized communities an additional factor is involved: children have been shown to be effectively influenced by the speech habits of their peer groups once they have made contacts with them in and out of school.

Cumulative changes in languages

Such changes, though slight at the time, are progressively cumulative. Since ready intercommunication is a primary purpose of language, as long as a community remains unitary, with strong central direction and a central cultural focus, such changes will not go beyond the limits of intercomprehensibility. But in more scattered communities and in larger language areas, especially when cultural and administrative ties are weakened and broken, these cumulative deviations in the course of generations give rise to wider regional differences. Such differences take the form of dialectal differentiation as long as there is some degree of mutual comprehension but eventually result in the emergence of distinct languages. This is what happened in the history of the colloquial Latin of the western Roman Empire, and it can be assumed that a similar course of events gave rise to the separate Germanic languages (English, German, Dutch, Danish, Norwegian, Swedish, and some others), though in this family the original unitary language is not known historically but inferred as "Common Germanic" or "Proto-Germanic" and tentatively assigned to early in the 1st millennium BC as the period before separation began.

This is how language families have developed. Most but not all of the languages of Europe belong to the Indo-European family, so-called because in addition it includes the classical Indian language Sanskrit and most of the modern languages of northern India and Pakistan. It includes as subfamilies the two families just mentioned, Romance and Germanic, and several others. It is assumed that the subfamilies, and from them the individual languages of the Indo-European family, are ultimately derived from a unitary language spoken somewhere in eastern Europe or western Asia (its exact location is still under debate), perhaps 5,000 years ago. This unitary language has itself been referred to as "Indo-European," "Proto-Indo-European," the "common parent language," or the "original language" (*Ursprache*) of the family. But it must be emphasized that, whatever it may have been like, it was just one language among many and of no special status in itself. It was certainly in no way the original language of mankind or anything like it. It had its own earlier history, of which virtually nothing can be inferred, and it was, of course, very recent in relation to the time span of human language itself. What is really special about such "parent" or "proto-" languages is that they represent the farthest point to which our available techniques and resources enable us to reconstruct the prehistory of our attested and living languages. Similarly constituted families of languages derived from inferred common sources have been established for other parts of the world; for example, Altaic, covering Turkish and several languages of Central Asia, and Bantu, containing many of the languages of central and southern Africa. For further details of these and other language families see LANGUAGES OF THE WORLD and the specialist articles on the major language families, subfamilies, and languages.

"Parent" or "proto-" languages

If enough material in the form of written records from past ages were available, it would be possible to group all the world's languages into historically related families. In addition, an answer could perhaps be posited to the question of whether all languages are descended from a single original language or whether languages emerged independently among several groups of early peoples (the rival theories of monogenesis and polygenesis, a controversy more confidently disputed in the 19th century than today). In actual fact, written records, when they are available, go back only a fraction of the time in which human speech has been developed and used, and over much of the globe written records are nonexistent. In addition, there are no other linguistic fossils comparable to the fossils of geological prehistory. This means that the history and prehistory of languages will not be able to go back more than a few thousand years BC and will be much more restricted in language areas in which few or no written records are available, as in much of Africa and in South America. Many languages will remain not related with certainty to any family. Nevertheless, the methods of historical linguistics, involving the precise and systematic comparison of word forms and word meanings (see further LINGUISTICS), have produced remarkable results in establishing language families on the same basis as Indo-European was established, in far less favourable fields. But any attempt by these means to get back to "the origin of language" or to reconstruct man's original language, if indeed there was one, is quite beyond the reach of science and will remain so.

Causes of language change. The fundamental cause of linguistic change and hence of linguistic diversification is the minute deviations occurring in the transmission of speech from one generation to another. But other factors contribute to the historical development of languages and determine the spread of a language family over the world's surface. Population movements naturally play a large part, and movements of peoples in prehistoric times carried the Indo-European languages from a relatively restricted area into most of Europe and into northern India, Persia, and Armenia. But language and race are by no means the same thing, and the spread of the Indo-European languages resulted, in the main, from the imposition of one of them on the earlier population of the territories occupied. In the historical period, within Indo-European, the same process can be seen at work in the western Roman Empire. Latin superseded the earlier, largely Celtic languages of the Iberian Peninsula and of Gaul (France) not through population replacement (the number of Roman soldiers and settlers in the empire was never large) but through the abandonment of these languages by the inhabitants over the generations as they found in Latin the language of commerce, civilization, law, literature, and, above all, social advancement and prestige.

Population movements

Conquest does not always lead to the supersession of a language. Greek survived centuries of Turkish rule and indeed remained a focus of national feeling, as has happened elsewhere in history. Much depends on the various circumstances and on the mutual attitudes of those involved; what must be kept quite clear is the difference between movements of peoples and the spread of languages. When linguistically homogeneous people enter and occupy a virtually empty area, as with most of Australia, the two movements coincide.

Languages do not just spread and compete with each other for territorial use. They are in constant contact, and every language bears evidence of this throughout its history. Modern Greek is full of words of Turkish origin, despite efforts made at various times since independence to purify the language by official action. The Norman Conquest and a period in which French was the language of the ruling class in England effected great changes on English and contributed a very substantial number of French words to English vocabulary; hence the quantity of near synonymous pairs available today: "begin, commence"; "end, finish"; "kingly, royal"; "fight, combat"; and so on.

These historical processes take place without any direct volition on the part of speakers as regards the language itself. Latin was learned as part of personal advancement, not for its own sake. Loans were incorporated almost without their being noticed, along with the concomitant cultural changes and innovations. Deliberate action directly related to a language does occur. The creation of pidgins involves some degree of linguistic consciousness on the part of their first users. More deliberate, however, have been various attempts at preserving the purity of a language, at least for some uses, or at arresting the processes of change. The care bestowed on the preservation of the Sanskrit used in religious ritual in ancient India and recent attempts to free Modern Greek from much of its Turkish vocabulary have already been noticed. For a period, under Nazi rule, efforts were made to replace some foreign words in the German language by words of native origin, and there have been movements to replace later accretions in English by words derived from Old English forms. In the long run, such attempts never succeed in preventing or reversing change; at best they preserve collaterally supposedly purer forms and styles for certain purposes and in certain contexts.

Attempts to prevent or reverse linguistic change

With the picture painted above of the tendency for languages to fragment first into dialects and then into separate languages, it might be thought that dialects are relatively late in appearance in the history of a language family. This impression is reinforced by the fact that most nonstandard dialects are unrepresented as such in writing, and so comparatively little is known about dialectal differences within most languages as one goes back in time. In this respect the very detailed knowledge of the Ancient Greek dialect situation is quite untypical.

In fact, dialect divisions must have been a feature of linguistic communities as early as there is any knowledge of them. Dialect splitting is fostered by isolation and loss of contact between groups within a speech community, and the sparse populations of earlier days, often nomadic and spread over large areas relative to their numbers, will have encouraged this process. It is simply the case that all but literate dialects have been lost in the past, and an artificial homogeneity is attributed to most ancient languages and to the so-called reconstructed parent languages of families.

Present-day conditions tend toward the amalgamation of dialects and the disappearance of those spoken by relatively few people. Urbanization, mass travel, universal education, broadcasting, ease of communication, and social mobility all foster rather large regional and social dialects, with special occupational types of language within them, in place of the small, strictly localized dialects of earlier times. This is one reason for the urgency with which dialect studies are being pursued in many Western industrialized countries, such as England and parts of the United States. If work is not done soon, many dialects may perish unrecorded (see also DIALECTS).

For the same reasons, dialect divisions that earlier would have widened into distinct languages are now unlikely to do so. One may compare the emergence of the separate Romance languages from once unitary Latin with the splitting of South American Spanish and Portuguese into different dialects of these two languages. These dialectal divisions are not now expected to widen beyond the range of intercomprehensibility. These same conditions, together with the spread of literacy, are leading to the extinction of languages spoken by relatively small communities. Such is the fate of most of the North American Indian languages, and Irish, Welsh, and Scots Gaelic may ultimately survive only as learned second languages, preserved as cultural focuses for their communities. But in situations like this, both past and present, the intervening period of extensive bilingualism and the concomitant use of two languages has its effect on the changes taking place in the dominant language, which is influenced by the phonetic and grammatical composition of the speakers' former language.

Extinction of languages

Language typology. Language families, as conceived in the historical study of languages, should not be confused with the quite separate classifications of languages by reference to their sharing certain predominant features of grammatical structure. These classifications of languages give rise to what are known as typological classes.

In fulfilling the requirements of open-ended creativity that are imposed on language by human beings, grammatical structure has things in common in all known languages, particularly at the deeper levels of grammar. All known languages have words or wordlike elements combined in accordance with certain rules into sentences; all known languages in some way distinguish nounlike and verblike sentence components; and all known languages have the means of embedding or subordinating one sentence within another as an included clause (*e.g.*, "the sun set" and "we returned home": "When the sun set we returned home"; "Joan was playing tennis" and "Joan twisted her ankle": "Joan, who was playing tennis, twisted her ankle," or "while she was playing tennis, Joan twisted her ankle").

Descriptive analyses of all the languages of the world have not been prepared, and, of course, there is information about only a minute number of those that are no longer spoken—namely, those few that were written. However, there is enough known to make the assertion of such universal features as have been given with fair confidence. These are often referred to as language universals; their nature and extent is the subject of discussion and research.

Broad types of language structure

Within these very general guidelines, however, languages exhibit various types of structure. This can most readily be seen by comparing the relations between the forms of words and their syntactic functions in different languages. Such a comparison is the basis of three broad types of language that have been distinguished since the beginning of the 19th century. They are, in fact, more like characteristics than they are types, in that most languages contain traces of all three of them, but in different proportions.

Classical Chinese made little or no use of word-form variation, such as is found, for example, in Latin, for grammatical purposes. Sentence structure was expressed by word order, word grouping, and the use of specific grammatical words, or particles. Such languages have been called isolating or analytic. Modern Chinese languages are much less analytic; Vietnamese is probably the most fully representative of this type. Some languages string together, or agglutinate, successive bits, each with a specific grammatical function, into the body of single words. Turkish is a typical agglutinative language: compare Turkish *evleri*, "houses" (accusative case), in which *ev* is the root meaning "house," *-ler* marks plurality, and *-i* is the sign for accusative, with Latin *domūs*, in which *-ūs* combines the representation of accusative and plural without the possibility of assigning either category separately to one part of the word ending. Latin is in this respect an inflectional, or fusional, language. In a more extreme example, Latin *i*, "go!" cumulatively represents in one fused form the verb meaning "go," active voice, imperative mood, second person, and singular number, each a grammatically distinct category.

English, like many other languages, is representative of all three types. In its use of word order alone to distinguish grammatical differences ("the dog chased the cat"; "the cat chased the dog") it resembles Classical Chinese rather than Latin. In a word form such as "manliness," in which each bit can be assigned a grammatical function ("man" the basic noun, *-li-* the adjective formative, and *-ness* the abstract noun formative), it makes use of agglutination, whereas plurals such as "men" and "geese" and past tenses such as "came" and "ran" fuse distinct grammatical categories into a word form in which only arbitrarily can one allot some sound segments, or letters, to one and some to the other.

Assigning languages to different types in this way involves a delicate procedure of balancing one part of the grammar against another and deciding which type of structure predominates and how well the other types are represented. Languages predominantly of each of the types are found in communities at all levels of civilization and in all types of culture.

Change in grammatical structures

In the course of transmission, grammatical structures change, just as do pronunciation and meanings, and in time the cumulative effect may be the transference of a language from one overall type to another, although it remains descended from the earlier language and therefore is just as much part of the same historical family. Latin is very different typologically from French in its grammatical structure, but French is nevertheless the form that Latin took in France in the course of time. In the grammatical relevance of word order, the absence of case inflections in nouns, and the use of verbal auxiliaries instead of single word tense forms, French is more like English, a distant cousin within the Indo-European family, than it is like Latin, its immediate progenitor (compare French *j'ai donné*, English "I have given," Latin *dedi)*. The two sorts of language classification, historical and typological, serve different purposes and are differently based. Language families group languages together on the basis of descent; *i.e.*, unbroken transmission from an earlier common parent language. The evidence is mainly systematic correspondences among the shapes of words of similar meanings (*e.g.*, Greek *patēr*, Latin *pater*, French *père*, German *Vater*, English "father"). Languages are put into typological classes, with the reservation already mentioned, on the basis of certain overall similarities of structure iriespective of historical relations. Although these two classifications may coincide with some languages, as is the case to a great extent in the Bantu family, they do so only contingently; being based on different data and oriented differently, they do not logically or necessarily imply each other.

In a way these two systems of classification involve the two most important aspects in which languages must be seen to be properly understood: as products of a continuous historical process and also as self-sufficient systems of communication in any one period. Both as a component of cultural history and as a central part of culture itself, language is able to reveal, more than any other human activity and achievement, what is involved in mankind's distinctive humanity.

BIBLIOGRAPHY. A bibliography for LANGUAGE is likely to overlap at least partially the bibliography for LINGUISTICS, as well as those given in the related specialist articles. This bibliography draws attention to some books that may be useful without prior specialist knowledge, and that develop in further detail the major topics introduced in the article.

EDWARD SAPIR, ***Language*** (1921, reissued 1970), one of the most appealing books on language ever written; LEONARD BLOOMFIELD, ***Language*** (1933, reprinted 1963), longer and more technical than Sapir's book, but a classic work, though Bloomfield's treatment of semantics is somewhat dated; JEAN F. WALLWORK, ***Language and Linguistics*** (1969), a short introduction to the study of language, and ***Language and People*** (1978), a brief discussion of the social dimensions of language; HERBERT H. and EVE V. CLARK, ***Psychology and Language*** (1977), an introduction to theories of language acquisition; DWIGHT L. BOLINGER, ***Aspects of Language,*** 3rd ed. (1981), a very useful wide-ranging survey of contemporary approaches to the subject; DAVID ABERCROMBIE, ***Elements of General Phonetics*** (1967), and PETER N. LADEFOGED, ***A Course in Phonetics*** (1975), introductions to the linguistic study of human speech; JOHN LYONS, ***Language and Linguistics: An Introduction*** (1981), introduces the reader to some of the most recent significant theoretical developments in linguistics; N. MINNIS (ed.), ***Linguistics at Large*** (1971), a collection of papers on different aspects of language; ROBERT H. ROBINS, ***A Short History of Linguistics,*** 2nd ed. (1979), a brief historical account of the study of language from antiquity to the present. DELL HYMES (ed.), ***Language in Culture and Society: A Reader in Linguistics and Anthropology*** (1964), contains a number of useful articles on the relations between language and life in society.

(Ro.H.R.)

Languages of the World

Languages may be classified either genetically or typologically. A genetic classification assumes that certain languages are related in that they have evolved from a common ancestral language. This form of classification employs ancient records (such as those for Latin) as well as hypothetical reconstructions of the earlier forms of languages, called protolanguages. Because information on the genetic affiliations of languages is sufficiently extensive, world surveys of languages are necessarily oriented in that way—sometimes exclusively so and sometimes in conjunction with typological classifications. Typological classification is based on similarities in language structure. There is not enough known concerning individual frames of reference in language typology to permit a worldwide typological classification.

Typological classifications

Before the conclusive demonstration that unwritten languages could be classified genetically, they were often relegated to a typological classification, which at one time was denigrated by scholars. Since 1917, however, the prestige of some kinds of typology has risen—in particular, that of grammatical typology. The best known typological frame of reference represents the grammar of a language, either as a whole or as a subsystem. Once a genetic classification has been established, typological classification may be superimposed on it in order to show change of language type, as from a predominantly inflectional language (*e.g.*, Proto-Germanic) to a predominantly isolating language (modern English), or to show features that are shared by languages in different but neighbouring branches in the same family (*e.g.*, Celtic and Germanic in Indo-European). The ultimate grammatical typology is that which treats subsystems that are, in one sense or another, universal to all human languages.

Lexical typologies, based on similarities in vocabulary structure, have been used in cognitive anthropology and psycholinguistics (*e.g.*, perception of colours and use of colour terms). The sociolinguistic frame of reference in typology provides classifications for varieties of language in terms of their functions and their ways of identifying social groups and cultural spaces; in addition, it brings order and integration to problems concerning national standards that are faced by new nations that have many nonstandard and nonwritten languages as well as languages that make use of writing.

Families, isolates, and phyla

A few points of terminology should be explained before surveying and classifying the world's languages. Language family is the label often used for a conservative genetic classification, one that can be attested only when an abundance of cognates (related words) is available. Phylum is the label for a liberal genetic classification that is attested with fewer cognates; it encompasses language families. Although a given phylum will have greater extension than any of the families included in it, only fragments of phonology will be reconstructable in the protolanguage. In actual linguistic usage, however, the term family is often employed to refer to a phylum; *e.g.*, the Hamito-Semitic family, the Sino-Tibetan family.

The label language isolate is used for a language that is the only representative of a language family, as Basque or the extinct Sumerian language; the presumptive but unknown sister languages of isolates are dead and unrecorded. A language isolate may be classified, along with normal language families, under the rubric of an extensive phylum (*e.g.*, Korean is sometimes classified as a member of the Ural-Altaic phylum) or left wholly unclassified (*e.g.*, Ainu in Japan). The label pidgin-creole is used for a language that has had so much vocabulary change that cognates for reconstructing the protolanguage from which it descended cannot be found. A pidgin is a contact language used for communication between groups having different native languages. When a pidgin becomes the native language of a community it is customarily called a creole.

This survey treats geographical regions of unequal size: huge and sprawling areas for the peripheral regions of Africa, Oceania, and the Americas but relatively compact areas for the focal regions within the Euroasiatic world. Nine regions—six in Eurasia, in all of which writing and standard languages are widespread—constitute a convenient basis for comparison and contrast. The regions of the Euroasiatic world are: Europe, South Asia, North Asia, Southwest Asia, East Asia, and Southeast Asia.

LANGUAGES OF EUROPE

The great majority of the languages spoken in Europe are of Indo-European and Uralic (especially Finno-Ugric) affiliation. In terms of numbers of speakers, the people in Europe who speak the languages of these families ale now fewer than those in non-European countries who also speak such languages. If a language is to be localized primarily in the region in which most people speak it, than Europe is no longer the chief locale of Spanish, for example, but rather Latin America.

An unusually small degree of genetic diversity is found among European languages: there are fewer language families in Europe than in any other continental-sized region of the world. In addition, literary traditions that have resulted in the preservation of earlier forms of present-day languages are found to a high degree among these languages. Every European language with a writing tradition has developed at least one standard that is recognized nationally, and the national standard often coexists with recognized regional standards.

A few European languages are used internationally, as lingua francas, but there is a low degree of pidgin-creole usage in Europe today.

Typological classifications have been superimposed on genetic classificationr of European languages in particular. For example, the italic branch of Indo-European languages may be grouped with the Greek, Celtic, and Germanic branches on the basis of certain structural features, as can Armenian with Greek and Indo-Iranian, and so forth.

Indo-European languages. The languages of seven of the nine extant branches of the Indo-European language family are spoken in Europe. Variability in determining the number of particular languages reflects variation in the criteria used (*e.g.*, mutual intelligibility between neighbouring dialects, known common or separate history versus sociocultural factors such as separate literary traditions or status as national languages of politically independent units), as well as the time period for which the criteria are applied. Thus, for example, it is possible to say on linguistic grounds that there are nine extant languages in the Romance subgroup of the Italic branch: Portuguese, Spanish, Catalan, French, Romansh, Ladin, Friulian, Italian, and Romanian. In applying the criterion of separate literary tradition, the list would be expanded by the addition of Provençal and Sardinian. To apply the criterion of status as a national language would reduce the list because Ladin, Friulian, Provençal, and Sardinian are not national languages; but the picture is complicated by the fact that Sardinia was once politically independent, and Andorra, in which Catalan is spoken, has not always been independent.

Variables in determining the number of separate languages

Similar difficulties in counting separate languages exist for all the branches in which several languages are spoken. In terms of areas of high mutual intelligibility (which do not entirely reflect historical development), there are only five modern Germanic languages: English, Frisian, Netherlandic-German (including Afrikaans and Yiddish), Insular Scandinavian, and Continental Scandinavian. If literary tradition and national criteria are considered, the number is increased by the division of Netherlandic-German into Standard High German, Low German, Dutch-Flemish, Afrikaans, Luxemburgian, and Yiddish; the division of Insular Scandinavian into Icelandic and Faeroese; and the division of Continental Scandinavian into Norwegian (New Norwegian, or Nynorsk, and Dano-Norwegian, or Bokmål), Danish, and Swedish.

For the Slavic languages there are 13 literary standards, but between the nuclei formed by these literary norms there are scarcely any linguistic boundaries because transitional dialects—both in terms of shared features and intelligibility—connect adjacent areas. In terms of more immediate intelligibility and to some extent in terms of shared features, the Slavic literary norms can be grouped into three zones: East Slavic (Russian, Belorussian, Ukrainian), West Slavic (Polish, Kashubian, Low Sorbian or Lower Lusatian, High Sorbian or Upper Lusatian, Czech, Slovak), and South Slavic (Slovene, Serbo-Croatian, Macedonian, Bulgarian).

Language boundaries are more clear-cut for the modern living languages in the remaining European branches of Indo-European: Celtic (the physical separation of the speakers of the languages contributes to the separate identification of Welsh, Breton, Irish Gaelic, and Scottish Gaelic), Baltic (the literary and political separation coincide with the separation of Lithuanian and Latvian), Greek (the separate historical development and lack of mutual intelligibility separate Modern Greek from Tsakonian), and Albanian (the political unity of Albania contributes to the single-language identification of its two divergent dialects).

Dialects of two languages in the Indo-Iranian branch of Indo-European are or were also spoken in Europe: the Jassic dialect of Ossetic, an Iranian language, formerly spoken in Hungary; and the European dialect of Romany, which spread all across Europe and into America. It may be, however, that only in Wales, Finland, and the Balkans does Romany still serve as the native language of some Gypsies.

Extinct languages

A number of earlier Indo-European languages that died out without descendants are known from written records and comments by contemporaries; these include several in the Italic branch (as Oscan, Umbrian, Faliscan, Venetic), at least two in the East Germanic group (Gothic and that spoken by the Burgundians, Vandals, and others), and three in the Celtic branch (Gaulish, Cornish, and the only recently extinct Manx). The classification as Indo-European or non-Indo-European for many other extinct languages remains uncertain because of the scarcity of data; *e.g.*, Pictish spoken in Great Britain. One form of Minoan, that represented by the Mycenaean Linear B syllabary, was shown to be an archaic Greek dialect when deciphered.

For more information on the Indo-European languages of Europe, see INDO-EUROPEAN LANGUAGES; CELTIC LANGUAGES; ITALIC LANGUAGES; ROMANCE LANGUAGES: BALTIC LANGUAGES; SLAVIC LANGUAGES; GERMANIC LANGUAGES; ENGLISH LANGUAGE; ALBANIAN LANGUAGE.

Finno-Ugric languages. In addition to the Indo-European languages, all but two of the languages of the Finno-Ugric branch of the Uralic family are also spoken in Europe. As in the case of Indo-European languages, variation exists in the enumeration of separate languages. For example, several varieties of Lapp are mutually unintelligible but are often classified as dialects of a single Lapp language. The various types have also been classified according to geographic areas or national boundaries (Norwegian, Swedish, Finnish, and Russian Lapp). In Baltic-Finnic, the Finno-Ugric subgroup most closely related to Lapp, the Finnish, Karelian, Veps, Ingrian, Estonian, Livonian, and Votic languages are often linked by transitional dialects between the central areas of a given pair. The other Finnic languages, Mari (Cheremis) and Mordvin, and both of the languages of the Permic subgroup (Udmurt, or Votyak, and Komi, or Zyryan) are spoken much further to the east, in the central area of eastern European Russia.

Geographic classifications

To the north of these, from the mouth of the Northern Dvina River eastward into North Asia there are speakers of Nenets (Yurak), a language belonging to the Samoyedic branch of Uralic. The remaining Finno-Ugric language of Europe, which belongs to the Ugric subgroup, is Hungarian. See also URALIC LANGUAGES.

Other languages. Maltese. Maltese, spoken on Malta, is an Arabic dialect, so long isolated from other dialects of Arabic and so heavily influenced by Italian that the resultant loss of mutual intelligibility with other Arabic speakers might justify classifying it as a separate Semitic language.

Basque. Basque, spoken in the Pyrenees in Spain and France, is the only other living language of western Europe that does not belong to the Indo-European family. Numerous inconclusive attempts have been made to link Basque genetically with other languages. See also BASQUE LANGUAGE.

Turkic languages. In addition to Turkish, spoken by a number of people in Bulgaria and elsewhere in the Balkans, several languages of the Turkic language group (considered as a branch of the Altaic language grouping) are spoken entirely in eastern Europe. Chuvash, the most divergent Turkic language, is found mainly in the Chuvash Autonomous Soviet Socialist Republic, Tatar in the Tatar A.S.S.R. and adjacent areas and in Romania and Bulgaria, Bashkir in the Bashkir A.S.S.R., Gagauz in the Ukrainian S.S.R. and Moldavian S.S.R. and in the Balkans, and Karaim in the southern Ukraine and Lithuania (spoken by fewer than 1,000 people). Most or all of the speakers of Crimean Turkish were removed to the Uzbek S.S.R. after World War II. See also ALTAIC LANGUAGES.

Extinct languages. The existence of a number of long-extinct non-Indo-European languages of Europe is known through the records of the Greeks and Romans and also through the preservation of varying amounts of written records of them. The most extensive records are those in the still undeciphered Etruscan, which is known to have been spoken in Italy from the 8th century BC to the 4th century AD (see also ETRUSCAN LANGUAGE). Several languages were spoken in the Iberian peninsula, of which Iberian (preserved in a few inscriptions and many coins) was spoken along the Ebro River and at one time as far east as the Rhône River. Also probably non-Indo-European was the language of the undeciphered Minoan Mycenaean Linear A inscriptions found on Crete (see also ANCIENT EPIGRAPHIC REMAINS).

LANGUAGES OF SOUTH ASIA

The genetic classification of the languages of India, Bangladesh, Pakistan, and the border states (*e.g.*, Nepal, Sikkim, and Bhutan) includes two subgroups—Indo-Aryan (Indic) and Iranian—of a single branch of Indo-European (called Indo-Iranian), some indigenous language families (as Dravidian), a few language isolates (as Burushaski), and some Sino-Tibetan languages.

Indo-Aryan (Indic) languages

Indo-Iranian languages. Except for Romany and the few Dardic languages spoken in Afghanistan, all of the languages of the Indo-Aryan (Indic) subgroup of the Indo-Iranian branch of Indo-European are spoken in South Asia. It is difficult to identify language boundaries in the Indo-Aryan group because, between any pair of literary standards, "transitional" dialects grade into one another, with no clear-cut language barriers. The problem is further complicated by the enormous dialect differentiation in most of the Indo-Aryan languages. In terms of lack of mutual intelligibility between literary standards, there are more than 20 Indo-Aryan languages. Although Sanskrit is a classical Indo-Aryan language, preserved in writing, it also enters so deeply into the vocabulary of present-day languages as to become, in some cases, the salient mark differentiating two dialects of one language. Thus, Hindi of India differs linguistically from Urdu of Pakistan chiefly in that the former may be heavily Sanskritized in vocabulary and the latter not.

Ethnolinguistic loyalties may also increase the number of languages distinguished; *e.g.*, the separate recognition of Bengali and Assamese. Most of the Indo-Aryan languages are spoken by many millions of speakers; *e.g.*, Bengali-Assamese, West Hindi, Bihari, East Hindi, Marathi, Lahnda, Maithili, Gujarati, Oriya, Sinhalese (in Sri Lanka [formerly Ceylon]), Sindhi, and Nepali. There are also large numbers of speakers of Indo-Aryan languages (especially West Hindi) in South Africa, the South Pacific, and the American Guianas.

The languages of the Dardic subgroup differ sufficiently from the other Indo-Aryan languages as to be sometimes classified as Iranian rather than Indo-Aryan or as a separate sub-branch coordinate with the Indo-Aryan and Iranian sub-branches. Kashmiri, spoken in Jammu and Kashmir, is the only Dardic language with a literary tradition. Shina is also spoken in Jammu and Kashmir; other Dardic languages, which are spoken mostly in Pakistan, have relatively few speakers.

Speakers of at least four Iranian languages are also found in South Asia, including Pashto speakers in Pakistan and Baluchi speakers in Pakistan and India (see also INDO-IRANIAN LANGUAGES).

Dravidian languages. Although the greatest concentrations of Dravidian speakers are in southern India, the more than 20 languages of this family are widespread in India, and one language, Brahui, is isolated in Pakistan, separated from its nearest sister language by 800 miles.

Four Dravidian languages have long literary traditions and are spoken by many millions: Telugu, Tamil, Malayalam, and Kannada. Tamil speakers are also found in Sri Lanka, Malaysia, Indonesia, Burma, Vietnam, South Africa, and in scattered island and coastal areas around the world. Among other, less widespread Dravidian tongues of India are Gondi, Tulu, Kurukh, and Kui. No convincing remote relationships between the Dravidian family and other families have been proposed (see also DRAVIDIAN LANGUAGES).

Munda languages. The 16 or so Munda languages are all spoken in India. Some scholars classify them as a separate language family; others point to similarities with certain languages of Southeast Asia and include them in an Austro-Asiatic grouping with Mon-Khmer, Vietnamese, and Nicobarese. Santali is the Munda language with the greatest number of speakers (a few million); Mundari, Ho, Sora, Kharia, and Korku have significantly fewer speakers (see also AUSTRO-ASIATIC LANGUAGES),

Nehali, Khasi, Burushaski

Other languages. Nahali, spoken by a few hundred people in the Nimār District of Madhya Pradesh, and Khasi, spoken by fewer than 200,000 people in the Khāsi and Jaintia Hills District of central Assam, may both be language isolates—*i.e.*, the sole known members of their families. Both seem to be remotely related to the Austro-Asiatic languages, however, and some scholars have tentatively classified Nahali as a Munda language. The other language isolate of South Asia, Burushaski, spoken by some 30,000 people in Pakistan, is without even remote known relatives.

Sino-Tibetan languages. Speakers of languages of most of the branches of the Sino-Tibetan language family are to be found in South Asia. All the languages of the Bodo (Bodo-Garo) branch of the Bodo-Naga-Kachin language group are spoken in Assam. Naga (Tangsa) languages are spoken in scattered locations from eastern Nepal into Burma. The Kachin languages are centred in north Burma, but some dialects are spoken in Assam, where there are also some speakers of Kukish (Kuki-Chin) languages and of Burrnish (Burmese-Lolo) languages. Dialects of the various divisions of the Tibetan language are distributed from Kashmir to Bhutan and southward into India (*e.g.*, Balti, Sharpa, Lhoke, Spiti). Speakers of close to 50 Gyarung-Mishmi (or Himalayan) languages are found from northeastern India to northern Assam, with their greatest concentration in Nepal. There is some scholary disagreement as to how the numerous Sino-Tibetan languages should be classified into branches and groups (see also SINO-TIBETAN LANGUAGES).

Tai languages. Some speakers of Khamti, a Tai language, live in Assam, where Ahom, another Tai language, is still used as a ceremonial language in religious rituals but is no longer spoken.

Use of English. In all parts of postcolonial South Asia, including Sri Lanka (formerly Ceylon), some people know English; these speakers, although relatively few in number, are the people most likely to travel to a state in which a South Asian language unknown to them is spoken. Hence, English is de facto the current interstate and international language of South Asia, although many Indians would prefer to adopt another language, such as Hindi or a Dravidian language, as the national language.

LANGUAGES OF NORTH ASIA

The languages of North Asia are those spoken 'from the Arctic Ocean to South Asia and China and from the Caspian Sea and Ural Mountains in the west to the Pacific Ocean in the east. In genetic classification, most languages of North Asia belong either to the Uralic family, to one of the three families of the Altaic language grouping (Turkic, Mongolian, and Manchu-Tungus) or to Indo-European. The genetic affiliations of the Paleosiberian languages, spoken exclusively in this region, are uncertain at present. Scholars have hypothesized that some of the languages may have once been American Indian languages whose prehistoric speakers backtracked from the New World into North Asia. That it is possible for pre-industrial man to go back and forth over Arctic waters is shown by the residence of those Eskimos who are now found on both the Russian and Alaskan shores of the Bering Strait. It has been claimed that all languages indigenous to North Asia, except the Paleosiberian ones and the recently intrusive Russian language, are genetically related in a Ural-Altaic phylum. This liberal classification is questioned by many scholars. Whether or not the three Altaic language groups are related to the Uralic languages, there is no doubt that all the so-called Ural-Altaic languages share many typological features, such as vowel harmony, agglutination (a type of word formation in which word elements are added together but still retain a separate, definite meaning), and a restriction against combining a plural noun with a quantifier (as though, in English, the plural noun "girls" had to appear as a singular noun in the phrase "five girl," rather than "five girls").

Ural-Altaic phylum

Uralic languages. Languages from two branches of the Uralic family are spoken in North Asia; their speakers are few in number. Two of the Ugric languages (the subgroup of the Finno-Ugric branch that includes Hungarian)—Mansi (Vogul) and Khanti (Ostyak)—are spoken on the Ob River and its southwestern tributaries. All of the languages of the Samoyedic branch are spoken in North Asia: Nenets (Yurak), speakers of which are scattered from the mouth of the Yenisey westward to the mouth of the Northern Dvina; Enets (Yenisey), also spoken around the Yenisey; Nganasan (Tavgi), spoken on the Taymyr Peninsula in Siberia; and Selkup (Ostyak), spoken south of Enets between the Taz and Tym rivers. Another southern Samoyedic language, Kamas (Sayan), had only one speaker in 1963 (see also URALIC LANGUAGES).

Altaic languages. Turkic languages. The Turkic languages are remarkable for their lack of diversity in spite of their wide occurrence in all the Euroasiatic regions except South Asia and Southeast Asia. Several of the numerous Turkic languages might be considered as a single language if it were not for the fact that mutual intelligibility between groups is impaired by differential borrowing from the various unrelated languages encountered in different regions. Thus, a Turkish speaker from Turkey might understand or largely understand an Uzbek speaker with more ease than the Uzbek speaker would understand Turkish, which has many loanwords from Persian and Arabic. Educated speakers of Turkic languages are able to read books in other Turkic languages after some adjustment to their varying spelling conventions and sound correspondences. Because such differences are identified with different Turkic ethnic groups, it is customary to identify the larger of these ethnic groups as speaking different Turkic languages, although some degree of intelligibility exists between them, as it does between Uzbek, Bashkir, and Tatar. In addition, some languages have dialects that are transitional between two recognized language groups; *e.g.*, some dialects of Kara-Kalpak are said to be transitional to Turkmen, and others are said to be transitional to Uzbek.

Distribution of Turkic in North Asia

In North Asia, Turkic languages are distributed from the southern extension of North Asia northeastward through central Siberia and include Turkmen in the Turkmen S.S.R., Iran, and Afghanistan; Uzbek in the USSR, mostly in the Uzbek S.S.R., and in Afghanistan; Kirgiz in the Kirgiz S.S.R. and in neighbouring areas from Afghanistan to China; Kara-Kalpak in the Kara-Kalpak A.S.S.R.; and Kazakh in the Kazakh S.S.R. Six or seven Turkic groups immediately north of western Mongolia are much smaller both in terms of numbers of speakers and the area over which they spread; in northern Siberia the Yakut extend from the Yakut A.S.S.R. to include the dialect spoken to the west by the Dolgan. Other Turkic languages are spoken in Southwest Asia, Europe, and East Asia.

Mongolian languages. The Mongolian, or Mongol, languages are dispersed throughout Central Asia from Afghanistan to Manchuria, occupying large parts of North Asia and East Asia. The problem of recognizing language boundaries (*i.e.*, of distinguishing separate languages) in the Mongolian family is complicated by the fact that differences between dialects are exaggerated in areas where Mongolian speakers have borrowed features of different unrelated languages but are minimized in areas where one dialect is spoken as a lingua franca over a wide area. Among the Mongolian languages are Mogul, spoken in Afghanistan, where it has been influenced by Iranian and Turkic languages; Mongour, spoken in Kansu Province of China and in Tibet, with noticeable effects of both Tibetan and Chinese in the language (Paoan, spoken in Kansu Province, is linguistically close to Mongour, but may be a different language); and Daghur, spoken mainly in Inner Mongolia and heavily influenced by Tungus languages. Additional languages include Ordos in Inner Mongolia, Kharchin in China, Oirat in the Sino-Russian border area from the Kirgiz S.S.R. to the Altai Mountains, and Buryat from the Buryat A.S.S.R. into Inner Mongolia. Some degree of mutual intelligibility exists between some of these, but this may in part be the result of the lingua franca use of Khalkha, the official language of the Mongolian People's Republic.

Manchu-Tungus languages. Speakers of the Manchu-Tungus languages are scattered from central interior Siberia to the shores of the seas of Japan and Okhotsk, including the Kamchatka Peninsula and Sakhalin Island. Those not near the coast live generally along the banks of the major rivers—the Yenisey, Tunguska, Khatanga, Lena, Amur, and Sungari. Detailed information on most of the Manchu-Tungus languages is scanty, and language names usually coincide with politico-cultural groups, rather than being based on a comparison of linguistic features or knowledge of mutual intelligibility. Borrowing that resulted from contact with speakers of Samoyedic (Uralic) languages to the west and northwest, Mongolian languages and Chinese to the south, and the various Paleosiberian languages to the north and east has further complicated the subclassification of the Manchu-Tungus languages by increasing the superficial differences among them. Most speakers of Manchu-Tungus languages are bilingual in the official language of their country, and many are replacing their native languages by Russian or Chinese. After the Manchu in China and Manchuria, the next most well known and numerous of the Manchu-Tungus peoples are the Evenki (whose name is sometimes applied as a generic term for all the Tungus tribes). Other groups include the Evens (or Lamuts), Nanay (or Gold), and other tribes with only 2,000 or fewer members. For more information on the Turkic, Mongolian, and Manchu-Tungus languages, see ALTAIC LANGUAGES.

Difficulties in Manchu-Tungus classification

Paleosiberian languages. Most of the so-called Paleosiberian people now live in northeasternmost Siberia in the area between the East Siberian Sea and the Sea of Okhotsk, including the Kamchatka Peninsula, and along the coast of the Sea of Okhotsk as far south as the Amur River, and on Sakhalin Island; peoples of another Paleosiberian group live far to the west along the middle and upper Yenisey River. The languages of the Paleosiberian people form four groups that are not only not related to each other but also have not been demonstrated to be related to any other genetic groups. The northernmost and most widespread of these linguistic groups and the only one that includes more than one living language is the Luorawetlan family, which consists of Chukchi, Kamchadal, and Koryak. Some scholars now classify Kerek and Aliutor as separate languages; these have otherwise been classified as dialects of Koryak.

The Yukaghir family includes one living language, Yukaghir (spoken by a few hundred people south of the Arctic Circle on tributaries of the Kolyma River and in the tundra between the Indigirka and Alazeya Rivers), and one language—Chuvantsy—that was spoken until the 20th century on the Anadyr River. Gilyak, spoken on Sakhalin Island and in the coastal and inland Amur River country of the mainland, has no known linguistic relatives. Ket (or Yenisey-Ostyak) is the only language of the Yeniseian or Yenisey-Ostyak family that is still spoken. The speakers of Ket live along the upper and middle Yenisey River, as did the speakers of its sister languages, Kott (Cottian-Manu), which became extinct in the 19th century, and Assan (Asan) and Arin, both of which became extinct in the 18th century (see also PALEOSIBERIAN LANGUAGES).

Indo-European languages in northern Asia, in addition to Russian, introduced only relatively recently, include the Iranian languages in the southwestern extension of North Asia (Tadzhik Persian in the Tadzhik S.S.R. and Baluchi in the Turkmen S.S.R.) and the long-extinct Tocharian, which penetrated into Central Asia as far as Chinese Turkistan (see also TOCHARIAN LANGUAGE).

Writing and literacy **in this** region. The earliest stimulus toward writing in North Asia was from China. The latest stimulus, from Soviet Russia, has brought literacy to those Altaic peoples whose languages were unwritten in tsarist times. In contrast to the written Altaic languages, the Paleosiberian languages in general remain preliterate. The Soviet educational policy is to encourage the use of native languages for education and for teaching preliterates to write. The standard form of writing Tadzhik, for example, is in the Cyrillic alphabet, and knowledge of this alphabet facilitates later learning of Russian, which is used for supranational communication in modern North Asia. Hence, Russian is the modern lingua franca for North Asia today. In the Mongol Empire of the 13th century, Turkic languages were used as languages of administration across North Asia from the Caspian Sea to Manchuria and, initially, in adjacent Euroasiatic regions conquered by Genghis Khan.

Role of Russian and Soviet policy

LANGUAGES OF SOUTHWEST ASIA

Languages spoken today in the area from Iran westward to the Mediterranean (in Iran, Iraq, Saudi Arabia, Jordan, Syria, Lebanon, and Israel) are Semitic, Indo-European, or Turkic. The languages in the two marginal subareas of Southwest Asia (in Afghanistan and in Turkey and the Caucasus between the Black and Caspian seas) far exceed the languages of Europe in genetic diversity.

At one time, Sumerian, now preserved in writing, was spoken as the first language of civilization in the ancient Near East; this language was neither Semitic nor Indo-European (see also SUMERIAN LANGUAGE). Early literary traditions and literacy for the elite began in this central area of Southwest Asia and extended from the Sumerian, Old Persian, and Akkadian literatures to Asia Minor (Hittite) in the north and to the Nile (Egyptian) in Africa. Akkadian and Persian seem to have been the first two languages put to wide international use.

Indo-Iranian languages. Almost all of the score of living languages of the Iranian subgroup of the Indo-Iranian branch of Indo-European are spoken in Southwest Asia and occasionally extend beyond into neighbouring regions. Persian has three separate literary standards that are not confined to the countries in which they centre (Iran, Afghanistan, and Tadzhik S.S.R.). More than half of the speakers of Pashto live in Afghanistan and the rest in South Asia. Kurdish is spoken in an area extending southward from southern Armenian S.S.R. into Turkey, Syria, Iran, and Iraq. Perhaps two-fifths of the speakers of Baluchi live in Iran and southern Afghanistan. Several other Iranian languages (or dialects) have many fewer speakers; these include Luri and Bakhtyārī, spoken only in Iran, and Munji and Shughni, spoken largely in Afghanistan, with only a few of their speakers in Pakistan or the Tadzhik S.S.R. One Iranian language, Yaghnobi, is spoken only in the Tadzhik S.S.R. Three Iranian languages are spoken almost entirely in the Caucasus: Tat, Talysh (with some speakers in Iran), and Ossetic.

The Dardic subgroups

The half a dozen Nuristani (Kafiri) languages spoken in Afghanistan, sometimes classified as members of the Dardic subgroup of Indo-Aryan, have more recently been classified by some scholars as constituting a separate branch of Indo-Iranian. In addition, some Lahnda (Indo-Aryan) speakers also live in Afghanistan. Two very divergent dialects of another Indo-Aryan language, Romany, are spoken in Southwest Asia—Armenian Romany and Asiatic Romany (the dialect of the Palestinian Gypsies). For more information on the Iranian and Indo-Aryan languages, see INDO-IRANIAN LANGUAGES.

Other languages. The sole language of another branch of Indo-European, Armenian, is spoken predominantly in the Armenian S.S.R., Georgian S.S.R., and Azerbaijan S.S.R., but also in Syria, Lebanon, Iran, Turkey, and in communities of Armenians in the United States, Egypt, and France (see also ARMENIAN LANGUAGE).

The long-extinct languages of the Anatolian branch of Indo-European, including Hittite, were once spoken in Southwest Asia (see also ANATOLIAN LANGUAGES).

Five Turkic languages are spoken primarily in Southwest Asia: Turkish, spoken in Turkey and surrounding countries largely to the north; Azerbaijani, spoken in the Azerbaijan S.S.R. and Iran; Kumyk, Karachay, and Nogay, spoken in the Caucasus. Three Turkic languages spoken predominantly in North Asia are also spoken in Southwest Asia: Uzbek, Turkmen, and Kirgiz.

One language of the Mongolian family is spoken in Southwest Asia—Mogul in Afghanistan; and Brahui, a Dravidian language, has a small fraction of its speakers in Afghanistan and Iran.

Caucasian languages. In addition to the Indo-European and Turkic languages spoken in the Caucasus, there are the over 30 languages belonging to three Caucasian language families. These may he remotely related to each other in a Caucasian phylum, in which the Northeast Caucasian family is more clearly related to the Northwest Caucasian family than the South Caucasian family is to either. Georgian, a South Caucasian language, is the most widely known Caucasian language, with speakers in the Georgian S.S.R., the Azerbaijan S.S.R., and adjacent parts of Turkey and Iran; it is the only Caucasian language with a long literary tradition. Other South Caucasian (Kartvelian) languages are Laz (Chan) and Svan. The Northwest Caucasian (Abkhazo-Adyghian) languages include Kabardian (Circassian), Abkhaz, Abaza, Adyghian, and Ubykh (almost extinct, now spoken by only a few people in Turkey). The approximately 25 languages of the Northeast Caucasian (Nakho-Dagestanian) family are spoken by people living mostly in the Dagestan A.S.S.R. These languages include Chechen, Ingush, Avar, Dargwa, Lakk, Lezgian, and Tabasaran, all of which (except Chechen) have fewer than 500,000 speakers. There is some scholarly disagreement concerning the classification of the Caucasian languages (see also CAUCASIAN LANGUAGES).

Semitic languages. Five Semitic languages are still spoken in Southwest Asia: Arabic; Hebrew, primarily in Israel; dialects of East Aramaic, still spoken in Israel, Syria, Iran, Iraq, and the Armenian S.S.R.; West Aramaic dialects, still spoken in Lebanon and Syria; and Modern South Arabic, spoken in southern Saudi Arabia and on nearby islands. Of the extinct Semitic languages, the best known are Phoenician, Akkadian (Babylonian and Assyrian), Moabite, and Ugaritic (see also HAMITO-SEMITIC LANGUAGES).

LANGUAGES OF EAST ASIA

Conservative versus liberal classification of the languages

Languages in East Asia are those traditionally spoken in China, Japan, and Korea; *i.e.*, those that occupy the region between North Asia and Southeast Asia. A conservative genetic classification reflects immense genetic diversity for East Asia by claiming that Ainu, Japanese, and Korean are neither related to each other nor to any other language in East Asia and that the Chinese languages (or dialects) belong in one family, Miao-Yao languages in another, and Tai languages in still another. A liberal genetic classification leaves Ainu isolated, includes Korean and Japanese in the Altaic family, and classifies some or all of the other groups as Sino-Tibetan.

Altaic languages. Languages from three of the major families of North Asia are spoken in China. Uighur, a Turkic language, is spoken in Sinkiang and Kansu Provinces of China as well as in the U.S.S.R. and southwestern Mongolia. Another Turkic language, Kirgiz, has some speakers in China. Manchu is the best known of the Manchu-Tungus languages and that with the longest literary tradition (dating from as early as 1599). After the Manchus established the last Chinese dynasty in 1643, their language was gradually replaced in most parts of China by Mandarin--except for formal and ceremonial occasions—but it is still spoken in scattered localities in Manchuria and in Chinese Turkistan.

Striking similarities in syntax have led some linguists to postulate a remote relationship between the Altaic languages and Korean and, less frequently, Japanese.

Korean, Japanese, and Ainu. Korean is spoken in Korea as well as by sizable populations in China and Japan (see also KOREAN LANGUAGE).

The Japanese language family includes, besides Japanese, several mutually unintelligible dialects spoken on the Ryukyu Islands by people who are bilingual in Japanese. Japanese is spoken by 100,000,000 people in Japan and by small groups in Taiwan, Brazil, and the U.S., especially in Hawaii (see also JAPANESE LANGUAGE).

Ainu, the remaining language in insular East Asia for which not even a remote relationship with other languages seems likely, is spoken by approximately 16,000 people on Hokkaido Island of Japan, on Sakhalin Island, and on the Kuril Islands.

Chinese language (dialects). Most important in terms of numbers of speakers and their influence on the other languages in East and Southeast Asia are the Chinese languages (often called dialects). In terms of mutual intelligibility among adjacent dialects, there are several Chinese languages: Mandarin, Wu, Cantonese, Hsiang, Kan-Hakka, and Min (or North Min and South Min). Mandarin is the native language of over 70 percent of the Chinese and is spoken as a second language by many of the native speakers of the other languages, both Chinese and non-Chinese, in China. It has traditionally been the language of administration. Although speakers of two different Chinese languages may not be able to understand one another when they talk, communication between them is possible in writing; conversely, the same written message is read aloud differently by speakers of different Chinese languages. The functional advantages of Chinese writing explains its perseverance for four millennia, but these advantages are partly offset by the difficulties each generation must experience in learning the thousands of character signs that are needed for literacy. Traditionally most Chinese were supposed to be illiterate, but with simplified characters and romanization, the majority of the people in the People's Republic are now literate. The Chinese languages are notable for their enormous numbers of speakers, and Mandarin has the largest number of speakers of any of the world's languages (about 525,000,000 native speakers).

A remote relationship in one family (Sino-Tibetan) has been postulated for the Chinese languages and all the other non-Altaic families that have languages spoken in China. There is no doubt that all these languages bear many similarities to Chinese, but it is unknown to what extent such similarities might be the result of borrowing rather than common origin. A remote relationship in an Austro-Tai phylum has been proposed for two of these families (Tai and Miao-Yao) and Austronesian.

Remote relationships in East Asia

Tai and Miao-Yao languages. All of the languages of the Kam-Sui language group, which is related to the Tai family, are spoken in China (in Kweichow, Hunan, and Kwangsi Provinces), with some dialects extending into Southeast Asia. Speakers of Miao-Yao languages are scattered over south central China and extend into Vietnam, Laos, and Thailand. Dialects of the Miao language include Red Miao, White Miao, Green or Blue Miao, and the more divergent Black Miao. The Yao languages are Yao (also called Man or Mien), Laka, and Punu.

Tibeto-Burman languages. The Tibetan, or Tibetic, language group includes at least two Tibetan proper languages spoken in Tibet, Nepal, Sikkim, and India: Central Tibetan, including Lhasa, the standard dialect of Tibet, and Western Tibetan. In addition there are many other languages in Sikkim, Nepal, Assam, India, and Bangladesh that are closely related to Tibetan proper.

Languages that are more distantly related to Tibetan in a Tibeto-Burman branch of the Sino-Tibetan family are spoken in East Asia over the borders of Burma; these languages, often called Burmic, includes dialects of the Burmese-Lolo (Burmish) subgroup (including Burmese) and the Kachin subgroup. For more information on the Chinese, Tibetan, and Burmic languages, see SINO-TIBETAN LANGUAGES.

Three general types of syntax, which partly overlap the liberal genetic classification, can be distinguished among languages in East Asia. First, Ainu is isolated syntactically as well as genetically. The second type is shared by Korean and Japanese. All Chinese languages are strikingly alike in syntax, and this third type is approximated among some non-Chinese languages of the Sino-Tibetan family and among some languages of Southeast Asia whose genetic classification is tentatively indeterminate.

LANGUAGES OF SOUTHEAST ASIA (INCLUDING AUSTRONESIAN)

Genetic diversity in mainland Southeast Asia

Southeast Asia is generally taken to be a region that includes both a mainland subregion, south of China and east of India, and an insular subregion, which includes the insular half of Malaysia, all of Indonesia, and the islands of the Philippines. Virtually all the languages of insular Southeast Asia belong to a single language family—Austronesian (Malayo-Polynesian). Mainland Southeast Asia, on the other hand, has various representatives from the Austro-Asiatic, Tai, and Sino-Tibetan language groups. Hence, genetic diversity is greater in mainland than in insular Southeast Asia. Austronesian languages extend out of Southeast Asia to the most distant culture areas in Oceania (Polynesia and Micronesia), where they are the only languages known aboriginally. One modern Austronesian language (Malagasy) is even spoken on the African side of the Indian Ocean in Madagascar.

Curiously enough, it is in Melanesia, between the Bismarck Archipelago and New Hebrides, that the most diverse Austronesian languages are spoken today; this provides grounds for the conjecture that the Proto-Austronesian language was spoken there millennia ago and that the daughter languages diversified as their speakers migrated over half the world, with Malay and Cham backtracking eventually to the mainland of Southeast Asia, out of which the ancestors of Proto-Austronesian speakers must have come.

In general, the name of the country and the name of the national language are the same in both insular and mainland regions of Southeast Asia. Thus, Pilipino (based on Tagalog) is the name of the national language of the Republic of the Philippines, even though Pilipino is learned as a second language by most Filipinos. The fear in all of Southeast Asia of indirect neocolonial domination motivates continued distrust of the old languages of colonialism—English, French, Dutch, Spanish—and now also of Japanese and Russian. A pidgin-creole—Neo-Melanesian, or Melanesian Pidgin English—is used as a lingua franca by speakers of Austronesian and other languages from southern Papua through Melanesia into Micronesia. This use is now being encouraged in the Australian territories as a bridge to learning English.

Though the languages in the mainland subregion of Southeast Asia are genetically diverse, they show widespread ranges of the same typological features, such as the use of distinctive tones and classifiers, among unrelated or remotely related languages.

Mon-Khmer languages

Austro-Asiatic languages. The Mon-Khmer group includes more than 50 languages—more than any other family that is centred primarily in or entirely in Southeast Asia. Mon-Khmer languages are spoken from Burma to Vietnam. In Cambodia, Khmer (Cambodian) is the official language; its speakers are also found in Thailand. Mon is also spoken in Thailand as well as in Burma.

The language of mainland Southeast Asia with the greatest number of speakers is Vietnamese, spoken in Vietnam and by smaller numbers of speakers in Cambodia, Thailand, and Laos. Muong, spoken in the central highlands of North Vietnam, is recognized as a separate, but related, language.

Classified by some scholars as a northern group of Mon-Khmer languages are several languages spoken in Burma (east of Mandalay), northwest Thailand, northern Laos, and to a lesser extent in northern Vietnam and in China. These are sometimes classified by others as a separate Palaung-Wa, or Salween, family, including Khmu, spoken in Laos and extending into Thailand, and Palaung, spoken in Burma.

Three small groups of related languages in Malaya (sometimes called Malaccan) are considered to be related to the Austro-Asiatic languages. They are the Jahaic, or Semang, languages, spoken in the inland area of northern Malaya and across the border in Thailand; the Senoic, or Sakai, languages, with speakers south of Kuala Lumpur on the coast and inland further south; and the Semelaic, or Jakun, languages, spoken south of the Senoic languages (see also AUSTRO-ASIATIC LANGUAGES).

Tai and Sino-Tibetan languages. At least a dozen languages of the Tai language family are spoken in Southeast Asia: Thai, or Siamese, in Thailand; Lao, in Thailand, Laos, and Cambodia; Yuan, in Thailand; Shan, in Burma; Black Tai (Tai Noir), in Laos and Vietnam; Khün and Khamti, in Burma; and White Tai (Tai Blanc), Tay, Nung, Tho, and Kelao (Ch'i-lao), all in Vietnam.

Over 8,000,000 Chinese are distributed throughout Southeast Asia; of these, almost 4,000,000 are in Thailand, 3,000,000 in Vietnam, and smaller numbers in Burma, Cambodia, and Laos.

Of the other language groups in the Sino-Tibetan family in Southeast Asia, the Burmese-Lolo (Burmish) group has the widest distribution and the greatest number of speakers. Burmese is spoken as a second language by perhaps 90 percent of those in Burma who have another first or native language. The Lolo languages are spoken in Burma, Thailand, Laos, and Vietnam; they include Lisu, Lahu, Akha, Mung, Punoi, Pyen, and others, a few of which extend into Assam. Karen languages are spoken in Burma and Thailand and include Sgaw, Pho, Pa-o (or Taungthu), and Palaychi. Most of the languages of the Kuki-Chin (Kukish) group are spoken in Burma. Kachin languages are also spoken in Burma (see also SINO-TIBETAN LANGUAGES).

Nicobarese and Andamanese

Insular language groups. In insular Southeast Asia one small language group, Nicobarese, consisting of the languages spoken on the Nicobar Islands, is, in a liberal classification, classified as Austro-Asiatic. The other insular family, Andamanese, consisting of the languages spoken on the Andaman Islands by perhaps fewer than 200 people, has only recently been supposed to be remotely related to the Papuan languages of Melanesia.

Austronesian languages. There are perhaps 500 languages in the Austronesian (Malayo-Polynesian) family, spoken in Malaysia and the Indonesian archipelago; the Philippines; parts of Vietnam, Cambodia, and Taiwan; on the main island groups of the South and Central Pacific; on New Guinea; and on Madagascar. According to one classification, these languages include, in addition to small subgroups, at least two large subgroups: Western Austronesian (or Indonesian) and Eastern Austronesian (often called Oceanic), which includes the Polynesian languages and some of the Melanesian and Micronesian languages. Those Austronesian languages spoken on the Southeast Asian mainland (Malay in Malaysia, Cham and eight other languages mostly in Vietnam, with speakers of some of them also in Cambodia) belong to a Western Indonesian subgroup, which includes Javanese, Sundanese, and Malay, including Bahasa Indonesia, the national language of Indonesia. Closely related to the Western Indonesian subgroup is the subgroup comprising around 100 languages of the Philippines and a few languages of northern Borneo and northern Celebes (including Tagalog, which includes Pilipino, the national language of the Philippines, and Cebuano, Ilongo, and Ilocano). Classed with the West Indonesian and Philippine languages are a small group of languages of Celebes (*e.g.*, Buginese and Makasarese), a few languages of Borneo, and Malagasy (used on Madagascar).

Languages of Polynesia

The languages of Polynesia, including Maori in New Zealand, Tongan, Tahitian, and Hawaiian, form a subgroup that is part of a larger Eastern Oceanic subgroup of over 100 languages, which includes besides the Polynesian languages such languages as Fijian and a number of languages of the Solomon Islands. At least seven of the languages of Micronesia (including Gilbertese, Trukese, and Ponapean) form another subgroup. There are more than 100 Austronesian languages in New Guinea and more than 100 Austronesian languages, not counted as Eastern Oceanic, that are spoken on smaller islands of Melanesia. Those few with as many as 10,000 speakers are all used as lingua francas in wider areas than those of their native speakers (Dobu in the D'Entrecasteaux Islands, Banoni in southwestern Bougainville, Panayati in the Louisiade Archipelago), Among the Austronesian languages still spoken on Formosa are Ami, Atayalic, Paiwan, and Bunan. There is some scholarly disagreement concerning the classification of the Austronesian languages (see also AUSTRONESIAN LANGUAGES).

NON-AUSTRONESIAN LANGUAGES OF OCEANIA

In effect, the non-Austronesian language areas of New Guinea and Australia together constitute a wedge in the midst of three Austronesian areas: Polynesia to the east, Micronesia to the north, and Indonesia to the west. A few non-Austronesian languages are found on the Indonesian islands nearest to New Guinea (on Halmahera as well as on Timor and Alor).

An exceptionally liberal genetic classification claims that the many non-Austronesian languages in Melanesia and the few in Indonesia all belong to one phylum. Conservative classifications recognize several or even many different language families and avoid the older name for them (Papuan), because it might suggest either that the unrelated families of non-Austronesian languages are branches of one Papuan family or else that non-Austronesian languages are found only in New Guinea (where Papua is the name of a political territory). On the other hand, no classification is challenged when it is said that all Australian languages are ultimately related and that they are related neither to Austronesian nor to non-Austronesian languages outside of Australia.

Multilingual societies of Melanesia

In Melanesia, in essence the non-Austronesian world beyond Indonesia, there is much contact between Austronesian and non-Austronesian languages. Many of the Melanesian societies are multilingual, especially those in New Guinea; in addition to their native language, speakers often learn a few secondary languages—those of their immediate neighbours or, most frequently, Neo-Melanesian (a pidgin-creole with an English-based lexicon), or both. In part of Papua, Police Motu, a pidgin based on an Austronesian language, is used as a lingua franca far beyond the territory of the few thousand native speakers of Motu. In Australia the same interest in mastering a multiplicity of languages is widespread, and Aborigines have developed another English-based pidgin-creole, quite different from Neo-Melanesian. Another parallel between Australian languages and the non-Austronesian languages north of Torres Strait is the disinclination of both to recognize or develop any one dialect of a language as a standard.

Papuan languages. Several hundred Papuan or non-Austronesian languages extend from the Santa Cruz Islands north and west into the Solomons and the Bismarck Archipelago, across New Guinea to Halmahera, Timor, and Alor. Until the late 1950s all discussions of the languages of New Guinea that treated more than small, closely related groups of languages stressed the fact that the hundreds of languages spoken in a comparatively small area seemed to be completely unrelated to each other except for a few groups of immediate neighbours. Until then, little was actually known about more than a few of the languages of New Guinea. This situation was changed in the 1960s, with the publication of further survey work in the Highlands Districts, which stated explicit relationships among a large group of languages.

Since the initial recognition of this fairly large group of related languages in the Highlands, called the East New Guinea Highlands phylum, more and more languages of New Guinea have been found to be at least remotely related to it (in a Central New Guinea phylum). It must be kept in mind, however, that it is difficult to enumerate languages and families among the Papuan languages because too little information has been obtained for most of the languages to identify language boundaries or make possible detailed comparisons. There remain a number of families and isolated languages that seem not to be related to other Papuan languages. A new liberal classification presented by the U.S. linguist Joseph Greenberg in 1971, however, treats all the Papuan languages as genetically related in an Indo-Pacific phylum, which also includes Andamanese. Most Papuan languages are spoken by only a few hundred to a few thousand speakers (see also PAPUAN LANGUAGES).

Indo-Pacific phylum

Australian aboriginal languages. All of the aboriginal languages of Australia are remotely related to each other. A few dozen of the 200 or so Australian languages still spoken account for 90 percent of the total number of speakers; these include the Aranda languages, Tiwi, Walbiri, and Western Desert, two languages spoken by over a score of separately named small groups scattered over a territory 900 miles long. Scores of languages are now spoken by fewer than six people each. The greatest diversity among the languages is found in extreme northern and northwestern Australia (Arnhemland and the Kimberley District); a single remaining family (Pama-Nyungan). with 177 languages, is distributed over the rest of Australia (see also AUSTRALIAN ABORIGINAL LANGUAGES).

In grammatical typology the non-Austronesian languages north of Torres Strait are heterogeneous, while the Australian languages are syntactically homogeneous and almost identical in patterns of sound combinations. Both Australian languages and non-Austronesian languages have dialects that are linked in a chain such that speakers at either end do not understand the vocabulary of speakers at the other end, although speakers of adjacent dialects can understand each other.

The two or more languages that were spoken on Tasmania until the later part of the 19th century are not related to Australian languages, but may belong to the Indo-Pacific phylum.

LANGUAGES OF AFRICA

European languages in Africa

Languages that came into Africa from another homeland include, among others, all the European languages associated with 19th-century colonialism. Although the majority of countries in Africa regained their freedom in the 1960s, they continue to use the European languages of the colonial period along with the numerous languages indigenous to Africa. Languages from Southwest Asia preceded the languages of European colonization: migrations of peoples to North Africa brought the Ethiopians almost three millennia ago and the Arabic speakers many centuries ago. The Phoenician circumnavigation of Africa in ancient times left traces—Phoenician coins—on the coasts but none in the interior. And long ago migrants from Indonesia reached Madagascar, 250 miles off the African coast. Before and during the colonial period, Arab and Indian traders reached East Africa, where today a few Indo-Aryan languages are spoken among Asian businessmen. The interior of Africa was not known to any non-Africans before the colonial period, but its prehistory can now be partially reconstructed. For example, there is evidence that the homeland of the protolanguage of the numerous Bantu languages was in Cameroon or an adjacent area in West Africa (or in both areas); that a prehistoric migration brought the Bantu speakers to Central and East Africa; and that these Bantu forced the speakers of Bushman and Hottentot languages to leave their homeland around Lake Victoria and move south to the Kalahari.

In all the postcolonial nations today, either English or Arabic or French serves both as an international language and as a functioning national language. The question still unresolved for many African nations concerns which of their indigenous languages to develop through writing and to standardize as the official language or languages of education and of the political state. The numerous pidgin-creoles, as Krio, are recent and colonial in inspiration; Sango in the Central African Republic is surely indigenous but not so surely a pidgin-creole. Most of the dozen or so languages used in trade, as Swahili in East Africa and Hausa in West Africa, tend to have great changes in vocabulary like pidgin-creoles, but they are not classified as pidgin-creoles; instead they are varieties of normal languages that function as lingua francas. Lingua francas of one sort or another are a prerequisite for the markets found throughout tribal and peasant Africa.

Despite the genetic diversity in South Africa and the even greater diversity in West Africa, a part of each of these subregions can be shown, on the basis of typology, to be a linguistic area. Thus, most linguists have found that most languages in West Africa distinguish vocabulary items and word elements by tone; in South Africa the clicks characteristic of Khoisan languages are also found among neighbouring Bantu languages like Xhosa and Zulu. The early use of typology to anticipate genetic classification, however, led to the claim that Africa was full of mixed languages—*e.g.*, Mbugu in Tanzania. But Mbugu, despite having borrowed Bantu prefixes and culture words from Bantu, can be shown to have a single line of origin—to have descended from a single protolanguage (Proto-Cushitic)—on the basis of its grammatical constituents (pronouns and verb forms) and basic vocabulary items that are cognate with other Cushitic languages.

Five branches of the Hamito-Semitic language family in Africa

Hamito-Semitic languages. The Hamito-Semitic (Afro-Asiatic) language family (considered a phylum by some) includes five branches spoken across North Africa from Mauritania to Somalia and beyond into Southwest Asia: Chad, Semitic, Cushitic, Berber, and the now extinct Egyptian-Coptic. The Chad branch consists of over 100 languages spoken in Nigeria, Niger, Cameroon, Ghana, Chad, and the Central African Republic. By far the most widespread is Hausa, estimated to be spoken by as many as 25,000,000 people, for at least one-third of whom it is a second language.

Five Semitic languages are spoken in Africa, if modern colloquial Arabic is counted as a single language throughout its range across North Africa and the Arabian Peninsula and if Gurage in Ethiopia is also counted as a single language. The Semitic languages in Ethiopia include Amharic, Tigrinya, Tigré, and Gurage (but the people grouped as Gurage may be speaking several separate languages).

Cushitic languages are spoken in Ethiopia, Somalia, The Sudan, Tanzania, and Kenya. The languages with the greatest number of speakers are Galla in Ethiopia, Somali in Somalia and Ethiopia, Sidamo, Hadya, and Afar-Saho. Some scholars consider a group of languages traditionally classified as Cushitic to be a separate branch of Hamito-Semitic, called Omotic. Spoken in Ethiopia, they include Welamo, with far more speakers than the other Omotic languages, Ari, Shako, Zaysse, and others with only a few thousand or a few hundred speakers.

The languages of the Berber branch are spoken from the western desert of Egypt west to the Atlantic and extend to Senegal on the coast and to northern Nigeria in the interior. One language that may have been Berber, Guanche, was formerly spoken on the Canary Islands. Berber languages include Shilha (Shluh), spoken in Morocco; Tuareg (Tamashek) in Algeria, Libya, Niger, and Mali; and Tamazight in Morocco and Algeria (see also HAMITO-SEMITIC LANGUAGES).

Nilo-Saharan languages. The Nilo-Saharan languages in central interior Africa include the Chari-Nile languages and others that are not closely related to each other or to the Chari-Nile group. (The validity of this grouping has been questioned.) The largest Chari-Nile division, Eastern Sudanic, includes over 60 languages, which are spoken from Chad to Kenya and Tanzania; it includes a group of languages often classified as a separate family or branch (Nilo-Hamitic), which appears in some classifications in the Hamito-Semitic family rather than the Nilo-Saharan one.

Among the major Eastern Sudanic languages are Teso in Uganda and Kenya, Dinka in The Sudan, Luo in Kenya and Tanzania, and Lango in Uganda. Only 4 of the 30 or so languages of the Central Sudanic subgroup of Chari-Nile are spoken by groups of over 100,000 people: Sara in Central African Republic and Chad, Lugbara and Lendu, in Uganda and Congo, and Mangbetu in Congo.

Among the Nilo-Saharan languages that are not classified as Chari-Nile is the Saharan group. Kanuri, its largest member, is spoken by 2,500,000 people in Nigeria, Niger, Cameroon, and Chad. In the Maba group, Masalit is spoken by 100,000 people in The Sudan. Songhai, often classified as a language isolate, is spoken by 400,000 people in Niger, Mali, Upper Volta, Nigeria, and Dahomey. Fur, also sometimes considered as an isolate, is spoken by over 170,000 people, mostly in The Sudan.

Bantu languages

Niger-Congo languages. Languages in the Niger-Congo (or Niger-Kordofanian) family are spoken all across Africa from Mauritania to Kenya and south into South Africa. There are almost 900 Niger-Congo languages, which have been classified into six genetic subgroups. The Bantu languages (of the Benue-Congo subgroup) far outnumber those of any other family in Africa, both in terms of number of languages and in terms of number of speakers per language (except that the total number of speakers of a single Semitic language, Arabic, exceeds the total of over 55,000,000 speakers of Bantu languages). Fifteen Bantu languages are spoken by more than 1,000,000 people; the following each have a few million speakers: Swahili, Rwanda, Rundi, South Sotho, Luba-Lulua, Xhosa, and Zulu. Other subgroups in the Niger-Congo family include only a few dozen languages, as those in the Mande subgroup in West Africa, which are spoken from Mauritania to Ghana (including Bambara, Mende, and Vai). The Gur (Voltaic) languages, spoken from Mali and the Ivory Coast to Nigeria, include Mossi, with 2,000,000 speakers, and numerous other languages with significantly fewer speakers. The West Atlantic languages, spoken from Senegal to Nigeria, include Fulani, spoken by 4,500,000–6,000,000 people (estimates vary), Wolof and Temne (each with over 500,000 speakers), and several other languages of less numerical import. Of the languages of the Adamawa-Eastern subgroup, spoken from The Sudan to Cameroon, only Sango, through its use as a lingua franca, may be known by as many as 1,000,000 people. The Kwa subgroup of Niger-Congo includes Twi (Akan), Yoruba (in Nigeria and extending into Dahomey), and Igbo (also known as Ibo; in Nigeria), each of which has over 1,000,000 speakers. Some scholars link the Kordofanian languages of Kurdufān Province in The Sudan with the Niger-Congo languages in a Niger-Kordofanian phylum.

Khoisan languages. The Khoisan family consists of about four dozen languages spoken in southern Africa and two click languages (Sandawe and Hadza) spoken in Tanzania that are not closely affiliated with any one group in the Khoisan family. Uncertainties in the number of languages and the number of language groups arise from the profusion of labels for various groups and the lack of detailed linguistic comparisons among large numbers of them. Most of the Khoisan languages have been considered to be on the verge of extinction, if not known to be already extinct, but recent estimates of the numbers of peoples grouped on the basis of their culture (Hottentot and Bushman) show many thousands of speakers. The Khoisan language estimated to have the most speakers is Nama, with about 40,000. For more information on the Nilo-Saharan (Chari-Nile), Niger-Congo, and Khoisan languages, see AFRICAN LANGUAGES.

LANGUAGES OF THE AMERICAS

Languages indigenous to the Americas were brought from Asia by the forebears of modern American Indians (including Eskimos), who left Asia after the dog was domesticated but before other animals were domesticated. Something is known about the culture of these Indians but nothing about their languages, which are known only after contact with European languages.

European languages in the Americas

Today there are six European languages in the Americas that serve as languages of both education and government administration. (Only one Indian language, however, functions in this dual role—Guarani of Paraguay.) These official languages and their number of primary political divisions are Spanish (18), Portuguese (1), Dutch (3)—all in Latin America and the Caribbean; English (2 in North America and 5 in the Caribbean);

French (1 in North America and 3 in the Caribbean); and Danish (1 in Greenland). Before the colonial period in Latin America and during the first century or two of that period, the following American Indian languages could also be classed as official or semi-official: Nahuatl (Nahua), the language of the Aztecs in Mexico and Central America; Chibcha-Muisca in Colombia; Quechua, the language of the Incas, in the Andean area; Tupí in Brazil; and Guarani in and around Paraguay. In addition to American Indian languages, two pidgin-creole languages are official in their own political divisions, Sranan (Taki-Taki) in Surinam and Papiamento in Curaçao. Other pidgin-creoles in the Caribbean, such as Haitian Creole, are being increasingly written.

Genetic diversity among languages of continental-sized areas can be expressed in terms of the number of minimum genetic classes taken as the usual basis for discussion by specialists of that area. Research may lead to a downward (or upward) revision, and a new number of minimum genetic classes is used as a basis for further discussion. For North America (north of Mexico) and for the 20th century, the basis for discussion has shifted three times so far: from about 50 families in the classification of the U.S. scholar J.W. Powell to six phyla in the classification of the U.S. anthropological linguist Edward Sapir, which was revised at the 1964 Conference on North American Indian Languages by splitting and reclassification (*e.g.*, of Sapir's Hokan-Siouan) and by merging (*e.g.*, the Muskogean family and a few isolates were added to Algonkian in the new Macro-Algonkian phylum). This third classification is summarized below. Proposals for a minimum number of genetic classes in South America range from more than 100 families to three phyla (in a recent liberal classification).

The Plains Indian sign language (hand talking) is still known, but Chinook Jargon and other pidgin-creoles in North America fell into disuse as soon as American Indians became bilingual in English, French, or Spanish.

Ten culture areas of North American Indians

North and Central American Indian languages. For North America north of Mexico, the summary of culture areas (before any American Indians were relocated by Europeans) by the U.S. anthropologist Harold E. Driver is a convenient basis on which to superimpose the various ways in which language classifications (genetic and typological) combine with cultures that are ecologically adapted to each of ten areas—the Arctic, Subarctic, Northwest Coast, Plateau, Plains, Prairies, East, California, Great Basin, and Southwest. The three variables (genetic, typological, and cultural) coincide approximately in the Arctic (the one language family, Eskimo-Aleut, does not include typologically diverse languages, but it does spread over a culture area that is not entirely homogeneous). In the Subarctic two language families are represented, Algonkian and Athabascan, which are distinct typologically as well as genetically. Northwest Coast and adjacent Plateau languages are genetically very diversified but surprisingly homogeneous in a diffusional kind of phonological typology. The languages in the treeless Plains and the midwestern Prairies are genetically and typologically diverse; all the language families represented, except Caddoan, are intrusive in the sense that their homelands lie outside the Plains and Prairie areas.

Language families in the East give an impression of a little typological similarity combined with considerable genetic diversity. On the opposite coast, California is surprisingly homogeneous in culture and in language typology but heterogeneous in genetic classification of languages. There are few languages and only two language families represented in the Great Basin, which is homogeneous in all respects. The adjacent Southwest is anomalous in all three variables considered here. Where it is culturally homogeneous, as between Pueblo societies, it is genetically and typologically diverse in language: four different language families are represented in Pueblo societies. Non-Pueblo societies of the Southwest are diverse culturally as well as linguistically.

Eskimo-Aleut. The three languages of the Eskimo-Aleut family are still spoken in their prediscovery areas from Greenland to Siberia and also on Komandor Island between the Aleutians and Kamchatka (see also ESKIMO-ALEUT LANGUAGES).

Athabascan. Over 20 languages of the Athabascan family are still spoken in four different culture areas: the Yukon and Mackenzie areas of the Subarctic (the centre of Athabascan diversity, with 17 living languages, including Chipewyan-Slave-Yellowknife and Carrier), the Northwest Coast (where only Hupa and Chasta Costa may still be spoken), the Southwest (where the Navajo dialect of what may be considered a single Southwestern Apachean language has more speakers than any other Indian language north of Mexico), and the Plains (where two Athabascan languages are more recently intrusive—Sarcee [Sarsi] from the Subarctic and Kiowa Apache from the Southwest). Three language isolates spoken in the Northwest Coast (Eyak, Tlingit, and Haida) are remotely related to Athabascan in the Na-Dené phylum, but Eyak is so much more closely related to the Athabascan family that it might be considered a divergent member of the family.

Macro-Algonkian phylum

Algonkian. The Algonkian family includes 13 languages still spoken, which belonged in the culture areas of the eastern Subarctic (*e.g.*, Cree, Ojibwa, Micmac, Malecite), the Prairies (*e.g.*, Fox, Potawatomi), the Plains (*e.g.*, Blackfoot, Cheyenne, Arapaho), and the East (where most Algonkian languages became or are now becoming extinct, with only the removed Shawnee and Delaware surviving in Oklahoma). Remotely related to the Algonkian languages in a Macro-Algonkian phylum are languages spoken further to the south in the East—the Muskogean family (including Choctaw-Chickasaw and Creek-Seminole) and several language isolates that are no longer spoken, as well as two almost extinct languages of the Northwest Coast that are more closely related to Algonkian (Wiyot and Yurok).

Macro-Siouan. The Macro-Siouan phylum is named for its most extensive component, the Siouan family, the extant languages of which belong in the Plains and Prairies, including Dakota, Crow, Winnebago, and Omaha-Osage. (The Siouan languages of the East, such as Ofo and Biloxi, are no longer spoken.) Less widely distributed than Siouan is the Iroquoian family (six languages, largely of the East, including Cherokee and Mohawk), the Caddoan family (Caddo in the East, Wichita and Pawnee in the Prairies), and two language isolates of the East (Catawba and Yuchi), more closely related to Siouan than to the other families in Macro-Siouan.

Hokan. The Hokan phylum includes several small families and a number of language isolates scattered from the Northwest Coast through California, with extensions into the Great Basin and the Southwest, and as far south as Meso-America. Hokan languages spoken by the greatest numbers of speakers include those in two families in Mexico, the Tlapanecan and Tequistlatecan, and in the Yuman family in Arizona and California.

Penutian. The Penutian phylum is the only group of languages in North America for which relationships with languages in South America have been traced convincingly. The Penutian languages are thus distributed from the Northwest Coast and Plateau areas through California (with a possible extension into the Southwest) and Meso-America into Bolivia, Chile, and Argentina. Many of the more than 24 Penutian languages north of Mexico are either no longer spoken or are spoken by fewer than ten people. In Meso-America, however, many native languages have a considerable number of speakers; *e.g.*, Mixe, in the Zoque family, has over 30,000 speakers, and the Mayan family includes some languages with several hundred thousand speakers, as Maya, Quiché, Kekchi, Cakchiquel, and Mam.

The Tanoan and Uto-Aztecan families

Aztec-Tanoan. The Aztec-Tanoan phylum consists of two families: the Tanoan (Kiowa-Tanoan) family with three languages in the Southwest, including those spoken by the Taos and the Santa Clara, and one language in the Plains (Kiowa); and the Uto-Aztecan family, with about a score of languages spoken from the Plateau and California into Meso-America, with relatively late extensions into the Plains. California Uto-Aztecan languages include Cahuilla and Luiseño; Great Basin languages include Paiute and Shoshoni, with the Ute and Comanche dialects in the Plains; Southwestern languages include Hopi and Pima-Papago; Meso-American languages include Nahuatl, the language of the descendants of the Aztecs. The million speakers of the several varieties of Nahuatl far outnumber the total number of speakers of all the other Uto-Aztecan languages.

Oto-Manguean. Languages of one North American phylum are located entirely in Meso-America—the Oto-Manguean phylum, consisting of five small families. The languages with the largest number of speakers are Otomí, Mixtec, and Zapotec.

Unaffiliated languages. In North America one large family (the Salish family in the Northwest Coast and Plateau) and several smaller families and language isolates (as the Wakashan family in the Northwest Coast and Tarascan in Meso-America) remain undetermined in phylum affiliation. Remote relationships that have been proposed for some of these are in conflict with other proposed relationships, with no overwhelming evidence presented for any one of the proposals.

South American Indian languages. Language names for South America are much more numerous than those for North America, but information on actual languages is generally sporadic and often lacking entirely. Even when the list of names is reduced to 350 for languages said to be still spoken, the data to which the names refer consist, for the most part, of brief word lists; or nothing more may be known than the fact that a tribe X is said to speak differently from a tribe Y. Though it is possible to know that certain languages are probably closely related, it is not always possible to say how closely; *i.e.*, whether they might be dialects of, or occasionally just different names for, the same language. At the opposite extreme of genetic relationship, it is clear that there are large groups of remotely related languages, but the paucity of data makes possible conflicting proposals. For at least one group of languages, those of the high cultures of South America—the Inca and the Aymara—and some of their neighbours, the problem of establishing genetic relationship is complicated by the problem of sorting out borrowings among them.

Andean-Equatorial phylum

The Andean-Equatorial phylum includes the greatest number of still-spoken languages (almost 200) and the three South American Indian languages with the greatest number of speakers (Quechua, Guarani, and Aymara). The living Andean-Equatorial languages comprise some 14 families and several language isolates. The Arawakan family includes the most languages—around 100—and has the widest distribution: across northern South America from French Guiana to Colombia and southward as far as Paraguay; formerly, Arawakan languages were also spoken in Central America and the islands of the Caribbean. Most Arawakan languages are spoken by not more than a few hundred people. More than two dozen languages of the Tupian family are still spoken over a large part of South America, mostly south of the Amazon River. Tupian languages include Guarani (Tupi-Guarani), spoken in a number of dialects by about 2,900,000 people in Paraguay, Brazil, Argentina, and Bolivia. Quechua, of the Quechumaran group, is spoken by around 12,000,000 people in Peru, Ecuador, Colombia, Bolivia, Argentina, and Chile. Some Quechua dialects are so divergent that they might be regarded as separate languages. The other Quechumaran language group, Aymaran, is spoken by about 1,900,000 people in Peru and Bolivia. Most other languages in the Andean-Equatorial phylum are spoken by only a few thousand persons.

The Ge-Pano-Carib phylum includes almost as many languages still spoken as the languages of the Andean-Equatorial phylum, but the former are all spoken by relatively small tribes, so that the total number of speakers of these languages is only a small fraction of the number of speakers of Andean-Equatorial languages. In terms of numbers of languages, the largest family in the Ge-Pano-Carib phylum is the Cariban (Carib) family, with some 60 languages still spoken in Venezuela, the Guianas, Brazil, and Colombia. Cariban languages were also formerly spoken in the Caribbean islands. Most Cariban languages have no more than 1,000 speakers. The other large family in the phylum, the Macro-Ge family, includes more than 25 languages in Brazil.

The languages of the Macro-Chibchan phylum, of which 39 may still be spoken, are distributed from Guatemala and Honduras southward into, and possibly beyond, Peru. The largest component of the phylum is the Chibchan family, of which 16 languages are still spoken from Nicaragua to northwest Colombia—these include Cuna, spoken on the Mulatas (San Blas) Islands of Panama as well as on the mainland of Panama and Colombia; Guaymi, spoken in Panama; and Paez in Colombia. For further information on the Indian languages of the Americas, see NORTH AMERICAN INDIAN LANGUAGES; MESO-AMERICAN INDIAN LANGUAGES; SOUTH AMERICAN INDIAN LANGUAGES.

BIBLIOGRAPHY. E.H. STURTEVANT, ***Linguistic Change*** (1917, reprinted 1961), was an important text in Indo-European comparative linguistics, until replaced by WINFRED P. LEHMANN, ***Historical Linguistics: An Introduction*** (1962). EDWARD SAPIR, ***Language: An Introduction to the Study of Speech*** (1921, reprinted 1957), presents a revision of the 19th-century whole-language typology. For an example of modern application of subsystem typology, see A.K. RAMANUJAN and COLIN MASICA, "Toward a Phonological Typology of the Indian Linguistic Area," in ***Current Trends in Linguistics***, vol. 5, pp. 543–577 (1969); and for an example of lexical domain typology, see BRENT BERLIN and PAUL KAY, ***Basic Color Terms: Their Universality and Evolution*** (1969). ANTOINE MEILLET and MARCEL COHEN (eds.), ***Les Langues du monde***, new ed. (1952), is a survey of languages of the world organized in terms of their genetic classification. Languages are also classified genetically in two more recent surveys: C.F. and F.M. VOEGELIN, "Languages of the World," in ***Anthropological Linguistics***, vol. 6–8 (1964–66); and THOMAS A. SEBEOK (ed.), ***Current Trends in Linguistics***, 13 vol. (1963–75)—individual volumes deal with geographic areas, and typological information on particular languages is presented. JOSEPH H. GREENBERG, "The Indo-Pacific Hypothesis" (pp. 807–871), and S.A. WURM, "The Papuan Linguistic Situation" (pp. 541–657), both in ***Current Trends in Linguistics***, vol. 8 (1971), exemplify variation in proposals for remote genetic relationships among the same set of languages. EDWARD SAPIR, 'Central and North American Languages," in ***Encyclopædia Britannica***, 14th ed. (1929), presented a classification of these languages in terms of six phyla; this classification was revised by a conference of specialists that resulted in the publication of c.~and F.M. VOEGELIN (comps.), ***Map of North American Indian Languages***, rev. ed. (1967). The culture areas of North American Indians are described in HAROLD E. DRIVER, ***Indians of North America***, 2nd ed. rev. (1969). See also the bibliographies for the various language and language family articles mentioned in the text.

(C.F.V./F.M.V.)

Laos

Laos is a small, landlocked, undeveloped country on the Indochinese Peninsula. It is bounded on the north by China, northeast and east by Vietnam, south by Cambodia, and west by Thailand and Burma. Following the contour of the Indochinese Peninsula, Laos extends more than 600 miles from northwest to southeast, with a total area of approximately 91,400 square miles (236,800 square kilometres).

In the 1950s Laos became a focus of struggle among the major powers of the world. Despite international agreements to neutralize and isolate the country from external threat and to support its unity and development, Laos continued until 1975 to be the scene of others' battles, and then became the object of political competition between Vietnam and the Soviet Union, on one hand, and the People's Republic of China, on the other, while its own people remained divided and in conflict.

Located in an area of strategic importance among contending powerful neighbours, Laos has neither the natural barriers nor a population large enough to withstand foreign encroachment. The majority of its estimated 3,546,000 people live in the lowlands and in the valley of the Mekong River in the western and central part of the country. The remainder live in small groups in the eastern hill areas. The people are divided by differences of religion, language, and custom. Another source of disunity is the fact that, until the 19th century, Thailand, Burma, and Vietnam either held territory that at present is a part of Laos or exercised suzerainty and indirect rule over parts of the land and its people. Although the peoples of Laos can look back to a golden age when the country was strong and united under its own kings, for the past two centuries it has been divided and weak, subject to contention among its neighbours.

Laos gained legal unity and the formal status of a nation on October 22, 1953, when France recognized the Kingdom of Laos as fully independent and sovereign; in December 1955 it was admitted to the United Nations. In reality, however, it was at best a divided state. In 1953 the Communist Pathet Lao, a dissident group supported by the Viet Minh military forces of Vietnam, established itself in the northeast and claimed to be the legal government. The Geneva Conference of 1954, while recognizing the unity of Laos and the legality of the kingdom, permitted the Pathet Lao forces to occupy the provinces of Phôngsali and Houaphan (Sam Neua), "pending a political settlement." No real settlement occurred, despite efforts by the leaders of Laos to integrate the dissidents, and internal warfare continued until 1975 as foreign forces supported rival Laotian factions and used Laos as a battlefield in the Vietnam war. Intra-Laotian strife became intertwined with the larger conflict. In 1975 the Pathet Lao gained control of the country, and the monarchy was ended and the Lao People's Democratic Republic inaugurated in December.

This article deals with contemporary Laos. For historical aspects, see LAOS, HISTORY OF; for an associated physical feature, see MEKONG RIVER.

Landscape. Dominating the landscape of Laos are its inhospitable, forest-covered mountains, which in the north rise to a maximum of 9,248 feet (2,819 metres) above sea level. The principal range lies along a northwest-southeast axis, but in the north there are lower, secondary ranges along a northeast-southwest axis. The ranges are broken by narrow, deep valleys through which rivers flow. A vital area strategically and politically is the Plain of Jars (a name derived from large prehistoric stone jars discovered there; Laotian Thông Haihin), a part of the Plateau de Xiangkhoang that often changed hands during the war. In the central and northern parts of the country, the mountains form part of the Chaîne Annamitique. The only lowlands lie alongside the eastern bank of the Mekong. The general slope of the land is upward to the east.

Drainage

The rivers on the eastern mountain slopes flow toward Vietnam and the South China Sea; the rivers on the western side drain into the Mekong, which flows in a southerly direction from the province of Yunnan in China to the South China Sea, forming Laos' boundaries with Burma and (for the most part) with Thailand. The floodplains of the lowlands are formed from the alluvial soils carried by the river and its tributaries. The only other important fertile area is the Plateau des Bolovens, at an elevation of about 3,500 feet (1,100 metres). The hills and mountainsides can be brought into temporary cultivation by the primitive method of slash and burn, but they quickly lose their fertility and the cultivators must move to other areas and repeat the process.

The climate in Laos reflects its location between the latitudes of 14° and 22° N. During the rainy season, May to October, the winds blow from the southwest and deposit an average rainfall of between 50 and 90 inches (1,300 and 2,300 millimetres). In the Plateau des Bolovens precipitation reaches 160 inches (4,100 millimetres) per year. The dry season, from November to April, is dominated by northeast winds. Temperatures average between 60° and 70° F (16° and 21° C) in the cool months of December through February, increasing to more than 90° F (32" C) in March and April, just before the rains. In the wet season, the average temperature is 80" F (27" C).

Laos has tropical rain forests of broadleaf evergreens in the north and monsoon forests of mixed evergreens and deciduous trees in the south. In the monsoon forest areas the ground is covered with tall, coarse grass called tranh; the trees are mostly second growth, with an abundance of bamboo, scrub, and wild banana.

Peoples. More than half the population is concentrated in the lowlands, where most are engaged in wet rice farming. The isolated valley communities preserve different traditions and different dialects. Village populations range between 50 and 2,000, usually located close to rivers and roads that give the people access to itinerant traders as well as to each other. Most villages are laid out around a main street or open area, farmlands being adjacent to the residential areas. Every village, if it can, has a pagoda and supports at least one Buddhist monk. The pagoda compound usually includes a public building that serves as a school and a meeting hall. Village leadership is usually divided, the headman having authority in secular matters and the monk in religious.

The hill peoples

The hill peoples are usually organized on tribal lines and live in smaller groupings. They are hunters and gatherers of forest products as well as farmers; their techniques of shifting cultivation prevent them from establishing permanent villages. Their political and social structures are varied. The tribal Tai have a stratified social structure and a political hierarchy, while the Mon-Khmer tend to have a simple political organization with a single headman. The Meo (Miao) tribesmen have a tradition of a king and chiefs; in theory their villages are tribal, but in fact they usually have a headman. Hill peoples living close to the Lao and Tai tend to acquire the languages and cultures of their neighbours and to engage in limited trade with them; those living at higher elevations remain unacculturated.

Urban life in Laos is limited to the capital, Vientiane, the former royal capital, Louangphrabang, and four or five large towns. With the exception of Louangphrabang, all are located near the Mekong in the floodplain area. Their populations are predominantly Lao, with many Chinese, Vietnamese, and Europeans. The Lao elite tends to be Westernized in its life-style and dress. By comparison with the cities of Thailand, Malaysia, or Vietnam, those of Laos are small and provincial.

Linguistic–political groups. The peoples of Laos are divided by language, culture, and location. Lao officials distinguish four basic linguistic–political groups: Lao-Lu, or valley Lao; Lao-Tai, or tribal Tai; Lao-Theng, or Mon-Khmer; and Lao-Soung, or Meo and Man. Mountain people sometimes are called Kha ("Slave"), a pejorative term.

The Lao-Lu live in the lowlands, on the banks of the Mekong and its tributaries, and in the cities. They speak Laotian Tai, which is closer to the language spoken by Thais in Thailand than it is to the language of the local Tai-speaking tribes. It is the language that the minorities living near Lao areas are gradually adopting.

The Lao-Tai include such local groups as the Black Tai and Red Tai, both names referring to the dress of the women; the Tai Neua, or Tai of the north; the Tai Phuan; and the Phon Tai. The Lao-Tai live in all parts of the country, chiefly in upland areas. The various dialects of the Lao-Tai are mutually intelligible.

Mon-Khmer

The Lao-Theng, better known as Mon and Khmer, or Mon-Khmer, include many groups of people scattered throughout Laos, northeastern Burma, northern Thailand, and southern China and are thought to be descendants of the earliest populations in the region. These people do not form a single coherent group but rather include between 25 and 30 distinct groups, some closely related, others only tenuously identified as part of this linguistic group.

The Lao-Soung, which include the Meo (Miao) and the Man (Yao), are believed to have come from southern China since the late 18th century. They are divided into subgroups, and neither constitutes a large proportion of the population of Laos. (For the languages, see further TAI LANGUAGES.)

The other distinct linguistic groups are few. Tibeto-Burman-speakers, who came from southern China, live in the north and northwest. Chinese and Vietnamese live primarily in the urban areas. Initially, French was the language of the Lao elite and of the cities, but by the 1970s English had begun to displace it. Under the leadership of the Lao People's Revolutionary Party, Vietnamese has become the third language of the elite.

Cultural and religious differences. Prior to the emergence of the Lao People's Democratic Republic in 1975,

Social structure

it was accurate to say that the Lao peoples had a distinct pattern of culture and dress. They also had a well-defined social structure. differentiating between royalty and commoners. The members of the elite were said to number about 2,000, which included only a few outsiders who were not descendants of nobility. Most of the elite lived in the cities. drawing their incomes from rural land rents or from urban occupations. After **1975** a new elite emerged representing the victorious leftist forces. Many of this group were of aristocratic origin.

Traditionally the **Lao-Tai,** or tribal Tai. were organized in groups larger than villages. called muong. Each was ruled by a hereditary ruler called the chao muong. Within this broad grouping. however. there were ethnic variations. Among the Black Tai. the nobility consisted of two descent groups. the Lo and the Cam. who provided the rulers of the *muong*. The religious leaders came from two other descent groups. the Luong and the Ka. The Black Tai tribal organization had three levels: the village; the commune. which was composed of a number of villages; and the overall *muong*. The latter two were ruled by nobles. while the village headman was selected from among the commoners by the heads of households. The Red Tai had a similar social structure. with the addition of a council of five to aid the chao muong. The nobility owned the land and had the right of service from the commoners. Not all of them were Buddhists; those living in the higher and more isolated areas retained their traditional culture.

The **Lao-Theng,** or **Mon-Khmer,** have no political or social structure beyond the village. They are led by a village headman. who is their link to the central government; but his role in the village is not clear. The people traditionally have been spirit worshippers; one subgroup. the Lamets. practices ancestor worship. Some have adopted Buddhism.

Among the **Lao-Soung,** the Meo have a tradition of a king and subchiefs and a large-scale organization. although in practice this is usually limited to the village. The village consists of several extended families. In some villages. all the heads of households are members of a single clan. and the head of the clan is the headman of the village. Where several clans reside together in a large village there are several headmen. one being the nominal head and the link to the government. The headman has real authority in the village and is aided by a council. The Meo have extended their organization beyond the village for military purposes. They are spirit and ancestor worshippers.

The religion of most of the people of Laos is Theravāda Buddhism. professed by most Lao and by a small number of other ethnic groups. The rest of the people are animists or spirit worshippers. Many see no contradiction in being both. since Buddhism shows the way to Nirvāṇa while spirit worship helps a person to cope with daily and local problems. Among the hill peoples. especially those who have migrated from southern China. there are groups that mix Confucian ideas with Buddhism and animism. There were Catholic and Protestant missionaries in the country before **1975.** but it is estimated that no more than **2** or **3** percent of the population is Christian. The Vietnamese. who live both in the cities and in the northeastern rural areas. practice a mixture of Mahāyāna Buddhism and Confucianism.

No complete census has ever been conducted in Laos. but estimates by the United Nations placed the population at 3.546.000 in **1978.** The birth rate was estimated to be 44.1 per 1.000. the death rate **20.3,** and the annual rate of increase **2.3** percent. To build the population. the government in **1976** prohibited the sale of birth-control devices. Considerable migration takes place in and out of China. Vietnam. and Thailand.

Economy. Mining. The natural resources of Laos include coal. iron. copper. lead. gold. tin. and precious stones. Only tin has been extracted on a commercial scale. though the others have been mined in primitive and unsystematic ways. About 1.000 tons of tin ore per year are produced from the mines at Phôntiou and Nong Sun. Agriculture. The chief occupation of the people is

Rice

agriculture, with an estimated 90 percent engaged in rice farming. Since the creation of the Lao People's Democratic Republic in 1975, natural calamities, including both drought and excessive rainfall, have prevented the people from achieving self-sufficiency in rice production. In the late 1970s the nation had to look to imports and gifts to make up for inadequate production. Modest amounts of corn (maize), sugarcane, tobacco, and cotton are produced. The forests provide teak and other woods, gum benzoin, cardamom, and stick lac. A major agricultural commodity that does not find its way into the statistics is opium, grown mainly by the Meo and traded illegally.

Nearly every household raises livestock—including cattle and buffalo—and poultry. Leather and hides are traded.

Under the revolutionary government, a serious effort is being made to relocate hill peoples onto the plains and to get them to adopt wet rice farming practices in place of their traditional slash and bum. It has been reported that some of the Meo have been forced to resettle in agricultural cooperatives in the region of the Plain of Jars. The majority of hill dwellers are resisting change, however, despite pressure and persuasion to alter their agricultural practices, social customs, and traditions. If the government persists in this policy it may provoke outright opposition to, and revolt against, the most serious challenge to Meo traditional life.

Hydroelectricity. A major hydroelectric project is under way on the Nam Ngum (nam, "river"), an effluent of the Mekong, about 40 miles (70 kilometres) north of Vientiane. Financed by Japan, West Germany, and several other countries, the project produces surplus electricity that is sold to Thailand.

Industry. The tiny industrial sector manufactures bricks and ceramics, matches, cigarettes, soft drinks and beer, rubber sandals, cloth, pottery, and plastic bags. By mid-1977 the government reported that nearly 80 percent of the small and medium-sized factories in the areas formerly under the royal government were back in production.

Trade and finance. The chief exports are timber, tin, coffee, leather and hides, cardamom, gum benzoin, and stick lac. The major buyers formerly were Singapore, Malaysia, Thailand, the United States, and Hong Kong. The major suppliers of imports were Thailand, Japan, the United States, France, and the United Kingdom. After 1975, however, this pattern of trade was disrupted, and new trading relationships are beginning to develop with Thailand and Vietnam and with Communist European states. Imports always vastly exceed exports in value.

In 1975 financial support from Western countries all but stopped; to halt inflation and reduce black markets, the old kip (Laotian unit of currency) was replaced in June 1976 with a new kip, at a greatly reduced value. This, together with greater state control of the economy and gifts from the Soviet Union, the People's Republic of China, Vietnam, and the United Nations, helped the government during its first difficult years.

Transportation. A major obstacle to the economic and social development of Laos is its transportation system. Rivers and roads are the major avenues of communication, supplemented by air transport. The Mekong River is the major north–south commercial artery; all but two sections of it—Chutes de Khone (Khone Falls) and the rapids of Khemmarat (Khemarat)—are navigable either all or part of the year. Large barges operated by Chinese ply the deeper sections of the rivers between towns, but most of the water traffic is carried in Lao-operated sampans and pirogues. The latter average 25 to 35 feet in length and can carry up to seven passengers and half a ton of cargo. Some of the mountain people build bamboo rafts and float their goods to market, selling the raft along with the goods.

River traffic

During French rule, a primitive network of roads was created. The main artery joined Saigon with Louangphrabang, and several lesser roads led eastward through the four mountain passes to Vietnam and to the main towns and population centres. During the 1960s, with U.S. assistance, an all-weather road was added between Vientiane and Pakse; another was to be built between Vientiane and Louangphrabang. In addition, the North Vietnamese developed a complex of roads and trails across eastern Laos for their own use during the war. Laos itself has no railways, but a railroad from Bangkok, Thailand, to the Lao border serves as a major artery.

The newest means of transport is the airplane. In the mid-1970s there were nine airports with permanent surface runways. The Wattay international airport at Vientiane connects with Bangkok, Phnom Penh and Hong Kong. This traffic was halted briefly in 1976, but by the next year regular air traffic with Thailand, Cambodia, and Vietnam resumed. There were plans to extend air service to Burma and China.

Administration and social conditions. Government. Before December 2, 1975, Laos was a constitutional monarchy. Real power rested with the prime minister and the legislature. There had been nominal political parties since 1947, when the constitution was promulgated, but they were loose coalitions of leaders with little popular following. In 1953 there were two main parties, the National Progressive and the Independent, and two splinter parties, the National Union and the Democratic. In 1958 the Lao Patriotic Front, backed by the Communist Pathet Lao, participated in the elections, as did the Peace Party; together they won several seats. In the late 1950s two new parties emerged, the Rally of the Lao People and the Committee for the Defense of the National Interest.

Beginning in 1973, when a cease-fire agreement was reached, a series of coalition governments sought to exercise power. The traditional elite continued to rule in urban areas, while the bulk of the people in the countryside remained outside the national political process. The coalition government gave way in December 1975 to a new body, the National Congress of People's Representatives, which, under the guidance of the Pathet Lao, met and passed several resolutions that ended the monarchy and replaced it with the Lao People's Democratic Republic. The King abdicated.

Supreme People's Council

The government is headed by a president, who is also chairman of the Supreme People's Council, an interim (pending elections) legislative body. The secretary general of the Lao People's Revolutionary Party (the only political party) serves as prime minister. The party, which replaced the Pathet Lao as leader of the Socialist revolution, was formerly called the People's Party of Laos and is the Communist core of the Lao Patriotic Front. It is organized much like other Communist parties, with a Central Committee headed by a Politburo. Its membership is estimated to be about 15,000.

The country is divided into 20 provinces, each subdivided into districts, which, in turn, are subdivided into towns and villages. At each level of local government there are "people's revolutionary committees," which receive directions from the Central Committee of the Lao People's Revolutionary Party.

Military forces. Between independence, in 1953, and the cease-fire, in 1973, the military forces grew to become a major institution. In addition to the Royal Laotian Army, Royal Lao Air Force, Laotian River Flotilla, and Lao National Police Corps, there were the separate armies of the Pathet Lao and the neutralists. The government forces numbered about 65,000 and received aid from the United States. The Pathet Lao army of 20,000, with 15,000 irregulars, was supported by North Vietnam and China. For a time during the 1960s the neutral force of 10,000 stood between the two, but in the late 1960s this group threw its support to the Pathet Lao.

Army

After the victory of the Pathet Lao (officially Lao People's Liberation Army from 1965), the Royal Laotian Army was in part integrated with it and the rest was disbanded. In the late 1970s the army had about 46,000 men, and there was a very small navy and an air force with about 2,000 personnel.

Medical care. The country has around 40 hospitals, supplemented by infirmaries and rural dispensaries. After 1975 and with the departure of the majority of medical doctors, the government began building village infirmaries in most of the provinces and training medical workers. Using medicinal herbs, these village medical workers provide most of the primary health care. Malaria and gastroenteritis are the major health problems.

Education. Education is being reorganized. After 1975 the government set up a number of agricultural schools, sent teachers to give literacy classes in provincial villages, and opened new primary, secondary, and teacher-training schools. It claimed that by mid-1978 some 2,000,000 of its people were literate.

Cultural life. The basis of Laotian culture is religion and tradition. Art, literature, music, and drama draw mainly from these sources, and there appears to be little Western influence outside Vientiane.

Religious basis of cultural life

Theravāda Buddhism entered the country in the 14th century and along with Hinduism has been a major influence on cultural and intellectual life. The story of the Buddha and Hindu myths are the subjects of the carvings and sculptures found in all religious places. In the south, Khmer influences on the peoples of Laos are strong; in the north, Burmese and Thai influences are readily apparent. As elsewhere in Southeast Asia, religious symbols, stories, and themes have been modified and localized. The snake, for example, representations of which adorn religious and royal buildings, represents the benevolent spirit of the water and the protector of the king.

The Laotians have a variety of folk arts, including weaving, basketmaking, wood and ivory carving, and silverwork and goldwork. There are a number of Laotian musical instruments, of which the *khene,* a bamboo wind instrument, is most widely known. Music is not written down but is played from memory. The musicians and their music are closely linked to religion.

Dancing is a profession rather than a form of recreation; the professional dance troupes travel throughout the country performing for religious celebrations or on important holidays. Their main themes are drawn from the Indian epics. All professional dancers are male, the female roles being performed by young men and boys.

Laotian literature is predominantly religious and linked to the Buddhist tradition. There is also a secular literary stream based on themes of the Hindu epic poems, which have been transmuted into popular language, as in the Laotian epic the *Sin Xay.* The popular poems and songs are often satirical.

Laos had five newspapers in 1966, all published by the government or by prominent leaders and of very limited circulation. Since 1975 there has been only one paper, *Siang Pasason* ("Voice of the People"), the news organ of the governing party. The National Radio of Laos broadcasts on several stations, and the Foreign Service provides programs in Khmer, English, French, Lao, Thai, Vietnamese, and many dialects; both are sponsored by the government. There is no television service.

Prospects for the future. Under the revolutionary government, the warfare that divided the country was brought to an end. The social and economic changes introduced were not uniformly popular, and many of the hill peoples, especially the Meo, opposed the reforms and provided for future internal war. The end of the war did not end Laos' involvement in t[illegible] military and political [illegible] of it neighbours. The [illegible]ic of Kampuchea by Vietnam, followed by the assault of the People's Republic of China upon Vietnam, had an effect on Laos. China openly criticized the strong influence of Vietnam, which shows no sign of loosening its hold upon Laos. Since Vietnam is now tied politically and economically to the Soviet Union, there is little likelihood that Western nations will offer Laos technical or financial aid.

Laos, History of

The Lao people, the predominant ethnic group in present-day Laos, are a branch of the Tai peoples who by the 8th century AD established a powerful kingdom, Nanchao, in southwestern China. From Nanchao the Tai gradually penetrated southward into the Indochinese Peninsula; their migration was accelerated in the 13th century by the Mongol invasions of southern China by Kublai Khan. The Lao, together with other Tai peoples, gradually supplanted various primitive tribes (collectively known as Kha, or "Slaves") that from the 5th century on had lived in what is now Laos under the suzerainty of the Indianized Khmer Empire of Cambodia. During the 12th and 13th centuries they established the principality of Muong Swa (later Luang Prabang, now Louangphrabang), which was ruled by various Tai leaders and the history of which survives in Laotian legend and myth.

The first Laotian state

Lan Xang. Recorded Laotian history begins with Fa Ngum, who founded the first Laotian state, Lan Xang (Kingdom of the Million Elephants), with the help of the Khmer sovereign at Angkor. He was a great warrior and, in 1353–71, conquered territories including all of present-day Laos and much of what is today northern and eastern Thailand. He extended the Indo-Khmer civilization to the upper Mekong River and introduced Theravada Buddhism, preached by Khmer missionaries from Angkor.

In 1373 Fa Ngum was succeeded by his son Phya Sam Sene Thai, who did much to organize the pattern of administration and defense for the kingdom. After his death in 1416, a long period of calm, broken only by a Vietnamese invasion in 1478, allowed his successors to complete the work of organizing Lan Xang. This period of peace and tranquillity ended with Photisarath (reigned

1520–47), who involved Lan Xang in a struggle against Burma and Siam that lasted two centuries. Photisarath waged three wars against Siam and succeeded in placing his son Sethathirath on the throne of the Tai state of Chiang Mai (Chiengmai), marking Lan Xang's maximum territorial expansion. On Photisarath's death, Sethathirath returned to occupy his father's throne. His reign was marked by the loss of Chiang Mai to the Burmese, by the transference of the capital from Luang Prabang to Vientiane, and by the repulsion of two Burmese invasions c. 1565 and 1570.

When he died (1571) the Burmese seized Vientiane (1574) and ravaged the country, which lapsed into anarchy until Souligna-Vongsa ascended the throne in 1637 and restored order. He fixed the frontiers with Vietnam and Siam by means of treaties and led two victorious expeditions against the principality of Chieng Khouang in the south. A defender of Buddhism and a patron of the arts, he embellished Vientiane and made it a centre of intellectual brilliance. His reign is considered by Laotians to be a Golden Age.

Vietnamese rule

When Souligna-Vonasa died in 1694, one of his nephews seized the throne with the help of a Vietnamese army, thus placing Lan Xang under Vietnamese rule and initiating a period of chaos ending in the partition of the kingdom of Lan Xang. Other members of the royal family refused to accept Vietnamese vassalage. With the northern provinces under their control, they declared themselves independent (1707) and established the separate kingdoms of Luang Prabang and Vientiane. The south seceded in turn and set itself up as the kingdom of Champassak (1713). Split into three rival kingdoms, Lan Xang ceased to exist.

Under foreign rule. During the 18th century the three Laotian states. continually at loggerheads. tried to maintain their independence from the Burmese and the Siamese who were contending for the control of western Indochina. Their weakness, resulting from their disunity, inevitably caused them to fall prey to the Siamese.

Vientiane, which had sided with the Burmese, was invaded (1778), annexed, and made a state subject to Siam (1782). Luang Prabang, which had supported the Siamese, was invaded by the Burmese (1752), who imposed their rule upon it until the Siamese supplanted them (1778). In the south, Champassak, which had supported Burmese revolt against the Siamese, was also invaded (1778) and transformed into a dependency of Siam. Each of these kingdoms was placed under the control of a Siamese commissioner. The kings of Champassak, Vientiane, and Luang Prabang were allowed to rule in their respective kingdoms but had to pay tribute to Bangkok. Their appointments to the throne were made in Bangkok.

Chao Anou (king of Vientiane 1805–28) attempted to shake off this yoke. First, he strengthened the bonds of allegiance uniting Vientiane to Vietnam (1806), whose influence in Indochina had grown to rival that of Siam. Next, he persuaded Bangkok to give his son the governorship of Champassak, thus extending his frontiers as far as the old southern boundaries of Lan Xang. Thinking that the British, who had just conquered Burma, were going to attack Siam, he led three armies against Bangkok (c. 1826). But the Siamese regrouped their forces, marched on Vientiane, and defeated Anou, who fled to Vietnam. Vientiane was pillaged and destroyed. In 1819 Anou attempted another attack but was again defeated. Vientiane was made a Siamese province.

For the Siamese the annexation of Vientiane was the first step toward the creation of a great empire. They next extended and consolidated their colonization of the left bank of the Mekong to protect themselves from an eventual Vietnamese expansion westward. They therefore garrisoned Champassak (1846) and Luang Prabang (1885) and stationed troops as far as the Chaîne Annamitique. Siamese expansion toward the northeast—where the mountain states were placed under the cosuzerainty of Vietnam and Luang Prabang—provoked the protests of the French, who had established a protectorate over Vietnam. France entered into negotiations with Bangkok (1886) to define the Siamese-Vietnamese frontier and won the right to install a vice consul in Luang Prabang. The office was entrusted to Auguste Pavie, who, owing partly to his popularity with the Laotians, succeeded in winning Luang Prabang over to France. After a number of Franco-Siamese incidents in the Mekong Valley, French ships made a show of strength off Bangkok. On the advice of the British, Siam withdrew from the left bank of the Mekong and gave official recognition to the French protectorate in the evacuated territory (1893). French annexation was completed by treaties with Siam (Thailand) in 1904 and 1907.

French protectorate

The French organized this territory as the Protectorate of Laos and allowed it autonomy in local matters. The kingdom of Luang Prabang survived, but the other provinces were placed under the direct authority of a French official. France paid little attention to Laos until 1941, when, under Japanese pressure, the Vichy government restored to Thailand the territories acquired in 1904. In March 1945 the Japanese drove the French from Indochina and proclaimed the independence of Laos.

Two movements sprang up at this time. The first was anti-Japanese and was represented by the court of Luang Prabang and Prince Boun Oum of Champassak; the second was anti-French (the Free Laos movement, or Lao Issara), was located in Vientiane, the former French colonial administrative centre, and was led by Prince Petsarath. These two movements remained in conflict until the return of French troops, which compelled the supporters of the Lao Issara to flee to Thailand. In 1946 France, in a temporary agreement, recognized the unity and internal autonomy of Laos under the king of Luang Prabang, Sisavang Vong. Finally, after the promulgation of a constitution and general elections, a Franco-Laotian convention was signed on July 19, 1949, by which Laos was granted a limited degree of self-government within the French Union. All important power, however, remained in French hands.

Although many of the Lao Issara leaders were prepared to work with the French under this new arrangement, their decision was opposed by a more radical group led by Prince Souphanouvong. Under Souphanouvong's presidency a new political movement, the Pathet Lao (Lao Country), was created (1950) that joined forces with the Viet Minh of Vietnam in opposing the French. The Pathet Lao remained unreconciled when the French took further steps toward granting independence to Laos in October 1953, while still retaining control of all military matters in the kingdom. Between 1950 and early 1954 the Pathet Lao gained strength in northeastern Laos and had a firm grip on two of the country's provinces when the Geneva Conference brought the First Indochina War to an end.

Geneva Conference

Independent Laos. At the Geneva Conference the 14 participating nations (including France, Great Britain, the U.S., China, and the Soviet Union) agreed on the establishment of Laos as a unified, independent buffer state between Thailand and North Vietnam, which were allied, respectively, to the West and to the Communist bloc. But this agreement, a compromise among the great powers, concerned only the international aspects of Laos' neutral status; the Laotians were left with the problem of making it work on the local level. The deep political divisions within Laos made it impossible for the country to function effectively as a neutral buffer state.

Relative calm prevailed during 1955–58 as a government of national union, including Pathet Lao representatives, sought to implement the Geneva accords. When elections held in 1958 showed there was significant support for the Pathet Lao, the right reacted by forcing the neutralist prime minister, Prince Souvanna Phouma, out of office and installing their own candidate, Phoui Sananikone. Then in July 1959 the right-wing forces in control of Vientiane imprisoned Prince Souphanouvong (he escaped a year later). In further violation of the Geneva agreement, the rightists accepted military aid from the U.S. and the Philippines. The Pathet Lao retaliated by seizing control of Phbngsali and Houaphan (Sam Neua) provinces, and a period of inconclusive hostilities followed. When Phoui showed some readiness to move toward a neutralist position, he was deposed by rightist army officers and his place was taken by Gen. Phoumi Nosavan. A period of great confusion followed as Phoumi Nosavan and his supporters were themselves deposed in a coup led by a parachute battalion commander, Kong Le, in August 1960, only to succeed in recapturing Vientiane, with considerable U.S. and Thai support, in the following December. By this stage the situation in Laos was a cause for growing tension between the U.S. and the Soviet Union.

Souvanna Phouma coalition

A change in U.S. policy under the new administration of Pres. John F. Kennedy brought acceptance of the concept of a neutral Laos, and in May 1961 the Geneva Conference was reconvened to seek a formula that would allow Laos to occupy a neutral position as a buffer zone. In June 1962 Prince Souvanna Phouma formed a new coalition government that included Pathet Lao, neutralist, and rightist representatives. Despite international support for such a solution, Laos could not disentangle its affairs from the war being fought in neighbouring Vietnam. Nor were the major political groupings within the country ready to give up control over those areas they dominated by means of their armed forces.

Increasingly from 1963, developments in Laos were linked with those in Vietnam. Sections of eastern Laos were a vital part of the Vietnamese Communist supply lines to the south (the Ho Chi Minh Trail), and, as the Vietnamese Communists gave their aid to the Pathet Lao, the U.S. joined in military support of the forces of the government in Vientiane. Despite the external assistance received by both sides, neither the government in Vientiane nor the Pathet Lao was able to break the pattern by which the territory of Laos was divided between them, with little apparent possibility of either gaining a decisive victory. In these circumstances, and with the U.S. and North Vietnam negotiating for a cease-fire in Paris, the Vientiane government and the Pathet Lao began negotiations in 1972 and signed a cease-fire in February 1973.

Beginning in that year, yet another effort was made to find a way to rule Laos through a coalition of rightists, neutralists, and the Pathet Lao. After further protracted negotiations, a Provisional Government of National Unity was inaugurated in April 1974 that had an equal number of members drawn from those who had been associated with the Vientiane government and from the Pathet Lao. Once associated with this provisional government, the Pathet Lao demonstrated a unity and an organizational ability that contrasted with the disunity of their rightist opponents. This enabled the Pathet Lao to take advantage of the opportunities offered by the declining fortunes of the anti-Communist regimes in Saigon and Phnom Penh. When those two cities fell in April 1975, morale dropped sharply among representatives of the right in Laos, and from May onward, as many of the most important rightist politicians and soldiers fled to Thailand, the Pathet Lao moved swiftly and firmly to establish control over the whole of the country.

Lao People's Revolutionary Party

After the Pathet Lao gained control over Laos, the existence of a Laotian Communist Party (the Lao People's Revolutionary Party, founded in 1955 as the People's Party of Laos) was revealed, and it is this party that controls the Lao People's Democratic Republic that was inaugurated in December 1975. Under Prince Souphanouvong as first head of state and Kaysone Phomvihane as first prime minister, the Lao People's Democratic Republic maintains close links with Vietnam, with which in July 1977 it concluded a series of wide-ranging military and economic agreements. Contradictory reports have emerged concerning the policies being followed by the new rulers of Laos, but there seems little doubt that the political, social, and economic programs they are pursuing represent a great break with the past.

Lao-tzu

Lao-tzu (in Pinyin romanization Lao-zi), "Master Lao," is the name by which the author of the Lao-tzu, or Tao-te Ching, one of the most famous books of ancient China, is usually known. He is considered the first philosopher of the Taoist school (Tao-chin), which, among the numerous movements of thought in the period of the Waning States (5th–3rd century BC), was the only one, along with the Confucianist school, to survive. The Tao-te Ching is not only important from the philosophical point of view; it is also one of the most sacred scriptures of the Taoist religion, which considered Lao-tzu a great saint and even worshipped him. Furthermore, this little book is by far the most translated work of all the literature of China, and Taoism was one of the major influences in Chinese thought until the Communist revolution (see TAOISM; TAOISM, HISTORY OF; TAOIST LITERATURE).

But if Lao-tzu is an important figure he is also a very obscure one, and the information provided by the historical sources is disappointing.

Ssu-ma Ch'ien's history

The principal document is the biography of Lao-tzu in the Shih-chi ("Historical Records"), by Ssu-ma Ch'ien. This historian, who wrote in about 100 BC, had little solid information concerning the philosopher. He says that Lao-tzu was a native of Ch'ii-jen, a village in the district of Hu in the state of Ch'u, which corresponds to the modern Lu-yi in the east part of Honan Province. His family name was Li, his proper name Erh, his appellation Tan. He was appointed to the office of shih at the royal court of the Chou dynasty (*c.* 1122–221 BC). Shih today means "historian," but in ancient China the shih were scholars specializing in matters such as astrology and divination and were in charge of sacred books. After noting the civil status of Lao-tzu, the historian proceeds to relate a celebrated but questionable meeting of the old Taoist with the younger Confucius (551–479 BC). The story has been much discussed by the scholars; it is men-

Lao-tzu (centre), detail from a Taoist temple fresco, southern Shansi, China. Yüan dynasty (AD 1279–1368). In the Royal Ontario Museum, Toronto.

tioned elsewhere, but the sources are so inconsistent and contradictory that the meeting seems a mere legend. During the supposed interview, Lao-tzu blamed Confucius for his pride and ambition, and Confucius was so impressed with Lao-tzu that he compared him to a dragon that rises to the sky, riding on the winds and clouds.

No less legendary is a voyage of Lao-tzu to the west. Realizing that the Chou dynasty was on the decline, the philosopher departed and came to the Hsien-ku pass, which was the entrance to the state of Ch'in. Yin Hsi, the legendary guardian of the pass (*kuan-ling*), begged him to write a book for him. Thereupon, Lao-tzu wrote a book in two sections of 5,000 characters, in which he set down his ideas about the Tao (literally "Way," the Supreme Principle) and the *te* (its "virtue"): the *Tao-te Ching*. Then he left and "nobody knows what has become of him," says Ssu-ma Ch'ien.

After the account of the voyage of Lao-tzu and of the redaction of the book, Ssu-ma Ch'ien alludes to other men with whom Lao-tzu was sometimes identified. One was Lao-Lai-tzu, a Taoist contemporary of Confucius; another was a great astrologer named Tan, who had an interview with Duke Hsien of Ch'in (384–362). Ssu-ma Ch'ien adds, "Maybe Lao-tzu has lived one hundred and fifty years, some say more than two hundred years." Since the ancient Chinese believed that superior men could live very long, it is natural that the Taoists credited their master with an uncommon longevity, but this is perhaps a rather late tradition because Chuang-tzu, the Taoist sage of the 4th century BC, still speaks of the death of Lao-tzu without emphasizing an unusual longevity.

To explain why the life of Lao-tzu is so shrouded in obscurity, Ssu-ma Ch'ien says that he was a gentleman recluse whose doctrine consisted in nonaction, the cultivation of a state of inner calm, and purity of mind. Indeed, throughout the whole history of China, there have always been recluses who shunned worldly life. The author (or authors) of the *Tao-te Ching* was probably a person of this kind who left no trace of his life.

The question of whether there was a historical Lao-tzu has been raised by many scholars, but it is rather an idle one. The *Tao-te Ching*, as we have it, cannot be the work of a single man; some of its sayings may date from the time of Confucius; others are certainly later; and the book as a whole dates from about 300 BC. Owing to these facts, some scholars have assigned the authorship of the *Lao-tzu* to the *t'ai-shih* (astrologer) Tan; while others, giving credit to a genealogy of the descendants of the philosopher, which is related in the biography by Ssu-ma Ch'ien, try to place the life of Lao Tan at the end of the 4th century BC. But this genealogy can hardly be considered as historical. It proves only that at the time of Ssu-ma Ch'ien a certain Li family (see above) pretended to be descended from the Taoist sage; it does not give a basis for ascertaining the existence of the latter. The name Lao-tzu seems to represent a certain type of sage rather than an individual.

Hagio-graphical legends

Beyond the biography in the *Shih-chi* and sporadic mentions in other old books, several hagiographies were written from the 2nd century AD onward. These are interesting for the history of the formation of religious Taoism (Tao-chiao). During the Later Han dynasty (AD 23–220), Lao-tzu had already become a mythical figure who was worshipped by the people and occasionally by an emperor. Later, in religious circles, he became the Lord Lao (Lao-chiin), revealer of sacred texts and saviour of mankind. There were several stories about his birth, one of which was influenced by the legend of the miraculous birth of Buddha. Lao-tzu's mother is said to have borne him 72 years in her womb, and he to have entered the world through her left flank. One legend gives an explanation of his family name, Li: the baby came to light at the foot of a plum tree (*li*) and decided that *li* (plum) should be his surname. Two legends were particularly important in the creed of the Taoists. According to the first, the Lao-chiin was believed to have adopted different personalities throughout history and to have come down to the earth several times to instruct the rulers in the Taoist doctrine. The second developed from the story of Lao-tzu's voyage to the west. In this account the Buddha was thought to be none other than Lao-tzu himself. In the 3rd century AD, an apocryphal book was fabricated on this theme with a view to combatting Buddhist propaganda. This book, the *Lao-tzu Hua-hu ching* ("Lao-tzu's Conversion of the Barbarians"), in which Buddhism was presented as an inferior kind of Taoism, was often condemned by the Imperial authorities.

The figure of Lao-tzu has never ceased to be generally respected in all circles. To the Confucianists he was a venerated philosopher; to the people, he was a saint or a god; and to the Taoists he was an emanation of the Tao and one of their greatest divinities. Under the T'ang dynasty (618–907), whose rulers belonged to the Li clan, he was worshipped as an Imperial ancestor.

BIBLIOGRAPHY. The texts of the *Shih-chi* concerning Lao-tzu have been translated and thoroughly discussed in a debate between H.H. DUBS and D. BODDE in the *Journal of the American Oriental Society*, vol. 61, 62, and 64 (1941, 1942, and 1944). For less technical accounts of the question, see ARTHUR WALEY, *Lao-tzu: The Way and the Power* (1934, reprinted 1956); H. WELCH, *Taoism: The Parting of the Way*, rev. ed. (1966); and M. KALTENMARK, *Lao tseu et le taoïsme* (1965; Eng. trans., *Lao Tzu and Taoism*, 1969). On the legends, see H. DORE, "Lao-tsé et le taoïsme," *Recherches sur le superstitions en Chine*, vol. 18 (1938), not very scientific, but gives much information; and ANNA K. SEIDEL, "The Image of the Perfect Ruler in Early Taoist Messianism: Lao-tzu and Li Hung," *History of Religion*, 9:216–247 (1969–70); and *La Divinisation de Lao tseu dans le taoïsme des Han* (1969), two studies that bring together much new material. A most complete bibliography by M. SOYMIE and F. LITSCH has been published in *Etudes taoïstes*, 3:18–40 (1968).

(Ma.K.)

Laplace, Pierre-Simon, Marquis de

His dynamical investigations into the stability of the solar system earned for mathematician Pierre-Simon Laplace the title the Newton of France. He successfully applied the Newtonian theory of gravitation to the solar system by accounting for all of the observed deviations of the planets from their theoretical orbits and developed a conceptual view of evolutionary change in the physical universe. Moreover, he demonstrated the usefulness of the probabilistic interpretation of scientific data.

Laplace was born on March 23, 1749, at Beaumont-en-Auge, Normandy, where his father was a peasant farmer. Little is known of his early life except that he quickly showed his mathematical ability at the military academy at Beaumont. At 18 he left his humble surroundings for Paris, determined to make his way in mathematics. He then composed a letter on principles of mechanics for the mathematician Jean d'Alembert, who recommended him to a professorship at the École Militaire.

Major work

In 1773 he began his major lifework—applying Newtonian gravitation to the entire solar system—by taking up a particularly troublesome problem: why Jupiter's orbit appeared to be continuously shrinking while Saturn's continually expanded. The mutual gravitational interactions within the solar system were so complex that mathematical solution seemed impossible; indeed, Newton had concluded that divine intervention was periodically required to preserve the system in equilibrium. Laplace announced the invariability of planetary mean motions, carrying his proof to the cubes of the eccentricities and inclinations. This discovery in 1773, the first and most important step in establishing the stability of the solar system, was the most important advance in physical astronomy since Newton. It won him associate membership in the Academy of Sciences the same year.

Applying quantitative methods to a comparison of living and nonliving systems, Laplace and the chemist Antoine Lavoisier in 1780, with the aid of an ice calorimeter that they had invented, showed respiration to be a form of combustion. Returning to his astronomical investigations with an examination of the entire subject of planetary perturbations—mutual gravitational effects—Laplace in 1786 proved that the eccentricities and inclinations of planetary orbits to each other will always remain small, constant, and self-correcting. The effects of perturbations were therefore conservative and periodic, not cumulative and disruptive. The opposite and secular inequalities of Jupiter and Saturn (accelerations and deceleration, respectively), for example, were due to a changing effect with a period of *929* years. Their inequalities were therefore not cumulative, but periodic.

Turning to the subject of the attraction between spheroids, Laplace in 1784–85 proved that the theorem concerning spheroids of revolution is true for any spheroids with common focuses and explored the problem of the attraction of any spheroid upon a particle situated outside or upon its surface. Through his discovery that the attractive force of a mass upon a particle, regardless of direction, could be obtained directly by differentiating a single function, Laplace laid the mathematical foundation for the scientific study of heat, magnetism, and electricity.

Laplace removed the last apparent anomaly from the theoretical description of the solar system in *1787* with the announcement that lunar acceleration depends on the eccentricity of the Earth's orbit. Although the mean motion (average angular velocity) of the Moon around the Earth depends mainly on the gravitational attraction between them. it is slightly diminished by the pull of the Sun on the Moon. This solar action depends, however, on changes in the eccentricity of the Earth's orbit resulting from perturbations by the other planets. As a result, the Moon's mean motion is accelerated so long as the Earth's orbit tends to become more circular; but, when the reverse occurs, this motion is retarded. The inequality is therefore not truly cumulative, Laplace concluded, but is of a period running into millions of years. The last threat of instability thus disappeared from the theoretical description of the solar system.

Traité de mécanique céleste and other publications

Laplace's *Exposition du système du monde,* a semipopular treatment of his work in celestial mechanics and a model of French prose published in *1796,* included his "nebular hypothesis"-cooling and contracting of a gaseous nebula—which strongly influenced future thought on planetary origin. His *Traitk de Mkcanique ckleste (Celestial Mechanics,* 1966), appearing in five volumes between *1798* and *1827,* summarized the results obtained by his mathematical development and application of the law of gravitation. He offered a complete mechanical interpretation of the solar system by devising methods for calculating the motions of the planets and their satellites and their perturbations, including the resolution of tidal problems. It made him a celebrity.

In 1814 Laplace published a popular work for the general reader, *Essai philosophique sur les probabilités.* This work was the introduction to the second edition of his comprehensive and important *Thkorie analytique des probabilités* ("Analytic Theory of Probability"), first published in *1812,* in which he described many of the tools he invented for mathematically predicting the probabilities that particular events will occur in nature. He applied his theory not only to the ordinary problems of chance but also to the inquiry into the causes of phenomena, vital statistics, and future events, while emphasizing its importance for physics and astronomy.

Probably because he did not hold strong political views he escaped imprisonment and execution during the Revolution. Laplace was president of the Bureau des Longitudes (Board of Longitude), aided in the organization of the decimal system, helped found the Société d'Arcueil, a scientific society, and was created a marquis. He served for six weeks as Minister of the Interior under Napoleon, who thought his record as an administrator was undistinguished. He died in Paris on March *5, 1827.*

BIBLIOGRAPHY. There is no definitive biography of Laplace, but the best account of his work is by SIR EDMUND T. WHITTAKER in *The Mathematical Gazette,* 33:1–12 *(1949);* ERIC T. BELL, *Men of Mathematics (1937,* reprinted 1961), also contains a lively biographical essay; see also H. ANDOYER, *L'Oeuvre scientifique de Laplace (1922).* The original documents relating to his life have almost all perished, most of them in a fire in *1925* that destroyed the home of his great-great-grandson, the Comte de Colbert-Laplace, and some during World War II in the bombardment of Caen. An important source of information is M.P. CROSLAND, *The Society of Arcueil: A View of French Science at the Time of Napoleon I (1967).* Laplace's collected works were published in Paris by Gauthier-Villars in 15 vol. *(1878–1912).* Translations of Laplace's works include *A Philosophical Essay on Probabilities (1902)* and *The System of the World, 2* vol. *(1830);* both are classics. The latter is a semipopular treatment of his *Celestial Mechanics,* 4 vol., trans. by NATHANIEL BOWDITCH, JERZY NEYMAN, and LUCIEN M. LE CAM (1828–*39,* reprinted *1966).*

(G.J.W.)

Laptev Sea

A marginal sea of the Arctic Ocean, the Laptev (Laptevykh More in Russian) takes the form of a wide bay situated between the shore of Siberia, the Taymyr Peninsula (Poluostrov), the islands of Severnaya Zemlya, and the New Siberian and Kotelny islands. It is connected in the west with the Kara Sea by the straits of Vilkits, Shokal, and Red Army and in the east with the East Siberian Sea by the Dmitry Laptev (Dmitriya Lapteva), Eterikan, and Sannikova straits. The Laptev Sea (formerly called the Siberian Sea) was named in *1935* in honour of Khariton and Dmitry Laptev, the brothers who were the first to map its shores (1735–40).

Physical characteristics. The sea's area is about 276,*000* square miles *(714,000* square kilometres), the volume of water *97,000* cubic miles, the average depth *1,896* feet, and the greatest depth *9,774* feet. The greatest length from southeast to northwest is *800* miles. The largest bays—Khatangsky, Olenyoksky, Buorkhaya, and others—cut into the low-lying, gently sloping shore. Numerous rivers, the largest being the Lena, Khatanga, Yana, Olenyok, and Anabar, flow into it, carrying about *150* cubic miles of freshwater, of which the Lena accounts for *77* percent. Several rivers form extensive deltas. There are several dozen islands with a total area of *1,461* square miles, primarily in the western part of the sea. The islands vary in landscape and origin. The steep, hilly shores of Severnaya Zemlya descend in glaciers to the sea, producing icebergs. The eastern shore of the Taymyr Peninsula is also hilly. The shores of the Peschany, Dunay, and other islands are low-lying and gently sloping. Low but steep shores are characteristic of the New Siberian Islands.

Occurrence of glacial remnants

Ancient rivers and glaciers played an important role in the formation of the relief of the bottom and of the shores of the sea, and even today, in the precipices of the shores of the New Siberian Islands, layers of relic ice of considerable thickness are found. Digging through the layers of ice has revealed numerous remains of animals of the preglacial period, including mammoths. The floor of the sea is a gently sloping plain, breaking off abruptly toward the Arctic Ocean. Depths of less than *160* feet occupy about *53* percent of its area, and depths greater than *3,300* feet, *22* percent. The bottom of the deepwater part is covered with silt, the shallower areas with sand and silt. In the eastern part of the sea, under a thin layer of deposits, occurs a layer of very old "relic" ice. As regards salinity, the thawing of ice and the inflow of fresh river water might have resulted in a layer of freshwater *53* inches thick. In the winter the salinity in the southeastern part of the sea is *20–25* parts per thousand (‰), in the northern part up to 34‰, and in the summer the salinity of the water falls to 5‰–10‰ in the southeast and 30‰–32‰ in the north.

Surface flows form a cyclonic water gyral, or rotation. Tides are primarily semidiurnal; the amplitude on the average is about *1.5* feet, excluding the Khatangsky Bay, where it approaches *6.5* feet. Tidal influence is exerted from the Arctic Basin, the tide range exceeding *8.2* feet.

Climate. The Laptev Sea has one of the most severe climates of the Arctic seas. The polar night (days on which the sun does not rise above the horizon) lasts about three months in the south and five months in the north. Air temperature below *32"* F (0° *C)* is observed in the north of the sea about *11* months and in the south nine months. The average temperature in January is *—24"* to —29° F *(—31"* to *—34" C),* the minimum about *—58"* F *(—50" C).* In July in the northern part the average temperature is just above the freezing point, in the southern part about 43° F (6° C), with a maximum 50° F (10° C). On the shores the maximum temperature can reach 75° F (24° C). The number of days with frost in July in the south is six, in the north 25. In winter there are frequent gales, blizzards, and snowstorms; in the summer, snow squalls and fogs. For most of the year the sea is covered with ice.

Water temperatures

The Laptev Sea is distinguished by its low water temperature. In the winter the temperature of the sub-ice level is 30.6° F (—0.8° C) in the southeastern part of the sea and 28.8° F (—1.8° C) in the northern part; in the deep regions it is from 29.1° to 28.9° F (—1.6° to —1.7° C). In the deepwater part of the sea, warmer Atlantic waters (up to 34.7° F, or 1.5° C) penetrate in a layer 800–1,000 feet (250–300 metres) deep. Beneath this layer the temperature is about 30.6° F (—0.8° C). In the summer, in icefree regions, a thin layer of water warms to 46°–50° F (8°–10° C) in the bays, 36°–37° F (2°–3° C) in the central part, and 32°–34° F (0°–1° C) in the north.

Economic activity. At the mouths of the rivers people earn their living catching salmon and other fish. Mammals found in the Laptev Sea include seal, sea hare, walrus, and polar bear.

The Laptev Sea is on the Northern Sea Route connecting Vladivostok and Arkhangelsk. Timber, building materials, and furs are the main cargoes. The main port is Tiksi. (Y.G.N./A.O.S.)

La Rochefoucauld

La Rochefoucauld became known in the 17th century as the leading exponent of the *maxime*, a peculiarly French type of epigram. The *maxime* utilizes utmost brevity to express, with the effect of shock and surprise, a truth or attitude from which palliation and explanation are absent.

Role in the Fronde

Heritage and political activities. François de La Rochefoucauld was born in Paris on September 15, 1613, the son of François, comte de La Rochefoucauld, and his wife, Gabrielle du Plessis-Liancourt. The son was known until his father's death in 1650 as the Prince de Marcillac. In 1628 he was married to Andrée de Vivonne, by whom he had four sons and three daughters. He served in the army against the Spaniards in Italy in 1629, in the Netherlands and Picardy in 1635–36, and again in Flanders in 1639. The public lives of both father and son were conditioned by the policies of Louis XIV's government, which by turns threatened and flattered the nobility. Though his father was created duke and made governor of Poitou, he was later deprived of that post when the loyalty of the family was called into question. His son was allowed by Cardinal Mazarin, the infant king's chief minister, to resume the governorship in 1646. The fact that his château at Verteuil was demolished by the crown, apparently without notice, in 1650 throws light on a main cause of the series of revolts between 1648 and 1653 known as the Fronde: the distrust and fear felt by the monarchy for the local independence of the nobility.

La Rochefoucauld, anonymous 17th-century portrait in the palace of Versailles.

Lauros–Giraudon

La Rochefoucauld was more vulnerable than most of his contemporaries, because throughout his life he seems to have been susceptible to feminine charm. In 1635 the Duchesse de Chevreuse had lured him into intrigues against the Cardinal de Richelieu, the chief minister of Louis XIII, an adventure that only procured for La Rochefoucauld a humiliating interview with Richelieu, eight days of imprisonment in the Bastille, and two years of exile at Verteuil. Later, his hatred for Mazarin and his devotion to Anne de Bourbon, duchesse de Longueville, sister of the Great Condé, who was the leader of the Fronde, led to an even more disastrous outcome. His own account of the weary alternation of plots and campaigns of the mutinous nobles throughout the revolts (1648–53) may be read in his *Mémoires.* His loyalty to the House of Condé did not increase his popularity with the crown and prevented him from pursuing any single policy for reform of royal or ministerial government. How far toward treason he allowed himself to be led, when the intentions of the reforming princes and nobility were superseded by personal ambitions, is shown by the draft of the so-called Treaty of Madrid of 1651, which laid down conditions of Spanish help to the French nobility. La Rochefoucauld not only signed the treaty but is thought by one scholar to have drafted it.

Two other features of his public career deserve mention, since they explain much of his writing—courage and litigation. The man who was to pen the aphorisms on courage and cowardice had certainly been in the forefront of battle. Within six years he was wounded in no fewer than three engagements. The injuries to his face and throat were such that he retired from the struggle, his health ruined and his peace of mind lost.

Financial and legal difficulties

His financial difficulties were no doubt intensified by war, his lands were heavily mortgaged, and but for the astute help of his agent he might not have been able to keep his establishment in central Paris, as he did from 1660 onward. He was forced to pay not only for fine living but for endless litigation. There is evidence of no fewer than five lawsuits in the space of three years, chiefly against other noble families, over questions of precedence and court ceremonial.

Yet in 1655 his literary endeavours were still before him. Thanks to the lasting and intellectually stimulating friendships with Mme de Sablé, one of the most remarkable women of her age, and Mme de Lafayette, he seems to have avoided politics for a while and gradually won his way back into royal favour, a feat sealed by his promotion to the knightly order of the Saint-Esprit at the end of 1661. Reading and intellectual conversation occupied his time as well as that of other men and women of a circle who listened to private readings of Pierre Corneille's classical tragedies and Nicolas Boileau's didactic poem on the principles of poetic composition, *L'Art poétique.* The circle was enlivened by a new game that consisted of discussing epigrams on manners and behaviour, expressed in the briefest, most pungent manner possible. The care with which La Rochefoucauld kept notes and versions of his thoughts on the moral and intellectual subjects of the game is clear from the surviving manuscripts. When the clandestine publication of one of them in Holland forced him to publish under his own name, it was clear that he had satisfied public taste: five editions of the *Maximes,* each of them revised and enlarged, were to appear within his lifetime.

The Maximes. The first edition of the *Maximes,* published in 1665, was called *Réflexions ou sentences et maximes morales* and did not contain epigrams exclusively; the most eloquent single item, which appeared only in the first edition and was thereafter removed by the author, is a three-page poetic description of self-interest, a quality he found in all forms of life and in all actions. The manuscripts also contain epigrams embedded in longer reflections; in some cases the various versions show the steps by which a series of connected sentences was filed down to the point of ultimate brevity. Beneath the general single statement, however, can be found a personal reaction to the Fronde, or to politics, often violent in its expression. For example

> ***Les crimes deviennent innocents, même glorieux, par leur nombre et par leurs qualités; de là vient que les voleries publiques sont des habiletés, et que prendre des provinces injustement s'appelle faire des conquêtes. Le crime a ses héros, ainsi que la vertu.*** (Crimes are made innocent and even virtuous by their number and nature; hence public robbery becomes a skillful achievement and wrongful seizure of a province is called conquest. Crime has its heroes no less than virtue has.)

It may have been hostile reception or the fear of revealing a political attitude that made him abandon this kind of epigram except for the almost unrecognizable No. 185: *"Il y a des hkros en mal comme en bien"* ("Evil as well as good has its heroes"). Modern readers forget that La Rochefoucauld's contemporaries would read recent history into statements that appear cryptic and opaque to posterity.

The Fronde was to La Rochefoucauld one of those moments of history that seemed to reveal men's motives at their worst. His exposure of the self-seeking that lay beneath conventional homage to morality has earned for him the reputation of a cynic, but his keener contemporaries are no less severe. The pungency and absence of explanation make his epigrams seem more scornful than similar statements embedded in memoirs. But La Rochefoucauld was concerned to convey something more than scorn, and beneath his professions of idealism he pinpointed a restless and unquenchable thirst for self-preservation. Virtue in the pure state was something he did not find:

> ***Les vertus se perdent dans l'intérêt comme les fleuves se perdent dans la mer*** (Virtues are lost in self-interest as rivers are lost in the sea).

This image of the sea recurred:

> ***Voilà la peinture de l'amour-propre, dont toute la vie n'est qu'une grande et longue agitation; la mer en est une image sensible; et l'amour-propre trouve dans le flux et reflux de ses vagues continuelles une fidèle expression de la succession turbulente de ses pensées et de ses éternels mouvements*** (Such is the picture of self-love, of which all life is one continuous and immense ferment. The sea is its visible counterpart and self-love finds in the ebb and flow of the sea's endless waves a true likeness of the chaotic sequence of its thoughts and of its everlasting motion).

Expression of moral and political attitudes

La Rochefoucauld has been called an Epicurean but his imaginative insights attached him to no doctrine. Like Michel de Montaigne and Blaise Pascal, he was aware of the mystery around man that dwarfs his efforts and mocks his knowledge, of the many things about man of which he knows nothing, of the gap between thinking and being, between what man is and what man does: ***"La nature fait le mérite et la fortune le met en oeuvre"*** ("Nature gives us our good qualities and chance sets them to work"). Some epigrams show a respect for the power of indolence, and others reveal an almost Nietzschean respect for strength. All these insights seem common to the French classical school of which he is so brilliant a member—though as an aristocrat he disdained being called a writer. These insights also accounted for his fame and influence on his disciples: in England Lord Chesterfield, the orator and man of letters, and the novelist and poet Thomas Hardy; in Germany the philosophers Friedrich Nietzsche and Georg Christoph Lichtenberg; in France the writers and critics Stendhal, Charles-Augustin Sainte-Beuve, and Andre Gide.

Artistry of the *Maxirnes*

Yet his chief glory perhaps is not as thinker but as artist. In the variety and subtlety of his arrangement of words he made the *maxime* into a jewel. It is not always the truth of the maxim that is so striking, but its exaggeration which can surprise one into a new aspect of the truth. He describes and defines—he has no time for more—but of the single metallic image he makes amazing use. He handles paradox to such effect that a final word can reverse the rest:

> ***On ne donne rien si libéralement que ses conseils*** (We give nothing so generously as . . . advice). ***C'est une grande folie de vouloir être sage tout seul*** (It is great folly to seek to be wise . . . on one's own).

La Rochefoucauld authorized five editions of the ***Maximes*** from 1665 to 1678. Two years after the last publication, he died in Paris during the night of March 16–17, 1680.

Though he did a considerable amount of writing over the years La Rochefoucauld actually published only two works, the *Mémoires* and the ***Maximes.*** In addition, about 150 letters have been collected and 19 shorter pieces now known as ***Réflexions diverses.*** These, with the treaties and conventions that he may have drawn up personally, constitute his entire work and of these only the ***Maximes*** stand out as a work of genius. Like his younger contemporary, Jean de La Bruyère, La Rochefoucauld was a man of one book.

BIBLIOGRAPHY. Three recent editions of La Rochefoucauld's writings in the "Pléiade Series" (1947, 1957, and 1962), give an idea of the movement of scholarship. Still indispensable, in spite of their date, are the *Oeuvres . . . ,* ed. by D.L. GILBERT, 4 vol. (1868–83); and E. MAGNE, ***Le Vrai visage de La Rochefoucauld*** (1923). For a general treatment, see W.G. MOORE, ***La Rochefoucauld: His Mind and Art*** (1969). Two good working editions of the ***Maximes*** are those by J. TRUCHET (1969), and by D. SECRETAN (1967). A mass of recent evidence on the background has been published by R. MOUSNIER in ***Lettres et mémoires adressés au chancelier Se'guier, 2*** vol. (1964).

(W.G.Mo.)

La Salle, Robert Cavelier, sieur de

René-Robert Cavelier, sieur de La Salle, a French explorer in North America, attempted not only to revolutionize the fur trade by the use of sailing vessels on the Great Lakes and the Mississippi, but also to found an empire for France in the West. His plans were too vast for achievement with the resources available to him, but by leading the first expedition to travel from the lakes of Canada to the Gulf of Mexico, La Salle made a prominent place for himself in the history of North American exploration.

La Salle, engraving by an unknown artist.

He was born at Rouen, Normandy, on November *22,* 1643, and was educated at a Jesuit college. La Salle first studied for the priesthood, but at the age of 22 he found himself more attracted to adventure and exploration and in 1666 set out for Canada to seek his fortune. With a grant of land at the western end of Île de Montreal, La Salle acquired at one stroke the status of a seigneur (*i.e.,* landholder), and the opportunities of a frontiersman.

Land grant in Montreal

The young landlord farmed his land near the Lachine Rapids, and, at the same time, set up a fur-trading outpost. Through contact with the Indians who came to sell their pelts, he learned various Indian dialects and heard stories of the lands beyond the settlements. He soon became obsessed with the idea of finding a way to the Orient through the rivers and lakes of the Western frontier.

If experience modified the visions of the dreamer, it enhanced the knowledge and skill of the pathfinder and trader. Having sold his land, La Salle set out in 1669 to explore the Ohio region. His discovery of the Ohio River, however, is not accepted by modern historians.

La Salle found a kindred spirit in Comte de Frontenac, the "Fighting Governor" of New France (the French possessions in Canada) from 1672 to 1682. Together, they pursued a policy of extending French military power by establishing a fort on Lake Ontario (Fort-Frontenac), holding the Iroquois in check, and intercepting the fur trade between the Upper Lakes and the Dutch and English coastal settlements.

Their plans were strongly opposed by the Montreal merchants, who feared the loss of their trade, and by the missionaries (especially the Jesuits), who were afraid of losing their influence over the Indians of the interior. Nevertheless, Fort-Frontenac was built where Kingston now stands, and La Salle was installed there as seigneur in 1675 after a visit to the French court, as Frontenac's representative. The governor had recommended him as "a man of intelligence and ability, more capable than anybody else I know here to accomplish every kind of enterprise and discovery. . . ." Louis XIV was sufficiently impressed by him to grant him a title of nobility.

At Fort-Frontenac, La Salle had control of a large share of the fur trade, and his affairs prospered. But his restless ambition drove him to seek greater ends. On another visit to France in 1677 he obtained from the King authority to explore "the western parts of New France" and permission to build as many forts as he wished, as well as to hold a valuable monopoly of the trade in buffalo hides.

Since the project had to be carried out at his own expense, however, he borrowed large sums in both Paris and Montreal, and he began to be enmeshed in a tangle of debts that was to blight all of his later enterprises. La Salle's proposals also roused still further the enmity of the Jesuits, who resolutely opposed all his schemes.

Preparations for the expedition to the Mississippi

When he returned to Canada in 1678, La Salle was accompanied by an Italian soldier of fortune, Henri de Tonty, who became his most loyal friend and ally. Early in the following year, he built the "Griffon," the first commercial sailing vessel on Lake Erie, which he hoped would pay for an expedition into the interior as far as the Mississippi. From the Seneca Indians above the Niagara Falls he learned how to make long journeys overland, on foot in any season, subsisting on game and a small bag of corn. His trek from Niagara to Fort-Frontenac in the dead of winter won the admiration of a normally critical member of his expeditions, the friar Louis Hennepin.

La Salle's great scheme of carrying cargo in sailing vessels like the "Griffon" on the lakes and down the Mississippi was frustrated by the wreck of that ship and by the destruction and desertion of Fort-Crevecoeur on the Illinois River, where a second ship was being built in 1680. Proud and unyielding by nature, La Salle tried to bend others to his will and often demanded too much of them, though he was no less hard on himself. After several disappointments, he at last reached the junction of the Illinois with the Mississippi and saw for the first time the river he had dreamed of for so long. But he had to deny himself the chance to explore it. Hearing that Tonty and his party were in danger, he turned back to aid them.

After many vicissitudes, La Salle and Tonty succeeded in canoeing down the Mississippi and reached the Gulf of Mexico. There, on April 9, 1682, the explorer proclaimed the whole Mississippi Basin for France and named it Louisiana. In name, at least, he acquired for France the most fertile half of the North American continent.

The following year La Salle built Fort-Saint-Louis at Starved Rock on the Illinois River (now a state park), and here he organized a colony of several thousand Indians. To maintain the new colony he sought help from Quebec; but Frontenac had been replaced by a governor hostile to La Salle's interests, and, instead of help, he received orders to surrender Fort-Saint-Louis. He refused to comply and left North America to appeal directly to the king. Welcomed in Paris, La Salle was given an audience with Louis XIV who favoured him by commanding the governor to make full restitution of La Salle's property.

Expedition to Mexico

The last phase of his extraordinary career centred on his proposal to fortify the mouth of the Mississippi and to invade and conquer part of the Spanish province of Mexico. He planned to accomplish all this with some 200 Frenchmen, aided by buccaneers and an army of 15,000 Indians—a venture that caused his detractors to question his sanity. But the king saw a chance to harass the Spaniards, with whom he was at war, and approved the project, giving La Salle men, ships, and money.

The expedition was doomed from the start. It had hardly left France when quarrels arose between La Salle and the naval commander. Vessels were lost by piracy and shipwreck, while sickness took a heavy toll of the colonists. Finally, a gross miscalculation brought the ships to Matagorda Bay in Texas, 500 miles west of their intended landfall. After several fruitless journeys in search of his lost Mississippi, La Salle met his death on March 19, 1687, at the hands of mutineers near the Brazos River. His vision of a French empire died with him.

La Salle provoked much controversy both in his own lifetime and later. Those who knew him best praised his ability unsparingly. He was considered "one of the greatest men of the age" by Tonty, who, like Frontenac, was among the very few who were able to understand the proud spirit of the dour Norman. Henri Joutel, who served under La Salle through the tragic days of the Texas colony until his death, wrote both of his fine qualities and of his insufferable arrogance toward his subordinates. In Joutel's view, this arrogance was the true cause of La Salle's death.

Undoubtedly, La Salle was hampered by faults of character and lacked the qualities of leadership. On the other hand, he possessed prodigious vision, tenacity, and courage. His claim of Louisiana for France, though but a vain boast at the time, pointed the way to the French colonial empire that was eventually built by other men.

BIBLIOGRAPHY. LOUISE P. KELLOGG, *Early Narratives of the North-West, 1634–1699* (1917), contains translations of original narratives of La Salle's companions; FRANCIS PARKMAN, *The Discovery of the Great West*, 5th ed. (1871, reissued 1956), embodies material from La Salle's own letters and other contemporary documents; LEON LEMONNIER, *Cavelier de la Salle et l'exploration du Mississippi* (1942), gives a balanced, modern French view of the subject; JOHN B. BREBNER, *The Explorers of North America, 1492–1806* (1964), summarizes impartially various estimates of La Salle's character and achievements.

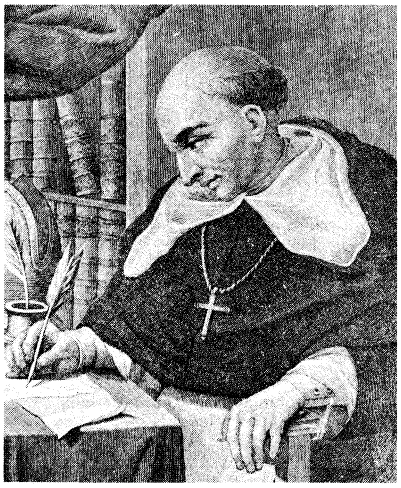
Las Casas, Bartolome de

Bartolomé de las Casas, an early-16th-century Spanish theologian and missionary in the Americas, was the first to expose the oppression of the Indian by the European and to call for the abolition of Indian oppression. A prolific writer and in his later years an influential figure of the Spanish court, he yet failed to stay the progressive enslavement of the indigenous races of Latin America. The son of a small merchant, Las Casas was probably born in Seville in August 1474. He is believed to have gone to Granada as a soldier in 1497 and to have enrolled to study Latin in the academy at the cathedral in Seville.

Early years in America

In 1502 he left for Hispaniola, in the West Indies, with the governor, Nicolás de Ovando. As a reward for his participation in various expeditions, he was given an *encomienda* (a royal land grant including Indian inhabitants), and he soon began to evangelize the Indians, serving as *doctrinero,* or lay teacher of catechism. Perhaps the first person in America to receive holy orders, he was ordained priest in either 1512 or 1513. In 1513 he took part in the bloody conquest of Cuba and, as priest-*encomendero* (land grantee), received an allotment of Indian serfs.

Although during his first 12 years in America Las Casas was a willing participant in the conquest of the Caribbean, he did not indefinitely remain indifferent to the fate of the natives. In a famous sermon on August 15, 1514, he announced that he was returning his Indian serfs to the Governor. Realizing that it was useless to attempt to defend the Indians at long distance in America, he returned to Spain in 1515 to plead for their better treatment. The most influential person to take up his cause was Francisco Jiménez de Cisneros, the archbishop of



Las Casas, engraving by an unknown artist.

Toledo and future co-regent of Spain. With the help of the Archbishop, the *Plan para la Reformación de Ins Indias* was conceived, and Las Casas, named priest-procurator of the Indies, was appointed to a commission to investigate the status of the Indians. He sailed for America in November 1516.

Las Casas returned to Spain the next year. In addition to studying the juridical problems of the Indies, he began to work out a plan for their peaceful colonization by recruiting farmers as colonists. His stirring defense of the Indians before the Spanish Parliament in Barcelona in December 1519 persuaded King Charles V, who was in attendance, to accept Las Casas' project of founding "towns of free Indians"—*i.e.*, communities of both Spaniards and Indians who would jointly create a new civilization in America. The location selected for the new colony was on the Gulf of Paria in the northern part of present-day Venezuela. Las Casas and a group of farm labourers departed for America in December 1520. The failure to recruit a sufficient number of farmers, the opposition of the *encomenderos* of Santo Domingo, and, finally, an attack by the Indians themselves all were factors that brought disaster to the experiment in January 1522.

Historia de las Indias

Upon his return to Santo Domingo, the unsuccessful priest and political reformer abandoned his reforming activities to take refuge in religious life; he joined the Dominican order in 1523. Four years later, while serving as prior of the convent of Puerto de Plata, a town in northern Santo Domingo, he began to write the ***Historia Apologe'tica.*** One of his major works, the *Apologética* was to serve as the introduction to his masterpiece, the *Historia **de las Indias.*** The ***Historia,*** which by his request was not published until after his death, is an account of all that had happened in the Indies just as he had seen or heard of it. But, rather than a chronicle, it is a prophetic interpretation of events. The purpose of all the facts he sets forth is the exposure of the "sin" of domination, oppression, and injustice that the European was inflicting upon the newly discovered colonial peoples. It was Las Casas' intention to reveal to Spain the reason for the misfortune that would inevitably befall her when she became the object of God's punishment.

He interrupted work on the book only to send to the Council of the Indies in Madrid three long letters (in 1531, 1534, and 1535), in which he accused persons and institutions of the sin of oppressing the Indian, particularly through the ***encomienda*** system. After various adventures in Central America, where his ideas on the treatment of the natives invariably brought him into conflict with the Spanish authorities, Las Casas wrote ***De único modo*** (1537; "Concerning the Only Way of Drawing All Peoples to the True Religion"), in which he set forth the doctrine of peaceful evangelization of the Indian. Together with the Dominicans, he then employed this new type of evangelization in a "land of war" (a territory of still-unconquered Indians)—Tuzutlan, near the Golfo Dulce (Sweet Gulf) in present-day Costa Rica. Encouraged by the favourable outcome of this experiment, Las Casas set out for Spain late in 1539, arriving there in 1540.

While awaiting an audience with Charles V, Las Casas conceived the idea of still another work, the ***Brevísima relación de la Destruccidn de las Zndias*** ("A Brief Report on the Destruction of the Indians"), which he wrote in 1542 and in which the historical events described are in themselves of less importance than their theological interpretation: "The reason why the Christians have killed and destroyed such an infinite number of souls is that they have been moved by their wish for gold and their desire to enrich themselves in a very short time." (***Destruccidn,*** Page 36).

Las Casas and the New Laws

Las Casas' work finally seemed to be crowned with success when King Charles signed the so-called New Laws (Leyes Nuevas). According to these laws, the ***encomienda*** was not to be considered a hereditary grant; instead, the owners had to set free their Indians after the span of a single generation. To ensure enforcement of the laws, Las Casas was named bishop of Chiapas in Guatemala, and in July 1544 he set sail for America, together with 44 Dominicans. Upon his arrival in January 1545, he immediately issued *Avisos* y *reglas **para confesores de españoles*** ("Admonitions and Regulations for the Confessors of Spaniards"), the famous ***Confesionario,*** in which he forbade absolution to be given to those who held Indians in *encomienda.* The rigorous enforcement of his regulations led to vehement opposition on the part of the Spanish faithful during Lent of 1545 and forced Las Casas to establish a council of bishops to assist him in his task. But soon his uncompromisingly pro-Indian position alienated his colleagues, and in 1547 he returned to Spain.

Las Casas then entered upon the most fruitful period of his life. He became an influential figure at court and at the Council of the Indies. In addition to writing numerous *memoriales* (petitions), he came into direct confrontation with the learned Juan Ginés de Sepúlveda, an increasingly important figure at court by reason of his *Democrates II* ("Concerning the Just Cause of the War Against the Indians"), in which he maintained, theoretically in accordance with Aristotelian principles, that the Indians "are inferior to the Spaniards just as children are to adults, women to men, and, indeed, one might even say, as apes are to men." Las Casas finally confronted him in 1550 at the Council of Valladolid, which was presided over by famous theologians. The argument was continued in 1551, and its repercussions were enormous.

The servitude of the Indians nevertheless was already irreversibly established, and, despite the fact that Sepúlveda's teachings had not been officially approved, they were, in effect, those that were followed in the Indies. But Las Casas continued to write books, tracts, and petitions, testimony to his unwavering determination to leave in written form his principal arguments in defense of the American Indian.

During his final years Las Casas came to be the indispensable adviser to both the Council of the Indies and to the King on many of the problems relating to the Indies. In 1562 he had the final form of the *Prólogo* to the ***Historia de las Zndias*** published, although in 1559 he had left written instructions that the work itself should be published only "after forty years have passed, so that, if God determines to destroy Spain, it may be seen that it is because of the destruction that we have wrought in the Indies and His just reason for it may be clearly evident." At the age of 90 Las Casas completed two more works on the Spanish conquest in the Americas. Two years later, on July 17, 1566, he died in the Dominican convent of Nuestra Seiiora de Atocha de Madrid, having continued to the end his defense of his beloved Indians, oppressed by the colonial system that Europe was organizing.

Assessment

At the suggestion of Francisco de Toledo, the viceroy of Peru, the King ordered all the works, both published and unpublished, of Las Casas to be collected. Although his influence with Spain and the Indies declined sharply, his name became well-known in other parts of Europe, thanks to the translations of the ***Destruccidn*** that soon appeared in various countries. In the early 19th century, the Latin American revolutionary Simón Bolivar himself was inspired by some of the letters of Las Casas in his struggle against Spain, as were some of the heroes of Mexican independence. His name has come into prominence again in the latter half of the 20th century, in connection with the so-called *Indigenistas* movements in Peru and Mexico. The modern significance of La Casas lies in the fact that he was the first European to perceive the economic, political, and cultural injustice of the colonial or neocolonial system maintained by the North Atlantic powers since the 15th century for the control of Latin America, Africa, and Asia.

BIBLIOGRAPHY. The most complete bibliography on Las Casas is *Bartolomé de las Casas (1474–1566) . . .*, compiled by LEWIS HANKE and MANUEL GIMENEZ FERNANDEZ (1954). The most important work to date, despite the fact that the author could not complete it, is MANUEL GIMENEZ FERNANDEZ, *Bartolomé de las Casas:* vol. 1, *Delegado de Cisneros para la reformación de las Indias. 1516–1517* (1953), and vol. 2, *Capellán de S.M. Carlos I, poblador de Cumaná, 1517–1523* (1960). A critical polemic work is that of RAMON MENENDEZ PIDAL, El *Padre de las Casas: su doble personalidad* (1963). For English readers the four studies of LEWIS HANKE supersede earlier works: *Bartolomé de las Casas: An Interpretation of His Life and Writings* (1951) ; *. . . Bookman, Scholar and Propagandist* (1952); *. . . Historian* (1952); and *Aristotle and the American Indians* (1959). The most complete edition of Las Casas' works is JUAN ANTONIO LLORENTE (ed.), *Colección de las obras del venerable obispo de Chiapas don Bartolomé de las Casas, defensor de la libertad de los americanos* (1822).

(E.Du.)

Laser and Maser

Lasers and masers are devices that produce a unique kind of radiation. Lasers produce an intense beam of light of a very pure single colour. Masers produce similar radiation, but in the microwave (radio) part of the electromagnetic spectrum. The names are acronyms derived from Microwave (or Molecular) Amplification by Stimulated Emission of Radiation (MASER) and Light Amplification by Stimulated Emission of Radiation (LASER). The difference between a maser and a laser is only that each operates in a different part of the spectrum, the maser in the radio spectrum and the laser in the light spectrum. Though the maser was invented first, the laser has proven much more useful.

Lasers represent the fulfillment of one of mankind's oldest dreams of technology, that of providing a light beam intense enough to vaporize the hardest and most heat-resistant materials. Lasers have been used to drill holes in diamonds for wire-drawing dies, to weld the retina of an eye to its supports to prevent detachment, and to perform microsurgery on parts of single cells.

Laser and maser principles. Atoms and molecules exist at low and high energy levels. Those at low levels can be excited to higher levels, usually by heat, and on reaching the higher levels they give off light when they return to a lower level. In ordinary light sources the many excited atoms or molecules emit light independently and in many different colours (wavelengths). If, however, during the brief instant that an atom is excited, light of a certain wavelength impinges on it, the atom can be stimulated to emit radiation that is in phase (that is, in step) with the wave that stimulated it. The new emission thus augments or amplifies the passing wave; if the phenomenon can be multiplied sufficiently, the resulting beam, made up of wholly coherent light (that is, light of a single frequency or colour in which all the components are in step with each other) will be tremendously powerful.

Einstein recognized the existence of stimulated emission in 1917, but not until the 1950s were ways found to use it in devices. U.S. physicist Charles H. Townes and colleagues built the first maser; shortly after, Townes and A.L. Schawlow showed that it was possible to construct a similar device using optical light; that is, a laser. Two Soviet physicists proposed related ideas independently. The first laser, constructed by the U.S. scientist T.H. Maiman in 1960, used a rod of ruby; since then many types of lasers have been built.

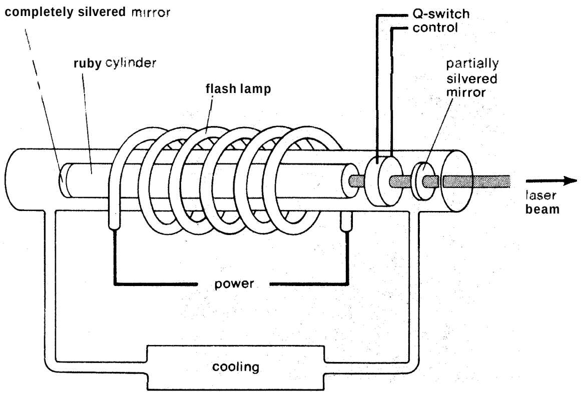

Figure 1: Q-switch, a special switching device that produces giant output pulse. In this example, a ruby laser is being used (see text).

TYPES OF LASERS

Of the several different types of lasers, produced by different means and useful for different purposes, the following are the most important.

Optically pumped solid lasers. One way to achieve the excitation of atoms to the higher energy level for laser action to take place is by illuminating the laser material with light of a frequency higher than that which the laser is to emit. This process is called optical pumping; the light pump must be of high intensity, as the process is usually rather inefficient.

An optically pumped laser consists of a rod of the material chosen, with the ends polished flat and parallel and coated with mirrors to reflect the laser light. The sides are left clear to admit the light from the pumping lamp, which may be a pulsed gas discharge, flashing on and off like a photographer's electronic flash bulb. It may be wound around the laser rod, positioned alongside, or focussed on it by a mirror (see Figure 1). The first operating laser utilized a rod of pink ruby, an artificial crystal of sapphire (aluminum oxide). Many other rare-earth elements have since been used, the most widely used being neodymium. Power outputs in the form of brilliant flashes of light of thousands of watts can be obtained.

Liquid lasers. Solid lasers have the disadvantage of occasional breakdown and damage at higher power levels because of the intense heat generated within the material and by the pumping lamp. The liquid laser is not susceptible to such damage; the crystalline or glassy rod is replaced by a transparent cell containing a suitable liquid, such as a solution of neodymium oxide or chloride in selenium oxychloride. Such cells can be made as large as desired to increase power output. Only a small number of inorganic liquids, however, will function as lasers.

Advantage of liquid lasers

Dye lasers. Certain organic dyes are capable of fluorescing; that is, re-radiating light of a different colour. Though the excited state of their atoms lasts only a small fraction of a second and the light emitted is not concentrated in a narrow band, many such dyes have been made to exhibit laser action, with the advantage that they can be tuned to a wide range of frequencies.

Dyes such as rhodamine *6G,* which emits orange-yellow light, can be made to lase (provide laser action) by excitation by another laser. Rhodamine 6G was the first dye for which continuous, rather than pulsed, operation was achieved, making possible the production of a continuous beam of tunable laser light. Another dye, methylumbelliferone, with the addition of hydrochloric acid, can be made to lase at wavelengths varying across the light spectrum from ultraviolet to yellow, producing laser light of almost any desired frequency within this range.

Gas lasers. Atoms in a gas discharge can be excited to radiate and produce light, as in a neon sign. Occasionally, a particular energy level will cause an exceptionally high number of atoms to accumulate within it; if mirrors are positioned at the ends of the discharge tube, laser action results. Though the conditions are unusual and occur for only a few of the many wavelengths at which the discharge emits, most gases can be made to exhibit laser

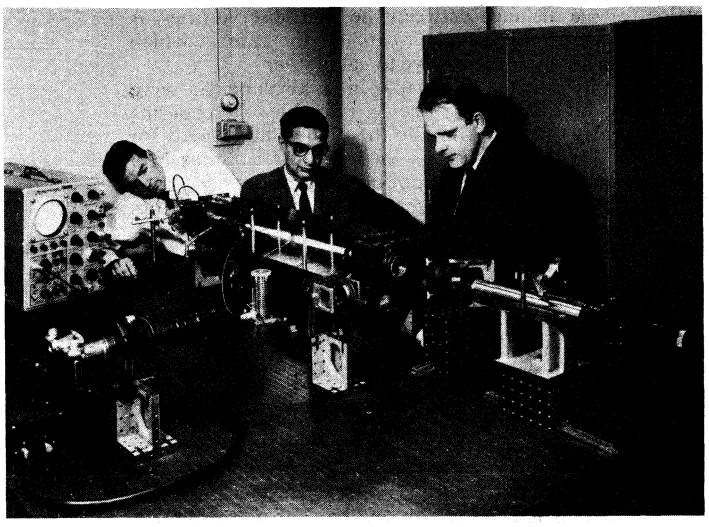

Figure 2: The first gas discharge laser, constructed by (left to right) Donald R. Herriott, Ali Javan, and William R. Bennett, Jr., and put in operation in late 1960.
By courtesy of Bell Laboratories

action at some wavelength under certain discharge conditions. The beam produced provides a nearly ideal straight line, valuable for alignment purposes in construction work (see Figure 2).

Gas dynamic lasers. If a hot gas is allowed to cool rapidly, the number of molecules in a low-energy state may decrease more rapidly and fall below the number in a higher energy state, thus permitting laser action. This condition can-be achieved by expanding burning carbon monoxide mixed with nitrogen through jet nozzles. High power outputs of over 30,000 watts can be obtained.-

Chemical lasers. Certain chemical reactions produce enough high-energy atoms to permit laser action to take place. Laser action can occur in carbon dioxide, for example, if it is present when the elements hydrogen and fluorine are reacting to produce hydrogen fluoride. Large amounts of energy can be released when only moderate amounts of the appropriate materials react.

Semiconductor lasers. A semiconductor laser consists of a flat junction of two pieces of semiconductor material, each of which has been treated with a different type of impurity. When a large electrical current is passed through such a device, laser light emerges from the junction region. Power output is limited, but the low cost, small size, and relatively high efficiency make these devices suited for short-distance communication (telephone, television, etc.) and for distance-measuring equipment.

Lasers as amplifiers and oscillators. Most lasers use the basic structure of a long, narrow column of active material terminated by small mirrors facing each other. Without the mirrors, the structure can be used to amplify a powerful laser beam, producing a still more intense output. With the mirrors, the structure becomes an oscillator, generating a beam whose wavelength is determined by two main factors: the spacing between the mirrors and the characteristics of the laser medium.

Lasers producing short, intense pulses. A shutter placed between the amplifying column and the end mirrors of a laser can prevent laser action as long as it is closed. If conditions are otherwise correct for laser action and the shutter is suddenly opened, the stored energy is released as a giant pulse of light lasting only a tiny fraction of a second, and having a peak power capacity that may be as high as several hundred thousand kilowatts. This is known as Q-switching. The Q-switch may be a mechanical shutter or, more usually, a liquid or solid optical shutter that is normally opaque but can be made transparent by the application of an electrical pulse. The shutter may also be an opaque dye which becomes transparent when exposed to laser light.

Normally a laser oscillates in several modes; that is, at several different frequencies. By synchronizing these modes, a process called mode-locking, even shorter, more powerful pulses can be obtained. Such pulses are useful in scientific investigations and in puncturing holes so rapidly that the surrounding material is not affected.

Tunable laser devices. For scientific purposes, it is highly desirable to produce lasers that can be tuned to a variety of frequencies, and this is possible with certain types. Dye lasers are especially good for this purpose, because they typically operate over a fairly wide frequency band; the desired wavelength can be selected by replacing one of the two mirrors with a mirror that reflects only the desired frequency, such as a diffraction grating. Certain solid lasers can be tuned over a smaller range by adjusting the temperature and orientation of the crystal. Others are capable of generating harmonics; that is, integral multiples of the frequency of an incoming laser beam. This characteristic of the crystal lithium iodate has been used in conjunction with an infrared beam to generate green laser light, which has good transmission characteristics through water.

MASERS

A maser oscillator requires a source of excited atoms or molecules and a resonator to store their radiation. The excitation must force more atoms or molecules into the upper energy level than in the lower, in order for amplification by stimulated emission to predominate over absorption. For wavelengths of a few millimetres or longer, the resonator can be a metal box whose dimensions are chosen so that only one of its modes of oscillation coincides with the frequency emitted by the atoms; that is, the box is resonant at the particular frequency, much as a kettle drum is resonant at some particular audio frequency. The losses of such a resonator can be made quite small, so that radiation can be stored long enough to stimulate emission from successive atoms as they are excited. Thus, all the atoms are forced to emit in such a way as to augment this stored wave. Output is obtained by allowing some radiation to escape through a small hole in the resonator.

The first maser used a beam of ammonia molecules that passed along the axis of a cylindrical cage of metal rods, with alternate rods having positive and negative electric charge. The nonuniform electric field from the rods sorted out the excited from the unexcited molecules, focussing the excited molecules through a small hole into the resonator. The output was less than one microwatt (10^{-6} watt) of power but the wavelength, being determined primarily by the ammonia molecules, was so constant and reproducible that it could be used to control a clock that would gain or lose no more than a second in several hundred years. This maser can also be used as a microwave amplifier. Maser amplifiers have the advantage that they are much quieter than those that use vacuum tubes or transistors; that is, they add very little noise to the signal being amplified. Very weak signals can thus be utilized. The ammonia maser amplifies only a very narrow band of frequencies and is not tunable, however, so that it has largely been superseded by other kinds, such as solid-state ruby masers.

Solid-state and travelling-wave masers. Amplification of radio waves over a wide band of frequencies can be obtained in several kinds of solid-state masers, most commonly crystals such as ruby at low temperatures. Suitable materials contain ions (atoms with an electrical charge) whose energy levels can be shifted by a magnetic field so as to tune the substance to amplify the desired frequency. If the ions have three or more energy levels suitably spaced, they can be raised to one of the higher levels by absorbing radio waves of the proper frequency.

The amplifying crystal may be operated in a resonator that, as in the ammonia maser, stores the wave and so gives it more time to interact with the amplifying medium. A large amplifying bandwidth and easier tunability are obtained with travelling-wave masers. In these, a rod of a suitable crystal, such as ruby, is positioned inside a wave-guide structure that is designed to cause the wave to travel relatively slowly through the crystal.

Solid masers have been used to amplify the faint signals returned from such distant targets as satellites in radar

Masers for satellite communications

and communications. Their sensitivity is especially important for such applications because signals coming from space are usually very weak. Moreover, there is little interfering background noise when a directional antenna is pointed at the sky, and the highest sensitivity can be used (see also SATELLITE COMMUNICATION). In radio astronomy, masers made possible the measurement of the faint radio waves emitted by the planet Venus, giving the first indication of its temperature.

Gas masers. Generation of radio waves by stimulated emission of radiation has been achieved in several gases in addition to ammonia. Hydrogen cyanide molecules have been used to produce a wavelength of 3.34 millimetres. Like the ammonia maser, this one uses electric fields to select the excited molecules.

One of the best fundamental standards of frequency or time is the atomic hydrogen maser introduced by U.S. scientists N.F. Ramsey, H.M. Goldenberg, and D. Kleppner in 1960. Its output is a radio wave whose frequency of 1,420,405,751.786 hertz (cycles per second) is reproducible with an accuracy of one part in thirty million million (30×10^{12}). A clock controlled by such a maser would not get out of step more than one second in 100,000 years.

In the hydrogen maser, hydrogen atoms are produced in a discharge and, like the molecules of the ammonia maser, are formed into a beam from which those in excited states are selected and admitted to a resonator. To improve the accuracy, the resonance of each atom is examined over a relatively long time. This is done by using a very large resonator containing a storage bulb. The walls of the bulb are coated so that the atoms can bounce repeatedly against the walls with little disturbance of their frequency.

Another maser standard of frequency or time uses vapour of the element rubidium at a low pressure, contained in a transparent cell. When the rubidium is illuminated by suitably filtered light from a rubidium lamp, the atoms are excited to emit a frequency of 6.835 gigahertz (6.835×10^9 hertz). As the cell is enclosed in a cavity resonator with openings for the pumping light, emission of radio waves from these excited atoms is stimulated.

LASER APPLICATIONS

The light produced by lasers is in general far more monochromatic, directional, powerful, and coherent than that from any other light sources. Nevertheless, the individual kinds of lasers differ very greatly in these properties as well as in wavelength, size, and efficiency. There is no single laser suitable for all purposes, but some of the combinations of properties can do things that were difficult or impossible before lasers were developed.

Lasers for alignment purposes

A continuous visible beam from a laser using a gas, such as the helium–neon combination, provides a nearly ideal straight line for all kinds of alignment applications. The beam from such a laser typically diverges by less than one part in a thousand, approaching the theoretical limit. The beam's divergence can be reduced by passing it backward through a telescope, although fluctuations in the atmosphere then limit the sharpness of a beam over a long path. Lasers have become widely used for alignment in large construction; *e.g.*, to guide machines for drilling tunnels and for laying pipelines. Laser beams are used to align jigs employed in producing large jet aircraft, permitting accuracies of a hundredth of an inch (0.25 millimetres) over distances of 200 feet (60 metres) or more.

A pulsed laser can be used in a light radar, sometimes called LIDAR, and the narrowness of its beam permits sharp definition of targets. As with radar (*q.v.*), the distance to an object is measured by the time taken for the light to reach and return from it, since the speed of light is known. LIDAR echoes have been returned from the Moon, facilitated by a multiprism reflector that was placed there by the first astronauts to land there. Now distances can be measured from an observatory on Earth to the lunar mirror with an accuracy of about one foot (30 centimetres). Simultaneous measurements of the mirror's distance and direction from two observatories, on different parts of the Earth, could give an accurate value for the distance between the two observatories. A series of such measurements can tell the rate at which continents are drifting relative to each other.

A vertically directed laser radar in an airplane can serve as a fast, high-resolution device (capable of rendering detail clearly) for determining the plane's altitude or for mapping fine details such as the contours of steps in a stadium or the shape of the roof of a house.

With a pulsed laser radar, returns can be obtained from dust particles and even from air molecules at higher altitudes. Thus air densities can be measured and air currents can sometimes be traced. A simpler LIDAR can serve to measure the height of cloud cover over airports.

Precise measurement of distances

The high coherence of a laser's output is very helpful in measurement and other applications involving interference of light beams. If a light beam is divided into two parts that travel different paths, when the beams come together again they may be either in step so that they reinforce, or out of step so that they cancel. Thus the brightness of the recombined wave changes from light to dark, producing interference fringes, when the difference in path lengths is changed by one-half of a wavelength (about ten millionths of an inch or 0.00025 millimetres for visible light). Such devices are called laser interferometers. Very small displacements can be detected, and larger distances can be measured with precision. With lasers, these measurements can be carried out over very long distances. Laser interferometers are being used to monitor small displacements in the Earth's crust across geological faults. In manufacturing, laser interferometers are being used to gauge fine wires, to monitor the products of automated machine tools, and to test optical components.

Lasers can be so monochromatic that a small shift in the light frequency can be detected. Light reflected from an object that is moving toward the laser is raised in frequency by an amount depending on the velocity of the object (Doppler effect). For a receding object the frequency is lowered. In either case, if some of the original and the shifted light are recombined at a photodetector, a signal at the difference frequency (the difference in frequency between the original and the shifted light) is observed, and even small velocities can be measured.

A laser can be constructed in which the light travels around a square or triangular ring. Waves are generated to travel around the ring in both the clockwise and counterclockwise directions. If the ring is stationary, these waves have the same frequency, but if it is rotated the frequency difference is proportional to the rate of rotation. Thus the ring laser can function as a gyroscope to sense rotations, even though it has no moving parts.

The brightness and coherence of laser light make it especially suitable for visual effects and photography that simulate third dimensional depth; *e.g.*, holography (*q.v.*).

The light from many lasers is relatively powerful and can be focussed by a conventional lens system to a small spot of great intensity. Thus even a moderately small pulsed laser can vaporize a small amount of any substance and drill narrow holes in the hardest materials. Ruby lasers, for example, are used to drill holes in diamonds for wire drawing dies and in sapphires for watch bearings. For biological research, a finely focussed laser can vaporize parts of a single cell, thus permitting microsurgery of chromosomes. Small spots, closely spaced, can be vaporized in an opaque film to record information for large computer memories.

The heating effects produced by a pulsed laser beam are both highly selective and extremely rapid. Thus ink can be removed from paper, making possible a laser eraser. The ink absorbs the laser light, is vaporized, and burns, while the paper remains unaffected.

Lasers for surgery

Strong heating can be produced by a laser at a place where no mechanical contact is possible. Thus one of the earliest applications of lasers was for surgery on the retina of the eye. Other surgical applications, using larger lasers, are being investigated.

Lasers are also used for small-scale cutting and welding. They can trim resistors to exact values by removing material, and can alter connections within integrated arrays of microcircuit elements.

A pulse of light from a laser can vaporize a sample of a substance for analysis by suitable instruments. By this method an extremely small sample can be analyzed without introducing contaminants.

The high brightness, pure colour, and directionality of laser light make it ideally suitable for experiments on light scattering. Even a small amount of light that is scattered with a change of wavelength or direction can be readily identified. In particular, a type of scattering known as the Raman effect produces characteristic wavelength shifts by which molecular species can be identified. With laser sources and sensitive spectrography, small samples of transparent liquids, gases, or solids can be analyzed. It is even possible to measure contaminants in the atmosphere at a considerable distance by Raman scattering of light from a laser beam.

Laser beams can be used for communications. Because the light frequency is so high (around 5 × 10'' hertz for visible light), the intensity can be rapidly altered to encode very complex signals. In principle, one laser beam could carry as much information as all existing radio channels; experimentally, seven television programs have been transmitted at one time. Laser light can, however, be blocked by rain, fog, or snow so that for reliable communications on Earth, the laser beam would need to be enclosed in protecting pipes. Meanwhile, lasers are useful for special purpose communications. For long distance communication through outer space, the great directionality of laser beams makes effective use of small amounts of power.

SAFETY CONSIDERATIONS

Some lasers, especially the higher power carbon dioxide and solid-state, produce beams so powerful that they could cause serious injury even at a great distance. These must be operated only when no inflammable materials are in its path and when there is no possibility of anyone being struck by the beam.

The largest numbers of lasers in use, however, are low power types, such as the helium–neon lasers widely used for alignment and measurement. The intensity of the laser light is not high enough to cause injury directly, but, since it is a highly directional beam, its light can be concentrated into a small spot by focussing. In particular, the lens of the eye can focus laser light to a small, intense spot on the retina and can damage this sensitive tissue. The light reflected from a mirror or even a shiny surface is nearly as dangerous as the direct beam. For such lasers it is essential to avoid looking directly into the beam or its reflection. Pulsed lasers are more hazardous because of the high peak intensity and because there is no chance to respond to the sudden flash.

There is little hazard, however, when the light of a low power continuous-wave laser is used to illuminate a diffuse surface. The light scattered by the object is spread in all directions and an eye at any substantial distance can intercept only a small fraction of the light.

Most lasers are far from being the death rays of science fiction. With reasonable precautions they can be used safely for many purposes. Safety standards and operating procedures are under study by various government public health and safety organizations, and high-power lasers are subject to regulations in many areas.

FUTURE PROSPECTS

Research on properties and applications of masers and lasers is active throughout the world. The search for ways of obtaining coherent light at additional wavelengths continues, even as gaps are being filled by tunable lasers. One persistent frontier of research is the problem of generating still shorter wavelengths for scientific purposes and possible other applications; constructing maser or laser-like devices, will become increasingly difficult as the wavelength is decreased. The rate of spontaneous emission increases rapidly as the wavelength is decreased, and it becomes correspondingly more difficult to maintain enough atoms in excited states to provide amplification. Moreover, for wavelengths approaching or in the extremely short X-ray region, no substance is as transparent as many materials are for visible light. Extra excitation will be needed to overcome losses due to this lack of transparency. It does seem possible that some kind of device to produce coherent X-rays by stimulated emission eventually will be constructed. Its uses can hardly be foreseen now, although holography to reveal the positions of atoms in molecules is a possibility.

X-ray lasers possible

Continuous-wave gas lasers in the visible or near-visible region provide very good standards of length. Their wavelength is chiefly determined by the particular gas atoms. There are small uncertainties introduced by the spacing of the end mirrors and by collisions in the gas discharge tube, however. The wavelength of an unstabilized helium–neon laser may vary by about ten parts in 1,000,000.

Much better accuracy is obtained by carefully adjusting the laser to oscillate at the precise centre of the band of wavelengths that the gas discharge can generate. Still better accuracy, about one part in 10^{12}, can be achieved by new methods that locate the exact centre frequency of the absorption resonance of molecules such as iodine. These molecules can be located outside the laser so as not to be disturbed by the gas discharge, and the wavelength that they absorb is very precisely reproducible. A laser of this sort might ultimately serve as a primary standard of length. More studies are needed to find the best of the several possible atomic or molecular wavelength standards and to ensure that it can be accurately reproduced in different laboratories.

It has become possible to measure the frequency of a light wave by using lasers. A microwave oscillator is first measured in terms of an atomic frequency standard such as the hydrogen maser or an atomic beam of the element cesium. High harmonics of the microwave oscillator are then generated by a silicon crystal and used to measure and synchronize the frequency of a laser in the infrared. In turn, harmonics of this laser are generated and used to control the frequency of a shorter wavelength infrared laser. After several such steps, the overtones of a near infrared laser produce visible light whose frequency is an exact, known multiple of a measured microwave frequency

In the near future, it should be possible to measure precisely the frequency and wavelength of the same visible laser beam, synchronized to some atom or molecule. It may then be best to define the basic standard of length in terms of the wavelength of the light of the chosen atom, and to define the standard of time in terms of the frequency of the same atomic oscillation.

Lassalle, Ferdinand

Ferdinand Lassalle was the leading spokesman for German socialism, after an unsuccessful revolution there in 1848, and one of the founders of the German labour movement.

Lassalle was born at Breslau on April 11, 1825 of Jew-

Lassalle, c. 1860.
Archiv *fur* Kunst und *Geschichie*

ish parents; his father, Heymann Lasal, or Loslauer, was a wholesale silk merchant and town councillor.

Early years

Ferdinand Lassalle—the spelling of the name dates from a stay in Paris in 1846—attended the Breslau classical high school but was expelled when he forged a signature on a school report. He attended a trade school in Leipzig in 1840, returned to Breslau in 1841, and passed his school-leaving examination in 1843. Diaries of this period show him as a "tumultuous personality," full of contradictions. On the one hand he says, "I have voluntarily renounced a life devoted to beauty in order to become a shop clerk," and on the other, "Now is the time to fight for the most sacred principles of humanity."

In 1843–44 he began to study philosophy, history, philology, and archaeology at the University of Breslau. In 1844–45 he continued his studies in Berlin, interrupting them only briefly in 1845 for an interlude in Breslau. In Berlin he first encountered the ideas of the German philosophers G.W.F. Hegel and Ludwig Feuerbach and of the French Utopian thinkers. Intending to take his degree and to qualify as a university lecturer with a thesis on the philosophy of Heracleitus, he made repeated studies of the subject in Paris between 1845 and 1847. Here he met the French social theorist Pierre-Joseph Proudhon and Heinrich Heine, the German poet.

Champion of Countess Hatzfeld

In 1846, in Düsseldorf, he met the unhappily married Countess Sophie Hatzfeld, who was trying to divorce her husband. Although not a lawyer, Lassalle conducted 35 lawsuits in her behalf and in 1854 finally obtained a divorce for her. Henceforth, he received an annual pension of 4,000 thalers from the countess, thus becoming financially independent. His lifelong relationship with the countess, though it was nothing more than that of son and mother, "stimulated gossip about Lassalle and immensely impeded his political career." Lassalle lived in Düsseldorf from 1848 to 1857 and took part in the revolution of 1848–49, by which the liberal middle class tried to attain a constitutional monarchy that would grant such civil rights as freedom of assembly and freedom of the press. During those days he established contact with Karl Marx and Friedrich Engels, the Socialist leaders. When Lassalle urged the militia to open revolt in November 1848 he was arrested and held in prison until his trial in July 1849. One of the few radical leaders who did not emigrate during the revolution, he remained in Germany after its collapse. Although he was repeatedly arrested, indicted, and sentenced to prison, Lassalle counted his years in Düsseldorf, where he was able to be active both as a writer and labour organizer, among the happiest of his life. In the period of reaction following the abortive revolution, he travelled to Switzerland, to the World's Fair in Paris in 1855, and to the Orient in 1856. He completed the Heracleitus manuscript and the tragedy *Franz von Sickingen* (1859), which assigns to personality a role in determining the course of history.

Lassalle and Bismarck

In 1857 Lassalle went back to Berlin, and in 1859 he settled permanently in the capital, where he became active as a political journalist. He met Marx in 1861, but, although they continued to correspond, they gradually became estranged. In contrast to Marx, Lassalle believed that the revolutionary phase had come to an end and that only a legal and evolutionary approach could hold hopes of success. With this goal in mind he held discussions with the Prussian prime minister Otto von Bismarck in 1863–64. Fourteen years after Lassalle's death Bismarck said of him, "He was one of the most intelligent and amiable men I have ever associated with, a man of great ambition and by no means a republican." Finding himself in a difficult political situation, Bismarck was, in the early 1860s, seeking allies in his struggle against the majority liberal opposition, while Lassalle was considering the concept of a monarchical welfare state. This was to be based on a universal suffrage for the three classes rather than on the existing suffrage that favoured the upper classes. He thus hoped, by integrating the working class into political and social life, to achieve a transition from a bourgeois state based on private property to a democratic constitutional state. Lassalle and Bismarck were attracted to each other by their many common characteristics. Lassalle in particular was distinguished by his charismatic personality and his paternalist notions of democracy, understandable in the context of a largely politically apathetic population.

The year 1862 produced a crisis in Lassalle's thinking when the rising in Italy led by Garibaldi did not, contrary to Lasalle's expectations, spread to other countries. Berlin remained utterly unreceptive to his ideas. Realizing that lecturing and distributing pamphlets to artisans' clubs and citizens' associations were not producing sufficient results, Lassalle began agitating in workingmen's associations in order to make his political aims known to the masses. Bismarck's conflict with the Prussian parliament led Lassalle to re-examine his liberal beliefs. He now began to study political economy. Lecturing on constitutional problems, he stated: "Initially, constitutional questions are not questions of law, but rather questions of power."

Organization of the "Suffrage Army"

In December 1862, Lassalle was asked by the executive committee of the "Central Committee to Convoke a General Congress of German Workers" to write a program for the congress. Lassalle at once recognized in the congress an opportunity to organize a "Suffrage Army." "Organize yourselves as a general German workingmen's association to agitate legally and peacefully, but untiringly and ceaselessly, for the introduction of universal and direct suffrage in all German provinces! This is the banner you must raise! This is the sign under which you will be victorious!"

In 1863–64 Lassalle hurled himself into the struggle for workers' rights, especially in the Rhineland. "Only the working class matters to me," he declared. When the ADAV (Allgemeiner Deutscher Arbeiterverein, or General German Workers' Association) was founded on May 23, 1863, in Leipzig, Lassalle was elected president for a five-year term. In Cologne he collaborated with a Socialist writer, Moses Hess, but other associates rebelled against Lassalle's authoritarian leadership and the cult of his personality he did nothing to discourage. His generally incendiary speeches were often followed by lawsuits.

Exhausted and disappointed over the insignificant results of his propaganda activity, Lassalle announced, "I am sick and tired of politics!" In Switzerland, where he went for a rest in July 1864, he met Helene von Dönniges. He courted her passionately, but encountering opposition from the young girl's family, he challenged her father and her former fiancé, Yanko von Racowitza, to a duel. Racowitza accepted, and on August 28, in a little forest near Geneva, the senseless duel was fought. Lassalle was struck in the abdomen and died August 31. He was buried in the Jewish cemetery in Breslau.

Assessment

Lassalle was for many decades considered a reformist heretic by the worker's movement, which then adhered to the deterministic notions of popular Marxism according to which the dictatorship of the proletariat was foreordained by history. By others Lassalle continued to be romantically glorified as a pioneer of Socialism.

Only since the time of Eduard Bernstein and the era of revisionism, when the German Social Democratic Party, aiming at becoming a party of the masses, set down the aims of parliamentary democracy and participation in government, has the modern significance of Lassalle been acknowledged. It is not the theorist or the organizer of a workers' party who is remembered, but, in the words of the German Social Democratic leader Carlo Schmid, a Lassalle "who in place of scientific analysis constantly fixed his sights on the true aim on history's horizon: the liberation of man from the position of object and the elimination of man's alienation from himself through the power of his own will."

Latin America and the Caribbean, Colonial

The colonial era in Latin America and the Caribbean began in the late 15th century with the first voyages of discovery in the New World (then thought to be part of the Indies) and ended in the 19th century with the successful movements for independence. The histories of these regions before and after the colonial era are covered in other major articles.

This article is divided into the following sections:

- I. The Spanish conquest of America
  - The great voyages
    - The voyages of Christopher Columbus
    - Other early explorations
  - The conquest of Mexico
  - The conquest of Peru
- II. Spain's colonial empire
  - Colonial government
    - The Council of the Indies
    - Viceroys, captains general, and audiencias
    - Provincial government
    - Restrictions on public officials
    - Municipal government
    - Other government offices
  - Spain's Indian policy
  - The colonial economy
  - Commerce, smuggling, and piracy
  - The church in the Indies
    - The missions
    - The Jesuits in Paraguay
    - The Inquisition
- III. Colonial Brazil
  - The formation of colonial Brazil
    - Colonization
    - Slave hunters
    - Rivals to the Portuguese
    - Shift to the south
    - Trade
  - Government and church
  - Masters and slaves
- IV. The Bourbon reforms and Spanish America
  - Reforms
  - Colonial economic growth
  - Decentralization
  - Defense of the empire
- V. The wars of independence
  - Background for the wars
    - Enlightenment and revolutionary influences
    - Beginnings of the independence movement
  - The independence of South America
    - Spanish South America
    - Brazil
  - The independence of Mexico

I. The Spanish Conquest of America

THE GREAT VOYAGES

Search for a sea route to the East

The discovery of America was a by-product of European efforts in the 15th century to find a sea route to the East and thereby to end the monopoly of Italian and Levantine middlemen over the lucrative trade in spices and other Oriental products. Portugal took a decisive lead; it had the advantages of a long Atlantic seaboard with excellent harbours, a large number of fishermen and sailors, and an aristocracy that had learned to supplement its meagre revenue from the land with income from trade and shipbuilding. In 1497 a fleet of four Portuguese ships commanded by Vasco da Gama sailed from Lisbon on a voyage that inaugurated the age of European imperialism in Asia. After rounding the Cape of Good Hope, Vasco sailed into the Indian Ocean and up the coast of East Africa and then to Calicut, the great spice-trade centre on the west coast of India.

The voyages of Christopher Columbus. The search for a sea road to the Indies inspired more than one solution. An obscure Italian seafarer, Christopher Columbus, became convinced that it was possible to reach the East from Europe by sailing westward across the Atlantic and that his proposed route was shorter than the route around Africa, a conception that underestimated the size of the earth and overestimated the size and eastward extension of Asia. About 1484 Columbus, who then resided in Lisbon, offered to make a voyage of discovery for John II of Portugal, but the king turned it down. Columbus next turned to Castile, where, after eight years of discouraging delays and negotiations, Queen Isabella agreed to support the "Enterprise of the Indies." The contract made by the Queen with Columbus named him admiral, viceroy, and governor of the lands he should discover and promised him a generous share in the venture's profits.

The "Enterprise of the Indies"

On August 3, 1492, Columbus sailed from Palos with three small ships—the "Pinta," the "Santa Maria," and the "Niña"—manned not by the jailbirds of legend but by experienced crews under competent officers. The voyage was remarkably prosperous, with fair winds the whole way out. On October 12 they made landfall at an island in the Bahamas, which Columbus named San Salvador. Cruising southward through the Bahamas, Columbus came to the northeastern coast of Cuba, which he mistook for part of Cathay (China). Next he sailed westward to explore the northern coast of an island that he named Española (Hispaniola), where he lost his flagship, the "Santa Maria." He then returned to Spain to report his supposed discovery of the Indies.

In response to Portuguese charges of encroachment on an area in the Atlantic reserved to Portugal by a previous treaty with Castile, King Ferdinand and Queen Isabella appealed for help to Pope Alexander VI, himself a Spaniard. The pontiff issued a series of bulls (1493) that assigned to Castile all lands discovered or to be discovered by Columbus and drew a line from north to south 100 leagues (345 miles) west of the Azores and Cape Verdes. To the west of this line was to be a Spanish sphere of exploration; to the east, Portuguese. To John II this line seemed to threaten Portuguese interests in the south Atlantic and the promising route around Africa to the East. Yielding to Portuguese pressure, Ferdinand and Isabella signed, in 1494, the Treaty of Tordesillas, establishing a boundary 270 leagues (930 miles) farther west.

Columbus returned to Espaiiola at the end of 1493 with a fleet of 17 ships carrying 1,200 colonists. The settlers soon gave themselves up to gold hunting and preying on the Indians; and Columbus, a foreigner, lacked the power and the personal qualities to control them. In 1496 he returned to Spain to report his new discoveries and to answer charges sent by disgruntled settlers.

The first two voyages had not paid their way, but the Spanish sovereigns still had faith in Columbus and outfitted a third fleet in 1498. On this voyage he discovered the island of Trinidad and the mouths of the Orinoco. He arrived in Española to find chaos. The Spaniards, disappointed in their hopes of quick wealth, blamed Columbus for their misfortunes and rose in revolt. To appease the rebels Columbus had to issue pardons and grant land and Indian slaves. Meanwhile, a stream of complaints against Columbus had caused the sovereigns to send out an agent, Francisco de Bobadilla, to supersede Columbus and investigate the charges against him. Bobadilla seized Columbus and sent him to Spain in chains. Although Isabella ordered Columbus' release, he never again exercised the functions of viceroy and governor in the New World. Columbus made one more voyage—in 1502–04—an unsuccessful search for a strait that would lead into the Indian Ocean. From Española, where he was not permitted to land, he crossed the Caribbean to the coast of Central America and followed it southward to the Isthmus of Panama. He finally departed for Española but was forced to land on Jamaica, where he and his men were marooned for a year.

Complaints against Columbus

Other early explorations. Other explorers followed and gradually made known the immense extent of the mainland coast of South America. In 1499 Alonso de Ojeda, accompanied by the Florentine Amerigo Vespucci, sailed to the mouths of the Orinoco and explored the coast of Venezuela. Vespucci personally directed another voyage, in 1501–02, under the flag of Portugal; this expedition, sent to follow up the discovery of Brazil by Pedro Álvares Cabral in 1500, explored the Brazilian coast and discovered the Rio de la Plata before turning back. To Vespucci it was obvious that the landmass thought by Columbus to be a part of Asia was really a new continent —a "fourth part of the world." Vespucci's letters circulated widely in the early 1500s and gave him the fame of being the first European to set foot on the South American continent. A German geographer, Martin Waldseemuller, honoured Vespucci by assigning on a map the name America to the area of Brazil. The name caught on and presently was applied to the whole of the New World.

The naming of America

A growing shortage of Indian labour and a general lack of economic opportunities for new settlers on Española incited Spanish slave hunters and adventurers to explore and conquer Puerto Rico, Jamaica, and Cuba between 1509 and 1511. In the same period efforts to found colonies on the coast of northern Colombia and Panama failed disastrously, and the remnants of two expeditions were united under the conquistador Vasco Núñez de Balboa to form the settlement of Darién on the Isthmus of Panama. Moved by Indian tales of a great sea, south of which lay a land overflowing with gold, Balboa led an expedition across Panama to the shores of the South Sea (Pacific Ocean). This aroused the jealousy of his father-in-law, Pedrarias Dávila, sent out by Charles V in 1514 as governor of the Isthmus, who contrived charges of treason and desertion; Balboa was tried, condemned, and beheaded in 1519.

The discovery of the South Sea helped confirm Vespucci's view that the so-called Indies formed no part of Eastern Asia. After 1513 the work of discovery centred on the search for a waterway to the East through or around the American continent. Ferdinand Magellan's circumnavigation of the globe in 1519–22 was too long to have commercial value. The net result was to enhance the value of America in Spanish eyes. Disillusioned with the dream of easy access to the East, Spain turned with concentrated energy to the task of extending its American conquests and to the exploitation of the human and natural resources of the New World.

THE CONQUEST *OF MEXICO*

In 1517 a slave-hunting expedition outfitted by Gov. Diego de Velázquez de Cuéllar of Cuba discovered the Yucatan peninsula of Mexico, inhabited by Maya Indians whose pyramids, temples, and gold ornaments revealed a native culture far more advanced than any the Spaniards had previously encountered. Encouraged by the gold and other signs of Indian wealth brought back by the expedition, Velázquez outfitted a new venture, which he entrusted to his kinsman Juan de Grijalba. Grijalba coasted down the Yucatan Peninsula and, in June 1518, reached the limits of the Aztec Empire. From near what is now the port of Veracruz, Grijalba sent one ship back to Cuba with the gold that had been gained by barter with the coastal Indians and sailed on westward with three other ships, perhaps as far as the river Pánuco, marking the northern limits of the Aztec Empire. He returned to Cuba in November.

Velázquez sent a third expedition, with some 600 men under Hernán Cortés, to conquer the Mexican mainland in February 1519. Because Velázquez had not yet secured from the emperor Charles an agreement authorizing conquest and settlement of the mainland, Cortés' instructions permitted him only to trade and explore.

Cortés' expedition to Mexico

Cortés' fleet first touched land at the island of Cozumel, off the coast of Yucatan. In March 1519, Cortés landed on the coast of Tabasco and defeated local Indians. In April he dropped anchor near the site of modern Veracruz, founding the town of Villa Rica de la Vera Cruz and appointing its first officials, into whose hands he surrendered the authority he had received from Velázquez. These officials then conferred on Cortés the title of captain general with authority to conquer and colonize the newly discovered lands (Cortés thus drew on Spanish medieval traditions of municipal autonomy to vest his disobedience with a cloak of legality).

Some days later the Aztec king Montezuma's (Moctezuma) ambassadors appeared in the Spanish camp. Apparently convinced that Cortés was the god Quetzalcóatl, who was returning to reclaim his lost realm, the envoys brought precious gifts—the finery of the great gods Quetzalcóatl, Tláloc, and Tezcatlipoca; a gold disk in the shape of the sun, as big as a cartwheel; an even larger disk of silver, in the shape of the moon; and a helmet full of small grains of gold—while pleading with Cortés not to seek a meeting with their king. By plying Cortés-Quetzalcóatl with gifts Montezuma hoped to dissuade him from advancing into the interior and reclaiming the god's lost throne. Suavely Cortés informed the ambassadors that he had come a long way to see and speak with Montezuma, and he could not return without doing so.

Cortés, becoming aware of the bitter discontent of tributary towns with Aztec rule, began to play a double game. He encouraged the Totonac Indians of the coast to seize and imprison Montezuma's tax collectors, and he then promptly obtained their release and sent them to the king with expressions of regard and friendship. He took two other steps before beginning the march on the Aztec capital at Tenochtitlán (now Mexico City). First, he sent dispatches to the emperor Charles seeking approval for his actions by describing the extent and value of discoveries; and second, to stiffen the resolution of his followers by cutting off all avenues of escape, he scuttled and sank all his remaining ships on the pretext that they were not seaworthy. Then, with his small army, he began a march on Tenochtitlán.

Advancing into the sierra, Cortés met and defeated in battle the Tlaxcalan Indians, traditional enemies of the Aztecs; the Tlaxcalans then formed an alliance with the white invaders. Next Cortés marched on Cholula, centre of the cult of Quetzalcóatl, where he claimed that the Cholulans were conspiring to attack him and staged a mass slaughter of the Cholulan nobility and warriors after they had assembled at his bidding in a great courtyard. Montezuma sent new envoys who brought rich gifts to Cortés but urged him to abandon his plan of visiting the Aztec capital; all of Montezuma's stratagems failed, and he welcomed Cortés at the entrance to the capital as a rightful ruler returning to his throne. The Aztec ruler even allowed himself to be kidnapped from his palace and taken to live as a hostage in the Spanish quarters.

Greeting of Cortés by Montezuma

A blunder on the part of his lieutenant Pedro de Alvarado thwarted Cortés' plan to use Montezuma as a puppet ruler. In Cortés' absence Alvarado ordered a massacre of the leading Aztec chiefs and warriors during a religious festival. This caused an uprising that forced the Spaniards to retreat to their own quarters. The tribal council deposed the captive Montezuma and elected a new chief, who launched vigourous attacks on the white invaders. In the midst of the struggle Montezuma died—killed by his own people as he appealed for peace, according to Spanish accounts; strangled by the Spaniards themselves, according to Indian sources. Threatened by a long siege and famine, Cortés evacuated Tenochtitlán at a heavy cost in lives. The surviving Spaniards and their Indian auxiliaries at last reached Tlaxcala.

In December 1520 Cortés, strengthened by Spanish reinforcements from Cuba, again marched on Tenochtitlan. A desperate struggle began in late April 1521. On August 23, after a siege of four months, the last Aztec king Cuauhtémoc surrendered; and Cortés took possession of the ruins that had been the city of Tenochtitlán.

From the Valley of Mexico the tide of conquest flowed in all directions. Guatemala was reduced by Pedro de Aivarado; Honduras, by Cortés himself. In 1527 Francisco de Montejo began the conquest of Yucatan (in 1542 the Maya Indians rose in a revolt that was crushed with great slaughter). Meanwhile, expeditions from Darién subjugated the Indians of Nicaragua; and thus the two streams of Spanish conquest, both originally starting from Espafiola, came together again.

For a brief time Cortés was undisputed master of the old Aztec Empire, renamed the "Kingdom of New Spain." The crown granted him the title of "Marquis of the Valley of Oaxaca" and the tribute and labour services of 23,000 Indian vassals. But the characteristic royal distrust of the great conquerors soon asserted itself. He was removed from his office of governor, and in 1539 he returned to Spain.

THE CONQUEST OF PERU

The golden kingdom beyond the South Sea

The conquest of Mexico challenged other Spaniards to match the exploits of Cortés and his companions and to discover the golden kingdom rumoured to lie beyond the South Sea. In 1519 Pedrarias founded the town of Panama on the western side of the isthmus, which became a base for exploration along the Pacific coast. Three years later Pascual de Andagoya crossed the Gulf of San Miguel and returned with more information about a land of gold called Birú (Peru). Pedrarias then entrusted command of a voyage of discovery southward to Francisco Pizarro, who, in turn, recruited two partners—Diego de Almagro, an adventurer of obscure origin, and Hernando de Luque, a priest who acted as financial agent for the trio. Two preliminary expeditions (1524 and 1526) yielded enough finds of gold and silver to confirm the existence of the elusive kingdom. Pizarro then left for Spain to obtain royal sanction for the exploration of Peru. He returned to Panamá with the titles of captain general and *adelantado* (provincial governor) accompanied by his four brothers and other followers.

In December 1530 Pizarro again sailed southward from Panamá with a force of some 200 men and landed in the spring on the Peruvian coast. Civil war was raging in the Inca Empire. Atahualpa, son of the late emperor Huayna Capac by a secondary wife, had defeated and imprisoned the lawful heir to the throne, Huáscar, and was moving toward the imperial capital of Cuzco when he received news of the arrival of white strangers. After an exchange of messages and gifts between Pizarro and Atahualpa, the two armies advanced toward a meeting at the town of Cajamarca, high in the mountains.

Pizarro planned to win a quick, relatively bloodless victory by seizing the emperor as Cortés had done with Montezuma. When Atahualpa and his escort appeared in the square of Cajamarca, they found it deserted, for Pizarro had concealed his men in some large buildings opening on the square. At a signal from Pizarro his soldiers, supported by cavalry and artillery, rushed forward to kill hundreds of terrified Indians and take the Inca prisoner.

Atahualpa attempted to gain his freedom by offering to fill his spacious cell with gold higher than a man could reach. Pizarro accepted the offer; but when the room had been filled to the stipulated height, he informed the Inca that he was to remain in "protective custody." Pizarro proposed to use Atahualpa as a puppet ruler to ensure popular acceptance of the new order, but he became convinced that Atahualpa was organizing a resistance movement against the Spaniards. After a farcical trial, a Spanish court found the Inca guilty of polygamy, idolatry, and the murder of his brother Huáscar, and it condemned him to burn at the stake—a sentence commuted to strangling when he accepted baptism. Atahualpa's enormous ransom of gold was divided among the Spaniards, and Hernando Pizarro was sent to Spain with Emperor Charles' share of the plunder. Hernando's arrival in Spain with his load of gold caused feverish excitement, and a new wave of Spanish fortune hunters flowed to the New World.

Atahualpa's ransom of gold

Francisco Pizarro, posing as the defender of the legitimate Inca line, now proclaimed Huáscar's brother, Manco, as the new Inca. But a formidable revolt, organized and led by Manco himself, broke out in many parts of the empire. A large Indian army besieged Cuzco for ten months but failed to take the city. Defeated by superior Spanish weapons and tactics and by food shortages in his army, Manco retreated to a fastness in the Andean Mountains; there he and his successors maintained a kind of Inca government-in-exile until 1572, when a Spanish military expedition entered the mountains, broke up the imperial court, and captured the last Inca, Tupac Amaru, who was beheaded in a solemn ceremony at Cuzco.

The siege of Cuzco had barely ended when fighting broke out between one group of the conquerors, headed by the Pizarro brothers, and another, led by Diego de Almagro, over possession of the city. Before these struggles ended Francisco Pizarro had been murdered and two Almagros, father and son, had suffered death on the block. A new round of fighting began in 1544 when a new viceroy arrived in Peru to proclaim the protective Indian legislation known as the "New Laws of the Indies." Led by Gonzalo Pizarro, the desperate conquistadors rose in revolt. The rebellion collapsed after the arrival of a new crown envoy, who suspended the New Laws and offered pardons and rewards to all repentant rebels. Gonzalo Pizarro, however, resisted to the last and was captured and executed. Peace and order were not solidly established in Peru until the administration of Viceroy Francisco de Toledo, who arrived in 1569.

II. Spain's colonial empire

COLONIAL GOVERNMENT

Political organization

The political organization of the Spanish Empire in America reflected the centralized, absolutist regime by which Spain itself was governed. In the Indies, as in Spain, there was a frequent contrast between the formal concentration of authority in the hands of royal officials and the actual exercise of supreme power on the local level by the great landowners.

The pattern of Spain's administration of its colonies was formed in the period between 1492 and 1550. The final result reflected the steady growth of centralized rule in Spain and the application of a trial and error method to the problems of colonial government. To Columbus, Cortés, Pizarro and other great expeditionary leaders, the Spanish kings granted sweeping powers that made these men practically sovereign in the territories they had won or proposed to conquer. Once the importance of these conquests had been revealed, however, royal jealousy of the great conquistadors quickly appeared; their authority was soon revoked or strictly limited, and the institutions that had been used in Spain to achieve centralized political control were transferred to America for the same end. By the mid-16th century the political organization of the Indies had assumed the definitive form that it was to retain, with slight variations, until late in the 18th century.

The Council of the Indies. The Council of the Indies, chartered in 1524, stood at the head of the Spanish imperial administration almost to the end of the colonial period. Although great nobles and court favourites .were appointed to the Council, especially in the 17th century, its membership consisted predominantly of lawyers. Under the king, whose active participation in its work varied from monarch to monarch, it was the supreme legislative, judicial, and executive organ of colonial government. One of its most important functions was the nomination of all high colonial officials to the king. It also framed a vast body of legislation for the Indies—the famous Laws of the Indies, first codified in 1681—and sought to obtain detailed information on the history, geography, resources, and population of the colonies (the relaciones, which incorporated this information, represent a rich mine of materials for students of colonial Spanish America). Often staffed by conscientious and capable officials in the early Habsburg period, the quality of the Council's personnel tended to decline under the inept princes of the 17th century.

Principal royal agents

Viceroys, captains general, and audiencias. The principal royal agents in the colonies were the viceroys, the captains general, and the *audiencias* (high courts). Viceroys and captains general had essentially the same functions, differing only in the greater importance and extent of the territory assigned to the jurisdiction of the former; each was the supreme civil and military officer in his territory. At the end of the Habsburg era, in 1700, there were two great American viceroyalties—the viceroyalty of New Spain, with its capital at Mexico City, included all Spanish possessions north of the Isthmus of Panama; that of Peru, with its capital at Lima, embraced all of Spanish South America except the coast of Venezuela. Captains general, theoretically subordinate to the viceroys but in practice virtually independent of them, governed large subdivisions of these vast jurisdictions. Smaller subdivisions, called presidencias, were governed by audiencias, with the judge-president acting as governor but with military authority usually reserved to the viceroy.

A colonial viceroy enjoyed an immense delegated authority, which was augmented by the distance that separated him from Spain. By background he might be a lawyer or even a priest, but more often he came from one of the great noble and wealthy houses of Spain. A court modelled on that of Castile, a numerous retinue, and the constant display of pomp and circumstance testified to his exalted status. In theory his freedom of action was limited by the laws and instructions issued by the Council of the Indies, but recognition of the need to adapt the laws to existing circumstances gave him a vast discretionary power. The 16th century saw some able and even distinguished viceroys in the New World; in the 17th century, however, the quality of the viceroys declined (in 1695, for example, the viceroyships of Peru and Mexico were, in effect, sold to the highest bidders).

The audiencia

A viceroy or captain general was assisted in the performance of his duties by an audiencia, which served as his council of state. The joint decisions of viceroy and audiencia had the force of law, giving the audiencia a legislative character, roughly comparable to that of the Council of the Jndies, in relation to the king. Although the viceroy was not obliged to heed the advice of the audiencia, its immense prestige and its right to correspond directly with the Council of the Indies made it a potential check on the viceregal authority. The crown thus developed a system of checks and balances that assured ample deliberation and consultation on all important questions but that also encouraged indecision and delay.

Provincial government. Provincial administration in the Indies was entrusted to royal officials, who governed districts of varying size and importance from their chief towns and who usually held the title of corregidor. Some were appointed by the viceroy; others, by the crown. They possessed supreme judicial and political authority in their districts and represented the royal interest in the town councils (cabildos). If not trained as a lawyer, a corregidor was assisted by a legal counsel (asesor) in the trial of judicial cases. Certain civil and criminal cases could be appealed from the municipal magistrates (alcaldes) to the corregidor, and from him to the audiencia.

Corregidores were of two kinds. Some presided over Spanish towns; others, *corregidores* de indios, administered Indian towns (pueblos), which paid tribute to the crown. A principal duty of a corregidor de indios was to protect the natives against fraud or extortion on the part of whites, but the corregidor was himself the worst offender in this respect. Perhaps the worst abuse of this authority arose in connection with the practice of *repartimiento*—the mandatory purchase of goods from the corregidor by the Indians of his district. Originally designed to protect the Indians from the frauds of private Spanish traders, the cortegidor's exclusive right to trade with the Indians became a means for his speedy enrichment at the expense of the natives.

Restrictions on public officials. A series of regulations was designed to ensure good and honest performance on the part of public officials. Viceroys and oidores (members of an audiencia) were forbidden to engage in trade or own land within their jurisdictions or to accept gifts or fees; even their social life was restricted. All royal officials faced a judicial review (residencia) of their conduct at the end of their term of office. This took the form of a public hearing at which all who chose could appear before the "judge of residence" to present charges or testify for or against the official in question. At the end of the process the judge found the official guilty or innocent of all or part of the charges and handed down a sentence, which could be appealed to the Council of the Indies. Another device, the *visita*, was an investigation of official conduct, usually made unannounced, by a visitador specially appointed for this purpose by the crown; or, in the case of lesser officials, by the viceroy in consulation with the audiencia. As a rule, the visita was no more effective than the residencin in preventing or punishing official misdeeds.

Royal control of local officials

Municipal government. The only colonial institution that satisfied to some degree local aspirations for self-rule was the town council, known as the cabildo or *ayuntamiento*. At an early date, however, the crown assumed the right to appoint the councilmen (*regidores*) and municipal judges; under Philip II and his successors it became the established practice for the king to sell these posts to the highest bidder, with a right of resale or bequest, on condition that a certain portion of the price be paid to the crown as a tax at each transfer. Throughout the colonial period the municipal governments were self-perpetuating oligarchies of rich landowners, mineowners, and merchants who frequently received no salaries and who used their positions to distribute municipal lands to themselves, to assign themselves Indian labour, and to serve the narrow interests of their class. Vigilantly supervised by the corregidor, who frequently intervened in its affairs, the cabildo soon lost such autonomy as it may have possessed in the early days.

Other government offices. The officials and agencies described above represented a small part of the apparatus of colonial government. There were large numbers of such officers as secretaries (escribanos), police officers, tax collectors of "the royal fifth," and alcaldes with special jurisdiction. Under Charles V such offices were often in the gift of high Spanish officials, who sold them to persons who proposed to go to the Indies to exploit their fee-earning possibilities; beginning with Philip II, many of these offices were withdrawn from private patronage and sold directly by the crown, usually to the highest bidder. In the second half of the 17th century, the sale of offices spread from fee-earning positions to higher salaried posts; as a result, in this period corruption became structural in the government of the Indies.

Power of the landowners

Although royal authority—represented by viceroys, *oidores*, corregidores, and other officials—was more or less supreme in the capitals and the surrounding countryside, the same was not true of the more distant regions. In such areas the royal authority was very remote, and the power of the great landowners was virtually absolute. On their large, self-sufficient estates they dispensed justice in the manner of feudal lords, holding courts and imprisoning peons in their own jails, and raising and maintaining their own private armies. Sometimes these powerful individuals combined their de facto military and judicial power with an official title that made them representatives of the crown in their vicinities. The contrast between the nominal concentration of power in the central government and the effective supremacy of great landowners on the local level was a legacy of the colonial period to independent Latin America, and it still remains a characteristic of the political life of many Latin American republics.

SPAIN'S INDIAN POLICY

From the first days of the conquest the Spanish government faced a problem of defining its attitude toward the American natives (wrongly called Indians) and of determining what relations should exist between the conquerors and the conquered. The Indian question had several facets; the first and most urgent was to harmonize the demand of the conquistadors for cheap Indian labour—frequently employed in a wasteful and destructive manner—with the crown's interest in preserving a large tribute-paying Indian population. There was a political issue, too; the Spanish kings were determined to prevent a concentration of land and Indians in the hands of colonists that might lead to the rise of feudal lords independent of royal authority.

The church also had a major interest in the Indian problem. If the Indians died out, there would be no pagan souls to save, and the good name of the church would suffer. Moreover, the church largely relied on Indian labour for the construction and service of its churches and monasteries in the Indies. For these reasons the church, in general, sympathized with and aided crown efforts to protect the Indians against excessive exploitation.

The Spanish dispute over Indian policy quickly assumed the form of a struggle of ideas. Spanish thought of the 16th century was strongly scholastic in character, and jurists and theologians argued over such questions as the nature and cultural level of the Indians, whether they were a subhuman race who might properly be conquered and made to serve the Spaniards, and the rights and obligations the papal donation of America to the Spanish monarchs conferred upon them. Behind these disputations, however, was a struggle between the crown, the church, the colonists, and the Indians themselves over who should control Indian labour and tribute—the foundations of the Spanish Empire in America.

The *encomienda*

Española was the first testing ground of Spain's Indian policy. Eager to prove to the crown the value of his discoveries, Columbus compelled the natives to bring in a daily tribute of gold dust. Later, yielding to the demands of rebellious settlers, Columbus distributed the Indians among them, along with the right to use the forced labour of the natives. This temporary arrangement, formalized in the administration of Gov. Nicolás Ovando and sanctioned by the crown became the ***encomienda,*** which consisted of the assignment to a colonist of a group of Indians who were to serve him with tribute and labour, while he assumed the obligation of protecting his Indians, paying for the support of a parish priest, and helping to defend the colony. In practice the *encomienda* in the West Indies proved to be a hideous slavery that decimated the Indian population of Española.

The first protests against this state of affairs were made by a group of Dominican friars who arrived in Española in 1510. King Ferdinand responded to their agitation by approving a code of Spanish–Indian relations—the Laws of Burgos (1512–13). These laws contained detailed regulations prescribing good treatment of Indian labourers; but these provisions were not enforced, and they did little more than sanction and regularize the existing situation.

A former ***encomendero,*** Bartolomé de Las Casas (*q.v.*), joined the struggle against enslavement and mistreatment of the Indians. Las Casas argued that the papal grant of America to the crown of Castile had been made solely for the purpose of conversion, and it gave the Spanish king no temporal power or possession in the Indies; the Indians had rightful possession of their lands by natural law and the law of nations; all Spanish wars and conquests in the New World were illegal. Las Casas' mature program called for the suppression of all ***encomiendas,*** liberation of the Indians from all forms of servitude except a small tribute to the crown in return for its gift of Christianity, and even the restoration of the ancient Indian states and rulers. Over these states the Spanish king would preside as "emperor over many kings" in order to fulfill his sacred mission of bringing the Indians to the Catholic faith and the Christian way of life. Las Casas' proposals seemed radical, but objectively they served the royal aim of preventing the rise of a powerful colonial feudalism in the New World. Not humanitarianism but self-interest explains the partial official support that Las Casas' reform efforts received during the reign of Charles V (ruled 1516–56).

The New Laws of the Indies

The climax of royal intervention came with the proclamation of the New Laws of the Indies (1542), which appeared to doom the *encomienda.* They prohibited the enslavement of Indians, ordered the release of Indian slaves to whom legal title could not be proved, barred compulsory personal service by the Indians, regulated tribute, and declared that existing ***encomiendas*** were to lapse on the death of the holder.

The New Laws provoked a great revolt in Peru; in New Spain they caused a storm of protest by the *encomenderos* and a large part of the clergy. Under this pressure the crown again retreated; it reaffirmed the laws forbidding Indian slavery and forced labour, but the right of inheritance by the heir of an *encomendero* was recognized and extended by stages to a third, fourth. and, sometimes, even a fifth life. Thereafter, or earlier in the absence of an heir, the ***encomienda*** reverted to the crown. In the natural course of events, the number of *encomiendas* steadily diminished and that of crown towns increased.

Meanwhile, the economic value of the ***encomienda*** to the colonists was declining. They had lost the right to demand labour from their tributaries (1549); they had also lost their fight to make the *encomienda* perpetual. The heaviest blow of all, however, was the catastrophic decline of the Indian population in the second half of the 16th century. In New Spain, according to recent calculations, the Indian population dropped from about 25,000,000 in 1519 to slightly over 1,000,000 in 1605. Disease, especially disease of European origin, against which the Indians had no acquired immunity, was the major immediate cause; but overwork, social disorganization, and loss of will to live were largely responsible for the terrible mortality associated with the great epidemics and even with epidemic-free years.

As the number of their tributaries fell and their income declined proportionately, many *encomenderos* and other Spaniards began to engage in the more lucrative pursuits of agriculture, stock raising, and mining. The decline of the Indian population, sharply reducing the flow of foodstuffs to Spanish cities and mining centres, stimulated a rapid growth of Spanish estates (haciendas), producing grain and meat.

The *repartimiento*

A new system, the ***repartimiento—under*** which all adult male Indians had to give a certain amount of their time in rotation throughout the year to work in Spanish mines and factories, on farms and ranches, and on public works—replaced the ***encomienda.*** The crown thus sought to regulate the use of an ever-diminishing pool of Indian labour. The Indians received a token wage for their work, but the ***repartimiento*** was also essentially a disguised slavery. In Peru, where great numbers of Indians were conscripted for labour in the silver mines of Potosi and in the Huancavelica mercury mine, the ***repartimiento*** (there known as the ***mita)*** was particularly disastrous.

The ***repartimiento*** did not provide a dependable and continuing supply of labour, and Spanish ***hacendados*** turned increasingly to the use of so-called free labour. From the first, such labour was closely associated with the system of debt peonage, which helped to bind and hold workers in a time of rapid population decline. The heavy weight of tribute and *repartimiento* burdens on the ever-diminishing native population, and the contraction of Indian communal lands as a result of Spanish encroachments, caused many Indians to become farm labourers working for wages, mostly paid in kind. An advance of money or goods bound the peon to work for his employer until the debt was paid, a miracle that rarely occurred. Despite its later evil reputation, peonage had some advantages for many Indians; it usually freed an

Indian from the recurrent tribute and repartimiento burdens, and it often gave him a piece of land that he could work for himself and his family.

If the hacienda offered many Indians a means of escape from intolerable burdens, it aggravated the difficulties of those who remained on their ancestral lands. The hacienda expanded at the expense of the Indian pueblo, absorbing whole towns and leaving others without enough land for its people when the population decline ended in the first half of the 17th century and a slow recovery began. The hacienda lured labourers from the pueblo, making it difficult for the Indian town to meet its tribute and *repartimiento* obligations.

Debt servitude assumed its harshest form in the numerous workshops (*obrajes*), producing cloth and other goods, that developed in many areas in the 16th and 17th centuries. Convict labour, assigned to employers by Spanish judges, was early supplemented by the "free" labour of Indians, who were often lured into these workshops by an offer of liquor or a small sum of money. Once inside the gates, they were never let out again.

Negro slavery

Side by side with the disguised slavery of repartimiento and debt servitude existed Negro slavery. For a variety of reasons—including the fact that Spaniards and Portuguese were accustomed to holding Muslim Negro slaves and the belief that Negroes were better able to support the hardships of plantation labour—Spanish defenders of the Indian did not display the same zeal on behalf of the enslaved Africans. The rapid rise of sugar cane agriculture in the West Indies in the early 1500s brought an insistent demand for Negro slave labour to replace the vanishing Indian. There arose a lucrative slave trade, chiefly carried on by foreigners under a system of contract (asiento) between an individual or a company and the Spanish crown. The high cost of slaves limited their use to the more profitable plantation cultures or to domestic servitude in the homes of the wealthy.

A small class of genuinely free, paid workers also came into existence at an early date; it included resident and migrant farm workers, miners, unskilled urban labourers, and skilled workers who practiced their trades in the Spanish towns, sometimes as journeymen, in Spanish-controlled guilds from which Indians, mestizos (persons of mixed Indian and European ancestry) and mulattoes were excluded as masters. Except for skilled workers, wages tended to remain at the subsistence level throughout the colonial period.

THE COLONIAL ECONOMY

The Conquest disrupted the traditional economy of the Indians and transformed the character and tempo of Indian economic activity. When the frenzied scramble for treasure had exhausted the available gold and silver objects, the encomienda became the principal instrument for extracting wealth from the vanquished. The Aztec and Inca peoples were accustomed to paying tribute to their rulers and nobility, but the Spaniards' demands were unlimited. Driven by visions of infinite wealth, the Spaniards exploited the Indians mercilessly.

As noted above, the Indian population decline, causing acute food shortages in the Spanish towns, created new economic opportunities for Spanish farmers and ranchers; moreover, it left vacant large expanses of land, which Spanish colonists occupied for wheat raising or as sheep and cattle ranges. By the end of the 16th century the Spanish-owned haciendas produced the bulk of agricultural commercial production and pressed ever more aggressively on the shrinking Indian sector of the colonial economy. The establishment of an entail (mayorazgo) assured perpetuation of the consolidated property in the hands of the owner's descendants.

Spanish colonial agriculture

Spanish colonial agriculture early produced wheat on a large scale for sale in such urban centres as Mexico City, Lima, Veracruz, and Cartagena, and maize, for the large Indian consumers' markets in Mexico City, Lima, and other cities. Sugar was brought from the Canary Islands to Española and became the foundation of the island's prosperity. From the West Indies, sugar quickly spread to Mexico and Peru. Sugar refining, with its large capital outlays for equipment and Negro slaves, was the largest scale enterprise in the Indies.

Wine and olives as well as sugar were produced in quantity in the irrigated coastal valleys of Peru. The silk industry flourished briefly in Mexico, but it soon declined because of labour shortages and competition from Chinese silk brought from the Philippines to the port of Acapulco. Other products cultivated by colonists on a capitalist plantation basis were tobacco, cacao, and indigo. Cochineal, a blood-red dye, was a unique Mexican and Central American export highly valued by the European cloth industry.

Spain enriched American economic life by introducing various domestic animals—chickens, mules, horses, cattle, pigs, and sheep. The mules and horses revolutionized transport, and the cattle and smaller domesticated animals greatly enlarged the continent's food resources, while providing hides for export to Spain and other European centres of leather manufacture, and hides and tallow for the domestic market, especially in mining areas. Sheep raisers found a large wool market in the textile factories that arose in many parts of the colonies.

In populous central Mexico, cattle trampled the Indian crops, causing untold damage, and the close grazing of sheep caused massive erosion by torrential rain on the slopes of valleys. By the end of the 16th century, however, the Mexican cattle industry had become stabilized; the exhaustion of virgin pasture lands, the mass slaughter of cattle for their hides and tallow, and the official efforts to halt grazing on Indian harvest lands, greatly reduced the herds. Gradually, the cattle ranches and sheep herds moved from the densely settled south and central areas to new permanent grazing grounds in the semiarid north.

A rapid increase of horses, mules, and cattle also took place in the empty grasslands (pampas) of the Río de la Plata, modem Argentina. The inhabitants of this area, fcrbidden to trade directly with the outside world and lacking precious metals or abundant Indian labour, traded illegally with Dutch and other foreign traders, who carried their hides and tallow to Europe; they also sent mules and horses, hides and tallow, to the mining regions of Upper Peru (Bolivia). Another centre of the cattle industry was the West Indies.

Mining

Mining, as the principal source of royal revenue in the form of the royal fifth (quinto) of all gold, silver, or other precious metals obtained in the Indies, received the crown's special attention and protection. Silver was the principal mining product. The great silver mine of Potosí in Upper Peru was discovered in 1545 and produced enormous quantities of the metal between 1579 and 1635; the rich Mexican silver mines of Zacatecas and Guanajuato were opened up in 1548 and 1558, respectively. The introduction of the patio process for separating the silver from the ore with mercury (1556) gave a great stimulus to silver mining. In the same period, important gold placers were found in central Chile and in the interior of New Granada (Colombia). The mining industry brought prosperity to a few and failure to the great majority.

Inefficient production methods, lack of capital to finance technological improvements, flooding, and similar problems, led to a sharp decline of silver production from about 1630 to the end of the century. This mining crisis depressed trade with Europe, since silver was the most important export item in Spanish America's balance of trade, and also had an adverse effect on internal commerce. Colonial agriculture and stock raising, which had expanded to satisfy the demand of the mining centres for grain, meat, hides, tallow, and work animals, also suffered.

Throughout the colonial period the majority of the natives continued, as before the Conquest, to supply their own needs for pottery, clothing, and other household goods. In the Spanish towns craft guilds, modelled on those of Spain, arose in response to the high prices for all Spanish imported goods. These guilds maintained control over the quantity and quality of production in luxury industries serving the needs of the colonial upper class. The 17th century saw a rapid growth of obrajes, many of which produced cheap cotton and wool goods for popular consumption. Most were privately owned, but some were operated by Indian communities to meet their tribute payments. Other primitive factories produced such items as soap, chinaware, and leather. A 17th-century depression, restricting colonial capacity to purchase imports, promoted this growth of colonial industry.

COMMERCE, SMUGGLING, AND PIRACY

Colonial trade

Control over all colonial trade, under the Royal Council of the Indies, was vested in the Casa de Contratación (House of Trade), established in 1503 in Seville. Commerce with the colonies was restricted until the 18th century to the wealthier merchants of Seville and Cádiz, who were organized in a guild that exercised great influence in all matters relating to colonial trade. Trade was concentrated in the three American ports—Veracruz in New Spain, Cartagena in New Granada, and Nombre de Dios (later Portobelo) on the Isthmus of Panama. The Seville merchant oligarchy and related merchant groups in the Indies (particularly the merchant guilds at Mexico City and Lima) deliberately kept the colonial markets understocked and in general played into each other's hands at the expense of the colonists, who were forced to pay exorbitant prices for all European goods acquired legally. Inevitably, the system generated colonial discontent and stimulated the growth of contraband trade.

To enforce a closed-port policy and protect merchant vessels against foreign attack, an elaborate fleet system was developed in the 16th century to convoy ships between American ports and to and from Spain. In the 17th century, as a result of Spain's economic decline and growing contraband trade, the fleet sailings became increasingly irregular.

Spanish industry, handicapped by its guild organization and technical backwardness, could not supply the colonies with cheap and abundant manufactures in return for colonial foodstuffs and raw materials. Prices to the colonial consumer also were raised by a multitude of taxes. As a result, the more advanced industrial nations of northern Europe sought to break into the large and unsatisfied Spanish-American markets, rejecting Spain's claim of domination over all the Western Hemisphere except the portion that belonged to Portugal. The foreign challenge to Spain's monopoly assumed the forms of smuggling, piracy, and colonization, as well as efforts to seize and occupy portions of the Indies.

Foreign challenge to Spain

England, under Queen Elizabeth, emerged as the principal threat to Spain's empire in America. Sir John Hawkins' slave-trading voyage to the West Indies in 1562 opened the English drive to penetrate the Spanish-American market and culminated in the near destruction of Hawkins' trading fleet by a Spanish naval force at Veracruz in 1568. English voyages of reprisal followed; they included the expedition of Francis Drake (1577), undertaken with the secret sponsorship and support of Queen Elizabeth, whose objects were to seize Spanish treasure ships, ravage Spanish colonial towns, and display English maritime prowess through a second circumnavigation of the globe.

In the 17th century foreign piracy and smuggling were supplemented by efforts to found colonies not only on the American mainland but in the Caribbean. The Dutch, at war with Spain with brief intervals since 1576, launched a military and commercial offensive against the Spanish West Indies; their principal instrument was the Dutch West India Company, organized in 1621. The Dutch captured the whole homebound Veracruz treasure fleet off the coast of Cuba in 1628. Capture of Curaçao, hard off the coast of Venezuela (1634), gave the Dutch an invaluable smuggling base and emboldened the French and English to seize both unoccupied and occupied Spanish islands—Barbados and St. Christopher, Martinique and Guadeloupe. In 1655 an English fleet, defeated in an effort to capture Santo Domingo, easily captured Jamaica. In the same period French corsairs began to settle the northwest comer of Española, virtually abandoned by Spaniards since 1605; by 1655 this region had become the French colony of Saint-Domingue, with a governor appointed by the trading Compagnie des Indes.

In this period piracy in the West Indies became a highly-organized and large-scale activity often enjoying the open or covert protection of the English governors of Jamaica and the French governors of Saint-Domingue. Piracy entered a decline following the Treaty of Madrid (1670) between England and Spain, by which the British government agreed to aid in suppression of the corsairs in return for Spanish recognition of its sovereignty over the British West Indian islands. French buccaneers, however, continued active until the Treaty of Rijswijk (1697), by which Spain formally recognized French possession of Saint-Domingue.

Smuggling

Pirates and privateers, however, inflicted fewer losses on Spain than those caused by foreign smugglers. Contraband trade steadily increased in the 16th and 17th centuries; and the European establishments in Jamaica, Saint-Domingue, and the lesser Antilles became bases for contraband trade with the Spanish colonies. Buenos Aires was another funnel through which Dutch and other foreign traders poured immense quantities of goods that penetrated as far as Peru. Smuggling flourished even at Seville and Cádiz where, by the end of the 17th century, French companies operating behind the facades of Spanish merchant houses dominated the legal trade with the Indies.

Spanish economists of the 17th century understood the principal cause of Spain's plight: its economic weakness. They offered sound criticisms and constructive proposals for reform. But they were powerless to change the course of Spanish policy, dictated by small mercantile and aristocratic cliques whose special interests and privileges were incompatible with the cause of reform.

THE CHURCH IN THE INDIES

Royal control over church affairs, in both Spain and the Indies, was founded on the institution of royal patronage (the ***patronato real***). Under diplomatic pressure from King Ferdinand, in 1508 Pope Julius II accorded to Spain's rulers the exclusive right to nominate all Church officials, collect tithes, and found churches and convents in America, ostensibly to assist them in the work of converting New World pagans.

The missions. Beginning with Columbus' second voyage, one or more clergymen accompanied every expedition that sailed for the Indies; and they came in growing numbers to the conquered territories. The friars who came to America in the first decades after the Conquest were, in general, an elite group. The products of a revival of asceticism and discipline in the medieval church, and especially of a reform movement, this vanguard group frequently combined with missionary zeal a sensitive social conscience and love of learning.

Conversion of Indians

The friars converted prodigious numbers of natives. In Mexico, the Franciscans claimed to have converted more than 1,000,000 by 1531; when persuasion failed, pressures of various kinds, including force, were used to obtain conversions. (To facilitate the missionary effort the friars studied the native languages and wrote grammars and vocabularies. Scholars devoted themselves to preserving and recording the history, religion, and customs of the ancient Indian peoples.) The work of conversion was less than wholly successful. The result of the missionary effort was generally a fusion of pagan and Christian religious ideas. To this day Indians in such lands as Guatemala and Peru continue to perform rites dating from the time of the Maya and the Inca.

The clergy had to battle not only the Indian tendency toward backsliding but also divisions within their own ranks. A serious conflict was waged during the 16th century between the secular and the regular clergy. Finally, a royal decree of 1583 stated the principle that secular clergy were to be preferred over friars in all appointments to parishes. From first to last, however, the colonies were a scene of strife between groups of clergy over their fields of jurisdiction.

A gradual loss of a sense of mission and of morale among the regular clergy also contributed to the decline of their intellectual and moral influence. By the late 16th century there were frequent complaints against the church's excessive number of convents and growing wealth. The principal sources of this wealth were legacies and other gifts from rich donors; invested in land and mortgages, it brought in more wealth. The last important order to arrive in Spanish America, the Society of Jesus (1572), had the largest number of rich benefactors and the most efficient administration.

Material wealth

Inevitably, this concern with material wealth weakened the ties between the clergy and the Indian and mixed-blood masses. Hand in hand with a growing materialism went an increasing laxity of morals (except among the Jesuits); concubinage became so common among the clergy of the later colonial period that it seems to have attracted little official notice or rebuke.

The missionary impulse of the first friars survived longest on the frontier, "the rim of Christendom." Franciscans first penetrated the great northern interior of New Spain; they also accompanied the Juan de Oñate expedition of 1598 into what is now New Mexico and dominated the mission field there until the end of the colonial period; and they were also found in such distant outposts of Spanish power as what are now Florida and Georgia. The early Jesuits worked among the Indians of California, were active in converting and pacifying the tough Chichimeca Indians of the north central plateau of Mexico and had exclusive charge of the conversion of the Indian tribes of the northwest coast of Mexico. Following the expulsion of the Jesuits from the Indies in 1767, the Franciscans replaced them in directing missionary work in California.

The mission was one of three closely linked institutions —the other two being the presidio, or garrison, and the civil settlement--designed to serve the ends of Spanish imperial expansion and defense on the northern frontier. This three-pronged attack on the frontier was not very successful. Certain tribes on the northern frontier, such as the Apache of Arizona, New Mexico, and Texas and the Comanche of Texas, never were reduced to mission life. The missionaries had greater success among such sedentary tribes as the Pueblo Indians of New Mexico; but even among these peaceful tribes, Indian revolts and desertions were frequent. In 1680 the supposedly Christianized Pueblo Indians revolted, slaughtered the friars, and maintained a decade of tenacious resistance to Spanish efforts at reconquest. The civil settlements were no more successful. By the end of the colonial period there were only a few scattered towns on the northern frontier, and continuous Indian raids made life and property insecure. Ultimately, the whole task of defending and civilizing the frontier fell on a chain of presidios stretching approximately along the present border between the United States and Mexico. In the end Spain was forced to adopt a policy of neutralizing the Apache and Comanche by the periodic distribution of gifts to these warlike tribes. When the outbreak of the Wars of Independence stopped the flow of gifts, the hostile Indians drove through the useless line of presidios into the interior of Mexico.

Expulsion of the Jesuits

The Jesuits in Paraguay. The most successful missionary effort, at least from an economic point of view, was that of the Jesuit establishment in Paraguay, which included more than 30 missions or reductions; these formed the principal field of Jesuit activity in America. Their strict discipline, centralized organization, and absolute control over the labour of thousands of docile Indians producing cotton, tobacco, hides, and other products enabled the Jesuits to make their missions a highly profitable business enterprise. Every effort was made to limit contact with the outside world. The life of the Indians was rigidly regimented in dress, housing, and the routines of work, play, and rest. Jesuit mission activity in the colonies ended as a result of a royal decree (1767) ordering the expulsion of the order from the colonies. Motives for this action included the conflict between the nationalistic church policy of the Bourbons and Jesuit emphasis on papal supremacy, suspicion of Jesuit meddling in state affairs, and belief that the Jesuit mission system constituted a state within a state.

The Inquisition. The Inquisition formally entered the Indies with the establishment by Philip II of tribunals of the Holy Office at Mexico and Lima in 1569. Before that time its functions were performed by clergy who were vested with or assumed inquisitorial powers. Its great privileges, its independence of other courts, and the dread with which Spaniards generally regarded the charge of heresy made the Inquisition an effective check on "dangerous thoughts," whether religious, political, or philosophical. Most of the cases tried by its tribunals, however, dealt with offenses against morality or with such minor deviations from orthodox religious conduct as blasphemy. Like the Spanish Inquisition, the Inquisition in the Indies relied largely on denunciations by informers and employed torture to secure confessions. Indians were originally subject to the jurisdiction of Inquisitors but were later exempted because as recent converts of supposedly limited mental capacity they were not fully responsible for their deviations from the faith.

III. Colonial Brazil

THE FORMATION OF COLONIAL BRAZIL

Brazil's existence was unknown when the Treaty of Tordesillas of 1494, between Spain and Portugal, assigned to Portugal a large stretch of the South American coastline. In 1500 Pedro Álvares Cabral, who had been sent with a large fleet to India, was driven far off his course and touched on the Brazilian coast. Cabral claimed the land for Portugal and sent a report of his discovery to the king. Portugal's limited resources, already committed to exploitation of the wealth of Africa and the Far East, made impossible full-scale colonization of Brazil. But the presence of a valuable dyewood (brazilwood) attracted merchant capitalists, who obtained concessions to engage in the brazilwood trade with the Indians. A few settlers —some castaways, others degredados (criminals exiled from Portugal to distant parts of the empire)—arrived and were often well received by the local Indians. In 1532 the first Portuguese town in Brazil, named São Vicente, was founded near the present town of Santos.

Hereditary captaincies

Colonization. Portugal's heavy commitments in the spice-rich East forced its kings to assign to private individuals major responsibility for colonization of Brazil. The Brazilian coastline was divided into 15 parallel strips extending inland to the uncertain line of Tordesillas. These strips were granted as hereditary captaincies to a dozen individuals, each of whom agreed to colonize, develop, and defend his captaincy or captaincies at his own expense. The captaincy system represented a fusion of feudal and capitalist elements. The grantee was both a vassal owing allegiance to his suzerain, the king, and an entrepreneur who hoped to derive large profits from his estates and from taxes obtained from colonists to whom he gave land. Few of the captaincies proved successful because few grantees possessed the capital and administrative ability required to attract settlers and defend against Indian attacks and foreign intruders.

Slave hunters. By the mid-16th century sugar had replaced brazilwood as the foundation of the Brazilian economy. Favoured by its soil and climate, the Northeast (now the states of Pernambuco and Bahia) became the seat of a sugar cane civilization featured by the large estates (fazendas), monoculture, and slave labour. The problem of labour was first met by raids on Indian villages, but Indian labour was unsatisfactory because the natives worked poorly and offered resistance ranging from attempts at flight to suicide. After 1550, planters turned increasingly to the use of Negro slave labour imported from Africa; but the supply of Negro slaves was often cut off or sharply reduced by the activity of Dutch pirates and other foreign foes, and the services of Brazilian slave hunters were in large demand throughout the colonial period. The most celebrated slave hunters were the bandeirantes (from a word meaning "banner" or "military company") from the upland settlement of São Paulo; often part Indian, they made slave raiding in the interior their principal occupation. As the Indians near the coast dwindled in numbers or fled before the invaders, the bandeirantes pushed ever deeper southward and westward, expanding Brazil's frontiers in the process.

Jesuit missionaries were the first to protest the enslavement and mistreatment of the Indians. The Jesuit program for the settlement of their Indian converts in *aldeas* ("villages"), where they would live under the tutelage of the priests, provoked the slave hunters and the planters. The Portuguese crown pursued for two centuries a policy of compromise that satisfied neither Jesuits nor planters. A decisive turn came in the mid-18th century under the Marques de Pombal, the foreign minister and later prime minister of José I, who, in 1759, expelled the Jesuits from Portugal and Brazil and secularized their missions. Pombal forbade Indian raids and enslavement and thus accepted the Jesuit thesis of Indian freedom; but, unlike the Jesuits, his policy did not segregate the Indians from the Portuguese community; it made them available as paid workers by the colonists, and it encouraged mingling between the two races. Meanwhile, the growth of the African slave trade, also encouraged by Pombal, reduced the demand for Indian labour and this brought a greater measure of peace to the Indians.

French and Dutch incursions

Rivals to the Portuguese. The dyewood, sugar, and tobacco of Brazil early attracted foreign powers. The French made sporadic efforts to entrench themselves on the coast, and, in 1555, they founded Rio de Janeiro as the capital of what they called Antarctic France. But French colonization in Brazil was weakened by Catholic-Huguenot strife at home, and, in 1567, the Portuguese ousted the French and occupied Rio de Janeiro.

The Dutch posed a more serious threat to Portuguese sovereignty over Brazil. The Dutch West India Company seized and occupied (1630–54) the richest sugar-growing portions of the Brazilian coast. Ultimately, weakened by tenacious Brazilian resistance and a simultaneous struggle with England, the Dutch withdrew, taking their capital and the lessons they had learned in the production of sugar and tobacco and transferring both to the West Indies. Thus the Caribbean islands were soon competing with Brazilian sugar in the world market, with a resulting fall of prices, and by the end of the 16th century the Brazilian sugar industry was on the point of collapse.

Shift to the south. The discovery of gold (1690) in the southwestern region opened a new economic cycle and began a major shift of Brazil's economic and political centre from north to south. Large numbers of colonists from the Northeast, accompanied by their slaves and servants, swarmed into the mining area, causing an acute shortage of field hands in the older regions, which continued until the gold boom had run its course by the mid-18th century. In 1709 the mining region was elevated to the status of a captaincy, with the name Minas Gerais. A few years later came the discovery that certain stones in the area, hitherto thought to be crystals, were really diamonds; and many adventurers turned from gold to diamond washing.

By 1750 the river gold washings of Minas Gerais were nearly exhausted; the diamond district also suffered a progressive exhaustion of deposits. But the mineral cycle left a permanent mark in the form of new settlements in the southwest, not only in Minas Gerais but in what later became the provinces of Goiás and Mato Grosso—Brazil's far west. The mining decline also spurred efforts to promote the agricultural and pastoral wealth of the region. The southward movement of population and economic activity was formally recognized, in 1763 when Rio de Janeiro became the seat of the viceregal capital.

Meanwhile, the Northeast experienced a partial revival based on increasing European demand for sugar, cotton, and other semitropical products. Brazilian cotton production made significant advances between 1750 and 1800, but then declined rapidly because of competition from the more efficient cotton growers of the United States. The beginnings of the coffee industry also date from the late colonial period.

The cattle industry

Cattle raising contributed to the advance of the Brazilian frontier and to the growing importance of the south. The intensive commercial agriculture of the coast and the concentration of population in such coastal cities as Baia and Pernambuco created a demand for meat that gave an initial impulse to cattle raising. Because the expansion of plantation agriculture in the coastal zone did not leave enough land for grazing, the cattle industry had to move inland; and by the second half of the 17th century the penetration of the San Francisco Valley was well under way. Powerful cattlemen, with their herds, their *vaqueiros* ("cowboys"), and their slaves, entered the backcountry; drove out the Indians; and established fortified ranches and villages for their retainers. The cattle industry later expanded to the extreme southern region of Rio Grande do Sul, colonized by the government to defend against Spanish expansionist designs. The cattle industry provided meat for the coastal cities and mining camps, draft animals for the plantations, and hides for export to Europe.

Trade. During the Portuguese union with Spain (1580–1640), Brazil's commerce was restricted to Portuguese nationals and ships. The Dutch, who had been the principal carriers of Brazilian sugar and tobacco to European markets, responded with extensive smuggling and with a direct attack on the sugar-growing northeast. Following its successful revolt against Spain, Portugal made a trade treaty with England whereby British merchants were permitted to trade between Portuguese and Brazilian ports. English ships, however, frequently neglected the formality of touching at Lisbon and plied a direct trade with the colony. Because Portuguese industry was incapable of supplying the colonists with the requisite quantity and quality of manufactured goods, England provided cargoes of textiles and other manufactures. The decree of free trade of 1808, issued by Prince John following the flight of the Portuguese royal family from Portugal to Brazil after French invasion of his country, only confirmed the virtual English monopoly of trade with Brazil.

GOVERNMENT AND CHURCH

Colonial administration

The donatory system of government soon proved unsatisfactory, because few donatories could cope with the tasks of defense and colonization they had assumed. A governmental reform followed. In 1549 Tomé de Sousa was sent out as governor general to head a central colonial administration for Brazil; and Baia, situated about midway between the flourishing settlements of Pernambuco and São Vicente, became his capital. Gradually the hereditary rights and privileges of the donees were absorbed by governors appointed by the king. As the colony expanded, new captaincies were created. In 1763, as noted above, the governor of Rio de Janeiro replaced his colleague at Baia as head of the colonial administration with the title of viceroy. In practice, however, his authority over the other governors was negligible.

During the period of Spanish–Portuguese union their colonial policies were aligned by the creation, in 1604, of the Conselho da India, whose functions resembled those of the Spanish Council of the Indies. In 1736 a newly created ministry of Marinha e Ultramar (marine and overseas) assumed the functions of the Conselho; under the king, this body framed laws for Brazil, appointed governors, and supervised their conduct. The governor or viceroy combined in himself military, administrative, and even some judicial duties. His power tended to be absolute but was tempered by the constant intervention of the home government, which bound him with precise, strict, and detailed instructions; by the counterweights of other authorities, especially the high courts (*relações*), which were both administrative and judicial bodies; and the existence of special administrative organs, such as the intendencies created in the gold and diamond districts, which were completely independent of the governor. His authority was also diminished by the vastness of the country, the scattered population, the lack of social stability, and the existence of enormous landholdings in which the feudal power of great planters and cattle barons was virtually unchallenged.

The Senado de Camara, or municipal council, was the most important institution of local government. Elected either by a restricted property-owning electorate or chosen by the crown, its membership represented the ruling class of planters, merchants, and professional men; its authority was limited by frequent intervention of the royal judge (ouvidor), who usually combined his judicial functions with the administrative duties of *corregidor.* Generally speaking, the greater the size and wealth of the city, and the farther it was from the viceregal capital, the greater were its powers.

The evils of Spanish colonial administration—inefficiency, bureaucratic attitudes, slowness, and corruption—were also prominent in the Portuguese colonial system. In vast areas of the colony, however, administration and courts were virtually nonexistent. Outside the few large towns, local government often meant the rule of great landowners, for it was from their ranks that royal governors invariably appointed the *capitães môres,* or district militia officers. With unlimited power to enlist, command, arrest, and punish, the *capitão môr* became a symbol of despotism and oppression. (The feudalism that still dominates the Brazilian backcountry can be traced to these colonial origins.)

Some improvement, at least on the higher levels of administration, took place in the 18th century under Pombal, who abolished the remaining hereditary captaincies, reduced the special privileges of the municipalities, and increased the power of the viceroy. He sought to promote the economic advance of Brazil in order to rehabilitate Portugal, whose state was truly forlorn.

Church affairs

In Brazil, as in the Spanish colonies, church and state were intimately united. By comparison with the Spanish monarchs, however, the Portuguese kings were almost niggardly in their dealings with the church; but their control over its affairs, exercised through the *padroado* —the ecclesiastical patronage granted by the pope to the Portuguese king in his realms—was as absolute. Rome, however, maintained a strong indirect influence through the Jesuits, who were very influential in the Portuguese court until expelled from Portugal and Brazil in 1759.

With some honourable exceptions, notably that of the Jesuits, the tone of clerical morality and conduct in Brazil was low. The clergy provided such educational and humanitarian establishments as existed in the colony; and from its ranks—which were open to talents and even admitted individuals of mixed blood, despite the formal requirement of a special dispensation—came most of the distinguished names in Brazilian colonial science, learning, and literature.

MASTERS AND SLAVES

Race mixture played a decisive role in the formation of the Brazilian people. The scarcity of white women, the freedom of the Portuguese from puritanical attitudes, and the despotic power of great planters over Indian and Negro slave women, all gave impetus to miscegenation. Of the three possible combinations—white-Negro, white-Indian, Negro-Indian—the first was most common.

In principle, and to a considerable degree in practice, colour lines were strictly drawn. But the enormous number of mixed unions and the resulting large progeny, some of whom were regarded with affection by white fathers and provided with some education and property, inevitably led to some blurring of colour lines and to a fairly frequent phenomenon of "passing," with a tendency to classify individuals racially, if their colour was not too dark, on the basis of social and economic position rather than by physical appearance.

Slavery in Brazil

Slavery played as important a role in Brazil's organization as did race mixture in its ethnic make-up. Slavery corrupted both master and slave, festered harmful attitudes toward the dignity of labour, and retarded the nation's economic development. The virtual monopoly of labour by slaves sharply limited the number of socially acceptable occupations in which whites or free mixed bloods could engage. This gave rise to a large class of vagrants, beggars, "poor whites," and other degraded elements who would not or could not compete with slaves in agriculture and industry. Given the lack of incentive to work on the part of the slave, the level of efficiency and productivity of his labour was very low.

The 20th-century Brazilian sociologist Gilberto Freyre has emphasized the patriarchal relations between masters and slaves in the sugar plantation society of the Northeast. But the slaves described by Freyre were usually house slaves, who occupied a privileged position and whose situation was different from that of the great majority of slaves, who worked on the sugar and tobacco plantations of Bahia and Pernambuco. A royal dispatch of 1700 denounced the barbarity with which owners of both sexes treated their slaves. The very low rate of reproduction among slaves and frequent suicides speak eloquently about their condition; many slaves ran away and formed *quilombos* (settlements of fugitive slaves) in the bush. The most famous of these was the so-called republic of Palmares, whose destruction required a major military campaign in the 17th century.

The nucleus of Brazilian social and economic organization was the *fazenda,* based on Negro slavery and centred about the *casa grande* (the "big house"); it constituted a patriarchal community that included the owner and his family, his chaplain and overseers, his slaves, his sharecroppers *(obrigados)*, and his *agregados,* or retainers. The system implied relations of mutual aid and a paternalistic interest in the welfare of the landowner's people; but it did not exclude intense exploitation of those people or the display of the most ferocious cruelty if they should dispute his absolute power.

Planter aristocracy

In the sugar-growing northeast, the great planters became a distinct aristocratic class. Most colonial towns were mere appendages of the countryside, dominated politically and socially by the rural magnates. These men often left supervision of their estates to majordomos and overseers, preferring to live in the cities. In the cities lived other social groups that disputed or shared power with the great landowners: high officials of the colonial administration; dignitaries of the church; wealthy professional men, especially lawyers; and merchants, usually European-born, who monopolized the export–import trade and financed the industry of the planters. The conflict between native-born landowners and European-born merchants, aggravated by nationalist resentment of upstart immigrants, sometimes led to armed struggle. An illustration is the War of the Mascates (1710–11) between Olinda, provincial capital of Pernambuco, dominated by the sugar planters, and its neighbouring seaport of Recife, controlled by the merchants.

IV. The Bourbon reforms and Spanish America

REFORMS

After the War of the Spanish Succession (1702–13), Spain was left with a more manageable, more truly Spanish, empire consisting of the kingdom of Castile and Aragon, and the Indies, and then turned its attention to implementing a program of reform. The ensuing revival of Spain is associated with three princes of the House of Bourbon—Philip V (ruled 1700–46) and his two sons, Ferdinand VI (ruled 1746–59) and Charles III (*q.v.*; ruled 1759–88). The work of national reconstruction reached its climax under Charles III, who attempted to revive Spanish industry and agriculture.

The outbreak of the French Revolution, which followed by a few months the death of Charles III in December 1788, brought the reform era effectively to a halt. Frightened by the overthrow of the French monarchy, Charles IV and his ministers turned sharply to the right; the leading reformers were banished or imprisoned, and the importation of French rationalist and revolutionary literature was forbidden. Yet the clock could not be entirely turned back, either in Spain or its colonies. Under Charles IV, for example, an expedition sailed from Spain (1803) to carry the procedure of vaccination to the Spanish dominions in America and Asia.

With colonial reform the Bourbons moved slowly and cautiously, because of the powerful vested interests identified with the status quo. There was no intention of giving more self-government to the colonists or of permitting them to trade more freely with the non-Spanish world. On the contrary, the Bourbons centralized colonial administration still further, with a view to making it more efficient, and their commercial reforms were designed to diminish smuggling and strengthen the exclusive commercial ties between Spain and its colonies.

Commercial and administrative reforms

Under the first Bourbons, efforts were made to check smuggling in the Caribbean by the use of ***guardacostas,*** which prowled the main lanes of trade in search of ships loaded with contraband. The depredations of these ***guardacostas*** led to English demands for compensation and finally to war between England and Spain in 1739.

The first Bourbons made few changes in the administrative structure of colonial government, contenting themselves with efforts to improve the quality of administration by more careful selection of officeholders. One major reorganization was the separation of the northern Andean region (present-day Ecuador, Colombia, and Venezuela) from the viceroyalty of Peru and its elevation to the status of a new viceroyalty, named New Granada, with its capital at Santa Fé (modern Bogota). This change reflected a desire to provide better protection for the Caribbean coast and especially the fortress of Cartagena; it also reflected the rapid growth of population in the central highlands of Colombia. Within the new viceroyalty, Venezuela was named a captaincy general, with its capital at Caracas and virtually independent of Santa Fé.

Colonial reform, like domestic reform, reached its peak under Charles III. In 1765 commerce with the West Indies was thrown open to seven ports besides Cádiz and Seville; this, coming at a time when Cuban sugar production was beginning to expand, stimulated the island's economy. This privilege was extended to other regions until, by a decree of free trade of 1778, commerce was permitted between all qualified Spanish ports and all the American provinces except Mexico and Venezuela, which were opened to trade on the same terms in 1789. Restrictions on intercolonial trade were also progressively lifted, but this trade was largely limited to non-European products. A major beneficiary of this was the Rio de la Plata area, which, in 1776, was opened to trade with the rest of the Indies. Meanwhile, the Casa de Contratación steadily declined in importance until it closed its doors in 1790. A similar fate overtook the venerable Council of the Indies; most of its duties were entrusted to a powerful colonial minister appointed by the king.

Failure of colonial reforms

The entrance of new trading centres and merchant groups into the Indies trade, the reduction of duties, and the removal of irksome restrictions, had the effect of increasing commerce, reducing prices, and perhaps diminishing contraband. But the Bourbon commercial reform ultimately failed in its aim of reconquering colonial markets for Spain for several reasons—first, the opposition of the still dominant merchant oligarchs of Cádiz, who resisted intercolonial trade and efforts to replace French and English manufactures in the export trade to the colonies with noncompetitive Spanish products; second, Spain's continuing industrial weakness, which the best efforts of the Bourbons could not overcome; and, third, Spain's closely related inability to keep its sea-lanes to America open in time of war with England, when foreign traders again swarmed in Spanish American ports.

Colonial economic growth. Perhaps the most significant result of the Bourbon commercial reforms was the stimulus given to economic activity in Spanish America. To what extent this economic growth should be ascribed to the Bourbon reforms and to what degree it resulted from the economic upsurge in western Europe in the 18th century cannot be stated with certainty. Stimulated by the Bourbon reforms and a growing European demand for sugar, coffee, tobacco, hides, and other staples, production of these products rose sharply. But this increase in agricultural production resulted from more extensive use of land and labour rather than from the use of improved implements or techniques. The inefficient ***latifundio*** (a large, poorly cultivated estate), using poorly paid peon labour, and the slave plantation accounted for the bulk of agricultural production. Such natural disasters as drought or excessive rains easily upset the precarious balance between food supplies and population, producing frightful famines (as in 1785–87 in central Mexico, when thousands died of hunger or diseases).

What sugar, cacao, and coffee were for the Caribbean area, hides were for the Río de la Plata. Rising European demand for leather and the opening of direct trade with Spanish ships in 1735 sparked an economic upsurge in the Plata area. By the end of the 18th century the ***estancias*** (cattle ranches) were often huge, with as many as 80,000 or 100,000 head of cattle. Meat gained in value as a result of the demand for salt beef. Markets for salt beef were found above all in the Caribbean area, especially Cuba, chiefly for feeding the slave population. The growth of cattle raising in La Plata was attended by concentration of land in ever fewer hands and took place at the expense of agriculture, which remained in a depressed state.

Silver mining revival

The 18th century also saw a strong revival of silver mining in the Spanish colonies. Peru and Mexico shared in this advance, but the Mexican mines forged far ahead of their Peruvian rivals. The crown, especially under Charles III, made serious efforts to encourage the industry by such means as tax reductions and the dispatch of foreign and Spanish experts to Mexico and Peru. These efforts were largely frustrated by the traditionalism of the mine owners, lack of capital to finance changes, and mismanagement. Yet the production of silver steadily increased; supplemented by the gold of Brazil, it helped to spark the industrial revolution in northern Europe and stimulated commercial activity on a worldwide scale. More especially, American silver helped the Bourbons meet the enormous expenses of their chronic wars.

Colonial manufacturing, on the other hand, began to decline late in the 18th century, principally because of competition from cheap foreign wares. The textile and wine industries of western Argentina and the textile production of Quito in Ecuador decayed as they lost their markets to lower-priced foreign wines and cloth. In the Mexican city of Puebla, production of chinaware slumped catastrophically between 1793 and 1802. Although Spain adopted mercantilist legislation designed to restrict colonial manufacturing, this legislation seems to have been a small deterrent to the growth of large-scale manufacturing. More important were lack of investment

Spanish and Portuguese America in 1784.

capital, preference for land and mining as fields of investment, and a semiservile system of labour that was harmful equally to the workers and to productivity.

DECENTRALIZATION

Under Charles III the work of territorial reorganization continued. The viceroyalty of Peru was further curtailed by the creation (1776) of the viceroyalty of the Rio de la Plata, with its capital at Buenos Aires. In 1783 the establishment of a royal *audiencia* at Buenos Aires completed the liberation of the Plata provinces from the distant rule of Lima. The inclusion of Upper Peru in the new viceroyalty, with the resulting redirection of the flow of Potosi silver from Lima to Buenos Aires, signified a major victory for the landlords and merchants of Buenos Aires over their mercantile rivals of Lima.

The trend toward decentralization reflected not only a struggle against foreign military and commercial penetration but also an awareness of the problems of communication and government posed by the great distances between the various provinces. One indication of this was the greater autonomy and the increased number of the captaincies general in the 18th century. Venezuela was raised to a captaincy general in 1777, Chile, in 1778.

The intendant system

Between 1782 and 1790 the intendant system was introduced to the colonies. The intendants—provincial governors who ruled from the capitals of their provinces—were expected to relieve the overburdened viceroys of many of their duties, especially in financial matters. The offices of *corregidor* and *alcalde mayor,* holders of which were notorious as oppressors of the Indians, were replaced in Indian districts by that of *subdelegado,* nominated by the intendants and confirmed by the viceroys. Many intendants at the height of the reform era were capable, cultivated men who not only worked to increase economic activity and revenue collection but also promoted education and other cultural projects. Most *subdelegados,* however, soon became as notorious as their predecessors for their oppressive practices; a common complaint was that they compelled the Indians to trade with them, although forbidden by the Ordinance of Intendants. The failure of the Indian and mixed-blood masses to profit by the 18th-century economic advance—whose principal beneficiaries were Creole (American-born Spaniards) landowners, mine owners, and merchants—helped to produce popular revolts of 1780–81 (of Tupac Amaru in Peru and of the *comuneros* in New Granada), which, although suppressed, shook Spanish power to its foundations in those areas.

DEFENSE OF THE EMPIRE

Increased revenue was a major objective of the Bourbon commercial and political reforms, needed for strengthening the sea and land defenses of the empire. Spanish losses in the Seven Years' War (1756–63), and especially the loss of Havana and Manila to the English (1762), resulted in efforts to improve the defense system of the colonies. Fortifications of important American ports were strengthened and colonial armies were created. Regular units were stationed permanently in the colonies or rotated between peninsular and overseas service, and a colonial militia was filled by volunteers or conscripts. To make military service attractive to the Creole upper class, which provided the officer corps of the new force, the crown granted extensive privileges and exemptions to Creole youth who accepted commissions, thus adding to the lure of prestige and honours protection from civil legal jurisdiction and liability, except for certain specified offenses. This led to the development of a special officer class, which survives in many Latin American countries.

V. The wars of independence

BACKGROUND FOR THE WARS

The Bourbon reforms combined with the growing European demand for colonial products in the 18th century to bring material prosperity and other benefits to the upper class Creoles. The improvements and refinements introduced by enlightened viceroys and intendants made life in the colonial cities more attractive; educational reforms and opportunities widened the intellectual horizons of Creole youth. These advances, however, only enlarged Creole aspirations and discontents. Increased production strained against the trade barriers maintained by Spanish mercantilism. Awareness of their economic importance made intolerable to the Creoles their virtual exclusion from commanding posts in government and the church.

Creole discontent

The conflict of interests between Spain and its colonies found expression in the cleavage between Creoles and peninsular Spaniards. This cleavage was a major cause of the Spanish American wars of independence.

Enlightenment and revolutionary influences. Enlightenment ideas contributed to Creole restlessness and discontent. The forbidden writings of G.T. Raynal, Montesquieu, Voltaire, and Rousseau undoubtedly were read by educated Creoles; and scientific works based on the premises of Descartes, Leibnitz, and Newton circulated freely in the colonies and helped to spread Enlightenment ideas. By 1800 such influences had partly renovated the intellectual climate of Spanish America and had given a rationalist, pragmatic stamp to Creole thought.

The United States War of Independence contributed to the growth of "dangerous ideas" in the Spanish colonies. Spain was aware of the ideological as well as the political threat to its empire posed by the United States. After 1783 a growing number of U.S. ships touched legally or illegally at Spanish American ports, sometimes introducing such subversive documents as the writings of the revolutionists Thomas Paine and Thomas Jefferson.

The French Revolution exerted greater influence on the Creole mind. The Colombian Antonio Nariiio translated and printed the French Declaration of the Rights of Man of 1789; he was sentenced to prison in Africa for ten years but later led the successful independence movement in Colombia. The French Revolution soon took a radical turn, and the Creole elite became disenchanted with it as a model. The most important direct result of the French Revolution was a slave revolt in the French part of Haiti under Toussaint-Louverture (*q.v.*) and other black leaders; by January 1, 1804, black revolutionaries in Haiti had established the first liberated territory in Latin America, but their achievement dampened rather than aroused support for independence among the Creole elite of the colonies (see HAITI, HISTORY OF).

Beginnings of the independence movement. In 1806 the revolutionary Francisco de Miranda landed on the shores of his native Venezuela with a force of some 200 foreign volunteers, but his call for an uprising met with no response, and he hastily withdrew. The colonial independence movement might have remained ineffectual if not for decisions and actions by European powers with very different ends in view.

Spanish–French alliance

A major cause of the revolutionary crisis was Spain's involvement in the European wars unleashed by the French Revolution. Spain became France's ally in 1796, and English sea power promptly drove Spanish shipping from the seas, virtually cutting off communication between Spain and its colonies. The alliance with France had other results. An English fleet sailed with a regiment of soldiers against Buenos Aires (1806). The English soldiers entered Buenos Aires meeting only token resistance, but Creoles and peninsular Spaniards soon rallied to expel their unwanted liberators; a volunteer army attacked and routed the occupation force, capturing the English general and 1,200 of his men. A second British invasion was beaten back with heavy losses. Impressed by the tenacious defense, the British commander agreed to evacuate both Buenos Aires and the town of Montevideo. With this victory, the Creoles of Buenos Aires had tasted power and would not willingly relinquish it again.

In Europe, Napoleon gradually reduced Spain to a helpless satellite. In 1807 Napoleon obtained from Charles IV permission to invade Portugal through Spain; and the Portuguese royal family and court escaped to Brazil in a fleet under British convoy. Popular resentment at the French presence in Spain forced Charles IV and his son Ferdinand to abdicate; Napoleon tried to place his brother Joseph on the Spanish throne.

An insurrection against the French occupation forces began in Madrid and spread across Spain beginning in 1808; it led to the formation of a national Cortes, or parliament, which met in Cadiz from 1810 to 1814 under the protection of English naval guns. The constitution, approved by the Cortes in 1812, provided a limited monarchy and freedom of speech and assembly, and it abolished the Inquisition. But the Cortes made few concessions to the American colonies; it invited American delegates to join its deliberations but made clear that the system of peninsular domination and commercial monopoly would remain essentially intact.

Creole plans for gaining power

In Spanish America events had transformed the remote prospect of independence into a realistic goal. Confident that the French armies would crush all opposition, Creole leaders prepared to take power with the pretext of loyalty to the "beloved Ferdinand." The confusion caused among Spanish officials by the arrival of rival emissaries who proclaimed Ferdinand or Joseph Bonaparte the legitimate king of Spain aided the Creole plans. In the spring of 1810, with the fall of Cádiz seemingly imminent, the Creole revolutionaries moved into action; charging viceroys and other royal officials with doubtful loyalty to Ferdinand, they organized demonstrations in Caracas, Buenos Aires, Santiago, and Bogotá that forced these authorities to surrender control to Creole-dominated local juntas. Their hopes of a peaceful transition to independence, however, were doomed to failure; their claims of loyalty did not deceive the groups truly loyal to Spain, and fighting soon broke out between patriots and loyalists.

THE INDEPENDENCE OF SOUTH AMERICA

The Latin American struggle for independence lacked a unified direction or strategy that was caused not only by the vast distances and other geographical obstacles to unity, but also by the economic and cultural isolation of the various Latin American regions. Moreover, the Latin American movement for independence lacked a strong popular base—the Creole elite, itself part of an exploitative white minority, feared the Indians, Negroes, and oppressed castes and usually sought to keep their intervention in the struggle to a minimum. This lack of regional and class unity helps explain why it took Latin America so long to achieve independence.

The struggle for independence had four main centres. In Spanish South America there were two principal theatres of military operations--one flowed southward from Venezuela, the other ran northward from Argentina; these two currents joined at Peru, the last Spanish bastion on the continent. The third centre, Brazil, achieved its own swift and relatively peaceful separation from Portugal. Finally, Mexico had to travel a difficult, devious road toward independence.

Bolivar's involvement in the movement

Spanish South America. Simón Bolivar of Venezuela is the symbol and hero of the struggle for independence in northern South America. Soon after his return to Venezuela from a visit to Europe (1804–07), he became involved in conspiratorial activity directed at overthrow of the Spanish regime. In April 1810, the Creole party in Caracas forced the captain general to abdicate, and a Creole-dominated junta took power. In 1811 a Venezuelan congress proclaimed the country's independence and framed a republican constitution that abolished special privileges and Indian tribute, but retained Negro slavery and made Catholicism the state religion. Meanwhile, the veteran revolutionary Francisco de Miranda had returned from England and assumed command of the patriot army.

Differences soon broke out between Miranda and his young officers, especially Bolivar. Amid these disputes came the earthquake of March 26, 1812, which caused great loss of life and property in Caracas and other patriot territory, but spared the regions under Spanish control. The royalist clergy proclaimed this disaster a divine retribution against the rebels. A series of military reverses completed the discomfiture of the revolutionary cause. With his forces disintegrating, Miranda negotiated a treaty with the royalist commander and then tried to flee the country, taking with him part of the republic's treasury. Bolivar and some of his comrades, regarding Miranda's act a form of treachery, seized him before he could embark and turned him over to the Spaniards. Miranda died in a Spanish prison four years later.

Bolivar was saved from a Spanish reaction by the influence of a family friend. Under a safe conduct, he departed for Colombia, which was still partially under patriot control. Given command of a small force to clear the Magdalena River of enemy troops, he employed a strategy featured by swift movement and aggressive tactics; he also judged his soldiers on merit without regard to social background or colour. His success gained Bolivar the rank of general in the Colombian army and won him the approval of a plan of his for liberation of Venezuela.

In a forced march of three months, Bolivar led a force of 500 men across jungles and swamps toward Caracas; as he approached the capital, the Spanish forces withdrew. He entered Caracas in triumph and received from the city council the title of "liberator"; soon afterward the congress of the restored republic voted to grant him dictatorial powers.

Bolivar's success was short-lived. The fall of Napoleon, in 1814, brought Ferdinand VII to the Spanish throne, released Spanish troops for use in America, and heartened the royalists. Meanwhile, the ***llaneros,*** or cowboys, of the Venezuelan plains joined the royalist cause. A mass of ***llaneros*** invaded Caracas, crushing all resistance; and in July 1814 Bolivar hastily abandoned the city and retreated toward Colombia with the remains of his army.

Bolivar found Colombia on the verge of chaos; despite the imminent threat of a Spanish invasion, the provinces quarrelled with each other and defied the authority of the weak central government. Concluding that the situation was hopeless, Bolivar left in May 1815 for the British island of Jamaica. Meanwhile, a Spanish army landed in Venezuela, completed the reconquest of the colony, and then sailed to lay seige to Cartagena; the city surrendered in December, and the rest of Colombia was pacified within a few months. Of all the Spanish American provinces, only Argentina remained in revolt.

Bolivar's "Letter from Jamaica"

Bolivar had an unshakeable faith in the triumph of independence. From Jamaica he wrote a famous document --"The Letter from Jamaica"—in which he affirmed his faith and argued that monarchy was foreign to the genius of Latin America; only a republican regime would be accepted by its peoples. Bolivar boldly forecast the destiny of the different regions, taking account of their economic and social structures (Chile, for example, seemed to him to have a democratic future; Peru, on the other hand, was fated to suffer dictatorship because it contained gold and slaves).

From Jamaica, Bolivar went to Haiti, where he received a sympathetic hearing and the offer of some material support. After two efforts to gain a foothold on the Venezuelan coast failed, Bolivar decided to establish a base in the Orinoco River Valley, distant from the centres of Spanish power. Roving patriot bands still operated in this region, and Bolivar hoped to win the allegiance of the ***llaneros,*** who were becoming disillusioned with their Spanish allies. In September 1816 Bolivar sailed for the Orinoco River Delta and made his headquarters at the town of Angostura (modern Ciudad Bolivar).

The patriot guerrilla bands accepted Bolivar's leadership, and he also gained the support of the ***llaneros.*** The end of the Napoleonic Wars had idled a large number of British soldiers; and many of these veterans came to Venezuela, forming a British legion that distinguished itself in battle on the patriot side. Bolivar was also helped by English merchants, who made loans that enabled him to secure men and arms, and by the mulish attitude of Ferdinand VII, whose refusal to make any concessions to the colonists caused the British government to lose patience and regard favourably the prospect of Spanish American independence.

Liberation of Colombia and Venezuela

On the eve of the decisive campaign of 1819, Bolivar summoned to Angostura a congress that vested him with dictatorial powers. His strategy for the liberation of Venezuela and Colombia was to strike a blow at Spanish forces from a completely unexpected direction; he advanced with an army of some 2,500 men along the Orinoco and Arauco rivers across the plains and then ascended the Colombian Andes until he reached the plateau where lay Bogota. On the field of Boyacá the patriot army surprised and defeated the royalists in a short, sharp battle and entered Bogotá. He then prepared for the liberation of Venezuela; in June 1821 patriot troops crushed the last major Spanish force in Venezuela at Carabobo. Save for some coastal towns and forts held by beleaguered royalists, Venezuela was free.

The independence of Spanish America remained precarious as long as the Spaniards held the immense mountain bastion of the central Andes. While Bolivar prepared an offensive from Bogota against Quito, he sent his lieutenant José Antonio de Sucre by sea from Colombia's Pacific coast to seize the port of Guayaquil. Even before Sucre arrived, the Creoles of Guayaquil revolted, proclaimed independence, and placed the port under Bolivar's protection. Advancing into the Ecuadorian highlands, Sucre defeated a Spanish army on the slopes of Mount Pichincha, near Quito. Royalist resistance crumbled on news of Sucre's victory; and the provinces composing the viceroyalty of New Granada — the future republics of Venezuela, Colombia, Ecuador, and Panama — were free. They were temporarily united into a large state named Great Colombia (Gran Colombia), established at the initiative of Bolivar by the union of New Granada and Venezuela in 1821.

Liberation of Argentina

Ever since the defeat of the British invasions of 1806–07, the Creole party, nominally loyal to Spain, had effectively controlled Buenos Aires. In May 1810, when word came that French troops had entered Seville and threatened Cádiz, an open town meeting convened to decide the future government of the colony. This first Argentine congress voted to depose the viceroy and establish a junta to govern in the name of Ferdinand. In 1813 a national assembly gave the country the name United Provinces of the Rio de la Plata and enacted such reforms as the abolition of *mita, encomienda*, titles of nobility, and the Inquisition. A declaration of independence, however, was delayed until 1816.

The junta promptly attempted to consolidate its control over the vast viceroyalty. The western interior provinces were subdued after sharp fighting. Montevideo, across the Rio de la Plata, remained in Spanish hands until 1814, when it fell to an Argentine siege. The junta met even more tenacious resistance from the gauchos of the Uruguayan pampa, led by Jose Gervasio Artigas, who demanded Uruguayan autonomy in a loose federal connection with Buenos Aires; but Artigas became caught between pressure from Buenos Aires and Portuguese forces who claimed Uruguay for Brazil, and he had to flee to Paraguay (Uruguay did not achieve complete independence until 1828). The Creoles of Paraguay defeated a force sent from Buenos Aires to liberate Asunción and proceeded to depose Spanish officials and proclaim the independence of Paraguay.

The junta's efforts to liberate the mountainous province of Upper Peru failed because of steep terrain, long lines of communication, and the apathy of the Indian population.

Upper Peru in Spanish hands represented a standing threat to the security of the La Plata provinces. The military genius of José de San Martin of Paraguay offered a solution to the problem. San Martin was a colonel in the Spanish army when revolution broke out in Buenos Aires. He promptly sailed for La Plata to join the patriot junta and was soon raised to command the army of Upper Peru. San Martin proposed a march across the Andes to liberate Chile, where a Spanish reaction had toppled the revolutionary regime established by Bernardo O'Higgins and other patriot leaders in 1810. Having liberated Chile, the united forces of La Plata and Chile would descend upon Peru from the sea.

San Martin's liberation of Chile and Peru

San Martin obtained an appointment as governor of the province of Cuyo, whose capital, Mendoza, lay at the eastern end of a strategic pass leading across the Andes to Chile. He spent two years recruiting, training, and equipping his Army of the Andes. The army began the crossing of the cordillera in January 1817, and in 21 days it issued on Chilean soil. A decisive victory at Chacabuco in February opened the gates of Santiago to San Martin. Another victory at Maipú (1818) ended the threat to Chile's independence. Rejecting Chilean invitations to become supreme ruler of the republic, a post assumed by O'Higgins, San Martin secured a number of ships in England and the United States and, in August 1820, sailed for Peru in a fleet of seven ships of war and 18 transports. He landed his army about 100 miles (160 kilometres) south of Lima but delayed moving on the Peruvian capital; he hoped to obtain its surrender by economic blockade, propaganda, and direct negotiation with Spanish officials. His strategy was successful; in June 1821 the Spanish army evacuated Lima and retreated toward the Andes. San Martin entered the capital and proclaimed the independence of Peru. But he then had to deal with counterrevolutionary plots and the resistance of Lima's elite to his program of social reform. Meanwhile. a large Spanish army manoeuvred in front of Lima, challenging San Martin to a battle which he dared not join with his much smaller force. San Martin became convinced that only monarchy could bring stability to Spanish America, and he sent a secret mission to Europe to find a prince for the throne of Peru.

San Martin met with Bolivar in Guayaquil (July 26–27, 1822); the proceedings are surrounded with an atmosphere of mystery. Argentine historians hold that San Martin came to Guayaquil in search of military aid but was rebuffed by Bolivar, who was unwilling to share with a rival the glory of bringing the struggle for independence to an end; San Martin then magnanimously decided to leave Peru and allow Bolivar to complete the work he had begun. Venezuelan historians argue that San Martin came to Guayaquil primarily to recover that city for Peru; they deny that he asked Bolivar for more troops and insist that he left Peru for reasons having nothing to do with the conference. Both interpretations tend to diminish the stature and sense of realism of the two liberators—San Martin must have understood that Bolivar alone combined the military, political, and psychological assets needed to solve the factional problems in Peru and to gain final victory over the powerful Spanish army in the sierra; given the situation in Lima, San Martin's presence there could only hinder the performance of those tasks. Viewed in this light, the decision of Bolivar to assume sole direction of the war and of San Martin to withdraw reflected a realistic appraisal of the Peruvian situation and the solution it required.

San Martin returned to Lima to find that in his absence his enemies had usurped his power. In September 1822, before the first Peruvian congress, he announced his resignation as protector and his impending departure. San Martin's departure left Lima and the territory under its control in serious danger of reconquest by the strong Spanish army in the sierra. Bolivar allowed the situation to deteriorate until May 1823, when the Peruvian Congress called on him for help. The scare produced by a brief reoccupation of the capital by the Spanish army prepared the Creole leaders to accept Bolivar's absolute rule.

Bolivar arrived in Peru in September 1823 and needed almost a year to achieve political stability and to weld his army and the different national units under his command into a united force. After a difficult ascent of the sierra, patriot forces won a victory near the lake of Junin (August 6, 1824). To Sucre fell the glory of defeating the Spanish army in the last major engagement of the war, at Ayacucho (December 9, 1824). Only scattered resistance at some points in the highlands and on the coast remained to mop up. The work of continental liberation was achieved (see further ARGENTINA, HISTORY OF; BOLIVIA, HISTORY OF; CHILE, HISTORY OF; COLOMBIA, HISTORY OF; ECUADOR, HISTORY OF; PARAGUAY, HISTORY OF; PERU, HISTORY OF; URUGUAY, HISTORY OF; VENEZUELA, HISTORY OF).

Brazil. Brazil made a swift, almost bloodless transition to independence. The idea of Brazilian independence first arose in the late 18th century as a Creole reaction to the Portuguese policy of tightening political and economic

The Portuguese court in Brazil

control over the colony. The first significant conspiracy against Portuguese rule was organized in Minas Gerais, but it was easily discovered and crushed. The French invasion of Portugal (1808), followed by the flight of the Portuguese court to Rio de Janeiro, brought large changes and benefits to Brazil. The Portuguese prince regent John opened Brazil's ports to the trade of friendly nations, permitted the rise of local industries, and founded a "Bank of Brazil." Brazilian Creoles took satisfaction in Brazil's new role and the growth of educational, cultural, and economic opportunities for their class; but this feeling was mixed with resentment at the thousands of Portuguese who came with the court and competed with Brazilians for jobs and favours.

The revolution of 1820 in Portugal precipitated Brazil's break with the mother country. The Portuguese revolutionaries framed a liberal constitution for the kingdom, but assumed a conservative posture toward Brazil; they demanded the immediate return of Prince John to Lisbon, an end to the system of dual monarchy that he had devised, and the restoration of the Portuguese commercial monopoly. John approved the new constitution and sailed for Portugal, leaving behind his son and heir Dom Pedro as regent and advising him that, in the event the Brazilians demanded independence, he should assume leadership of the movement and set the Brazilian crown on his head.

Soon it became clear that the Portuguese Cortes intended to abrogate all the liberties and concessions won by Brazil since 1808. One of its decrees insisted on the immediate return of Dom Pedro from Brazil in order that he might complete his political education. But Dom Pedro, urged on by Creole advisers who saw a golden opportunity for an orderly transition to independence, rejected the Portuguese demand, issued his famous Fico ("I remain"), and in December 1822, having overcome slight resistance from Portuguese elements, was formally proclaimed constitutional emperor of Brazil (see also BRAZIL, HISTORY OF).

THE INDEPENDENCE OF MEXICO

A social revolution

In Mexico the movement for independence took an unexpected turn; the Indian and mixed-blood masses joined the struggle and for a time converted it from a quarrel between the Creole and Spanish-born peninsular elites into a social revolution.

In 1810 a Creole plot for independence was being hatched in the important industrial and mining centre of Querétaro; its leaders included Miguel Hidalgo, a priest in the town of Dolores known for his sympathy with the Indians. Informed that their plot had been denounced to Spanish officials, the conspirators decided to launch their revolt before preparations were complete. On September 16, 1810, Hidalgo called on the Indians of his parish to rise against their Spanish rulers; he appealed to the religious fanaticism of the natives by proclaiming the Virgin of Guadalupe the patron of his movement. After his first victories Hidalgo issued decrees abolishing slavery and Indian tribute and ordering the restoration of lands to the Indian communities. These measures gave the Mexican revolution a popular character largely absent from the movement for independence in South America, but they alienated the many Creoles who desired independence without social revolution.

Hidalgo could not weld his Indian horde into a disciplined army or capitalize on his early victories. Within a year he was captured, condemned as a heretic by an Inquisitorial court, and shot. A mestizo priest, José Maria Morelos, assumed leadership of the revolutionary struggle; he liberated most of southern Mexico, then summoned a congress that proclaimed independence and framed a republican constitution. Morelos extended Hidalgo's social reforms by prohibiting all forced labour and forbidding the use of racial terms. Like Hidalgo, Morelos also had differences with Creole associates that hampered his conduct of the war, and his premature efforts to install a constitutional regime also hindered his military efforts. In 1815 he, too, was captured by the Spaniards and shot.

Conservative–rebel alliance

The revolution then declined into a guerrilla war waged by many rival chiefs. Royalist armies gradually extinguished the remaining centres of resistance. The Spanish revolution of 1820 abruptly changed this state of affairs. Fearing the loss of their privileges, conservative clergy, army officers, and merchants in Mexico schemed to separate from the mother country and establish independence under conservative auspices. Their instrument was the Creole officer Agustin Iturbide, who had waged implacable war against the patriots. Iturbide offered peace and reconciliation to the principal rebel leader, Vicente Guerrero; his plan combined independence, monarchy, the religious supremacy of the Roman Catholic Church, and the civil equality of Creoles and Spaniards. For the moment Iturbide's program offered advantages to both sides.

The united forces of Iturbide and Guerrero swiftly overcame scattered loyalist resistance. On Septembr 28, 1821, Iturbide proclaimed Mexican independence; and eight months later a congress selected by Iturbide confirmed him as Agustin I, emperor of Mexico. Iturbide's empire had no popular base, however, and within a few months he had to abdicate and depart for Europe, with a warning never to return. In 1824 Iturbide landed on the Mexican coast with a small party, was promptly captured by troops of the new republican regime, and was shot (see also MEXICO, HISTORY OF).

BIBLIOGRAPHY

General works: CHARLES GIBSON, *Spain in America* (1966), the best short survey, incorporates the latest scholarship and has a valuable bibliographical essay; JOHN H. PARRY covers the same ground somewhat more amply in his well-written *The Spanish Seaborne Empire* (1966). SILVIO A. ZAVALA, *El mundo americano en la época colonial,* 2 vol. (1967), is a work of synthesis by a leading Mexican historian. STANLEY J. and BARBARA H. STEIN, *The Colonial Heritage of Latin America: Essays on Economic Dependence in Perspective* (1970), brief but insightful, shows the continuity of Latin American economic patterns from colonial times to the present. Among older works, CLARENCE H. HARING, *The Spanish Empire in America* (1947, reprinted 1963), remains indispensable for colonial institutions. BAILEY W. DIFFIE, *Latin American Civilization: Colonial Period* (1945), is a work of formidable scholarship and sharply defined viewpoints on various controversial topics. For a comprehensive collection of source materials on the colonial period, see BENJAMIN KEEN (comp.), *Readings in Latin America Civilization,* 1492 *to the Present,* 2nd ed. (1967).

Spanish Conquest of America: CARL O. SAUER, *The Early Spanish Main* (1966), critically examines the impact of the discovery on the Indian population of the Caribbean. WILLIAM H. PRESCOTT, *History of the Conquest* of *Mexico,* 3 vol. (1843, reprinted 1966), and *History of the Conquest of Peru,* 2 vol. (1908, reprinted 1963), remain classics, unsurpassed for breadth of conception and literary charm, but their romantic attitudes clearly reveal the books' age. JOHN HEMMING, *The Conquest of the Incas* (1970), supersedes all previous accounts.

Spain's colonial emprre: PHILIP W. POWELL, *Soldiers, Indians, and Silver: The Northward Advance of New Spain,* 1550–1600 (1952); and EUGENE H. KORTH, *Spanish Policy in Colonial Chile* (1968), examine Spanish–Indian relations. LEWIS U. HANKE, *The First Social Experiments in America* (1935), and *The Spanish Struggle for Justice in the Conquest of America* (1949), discuss the intellectual history of the Conquest; while his *Aristotle and the American Indians* (1959), studies the controversy between Las Casas and Juan Ginés de Sepdlveda over the nature and capacity of the Indians. For Messianic and Utopian influences in the Conquest, see JOHN L. PHELAN, *The Millenial Kingdom of the Franciscans in the New World,* rev. ed. (1969). For a reappraisal of Spain's Indian policy that questions some of Lewis Hanke's premises, see BENJAMIN KEEN, "The Black Legend Revisited: Assumptions and Realities," *Hispanic American Historical Review,* 49:703–719 (1969). On race relations in the colonial period, see the thoughtful survey of MAGNUS MORNER, *Race Mixture in the History of Latin America* (1967). Controversy surrounds the question of the size of pre- and post-Conquest Indian populations. S F. COOK and WOODROW BORAH made an illuminating series of studies that indicate a very large Indian population in 1519, followed by a demographic catastrophe in the sixteenth and seventeenth centuries, consolidating their findings in *The Indian Population of Central Mexico, 1531–*1610 (1960). For comparison, see the sharply divergent findings of ANGEL ROSENBLAT, *La población de América en* 1492:

Viejos y nuevos calculos (1967). FRANCOIS CHEVALIER, ***La Formation des grands domaines au Mexique*** (1952; Eng. trans., ***Land and Society in Colonial Mexico: The Great Hacienda,*** 1963), a landmark in the study of colonial land systems, traces the interplay of demographic and economic trends in the development of the hacienda. JAMES LOCKHART deftly analyzes the structure of Spanish society in colonial Peru in ***Spanish Peru, 1532–1560*** (1968).

The ***encomienda*** has been the subject of careful study. Two pioneer works are L.B. SIMPSON, ***The Encomienda in New Spain,*** rev. ed. (1950); and SILVIO A. ZAVALA, ***La encomienda indiana*** (1935). CLARENCE H. HARING, ***Trade and Navigation Between Spain and the Indies in the Time of the Hapsburgs*** (1918), remains a standard work. On land systems, see J.M. OTS CAPDEQUI, ***España en América: El régimen de tierras en la época colonial*** (1959). On mining, see MODESTO BARGALLO, ***La minería y la metalurgia en la America Española durante la época colonial*** (1955), for a general survey.

For the relations between church and state, see JOHN L. MECHAM, ***Church and State in Latin America,*** rev. ed. (1966); and WILLIAM E. SHIELS, ***King and Church: The Rise and Fall of the Patronato Real*** (1961).

Colonial Brazil: CAIO PRADO, *Formacão do Brasil Contemporañeo* (1942; Eng. trans., ***The Colonial Background of Modern Brazil,*** 1967), is an excellent introductory survey. See also CHARLES R BOXER, ***The Dutch in Brazil, 1624–1654*** (1957), and ***The Golden Age of Brazil, 1695–1750*** (1962). DAURIL ALDEN, ***Royal Government in Colonial Brazil*** (1968), is a model monograph. GILBERTO FREYRE, *Casa Grande e Senzala,* 2 vol. (1943; Eng. trans., ***The Masters and the Slaves,*** 1946), a work of great literary charm, portrays Portuguese colonizers as almost free from colour prejudice and Brazilian slavery as relatively mild. For opposing points of view, see CHARLES R. BOXER, ***Race Relations in the Portuguese Colonial Empire, 1415–1825*** (1963); and MARVIN HARRIS, ***Patterns of Race in the Americas*** (1964). On the economics of colonial Brazil, see ALEXANDER MARCHANT, ***From Barter to Slavery*** (1942), which stresses the mixed feudal-capitalist character of early Brazilian economy; and CAIO PRADO, ***op. cit.***

The Bourbon reforms and Spanish America: JOHN LYNCH, ***Spanish Colonial Administration, 1782–1810*** (1958), discusses colonial political reform. For the transmittal of Enlightenment ideas to Latin America, see the essays in ARTHUR P. WHITAKER (ed.), ***Latin America and the Enlightenment,*** 2nd ed. (1961).

Wars of independence: ROBIN A. HUMPHREYS, "The Fall of the Spanish American Empire," ***History,*** 37:213–277 (1952), is a perceptive interpretive essay, while he and JOHN LYNCH (eds.) bring together varied viewpoints in their anthology, ***The Origins of the Latin American Revolutions, 1808–1826*** (1965).

(B.K.)

Latvian Soviet Socialist Republic

Latvia, which had been an independent republic since 1920, was constituted as one of the 15 republics of the Soviet Union on July 21, 1940, and was proclaimed a Soviet Socialist republic on August 5. Situated in the Soviet west on the shores of the Baltic Sea and the Gulf of Riga, it covers an area of 24,600 square miles (63,700 square kilometres). In the north it borders on the Estonian Soviet Socialist Republic, in the east on the Russian S.F.S.R., and in the south on the Lithuanian S.S.R. The overall length of Latvia's borders is 1,120 miles (1,800 kilometres), of which 307 miles (494 kilometres) are coastal. The capital is Riga (Riga in Latvian). For the history of Latvia, see BALTIC STATES, HISTORY OF THE.

The natural landscape. ***Relief.*** Latvia is essentially an undulating plain, with fairly flat lowlands alternating with hills. The eastern part is more elevated, the most prominent feature being the central Vidzeme (Livonia) elevation, which reaches a maximum height of 1,020 feet (311 metres). In the southeast the highest point is 948 feet (289 metres). The Kurzeme (Courland) elevation in the west is cut by the Venta River into western and eastern parts. Between the central Vidzeme and Latgalē (Latgallian) elevations lies the East Latvian Lowland, partly crossed by moraine ridges that impede drainage; there are many peat bogs in this area.

The shores of the Baltic and the Gulf of Riga are only slightly indented, and there are considerable stretches of excellent sandy beaches.

Drainage and soils. Latvia contains a multitude of rivers belonging to the Baltic drainage area. The largest are the Western Dvina, locally called the Daugava (with a total length of 224 miles in Latvia), the Gauja (Russian Gauya), the Venta, and the Lielupe. Amid the hills, many of which are forested, are numerous lakes, ranging from a few acres up to 12 square miles (30 square kilometres) in area. Soils are predominantly podzolic, though calcareous soils characterize the Zemgale Plain. Swampy soils are found in some areas, particularly the East Latvian Lowland. Erosion is a problem in the more intensely cultivated hilly areas.

The Daugava **River**

Mineral deposits. Mineral resources are confined to gravel, sand, dolomite, limestone, clay, and peat. Oil has been discovered in the Courland Peninsula, but reserves have not yet been explored.

Climate. The climate is influenced by the prevailing air masses coming from the Atlantic. Humidity is high, and the skies are usually somewhat cloudy; there are only 30 to 40 days of sunshine per year and 150 to 180 completely overcast days. Average precipitation is 22–24 inches (about 550–600 millimetres) on lowlands and 28–31 inches (about 700–800 millimetres) on elevations. Southwesterly and southerly winds prevail. The frost-free season lasts from 125 to 155 days. Summers are cool and rainy more often than not. The mean air temperature in June is 63° F (17" C) with occasional jumps to about 93" F (34" C). Winter sets in slowly and lasts from the middle of December to the middle of March. The mean January temperature ranges from 28° F (—2" C) on the coast to 19° F (—7° C) in the east. There are occasional drops to —40" F (—40" C).

Vegetation. Some 67 percent of Latvia is covered with forests, meadows, pastures, swamps, and wasteland. Forests, which account for 38 percent of the total area, are a dominating feature of the republic's natural scene; about 10 percent of the forests are cultivated. The larger forest tracts are to be found in the northern part of the Courland Peninsula, along the left bank of the Daugava, and in the northeast. Conifers (pine and spruce) predominate. Of the deciduous species, birch, aspen, and alder occur more commonly. Meadows are found everywhere, both in the river valleys and among the hills.

Forest animals

Fauna. Latvia's fauna is typical for a region with mixed forests; there are squirrel, fox, hare, lynx, and badger. Somewhat less common are ermine and weasel. Conservation measures have resulted in an increase in the number of deer and elk and reintroduced beaver.

The numerous birds include the nightingale, oriole, blackbird, woodpecker, owl, grouse, partridge, finch, tomtit, quail, and lark. Storks and herons are found in the marshes and meadows.

Population. According to estimates of 1976, the population of Latvia was 2,499,000. The bulk of the people are Latvians (56.8 percent at the census of 1970, down from 62 percent in 1959 and from more than 75 percent in 1935) and Russians (29.8 percent, up from 26.6 percent in 1959). The Latvians, or Letts, speak one of the two surviving Baltic languages, the other being Lithuanian (see BALTIC LANGUAGES). In 1935 about 68 percent of them were Lutheran, 26 percent Roman Catholic. The ancestors of the present-day Latvians were the Latgals (Latgallians), who in the 9th century lived in the northeastern part of the present republic and who absorbed the Kurs (Cours, Couronians) and Livs. Two other early Latvian tribes were the Selonians and the Zemgals (Semigallians).

The total number of towns and urban settlements in the republic is 92. A considerable proportion of these have populations of 50,000 or more. In 1975 the urban population was 1,623,000 (65 percent), a proportion that is tending to increase. Immigrant Russians tend to settle in the cities; about 80 percent of the Russian population was urban in 1970, as against only 52 percent of the Latvians. The density of population was 100.8 per square mile (38.9 per square kilometre), and the growth rate in 1970 was 34 per 10,000 (though the natural growth rate of the Latvians themselves was only 29).

The economy. Industrialization in Latvia began in the latter part of the 19th century, and by the 1970s it was the most heavily industrialized republic of the Soviet Union.

More than 56 percent of the annual national income is derived from industry, 21.7 percent from agriculture, 6.6 percent from building, 4.4 percent from transport and communications, and 11.3 percent from trade and other activities.

Energy. Latvia produces approximately half of its own energy requirements, the remainder being derived from imported fuel and from the unified power system of the northwest regions of the Soviet Union. On the Daugava River stand the major hydroelectric stations—Pļaviņas (825,000 kilowatts), Kegums (68,000 kilowatts), and Riga (384,000 kilowatts). There are thermoelectric stations in Riga and other cities. Total production of electric energy in 1975 was 2,885,000,000 kilowatt-hours. All the stations are integrated in a single power grid, which in turn is incorporated in the power grid of the Soviet northwest.

Manufactures. Machine building and metal engineering are the leading manufacturing activities. Labour-intensive goods—that is, items utilizing small quantities of raw materials and much labour—such as radios and scientific instruments, are produced in quantity. Durable consumer goods, such as refrigerators, washing machines, motorcycles, and motor scooters, are also produced. The heavy engineering sector turns out ships, rolling stock, streetcars, power generators, diesel motors, and agricultural implements. The light consumer goods industry, concentrating on textiles, shoes, and hosiery, is sufficiently well developed that its products can be exported to other Soviet republics. There are many food-processing enterprises.

Agriculture and fisheries. Agricultural specialization is in dairy farming and meat production. Of the agricultural land, some 65 percent is used for crops, the remainder mainly for pasture. Of the crops, grain is the most important, industrial crops (sugar beets and flax) occupying only about 3.2 percent of the total crop area.

Collective and state farms

Collectivization of agriculture was accomplished, against resistance, in 1947–50. In the mid-1970s there were some 403 collective farms and 230 state farms. Agriculture is mechanized, permitting intensive farming. At the end of 1975 there were 1,389,000 head of cattle, including 586,000 milk cows; 1,195,000 pigs, and 7,684,000 poultry. The republic produced in that year 1,799,000 tons of milk, 250,000 tons of meat, and 666,000,000 eggs. The total grain yield reached 1,243,000 tons.

Latvia accounts for 5.8 percent of the Soviet Union's fish catch.

Transport. All types of transport are found in Latvia. The overall length of railway lines is 1,600 miles (about 2,600 kilometres), Latvia ranking first among the union republics in the density of its rail network. Railways account for 97 percent of freight traffic (22,000,000,000 ton-miles, or 32,000,000,000 ton-kilometres, in 1970). The republic's highways total 15,100 miles, of which 8,100 miles are hard-surfaced. The length of navigable internal waterways is 224 miles (360 kilometres). Much Soviet foreign trade is conducted via the seaports of Riga and Ventspils, which are open the year round. Riga has air links with Moscow and other large cities of the Soviet Union, and there is some internal air service.

Administration and social conditions. ***Government.*** The highest formal organs of government in Latvia are the Supreme Soviet, members of which are elected for a period of four years, and the Presidium. The Supreme Soviet appoints the Council of Ministers and elects the Supreme Court and the Presidium. The latter exercises power between sessions of the Supreme Soviet. Administration is the responsibility of the Council of Ministers, which drafts economic development plans and oversees their implementation. For administrative purposes the republic is divided into 26 *rayony* (districts) and 56 cities. At the local level, government is exercised by district, city, and village soviets, elected for terms of two years.

Justice is administered by people's courts, the judges of which are elected for terms of two years.

The Communist Party of Latvia

The Communist Party of Latvia, like its counterparts in the other union republics, is in fact the only source of political power, under the Communist Party of the Soviet Union. When the Latvian S.S.R. was constituted, the party was minuscule, but membership had reached about 144,000 by 1976. Western students of the Soviet Union conclude, however, that the party is dominated by non-Latvians (mainly Russians and other Slavs) and by russified Latvians who have lived in Russia for large parts of their lives. The Komsomol (Young Communist League) has about 276,000 members.

Education. General literacy was achieved in Latvia in the 1890s. The educational system is composed of eight-year and 10-year general schools, of which there were some 1,100 with 400,000 pupils, in 1974–75; specialized secondary schools (41,000 students); and 10 higher educational establishments (44,000 students, among whom, however, the proportion of Latvians is declining). About 82,000 children attend preschool establishments. There is a variety of institutions for extracurricular studies.

Teaching in the general schools is in Latvian or Russian or both; the number of bilingual schools (240 in 1967, out of a total of 1.200) is increasing. In Latvian-language schools the study of Russian is compulsory.

Scientific work is carried on at the institutes of the Latvian Academy of Sciences (founded in 1946), in higher educational establishments, and in research institutes. The number of scientific workers totalled 11,200 in 1974.

Health and welfare. In 1974 Latvia had 9,500 doctors, or 38 per 10,000 persons (one of the highest rates in the world); there were 31,000 hospital beds, or 125 per 10,000 persons. The republic's sanatoriums accommodate around 10,000 patients. Social insurance embraces factory and office workers and collective farmers. Its budget is administered by trade-union organizations, which pay out benefits in cases of disability, pregnancy, childbirth, or death and which administer pensions.

Cultural life. Amateur art thrives in Latvia. Clubs and individual enterprises have drama groups, choirs, ensembles, orchestras, and dance companies. The song festivals that have been held in Latvia since 1873 are still very popular; every five years the local districts and towns hold their own festivals and then send their best choirs, orchestras, and dance companies to the national festival, held at a park in Riga. The republic has a conservatory of music, an academy of arts, and a number of specialized secondary educational establishments for students of music, painting, and the applied arts.

Noted Latvian composers include Jāzeps Medins, Jānis Medins, and Emēlis Melngailis.

Modern Latvian literature dates from the late 19th century; the national epic, *Lāčplēsis* ("Bear Slayer"), by Andrejs Pumpurs, was published in 1888. Jānis Rainis, who died in 1929, is generally considered to be the most important Latvian writer. Three houses now publish literature in Latvian, Russian, and other languages. In 1974 they published 2,430 titles (of which, however, only a little more than 51 percent were in Latvian, down from 81 percent in 1945). Newspapers and magazines are published in Latvian and Russian. Like the other Baltic republics, Latvia is better supplied with radio receivers than the rest of the Soviet Union and receives foreign broadcasts. Television broadcasts are part local, part from Moscow; a large part of television transmission is in Russian. The Riga Film Studio produces full-length feature films as well as documentaries, short subjects, cartoons, and newsreels.

An important national tradition is the festival of Midsummer Eve (St. John's Eve, or Janu Naktis) and Day, which, though officially abolished by the government in 1960, continues to be observed.

Prospects. National five-year plans in the 1970s called for further growth of the electrotechnical, radiotechnical, medicinal, electronic, consumer goods, meat, milk, and fish industries. Further agricultural specialization, notably in milk, meat, and bacon, was also emphasized. It was hoped that living standards also would be improved.

Of great concern to Latvians, both in the republic and abroad, is the possibility of loss of ethnic identity, as a consequence of immigration of non-Latvians, together with a very low rate of natural increase among the Latvians themselves (the lowest rate in the Soviet Union), combined with the widespread use of the Russian language.

(P.V.G./Ed.)

Laud, William

Archbishop of Canterbury from 1633 to 1645 and a leading figure on Charles I's privy council, William Laud played a large part in shaping the policies of religious uniformity and authoritarian royal government, resistance to which was one of the major causes of the English Civil War.

By courtesy of the Archbishop of Canterbury, copyright reserved by the Courtauld Institute of Art and the Church Commissioners

Laud, painting by Sir Anthony Van Dyck, 1833. In Lambeth Palace, London.

Academic and churchman

Laud was born in Reading on October 7, 1573, the son of a prominent clothier. From Reading Grammar School he went on to St. John's College, Oxford, and until he was nearly 50 combined the successful but unspectacular careers of academic and churchman. He was soon associated with the small clerical group, followers of the patristic scholar Lancelot Andrewes, who, in opposition to Puritanism, stressed the continuity of the visible church and the necessity, for true inward worship, of outward uniformity, order, and ceremony. In 1608 Laud entered the service of Richard Neile, bishop of Rochester, with whose help he secured a succession of ecclesiastical appointments. From 1611 he was a royal chaplain and came gradually to the notice of King James I. His lifelong conflict with John Williams, later bishop of Lincoln and archbishop of York, began when both sought advancement through the patronage of Charles's favourite, the Duke of Buckingham. During Buckingham's years of power, Laud was his chaplain and confidant; and he established a dominant voice in church policies and appointments. He became a privy councillor in 1627 and, a year later, bishop of London.

Persecution of Puritans

In his London diocese, Laud devoted himself to combatting the Puritans and to enforcing a form of service in strict accordance with the Book of Common Prayer. The wearing of surplices, the placing of the communion table—railed off from the congregation—at the east end of the chancel, and such ceremonies as bowing at the mention of the name of Jesus were imposed, though cautiously enough to avoid unmanageable opposition. Churches, from St. Paul's Cathedral down to neglected village chapels, were repaired, beautified, consecrated. To religious radicals, all such reforms seemed moves toward popery, At Oxford, where Laud was chosen president of St. John's in 1611 and chancellor in 1629, new statutes, new endowments, and new buildings improved the university, both as a centre of learning and as a training ground for Laudian religion. On the death of George Abbott in 1633, Laud became archbishop of Canterbury; but he had already, by instructions issued in the King's name and by his ruthless energy in the royal prerogative courts of Star Chamber and High Commission, extended his authority—with varying success--over the whole country. From 1634 to 1637 visitations of every diocese (including, after strong resistance by Williams, that of Lincoln) showed the extent of deficiencies within the Anglican Church and the strength of Puritan practices. A succession of detailed orders from the Archbishop laid down the remedies. Preaching, to Puritans the essential task of the ministry, was to Laud a most dangerous source of "differences" in religion to be curtailed and controlled. In London his attack on Puritan "lectureships" culminated in the overthrow of the "feoffees for impropriations," the City organization for buying up tithes and church patronage for the benefit of Puritan clergy. The printed word was dangerous, too: celebrated Puritan propagandists such as Alexander Leighton and William Prynne were mutilated and imprisoned. Occasionally, Laud was less harsh than his enemies admitted, especially to the clergy. But he rejected all conciliation of the Puritan movement, whose strength and qualities he never understood. He had, in fact, much in common with some forms of it: the unrelenting quest for the godly life, the intolerant certainty of his own rectitude, the hatred of corruption and extravagance. He could do much to diminish inefficiency, pluralism, absenteeism, and sheer idleness. But his wider efforts to overcome the poverty of clergy and parishes and restore something of the church's position as a great and powerful landowner had extremely limited success.

To Laud, the strength of the church was inseparable from that of the state. Conflict between royal and ecclesiastical power was a possibility he never faced: under Charles I both could be exalted simultaneously. Holding no state office, he used his position on the privy council and his influence over the King to attack "the Lady Mora" (delay) in what he considered her first personification, the treasurer Richard Weston, and afterward in other ministers. His most effective direct impact on government was in the social policy he applied through the council and the courts. Exacting landlords and unscrupulous officials were attacked, and the poor were protected against everyone except the state itself. In all this his one constant ally was Thomas Wentworth (later the earl of Strafford), from 1633 lord deputy in Ireland. Laud and Wentworth corresponded regularly and frankly on their joint struggle to establish "thorough," as their rigorous policy came to be called. But by 1637 both began to see, dimly, the storm that was about to break upon them. The further trial of Prynne, together with other radical Puritans such as Bastwick and Burton, demonstrated not success for Laudian suppression but rather huge popular support for the opposition. The resistance of the gentry was consolidated by the extended demand for "ship-money," the most hated of Charles's non-parliamentary levies. Attempts by Charles and Laud to impose Anglican forms of worship in Scotland provoked fierce resistance there. English forces were sent northward, and in 1639 the "Bishops' Wars" began.

Trial and execution

In the spring of 1640 Parliament met for the first time in 11 years and with it the clerical assembly, the Convocation, which laid down in a new set of canons the principles of the Laudian church. They explained the prescribed ceremonies as "fit and convenient" rather than essential. But they added to the popular hatred of Laud shown in mass demonstrations, petitions, and leaflets. In December, formally accused of high treason, he was taken to the Tower. His trial, managed enthusiastically by Prynne, began only in 1644, in the midst of the Civil War. As with Strafford, the Commons had to abandon legal proof and resort to an ordinance of attainder, accepted hesitantly by the lords. On January 10, 1645, the Archbishop was beheaded.

Laud was never much liked, even by his allies. A humourless, dwarflike figure, uninterested in court pleasures, unmarried, tactlessly impartial in his condemnations, he could never establish a party of influential supporters. During the war and interregnum, royalists and peacemakers generally preferred to forget him. At the Restoration, in 1660, outward Laudian forms were accepted but by a church less significant than ever to the community and the individual. Few in the 18th century saw Laud as a martyr. In the 19th century the historian Thomas Babington Macaulay's fierce contempt for the "ridiculous old bigot" inspired the schoolbooks of many generations. The Oxford Movement, a movement of High Anglican reform in the 1840s, tried unconvincingly to re-establish him as a religious leader, and High Anglican clergy have remained his principal supporters. But at the turn of the 19th century, the Civil War historian Samuel Rawson Gardiner stressed Laud's abilities and integrity and regarded the links with authoritarian politics as his "misfortune."

In the 20th century, the eminent English historian H.R. Trevor-Roper has set against his narrow-minded methods the comprehensive idealism of his social policy, "coloured over by the accepted varnish of an appropriate religious doctrine." Laud, as he himself was well aware, failed; but his devotion to a coherent purpose and his repudiation of hypocrisy, compromise, and corruption in allies and enemies of whatever class were rare and admirable qualities.

(D.H.P.)

Laurales

Laurales is a fairly large order of flowering plants, consisting of 11 families with a total of about 70 genera and more than 2,500 species. The order is of interest not merely because of its abundance but also for its utilitarian, morphological (structural), and phylogenetic (evolutionary) importance.

Economic importance of the laurel family

General features. ***Utility.*** Of the 11 families, the laurel (Lauraceae) is the most useful to man. The leaves and bark of several species such as those of ***Lindera*** (benzoin), *Litsea*, and ***Laurus*** (laurel) are of medicinal value. Some, like the South African ***Ocotea bullata*** (stinkwood), yield useful timber. Most of the world's supply of natural camphor, used in the manufacture of colloidin and explosives, comes from *Cinnamomum camphora*, a native of Japan and Taiwan. Essential oil containing up to 80 percent of safrole, used in the perfume industry, is obtained from the roots of ***Sassafras** officinale* and the wood of two Brazilian trees, ***Ocotea preteosa*** and ***O.** cymbarum.* Cinnamon spice is derived from the bark of ***Cinnamomum zeylanicum,*** a native of Ceylon and southern India. Cinnamon bark and leaf oil are also used in medicine and perfume. ***Persea americana,*** the avocado pear, an evergreen tree native to the rain forests of Central America, is economically important in the U.S. South and Hawaii, and in Brazil, South Africa, and tropical Australia. Its edible fruits contain a higher percentage of protein than any other fruit.

Other families of Laurales are economically less important. *Peumus boldus* (family Monimiaceae), of Chile, yields boldo wood used in cabinet-making. ***Doryphora sassafras,*** of the same family, is a source of essential oil. Some species of the families Calycanthaceae and Chloranthaceae are grown as ornamentals.

Size range and diversity of structure. Members of the order produce their own food by photosynthesis (***i.e.***, are autotrophic) with the exception of *Cassytha*, a rootless, vinelike stem parasite without proper leaves; it grows on many species of flowering plants. Four of the families—Austrobaileyaceae, Amborellaceae, Lactoridaceae, and Calycanthaceae—are exclusively shrubs; the other seven are predominantly trees. Some members of the laurel family (Lauraceae) attain great size; *Cinnamomum* ***camphor~***, for example, reaches a height of about 100 feet ***(30*** metres) and ***Persea americana*** grows up to 60 feet (18 metres) or more.

Primitive and advanced structures

The Laurales order shows great diversity in vegetative and floral structure. Unlike most other flowering plants, the wood in ***Amborella*** and ***Sarcandra*** (family Chloranthaceae) is devoid of vessels (water-conducting tissues made of special hollow cells). In ***Austrobailrya*** (family Austrobaileyaceae), a woody vine, the wood has vessels, but exhibits other primitive characteristics. On the other hand, the families Lactoridaceae, Calycanthaceae, and Lauraceae show some features considered to be advanced.

The plants of the genus ***Austrobaileya*** are more simple. Their phloem (the part of the vascular system that transports food), unlike that of other flowering plants, is devoid of companion cells—a characteristic of coniferous plants. Typical sieve tubes (the normal arrangement of phloem tissue) are also absent in this genus; instead, its long and overlapping phloem-tissue cells lack the characteristic terminal sieve plates, with small holes that lead to the next cell. Further structural simplicity is seen in the phloem sf ***Austrobaileya,*** and also the family Calycanthaceae, which lack sclerenchyma (thick-walled cells). On the other hand, the presence of sieve cells with single, transverse end plates is an advanced development in the Calycanthaceae family.

The order demonstrates considerable diversity in floral structure even though many families, particularly the Amborellaceae, Trimeniaceae, and Lactoridaceae are not completely described as yet. The genus ***Austrobaileya*** has probably the most primitive floral structure of the order. Its flower is bisexual and hypogynous (the flower parts are joined at the base of the female structure. or ovary, a condition sometimes called "superior ovary"), and its numerous floral parts are arranged spirally. The stamens (male pollen-producing structures) are laminar (flat, or petallike) and the carpels (simple ovaries) each have numerous ovules, or developing seeds. In the families Gomortegaceae and calycanthaceae, also, the flowers are bisexual (with both male and female organs). In ***Amborella*** (family Amborellaceae) the flower is unisexual (one plant with either male or female flowers); all other families are polygamous (with both unisexual and bisexual flowers on the same plant).

The flower form is usually hypogynous ("superior ovary") in the families Trimeniaceae, Lactoridaceae, and Lauraceae; rarely, as in ***Hypodaphnis,*** it is epigynous, or inferior ovary, with the petals, sepals, and stamens arising at the upper end of the ovary, which they enclose, forming what is called the floral tube. In all the other eight families the flower form is either perigynous ("half inferior") or epigynous.

Stamens, carpels, and ovules

In the family Lactoridaceae the stamens are laminar with protruding connectives and the pollen is held in permanent tetrads (groups of four), as in the Winteraceae family and some members of the Annonaceae family (both of the order Magnoliales). In the families Hernandiaceae, Chloranthaceae, Lauraceae, and Gyrocarpaceae the gynoecium (female flower parts) consists of a single carpel with a single ovule. Other families have more than one carpel; in the families Trimeniaceae and Gomortegaceae they are united; in the others, free. In the Lactoridaceae family the ovule number per carpel is six, in the Calycanthaceae family it is one or two; all others have a single ovule.

The fruit is winged in the families Hernandiaceae and Gyrocarpaceae. In the families Trimeniaceae, Monimiaceae, Gomortegaceae, Chloranthaceae, and Lactoridaceae the seed is endospermous (*i.e.*, it contains endosperm, a nutritive starchy tissue for the developing embryo), and the embryo is small. In contrast, exalbuminous (without endosperm) seeds with large embryos occur in the families Hernandiaceae, Calycanthaceae, Lauraceae, and Gyrocarpaceae.

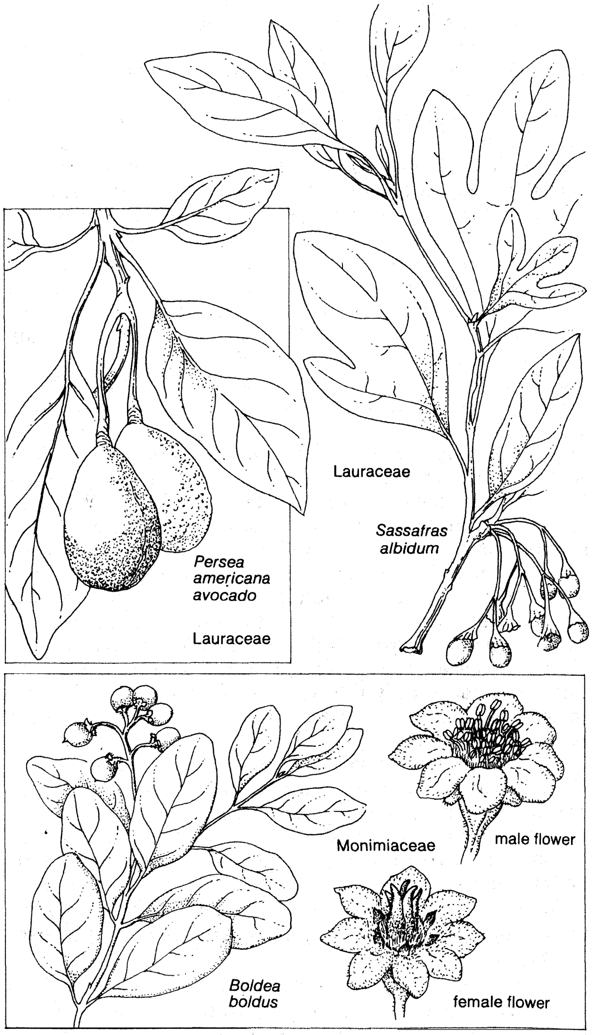
Distribution and abundance. Plants of the Laurales order occur generally in the tropics or subtropics. Some families are widely distributed; others in the order are restricted. Lactoridaceae, for example, is confined to the

Islas Juan Fernández, 400 miles (645 kilometres) west of Chile, others to places like Chile, New Caledonia, Australia, or islands of the Pacific Ocean. A few species occur in warm temperate regions: in North America, extending to Canada; in Africa; and in southern Europe, where *Laurus nobilis* (family Lauraceae) extends to the Mediterranean.

Phylogenetic importance. The Laurales order occupies an important place in the phylogeny, or evolutionary history, of the flowering plants. Of the ten genera of dicotyledons (plants with two "seed leaves") with primitive, vesselless xylem (water-conducting tissue) two are included in the Laurales order; the rest in the Magnoliales order. The only flowering plant species without companion cells and true sieve tubes (Austrobaileya) also belongs to the Laurales order. On the other hand, in several families, floral evolution has advanced to the level of epigyny (inferior ovary) and unisexuality. Thus, many of the evolutionary trends observed among the flowering plants as a whole are retained in this and in the related and probably more primitive order, the Magnoliales.

Futhermore, distribution of several members of this order is restricted to areas that are relatively little explored botanically. The living and fossil plants of such regions, when more completely studied, will yield valuable data for understanding the origin and evolution of the flowering plants. Phylogenetic study of the Laurales order might well be further intensified and extended.

Natural history. Life cycle. Very little is known about the life cycle in six of the families of the order (Austrobaileyaceae, Amborellaceae, Trimeniaceae, Gomortegaceae, Hernandiaceae, and Lactoridaceae, and such knowledge is far from complete in families like Monimiaceae.



Representative plants from the two largest families of the laurel order.

The flowers of the Calycanthaceae family are remarkably adapted for pollination by beetles. The food provided by the tips of some of its tepals (similar-appearing flower petals and sepals) and the prolonged connectives of the stamens attract the beetles, which also eat the nectar secreted by the inner staminodes (sterile stamens, usually flat and petallike). In doing both, the beetles serve in pollination. It has been suggested that the position of the carpels on the concave receptacle might offer protection to the ovules from the foraging beetles.

Unusual mode of nectar secretion

The mode of secretion of nectar from the glandular appendages of the stamens in the Lauraceae and Monimiaceae families has been studied. In the Lauraceae family, the epidermis ("skin") and cuticle (a waxy coating) of the bud break down just before the opening of the flowers; the nectar then is secreted through the intercellular spaces of the flower tissues. In the Monimiaceae family, there is no secretion of nectar before the beginning of flower opening, and the epidermis is not as extensively damaged as in the Lauraceae family. Numerous bees, blowflies (Calliphora), and mites visit the flowers for the nectar.

There is little uniformity in pollination and other processes of the life cycle within the order. In some members of Laurales, such as species of *Beilschmiedia* (Lauraceae) and Hortonia (Monimiaceae), the staminal appendages do not function as nectaries. In *Persea americana* (avocado) the flowers open twice and pollination is brought about by bees. In Sri Lanka (formerly Ceylon), *Cinnamomum* zeylanicum (Ceylon or true cinnamon) flowers in May and fruits mature within two or three months; this is probably true of other tropical species.

Ecology. The Laurales order is mostly tropical and subtropical and its species are mostly evergreen. Some members of the Lauraceae and Calycanthaceae families also grow in warm temperate regions, where they are deciduous. Calycanthus fertilis, Sassafras albidum, *Per*sea borbonia (sweet bay), *Litsea* aestivalis, and *Lindera* benzoin (spice-bush), for example, are among the characteristic species in the deciduous forests of eastern North America, where climatic conditions are similar to northwestern Europe and parts of eastern Asia.

Some species of the Eauraceae family, like *Cinnamo*mum *camphora* (camphor tree), are not particularly demanding in their environmental and soil requirements. The camphor tree grows well at elevations of 3,000—4,000 feet (900—1,200 metres) and even up to 45° (latitude) north and south of the Equator. In contrast, *Cinnamomum* zeylanicum is sensitive and thrives best only on the white sandy soils of Sri Lanka.

Laurel order compared with Magnolia order

Form and function. Despite the great diversity of structure among families of the order, some structural features common to all serve to distinguish the Laurales from other orders. Like the related Magnoliales, the Laurales order is composed of species that are all woody and that have ethereal (aromatic) oil cells. Those species are further characterized by pollen grains with no more than two grooves, and by a primitive nodal anatomy (arrangement of vascular bundles at the juncture of leaf and stem) of the type called unilacunar. The stamens have nectar-bearing appendages, and, in most species, the anthers split open when ripe by means of valves. The female structures usually consist of a single carpel. Unlike the Magnoliales order, which has generally primitive leaflike carpels and stamens, most Laurales species have more specialized floral organs.

Evolution and paleontology. Well-preserved fossils resembling living genera of the Lauraceae family, such as Sassafras, *Cinnamomum,* and *Persea,* have been found in Lower and Upper Cretaceous rocks (about 65,000,000 to 136,000,000 years old) in several localities in Europe and America. Since those genera at that time were already as highly specialized as their modem counterparts, it may be inferred that they must have had a fairly long history of evolution before the Cretaceous Period. In the absence of fossil evidence, however, no reliable conclusions as to the origin and early phylogeny of the family can be drawn.

Pollen similar to that of the fossil genus *Clavatipollenites* from the Lower Cretaceous Period shows some tenuous resemblances to that of the family Chloranthaceae. The fossil history of other families is virtually unknown.

In view of the present paucity of information on the paleontology of the order, evolutionary interpretations must of necessity be based on comparative morphological studies of present-day groups. The Austrobaileyaceae family is thus placed lowest in the evolutionary scale because of the preponderance of its apparently primitive vegetative and floral characters, such as the absence of companion cells and typical sieve tubes, the primitive cambium and wood anatomy, numerous spirally arranged flower parts, laminar stamens, and numerous ovules per carpel.

The Amborellaceae family also manifests many primitive features including vesselless xylem, spirally arranged perianth (sepals and petals), and stamens with a broad filament. At the same time, however, its members have advanced to the level of unisexuality. An uncertain affinity to the Monimiaceae family has been suggested.

Relationships of families within the order

Many authorities consider Lactoridaceae to be an isolated family. Some assign it a relatively primitive place, near the Winteraceae family (order Magnoliales), while others give it a relatively higher place, assuming that it had a common origin with the family Chloranthaceae. Still others suggest that its mode of growth, stipules, and anatomy all indicate a relationship with the families Piperaceae (order Piperales) or Polygonaceae (order Polygonales). But without adequate data none of these views can be supported.

Of the Trimeniaceae family still less is known; all that can be said is that it exhibits a mixture of primitive and advanced features. Some authors, however, suggest an affinity with the Monimiaceae family.

The families Monimiaceae, Gomortegaceae, Hernandiaceae, Lauraceae, and Gyrocarpaceae have been found to be more specialized and more closely related to one another than other Laurales families. Of these. it has been suggested that the Monimiaceae family, with the greatest range in floral structure, constitutes the parent family from which the others have evolved. Its protoxylem strand patterns (developing form of xylem, or woody tissue), wood anatomy, and embryology all are similar to those of the other four families. In the five-family group, Gyrocarpaceae seems to be the most highly specialized. Its vessel cell end walls are inclined less, its medullary ray tissue (wood rays) is more specialized, its floral structure is generally reduced, and the family exhibits a peculiar type of embryo-sac development.

The floral hypanthium, a saucer-like structure formed from the fused bases of the petals and sepals, is common to the less specialized Calycanthaceae family and the parent Monimiaceae family. The subfamily Siparunoideae of Monimiaceae also resembles Calycanthaceae in the absence of staminal appendages. The Calycanthaceae family also shares numerous anatomical features with the Lauraceae family, but there is little morphological evidence to support its suggested affinities to the Rosales or the Magnoliales orders. Its pollination by beetles has been considered a primitive feature only because other types of insects appeared later in the geological time scale.

The affinities of the Chloranthaceae family have also been much disputed. Some authors have placed it in the order Piperales, but the nodal anatomy, opposite stipulate leaves, united petiole (leaf stalk) bases, and inferior ovary with its solitary pendulous ovule all put this family outside the Piperales order. Those features plus staminal appendages indicate an affinity with the Monimiaceae family. Thus, with the possible exception of the families Austrobaileyaceae and Lactoridaceae, all other families in the Laurales order can probably be derived from a Monimiaceous stock.

Although the Laurales order is more advanced than the Magnoliales, it seems more probable that it originated independently, rather than from the Magnoliales order. Because the Lactoridaceae family possesses a combination of features of both orders, it has been suggested that both Laurales and Magnoliales had a common origin and had early diverged along separate evolutionary lines.

Classification. *Distinguishing taxonomic features.* As early as 1950, the woody plant families having ethereal oil cells and monocolpate (single-furrowed), derived polyporate, or acolpate pollen were divided into two groups—one with unilacunar and the other with trilacunar or multilacunar nodal anatomy. The Laurales order as presented here corresponds to the unilacunar group. Certain other features are also characteristic of several members of the order although a few families do not share them. These include the polygamous flowers, the presence of staminal appendages, anthers that open by means of valves, two pollen sacs per anther, and the single pendulous ovule per carpel.

Annotated classification. The scope of the order Laurales as presented here is a recent and authoritative treatment (see below, *Critical appraisal).* The delimitation of this order and the taxonomic position and delimitation of its families, however, differ in some respects in other classification systems.

ORDER LAURALES

Plants woody; ethereal oil cells present; pollen monocolpate, derived polyporate, or acolpate; nodal anatomy unilacunar; staminal appendages often present.

Family Austrobaileyaceae

Woody vines. Phloem devoid of companion cells and true sieve tubes. Leaves opposite, entire (smooth margined), simple, stipulate. Floral parts numerous, spirally arranged; stamens laminar. Ovules many. One genus, *Austrobaileya,* with two species, native to Queensland, Australia.

Family Amborellaceae

Vesselless shrubs. Leaves alternate, distichous (in two ranks). Flowers solitary, unisexual; perianth spirally arranged. Stamens with broad filament. Ovule orthotropous. One genus, *Amborella,* with one species restricted to New Caledonia.

Family Trimeniaceae

Trees or shrubs. Leaves exstipulate. Flowers polygamous, in panicles. Calyx 4 to numerous; corolla none. Stamens 4 to numerous. Carpels 1 or 2 fused, with a single ovule. Fruit drupaceous. Seed endospermous. Four genera with 15 species distributed in east Malaysia, east Australia, and on islands of the Pacific Ocean.

Family Monimiaceae

Trees and shrubs. Flowers solitary, or in cymes; usually unisexual; perigynous. Perianth inconspicuous or absent. Hypanthium present. Stamens numerous or few; glandular appendages usually present; anther dehiscence by valves or by longitudinal slits; pollen sacs 2 or 4. Carpels numerous each with a single ovule. Seed endospermous; embryo small. Twenty genera with 150 species distributed chiefly in southern tropical regions including Madagascar, Australia, Polynesia, New Zealand, Chile, New Guinea, and New Caledonia.

Family Gomortegaceae

Trees. Flowers bisexual, epigynous. Sepals 7 to 10, spirally arranged. Petals absent. Stamens 2 to 11 with glandular appendages; pollen sacs 2; valvular dehiscence. Carpels 2 to 3, united. Seed endospermous. One genus, *Gomortega,* with 1 species confined to Chile.

Family Hernandiaceae

Tropical trees or shrubs. Leaves with palmate venation. Flowers bisexual or unisexual, epigynous. Perianth 6 to 10, biseriate. Stamens 3 to 5, with staminal appendages; anther dehiscence longitudinal; pollen sacs 2. Carpel 1; ovule 1. Seed exalbuminous. Two genera with 50 species distributed in tropical Central America, the West Indies, the northern edge of South America, west central Africa, Madagascar, South Africa, and the islands of the South Pacific.

Family Chloranthaceae

Tropical and subtropical herbs, shrubs, or trees. Flowers unisexual or bisexual, often epigynous. Perianth none or minute calyx present in female flowers. Stamens 1 or 3 united with longitudinal dehiscence; staminal appendages present; pollen sacs 2. Carpel 1; ovule 1. Seed endospermous. Five genera with 65 species distributed from Jalapa, Mexico southward in South America.

Family Lactoridaceae

Shrubs. Leaves with large membranous stipules. Flowers unisexual or bisexual. Perianth 3. Stamens in 2 whorls of 3 each, laminar; connective projecting; pollen in permanent tetrads. Carpels 3, with 6 ovules in each. Seed endospermous. One genus, *Lactoris,* with 1 species native to the Islas Juan Fernández.

Family Calycanthaceae

Shrubs. Cortical vascular system present; flowers bisexual, perigynous, hypanthium present. Perianth of numerous spirally arranged tepals. Stamens 5 to 10; pollen sacs 2. Food bodies present on the tepals (sepals and petals) and stamens. Carpels numerous with 1 or 2 ovules in each. Seed exalbuminous. Embryo large. Two genera, with 7 species distributed in east Asia, northeast Australia, and North America.

Family Lauraceae

Tropical and subtropical trees and shrubs. Flowers bisexual, rarely unisexual. Perianth in 2 whorls of 3 each. Stamens in 3 or 4 whorls of 3 each, some of them modified into staminodes; glandular appendages present; 2 or 4 pollen sacs; valvular dehiscence; third whorl extrorse, others introrse. Carpel 1, ovule 1. Seed exalbuminous. Embryo large. Thirty genera with 2,500 species distributed largely in tropical regions, most abundantly in Southeast Asia from Australia to Japan and in tropical America.

Family Gyrocarpaceae

Small trees or shrubs. Inflorescence a thyrse (*i.e.*, the main axis is a raceme, or long central stem bearing flowers on short side stems, the secondary axes are cymes). Flowers bisexual or unisexual. Perianth 8. Stamens 3 to 5; glandular appendages present; valvular dehiscence; pollen sacs 2; 3 or 4 staminodes sometimes present. Carpel 1, ovule 1; gynoecium inferior; fruit a samara (a dry one-seed winged structure). Seed exalbuminous; embryo large. Two genera with 22 species distributed in tropical and subtropical regions of the world.

Differing viewpoints concerning the limits of the Laurel order

Critical appraisal. The scope of the Laurales order varies in other systems of classification. Some authorities include the Myristicaceae family and exclude the Calycanthaceae and Chloranthaceae families, placing Calycanthaceae in the Rosales order and Chloranthaceae in Piperales. Others include the Calycanthaceae family. The Lactoridaceae family has often been placed in the order Magnoliales near the Winteraceae family. Similarly, earlier authors have included all these families in the order Ranales or Magnoliales along with other woody families. Recently, however, most taxonomists have included the families Monimiaceae, Lauraceae, Gomortegaceae, Hernandiaceae and Gyrocarpaceae in the Laurales order as distinct from the Magnoliales order.

There is some disagreement among taxonomists concerning the delimitation of certain families. The parasitic genus *Cassytha* is sometimes segregated from the Lauraceae family into a separate family Cassythaceae, but recent morphological studies have lent no support to this treatment. Some systematists have removed the genera ***Atherosperma*, *Siparuna*, *Laurelia*, *Daphnandra*** and ***Doryphora*** and a few others from the Monimiaceae family into a separate family Atherospermataceae. The families Hemandiaceae and Gyrocarpaceae were merged in earlier systems but their separation now seems justified.

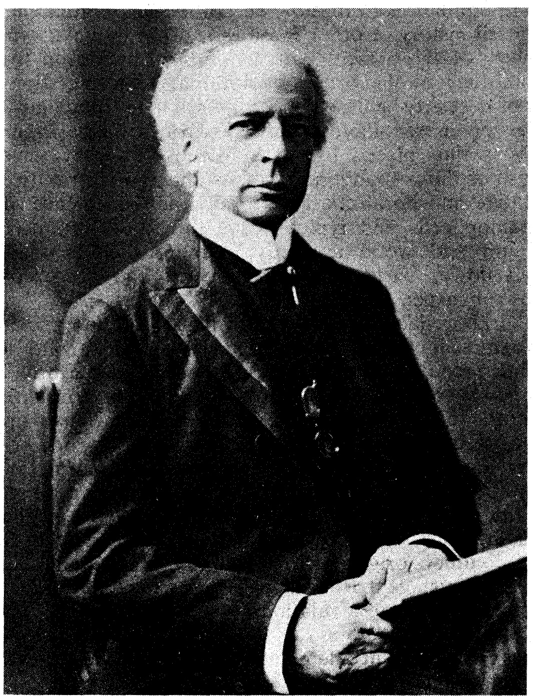
Laurier, Sir Wilfrid

The first French Canadian to serve as prime minister of the Dominion of Canada, Sir Wilfrid Laurier spent his 30 years as leader of the Liberal Party and his 15 years as prime minister in working, as he put it, "to promote unity and harmony and amity between the diverse elements of this country." Yet in the end, defeated by the covert alliance of French-Canadian nationalists and inflamed British imperialists, he left behind him a country internally still unreconciled.



Laurier.
National Film Board of Canada

Early life and education

He was born in the small farming town of Saint-Lin, north of Montreal, on November 20, 1841, of French-Canadian parents. He studied under a Scottish tutor in the nearby village of New Glasgow before being sent to the college at l'Assomption, where he received literary training under Catholic priests. He then studied law at McGill University in Montreal and was called to the bar in 1864. His bicultural education, most unusual at the time, may have played a part in his lifelong dedication to Canadian unity. While at McGill, he became a leading member of the Institut Canadien, a political club of advanced liberals (Les Rouges) with anticlerical and republican views. Later he joined the law offices of one of the leading Rouge politicians and contributed a number of articles to radical newspapers, one of which he edited for a few months in the mid-1860s.

In 1866, for reasons of health, Laurier moved to Arthabaska, where he opened his own law practice. In 1868 he married Zoe Lafontaine of Montreal, and despite a long relationship with Emilie Lavergne, his law partner's wife, his childless marriage seems to have been a happy one. In 1871 he was elected to the opposition benches of the provincial legislature of Quebec, where his first speech, an eloquent plea for educational reform, attracted much attention. In 1874 he was elected to the Canadian House of Commons, of which he was to be a member until his death.

Rise to leadership

As Laurier gradually rose to become minister of internal revenue (1877–78) and eventually to leadership of the opposition Liberal Party in 1887, he persistently sought to bring together his countrymen on the issues that have since been recognized as the dominant themes of modern Canadian politics: the relations of church and state, the bicultural entente between French and English-speaking Canadians, and the country's association with the British Empire and relations with the United States. One of the political highlights of these years for Laurier was his famous speech on Liberalism delivered in 1877 in the city of Quebec. In that speech he set himself against both the Quebec politicians who attempted to form a Catholic party and the extremist elements in his own group who sought to exclude the clergy from all political activity. Because of his skillful statesmanship, the cold antagonism between conservative churchmen and liberal politicians gradually began to thaw; after 1896 no anticlerical ever attained important public office and no cleric officially interfered in politics.

In 1885 Laurier became a national figure when he delivered a moving plea of clemency for Louis Riel, who had led a rebellion of the Métis (people of mixed French and Indian extraction) in Manitoba and whose death sentence provoked violent outbursts between the French Catholic nationalists in Quebec and the Britannic groups in Ontario. Showing great courage, Laurier, though not condoning Riel's actions, charged the government with mishandling the rebellion. Although he did not succeed in saving Riel, he established his reputation as a man of principle and high ideals. Throughout his political life, he emphasized moderation and compromise and gradually became recognized as the only leader able to effect a national reconciliation.

At the same time, he was turning his personal magnetism into a valuable political weapon. Between 1887 and 1896, he perfected his party's organization, refined Liberal strategy, made political alliances, assessed local partisans, and judiciously applied his personal charm to winning over Conservative adversaries and dissident Liberals. He infused new life into his party, for instance, by campaigning vigorously for unrestricted reciprocity, the grant of mutual commercial privileges, with the United States. After the policy had served its purpose, however, he dropped it from his platform in 1893. Between 1895 and 1896 he spoke at between 200 and 300 meetings, thus personally reaching some 200,000 voters. In mid-1896, with the Conservative government divided and disorganized, he easily carried the Liberal Party to victory in the general election.

Laurier's "national policy"

Intent on heading an administration of national unity, Laurier attracted to his first cabinet men who had won distinction in their own provinces. His "national policy" consisted of protection for Canadian industries, the settlement of the west, and the building of an effective transportation system. The years between 1896 and 1911 became a boom period for which the Prime Minister himself provided the slogan: "The Twentieth Century belongs to Canada." The budget of 1897 lowered tariffs but established a protection policy that lasted until 1911. Laurier's land and emigration policy perhaps remains as the basic achievement of his government. During 15 years more than 1,000,000 people moved into Manitoba and into the western territories, which in 1905 became the provinces of Saskatchewan and Alberta. Wheat became the major product of the new Prairie Provinces; towns and ports sprang up; railroads flourished; and in 1903 Laurier announced that a second transcontinental rail system would be built: the Canadian west had become the granary of the world.

Meanwhile, the Prime Minister's attention had been diverted to external affairs. In 1897, 1902, 1907, and 1911 he attended Imperial Conferences at which he steadily resisted British proposals for closer ties that might commit Canada to defense responsibilities. He sincerely admired the institutions and liberal policies of Great Britain —he accepted a knighthood (1897) and once declared that he would be proud to see a Canadian of French descent affirming the principles of freedom in the British Parliament—yet he would never agree to any dilution of Canadian autonomy. Thus, from his policies there began to emerge the modern concept of a British Commonwealth of independent states.

Britain's South African War of 1899 marked the start of Laurier's decline. Quebec nationalists denounced his decision to send a force of 1,000 men, while English Canadians thought the number insufficient. Then, a series of invidious disputes—over denominational schools in the Northwest, Sunday observance laws, the restrictions of French linguistic rights in Manitoba and Ontario—kept widening the rift between the nationalities in the east and new Canadians in the west and between Laurier and his cabinet. As the election of 1911 approached, the Prime Minister attempted to reunite his factious party by negotiating a treaty of reciprocity with the United States, but he failed. Reciprocity did not distract Quebec from the convincing argument that each one of Laurier's compromises was a surrender of French Canada's fundamental rights. Among the Britannic Canadians, reciprocity seemed an opportunistic capitulation to the United States, the first step toward annexation. In a month of bitter campaigning in 1911, the 70-year-old Prime Minister delivered more than 50 speeches yet could not overcome the powerful combination of Imperialist business interests and bigoted nationalism. He retired with the dignity Canadians had learned to expect of him and spent his remaining years as leader of the opposition. He died in Ottawa on February 17, 1919.

Assessment

To his faithful followers, especially in Quebec, where his surname is used as a first name by many other Canadians, Laurier is a charismatic hero whose term of office was a happy time in Canadian history. He worked all his life for cooperation between French and English-speaking Canadians while he strove to keep Canada as independent as possible from Britain. His personal charm and dignity, his great skill as an orator, and his great gifts of intellect won the admiration of all Canadians and non-Canadians alike.

BIBLIOGRAPHY. Authoritative biographies of Laurier are L.O. DAVID, *Laurier: sa vie—ses oeuvres* (1919); and O.D. SKELTON, ***The Life and Letters of Sir Wilfrid Laurier, 2*** vol. (1921, reprinted 1965). These were written by friends and/or close political associates of the subject and naturally treat him most sympathetically. Also laudatory is SIR JOHN WILLISON, ***Sir Wilfrid Laurier and the Liberal Party: A Political History,*** 2 vol. (1903). A number of younger historians have begun a reappraisal of Laurier's life and work; among these, PAUL STEVENS, "Wilfrid Laurier: Politician," in M. HAMELIN (ed.), ***The Political Ideas of the Prime Ministers of Canada*** (1969), is of great interest.

(J.Mo.)

Lavoisier, Antoine-Laurent

A French chemist and the father of modern chemistry, Antoine-Laurent Lavoisier was a brilliant experimenter and many-sided genius. He was born in Paris on August 26, 1743. His father, an *avocat au parlement* ("parliamentary counsel"), gave him an excellent education at the Collège Mazarin, where he studied mathematics, astronomy, chemistry, and botany. In 1766 he received a gold medal from the Academy of Sciences for an essay on the best means of lighting a large town. Among his early work were papers on the analysis of gypsum, on thunder, and on the aurora, and a refutation of the prevalent belief that water is converted into earth by repeated distillation. He also accompanied the geologist J.-E. Guettard (1715–86) on a long geological trip and assisted him in preparing his mineralogical atlas of France. In 1768 he

Lavoisier, with his wife, oil painting by Jacques-Louis David, 1788. In the collection of the Rockefeller University, New York.

was nominated *adjoint-chimiste* ("associate chemist") to the academy. He passed through all the grades in the academy, was director in 1785, and was made treasurer in 1791. His father bought him a title of nobility in 1772.

Career of public service. In 1768 he became an assistant in one of the revenue-collecting departments of the government, subsequently becoming a full titular member of the Ferme Générale, the main tax-collecting agency. Appointed *régisseur des poudres* (a "director of gunpowder") in 1775, he abolished the vexatious search for saltpetre in the cellars of private houses, increased the production of the salt, and improved the manufacture of gunpowder. In 1778 he started a model farm at Fréchines, where he demonstrated the advantages of scientific agriculture. In 1785 he was nominated to the committee on agriculture and as its secretary drew up reports and instructions on the cultivation of crops, promulgating various agricultural schemes. Chosen a member of the provincial assembly of Orléans in 1787, he planned the improvement of the social and economic conditions of the community by such means as savings banks, insurance societies, canals, and workhouses. He advanced money without interest to the towns of Blois and Romorantin for the purchase of barley during the famine of 1788. He was associated with committees on hygiene, coinage, the casting of cannon, and public education. Lavoisier was a member of the nobility of the Blois district. In 1789 he drew up the code of instructions *(cahier)* for the guidance of the deputies to the States General, to which he was elected alternate deputy. He was secretary and treasurer of the commission appointed in 1790 to secure uniformity of weights and measures throughout France. This led to the establishment of the metric system.

Lavoisier's fate in the Revolution

Lavoisier's membership in the Ferme Générale was alone sufficient to make him an object of suspicion to the authorities during the French Revolution. The extremist revolutionary Jean-Paul Marat accused him of putting Paris in prison and of stopping the circulation of air in the city by the wall erected at his suggestion in 1787. In August 1792 he had to leave his house and laboratory. In November the Revolutionary Convention ordered the arrest of the former members of the Ferme Générale, and in May 1794 they were sent to be tried by the revolutionary tribunal. The trial lasted only part of a day. Lavoisier and 27 others were condemned to death. That same afternoon, May 8, he and his companions, including his father-in-law, were guillotined at the Place de la Révolution (now Concorde). His body was thrown into a common grave.

Scientific achievements. Lavoisier's name is indissolubly associated with the overthrow of the phlogistic doctrine, which had dominated the development of chemistry for more than a century, and with the establishment of the foundations upon which modern science rests.

Work on combustion

On November 1, 1772, Lavoisier deposited with the Academy of Sciences a note stating that sulfur and phosphorus when burned increased in weight because they absorbed "air," while the metallic lead formed from litharge by reduction with charcoal weighed less than the original litharge because it had lost "air." The exact nature of the airs concerned in the processes he did not explain until after the preparation of "dephlogisticated air" (oxygen) by Joseph Priestley in 1774. Then, perceiving that in combustion and the calcination of metals only a portion of a given volume of common air was used up, he concluded that Priestley's new "air" was what was absorbed by burning and that "nonvital air," azote, or nitrogen, remained behind.

In a memoir presented to the academy in 1777, read in 1779 but not published until 1781, he assigned to dephlogisticated air the name oxygen, or "acid producer," on the erroneous supposition that all acids were formed by its union with a simple, usually nonmetallic body. Combustion was explained by Lavoisier not as the result of liberation of hypothetical phlogiston but as the result of the combination of the burning substance with oxygen. On June 25, 1783, he announced to the academy that water was the product formed by the combination of hydrogen and oxygen; in this, however, he had been anticipated by the English chemist Henry Cavendish. From his knowledge of the composition of water, Lavoisier was led to the beginnings of quantitative organic analysis. He burned alcohol and other combustible organic compounds in oxygen and from the weight of water and carbon dioxide produced calculated their composition.

The spread of Lavoisier's doctrines was greatly facilitated by the defined and logical form in which he presented them in his *Traité élémentaire de chimie* (1789), and eventually they were adopted universally.

In addition to his purely chemical work, Lavoisier, mostly in conjunction with the mathematician and astronomer Pierre Laplace, devoted considerable attention to physical problems, especially those connected with heat. The two carried out some of the earliest thermochemical investigations, devised an apparatus for measuring linear and cubical expansions, and employed a modification of Joseph Black's ice calorimeter in a series of determinations of specific heats. Regarding heat (*matière du feu*) as a peculiar kind of imponderable matter, Lavoisier held that the three states of aggregation—solid, liquid, and gas—were modes of matter, each depending on the amount of *matière du feu* with which the substances concerned were associated. He also worked at fermentation, respiration, and animal heat, looking upon the processes concerned as essentially chemical in nature. A paper discovered many years after his death showed that he had anticipated later thinkers in explaining the cyclical process of animal and vegetable life.

BIBLIOGRAPHY. *Oeuvres de Lavoisier*, 6 vol. (1864–93), is a collected edition of Lavoisier's writings that includes all his main works and memoirs from the academy volumes as well as numerous letters, notes, and reports. D. MCKIE, *Antoine Lavoisier: Scientist, Economist, Social Reformer* (1952), is an authoritative biography that contains all relevant details of Lavoisier's life and work. D.I. DUVEEN and H.S. KLICKSTEIN, *A Bibliography of the Works of Antoine Laurent Lavoisier, 1743–1794* (1954) together with the *Supplement* (1965), is definitive and contains a description of all Lavoisier's writings together with copious explanatory annotations.

(D.I.D.)

Law, Western Philosophy of

Philosophy of law is concerned with the formulation of concepts and theories to aid in understanding the nature of law, the sources of its authority, and its role in society. In English-speaking countries the term "jurisprudence" is often used synonymously and is invariably used in reference to particular subdivisions of the field. (For material on non-Western law, see ISLAMIC LAW; CHINESE LAW.)

To the extent that it implies some necessary link or coincidence with general philosophy, the phrase "philosophy of law" may be somewhat misleading, for philosophy of law is mostly untouched by the conflicts of different philosophical schools, and its practitioners may without incongruity draw on diverse philosophical outlooks—on Logical Positivism for some analytical problem of the structure of legal orders and, simultaneously, on Existentialism for a problem of sociological jurisprudence or justice, for example—without commitment in any such instance to an entire philosophical outlook.

Nor can one treat philosophy of law as a specialized branch of philosophy such as ethical or political philosophy, epistemology, or logic, for in philosophy of law all these branches may make contributions. Ideas that may illumine jurisprudential problems must indeed be sought not only in philosophy but in all systematic bodies of thought. Only if "philosophy" is interpreted in its least technical and broadest sense does "philosophy of law" cease to be a misnomer.

PROBLEMS OF THE PHILOSOPHY OF LAW

Three major subdivisions of philosophy of law

Various approaches to the philosophy of law. For practical reasons, such as to avoid overlappings, it is convenient to organize jurisprudence into three principal branches only: analytical jurisprudence, sociological jurisprudence, and the theory of justice.

Analytical jurisprudence. The analytical questions in jurisprudence are concerned with articulating the axioms, defining the terms, and prescribing the methods that best enable one to view the legal order (or part of it) as a self-consistent system and that maximize awareness of its logical structure. Perhaps the most rigorous solutions are those which, like that of Hans Kelsen, a contemporary Austrian–American legal philosopher, attempt to identify structural or relational features as being necessarily entailed in the meaning of legal norms or in lawyers' intellectual operations with them (see below ***Pure theory* of *law***). Alternatively, the basis for logical structuring may be found in some imputed attribute of law not itself inherently structural. The 19th-century English legal philosopher John Austin, for example, thought it an essential preliminary to his quest for a logical system in law to clarify what was involved in his assumption that law always consists of "commands." This clarification is important, but the claim that such a clarified version of a common assumption necessarily amounts to an analytical model of law seems unwarranted.

On more modest levels, the analyst may seek to infuse clarity and orderliness into some particular branch of a legal system or even into the applications of some particular rule. Such work shades over, on the one hand, into ordinary legal analysis and, on the other, into jurisprudential efforts to clarify the meaning of particular legal terms. Analysis of a particular word or even a particular branch of law will usually, by necessity, be particularist in the sense that it works upon legal materials found only in one particular legal system. In between particularism and universalism lie what are sometimes called comparative approaches, in which analytical jurisprudence is applied to materials drawn from more than one (but not from all) legal systems.

Sociological jurisprudence. The sociological questions in jurisprudence are concerned with the actual effects of the law upon the complex of attitudes, behaviour, organization, environment, skills, and powers involved in the maintenance of a particular society. Conversely, sociological jurisprudence is also concerned with the effects of social phenomena on both the substantive and procedural aspects of law, as well as on the legislative, judicial, and other means of forming, operating, changing, and disrupting the legal order. The fact that men in a given time and place hold particular ideas and values, including ideals of justice, is itself a fact the relation of which to law must be studied; but the focus is sharply different from that in the study of theories of justice. Its focus is descriptive, not normative; it is concerned with what is or with what goes on, not with what ought to be or ought to go on.

The theory of justice. The theory of justice is concerned with the evaluation and criticism of law in terms of the ideals or goals postulated for it. This involves the identification and articulation of the values that the legal order seeks to realize. This aspect of jurisprudence is inextricably interwoven with ethical and political philosophy, and theories of justice thus tend to parallel the full range of ethical and political philosophies.

Law, morality, and natural law. A consideration of fundamental importance in the philosophy of law is that of the distinction between law and morality. The importance of the distinction is illustrated by the main questions to which it gives rise: (1) How far and in what sense should the law of a community seek to give effect to its morality? (2) Is there a moral duty to obey the law even when it does not embody morality, and, if so, are there any limits to this duty? (3) When a legal rule directs conduct that morality forbids, which should the citizen obey? (4) Is there ever (and, if so, when is there) a duty to overthrow an entire legal system because of its conflict with morality?

Definitions of morality

In all these questions the word "law" refers to the specialized form of social control familiar in modern, secular, politically organized societies. The word "morality" in the four questions may, however, refer to any of the following: (1) the community's relevant factual behaviour patterns (its mores); **(2)** its socially approved behaviour patterns, as sanctified by some widely held rational or religious ideal, whether observed in practice or not (social morality); or (3) the moral ideals accepted by each individual as binding on himself and on others, whether or not those others agree (individual morality). All these, like law, are means of controlling human conduct by setting normative standards; and all three have a constantly changing interaction with each other, as well as with law.

The fact that legal and moral norms vary from place to place and from one historical period to another lies in part behind a persistent theme in the philosophy of law: the search for unchanging norms that are universally valid. Clearly, the most certain way of establishing such norms would be to base them on widely observed facts, such as man's social propensities or the ubiquitous importance of kinship in social organization, which supposedly reveal something fundamental about the nature of man and his adjustment to the world. The attempt to base norms on some such category of facts has for two millennia been associated with the concept of natural law (*q.v.*). This concept has many versions, the principal of which are outlined in the historical survey below, but the significance of the topic merits some separate preliminary discussions.

Aristotle's conception of natural law

It has always been possible to trace a mainstream of natural-law thought. flowing from Aristotle's premise that the "nature" of any creature, from which obligations must be derived, is what it will be in its fullest and most perfect development. For man, this means what he is when the powers and qualities distinguishing him from other creatures, namely, his reason and his impulse to social living, are fully developed. Natural law embodies those obligations that will appear if mankind's reason and sociality are fully unfolded.

A major difficulty presented by this attempt to develop normative standards appears to be that it is very difficult to demonstrate, let alone create a sense of obligation toward, values that are only immanent. All theories of natural law, moreover, have found it necessary to rely on what are essentially intuitions or preconceptions as to what man's true nature is. All such theories acknowledge, for instance, that the full development or fulfillment of an entity is not the same as its mere continued existence, that there may be a "warping" or "impeding" of the natural tendencies, so that what exists may then "be said to be unsound or incorrect." Thus, mere factuality is not a sufficient source of obligation. Similarly, St. Thomas Aquinas himself, in identifying the "inclinations" from which men may learn natural law, found it necessary to order these in grades of inclination, so that those inclinations most closely related to reason and sociality take priority over those concerned (for example) with procreation and self-preservation. The criteria by which such a hierarchy is ordered must be drawn from sources other than the factual inclinations themselves. The "lower" grades (such as self-preservation) may well be based on something like instinct; but the question arises at the higher grades whether there is any comparable instinct by which men seek to find moral precepts binding all of them in common. Aquinas here appealed to synderesis, a kind of sympathetic understanding found in men, a disposition (habit) of the practical intellect inclining them to the good and murmuring against evil.

To derive from this synderesis a universal natural law, however, it would be necessary to demonstrate some "universal conscience" of all mankind. But natural lawyers faced with the fact that men's consciences do not coincide explain that conscience may err and reason be corrupt. Invocation of synderesis is in fact helpful not as an account of how one may arrive at factually based normative standards but as an illustration of the psychological tendency of men to assert values.

HISTORICAL SURVEY OF LEGAL THEORIES

The ancient world. ***Greek thought.*** The major contribution of Greece was a body of philosophical and cosmological ideals about justice, more apt for orators' appeals to popular assemblies than for preceptual application to day-to-day life situations.

Early Greek cosmologies, embedded in some of the earliest myths, had seen the individual as held within a kind of transcending harmony of the universe, emanating from the divine law (logos) and expressed in relation to human life in the law (nomos) of the polis, the city-state. The later Sophists, however, who examined critically all assumptions relating to life in the city-state, pointed to the wide disparities in human law and morals and rejected the claim that this human law (nomos) necessarily reflected any universal law (logos). Taking man as "the measure of all things," they rejected any claims of his law (nomos) to absolute value and saw law and justice and values generally as created by men's reasons, in their multitudes and generations, in all their individuated, relativistic, and historically changing dimensions.

Plato's idea of law

In the restless intellectual and political climate of 5th-century Athens, Plato was concerned to redefine the nature of justice by relating it to something far more permanent and absolute than the nomos of the city-state. He assigned "reality" to the unchanging archetypal forms—*i.e.*, the ideas--of things rather than to the ephemeral phenomena as superficially and confusedly perceived by individual men unenlightened by philosophy (see PLATO; IDEALISM). In the utopia described in The Republic, Plato defines justice in an architectonic sense: justice prevails when the state is ordered in accordance with the ideal forms ascertained by its philosopher-kings and is thus unrelated to the nomos of the city-state. There is no need for human law, since transcendental knowledge rules. In his later thought, however, as revealed in *Politicus* (the "Statesman") and the Laws, when he is concerned to describe a more practicable but nevertheless "second best" state, Plato assigns to law a role almost as important as that of knowledge in The Republic. A famous classification of states given in Politicus is indeed based on the criterion of whether or not they are ruled by law. The law as Plato here conceived it, however, was not mere convention or the imperfect individual judgments of men but a reflection of the common human reason in its full development. To this extent the rule of law might approximate the ideal rule of knowledge envisaged in The Republic, for in the inherited law of men is crystallized that much wisdom of which they are capable.

And yet it was difficult for Plato to find justification for such an argument in his basic philosophical position, with its emphasis on the contrast between the mere opinion of ordinary men and the transcendental knowledge of the philosopher. Aristotle, who in common with Plato held a view of nature or reality that transcended the variability of things as perceived by the senses, was, however, able more successfully to defend the validity of a law resulting from the practice of ordinary men. For Aristotle's transcendental reality is more firmly related to things as they are: it comprises that which they will become as their potentialities unfold in nature toward the end that is theirs in nature. Man, in his nature, is moral, rational, and social, and his law may be judged by the extent to which it facilitates the development of these innate qualities.

The Stoic conception of natural law

The Greek conception of natural law underwent further refinement by the Stoic school of philosophy, which became active toward the end of the 4th century BC. The Stoics posited the existence of a natural law, the *jus naturale*, which was an emanation of the lex *aeterna*, the law of reason of the cosmos. The existence of an innate reason in men linked everyone with the cosmic order and subjected all to a universally valid moral law. This latter concept thoroughly infused Roman thinking, largely as a result of the influence of Stoic philosophy on Rome.

Roman thought. Greek law scarcely survived as a system, because it never developed a class of legal specialists or abandoned its lay administrators or its popular tribunals of grotesque size. Roman law, on the other hand, developed through the efforts of expert jurisconsults (learned lawyers) and praetors (magistrates) into a permanent heritage of Western society. By its adoption into works such as Cicero's De re *publica* as well as in the work of the great jurisconsults, Stoic speculation concerning reason and nature was brought onto the level of precepts for concrete problem solving. The crude, tribal *jus* civile ("civil law") of the Romans was thus transformed into a natural-law-based jus *gentium* (law applying to all people), a set of principles common to all nations and appropriate, therefore, for application to foreigners as well as Romans.

Hebrew *thought.* In the Talmud there is an assertion that "Whatever decision of a mature scholar in the presence of his teacher will yet derive from the Law (Torah) that was already spoken to Moses on Mount Sinai." In theory, this presupposed that the Oral Law must respect every jot and tittle of the revealed written law. Yet the richness, ambivalences, and silences of what was written, in relation to a changing world, still left the widest freedom to the scholarly reason of the rabbinical exegetes into whose care both the written law and the Oral Law finally came.

The operations of the rabbinical schools and courts over many creative centuries, especially during and following the first Babylonian Exile, resembled those of the great Roman jurisconsults and the great judges of the common-law tradition. One Talmudic story tells of a doctrinal rift between the majority of a rabbinical court led by a great rabbi and a dissenting but no less great rabbi, in which the dissenter successfully summoned the authentic voice of God onto his side of the argument. To this intervention the majority of the court responded: "The law is not in heaven, the law has been handed down to us on earth from Mount Sinai, and we no longer take notice of heavenly voices. . . ." And the story relates that, at that point, God said with a smile to Elijah the prophet, with whom he was walking: "My children have defeated me, my children have defeated me." But this was an indulgent ratification, not an implacably cruel wrath such as the Greek god brought down on the head of Prometheus. Thus, even against divine intervention, the learned stood their ground, relying for the interpretation of the law on their own wisdom and reason.

The Middle Ages. Augustine. St. Augustine of Hippo, in attempting to refute the pagan assertion that Christianity was responsible for the decline of Roman power, reintroduced Stoic philosophy alongside Judeo-Christian thought into the stream of modern jurisprudential speculation. He placed God's reason beside God's will as the highest source of the unchangeable, eternal, divine law binding directly on man and all other creatures. The divine law was thus accessible to both man's reason and his faith and was not, as St. Paul had largely concluded, the product of his will alone and hence not rational in terms of human as opposed to divine reason.

At a second level, Augustine placed the no less unchangeable natural law, being the divine law as man is given the reason, heart, and soul to understand it. The third level, of temporal, or positive, law (for him, the Roman law of the Christian Roman Empire), was warranted by the eternal divine law, even though it changed from time to time and from place to place, so long as it respected the limits laid down by the divine and natural law. This rationale of secular power, some have thought, preserved the idea of government under law through the disintegration of the ancient world, for recultivation in the revival of learning of the 12th and 13th centuries.

Scholasticism. Aquinas, like Augustine long before, succeeded in quieting momentarily the competing claims of the will against the reason of God, the struggle between "voluntarism" and "rationalism," as the underlying basis of the eternal and natural law. Aquinas, like Augustine, gave a plausible place to both natural law and temporal (or positive) law under the eternal law. Human, or positive, law is a creation of human reason for the common good, within limits that natural law prescribes, so that even this proceeds from right reason and therefore from the eternal law. Such positive law as violated the natural and thus the eternal law "was not law" or merely was not binding "in conscience."

Voluntarism of Duns Scotus

The tendency to make reason prevail over will (as in Plato's call for philosophers to be kings or the Arab Averroes' call for philosophers to interpret what is revealed) was challenged by a voluntarist countermovement at Paris and Oxford in the quarter of a century after Aquinas' death in 1274. A Franciscan, John Duns Scotus, insisted on the uniqueness of all beings as finally traceable to the uniqueness of God's will. All precepts, even of the divine law, depend on the single precept "Love God," and, since not reason but will gives access to this, there is no natural law accessible to man's reason. All that can be required of human, or positive, law is that it must be "consonant" with the precept "Love God," or with any other precept willed by God.

The Renaissance period to the 18th century.

Machiavelli. Machiavelli presented himself (on one interpretation, at least) as seeking to escape from both transcendent will and transcendent reason into the empirical, into life as it is, observed through the eyes of a worldly man whose mind is uncluttered with philosophical and theological preconceptions. He can be understood, in his own words, to be seeking "what a principality is, the variety of such States, how they are won, how they are held, how they are lost." This conception was the more remarkable in 1513, since such an approach had then barely been promulgated for study of the physical world. It had still, indeed, to await its major manifesto in that sphere until Francis Bacon's ***Advancement of Learning*** at the end of the century.

The normative element in Machiavelli's thought

Even on the more favourable view of Machiavelli's aim —*i.e.*, as describing, rather than prescribing, political behaviour—it remains true that he saw this description as ancillary to the art of maintaining the state and its ruler, so that this maintenance is a kind of end in itself. The omnipotence—unrestrained by law or morality—that he both ascribes and prescribes to the prince is thus a product not so much of his scientific detachment as of his tendency to view political power as a value, as an end in itself.

Natural law and social-contract theory. The supremacy of the human lawgiver, as posited by Machiavelli and in their diverse ways also by the French and English political theorists Jean Bodin and Thomas Hobbes and others, interwove in the following centuries with continued insistence by Grotius and others on the dominance of the divine reason and man's participation in it, by which he has access to the natural law.

The views of Hugo Grotius

The Dutch political and legal philosopher Hugo Grotius, amid the political expediencies and anarchy of the Thirty Years' War (1618–48), sought to introduce a degree of normative restraint among the monarchical rulers of the newly emerged sovereign states of Europe and to establish a basis in natural law for a rejection of *raison d'état* as a just cause for war, as well as for legal limits on the means and modes of violence in war. Even if the wills of sovereign states form the basis of the international order, Grotius argued, "the totality of the relations between States" is still "governed by law." That law he found in an updated version of the Stoic natural law, as naturalized into Roman law and Christian theology.

With Grotius, as with the Stoics, the normative or moral power of the natural law derives from the fact that man's innate nature (itself part of the nature of the cosmos) and his propensities are viewed as ideal or inherently good. In Grotius' own time, however, there arose a skepticism toward such unfounded optimism, a skepticism that underlies the thought of Hobbes.

With Hobbes (1588–1679), as with the Greek Sophists, the nature of man is not the ideal nature of Grotius and the Stoics. It is rather man's supposed actual nature, before sociality and authority have tempered it. Man, in a state of nature, is motivated by desire and aversion and most of all by the desire to preserve his biological existence. This need for security is best met by all men vesting their rights of self-help in a sovereign, whether that sovereign be a single man or an assembly of men, and subjecting themselves to the laws of that sovereign, or "great Leviathan."

The reason why men must obey the law of the sovereign state, which is the only institution capable of protecting men against each other, is thus based firmly in Hobbes's conception of man's nature, albeit a very different conception from the idealist premises of earlier theories of natural law. Natural-law theorizing after Hobbes is thus divided into two streams.

Judicial supremacy. By the beginning of the 17th century the idea of applying natural law as a test of the validity of the positive law (the law as it is found within a jurisdiction) had passed from the province of speculative writers to courts of law. The English jurist Lord Coke, in Bonham's case in 1610, was already referring to the tradition that "when an act of Parliament is against common right or reason or repugnant or impossible to be performed, the common law will control it, and adjudge such act to be void." About a century before that, an English treatise known as "St. Germain, Doctor and Student" had already presented a three-tier hierarchy of the law of God, natural law (the law of reason), and human (positive) law, obviously deriving from Augustine and Aquinas.

Natural law and American constitutionalism

In the United States in the next century, constitutional theory became highly infused with ideas of natural rights. The Declaration of Independence, with its assertion of the self-evident rights of life, liberty, and the pursuit of happiness, marked the beginning of a continuing natural-law influence on American constitutional development. The power of the judiciary to "review" legislation for consistency with a written constitution was taken in the United States to import the power to declare it void, constitutional law being analogized to natural law. Indeed, American judicial statements of 1814, 1822, and 1831 asserted the power of the judiciary to strike down statutes for violation not only of explicit constitutional restraints but also of "eternal principles of justice which no government has a right to disregard." The analogy of constitutional and natural law did not necessarily require that the power to strike down legislation should be a judicial power: this was not so in ancient Rome, nor is it always so in modern civil-law countries. It is arguable that such a judicial repository of the power of final review is unavoidable, since the legislature cannot be expected to annul its own acts; and the executive, even if it were not a party to such acts, is scarcely equipped for the tasks of objective interpretation involved. Yet there are real difficulties of policy and principle raised by giving the judiciary the final word. A distinction must first of all be made among diverse constitutional restraints. Safeguards for such rights as free speech and assembly and access to courts, which help to assure the responsibility of rulers and to prevent the fall of democracy into tyranny or demagoguery, may well be placed in the final custody of judges. But, beyond this point, others have argued, judicial supremacy, in enforcing restraints laid down by the Founding Fathers of an earlier generation, may clearly constitute an obstacle to the implementation by the courts of a society's present convictions.

Decline of natural law. If man is the measure of all things, as the Sophists taught, then a given society of men is the measure of its culture, including its moral and legal standards. In the modern period the French jurist and political philosopher Montesquieu's ***De l'esprit des lois*** (1748) and ***Lettres persanes*** (1721) offered the thesis that a people's law and justice are determined by the particular factors and environment that operate upon them. They thus could not, as the natural-law theory of the time held, be unchanging from age to age and from people to people. The French sociologist Auguste Comte's ***Système de philosophie positive*** (1851–54), which set out to explain positive laws, like other social facts, by reference to verified hypotheses concerning cause and effect and interaction, was similarly antithetical to natural-law theory as it had so far developed. To Comte, metaphysical concepts about such abstractions as ideal essences belonged to a past stage in man's intellectual development. And Darwin's ***On the Origin of Species by Means of Natural Selection*** (1859), the English philosopher Herbert Spencer's positivism, and other related thinking of the period provided a biological model of self-development of organisms and institutions through a struggle in which survival was a function of challenge and response in the given environment. Change and adaption, rather than constancy and inviolability, were thus at the heart of their system.

Under the leadership of anthropologists, analyses of man's internal process of response to the exigencies of existence within a particular culture—to conscious and subconscious psychic drives and motivations—deeply affected the jurisprudential study of law and society and helped to bring natural-law thinking to a 19th-century nadir. In the anthropologist Bronislaw Malinowski's most mature statement on the matter, he distinguished four major meanings of the word law as important in understanding the growth of civilization. They included "laws of nature" in the scientific sense of rules governing men's conscious adaptations to the environment; rules of "efficiency" and "convenience" according to which the group lives; rules for conflict adjustment; and rules about enforcement of the last two. No conception of natural law, which had engaged earlier thinkers for two millennia and more, was included.

Idealism and justice. Another line of thought, which was also divorced from natural-law concepts, was contained in the Idealist philosophy of Immanuel Kant. Fundamental to Kant's ethical and jurisprudential reasoning is the premise that all moral concepts have their basis wholly in a priori thought, that they can be arrived at by reason alone, without reference to experience or recourse to intuition of rules alleged immanent in experience (see KANTIANISM). Man, furthermore, is a free agent whose actions are determined by aims that he is at liberty to select. From such premises Kant deduced the nature of an ideal law, in which is implicit a theory or criterion of justice. This ideal law comprises the conditions under which all members of society can enjoy the maximum freedom from subjection to the arbitrary will of others.

Kant's ideal law

But Kant's supposedly a priori concepts are in fact as transcendental as anything natural lawyers have offered. It is thus not surprising that later thinkers, such as Johann Fichte, Kant's Idealist successor, had little difficulty in putting the new Kantian wine into natural-law bottles.

The 20th century saw a fresh attempt at the Kantian approach in the work of the German legal philosopher Rudolf Stammler. Adopting the Kantian position that knowledge is independent of sensory experience, Stammler set out to discover pre-experiential categories, or "pure forms," of thinking about law. Stammler arrived at a social ideal of a "community of free-willing men," an ideal that he claimed to have universal validity because of its supposed a priori basis. Having thus arrived at a "pure" ideal of society, untainted by empirical content deriving from sense perception, he felt able to formulate equally pure principles for just law that would regulate his ideal society. Stammler's pure idea of society comprised the harmony of individual and common purposes: his pure idea of just law thus comprised those principles conducive to such harmony—the mutual respect of individuals for each other's purposes and the participation of all in the achievement of the common purposes.

The different stream of Idealism flowing from Hegel's philosophy of history (see HEGELIANISM) was fed into jurisprudence by Josef Kohler, Stammler's close predecessor in that subject in the Berlin University. His work is still another effort to relate social facts and the norms of justice by exposing the immanence of values in facts—in "civilization" in Kohler's case.

In perspective, these idealisms, despite their formal or philosophical antagonism to "rationalism" and natural-law thinking, seem to have reinforced in the age of the Industrial Revolution the individualist and libertarian trends that natural law had built up successively against medieval church and empire, the shackles of medieval social, political, and economic organization, and 18th-century despotism.

The 19th and the 20th centuries. ***Analytical Positivism.*** The close of the 18th century witnessed a reaction against both Kantian Idealism and iusnaturalism (natural-law theorizing). The scientific temper of the age, reflected in the practical achievements of the early decades of the Industrial Revolution, was not conducive to deductive reasoning from a priori hypotheses, which appeared an impractical method of solving the problems of complex societies. Such problems might better be approached via a thorough analysis of existing law and institutions. This new climate of opinion came to be known as Positivism.

Meaning of Positivism in jurisprudence

Among the chief meanings of Positivism in the legal-analytical sphere are the separation of law as it is and law as it ought to be, stress on the analysis of legal concepts, reliance on logical reasoning in the search for applicable law, and denial that moral judgments can be based on observation and rational proof. Anglo-Saxon analytical Positivism has directed itself mainly to the logical dissection, appraisal, and clarification of the precept element of law, ignoring the elements consisting of lawyers' traditional techniques and received ideals. By the nature of its tasks, analytical jurisprudence does not concern itself with either the facts surrounding or the consequences flowing from legal precepts or with their ethical evaluation, though particular analysts may also be interested in those matters.

Analytical Positivism in England began with the work of the philosopher and legal reformer Jeremy Bentham. His work influenced John Austin, the most outstanding figure in English jurisprudence, who set out to analyze the notions pervading English law. In order to delimit his subject, he defined positive law as the commands of a sovereign addressed to political inferiors and backed by threats of evil in the event of disobedience. Positive law might well be derived from moral precepts and other sources, but such precepts become law only when commanded by a sovereign.

The analytical-Positivist attitude has continued to influence thinkers, although the particular approach of Austin is now of historical interest only. Logical analysis is clearly a tool that may be employed in many spheres of jurisprudence, and its importance thus transcends the limits of any one school. Analysis means little in itself; its value depends largely on the validity of the premises from which the argument is made and on the relevance of the subject matter that is chosen for analysis. The paramountcy for the analytical Positivist of questions of logical order and consistency represents a permissible deviation, yet still a deviation, from the wider concerns of ordinary lawyers and students of law and society generally. This is not to say that there is a necessary conflict between the requirements of justice among changing social facts and those of logical consistency of precepts. It means only that there is surely no necessary (nor indeed usual) coincidence between them.

Historical Positivism. In discarding speculative cosmology, the a priori, and the self-evident, 19th-century historical jurisprudence opened the way for the search for the realities of law through empirical observation—for a sociodescriptive rather than a logico-analytical-Positivist jurisprudence.

The leading figure in the historical school was the German jurist Friedrich Karl von Savigny, who confronted the natural-law aspiration for a universal human code with the singularity of the law of particular peoples resulting from their unique sociocultural experiences.

For Savigny, law rests on the ***Volksgeist,*** or innate popular consciousness; law ***par excellence*** is customary law. He recognized, of course, that the details of a developed legal system do not spring from simple group intuition. With maturity, both life and law become more specialized and artificial, creating a dualism in more mature law. Part of such a system still rests directly on the popular consciousness and way of life ("the political element"); but this becomes elaborated by jurists, be they Roman jurisconsults or common-law judges, who in this respect represent the community ("the technical element").

Savigny's emphasis on the need of legal change to respect the continuity of the ***Volksgeist*** offers a pre-Darwinian concept of juristic evolution. The ***Volksgeist*** corresponds to modern notions of social rather than biological inheritance. Savigny's sense of the impotence of legislatures in the face of the restraints imposed by the ***Volksgeist*** foreshadows modern recognition of the social and psychological limits of effective legal action.

The English legal historian Sir Henry Maine's dual academic concern with both English law and Roman law challenged him to explain their independent yet often parallel growths and may well have redeemed him from Savigny-like overemphasis of national uniqueness. His concern led him to a comparative historical jurisprudence seeking hypothetical "laws" of development controlling all legal systems. He saw changes in substantive law and in the machinery and modes of legal enforcement and growth as moving in pace with certain recognizable stages in social growth, from primitive, kin-organized society to the mature, complex commercial and industrial societies of Europe.

Maine's experience in India after the publication of his *Ancient Law* in 1861 broadened his interests so that he embraced less well known and less developed systems, such as the Brehon, Hindu, Welsh, Germanic, Anglo-Saxon, and Hebrew. His breadth of interest matched the concurrent growth in anthropological study of primitive peoples.

Maine's work shows the strong combined influence of the analogy of biological to social evolution and of the Hegelian philosophy of history. The consequent, somewhat mechanistic tenor of his interpretations resulted in his being accused by many anthropologists and legal historians of making false assumptions concerning the pattern and sequence of social development.

The Marxist conception of law

Economic interpretations. Certain residues of the Marxist economic interpretation of history have won a central place in sociological jurisprudence (see below ***Sociological jurisprudence),*** as indeed in most branches of social science. One such persistent trend of thought is the close interrelatedness of legal, ethical, economic, and psychological inquiries; another is the pre-eminence among these of economic factors. According to Marxist doctrine, the political and judicial systems—the state and the law—represent the superstructure of society, their nature being determined by the economic base—the mode of production and exchange. The state and its repressive law are but instruments of class domination, becoming redundant under Communism, which has no need of coercion. During the transition to full Communism, they would "wither away." There were, of course, softenings of this bold doctrine in its original authors, with admissions that the ethical or legal superstructure should not be seen as a merely passive effect; and Lenin himself pressed to extremes both the passion of the original thesis and its qualifications. Lenin, indeed, saw state power as an essential weapon of the proletarian dictatorship until the movement to a full Communist society should be completed.

The first half-century of the Soviet Union, with its steady consolidation of state power and its attendant law, has imposed the severest strains on the withering-away prediction. The general tenor of explanation is that the "law" the disappearance of which is prophesied refers only to the kind of coercive order manifest in such instrumentalities as the courts, police, and jails of capitalist countries.

Within these sweeping theses of Marxist thinking, more modest subtheses have played a valuable part. The Socialist jurist Karl Renner, for example, in his ***Rechts-institute des Privatrechts und*** *ihre soziale Funktion* (1929), was concerned to show that the legal conception of ownership, formulated in early economies, had profound new effects when continued as an institution of the 19th-century economy. It then, through the law of property and contract, alienated into private hands great segments of what should be in the public domain.

Even more notable are the German sociologist Max Weber's studies of the correlations of socioeconomic and ethicojuristic change, freed of the straitjacket of economic determinism. In these, the impact of unique factors or combinations of factors in particular civilizations is taken into account, including the existence of accepted systems of values, immediate and ultimate, which may (and in Weber's view did) have a decisive effect on the emergence of the Western capitalist system.

Sociological jurisprudence. The historical jurisprudence of the earlier part of the 19th century became subject to the influence of the developing social sciences, which attempted to explain law in its social context. The result was the emergence of a sociological school of jurisprudence.

The early decades of sociological jurisprudence combined 19th-century faith in progress, social evolution, rationalism, humanitarianism, and political pluralism with a sanguine belief that the Newtonian model of natural science would also hold for the social sciences. It was affected by questions of whether the social sciences are truly sciences, what their mutual boundaries are, and whether they can be integrated or somehow transcended by some subject such as sociology or anthropology.

An outstanding figure of the early sociological school was a German, Rudolf von Jhering, who in the 1860s contributed to the intellectual stream a theory of justice predicated on a view of law as a social phenomenon. He saw law as an outcome of the struggle of men to fulfill their purposes and of the force that they marshal behind this. Another historical jurist, the German Otto von Gierke, stirred a related interest with his emphasis on the importance of the inner life and activities of groups and associations as sources of binding social norms. This opened up jurisprudence to some psychological issues. Gierke's work also contributed to the later American Neorealism through its influence on Oliver Wendell Holmes, Jr., and to the theory of the "living law" of the Austrian jurist Eugen Ehrlich, in the first decade of the 20th century. Ehrlich insisted on the profuse norm-creating activities of the countless associations in which men are involved.

Early 20th-century views

At the beginning of the 20th century a great variety of psychological hypotheses were brought to bear on law. A theory of dynamic psychic drives, for example, was propounded by an American sociologist, Lester F. Ward, who argued that such drives could be utilized in social planning. Freud's exploration of psychic activity on a subconscious level, as well as studies of the nonrational and the irrational in the social process by the Italian and German sociologists Vilfredo Pareto and Max Weber, were also profoundly influential.

Revival of natural-law theories. Iusnaturalism, in the sense of the assertion of an order of norms for human conduct transcending human will, to which the validity of positive law is subjected, has certainly experienced a 20th-century revival. The massive human delinquencies of the century, such as those of the Nazis, have been important in stimulating these modern natural-law yearnings. The revival, indeed, has rarely overthrown dominant Positivist positions, but it has certainly reopened some questions that Positivists have not adequately faced.

Contributions to this re-emergence have come from varied directions, rather than from a single intellectual movement. They have often avoided explicit reference to natural law and have even expressed hostility or ridicule toward it. The German Stammler and the French jurist François Gény were certainly among its pioneers. Gény's ***Méthode*** *d'interprétation* (1899) displayed the inescapably creative (or lawmaking) role of the judiciary even under a comprehensive code such as the Code Napoléon. It led him to the questions of what are "the sources of law" and where does the legislator's prescription fall short. Answers to such questions must be based on the facts of each particular situation to be adjusted—the legislator cannot impose his view on the court. This line of thinking foreshadowed a variety of doctrines about "the nature of things" or "the nature of facts," all of which shared the idea that the decisive nature of a situation has its base in the facts for which men seek governing law. The properties and circumstances of these facts themselves afford immediate guidelines for just regulation. The fact situation, if only its essence will be perceived, has the superior applicable norms immanent within it.

In his ***Lehre von*** *dem* ***richtigen Recht*** (1902), Stammler sought, as described above, the a priori social principles of just law concerning respect for and participation by all members. His call for "natural law with a changing content" based on these a priori principles quickly became a 20th-century slogan.

Even as this express reinvocation of natural law was proceeding, the French public lawyer Léon Duguit was expressly denouncing it. Duguit's concern was to place law and lawyers within what he saw to be the correct frame. This he found in Émile Durkheim's Positivist sociology. This led him, with some paradox for a contemner of natural law, to insist that law is but *"le produit spontané des faits"* ("the immediate result of the facts"). The observed "facts" of social solidarity arising from economic specialization of functions generated, Duguit argued, the society's norms. Breach of these norms causes social disorder and a spontaneous movement toward readjustment. Even a supreme legislator was bound (Duguit affirmed) by this objective "rule of law," so that his acts violating it are void, even apart from any other constitutional restraint. All this bears the clear iusnaturalist mark of the assumed immanence in observed facts of a transcending and overriding order. It pays cryptic homage to a natural law, fealty to which Duguit denied.

The German legal philosopher Gustav Radbruch's turn toward natural law at the end of a life of great contributions to democratic legal relativism and Positivism was very different. Positivism, Radbruch argued, had encouraged German lawyers to stand by at Nazi barbarism, declaring *"Gesetz ist Gesetz"* ("Law is Law"). Nor was Radbruch's turn to natural law in any way cryptic. He came to declare quite openly that:

> where justice is not even striven for, where equality which is the core of justice is constantly denied in the enactment of positive law, there the law is not only "unjust law" but lacks the nature of law altogether.

The linkage with the revived natural law of the legal institutionalism of the French legal philosopher Maurice Hauriou and the writer and historian Georges Renard is different again. As with Duguit, the linkage is not proclaimed, but no overt hostility disguised their obvious sympathy for Thomist positions. Theirs is a Catholic version of institutionalism (which regards social institutions such as the family or the corporation as expressing the social reality underlying the law). The natural-law assumptions are apparent in the insistence on "the principles of organization," the "communion" of members in realizing "durable ideals," and the placing of men's powers of organization into the service of such ideals, as essential elements of any institution. For them, as for Duguit, the principles of justice were principles of social organization, immanent and self-evident.

It has been tempting for many to seek kinships between natural law and Existentialism, as was attempted by the German legal philosopher Werner Maihofer. Such efforts seem, however, destined to denature either Existentialism or natural law itself. Even in all their varieties, Existentialist positions approach no nearer to natural law than to assert that the traumas, anxieties, and demands of mere "existence" confront men with fateful value choices. Yet this is far short of asserting that any transcending principles of harmony may be discoverable.

Abstract symbols such as "social solidarity," "the principles of social organization," or "immanence in the facts of social life" are by virtue of their ambiguity susceptible to misappropriation by absolutist governments. The same may be said of Savigny's *Volksgeist* notion, as witness its affinity to the racialism of Nazi law. Thus, while the modern revival of natural law has been in part a revulsion from totalitarianism, it can also be exploited to rationalize totalitarianism.

There is another paradox also: The growth of the social sciences has invited restatement of natural-law traditions in terms of social ideals. Yet the very complexity of the social and economic orders and of their attendant sciences has placed forbidding barriers before the aspiration to base justice or other values on "objective" knowledge. Some have been tempted to hope that natural law may somehow overleap such barriers.

Pure theory of law. In part, at least, the influence of the distinguished legal philosopher Hans Kelsen's "pure theory of law" reflects early 20th-century skepticism about natural law and sociology, to both of which Kelsen opposed his claimed purity of method; *i.e.,* a method free from contamination by values of any sort.

He asserted, first, that legal theory was properly a science in the sense of an uncommitted, value-free, methodical concern with a determined object of knowledge. Second, he argued, legal theory must be isolated from psychological, sociological, and ethical matters. Third, purity of method permits the analyst to see that every legal system is in essence a hierarchy of norms in which every proposition is dependent for its validity on another proposition. The justification for describing any particular rule as law thus depends on whether there is some other proposition standing behind it, imparting to it the quality of law. This regression is continued until the *Grundnorm,* or "basic norm," is arrived at. The basic norm derives its validity from the fact that it has been accepted by some sufficient minimum number of people in the community.

Kelsen's hierarchy of norms

Kelsen's assertion that norms can spring only from other norms seems but another way of stating his rejection of the relevance of facts to values and, therefore, of iusnaturalism and sociology to his pure science of law. Yet finally it has seemed to many dubious whether the Kelsenite theory itself escaped the *liaison fatal* between facts and norms; for, if all legal norms must finally hang on the basic norm, then whatever it is that the basic norm hangs on must be nonlaw. And whether the basic norm hangs on "habitual obedience to determinate persons," as the English legal philosopher John Austin in effect proposed a century before, or on "efficaciousness," as Kelsen proposed, what it hangs on is fact rather than norm. Critics have complained that, at most points in the creation of norms in Kelsen's system, what is decisive is the intervention of acts of will of persons endowed by higher norms with norm-making authority. The determination whether such acts of will have occurred is a factual inquiry, to the decisiveness of which Kelsen's pure theory gave little weight.

Modern schools of realism. The American jurist Oliver Wendell Holmes's description of law in 1897 as "what the courts will do in fact" and of the "real ground" of decisions as resting often in some "inarticulate major premise" rather than in expressed reasons gave 20th-century legal realism its central theme.

Certain features are common to the "realist" jurists. They include (besides the above-mentioned concern with "the law in action") stress on the social purposiveness of law, on the endless flux in both society and law, on the need to divorce the "is" and the "ought" for purposes of study and to question all orthodox assumptions made by lawyers, and in particular on the need to substitute more realistic working categories for current lawyers' generalities. Among the orthodoxies thus challenged, these writers tended to include the works of early sociological jurisprudence. Yet it is clear, from the present perspective, that the concerns common to the realists and the more orthodox sociological jurists were far more important than the ephemeral if bitter conflicts that at first flared up between them. The American realists in their important surviving contributions have for the most part reinforced, clarified, and elaborated a number of main insights, notably about rule uncertainty and fact uncertainty, which they shared with sociological jurisprudence.

Scandinavian realism

Scandinavian realists, while temperamentally akin to their American colleagues, were rather different in intellectual concerns. Methodologically, they invoked a somewhat gross empiricism, leading them to deny that the law could be the subject of scientific inquiry at all, since its concepts and principles are not founded on spatial and temporal data of experience. Taking lawyers' talk of the will of the sovereign very literally, they were concerned to show that there is no such will of common content and that even legislators who enact a code are merely rubber stamping what others drafted.

The Swedish jurist Axel Hagerstrom insisted that the idea of rules of law as commands is an idea not corresponding with facts. His disciple Karl Olivecrona added that this false idea results from the syntactical imperative form used in modern legislation. Such rules, he urged, were commands only in a depersonalized sense. He preferred to describe them as "independent imperatives." Such "imperative statements about imaginary actions, rights, duties" may not be directed to any particular persons. Yet, even if some legal rules are directed "so to say, into the air," others are certainly directed to particular persons. If any form of imperative notion is to be preserved, it should be one that accommodates both situations.

Some of the problems that these writings address are rather tied to the special experience of their authors' own legal cultures. Others reach out independently toward truths already reached earlier in Anglo-American jurisprudential scholarship, especially as to the merely noetic and conceptual (rather than physical or psychological) nature of rights, duties, and liabilities.

THE STATUS OF CONTEMPORARY PHILOSOPHY OF LAW

By the middle of the 20th century, serious scholars no longer argued for or against the exclusive imperium of either the analytical logical, the justice-ethical, or the sociological approach. Whether jurisprudence is a single field in some scientific sense or whether its unity lies in the need to serve the intellectual needs of those concerned with making, applying, improving, or generally understanding law, all the above areas are included within it.

The "revolt against formalism"

A characteristic feature of contemporary jurisprudence is what has come to be known as "the revolt against formalism"; that is, against preoccupation with the technical and logical aspects of law. It can be traced back to Savigny's early-19th-century reaction against natural law, to Jhering's attacks on the German Pandectists (commentators on Roman law), and to Maine and the work of the anthropologists and early sociological jurists. Its early pressure was toward broader and deeper history, toward recognition of the organic nature of the processes of cultural growth, and toward problems of social action and the value choices therein entailed.

In the United States the legal philosopher Morton White identified five later contributing strains of thought, including the pragmatism of John Dewey; the economist Thorstein Veblen's institutionalism, rejecting both the abstractions of classical political economy and the fatalism of the Marxist interpretation of history; the revolt within jurisprudence of the American legal realists already described; and the approach to history as no mere chronicle of kings and battles but rather as a product of underlying economic forces and a guide to present and future civilizations.

The sometimes-overhasty iconoclasms of this revolt have proved less important than its positive affirmations. It has affirmed, for example, that the evaluating activities of justice must somehow move alongside the describing activities of sociological jurisprudence, that the choices of ethics, social policy, and justice still remain to be made when all the empirics of social science are done. The central question includes not merely what are the facts but also what should be done about the facts. These affirmations reject any regression to simple amoralism, stirring new temptations to return to natural law or other intuitive absolutes.

There are important advantages in the drive, characteristic of much contemporary social science, for overall cognition of the social and legal orders and the identification of key points for social action within them. But there are also dangers, for, especially with subject matters such as the law, systematic theory and overall cognition can rarely be of aid save in the rather long run, for which present decision makers cannot usually wait.

Growth of the sociological school. The most eminent pioneers and champions of modern sociological jurisprudence were Roscoe Pound in the United States and Hermann Kantorowicz in Europe. For both, the task of sociological jurisprudence, though orientated mainly to practical administrative or legislative problems, included that of framing hypotheses (as to the limits of effective legal action, for example) on which to base general laws of the operation of law in society.

Methodology of sociological jurisprudence

As with the social sciences, the principal methods available to sociological jurisprudence are those of survey, statistical analysis, comparative observation, and experimentation. The controls and corrections available usually fall far short of those of the natural-science models. Much work in sociological jurisprudence has merely brought to bear upon the law relevant findings from other social sciences. But it may also generate its own findings, as it has done in relation to traffic laws, control of moneylending, credit unions, bankruptcy laws, the effect of antitrust practices or of poverty on legal rights, the theory of appellate judicial decision making, and a host of other matters. Examinations of the prehistory and aftercareers of convicted criminals and of persons on probation or parole, probings of family and environmental influences bearing on potential deviance, and attempts to identify decisive factors predictive of future deviance are among the staples of sociological jurisprudence.

Sociological jurisprudence is confronted by the questions whether (and, if so, how and how far) it is possible through empirical methods to approach central issues of social action that involve value judgments. The fact that lawyers are necessarily involved with ideas of obligation, values, and norms sharpens this confrontation. A second group of problems arises from the high level of individuality of men, groups, and societies, from the unending variety of their emotions, roles, and expectations, and from the feedback effects on human behaviour that the empirical observation and testing of that behaviour brings about.

These problems give central importance to efforts to develop frames of social knowledge that give due place to both facts and values. Such inquiries show the great complexities of values held and their intricate and dynamic relation to the physical and cultural environments.

The study of law in society thus shares with anthropology and other social sciences a central interest in roles and functions as basic meaningful categories and in certain mechanisms and channels whereby conduct is thought to become socially meaningful. These notions are thought to permit the analysis of complex social situations into more refined terms, such as constituent goals, tasks, expectations, and allocated rights, powers, and duties.

As to the mechanisms or channels through which conduct becomes socially meaningful, earlier thought tended to explain social norms as built up from individual instances through group usages and mores that then crystallize in institutions such as law. Insofar as this suggests a cumulative movement or process, current thought would regard it as oversimplified. The growth of socio-ethical convictions is rather to be seen in terms of symbolic interaction between individuals. A particular society may be seen, in this light, as a collection of individuals with a culture that has been learned by symbolic communication from other individuals back through time, enabling members to gauge their behaviour to each other and to the society as a whole.

The future of sociological jurisprudence. In his famous program of 1911–12, Pound formulated a series of rather practical objectives for the movement, including making studies of the law in action, of the means of more effective legislation and law enforcement (by creation of ministries of justice, for example), of legal and judicial reasoning, of legal history in its social context, and of the role of the legal profession. An early quip against the sociological school was that it was like a great orchestra constantly tuning its instruments but never actually playing. Yet many practical tasks have been performed, and the school continued to show a gathering momentum and a widening range of concerns.

The maladjustments and inadequacies of the law gave to early sociological jurisprudence an intensely activist drive, directed to ad hoc remedies, and a great deal of the relevant work is still of this nature. Especially since 1945, however, juristic work on the relations of law and society has come into more fruitful contact with other social sciences, leading in turn to greater stress on cognition of the social and economic orders in their complex unity. Whatever the difficulties of designs for an overall analysis of the social system, some adjustment toward them is inevitable for sociological jurisprudence. This is in part, no doubt, a result of the waning of interest in many of the kinds of ad hoc problems with which it was initially concerned. But the interest in sociological theory also results from growing awareness that some problems require to be approached on a wider basis. This has created new stirrings of the turn-of-the-century ambition that the study of law in society become a specific branch of social science, concerned with framing and testing general laws governing law as a social phenomenon.

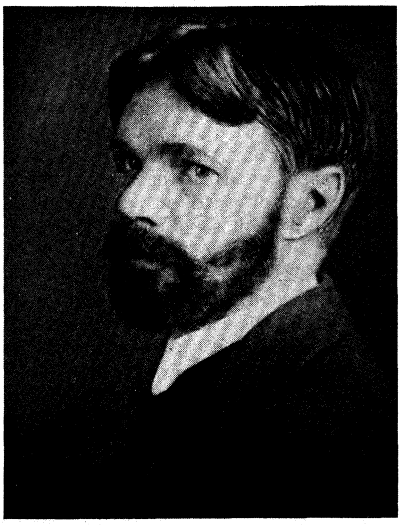
Lawrence, D.H.

One of the most original and controversial English writers of the 20th century, D.H. Lawrence revealed the instinctual forces in human nature, presenting a bitter critique of modern industrial society.

Life and works. David Herbert Lawrence was born on September *11, 1885,* at Eastwood, Nottinghamshire. He was the fourth child of a coal miner; his mother had been a teacher and had written poetry. After winning a scholarship to Nottingham High School (1898), and a short time as a clerk, and as a pupil–teacher at Eastwood, at *21* he went to University College, Nottingham. In *1908* he left Eastwood for Croydon to teach at the Davidson Road School.



D.H. Lawrence.
Elliott and Fry

Lawrence had already begun writing, his first published work being a story in the *Nottinghamshire Guardian.* His first literary friend was Ford Madox Hueffer (Ford Madox Ford), who placed his first novel, *The White Peacock* (1911), and published his work in the *English Review.* Hueffer did not like *The Trespasser* (1912), Lawrence's second novel, based on a visit to the Isle of Wight with a friend he calls "Helena"; but Edward Garnett (then reader to the publishers, Duckworth and Co.) did, and Garnett became for a time Lawrence's most helpful literary friend.

Early works and recognition

An epoch in Lawrence's life that was to cease only with his death began when he met Frieda Weekley in April *1912.* She was the aristocratic German wife (*née* von Richthofen) of the professor who had taught Lawrence at Nottingham. Lawrence left with her for Germany in May *1912.* So began a restless, nomadic, gypsying life, and a difficult but intensely intimate relationship that was to form the underlying theme of much of Lawrence's later fiction. While abroad Lawrence was working on *The Rainbow.* He returned with Frieda to England in June *1913* and while there met the critic John Middleton Murry and Katherine Mansfield, the writer. After living for a time in Italy, Lawrence and Frieda returned to England and were married in July *1914.* Meanwhile *Sons and Lovers* (*1913*), his first mature novel, was not selling widely, but it made him well known. His first volume of short stories, *The Prussian Officer and Other Stories,* was published in *1914;* his first volume of poems, *Love Poems and Others,* had been published in *1913.*

The years of World War I were a dark period in Lawrence's life. Wandering restlessly about England, he dreamed of an ideal community, "Rananim," into which to escape from the horrors of the contemporary world and intermittently urged his friends to join him in it, wherever it should be; unfortunately, these friends included many talented but egotistic people who disliked each other, as their later memoirs have shown, One of them at this time was Lady Ottoline Morrell, the wife of a member of parliament, who lived at Garsington Manor, near Oxford. Flamboyant, stately, and eccentric, with a beautiful home and considerable social power, she was a devoted and kindly patron of literature and the arts. Her striking personality emerges clearly in a collection of her writings, *Ottoline (1963,* ed. by R. Gathorne-Hardy). In *1915* Lawrence earnestly hoped that she would assist him in forming a new community. He met Bertrand Russell at Garsington; they planned a series of lectures together and exchanged many letters but soon quarrelled. The "Breadalby" chapter of *Women in Love* shows Lawrence's revulsion from the Garsington milieu. Meanwhile *The Rainbow,* which had already caused a rift between Lawrence and Edward Garnett, was officially banned as obscene. Lawrence, in despair with Lady Ottoline, turned to Murry; they collaborated in a short-lived magazine, *The Signature,* but the collaboration was not wholehearted, and Murry and Katherine Mansfield disliked *The Rainbow. A* planned emigration to Florida was postponed, partly because of Lawrence's health and partly because of difficulties over Frieda's passport; so in 1916 the Lawrences went to live in a cottage at Zennor, near St. Ives, Cornwall, and the Murrys came to live nearby. But there was conflict between the two couples, which may be reflected in *Women in Love,* in which "Gudrun" suggests traits of Katherine Mansfield. After conscription came into force (May 1916), Lawrence underwent several unpleasant experiences at the hands of the military authorities. His first "medical" and other wartime ordeals are vividly described in the "Nightmare" chapter of *Kangaroo* (1923). During 1917 an atmosphere of suspicion and hostility grew around the Lawrences in Cornwall; Lawrence was distrusted because he wrote and had a beard and because his wife was German. Ordered by the police to leave in October 1917, they spent the rest of the war in London and Derbyshire.

Postwar years

After the war Lawrence resumed his friendly relationship with Murry, who accepted an article of his for *The Athenaeum*, but the rejection of a second article led to another quarrel, and the two men did not meet for some years. Lawrence then thought of going to the United States, and in order to raise money from an American publisher wrote his brilliant, if idiosyncratic, *Studies in Classic American Literature* (1923). Meanwhile, Frieda left for Germany in October 1919; Lawrence went to Italy, where he met Norman Douglas at Florence, and Douglas' friend Maurice Magnus, thus beginning a tragicomic relationship described in Lawrence's introduction to Magnus' *Memoirs of the Foreign Legion* (1924). The Lawrences later took a house near Taormina in Sicily. Lawrence's trip to Sardinia at this time led to his travel book *Sea and Sardinia* (1921). During 1920 his financial position improved; his work began to sell in the United States, and he found a London publisher (Martin Secker) who was willing to reissue *The Rainbow* and to bring out *Women in Love* (1921). One of the books he sold to Secker was *The Lost Girl* (1920). In the summer of 1920 the Lawrences went to stay with Frieda's mother in Germany, and there Lawrence wrote *Fantasia of the Unconscious* (1922), a treatise on his psychological theories; shortly afterward he completed *Aaron's Rod* (1922).

Throughout 1921 Lawrence's desire to leave Europe was growing. Wandering about Italy, Germany, and Austria, with Frieda or alone, he grew restless, and his disgust with Europe was accentuated by trouble over *Women in Love,* which had been attacked in the London gutter press as "a loathsome study of depravity." He therefore accepted an invitation from an American couple, Earl and Achsah Brewster, who were studying Buddhism in Ceylon, to take a bungalow there with Frieda, But, soon repelled by Buddhism and Ceylon, the Lawrences went on to Australia. The novel that resulted from this visit, *Kangaroo,* shows Lawrence momentarily weary of his mystic doctrines of sex and power, and the messianism of *Aaron's Rod,* and conscious of the consequences to himself and Frieda of their mode of life. In the summer of 1922 Lawrence at last decided to accept an invitation from Mabel Dodge, a rich American woman who had admired *Sea and Sardinia,* to join her at Taos, New Mexico.

In a singular work, *Lorenzo in Taos* (1932; Lawrence was often called Lorenzo by his friends), Mrs. Dodge (Luhan) has described the difficult relationships between herself, Lawrence, Frieda, and others who settled there. In March 1923 Lawrence left for Mexico, where he became fascinated by Aztec civilization; retiring to a watering place on Lago de Chapala, he began *The Plumed Serpent.* He left for New York in July, planning to return to Europe but, homesick for Mexico, decided not to go; his indecision exasperated Frieda, and she went off to Europe alone. In December 1923 Lawrence arrived in London and was met by Frieda and Murry. During their estrangement, Murry had adversely reviewed Lawrence's major novels; moreover, Lawrence had quarrelled with Katherine Mansfield. After her death (January 1923) Lawrence and Murry were reconciled, but Lawrence was not enthusiastic about Murry's new paper, *The Adelphi,* and it appears likely that he was increasingly unhappy about the friendship developing between Frieda and Murry. Soon Lawrence was sounding out his friends to find out which of them would return with him to Mexico to form the nucleus of a new society: Catherine Carswell, in *The Savage Pilgrimage*, has described the famous Café Royal dinner at which Lawrence made this appeal. In March 1924 the Lawrences, with their aristocratic friend Dorothy Brett, left London for Taos, where opposition between Mabel Dodge and Frieda was complicated by "Brett's" presence. During the winter of 1924–25 Lawrence was seriously ill, and for the rest of his life his health became increasingly bad.

Lawrence returned to Europe in September 1925. In the same year his fine short novel *St. Mawr* was published (in a volume also containing "The Princess"), and his Mexican novel, *The Plumed Serpent,* appeared in 1926. While the Lawrences were living at Spotorno, near Genoa, the final breach occurred with Murry, because (according to Murry) he would not accept Lawrence's invitation to join the Lawrence circle there, which included Lawrence's sister, Frieda's daughter and the faithful "Brett." in April 1926 the Lawrences moved to Florence; Lawrence's interest in the ancient Etruscans bore fruit in his posthumously published *Etruscan Places* (1932). During 1926 Lawrence and Aldous Huxley became close friends. Lawrence's last years were chiefly spent in painting pictures and in writing and rewriting his last novel, *Lady Chatterley's Lover,* to discharge his accumulated bitterness about society and to assert his belief in the healing possibilities for civilization of a new relationship between men and women. Published in a limited edition in Florence (1928) and in Paris (1929), this appeared in an expurgated version in 1932. The full text was only published in 1959 in New York and in 1960 in London, when it was the subject of a sensational court case *(Regina* v. *Penguin Books Limited)* that turned largely on the justification of the use in this novel of "tabooed" sex words.

Friendship with Aldous Huxley

Lawrence's health grew rapidly worse while he was working on *Lady Chatterley,* and his *Pansies* (1929), light verses thrown off during this period, shows his social mortification also. At this time he also composed the poignant story *The Man Who Died* (1931). The pirating of *Lady Chatterley* in the United States and the closing by the police of an exhibition of his paintings in London (1929) angered him, and he relieved his anger through more sarcastic verses: *Nettles* (1930) and *More Pansies,* included in *Last Poems* (1932). From June 1928, when he left Florence, until his death, he went from place to place in a desperate struggle for life. He worked until the end, completing *Apocalypse* (published in 1931), a commentary on the Book of Revelation.

Lawrence died of tuberculosis on March 2, 1930, at a sanatorium in Vence, near Antibes.

Personality and genius. The fascination of Lawrence's personality is attested to by all who knew him, and it abundantly survives in his letters, his fiction, his poetry, his numerous prose writings, and in biographical accounts. Judgments on him range from Catherine Carswell's picture in *The Savage Pilgrimage* (1932) as charming, wise, and sympathetic, to Murry's in *Son of Woman* (1931; reprinted with new introduction, 1954), as tortured, sick, and filled with hatred. The only certain conclusion is that he was a many-faceted and complex being, the understanding of whose thought, "message," and art cannot for long be separated from investigation of his own psychological and social problems. But above all he was an original genius who achieved at least a considerable realization of his power in imaginative terms.

Technique and vision as novelist

As an imaginative writer, Lawrence is a remarkable compound of the naturalistic novelist and the poet, the realist, and the mystic. But on the whole he ranks with Melville and Emily Bronte rather than with Balzac and Tolstoy; he communicates a vision, rather than creates an autonomous world of characters. His unmistakable qualities are a flamelike intensity, an elevation, an urgent movement; he transmits a feeling of inward sympathy with all he depicts, whether it belongs to the human world or to the world of animal life or of inanimate matter.

Lawrence's novels do not give fully harmonious expression to his genius. The greatest of them, and the most representative of his powers as a novelist, are *The Rainbow* and *Women in Love*—large canvases in which much of the detail is blurred or drawn hastily but which as a whole have a sweeping imaginative effect. His subject here is the relations between men and women in marriage. In all his best work the depths of sexual relationship are sounded, its reality is illuminated, its meaning is restated with audacious courage. Lawrence's characters are not heroes of romance but "ordinary people"; the farm people of *The Rainbow,* the rootless Bohemians of *Women in Love,* belong to a recognizable social world. But these novels lack realism in that they do not bring out the pressure of social forces that, even had the lovers ignored them, would have made themselves felt. Lawrence's "world" is intensely subjective; the world outside the lovers is excluded or rejected with scorn. Although in his later novels the sexual theme is connected to other aspects of reality—in *Aaron's Rod,* to the communist upheaval in Italy after World War I; in *Kangaroo,* to an (imaginary) fascist movement in Australia; in *The Plumed Serpent,* to the struggle between Catholicism and the insurrectionary peasants of Mexico; in *Lady Chatterley's Lover,* to industrial conditions in the English midlands—yet the fiery intensity of *The Rainbow,* because of Lawrence's concentration on the sexual theme, is missing from these later works.

Characters of the novels

Lawrence's male characters are not as a rule fully defined. It is often hard to distinguish between a Will Brangwen and a Skrebensky *(The Rainbow),* a Rupert Birkin and a Gerald Crich *(Women in Love),* in their states of esoteric stress and turmoil. Don Cipriano of *The Plumed Serpent* seems to think and feel at times remarkably like the mysterious gamekeeper (Mellors) of *Lady Chatterley,* or the restless novelist-hero of *Kangaroo.* Lawrence's women are more distinct personalities, but they all have a noticeable family resemblance; the dominating willpower of Lawrence's mother, the imaginative sympathy of "Miriam" *(Sons and Lovers),* the tenacious feminine resistance of Frieda, reappear in various guises. Lawrence's novels describe the continuous history of a relationship between a single pair of people; sometimes the fictional dress is transparent, as in "The Captain's Doll." But generally in Lawrence's shorter fiction, his "tales," he achieves a greater impersonality and a more manifest creative power; stories as different as "England, My England," "The Horse Dealer's Daughter," or "The Woman Who Rode Away" testify to an imaginative range not always predictable from his novels.

Criticism and books of travel

Powerful and audacious as Lawrence's work in fiction is, it does not always create in the reader a sense of irresistible reality. Lawrence's experience and his sympathies were wide, but his writing shows a certain fixity of outlook, a narrow and obdurate concentration of vision. His later work sometimes shows a strain, a didactic harshness, an arbitrariness in the making of points or the development of situations. Some of this may be due to the lung disease that sapped his later years and that may have contributed to the moods of anger, sarcasm, or misanthropy recurring so frequently after 1920. But Lawrence's books as a whole show a remarkable breadth and generosity of interest. His work includes (besides fiction) poetry, drama, criticism, books of travel, and translations. His marvelous descriptive gifts record memorably his reactions to places and people all over the world, in England, Italy, Mexico, and Australia, and he gives a new form and importance to the journal of travel. In *Studies in Classic American Literature* he practices an equally unprecedented mode of criticism, studying the strange emergence of the new American "consciousness" and the American world vision. Even his excursions into metaphysics in works such as "The Crown" (1925), or *Fantasia of the Unconscious,* are full of his characteristic poetry and lit by glints of his attractive humour. The mystery and wonder of *Twilight in Italy* (1916), the power and wit of the *Studies,* the occasional profundity of one of his more neglected works, the "Study of Thomas Hardy" (in *Phoenix,* 1936), prevent these works from being relegated to a secondary place.

Lawrence's poetry

Lawrence's poetry deserves separate mention. In his early poems, except when he is writing in the dialect of his youthful environment, his touch is often unsure, he is too "literary," he is not fully the master of conventional forms. But by a remarkable triumph of development, he evolved a mode of writing that in its freedom and spontaneity allowed him to express what he called the palpitating moment of being and the naked self. His poetry is often of great biographical interest, as in the series of poems *Look! We Have Come Through* (1917). But his most original contribution to the art of verse is *Birds, Beasts and Flowers* (1923), in which he creates an unprecedented poetry of nature, based on his experiences of the Mediterranean scene and the southwestern United States.

No account of Lawrence's work, however brief, can omit his unsurpassable letters. In their variety of tone, vivacity, and range of interest, they convey a full and splendid picture of himself, his relation to his correspondents, and the exhilarations, depressions, and prophetic broodings of his wandering life. They form perhaps the best introduction to his work as a whole.

Style. Lawrence, though a great writer, was not always the most careful or exact. Emotionalism sometimes blurred his vision, and repetitiveness marred his style. Of this last mannerism he himself was fully conscious, and it is only fair to quote his own defense of it in a special preface that he wrote (September 1919) for the American edition of *Women in Love:* ". . . fault is often found with the continual, slightly modified repetition. The only answer is that it is natural to the author; and that every natural crisis in emotion or passion or understanding comes from this pulsing, frictional to-and-fro which works up to culmination." Lawrence's language in all his writings expresses the immediate feeling of life. Sometimes he falters, trying to seize some sensation or intuition too rapid and intangible to be caught; sometimes he overinsists, repeats himself, falls into jargon. But his cultivation of the "organic" style of composition, his refusal to isolate the reason from the passions and the nerves, can lead to great triumphs of symbolic art, which make the work of more deliberate artists seem contrived and cold; the scenes among the sheaves and the dunes in *The Rainbow,* the episode in *Women in Love* where Birkin shatters the image of the moon in water, are among these triumphs. Always he seeks to express, whether in novels, poems, or essays, the wholeness of man; and whatever he evokes becomes rich with the feeling of the deepest impulses of life. In the modern world, which he found turbid and confused, he worked through his art to discover form and coherence.

MAJOR WORKS

NOVELS: *The White Peacock* (1911); *The Trespasser* (1912); *Sons and Lovers* (1913); *The Rainbow* (1915; expurgated ed., 1916); *Women in Love* (completed 1916, privately printed 1920; first Eng. ed., 1921); *The Lost Girl* (1920); *Aaron's Rod* (1922); *Kangaroo* (1923); *The Boy in the Bush* (1924), in collaboration with M.L. Skinner; *St. Mawr* (1925), also contained the story, "The Princess"; *The Plumed Serpent* (1926); *Lady Chatterley's Lover* (privately printed 1928; expurgated ed., 1932; full text, 1959); *The Escaped Cock* (1929; published as *The Man Who Died,* 1931); *The Virgin and the Gipsy* (1930).

POETRY: *Love Poems and Others* (1913); *Amores* (1916); *Look! We Have Come Through* (1917; new ed., with additions, 1958); *New Poems* (1918); *Bay: A Book of Poems* (1919); *Tortoises* (1921); *Birds, Beasts and Flowers* (1923; new ed., with prefatory notes to each section, 1930); *Collected Poems,* 2 vol. (1928); *Pansies* (1929); *Nettles* (1930); *The Triumph of the Machine* (1930); *Last Poems,* ed. by R. Aldington and G. Orioli (1932).

SHORT STORIES: *The Prussian Officer and Other Stories* (1914); *England, My England and Other Stories* (1922), including "Samson and Delilah" and "The Horse Dealer's Daughter"; *The Ladybird* (1923; published the same year in the U.S. under the title *The Captain's Doll),* including "The Fox" and "The Captain's Doll"; *Sun* (1926); *Glad Ghosts* (1926); *Rawdon's Roof* (1928); *The Woman Who Rode Away and Other Stories* (1928); *Love Among the Haystacks, and Other Pieces* (1930).

PLAYS: *The Widowing of Mrs. Holroyd* (1914); *Touch and Go* (1920); *David* (1926).

TRAVEL BOOKS: *Twilight in Italy* (1916); *Sea and Sardinia* (1921); *Mornings in Mexico* (1927).

OTHER WORKS: *Movements in European History* (1921); *Psychoanalysis and the Unconscious* (1921); *Fantasia of the Unconscious* (1922); *Studies in Classic American Literature* (1923); *Reflections on the Death of a Porcupine and Other Essays* (1925); *Pornography and Obscenity* (1929); *Assorted Articles* (1930); *Apocalypse* (1931); *Phoenix,* ed. by Edward D. McDonald (1936, 1961); *Phoenix* 11, ed. by Warren Roberts and Harry T. Moore (1968).

BIBLIOGRAPHY. EDWARD NEHLS (ed.), *D.H. Lawrence: A Composite Biography,* 3 vol (1957–59), is of unique value as a detailed record of Lawrence's life compiled from various sources. Among the most important of the personal accounts by people who knew Lawrence are JESSIE CHAMBERS (E.T.), D H. *Lawrence. A Personal Record*, 2nd ed. (1965); FRIEDA LAWRENCE, *Not I, But the Wind* (1934); CATHERINE CARSWELL, *The Savage Pilgrimage* (1932); and JOHN MIDDLETON MURRY, *Son of Woman* (1931). RICHARD ALDINGTON, *Portrait of a Genius, But . . .* (1950); and HARRY T. MOORE, *The Intelligent Heart* (1954), are comprehensive biographical studies.

Lawrence's *Letters,* ed. by A. HUXLEY (1932) and by HARRY T. MOORE, 2 vol. (1962), are an indispensable asset to the study of his life and works. as are his *Letters to Bertrand Russell,* also ed. by MOORE (1948). Of the many modern critical accounts, pride of place should still be given to F.R. LEAVIS, *D.H. Lawrence: Novelist* (1955). A different critical emphasis is to be found in GRAHAM HOUGH, *The Dark Sun* (1956); ELISEO VIVAS, *D.H. Lawrence: The Failure and the Triumph of Art* (1960); and two valuable recent studies, JULIAN MOYNARAN, *The Deed of Life* (1963); and *HM.* DALESKI, *The Forked Flame* (1965).

Lawrence's own literary criticism is widely represented in *Selected Literary Criticism,* ed. by A. BEAL (1955).

(W.W R.)

Lawrence, T.E.

Thomas Edward Lawrence, an archaeological scholar turned war hero (as "Lawrence of Arabia") in 1914–18, became a myth in his own lifetime even before he published his own version of his legend, *Seven Pillars of Wisdom,* which is one of the greatest modem epics in the English language. Although it is Lawrence as myth and enigma who continues to inspire interest in the man and his work—for he renounced the concomitants of fame to enlist in the ranks—his accomplishments themselves were solid enough for several lives. More than a military leader and inspirational force behind the Arab revolt against the Turks, he was a superb tactician and highly influential theoretician of guerrilla warfare. His *Seven Pillars of Wisdom* is a stylistically self-conscious yet masterly memoir, unique in his age, while his sharply etched service chronicle, *The Mint,* and his mannered prose translation of the *Odyssey* have added to a literary reputation further substantiated by the immense and fascinating correspondence that establishes him as one of the major letter writers of his generation.

Early life. Lawrence was not his legitimate name, and he once wryly told a friend that his *Odyssey* might well be called "Chapman's Homer," for he was born in Wales (at Tremadoc, Caernarvonshire) on August 15, 1888, to Sir Thomas Chapman and Sara Maden, the governess of Sir Thomas' daughters at Westmeath, with whom he had escaped from both marriage and Ireland. As "Mr. and Mrs." Lawrence, the couple had five sons (Thomas Edward was the second) during what was outwardly a marriage with all the benefits of clergy. In 1896 the family settled in Oxford, where T.E. (he preferred the initials to the names) attended the High School and Jesus College. Medieval military architecture was his first interest, and he pursued it in its historical settings, studying crusader castles in France and (in 1909) in Syria and Palestine, submitting a thesis on the subject that won him first-class honours in history in 1910. (It was posthumously published, as *Crusader Castles,* in 1936.) As a protégé of the Oxford archaeologist D.G. Hogarth, he acquired a demyship (travelling fellowship) from Magdalen College and joined an expedition excavating the Hittite settlement of Carchemish on the Euphrates, working there from 1911 to 1914, first under Hogarth and then under Sir Leonard Woolley, and using his free time to travel on his own and get to know the language and the people. Early in 1914 he and Woolley, and Capt. S.F. Newcombe, explored northern Sinai, on the Turkish frontier east of Suez. Supposedly a scientific expedition, and in fact sponsored by the Palestine Exploration Fund, it was more a map-making reconnaissance from Gaza to Aqaba, destined to be of almost immediate strategic value. The cover study was nevertheless of authentic scholarly significance; written by Lawrence and Woolley together, it was published as *The Wilderness of Zin* in 1915.

Archaeological studies

Service during World War I. The month the war began, Lawrence became a civilian employee of the Map Department of the War Office in London, charged with preparing a militarily useful map of Sinai. By December 1914, he was a lieutenant in Cairo. Experts on Arab affairs—especially those who had travelled in the Turkish-held Arab lands—were rare, and he was assigned to intelligence, where he spent more than a year, mostly interviewing prisoners, drawing maps, receiving and processing data from agents behind enemy lines, and producing a handbook on the Turkish Army. Although restless and vaguely ambitious, he enjoyed the intrigue and confusion common to all headquarters staffs; in mid-1915, however, his brothers Will and Frank were killed in action in France, and T.E. was reminded cruelly of the more active front in the West. Egypt at the time was the staging area for Middle Eastern military operations of prodigious inefficiency—a sideshow of wasteful desert campaigns and a bloody, bungled frontal assault on the Dardanelles at Gallipoli. A trip to Arabia convinced Lawrence of an alternative method of undermining Germany's Turkish ally. In October 1916 he had accompanied the diplomat Sir Ronald Storrs on a mission to Arabia, where Husayn ibn ʿAlī, *amīr* of Mecca, had the previous June proclaimed a revolt against the Turks. Storrs and Lawrence consulted with Husayn's son Abdullah and Lawrence received permission to go on to consult further with another son, Fayṣal, then commanding an Arab force southwest of Medina. Back in Cairo in November, Lawrence urged his superiors to abet the efforts at rebellion with arms and gold and to make use of the dissident *shaykh*s by meshing their aspirations for independence with general military strategy. He rejoined Fayṣal's army as political and liaison officer.

Guerrilla leader

Lawrence was not the only officer to become involved in the incipient Arab rising, but from his own small corner of the Arabian Peninsula he quickly became—especially from his own accounts—its brains, its organizing force, its liaison with Cairo, and its military technician. His small but irritating second front behind the Turkish lines was a hit-and-run guerrilla operation, focussing upon the mining of bridges and supply trains and the appearance of Arab units first in one place and then another, tying down enemy forces that otherwise would have been deployed elsewhere, and keeping the Damascus-to-Medina railway largely inoperable, with potential Turkish reinforcements thus helpless to crush the uprising. In such fashion Lawrence — "Amir Dynamite" to the admiring Bedouins — committed the cynical, self-serving *shaykhs* for the moment to his king-maker's vision of an Arab nation, goaded them with examples of his own self-punishing personal valour when their spirits flagged, bribed them with promises of enemy booty and English gold sovereigns.

Capture by the Turks

Aqaba — at the northernmost tip of the Red Sea — was the first major victory, seized after a two-month march on July 6, 1917. Thenceforth, Lawrence attempted to coordinate Arab movements with the campaign of Gen. Sir Edmund Allenby, who was advancing toward Jerusalem, a tactic only partly successful. In November Lawrence was captured at Darʿā by the Turks while reconnoitring the area in Arab dress and was apparently recognized and homosexually brutalized before he was able to escape. The experience, variously reported or disguised by him afterward, left real scars as well as wounds upon his psyche from which he never recovered. The next month, nevertheless, he took part in the victory parade in Jerusalem and then returned to increasingly successful actions in which Fayṣal's forces nibbled their way north, and Lawrence rose to the rank of lieutenant colonel with the Distinguished Service Order (DSO). By the time the motley Arab army reached Damascus in October 1918, he was physically and emotionally exhausted, having forced body and spirit to the breaking point too often. He had been wounded numerous times, captured, and tortured; had endured extremities of hunger, weather, and disease; had been driven by military necessity to commit atrocities upon the enemy and even murder his own wounded to prevent the Turks from doing worse; and had witnessed in the chaos of Damascus the defeat of his aspirations for the Arabs in the very moment of their triumph, their seemingly incurable factionalism rendering them incapable of becoming a nation. (Anglo-French duplicity, made official in the Sykes-Picot Agreement, Lawrence knew, had already betrayed them in a cynical wartime division of expected spoils.) Disillusioned and distinguished, Lawrence left for home just before the Armistice and politely refused, at a royal audience on October 30, 1918, the Order of the Bath and the DSO, leaving the shocked King George V (in his words) "holding the box in my hand." He was demobilized as a lieutenant colonel on July 31, 1919, afterward calling his war's end status as a colonel "temporary" and "acting" (to expedite travel from Cairo to London).

Postwar activities. A colonel at 30, Lawrence was a private at 34. In between he lobbied vainly for Arab independence at the Paris Peace Conference in 1919 (even appearing in Arab robes) and lobbied vainly against the detachment of Syria and Lebanon from the rest of the Arab countries as a French mandate. Meanwhile he worked on his war memoir, acquiring for the purpose a research fellowship at All Souls College, Oxford, effective (for a seven-year term) in November 1919. By that time his exploits were becoming belatedly known to a wide public, for in London in August 1919 an American war correspondent, Lowell Thomas, had begun an immensely popular series of illustrated lectures, "With Allenby in Palestine and Lawrence in Arabia." The latter segment soon dominated the program, and Lawrence, curious about it, went to see it himself.

Adviser on Arab affairs

Lawrence was already on a third draft of his narrative when, in March 1921, he was wooed back to the Middle East as adviser on Arab affairs to the colonial minister, then Winston Churchill. After the Cairo political settlements, which redeemed a few of the idealistic wartime promises Lawrence had made, he rejected all offers of further positions in government; and, with the covert help of his wartime colleague, Air Marshal Sir Hugh Trenchard, enlisted under an assumed name (John Hume Ross) in the Royal Air Force on August 28, 1922. He had just finished arranging to have eight double-columned copies of the revised and rhetorically inflated 330,000-word text of ***Seven Pillars of Wisdom*** run off by the press of the ***Oxford Times*** and was emotionally drained by the drafting of his memoir. Now he was willing to give up his £1,200 Colonial Office salary for the daily two shillings ninepence of an aircraftman, not only to lose himself in the ranks but to acquire material for another book. He was successful only in the latter. The London press found him at the Farnborough base, the ***Daily Express*** breaking the story on December 27. Embarrassed, the RAF released him early the next month.

Finding reinstatement impossible, Lawrence looked around for another service and through the intervention of a War Office friend who had served in the desert war, Sir Philip Chetwode, was able to enlist on March 12, 1923, as a private in the Royal Tank Corps, this time as T.E. Shaw, a name he claimed to have chosen at random, although one of the crucial events of his postwar life was his meeting in 1922, and later friendship with, George Bernard Shaw. (In 1927 he assumed the new name legally.) Posted to Bovington Camp in Dorset, he acquired a cottage nearby, Clouds Hill, which remained his home thereafter. From Dorset he set about arranging for publication of yet another version of ***Seven Pillars,*** this one based upon editorial suggestions made by friends among whom he circulated five copies of the Oxford text—notably George Bernard Shaw, who suggested lowering the emotional pitch and blue-pencilling the possibly libellous and politically questionable passages. (It may have been the puritan in Shaw that resulted, too, in excision of the most gamy homosexual passages about the behaviour of the Arab troops when without women.) About 13 percent of the text was pruned for the famous 128-copy subscription edition of 1926, sumptuously printed and bound and illustrated by notable British artists commissioned by the author.

Major literary works

Seven Pillars of Wisdom (posthumous trade edition 1935, with subsequent editions since) remains one of the few 20th-century works in English to make epical figures out of contemporaries. Overpopulated by adjectives, often straining for effects and for "art," it is, nevertheless, an action-packed narrative, replete with incident and spectacle, filled with rich character portrayals and a tense introspection that bares the author's own complex mental and spiritual transformation. Confessedly inexact and subjective, it combines the distances of heroic epic and the closeness of autobiography.

To recover the costs of printing ***Seven Pillars,*** not even possible through the 30-guinea subscription price, Lawrence agreed to a trade edition of a 130,000-word abridgment, ***Revolt in the Desert.*** By the time it was released in March 1927, he was at a base in India, remote from the publicity both editions generated; yet the limelight sought him out. Unfounded rumours of his involvement as a spy in Central Asia and in a plot against the Soviet Union caused the RAF (to which he had been transferred in 1925 on the intervention of George Bernard Shaw and John Buchan with the prime minister, Stanley Baldwin) to return him to England in 1929. In the meantime he had completed a draft of a semifictionalized memoir of Royal Air Force recruit training, ***The Mint*** (published 1955), which in its explicitness horrified Whitehall officialdom and which in his lifetime never went beyond circulation in typescript to his friends. In it he balanced scenes of contentment with air force life with scenes of splenetic rage at the desecration of the recruit's essential inviolate humanity. He described dehumanization as an ironic good, the metaphor of minting conveying the concept of men being stamped into the uniform image necessary for discipline and interchangeability; and he aimed at communicating the feel of life at a training camp and at a working station, using short-journal-entry chapters, which ranged from the oppressive and humdrum, as well as the sentimental and lyrical, to the stark, the brutal, and the obscene. Published a generation late, its improprieties of language and its experiments in the surreal, the sadistic, and the grotesque lost their force. He had also begun, on commission from the book designer Bruce Rogers, a translation of Homer's ***Odyssey*** into English prose, a task continued at various RAF bases from Karāchi in 1928 through Plymouth in 1931. It was published in 1932 as the work of T.E. Shaw, but posthumous printings have used both his former and adopted names. The work remains an effective prose translation of Homer, blending simplicity and archaic affectation and using to advantage the know-how gained in primitive desert conditions and acquired as aircraft mechanic and boat handler to enrich the language with unhackneyed accuracy.

No additional book by Lawrence was published in his lifetime other than a minor translation he had done under his J.H. Ross pseudonym, Adrien le Corbeau's *Forest Giant* (1924), although his wartime *Arab Bulletin* dispatches to Cairo (adapted into *Seven Pillars)* appeared as *Secret Despatches from Arabia* and a miscellany as *Oriental Assembly* (edited by A.W. Lawrence), both posthumously in 1939. His first postwar writings, including a famous essay on guerrilla war and a magazine serial version of an early draft of *Seven Pillars*, have been published as *Evolution of a Revolt* (edited by S. and R. Weintraub, 1968). *Minorities* (1971) reproduced an anthology of more than 100 poems Lawrence had collected in a notebook over many years, each possessing a crucial and revealing association with something in his life.

Last years. Lawrence's last years were spent among RAF seaplanes and seagoing tenders, although officialdom refused him permission to fly. In the process, moving from bases on the English Channel to those on the North Sea and leading charismatically from the lowest ranks as Aircraftman Shaw, he worked on improved designs for high-speed seaplane-tender watercraft, testing them in rigorous trials and developing a technical manual (*The* 200 *Class Royal Air Force Seaplane Tender,* 1932) for their use. A stencilled and duplicated production, it was as unpretentious as his first book had been opulent.

Retirement and death

Discharged from the Royal Air Force on February 26, 1935, Lawrence returned to Clouds Hill to face a retirement, at 46, filled alternately with optimism about future publishing projects and a sense of emptiness. To Lady Astor, an old friend, he described himself as puttering about as if "there is something broken in the works . . . my will, I think." A motorcycling accident on May 13 solved the problem of his future. He died six days later without regaining consciousness.

Lawrence found despair as necessary as ambition. He lived on the masochistic side of asceticism, and the nonphysical part of his self-punishment involved creating within himself a sense of deep frustration to immediately follow, and cancel out, high achievement by denying to himself the recognition he had earned. At its most extreme it involved a symbolic killing of the self, a taking up of a new life and a new name. Under whatever guise, he was a many-sided genius who by his achievements denied himself the privacy he constantly sought and by the manufacture of his myth, however solidly based, created in his own person a characterization rivalling any in contemporary fiction.

BIBLIOGRAPHY. RICHARD ALDINGTON, *Lawrence of Arabia: A Biographical Enquiry,* new ed. with introduction by CHRISTOPHER SYKES (1969), a searching, often scurrilous attack on Lawrence; DAVID GARNETT (ed.), *The Essential* T.E. *Lawrence* (1951), the only anthology of Lawrence's writings, comprising in effect, a brief autobiography—includes extracts from *Leaves* in *the Wind* (a probable continuation of *The Mint,* which never went beyond a few pages) and *The* 200 *Class Royal Air Force Seaplane Tender;* ROBERT GRAVES, *Lawrence and the Arabs* (1927), a book vetted by Lawrence; PHILLIP KNIGHTLEY and COLIN SIMPSON, *The Secret Lives of Lawrence of Arabia* (1970), an expansion of their 1968 London *Sunday Times* articles including much new material but also some indefensible surmises; A.W. LAWRENCE (ed.), *Letters to T.E. Lawrence* (1962), does not include the correspondence of Mrs. Bernard Shaw, who wrote Lawrence hundreds of letters; T.E. LAWRENCE, *T.E. Lawrence to His Biographer, Robert Graves* (1938), and *T.E. Lawrence to His Biogrupher, Liddell Hart* (1938), both reprinted in one volume, 2nd ed. (1963), Lawrence's letters, notes, and interlinear emendations concerning both men's biographies, with their explanatory interpolations; *The Letters of T.E. Lawrence,* ed. by DAVID GARNETT (1938), and *The Home Letters of T.E. Lawrence and His Brothers,* ed. by A.W. LAWRENCE (1954), two collections that have assembled a substantial sample of his extant correspondence; A.W. LAWRENCE (ed.), *T.E. Lawrence, by His Friends* (1937), a mostly adulatory but biographically important collection, with an appendix listing the books in Lawrence's Clouds Hill library at the time of his death, with transcriptions of flyleaf inscriptions where they appear; B.H. LIDDELL HART, "T.E. Lawrence," in *Arabia and After* (1934), a biography written by the foremost writer on military tactics of his time; SULEIMAN MOUSA, *T.E. Lawrence: An Arab View* (1966; orig. pub. in Arabic, 1962), denigrates Lawrence's veracity and impact on the Arab revolt, and considers him a less-than-covert Zionist; ANTHONY NUTTING, *Lawrence of Arabia: The Man and the Motive* (1961), builds a portrait of Lawrence as masochist; TERENCE RATTIGAN, *Ross: A Dramatic Portrait* (1960), a play with acute psychological insight into Lawrence, but not dependable as history or biography; VYVYAN RICHARDS, *T.E. Lawrence* (1939), an admiring biography by a wartime friend; LOWELL THOMAS, *With Lawrence in Arabia,* new ed. (1967)—Thomas was a war correspondent in Arabia when he first met the subject of his famous lecture; JEAN BERAUD-VILLARS, *Le Colonel Lawrence; ou, La recherche de l'absolu* (1955; Eng. trans., *T.E. Lawrence: or, The Search for the Absolute,* 1958), one of the best studies of Lawrence—sound scholarship where it does not exaggerate Lawrence's Francophobia; STANLEY WEINTRAUB, *Private Shaw and Public Shaw: A Dual Portrait* of *Lawrence of Arabia und G.B.S.* (1963), Lawrence as seen from the perspective of his crucial postwar friendship with both Shaws—Bernard and Charlotte.

Bibliography: ELIZABETH W. DUVAL, *T.E. Lawrence: A Bibliography* (1938), out of date but still useful; J.M. WILSON, *A Bibliography of T.E. Lawrence* (1972), not a full-scale descriptive bibliography, but a checklist, with notes, of publications and textual variants, as well as a list of primary biographical sources.

(S.We.)

Lead Products and Production

Lead, a heavy, malleable, durable metal with a low melting point, has found a wide range of applications throughout history and in terms of world tonnage today remains one of the most important metals produced.

History. The Egyptians may have used lead as early as 5000 BC. Applications in the ancient world included use as weight standards, in coinage, for ornamental objects, for refining silver, as solder, and as a glaze for pottery. The Egyptians used red lead, an oxide of lead, as a cosmetic pigment. A lead figure dating from 3800 BC was found at the temple of Osiris, on the site of ancient Abydos, and is now in the British Museum. About 2000 BC the Phoenicians were mining lead deposits in Spain, and it was at about the same period that the Chinese first employed lead in their monetary system. Later, when silver coins replaced lead, the mining of lead was prohibited to prevent counterfeiting, but lead became and remained the principal metal used to debase silver for counterfeiting purposes into modern times.

Lead was well known in biblical times and is used metaphorically in Exodus in noting that the pharaoh's host "sank as lead" in the Red Sea. The Hanging Gardens of Babylon, built about 600 BC, are said to have had floors sheathed with sheets of lead soldered together to hold the soil and moisture.

Lead in Roman times

The lead mines at Laurium, Greece, flourished in the 5th century BC and in the 3rd century BC the Romans operated mines in the Rio Tinto region of Spain. The Romans used lead pipe extensively, and fabricated it in 15 standard-sized diameters, all ten feet (3 metres) long. Many sections of pipe in almost perfect condition have been unearthed at Pompeii, Rome, and Roman sites in England. Indeed, the Latin word for lead was *plumbum,* denoting water conductors or spouts; from it is derived the word plumber. The Romans also made wide use of lead in soldering.

Lead applications multiplied in the Middle Ages; lead "cames" held the fragments of stained-glass windows together, and lead gutters, drainpipes, and interior pipes were fashioned for churches, monasteries, castles, and houses.

Almost since the beginning of warfare, lead has been important in missiles because of its low melting point (which made it easy to fabricate) and its high density. Lead chunks were hurled with slings, and molten lead was poured on attackers from fortress walls. Lead bullets and shot have been used since the inception of firearms.

The medieval alchemist, who preceded today's chemist and metallurgist, considered lead the father of all metals, and its low melting point was a factor that led him to try to convert it to a substance that would transform other base metals into gold.

In the United States, now the world's major lead-producing country, lead mining and smelting began in Virginia in 1621. Lead ores from the Mississippi Valley were used from 1700 to 1867, when the first of the great western mines was opened.

Lead ores: galena. Galena (lead sulfide), by far the most important primary lead ore mineral, frequently contains as impurities zinc, copper, cadmium, bismuth, arsenic, antimony, and silver; often the silver value is greater than that of the lead, in which case it is a true silver ore. A primary mineral is formed by natural processes and unaffected by subsequent events, while a secondary mineral is affected in some way; for example, by weathering. Other primary lead minerals are clausthalite, altaite, jordanite, kobellite, boulangerite, aikinite, jamesonite, and bournonite. Carbonates and sulfates, formed by weathering, are the chief secondary minerals. The most common, cerussite (lead carbonate), is formed by the action of carbonate groundwaters on galena. Anglesite (lead sulfate) is derived from galena that has been contacted by sulfate solutions generated from the oxidation of sulfide minerals. Other oxide minerals of lesser importance are wulfenite, vanadinite, and pyromorphite. Lead is rarely found in its elemental form.

Over 95 percent of mined lead is from primary ores in which galena is the preponderant lead mineral. Galena is usually intermixed with other sulfides, chiefly sphalerite (zinc sulfide) and the sulfides of iron: pyrite and marcasite, less commonly with chalcopyrite (copper and iron sulfides). Lead ores constitute the chief source of silver, usually in solid solution with galena.

PRODUCTION PROCESSES

Mining. The widely varying characteristics of lead ores have given rise to many mining techniques, of which underground methods predominate. Most lead deposits occur at moderate depths in narrow channels called veins or in deposits of roughly spherical shape (lodes). Both veins and lodes are of varying thicknesses. Holes are drilled for blasting, often by large mounted diamond drills or carbide percussion drills. After blasting, the broken ore is sorted and loaded onto cars or continuous belts for transportation to the surface. Most modern lead mines are highly mechanized.

Ore treatment. Although galena contains 86.6 percent lead, it usually occurs dispersed with other minerals, and in some places, ores with as little as 3 percent to 30 percent lead are mined.

Preparation for roasting. Lead ore is prepared for roasting by grinding, flotation, and concentration. First, the ore is ground and classified by particle size: approximately 70 percent is less than 0.0017 inch in diameter, and 90 percent less than 0.0029 inch; some particles are less than 0.0003 inch. The ground and classified ore, which is a mixture of lead sulfide and worthless rock called gangue, passes to large tanks where flotation takes place.

Flotation separation process

Flotation, which has supplanted earlier methods of mechanical and gravity separation, takes advantage of the fact that water with a suitable wetting agent added to it, wets gangue but not lead sulfide. In the flotation tank, the ground and classified ore is mixed with water and some flotation agent such as oil. The lead sulfide attaches itself to the oil, which is turned into froth by bubbling air into the mixture, and then is floated off the top. The wet gangue sinks to the bottom of the tank and is discharged.

Concentration involves aggregating the tiny particles of lead sulfide; this is done with the aid of an agent such as lime or alum. Filtered to reduce its water content to about 10 percent, the concentrate then passes to the smelter. Concentrates include 45 to 60 percent lead, along with varying amounts of impurities: 10 to 30 percent sulfur, up to 15 percent zinc, 8 percent iron, 3 percent calcium oxide, 3 percent copper, 2 percent antimony, and small amounts of arsenic, bismuth, gold, silver, and other elements.

Roasting. Before lead concentrates can be added to the furnaces, they must be treated to lower the sulfur content because the ordinary furnace does not reach a high enough temperature to reduce lead sulfide. Substances such as limestone, iron ore, silica, coke, etc., are mixed with ore concentrate; these fuse with the sulfur in the lead sulfide to form compounds. The ore mix is laid on a moving grate; air is blown through the mass; sulfur acts as the main fuel, forming sulfur dioxide, which is usually recovered for sulfuric acid manufacture. The mix is fused into a strong, homogeneous material called sinter, comprised primarily of oxides of lead, iron, and zinc, with substantial amounts of metallic lead and a little sulfur. The porous sinter mass is broken into lumps as it is discharged from the moving grate. Sinter clinkers up to five inches (125 millimetres) in size are passed over grates to remove the fine particles, which are stored for blending with other materials prior to reduction in the blast furnace. Reduction is the removal of oxygen from a compound; for example, reduction of lead oxide yields metallic lead.

Smelting. Smelting is the continuous reduction of ore constituents to metal, generally carried out in a blast furnace, which consists mainly of a water-jacketed shaft or column up to 24 feet (7.2 metres) high with a rectangular cross section and is loaded from the top. The lead or charge consists of properly proportioned sinter, limestone, coke, silica, and other fluxes. Orifices called tuyeres, through which air is blasted, are positioned just above a crucible at the bottom of the shaft. The crucible collects molten lead and is arranged with a suitable siphon well so that the molten lead can be removed from the furnace without affecting the blast pressure within the furnace. Ports to discharge slag and metallic waste (matte) are located near the top of the crucible. Sight glasses that allow for visual inspection of the smelting reaction are located in the tuyeres. Air is injected to aid combustion and to complete the formation of metallic oxides, which are then chemically reduced to metal by the coke and carbon monoxide present. Nonmetallic waste forms a slag with the fluxing materials. A balanced smelting charge of iron, limestone, and silica yields a slag that is fluid. When the coke and sinter ratio is not correct, there is an improper reduction of ore to metal.

Blast-furnace operation

Reverberatory furnace smelting, in which a furnace charge is held in a basin-like vessel and heated by flames on the surface to effect the reduction, is rarely practiced in lead refining as it requires that the ore contain 70 percent or more lead.

The output of the blast furnace is lead bullion, which contains dissolved metallic and nonmetallic (oxide and sulfide) impurities. Slag, matte, and other products of the blast furnace are either further treated to recover metal values or scrapped.

Drossing. Lead bullion is maintained in a molten state just above its melting point in a drossing kettle, which contains up to a hundred tons. (The term dross refers to any solid scum floating on top of a metal bath comprised of metal oxides, sulfides, metallic compounds, etc.) At temperatures of about 330" C, remaining impurities are brought to the surface by stirring, by the addition of small amounts of sulfur, and by agitation with submerged air lances and are removed by skimming.

Refining. The bullion is transferred to the refinery either as a pumped liquid or as large cast blocks, weighing as much as ten tons.

Electrolytic refining. Electrolytic refining involves purifying the bullion by means of electricity. If electrolytic refining is to be practiced, the bullion is cast into anodes (or plates) weighing several hundred pounds. These are hung in electrolytic tanks where they dissolve; pure lead is deposited on a thin sheet of lead that serves as the cathode. Impurities left behind can be recovered by many complex operations.

Kettle ***refining.*** Kettle refining of bullion is complex, but the recovery of by-product silver and gold is simpler and faster. All of a number of kettle-refining processes or modifications have the following steps: softening, desilverizing, dezincing, and debismuthizing. Softening refers to removal of impurities that harden lead, such as antimony, arsenic, tin, zinc, and others. Large-capacity steel pots or reverberatory furnaces are used to hold the bullion at red heat. Blowing with air or applying suitable oxidizing reagents oxidizes impurities. The oxidation is selective and oxide drosses or slags in which each element is concentrated can be removed by skimming.

Oxidation of impurities

Silver is removed from softened lead by adding zinc and raising the temperature sufficiently to melt it (about 540" C). With stirring, the molten zinc reacts, forming compounds with gold and silver, plus traces of copper and nickel. 'These zinc compounds are lighter than the metallic lead; on cooling, they form a crust that is removed. The gold and silver are recovered in a parting plant. The lead is now treated for removal of the remaining zinc by a vacuum process. The zinc recovered from the vacuum retort. along with that from the parting plant, is reused.

If the bismuth content is too high, the softened lead is next debismuthized. The operation is similar to desilverizing, except that a combination of calcium and magnesium metals are used as the reagents to form high-melting-point intermetallic compounds with bismuth, which are skimmed off and treated for recovery of bismuth.

The refining processes yield pig lead of good marketable uniformity and purity. Large quantities of pig lead are available, 99.999 percent pure.

MAJOR USES

Lead is widely used both in the metallic form and in chemical compounds.

Storage batteries. The lead-acid storage battery, the largest single use for lead, remained in the early 1970s the most dependable apparatus by which electrical energy can be conveniently stored for future use. Economy, reliability, and the ability to deliver large amounts of energy in a short time have made it an essential part of every automobile. Storage-battery grids require a metal with a low melting point, high corrosion resistance, and certain electrical properties. The modern automotive SLI (starting, lighting, ignition) battery consists of about one-third lead metal (grids, posts, and connectors) and two-thirds litharge (lead monoxide). The lead metal, 6 to 12 percent antimonial lead plus a small amount of tin, is almost wholly recovered by smelting secondary materials, mostly scrap storage batteries. Litharge mixed with sulfuric acid to a paste consistency for incorporation into the metal grid is usually made from primary (mined) lead because impurities such as silver and bismuth cannot be removed economically during refining of secondary (salvaged) lead.

Storage batteries are also used as a standby source of power for telephone exchanges, power companies, hospitals, submarines, etc. The thicker grids used for this type of service do not require the casting properties of the SLI batteries. In order to minimize the self-discharge caused by antimony-containing grids, pure lead or calcium-lead alloy is used. The calcium content of 0.06 to 0.08 percent in lead yields an alloy of essentially the same physical properties (primarily improved mechanical strength) as 4 percent antimonial lead, necessary characteristics in battery production and use. Large industrial batteries supplying energy for electric locomotives, industrial trucks, and some experimental electric automobiles usually have antimonial lead grids.

Chemical lead. Lead is used extensively in the construction of chemical-plant equipment. If unalloyed lead is used it is generally of the grade commonly known as chemical lead, sometimes termed acid lead, or copper lead. The term chemical lead denotes a metal of very high purity: standards vary slightly from country to country. Chemical lead forms a tightly adherent, insoluble lead sulfate film in sulfuric acid solutions. As sheet, pipe, rod, etc., it is readily welded (burned) into complex structures for holding and conveying sulfuric acid mixtures. Other materials, such as plastics, rubber, etc., have been used for similar operations, but lead's demonstrated corrosion resistance over a wide range of conditions, its ease of repair, and, after a long useful life, its high salvage value have enabled it to retain its position as a material of construction in the chemical industry. A 6 percent antimony-chemical lead alloy is used where greater strength or fatigue resistance is required. The use of 6 percent alloy is restricted to temperatures below 125° C because of its lower melting point. Similar alloys are used with phosphoric acid, hydrofluoric acid, chromic acid, and other corrosive environments where insoluble protective films are formed. Each different smelter uses a proprietary alloy as insoluble anode in chromium plating, and electrowinning (recovery by electrolysis) of copper. To achieve a higher order of strength, lead-lined and lead-covered steel pipe, fittings, valves, and vessels are used with lead metallurgically bonded to the substrate to maintain suitable heat transfer.

Other uses. The electric cable in industry is a major user of lead. Lead alloys, usually 1 percent antimonial lead, can be easily extruded, forming an impervious corrosion-resistant cover on telephone and power cables. When the cable is replaced, the sheathing can be recovered by a simple stripping operation, refined, and used to cover new cable.

Lead has a longer record of satisfactory performance than any other water-service pipe material. The flexibility of lead pipe allows adjustment to ground settlement without damage, and minimizes the number of joints. Lead is also used for caulking joints in cast-iron water mains and sewer and soil pipes. Because it withstands the effects of polluted air and water, lead is useful in drainage and venting systems.

Sheet-lead roofing and flashing have long been used on buildings because of their durability under all types of climatic conditions. The development of special alloys capable of resisting buckling due to alternating high and low temperatures (thermal cycling) has caused a renewed interest in the use of lead in modem architecture. Special joint designs have also helped in the construction of essentially maintenance-free roofs, reflecting pool liners, etc., and soft lead cames are easily worked to form leaded art-glass windows.

Architectural applications

Ammunition, both military and sporting, accounts for a large use of lead. Spherical shot for shotgun use is made by pouring molten 2 to 6 percent antimonial lead, with up to 1 percent arsenic added, through suitable sieves at the top of a 125-foot tower. The molten alloy, while dropping, forms a true sphere before solidifying near the bottom of its fall. The shot is collected in water, removed, dried, and sorted for size and sphericity. Military ammunition is formed into bullets by swaging (cold-shaping) extruded wire in suitable dies.

The densest of the common metals, lead is widely used for radiation shielding. It prevents the penetration of gamma rays and neutrons, and since it does not itself become radioactive, it may be used continuously. High density glasses, containing as much as 80 percent lead oxide, are used as windows in radiation installations.

Due to its limpness and high density, lead is finding expanding use in the control of noise pollution. Thin-cast sheet lead is used for encasing noisy machinery, or in room partitions for keeping noise out. Jet airliners use a lining of an adhesive-backed layer of vinyl plastic compounded with lead powder to keep the noise level in the passenger compartment to a minimum.

LEAD ALLOYS AND COMPOUNDS

Lead alloys. The mechanical properties of pure lead are quite poor; therefore, when more strength is required, lead is alloyed with other elements.

Antimony. The most common metal used is antimony, which on additions up to 12 percent by weight not only increases the tensile strength of the alloy as much as four times but also lowers the melting point. As noted earlier, antimonial lead is used as a storage-battery grid metal.

Tin. Tin alloyed with lead in amounts from 2 to 70 percent by weight forms the solders widely used in industry. Not only is the strength of the alloy increased with higher tin content but the melting point decreases from 327° C for lead to 183° C for 63 percent tin-37 percent lead. Solders of 2 percent tin-lead are used for automatic soldering of tin-coated steel cans. Industrial solders, used for such applications as automotive radiators, contain from 5 to 30 percent tin. The electronic solders are generally of the lowest melting point (63 percent tin), so that the temperature-sensitive components will not be damaged.

Industrial soldering alloys

Casting alloys. Lead alloys containing antimony and tin form a series of low melting metals with excellent casting properties and the ability to produce intricate castings with excellent detail. Linotype metal with 4 percent tin and 12 percent antimony, used for casting the finest printer's type, exhibits suitable strength for use on a press. Electrotype and stereotype metals used by printers also have excellent casting properties. Ornamental castings, which are usually plated with silver or other metals, are made with 11 percent antimonial lead, with about 0.5 percent arsenic added to increase the strength and to yield better detail and a smooth-surface finish. Lead alloyed with varying combinations and amounts of bismuth, tin, cadmium, antimony, indium, or gallium yields a series of metals that have very low melting points, culminating in one so low that it can be melted in the palm of the hand. Such alloys, rated as to melting point, are widely used for equipment of very high reliability.

Bearing metals. Lead-base bearing metals are usually antimonial lead with additions of tin or copper or both and arsenic to increase the compressive strength. The ability of these alloys to maintain a thin film of lubricating oil at relatively high loads and speeds prevents wear on the bearing-metal surface. The alloys are sufficiently soft so that even in case of lubrication failure no damage is done to the rotating shaft. The use of thin layers of bearing metal, with a stronger backing material reinforcing the lead alloy, increases the load-carrying capacity of such bearings.

Lead **compounds.** At least a third of all lead produced is used in chemical compounds. Most of the uses of lead discussed thus far are not consuming uses, in that the metal eventually returns as scrap for secondary refining and reuse. The chemical compounds, which generally use corroding lead (lead refined to a high degree of purity) as a base, are generally dissipated into the atmosphere or elsewhere so that recovery is impossible.

Gasoline additives. A major use of lead compounds in the 1960s was in gasoline additives, such as tetraethyl lead to form the antiknock, high-octane gasoline required by high-compression internal combustion engines. This use was declining in the 1970s owing to air-pollution problems.

Paint pigments. The earliest known and one of the most widely used lead paint pigments is white lead (basic lead carbonate). A process for making white lead starts with metallic lead blown with steam or air to produce a fine powder, which is then treated with acetic acid, air, water, and carbon dioxide gas in long, revolving wooden cylinders. The process requires about 12 to 14 days for conversion. Recent modifications of the process use litharge as the starting reagent to shorten the production time. The outstanding characteristic of white lead is its chemical affinity for paint vehicles, becoming an integral part of the paint film. This reinforcement results in a tough, flexible film, unusually resistant to embrittlement.

Basic lead sulfate, also called basic sulfate white lead, is a pigment used in mixed paints with the same properties as basic carbonate white lead.

Red lead (Pb_3O_4) is manufactured in furnaces by heating litharge at a carefully controlled low temperature. Litharge takes up more oxygen to form red lead. **A** part of the litharge usually remains unconverted in the core of red lead particles. **A** 98 percent true red lead is used for paint.

Litharge. Litharge (lead monoxide) is one of the most important and widely used metallic compounds. It is produced by melting pig lead in the presence of air, or occasionally by burning lead to a fume in the presence of oxygen. It is possible to produce a specific type of litharge for almost any use, and the various commercial grades are generally known by the uses to which they are put. Storage batteries account for the largest consumption of litharge. Battery litharge is very pure and may be blended with some red lead and other additives to form the active material of the plates. Glassmaker's litharge is a high-purity flake or powder, which must be free of iron or other impurities that would discolour the glass. Similarly, pottery maker's and enameller's litharge must be pure. Porcelain-enamelled aluminum sheets have litharge as a major constituent in the coating. Colourmaker's litharge is reacted with acetic acid to form lead acetate. Various compounds added to the lead acetate precipitate a number of pigments, such as chrome yellow, chrome red, and chrome green.

Other compounds. Lead arsenate, an insecticide, can be prepared by dissolving litharge in arsenic acid, with acetic or nitric acid as the catalyst, or litharge may be converted to lead acetate or nitrate and allowed to react with sodium arsenate.

Lead azide is an initial detonating agent for high explosives, such as TNT. Crystalline lead azide is prepared by the slow addition of a dilute solution of sodium azide to a constantly stirred dilute solution of lead acetate or nitrate. The precipitated azide is washed with water and stored under water or a 50–50 mixture of water and ethyl or methyl alcohol. By varying procedures it can be prepared as a colloid or treated with starchy compounds called dextrins to achieve certain properties.

Lead dioxide (PbO_2) is formed electrolytically by anodic oxidation of metallic lead. In neutral or alkaline solutions the alpha crystalline form of lead dioxide is formed. In acid solutions the beta crystalline form results. Both forms have been identified in the positive plates of storage batteries.

Unless stabilizers are added, the widely used vinyl plastics (polyvinyl chloride) suffer a breakdown due to heat and light, rendering the plastic brittle and discoloured. Stabilizers take up hydrogen chloride released in the degradation. Theoretically, litharge would be a very efficient acid acceptor, but the nature of vinyl stabilization goes beyond mere acid acceptance, and various other chemical and physical actions must be incorporated into a desirable stabilizer or combination. A series of reaction products of litharge with various organic and inorganic acids are widely used as vinyl stabilizers.

Lead compounds as vinyl stabilizers

Lead oxide was used as a major constituent of glass by the Chinese as early as the 6th century. The glass was strongly discoloured by impurities such as copper. The use of lead oxide in glass to achieve clarity was unknown until the invention by George Ravenscroft of English crystal, or flint glass, in 1675. Lead oxide yields a glass with a high index of refraction, which accounts for the brilliance of cut lead crystal and for its use in optical lenses. It also lends weight and resonance to the glass.

Economic importance. On the basis of tonnage of metal refined, lead is the fifth most important metal, after iron, aluminum, copper, and zinc.

World consumption of primary lead for the mid-1970s exceeded 3,000,000 tons annually, of which about 40 percent was consumed by the U.S., a third by the Soviet Union, and the remainder by the rest of the world.

Learning, Animal

Ways of defining learning and of interpreting observed behaviour depend, in a fundamental way, on the view taken of the basic nature of the learner. Some of the difficulties in definition are considered in the article LEARNING THEORIES.

All living organisms adjust or adapt to changes in the stimulation they receive from their environment. In other words, they receive and store information; this is in large measure equivalent to saying that they learn. In a very limited and special sense it can be said that plants learn (insofar as they receive and store information), and efforts to distinguish between animals and plants on this basis alone are not satisfactory. Indeed, certain groups of organisms—*e.g.*, slime molds and Euglena—can, at one stage of their life cycle, be regarded as plants and at another as animals. From the point of view of learning, however, the most important difference is that plants on the whole are fixed or sedentary, while animals generally are mobile and active.

Animals are in fact essentially predatory-behaviour machines that must go out and find and catch their food; or at least they must be equipped with special devices, as in so many marine organisms, for filtering food out of water, sweeping it toward themselves, and ingesting it in some form or other. This emphasis on the importance of movement in animals is absolutely fundamental. Once an animal starts to evolve movement, as distinct from being passively carried along by currents in the lake or sea or by wind, it may evolve in two directions: (1) it can either move in an entirely random manner, in which case the movement itself must bring it into contact with all that it needs (including, of course, food, oxygen, and water) and ensure normal development and survival of a sufficient proportion of the species; or (2) if such random movement is not sufficient, then there must be directed movement, which can be of many different kinds (see LOCOMOTION, ANIMAL). The first essential of directed movement is that there must be special devices for detecting objects in the environment that can give guidance, either direct or indirect. The more precise and elaborate these movements become, the greater will be the evolutionary pressure to develop more and more precise sense organs. If an animal is to move in a particular direction it will be able to perform much better by being elongate, perhaps to some extent "streamlined." This, of course, implies that the most acute sense organs, as well as the point at which food is absorbed, will tend to be at the front end—*i.e.*, the animal should have some kind of "head." Even below this level of evolution, however, animals use information collected about past events as a guide to the future, evidence of having learned some of the predictable regularities in their environments.

Much of the potential for animal behaviour seems so strongly ingrained and so very little influenced by past experience that it may be called inborn, unlearned, or instinctive; that is to say, many animals are innately programmed directive machines (see INSTINCT). It is when organisms can perceive and change their behaviour as a result of their perceptions that they are said to learn. Learning, then, is the organization of behaviour as a result of individual experience. This definition indicates the minimum qualities a phenomenon must have in order to be classed as an example of learning and avoids the confusion that is bound to result if an attempt is made to define the manner in which the phenomenon is brought about. Although the views as to the ways in which learning is mediated in an organism continuously change with the acquisition of new knowledge about structure and physiology, the basic idea of learning remains the same. That is to say, learning must first be defined behaviorally, after which it can be considered physiologically, when possible.

Definition of learning

It has often been suggested that learning in general is adaptive—it manifests itself by adaptive changes in individual behaviour as a result of experience. It is true that most learning usually is adaptive in the sense that it is a mode of adjustment that enables an animal to survive. This in fact has been included in the definition, because the word organization itself implies adaptiveness in some degree. Learning is also often regarded as something that is relatively long lasting, something that has a more or less enduring effect on behaviour. Again, this fits in with the general definition of learning, but the length of its effect may vary from changes of exceedingly brief duration to changes that last a lifetime.

The following articles are related to the subject of learning in animals, including man: BEHAVIOUR, ANIMAL; INSTINCT; LEARNING, PERCEPTUAL; LEARNING, PSYCHOMOTOR; LEARNING THEORIES; MEMORY: RETENTION AND FORGETTING. This article is divided into the following major sections:

- I. Types of learning
  - Habituation
  - Associative learning
- II. Behavioral and physiological aspects of learning
  - Stimulus–response and cognitive mechanisms
  - Neurophysiological mechanisms
- III. Evolution of learning ability
  - Learning in invertebrates
  - Learning in vertebrates

I. Types of learning

HABITUATION

It is almost impossible to divide the various types of learning into categories that are mutually exclusive, that can be sharply defined, and that cover the entire range of animal learning. It is convenient, however, to start with habituation, because this phenomenon appears to be the simplest form of learning. It can be defined as the relatively persistent waning of a response as a result of repeated or continuous stimulation that is not associated with any kind of reward or reinforcement. Habituation is further characterized as being specific for a particular stimulus, and its relative permanence also distinguishes it from such temporary manifestations as fatigue and sensory adaptation (*e.g.*, becoming oblivious to distracting sounds). Habituation thus implies a tendency of an animal merely to drop those responses that experience indicates are of no value in its life. As the simplest form of learning, habituation is quite effective in lower animals because organisms do not need more than one type of sensory mechanism to become habituated to a particular kind of stimulus. This rules out, of course, any learning by these organisms in which two or more different kinds of stimuli, received by two or more different kinds of sensory mechanisms, must be coordinated to produce either a new response or an old response in a new context.

Simplest form of learning

As a form of learning, habituation is known to occur in response to all types of stimuli and in animals of all grades of organization, including the most primitive one-celled organisms (protozoans). A classic example of habituation is provided by the snail Helix albolabris. When the surface on which the snail is crawling is subjected to a mechanical shock, the snail immediately withdraws its tentacles for a short time. If the mechanical shock is repeated at regular intervals and if the intensity of the stimulus is maintained at a constant level, the extent and duration of tentacle withdrawal steadily decrease until the animal has become completely indifferent (habituated) to the stimulus. If, during the course of the experiment, the intensity of the stimulus is increased, the response reappears for a short time, only to wane again on repetition. In due course the animal becomes so accustomed to the vibrations that a series of 50 to 60 of them will not produce any visible response; indeed, it may be difficult to cause complete tentacle withdrawal even with a very violent jolt.

The investigation with the snail provides ample evidence that the effects produced by habituation are not ordinary physiological fatigue. This is because a more intense stimulus tends to restore the response to the original stimulus, and "fatigue" that can be overcome by a more intense stimulus of the same kind is a contradiction in terms. If, on the other hand, the vibrations are interrupted by 30-second intervals during which the animal receives no stimulation, the response resumes after the jolting begins again. If the process is continued, however, a half-minute rest no longer suffices to restore the response, indicating that there are different degrees of habituation that could doubtless be graded according to the length of rest time necessary to reactivate response.

In contrast to the simple habituation just described, the waning of responses in higher animals incorporates a number of complicating features, even though the phenomena appear behaviorally identical to those in lower animals. Rats in which the spinal cord has been severed from the brain, for example, will continue to exhibit behavioral changes that are clearly habituatory in nature and that last for days. Moreover, although the orientation reflex in dogs (the innate pattern of reactions that occur in response to a stimulus) can be distinguished or changed by habituation, the process seems to indicate that some sort of complex reorganization in the nervous system is responsible for or superimposed upon the decrease in strength of the original response. It would appear, therefore, that the mechanisms underlying habituation become more elaborate as organisms become more complex.

ASSOCIATIVE LEARNING

Classical conditioning. Although the philosophical concept of associationism (the connection between a stimulus and response that had not existed before) has had a long and significant history traceable back to ancient times, and although the concept was applied to experimental studies of human learning in the 1880s, modern psychological study of associative learning in animals did not begin until just before the end of the 19th century. At that time a group of Russian physiologists became the first to offer some sort of physiological explanation of how a previously fixed and perhaps inherited behaviour pattern might be modified and adapted by becoming associated with new stimuli through learning.

Pavlov's *experiments*. During his studies of the physiology of digestion, Ivan Pavlov, who became by far the most influential of the Russian investigators at the end of the 19th century, stumbled on the fact that the quantity and timing of the secretion of salivary juices in the dog are controlled by the brain under the influence of sensory stimuli that shortly precede the release of the saliva. In an attempt to show the quantitative relationship between the stimuli and the subsequent flow of saliva, Pavlov devised an experiment in which he trained a dog to stand perfectly Still in a soundproof chamber. A special harness worn by the animal made it possible for Pavlov to measure the salivary flow when food, in the form of meat powder, was mechanically offered to the dog or placed directly on its tongue.

Conditioned reflex or classical conditioning

It was his study of salivation in dogs that led Pavlov to his theory of the conditioned reflex, or classical conditioning, as it is now usually called. Pavlov at first thought the mechanism that produced the flow of saliva as a result of the taste of meat was an inherited or fixed reflex (unconditioned) response. (A reflex is a simple involuntary response to a stimulus, such as the quick withdrawal of the hand when it touches a hot object.) He then found, however, that he was able to influence (condition) that response by exposing the dog, immediately before the meat powder (unconditioned stimulus) was offered, to such cues (conditioned stimuli) as a bell, a buzzer, or a flashing light. Thus, by his experimental method, Pavlov was deliberately eliminating, as far as possible, all general behaviour and behavioral reactions of the dog so as to isolate this one response, the conditioned reflex. Essentially, then, classical conditioning denotes the process by which an animal acquires the capacity to respond (*e.g.*, to salivate) to a given stimulus (bell, buzzer, etc.) with the same reflex action that can be elicited by another stimulus (the reward or reinforcement) when the two stimuli are applied concurrently (or in overlapping sequence) for a number of times.

Anticipatory behaviour

Limitations of classical *conditioning*. Pavlov's work led to an enormous spate of research in the physiology of behaviour, and for a long time the conditioned reflex provided the best technique for enabling at least a part of a learning process to be investigated quantitatively and to be subjected to an exact analysis. As work advanced over the years, however, it became increasingly evident that the classical-conditioning experimental technique artificially isolates, to an extreme degree, part of the total learning process of the higher animals—particularly that of mammals, such as rats and man. Moreover, the reflex relationship between stimulus and response is not a simple one. Indeed, because higher animals always respond in some degree to the conditioning situation as a whole, not just to the stimulus alone, it became apparent that the conditioned response in such animals is always in fact "anticipatory." The animals behave as if they were "expecting" the unconditioned stimulus rather than just associating the unconditioned response with the new stimulus. In other words, a dog does not salivate in response to a bell or other stimulus simply because it has been trained to do so (the conditioned response) but because it is anticipating the food that it will receive (the unconditioned stimulus). Furthermore, although the classical-conditioning procedure may involve the association of a new stimulus with the unconditioned response, it has been found that the intensity of the conditioned response is seldom the same as the unconditioned one—*i.e.*, a dog does not salivate as much in response to a buzzer as it does in response to food—a fact that Pavlov failed to observe adequately.

If the restrictions on the animal's freedom of movement usually imposed in conditioning experiments are removed, the conditioned response is then accompanied by behaviour that appears to the observer to be appetitive to the occurrence of the unconditioned stimulus. Still further, it has been shown that dogs, for example, will salivate to a conditioned stimulus even if, during the training trials, salivation to the unconditioned stimulus is blocked by the drug atropine. Thus, in higher animals at least, it now appears that conditioning occurs as a consequence of the simultaneous stimulation of two areas of the brain, for if one part of the brain is blocked, another part can still respond. At the level of such lower animals as the earthworm, on the other hand, conditioned behaviour can be regarded as pure classical conditioning because it seems to involve little more than a simple change in stimulus–response relations. Hence, as defined behaviorally, classical conditioning, like habituation, covers changes that differ greatly in complexity.

The pattern of activity in trial-and-error learning

Trial-and-error learning. The concept of trial-and-error learning resulted from watching animals obtain rewards (*e.g.*, food) upon the successful completion of certain tasks, such as rats finding their way through a simple maze or kittens escaping from an enclosed box by pressing a lever. In such situations the animal is always active, directing its attention first to one and then to another part of the experimental chamber; sniffing, pushing, pulling, biting, clawing, and, above all, running around until it more or less accidentally hits upon the action or system of actions that brings the desired reward. The action itself need not be and, indeed, seldom is immediately directed toward the achievement of a desired goal; the kitten in the box or the rat in the maze is not in a position to see, even if it could understand, the relationship between its actions and the acquisition of the desired objective. Thus, trial-and-error learning involves the use of a reinforcement (*i.e.*, a reward) to encourage the

The Two Types of Conditioning as Components of Trial-and-Error Learning

key: **C.A.$_i$—involuntary** element in consummatory act (*e.g.*, salivation); **C.A.$_v$—voluntary** element in consummatory act (*e.g.*, mastication); **Rsp.$_v$—voluntary** act as part of appetitive behaviour giving **St.$_p$**; St.,—external stimulus (*e.g.*, buzzer); **St.$_p$—stimulus** arising within the animal (proprioceptive)

'That is, food.

selection of a proper response from a variety of behaviours in a given situation, until eventually an association is established between the stimulus or situation and the one correct response for obtaining the reinforcement. In such cases the reinforcement is preceded by both the stimulus and the requisite response, which, unlike classical conditioning, is not the inevitable inherited response to the reinforcement. Many other names are used to describe this type of learning, among which operant conditioning, instrumental conditioning, and action conditioning are the best known.

Operant conditioning methods. The relation between trial-and-error learning and operant conditioning is best explained by means of an experiment that also serves to indicate the difference between the classical-conditioning procedure and the action-conditioning procedure. In this experiment a guinea pig is placed in a comfortable harness, after which a buzzer is turned on and continues to buzz until the animal accidentally makes a particular movement that has been selected by the experimenter. When this action is performed, which may be a turning of the head—say, to the right—the buzzer is immediately stopped, and a portion of food (*e.g.*, a carrot) is delivered automatically to a food receptacle in front of the animal. Hence, in this case, the stimulus is the buzzer, the reward or reinforcement is the food, and the correct response is the turning of the head to the right. As head movements become more frequent, the animal soon learns to obtain food by turning its head only to the right. Eventually, the animal learns that it can ignore the external stimulus (the buzzer) entirely and associates its own voluntary act (turning of the head to the right) with the coming of a reward, an action that it will then continue to perform, even in the absence of the buzzer, in anticipation of obtaining food.

Types of operant-conditioning responses

Two types of responses involved in operant conditioning have been recognized: respondents, those responses that are immediately elicited by known stimuli; and operants, those responses that, prior to conditioning, are not necessarily correlated with any identifiable stimulus. The knee jerk in response to a tap on the knee is a respondent; the pressing of a lever to obtain food is an operant. In a typical operant-conditioning experiment, an animal is first trained to operate a mechanism by an appropriate response, such as the pressing of a lever by a rat or the pecking of a disk by a pigeon in the manner already described. Then the operant so selected can be used in isolation to study the effect of different programs or schedules of reinforcement. A suitable reinforcer is delivered to the subject either with every response or on a previously arranged schedule—*e.g.*, with every nth response or on the first response after an interval of *n* seconds from a previous response or reinforcement. This "schedule of reinforcement" is of crucial importance in determining the subsequent rate and pattern of responding, since it has been found that there is a decrease in the rate of responding—that is, an extinction of the response—by withholding reinforcement.

Nature of trial-and-error learning. As the above examples indicate, trial-and-error learning contains elements of both classical conditioning and instrumental, or operant, conditioning. Indeed, under natural conditions with normally behaving higher animals, instrumental, or operant, conditioning is only an isolated part of the total learning process, just as classical conditioning is only a part. Normally, the two are combined in varying proportions and adjusted in varying ways (see the Table).

Again, as has been the case for the different types of learning already described, the complexity of the behaviour that results from trial-and-error learning varies with the evolutionary level of the organism. Moreover, the criteria of what constitutes trial-and-error learning may embrace phenomena of enormous differences in complexity. There are fundamental differences, for example, between the learning of a maze by insects and by rats. The insect in the maze first masters each turn separately and later exhibits the habits thus formed in a stereotyped way. Starting with the first run, the rat, on the other hand, integrates its learning of each turn with its overall mastery of the maze pattern. Once the maze has been mastered, the rat can readily learn to run it in the reverse direction or under changed conditions, whereas insects have only a limited ability to do this. Thus, it is evident that in trial-and-error learning an integration of many different stimuli is proceeding all the time––in other words, the animal is engaged in a continuous process of perceptual organization.

Latent learning. Latent learning is a type of associative learning that takes place in the absence of any patent reward. Rats that have been allowed to run through a maze unrewarded for a period of several successive days will learn the pattern faster and with fewer errors when finally rewarded with food than will other rats that have never run the maze before but received food from the start of the learning sessions. Obviously, the initially unrewarded groups must have learned something during their early trials; their learning is latent because it did not become evident until activated by the reward.

As is described later, latent learning appears to be of great importance in the normal behaviour of higher animals in the wild. In itself, however, latent learning is not a hard-and-fast category; it is very much like trial-and-error learning, some of which can also occur in the apparent absence of reward. As a matter of fact, it is because learning can take place without any obvious reward that the concept of reward or reinforcement in the learning process has become an extremely tenuous one. Rather, it would appear that latent learning, as well as the concept of insight and insight learning, both of which are described in the next section, depend to a considerable degree on the processes of organizing sensory perception.

Insight learning. The concept of insight in animal learning has been the subject of experiment and debate among psychologists ever since the term was first introduced in 1921. Even today its use still causes many difficulties, though much progress has been made in understanding the nature of insight learning. Evidence for the existence of insight was provided by a famous experiment with captive chimpanzees confined in a large, lofty room with walls that they could not climb. A favourite food

Experimental evidence for the existence of insight

(*e.g.*, a bunch of bananas) was hung from the ceiling, well beyond the reach of the animals, and scattered about the room were several wooden boxes. After a number of unsuccessful attempts to reach the bananas by jumping for them, the chimps would abandon their efforts and sit quietly, appearing somewhat dejected. Then, in a typical case, one of the chimps would look at the various boxes and glance upward at the bananas. Suddenly he would drag one of the boxes into the centre of the room, stand on it, and try to reach the fruit. When he found that the box was not high enough, he would get another box and stand it on the first, again without success. After putting a third box, often very precariously, on top of the other two, he was able to climb the rather unstable structure and reach the fruit.

It was concluded that the chimps had suddenly realized the potentialities of the boxes; having done so, they were able to proceed to an intelligent solution of the problem. The ability to achieve this solution, however, obviously depended on a new organization of the animals' visual, tactile, and spatial perceptions, such that they were able to embark on a new course of action appropriate to the situation. Although the chimps appeared to solve the problem without any apparent trial-and-error behaviour, some psychologists have suggested that trial and error may have been the way in which various ideas were considered and rejected mentally. On the basis of such experiments, insight learning has been defined either as the sudden production of a new adaptive response that is not arrived at by trial-and-error behaviour or as the solution of a problem by the sudden adaptive reorganization of experience.

Experimental situations were also devised to determine if rats could learn insightfully under systematically controlled laboratory conditions. Most of these tests concerned the ability of an animal to make a detour around an obstacle without any preliminary trial-and-error behaviour. The obstacle was placed in a maze that the rats had already mastered; the fact that they almost immediately successfully circumvented the obstacle by taking a new path through the maze indicated that rats can learn by insight. Moreover, the performance of animals in this kind of test provides evidence of what many would call "intelligence." It is extremely difficult, if not impossible, to arrive at a satisfactory general definition of intelligence relative to animal experiments because much depends both upon the innate capabilities of an animal and upon its previous experience, full details of which are often lacking. It is obvious, however, that when an animal arrives at an insightful solution, it does so by abstracting certain features of its experience and relating them. Thus, it can be said that the first thing on which intelligence depends is the degree of abstraction of which an animal is capable.

Imitation. Imitation has often been regarded as evidence of a high degree of insightful behaviour, but this by no means follows unless the term is used in a critical and restricted manner. In fact, a number of behaviorally diverse phenomena are often included under the heading of imitation.

Social facilitation. One type of imitation is social facilitation, which is a pattern of behaviour already in an individual's repertoire that he performs when he sees the same behaviour being performed by other individuals. Yawning is a common example of such behaviour in man. Because the effect is immediate, learning need not be involved; though, of course, the propensity to exhibit social facilitation may depend upon learning.

Yawning as an example of social facilitation

Local enhancement. Another phenomenon sometimes classed as imitation is local enhancement, which is an increased tendency to respond to an environmental feature as a consequence of another individual's response to it. For instance, the habit of removing caps from milk bottles probably spreads through a local population of titmice (*Parus* species) partly because of local enhancement. In another example the greenfinch (*Carduelis chloris*), having once learned to discriminate between palatable and unpalatable foods, may start to eat unpalatable substances again after seeing an untrained companion do so. The reverse also occurs, as when one bird learns to avoid a potentially dangerous situation by observing the behaviour of experimental birds.

True imitation. The ability of true imitation, which implies the copying of an otherwise improbable act or utterance, is in the main restricted to man and to such other primates as chimpanzees and capuchin, macaque, and rhesus monkeys. For example, cats, weasels, and other hunting animals learn the best methods of killing their prey by watching their parents doing so. Even more striking is the way in which the chimpanzee "Washoe" learned the gestures of the American sign language by watching her human teachers (see below). It should be emphasized that true imitation need not necessarily include auditory–vocal imitation of animals such as birds. If, as just defined, true imitation means the copying of a novel or otherwise improbable act or utterance, then true visual imitation becomes something that apparently involves self-consciousness and something of intent to profit by another's experience.

Because song and call notes play such an important part in the social organization of birds, the subject of vocal imitation must be handled with care; it may, in many cases, actually be a kind of trial-and-error phenomenon. This is because the action of uttering a sound is unique among all actions in one very important respect: whereas action of any other kind cannot be perceived by the actor in the same way in which it is perceived by fellow creatures and in which he perceives their actions, the sounds he and they utter are, presumably, perceived by him and by them in much the same way. In short, animals are unable to see themselves as others see them, but they may very easily be able to hear themselves as others hear them. A creature (a child or other animal) endowed by nature with a number of vocal mechanisms that enable it to utter a variety of sounds expressing various emotions or impulses is an example. Whenever any mechanism is activated, the creature hears its own voice uttering a corresponding sound; in consequence, this sense impression becomes associated with the particular mechanism, and the hearing of a sound will tend to activate it. When the creature hears the sounds uttered by another, they have the same effect; namely, insofar as the creature responds by vocal utterance, it will tend, by virtue of the preformed association, to utter the same sounds that it hears. Thus, the apparently very complex and elaborate imitation of sounds by birds may be explained on the basis of trial-and-error. Such vocal imitation, characteristically a phenomenon of bird life, is a major factor in the system of vocal communication developed by birds (see COMMUNICATION, ANIMAL).

Tool use and construction. It is often argued that the ability to use a tool is evidence of a high degree of mental development. If the use of tools is considered to be the manipulation of inanimate objects for a particular end, then the vast majority of birds that manipulate grass, stems, leaves, moss, and other materials to make their nests would be tool users. This view is not adopted here, however, because even though the material used in building a nest is manipulated during the construction process, it is not actually used as a tool to make the structure. Also ruled out are those cases in which predators break open the protective shells of prey by smashing them against a rock or stone or by dropping them from a considerable height. Similarly, the bearded vulture (*Gypaetus barbatus*) is excluded as a tool user, even though it drops bones from a great height so that it can pick out the marrow from the broken remnants.

Tool-using birds and mammals

Recognized by most investigators as a genuine case of an animal that uses a tool is the satin bowerbird (*Ptilonorhynchos violaceus*); it employs fibrous material as a brush with which to paint the sticks of its bower with a coloured substance made from berries or charcoal. Still more remarkable is the woodpecker finch (*Camarhynchus pallidus*) of the Galapagos Islands, which feeds by using a cactus spine or a twig as a tool with which to probe into bark crevices; an insect or a spider that runs out is seized by the bird and eaten. The Australian black-breasted buzzard (*Haemirostris melanosterna*) is said to drive emus from their eggs and then fly aloft with a stone in its claws that it drops on the eggs. Another feeder on eggs, the Egyptian vulture (Neophron percnopterus), picks up as large a stone as its bill can hold and then, standing very erect, throws the stone at an ostrich egg repeatedly until the egg shell breaks.

Among mammals, one tool user is the California sea otter (*Enhydra lutris* nereis), which feeds on large mollusks, such as the abalone. The animal dives to the sea bottom to pick up a small boulder or a large stone with one foreleg and an abalone with the other. Then, while floating on its back with the stone resting on its chest, the otter breaks the shell of the abalone by hammering it against the stone. The stone is dropped as soon as the meat is accessible; when the meal is finished, the otter returns to the bottom for another mollusk and may even come up with the same stone. Clearly in this case the otter intentionally selects a stone as a tool, and all the behaviour involved here is striking evidence of at least elementary planning and foresight.

In the above examples, objects, although chosen as tools, are not worked or modified in any way by the animals that use them. Among scholars, it has always been assumed that the ability to make tools is characteristic only of man.

This assumption is now in doubt, however, because chimpanzees in the wild have been observed making tools from sticks for use in capturing termites for food. A chimp first breaks off a suitable branch from a tree, after which it strips off the leaves and then thrusts the tool so formed into the entrance of a nest of termites, which cling to the stick. The chimp then draws the tool through its lips, wiping off the clinging termites. In another remarkable tool-making feat chimpanzees, during the dry season chew leaves and thrust wads of them into small holes in rocks in which water has accumulated. When the chewed leaves are withdrawn, the chimps suck the absorbed water from them. Other examples of what appear to be insightful learning behaviour are mentioned below in connection with particular animal groups.

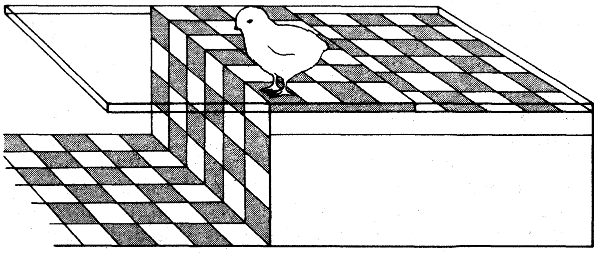
Perceptual learning. It has been emphasized that the categories of learning described above are not mutually exclusive and that each contains examples differing greatly in complexity. One important reason is the varying extent to which perceptual learning is involved (see LEARNING, PERCEPTUAL). In other words, an organism may modify the way it perceives stimuli as a result of continued or repeated exposure to them, even in the absence of any conventional reward. Thus, although rats reared in darkness during the first few months of life can learn later to discriminate between a circle and a triangle, other rats that have had early exposure to the same geometrical forms (but without any discriminating reinforcement) appear to learn faster how to distinguish between the figures when taught to do so. The effect, however, is dependent on the experimental conditions. When the early experience is with forms made from metal cutouts, subsequent discrimination learning is much more efficient than when the same forms are merely painted on a flat surface. It has been suggested that the difference lies in the attention-getting properties of the cutouts, which show depth at their edges.

The ability of rats to make abstractions

The ability to abstract certain properties of a stimulus has been studied with rats required to discriminate the magnitudes—successively, but in varying order--of brightness, area, and height and, also, the form of different stimuli. It has been found that although animals reared in the dark and given visual experience only during the testing periods showed a gradual improvement on the magnitude problems, their performance on all tests was inferior to that of light-reared animals. The difference in improvement in the magnitude problems, each of which was essentially a novel one, was interpreted as indicating that the animals responded not simply to a difference in brightness, size, or height but to differences in various properties of the stimulus itself. Similarly, when the performance of rats that had been reared in different ways was tested in a tactile–visual discrimination problem by exposure to three-dimensional forms (a cross and a triangle), the results supported the view that learning of various properties of the stimulus had been achieved. From these results it seems that the animal must first learn to differentiate between the various characteristics of the stimuli; that is, to differentiate tactual and visual cues related to the edges and angles of the forms. At the same time, they must also learn which of the objects is associated with food and which is not.

Many animals, such as chicks and rats, can respond to visual stimuli that indicate depth and solidity the first time they have an opportunity to use their eyes. One of the most striking of such responses is the reluctance to cross a visual cliff (see the Figure). This response may be retained, although it may become weaker, even if the animal is kept in total darkness for a considerable period. Such behaviour in mammals appears to be more sensitive to visual deprivation than that in birds.

From R.A. Hinde. *Animal Behaviour*, 2nd ed.; © 1970, reprinted by permission of McGraw-Hill Book Co.



Visual cliff.
The chick is reluctant to cross what appears to be a drop, although the unseen glass extension will provide support.

The development of correct visual responses in young kittens is greatly facilitated when active movement by the animal is part of the visual experience. When one kitten was maintained in a box mechanically linked to the movements of another kitten, so as to provide passive movement with the same visual experience as that gained by the active kitten, the inactive individual was inferior to the active one in learning movements. Such activity by the animal during the learning process is apparently another aspect of latent learning—namely, exploratory learning. It is the nature of most higher animals and a surprising number of lower ones, such as insects, actively to explore their environment and to learn its main features and their relationships—in other words, to "learn their way about."

Imprinting. Imprinting is an instructive example of the way in which the range of stimuli capable of eliciting a response can be limited and refined by experience. In 1873 an investigator observed that a newly hatched duckling or gosling will follow practically any moving object in the same way that it follows its own parent. This observation was not the first of its kind on this subject; the 1st-century Roman author Pliny the Elder wrote of "a goose which followed Lacydes as faithfully as a dog." A German ornithologist observed the same phenomenon in 1910 and christened it *Prägung*, which was translated into English as "imprinting."

Following behaviour in birds

Although imprinting is not fundamentally different from other forms of learning, it has certain properties that make it of particular interest. It is a process by which an animal—particularly the young of ground-dwelling birds, which leave the nest soon after hatching and so, being dependent on their parents for food or warmth, have to maintain contact with them by vision—may, accidentally, develop a preference for anything (animal or object) other than its own kind. Such a preference is shown by following behaviour. Although learning of the imprinting type is pre-eminently an avian phenomenon, following behaviour similar to that characteristic of imprinting in birds can be observed in young mammals that have been separated early from their parents. Such behaviour is much less common in mammals, however, because they are primarily creatures in which the sense of smell is highly developed, and it is this sense that is most likely to be the dominant one in establishing mother–offspring and sibling relations.

Sensitive period. One of the most remarkable characteristics of imprinting is its restriction to a limited sensitive period, which sometimes may be of only a few hours' duration. Among chicks and mallard ducklings, for example, imprinting is most effective from 13 to 16 hours after hatching. Thus, chicks will not follow a novel moving object (*e.g.*, a man) when they are only a few hours old nor when they are several days old but only during the intervening period. Moreover, the intensity of the sensitive period varies among animal species; even in animals of the same species, the sensitive period may be different for auditory and visual stimuli.

The period seems to begin as soon as the locomotory ability of the animal has developed sufficiently for following; the period is not always terminated, however, by a waning of the tendency to follow. Such birds as coots (Fulica atm), for example, will tend to follow one new object after another up to at least 60 days of age, but only when tested in an environment with which they are familiar. Some young birds will follow objects of almost any colour, shape, or size, from a matchbox to a man. There is much evidence that in some species the sensitive period is terminated by the establishment of other types of behaviour, fear responses in particular, which inhibit the tendency to follow.

Environmental influences on the sensitive period

Several experiments clearly indicate the influence of the environment on the nature and length of the sensitive period; for example, moorhens (*Gallinula* chloropus) and coots reared in groups in pens shielded from the general environment do not follow models to any extent; birds reared in more exposed pens, however, follow readily. In chicks the sensitive period is extended by rearing them in isolation; in ducks, by rearing them in diffuse light. Although many young birds are naturally more attracted to moving objects than to stationary ones, there is no absolute distinction between static and mobile stimuli: chicks may be attracted to static objects or to a general environmental quality or pattern in a manner akin to imprinting. In such cases the persistence with which chicks avoid a mobile object is reduced if the object is coloured in a pattern similar to that of the walls of the pen in which they have been reared. This indicates that, within a few days after hatching, chicks learn the characteristics of their pens well enough to be able to discriminate objects that are sufficiently dissimilar from those to which they are accustomed. This behaviour is particularly enhanced by the conspicuousness of the pattern with which the walls of the home pen are painted: the more conspicuous (and therefore presumably more easily learned) the home environment, the longer the chicks avoid differently painted models in the test pen.

Attraction of *conspicuous* objects. Imprinting raises the question of cause: why does the newly hatched bird approach conspicuous or moving objects in the first place? Parental calls may normally play an important role in the laboratory, but naive birds will approach silent objects equally well. Imprinting is not by any means peculiar to young birds, however, for the young of many animal species tend to approach a stimulus of low intensity and to flee from one of high intensity, which is more or less what happens in the imprinting situation. Thus, within certain limits it can be said that the more conspicuous an object, the more likely it is to be followed or approached in an initial exposure during the sensitive period.

It should be emphasized that even the newly hatched chick has a high level of behavioral organization and does not wait passively until exposed to a conspicuous object; rather, it shows behaviour that is likely to bring it into contact with the object. One investigator has found that chicks are more active a few days after hatching in a gray environment than in one painted with black and white stripes, even though both reflect the same total amount of light. This suggests an inverse relationship between activity and the complexity of the environment; that is, the active chick is likely to find less complex stimuli more appropriate for imprinting. It has also been shown in day-old chicks and ducklings that a conspicuous stimulus of the type used in imprinting experiments is reinforcing on the first occasion it is encountered; such birds rapidly learn to press a pedal that switches on a flashing light. There is also a sensitive period during which the light acts as a reinforcer; the readiness to learn the response decreases to a minimum about 48 hours after hatching, which is about the time when there is a corresponding peak in the persistence with which chicks in an imprinting situation avoid the models. Thus, during the course of the sensitive period, the birds develop a preference for the object with which they are rewarded. Imprinting and operant conditioning therefore proceed hand in hand, with imprinting narrowing the range of stimuli that can have reinforcing properties.

The role of familiarity in imprinting

Relationship to perceptual learning. It would appear that imprinting consists largely of the development of familiarity with a moving object. Specific rewards, such as food or contact with the moving object or model, are not necessary. Under ordinary barnyard conditions, chicks become familiar with at least two types of moving objects, the mother and the siblings; under experimental conditions, coots similarly learn to follow several different objects. If familiarity is the main issue, then imprinting would seem to be closely related to perceptual learning, for in both cases the responsiveness to a stimulus is influenced by a previous experience with the stimulus, independent of its association with any rewards. If this is indeed the case, then imprinting can be a valuable tool for investigating the genesis of the perceptual aspects of behaviour, for any learning during the sensitive period would be revealed in contexts other than that of the following response. Thus, the performance of chicks in the discrimination problem described above was improved when one of the patterns to be discriminated was the same as that on the walls of the home pen. This is similar to the test used for perceptual learning. It has also been found that early imprinting to a flickering light (visual flicker) made it easier to teach an animal to approach or avoid the same stimulus a month later. This effect was found, however, only in those individuals that exhibited the following response to the stimulus during the imprinting period, suggesting that mere exposure to the stimulus is not sufficient for the early perceptual learning to occur. Thus, it may be necessary for the stimulus to become associated with a response of some kind, although it does not have to be the same response that is used in subsequent testing to reveal any perceptual learning.

The conclusion that, during the sensitive period, conspicuous objects have a reinforcing effectiveness for naïve birds that seems to increase with familiarity is consistent with many of the findings of imprinting experiments. For instance, an imprinted bird shows a searching behaviour when the object is absent; in addition, the willingness to follow an object and to respond to it selectively tends to increase with experience. The evidence also indicates that reward is unnecessary for imprinting, that objects which at first invoke fear may later (after habituation and familiarity) elicit following responses, and that unfamiliar objects are more likely to elicit following if presented in the same situation in which the bird has previously been imprinted to other objects.

A feature of imprinting that once attracted much interest was the effect it was supposed to have on the subsequent social, sexual, and parental behaviour of the adult individual. Cases have been reported in which the sexual preference of the adult bird was more or less irreversibly determined by the types of companions or objects to which the bird had been imprinted in its early life. In some cases at least, this effect may be the result of an early imprinting experience that produces fear of the object, thus affecting later sexual responses.

II. Behavioral and physiological aspects of learning

What an animal will learn is not merely a matter of its learning capacity; there are many constraints and restrictions that impinge upon its basic learning ability—*e.g.*, the limitations of its sensory and perceptual mechanisms. Because of such limitations, an animal is more likely to react to some stimuli than to others; therefore, it learns

Constraints and restrictions to learning

more about some than about others. Furthermore, all stimuli to which an organism is responsive in some contexts may not be effective in producing learning in other contexts. Thus, an octopus compensates posturally for the weight of objects it picks up in its arms, but it is unable to learn to distinguish between objects that differ only in weight. Similarly, although bees can learn to orient themselves by complex shapes when steering a course to and from the hive, they cannot learn to recognize such shapes when they are used as signals to indicate the presence or absence of food on a tray.

Another important fact often not taken into consideration to account for differences in learning ability is that the reinforcing effect of such circumstances as food, water, or warmth is not an intrinsic property of the stimulus but of the animal; which means that their value to the animal must have been established by natural selection. Consequently, although the responses and the general "intelligence" of two related species may appear very similar, if not identical, in conventional laboratory tests in which food and water are employed as reinforcers, the learning capacities of the same two species may be very different when studied in other situations. In other words, under more natural conditions in which naturally occurring stimuli are used as reinforcers, one species may learn in a context in which the other does not, whereas both species had learned equally as well in the laboratory. Sunfishes (Centrachidae) of the Northern Hemisphere, for example, can orient their movements by the position of the sun when first exposed to it, even after having been reared in artificial light, provided the sun moves from left to right when they face it. If, however, the sun is moving from right to left when they face it, as it would in the Southern Hemisphere, they cannot orient their movements to it; hence, these fishes are restricted to northern waters. By contrast, a cichlid fish (Aequidens portalegrensis), whose range spans the Equator, can orient itself by either the northern or southern sun but not both, depending on which way the fish was facing when it first saw the sun.

The last example illustrates how the normal environment may restrict what is learned: in this case the mature cichlid fish can only respond to the sun in the Southern Hemisphere if its first experience was with a sun that appeared to move from right to left. Similarly, birds that leave the nest soon after hatching become imprinted to their parents rather than to other conspicuous objects because their parents are both available and moving, and the newly hatched offspring are sufficiently developed to be able to follow them. In contrast, birds that are reared for a time within the nest may well become imprinted to conspicuous objects in the environment, in addition to or instead of their parents. Thus, as all of the preceding examples indicate, all of the natural limitations and constraints on learning must by analyzed in order to identify the conditions necessary for learning to take place.

STIMULUS–RESPONSE AND COGNITIVE MECHANISMS

In the discussion of classical and operant conditioning, examples were considered of what may be called the stimulus–response (S–R) theory. In these examples a new S–R relationship was brought about by one or more procedures involving some kind of reward or reinforcement. It was once thought that classical conditioning applied only to involuntary visceral responses (*e.g.*, those of the salivary glands or the digestive system) and that operant conditioning applied only to voluntary responses (*e.g.*, purposeful movements of the limbs). This implied that if visceral responses could be modified only by classical conditioning, they could be learned and maintained only by using stimuli that had the ability to elicit the same response. If, on the other hand, visceral responses could be learned by operant conditioning, they could be acquired and maintained in a variety of ways. Indeed, in recent years it has been shown that operant conditioning is effective on a wide variety of visceral and other involuntary responses, such as heart rate, intestinal contractions, blood pressure, urine formation, and brain-wave activity. It has even been found that, in some cases at least, learning can take place while an animal is immobilized by a muscle-paralyzing drug (curare), and that anything learned by the animal while in this condition can be transferred to the nondrugged state. As a result of such findings, there has been a strong tendency for some investigators to subsume all learning under the S–R theory.

Modification of involuntary responses

On the other hand, another school of theorists strongly rejects the conclusion that all learning can be explained in terms of the S–R theory. These theorists believe that, in many cases, learning is often a restructuring of internal processes in the central nervous system, in a manner that is not necessarily the same as the mechanism involved in S–R learning. Thus, because those who hold this view are concerned with cognition (the internal acts or processes involved in knowing or perceiving), they are usually called cognitive theorists. A simple example serves to indicate the difference between the two. According to the S–R theory, a rat masters a maze by learning which responses must be made to which stimuli. The cognitive theory, however. might involve the assumption that the animal is learning a "cognitive map" of the maze in such a way that it acquires a knowledge of "what leads to what"—*i.e.*, that one particular stimulus will be followed by another one. Although the results of many learning experiments can be interpreted in terms of either theory, the difference between them is, nonetheless, an important one.

Role of reinforcement. Because the role of reinforcement in the formation of S–R relations is often a particularly crucial one, it merits further consideration. There have been many suppositions concerning reinforcement, one of which is the theory of contiguity. According to this theory, the only reinforcement needed for the association of stimuli and responses is that there be a certain temporal relationship between them. The problem with this theory is that not all stimuli or responses that occur in a time sequence become associated, hence it is still necessary to explain why some things are learned and others are not. Among the many attempts to overcome this difficulty is the suggestion that perhaps there is some motivational state that determines the stimuli to which the organism will attend; thus, the stimuli that become associated with each other or with responses govern what happens. In such a case, reward or reinforcement confirms an expectancy about the nature of the environment.

The theory of contiguity

Internal reinforcement. Many theories concerning the concept of internal reinforcement have been advanced. It has been proposed, for example, that such reinforcement can be a satisfaction of a biological need or drive (drive reduction), that it can come from the removal of stimuli associated with such a drive (drive–stimulus reduction), or that it can be the result of the appearance of stimuli previously associated with the drive (secondary reinforcement). Although such suggestions have been useful and evidence exists to support some of them, it now seems clear that they do not provide an answer in all instances. Thus, although drive reduction (*e.g.*, alleviation of thirst) may be reinforcing, reinforcement is not necessarily associated with it. And, although consummatory behaviour (*e.g.*, drinking) can be reinforcing, the consummatory response may not necessarily be the most important reinforcing event in that particular train of behaviour. Indeed, the kinds of stimuli that can be reinforcing seem almost infinite; rats and monkeys can learn to press a lever if rewarded by an increase in illumination. Yet other studies have shown the opposite effect; animals can learn to press a lever to decrease illumination. And in some experiments the rats wanted to turn the light both on and off; apparently they wanted novelty above all else.

Other significant examples providing evidence that internal reinforcement is widespread in cognitive learning concern searching image, reward expectancy, and selective attention. Much repetitive behaviour that involves a scanning of the environment until a particular set of stimuli is encountered can be understood on the assumption that the animal is using a "searching image." Thus, a bird such as the European jay (*Garrulus glandarius*) accustomed to feeding on plump caterpillars will fail to see so-called "stick" caterpillars, which have a close protective resemblance (camouflage) to small twigs, when such caterpillars are placed on the branches of trees in an aviary. Should the bird chance to touch one, however, and find that it moves and is edible, the bird will then examine actual sticks or twigs persistently for a while. If it finds no more "stick" caterpillars, the bird will stop searching for them and resume his search for the plump caterpillars. In other words, the bird behaves as if it were internally "expecting" a different kind of reward and exercises selective attention toward the situation that will provide that reward.

Novelty of environment. Many animals in captivity will work apparently to obtain novelty of environment. The reward value in the novelty of either increased or decreased illumination, for example, may really be related to the normal rhythm of light and darkness in the animal's life. Thus, when deer mice (*Peromyscus maniculatus*) are allowed to control their illumination in the laboratory by lever pressing, they tend to select light intensities similar to those they would experience at corresponding times of the day in the wild. Deer mice in captivity will also spend long periods of time running inside a turning wheel, but the reinforcing nature of wheel running is far from simple. If the speed or difficulty of the turning wheel are programmed in any way by the experimenter, the deer mice will invariably change the program when provided with levers that enable them to do so. It is as if the mice want to program their own running instead of having it programmed for them.

Exploratory behaviour in reinforcement

Learning also tends to be facilitated when animals have access to objects that can be played with; indeed, all sorts of situations that involve exploratory activity have been found to be reinforcing. Exploratory behaviour tends to cease, however, without any change in the outer environment (external stimulation), suggesting that the reinforcement of the exploratory activity must arise internally. In other words, because exploratory behaviour is elicited by novel stimuli, it comes to an end when, as a result of certain internal changes, the stimuli cease to be novel. This is in accordance with the restructuring of processes in the central nervous system as proposed by the cognitive theorists.

Conceptualization. The extent to which animals other than humans are capable of concept formation has been dramatically demonstrated. Pigeons have been trained to respond to the presence or absence of human images in photographs. The people depicted might be anywhere on the photograph; they might be clothed or nude, adults or children, in varied postures, of any race. Indeed, the pictures are so varied that simple stimulus characterization seems impossible; the results suggest remarkable powers of conceptualization by pigeons as to what is "human."

In another conceptualization experiment, monkeys have been trained to select the pictures of three different insects from among pictures of leaves, fruit, and branches of similar size and colour. In later tests the monkeys showed significant preferences for any insect pictures over those of other natural objects. Experiments with numbers (*i.e.*, "counting") done with birds and some nonhuman mammals provide striking evidence for the existence of number conceptualization in animals.

NEUROPHYSIOLOGICAL MECHANISMS

Memory and learning. It is naturally and correctly assumed that with all animals above the one-cell level of organization, some kind of nervous system is the primary mechanism for governing the changes involved in learning. It follows, therefore, that any system concerned with learning must also be concerned with memory, the storage of information (see MEMORY: RETENTION AND FORGETTING). Both psychologists and neurophysiologists have long been involved with what seems superficially to be a very clear-cut difference between two types of memory, short-term and long-term. This difference has been thought to indicate that there are two kinds of storage processes in the brain; one in which retention decays very rapidly and one in which retention is more or less permanent. Most people, for example, can remember a new telephone number only for a few seconds or at the most for a minute or two after first using it; in contrast, one brief experience of some other kind may become impressed, apparently indelibly, on the "consciousness." The distinction between the two types of memory is also based on the fact that a person who has suffered a brain concussion loses his memory for events that occurred just before the accident but not for earlier ones.

Considerable research on the function of memory in learning has been carried out with human subjects and with animals. It has been found, for instance, that when an electroconvulsive shock is administered to rats at various intervals following a training trial, the animals that receive the shock within a few minutes of the trial subsequently perform what they were taught less well than do those that receive the shock at later intervals. Similar evidence obtained by the use of certain anesthetics also supports the existence of short- and long-term memory. Moreover, the short-term storage system is held to be distinct from a very short-term preperceptual trace (one that decays in about half a second); in order for something to be recalled subsequently, subjects must respond to the material either during its presentation or within the half-second period afterward.

Suppositions concerning short-term and long-term storage systems

To account for the preperceptual trace, the short-term storage system, and the long-term storage system, it is assumed that the short-term system is mediated by neural mechanisms that decay autonomously with time and that are liable to interruption by many kinds of stimuli. The long-term system, on the other hand, is believed to be either permanent or nearly permanent, although the stored association may be subject to slow decay as a result of long disuse. It has also been assumed that long-term storage requires the preceding short-term neural activity for its fixation. This means that no long-term retention can develop if the formation of the short-term memory has been disrupted in any way, such as distractions of attention or electroconvulsive shocks. Much recent work on this subject, however, is causing drastic revision and rethinking of previous suppositions. For instance, there now seems little clear evidence that the disruptive treatment applied to the short-term memory system really affects storage; it could equally well impair recall.

The importance of time as a factor in fixing long-term memories has been demonstrated in the behaviour of such animals as the octopus. A blind octopus, for example, soon learns to reject inedible objects by means of tactual (touch) cues. If such an object is presented to the same arm briefly in a rapid series of trials, the object is rejected by that arm of the animal but not by the other arms. If, however, the trials are more widely spaced in time, the effect spreads to the other arms, all of which will eventually refuse the inedible object. This suggests that learning through one of the arms takes time to spread through the parts of the octopus brain that mediate the behaviour of the other arms.

Problems in explaining neurophysiological learning mechanisms. In considering the possible neurophysiological mechanisms of learning, there is at present no evidence that any single nerve cell (neuron) can perform the kind of operation necessary for comparing stimuli, as in the various kinds of associative learning. Even with habituation, which does not necessarily require simultaneous comparison, tnere is only scant evidence that one nerve cell is sufficient to bring about this simple form of learning. But even if one nerve cell can display the changes that appear to be associated with the simplest cases of behavioral habituation, this does not account for more complex examples of this phenomenon. In the closest link between habituation and association learning (the resemblance of the former to the processes of extinction and reflex inhibition that are so characteristic of the classical conditioning pattern, as well as of the more elaborate types of associative learning), there seem to be grave difficulties in supposing that behavioral habituation and extinction share the same underlying neural process, let alone that they are determined by the same neurophysiological mechanisms.

The problem of the relations between neurons

It follows that, if these conclusions are correct, investigators must look to the relations between neurons, often very large numbers of them, for any general physiological explanation of the mechanism of learning. Even then, given the many different kinds of neurons with their many different kinds of physiological properties and the many different kinds of junctions between them, there is no a priori possibility that the learning and memory functions of the nervous systems in both lower and higher animals can ever be explained. Indeed, theory has far outrun experimental evidence. There are innumerable examples of what can be called "wiring diagrams," according to which learning functions of nervous systems are explicable. It is even easy either to produce a mathematical model of relationships between nerve cells that would allow for pattern recognition or to argue plausibly that nerve nets, mainly random with regard to relationships between the individual neurons, could be efficient in the performance of many simple learning tasks. But, although elegant neural mechanisms can be imagined for learning form and pattern recognition and although impressive hardware models or mock-ups can be constructed that confirm theoretical conclusions, the physiological processes involved in learning and behaviour remain poorly understood.

The magnitude of the problems is apparent if the staggering number of stimuli to which an animal (including man) can respond selectively are considered. Obviously, the nervous system discriminates between a vast number of possible stimulus configurations, yet it is unlikely that there could be a separate mechanism for every object that an organism can recognize. A related problem is the question of the quantity of information that a nervous system of measurable size can store. The problem here is to determine to what extent memories are stored as discrete units or in complexes of associations. Many psychologists have thought that specific memories lose their identities by being organized into schemata, each experience being incorporated into an organization of experiences that are connected by a common experience. In such a case, recall would then be regarded as governed by generalization. Not until basic problems of this kind are better understood will it be possible to make reasonable estimates of the mental content of human brains.

Whatever the final answer may be, however, it is known that the memory store of some individuals is much larger than that of others. It was said of the 19th-century French philosopher Auguste Comte, for example, that, when writing a book, he never put a word on paper until he had composed the entire work, even the form of the sentences, in his head. Then, by an extraordinary feat of memory, he wrote the whole book and sent it to the printer without making any changes. Similarly, the Hungarian musician Franz Liszt could sight-read the most complex musical scores without error and apparently never forgot a work once he had seen and played it. For decades of life, until the impairments of aging become acute, the memory systems of such people seem impossible to satiate. Yet, although these and other problems are difficult to resolve and although much more experimental work remains to be done, the evidence is encouraging that neurophysiological changes are responsible for such behavioral adaptations as learning.

III. Evolution of learning ability

LEARNING IN INVERTEBRATES

For many years there has been controversy as to whether or not protozoans, such as the amoeba or paramecium, can "learn." Because some early observations with the amoeba failed to take into account certain changes in the physiological conditions of the animal, many experiments that were thought to have proved the existence of learning in these organisms were subsequently shown to be explicable on the basis of different and simpler hypotheses. Nevertheless, a number of instances indicate that both habituation and elementary associative learning do occur in some of the protozoans.

The nerve net in coelenterates

Evolution of neural structures. The coelenterates, a group of simple multicellular animals that includes sea anemones and jellyfishes, have specialized sense organs that are connected by a very diffuse kind of nervous system called a nerve net. Although there are no structures that remotely resemble a brain or spinal cord, the nerve net of a sea anemone contains about 100,000 cells and is able to mediate surprisingly complex behaviour, including oriented movement toward or away from chemical stimuli and such locomotory behaviour as rhythmic swimming movements. Sea anemones clearly exhibit habituation; more evidence is needed, however, before associative learning can be definitely attributed to these creatures, although it probably occurs. It has been suggested that the rhythmic nature of the activities in coelenterates, as well as the many cells in their nerve nets, may be the forerunners of the processes and structures out of which the central nervous activity of more complex organisms could have evolved.

The "memory molecule"

The free-living aquatic flatworms (*e.g.*, planarians) represent a very primitive stage in the evolution of a central nervous system, which in man and other higher animals consists of the brain and spinal cord. Groups of nerve cells (ganglia) in the planarian's head provisionally have been called a brain, and nerve cords extend along the entire length of the animal. After much controversy, it now seems safe to conclude that planarians do possess the capacity to learn; this includes both habituation and elements of associative conditioning. It also seems well established as a result of experiments with planarians that the substance ribonucleic acid (RNA) may transmit the effects of learning. When RNA is extracted from the bodies of flatworms that have learned to respond to paired light and shock treatment, it causes similar changes in behaviour in untrained planarians of the same species into which it is injected, thus confirming the assumption that RNA may behave as a "memory molecule." The mode of action of the injected RNA in flatworms is, however, completely obscure at present, and the early hopes of explaining memory storage in higher animals and in man in terms of DNA–RNA systems seem now to have faded nearly to the vanishing point.

The segmented worms or annelids—such as earthworms, sandworms, and leeches—have a much more highly developed nervous system than do the planarians; it includes a clearly defined brain and a double nerve cord with ganglia in each segment. Habituation and classical conditioning can be easily demonstrated in this group, and trial-and-error learning of a level sufficient to enable the animal to master a simple T-shaped maze has been shown. It seems, however, that although the annelid brain is implicated in some way in the learning process, it does not serve as a unique, discrete memory-storage centre.

Thus far, the evolution of anatomic complexity among animals has paralleled a fairly steady advance in learning capacity from simple habituation to associative learning, which appears first as classical conditioning and then as trial-and-error learning or operant conditioning. It is as if evolutionary progress in the powers of behavioral adjustment consists of elaborating and coordinating new types of responses that are built upon and act with the simpler ones of more primitive animals. That is, if habituation and classical conditioning are found low in the animal scale, they will also be found higher up, coexisting with more elaborate responses and with more highly developed sense organs and nervous systems.

Memory of the home range in arthropods and mollusks

Although the nervous system of arthropods (*e.g.*, insects, spiders, crabs) and mollusks (*e.g.*, snails, clams, octopuses) is of the same general type as that of annelids, it has much more complex sense organs—especially visual organs and proprioceptors (organs for sensing body position and movement). Such a big step in evolutionary development appears to have taken place at the stage at which it became necessary for an animal to find its way about or, in effect, to find its way back to a known home range or territory when displaced from it. Organisms with this ability, including the animals as low in the evolutionary scale as insects and snails, behave as if they had some kind of inner map of the region around whatever may be the centre of life—*e.g.*, a nest. Indeed, at first sight no fundamental advance in the ability to organize the perception of environmental features seems to exist between an insect such as a wasp and a more highly evolved vertebrate. Among the simpler mollusks, such as snails and slugs, even the more primitive forms behave as if they had an internal map of the environment that enables them to find their way home. Among the higher mollusks (*e.g.*, octopuses and squids), the neural structures, as well as visual and tactile sense organs, are as complex as those of many vertebrates.

Organizational patterns by neural elements. In addition to the highly organized and efficient memory of the home range found in some insects are the outstanding orientation abilities and direction-indicating powers of the honeybee. Experienced beekeepers know that, when a hive is moved to a new location, the worker bees coming out on foraging flights will pause and circle in increasing arcs around the new site for a few moments before flying off. It is clear that, in these brief survey flights, the insects learn the relative positions of new landmarks well enough to enable them to find their way back to the hive minutes or even hours later. Such behaviour raises the question of the number of nerve cells and the complexity of organization in the brain or other regions of the central nervous system required to mediate performances of this kind. It was this problem that prompted Charles Darwin to observe

> . . . it is certain that there may be extraordinary mental activity with an extremely small absolute mass of nervous matter: thus the wonderfully diversified instincts, mental powers, and affections of ants are notorious, yet their cerebral ganglia are not so large as a quarter of a small pin's head. Under this point of view, the brain of an ant is one of the most marvellous atoms of matter in the world, perhaps more so than the brain of man.

It is generally accepted that the outer shell (cortex) of the human brain contains about 10,000,000,000 neurons with an equal number of supporting, or glial, cells. In the octopus, which has behavioral achievements equal to those of many vertebrates, the nervous system is estimated to contain 5,000,000 neurons. It would seem that a bee's brain, despite its learning ability, certainly contains no more than 100,000 nerve cells, and that of ants considerably fewer. Yet 100,000 nerve cells is not vastly greater than the number found in the nerve net of a sea anemone. If "modelling" of the real world first appears somewhere in the scale between sea anemones and bees, it does not seem that this new faculty is the result of a vast increase in the number of nerve cells but rather that it results from changes in their pattern of organization.

Since a bee can do so many tasks with a brain of less than one cubic millimetre in volume, the functions of the remaining million or so cubic millimetres of the human brain are a matter for speculation. Whether in hunting wasps ***(Ammophila)*** or in man, the internal map or perceptual model of the real world is derived (abstracted) from changing patterns of sensory stimulation. This implies that within each organism, a process of abstraction from the highly varied patterns of individual stimuli occurs. Yet, however different the varied successive patterns of stimuli may be as perceived by wasps and man, they form a single coherent relationship that is determined by the same external conditions to which both are exposed. This suggests that the coherence and unity which our experience leads us to believe exist in the world of external phenomena also exist in the internal models created by the central nervous systems of different organisms. The ability of an organism to derive information from sensory stimuli (what might be called its level of abstraction), however, varies with the evolutionary grade of the organism.

Nature of intelligence. Despite the differences in neural structures of lower and higher organisms that are reflected in their ability to make abstractions, there appear to be certain, as yet unknown, properties controlling behaviour that are common to all organisms. Only when these common factors have been determined will it be possible to ascertain the true nature of intelligence, which obviously is not simply the result of more elaborate behaviour or of more highly refined nerve circuits. In order to understand the nature of intelligence, it is essential to understand first the way in which a species survives in the environment in which it lives and how it adapts to it. In order to measure an animal's intelligence, therefore, it is necessary to study a particular aspect of the animal's response to its environment and to devise tests to determine its learning ability as judged by its performance in that situation. But, because each species has different adaptations for coping with different situations, there is no single test of intelligence that is equally suitable for all species of animals. Even if a species appears to be deficient in some task as defined by a particular type of test, it is necessary, before the relevance of the result can be substantiated, to refer to the natural situation; in this way, a deficiency in one type of test may be compensated by superior performance in other types of tests. The ability to perform abstractions, "to conceptualize" (see CONCEPT FORMATION), is an important criterion in such tests, although this may largely reflect differences in sensory, perceptual, or motor functioning rather than differences in learning ability. The ability to reverse a learning process when required by changing circumstances is another important criterion. Experiments on learning in a large number of species indicate that, although the number of trials required for conditioned-reflex formation differs little between the goldfish and the chimpanzee, the rate of extinction (reversal) is slower or absent in the lower species. Within the vertebrates great differences exist regarding some aspects of this particular type of learning ability; small differences exist regarding others.

The relationship between intelligence and environmental factors

Among the invertebrates, an increase in the rate of learning and the complexity of problems that can be learned is clearly evident in the progression up the evolutionary scale from worms to ants; further increases are evident in lower vertebrates. Yet, in the entire animal kingdom only mammals (*e.g.*, rats and man) have been shown to be clearly better than insects in maze learning. This again illustrates the point that a fundamental step in learning ability is achieved whenever a species needs to find its way about. As mentioned previously in the discussion on trial-and-error learning, in the learning of a maze by an insect and a rat it has been found that the insect first masters the local choice points (where the maze branches), then later integrates the habits thus formed in a stereotyped way. By contrast, the rat starts both its local learning and its overall integration on the first run through the maze. Furthermore, once the maze has been learned, the insects have only a limited ability to learn to run it in the reverse direction or under changed conditions, but rats can do so readily.

Differences in ability to develop a learning set

Learning to learn. This would appear to indicate another difference in learning; namely, the ability to achieve a "learning set" or, as it is often put, "the ability to learn to learn." In other words, whereas rats seem to have the ability to learn any new behaviour required—*e.g.*, to run the maze in the opposite direction—the insects, once they have learned to run a given maze, are much more rigid in maintaining their behaviour. The insects may thus be said to be relatively inferior in developing a learning set. Rhesus monkeys appear to have a greater ability in learning to learn than do squirrel monkeys and marmosets. The learning performance of pigeons is comparable to that of cats; birds have a phenomenal ability for direction finding and orientation. Among mammals, the only reliable evidence for differences in learning ability between primates (*e.g.*, monkeys and man) and all the others is derived from "learning set" experiments.

Further discussion of the differences in learning capacity among lower animals will not be any more illuminating for, as suggested above, the situations under which such animals demonstrate their learning behaviour in nature have seldom been sufficiently analyzed. It should be of interest, however, to consider the higher animal groups (*i.e.*, fishes, birds, mammals) in terms of the exceptional features of their learning ability.

LEARNING IN VERTEBRATES

Fishes. Fishes are the dominant class among vertebrates, both in numbers of individuals and in numbers of species. There are probably more than 18,000 species, about 90 percent of which are bony fishes.

Significant behavioral characteristics. From the behavioral point of view three characteristics of fishes appear to be particularly significant. First is their elementary social behaviour, which expresses itself in their tendency to form schools or shoals. Second, the lack of prehensile (grasping) organs (*e.g.*, hands) and the small part that manipulation plays in the lives of most fishes might be expected to limit their powers of space perception. The third characteristic tends to counteract the second, however: most fishes actively move in a three-dimensional world for most if not all of their lives. Although there may be no obstacles present in the open sea, fishes that inhabit lakes, rivers, and coastal regions must constantly negotiate obstacles that they encounter. Such behaviour must aid substantially in the development of competence in spatial orientation and control.

Because many fishes form shoals or schools either with only their own species or with other species as well, they have ample opportunity to develop visual recognition of species by an imprinting-like process. Little firm evidence, however, exists of individual recognition among fishes. Moreover, because some species travel long distances during their life cycle, they also have ample opportunity to develop recognition of their local or home territory as well as to orient themselves over larger geographical ranges, as is observed in salmon returning from the sea to the breeding territories where they were born.

Exploratory learning by the goby fish

One of the most remarkable examples of exploratory learning is provided by the goby fish (Bathygobius *soporator*), a species that inhabits tidal pools. These fishes are so well oriented that they can jump from pool to pool at low tide without any significant risk of finding themselves on dry land. Yet it is known that the fishes are unable to see the neighbouring pools before leaping. The only apparent conclusion to account for such behaviour is that the gobies swim over rock depressions at high tide and thereby learn the general features and topography of the limited area around the home pool. Then, using the memory that they have acquired, they accurately jump from one pool to another at low tide.

Migratory behaviour. Although many laboratory experiments have been concerned with the ability of fishes to learn to make detours and to master simple mazes, the results of these tests are meagre compared with the well-documented migratory and homing performances of such fishes as salmon, trout, and white bass in the wild (see MIGRATION, ANIMAL). Most fish migrations involve the movement of larvae or young fishes from the places where they were hatched to their normal feeding habitats and a subsequent return journey to the spawning grounds. There is now indisputable evidence that a high proportion of some species of salmon and trout succeed in returning to the same streams in which they hatched. In transplantation experiments with the chinook salmon (*Oncorhynchus* tshawytcha), it has been found that, when the eggs were transplanted from one river to another, the fishes returned to the river in which they were hatched, not to the one in which the eggs were spawned. In another experiment, over a period of four years 97.9 percent of the steelhead trout (Salmo *gairdneri*) recovered had returned to their home stream, and only 2.1 percent of them went to a stream four miles distant; similar figures have been obtained for silver salmon (*Oncorhynchus milktschitsch*) in the same streams.

It is clear that the return of these fishes cannot be explained on the assumption that the intervening period of feeding and maturation has been spent in the neighbourhood of the native stream. Indeed, one species of chinook salmon (O. nerka) normally travels approximately 100 miles (160 kilometres) a day when returning from the ocean to its home stream to spawn; one salmon species (*Salmo salar*) is known to have travelled at the rate of 60 miles (100 kilometres) a day for 12 days for the same purpose. Among the large number of possible stimuli that may serve as guides or reference points during these astonishing homing achievements, water currents are among the more important. Fish also rapidly learn to keep a particular course and direction, employing orientation by the sun as a basis and then using many different clues for maintaining a steady course. Despite this ability, it seems clear that successful return in many cases cannot be the result of visual memory of the home or the route to it. This is because a young salmon descending a stream toward the ocean for the first time proceeds slowly, "playing" along near the shore and probably drifting passively downstream with the current for long stretches of the route. As a returning adult, the same fish swims strenuously upstream in deeper waters of the same river, often separated from its earlier downstream path along the shore by a distance that is greater than its visual range. Therefore, a possible alternative to visual memory is the assumption that the salmon has the ability to learn and to remember the chemical characteristics of both the water and the stream bed. This enables the animal to return to the stream of its nativity anywhere from two to six years after having left it.

Stimuli that serve as reference points for fishes

It has been demonstrated among migratory fishes that their chemical sense organs can detect small but probably constant differences in the chemical characteristics of water from different streams and ocean currents, including differences in salinity (see CHEMORECEPTION). Moreover, a learned olfactory preference for the waters of the home stream has been demonstrated experimentally in such fishes. Other cues for learning include differences in temperature, acidity, proportion of dissolved gases, density, and general turbulence. Added to these might be the recognition of characteristic sounds made by waterfalls and rapids, the memory of the general nature of the river bottom —which, of course, is partly visual—and perhaps the memory of the type of food obtained in the home stream. As for the route in deeper waters of the sea, there is the possibility that many fishes learn the contours of the bottom by making noises that echo back from the sea floor; or, for those fishes unable to make sounds, there is the possibility of learning contours through the resonant effects of surface wave noise on the bottom.

Translated into laboratory terms, the homing performance of a salmon is very much like learning to run a gigantic and complex maze in reverse after having gone through it only once and in the other direction two to six years before. Although the fish may not remember every detail of the hundreds of miles its journey may cover, it must be supposed that it remembers the characteristics of different sections, particularly those of the various choice points; *i.e.*, the junctions of the tributaries with the main rivers. Even given such assumptions in an attempt to simplify the problem faced by the returning fish, its performance is still an astonishing feat.

Birds. Orientation. Birds provide remarkable examples of long-distance orientation, particularly those species in which the young birds migrate to winter quarters before the adults do, thereby exhibiting an instinctive ability to fly in the appropriate direction. In these and other species the urge to migrate appears to be controlled by chemicals in the body called hormones. As a result of experiments in orientation cages with migratory birds, it has been established that many of them will flutter in the compass direction toward which they would be expected to fly at that time of year. Under these conditions such birds as starlings (*Sturnus* vulgaris) remain oriented (flutter in the correct direction) only as long as the sky and the sun are not obscured. If mirrors are used to change the apparent direction of the sun, the orientation of the birds changes accordingly. Although the position of the sun changes with the time of day, the direction of migration does not. Obviously, the bird must be able to correct for the movement of the sun by some sort of internal clock mechanism. This inner clock, which depends on the daily light–dark cycle, can be upset by providing an artificial cycle that is out of phase with the natural daily rhythms (see PERIODICITY, BIOLOGICAL).

Exactly how migrating birds use the sun is still somewhat obscure, although some species such as starlings can orient by using the horizontal (azimuthal) direction alone; others may be able to anticipate what the sun's position will be when it reaches its highest point in

The role of celestial bodies in long-distance orientation by birds

the sky. Because, in the Northern Hemisphere, this point is always directly south, it can serve as a fixed reference for the migrating animal. Naturally, nocturnal migrants have a different problem. When various warblers migrate in the autumn, they are able to maintain their direction at night even when they can only see the central part of the sky, but they become disoriented when the stars are hidden by clouds. In these cases it seems that the birds are responding to star patterns, especially those in the neighbourhood of the North Star. But in addition to the relatively simple problem of maintaining correct orientation, migratory flight also involves formidable sensory and perceptual problems to the bird which are not yet fully understood. Moreover, it has often been claimed that birds have a magnetic sense that serves as a compass, but the evidence for this is far from convincing.

In more complex orientational tasks, birds forcibly transported long distances from their nesting area during the breeding season are often able to return to the nest with such speed and reliability that random search for familiar landmarks seems unlikely to be the sole explanation. When Manx shearwaters (*Puffinus puffinus*), for example, were taken from their breeding burrows on the island of Skokholm off South Wales (Pembrokeshire) and transported in blacked-out boxes to Cambridge, England, where they were released, they covered the return journey to Skokholm (approximately 290 miles, or 470 kilometres) in as little as six hours. Because this species does not usually fly over land, most of the entire route must have been completely unfamiliar to them. Even more remarkable was a bird of the same species that was taken by airplane to Boston, Massachusetts. After being released, the bird returned to its Skokholm burrow in 13 days, having covered the journey of 3,050 miles (4,900 kilometres) at an average speed, assuming daylight flight only, of more than 20 miles (30 kilometres) per hour. In this case the bird could not possibly have been familiar with the east coast of North America and the western Atlantic Ocean because this area is well beyond its normal geographical range. In another of the many striking examples of experimentally relocated oceanic birds, the longest homing flight has been that of a laysan albatross (*Diomedea immutabilis*); it flew from the Philippines to Midway Island, a distance of 4,120 miles (6,630 kilometres), in 32 days. The fastest homing flight by a bird of this species was from Whidley Island, Washington: 3,200 miles (5,100 kilometres) in 10.1 days, or about 370 miles (600 kilometres) per day. In what is in some respects an even more astonishing feat, a much smaller bird, Leach's petrel, covered nearly 3,000 miles (5,000 kilometres) at an average rate of 217 miles (349 kilometres) per day.

Navigation. When birds are released in most experimental relocations, they set out immediately in the approximate direction of home. This would indicate that upon release the bird is already oriented toward home; it then performs as if it were fixing its present position on a flat map, calculating the course to steer, and effectively following it. This does not mean that the bird calculates in the same way as a human navigator. In fact, knowledge of the entire process is still so incomplete that it is not even yet known how the bird fixes its position on release. It has been established, however, that birds do not respond to forces resulting from the earth's magnetic field, nor is it likely that they respond to forces relative to the earth's rotation (Coriolis forces). Observation of the sky, on the other hand, seems important; many species are disoriented when the sky is overcast, and they "home" less effectively if they cannot see the horizon from the point of release than if the entire sky is visible.

Navigating by the sun

In contrast to the honeybee, birds do not have the ability to detect the pattern of polarised light reflected from the blue sky to aid them in their orientation flights. As a possible alternative, it has been suggested that day-flying birds orient themselves by observing the sun's arc at the location at which they are released and relating it to the characteristics of the sun's arc at home. For this system to be effective, the bird would have to observe the sun's movement over a small part of its arc, and then somehow compute the highest point of the arc to determine geographical south and local noon. Comparison of the remembered sun's noontime altitude at home with the observed noon altitude gives the difference in latitude, and comparison with the sun's noontime azimuth at home gives the difference in longitude. It seems more probable, however, that the difference in longitude is a direct time difference that is related to some kind of internal clock, the existence of which is now fairly well established. Astonishing though these conclusions may be, they seem to be inescapable on the basis of present information; in fact, this theory is simpler than many other hypotheses that have been advanced.

The hypothesis just described has been criticized on the grounds that it is improbable that a bird can make measurements of the required accuracy. Moreover, initial orientation sometimes appears to have occurred even before the sun has moved any appreciable distance along its arc. It seems, however, that a number of these objections are irrelevant. It has been shown, for example, that some species of birds have a tendency to orient in a particular direction, usually one that is characteristic of the stock or population, for a short while after release; during this time the position of the sun changes. Indeed, it has also been shown that pigeons can detect a movement as slow as that of the sun, as can crabs. There can be little doubt, therefore, that sun navigation occurs widely among birds, but exactly what is measured and with what degree of precision remain matters of dispute. However satisfactory the sun-orientation hypothesis may be, it does not account for the abilities of the many species that orient and navigate at night. Although birds can orient—reliably face an expected direction—in the night sky by using star patterns, there is no absolute evidence that they can actually navigate (*i.e.*, find their way about) by this method.

Nature of flight paths

The actual path followed by birds on homing flights has been studied in recent years by radio transmitters that are small enough to be attached to migrating birds without interfering with their flight abilities. The use of such tracking devices has revealed that the paths are often much straighter than investigators previously suspected. Still more extraordinary are the flight paths of some nocturnal spring migrants returning to their summer homes. In one such case a Swainson's thrush (Hylocichla *ustulata*) carrying a radio transmitter weighing only three grams (0.1 ounce) was tracked through the night by a receiver after it took off from Champaign, Illinois, until it landed eight hours later at its destination in Wisconsin, a point that was 450 miles (725 kilometres) away according to the map. The actual track flown measured only 453 miles (729 kilometres), a performance more remarkable than it may seem because the bird's slightly curved path was compensating for the curvature of the earth. Even if the bird had been flying a compass course, such accuracy would be the envy of a human navigator. In another case of a bird starting from Champaign, Illinois, a gray-cheeked thrush (Hylocichla minima) was tracked for 400 miles (600 kilometres) under a clear night sky as it flew at a speed of 50 miles (80 kilometres) per hour with the help of a 20-mile-per-hour (30-kilometre-per-hour) tailwind. After 140 miles (225 kilometres) its course took the bird over Lake Michigan; the plane following it, however, had to go overland for safety. After contact with the bird was renewed in Wisconsin, the plane had to turn back because of a thunderstorm; the thrush continued, despite the bad weather.

What do these results indicate in terms of known animal learning capacity? It must be accepted, of course, that birds have an initial innate ability to perceive and to coordinate readings from various stimuli in the environment, such as the rate of movement and altitude of the sun and possibly also of the stars. In the case of the thrushes, it also must be presumed that they had some visual knowledge of the environment and may have flown a similar route, at least in the opposite direction, a few months previously. With night fliers, however, it is doubtful that visual landmarks are of much help, particularly over a large body of water during a thunderstorm.

Aids to orientation and navigation. In homing experiments, in which a bird is transported in a closed box, it is apparent that the bird has no plan or map in its head based on previous experience to guide it. Although such birds clearly seem to have compass orientation to help them at the outset and landmarks near home toward the end of their flight, in between they appear to be truly navigating. With night fliers and often with day ones, celestial cues, whether from the stars or from the sun, frequently are lacking. Even when it seems possible that returning migrants might be orienting by recognizable landmarks, they often appear to disregard them as navigational aids. Thus, birds migrating over the Gulf of Mexico and its shores occasionally alter their direction, seemingly on the basis of geographic features, yet large rivers that course inland apparently are seldom employed as guides.

Use of winds

No doubt birds recognize many characteristics of the wind. Generally, they select those that are favourable for their goal; when forced to use unfavourable winds, however, they correct to a high degree for lateral drift. Migrants appear to select wind speeds within their flight capabilities; water fowl, for example, select wind speeds above 30 knots (nautical miles per hour) and passerine birds (*e.g.*, sparrows and robins) above ten knots. Because the birds appear to be able to determine the direction and strength of the wind, it is plausible that they may also use the wind as an orientation reference. It is known that winds blowing across terrain develop turbulence that migrating birds might be able to detect. It may well be that such turbulence serves as an additional means of orientation during migratory flights.

It is also important to consider other possibilities as aids to orientation and navigation. More needs to be known not only about the sensory physiology of birds but also about the atmospheric ecology of migration when neither sky nor ground is visible. It is possible, too, that birds might detect differential wind patterns experienced by upper and lower members of a flock during a flight and communicate this information to each other by certain calls. Many meteorological conditions may produce detectable updrafts that provide useful information about the direction of wind and wind patterns.

Oceanic aids

Over the oceans it is conceivable that birds may be able to detect local characteristics of air-temperature circulation, cloud formation, and the wave pattern of the water caused by the wind. Similarly, landfall on islands may be easier than supposed, because of the fact that the oceanic islands often have a characteristic cloud formation above them, clearly visible from 100 or more miles away. Moreover, because such islands in areas of steady winds may act as barriers that interrupt the wave pattern on the sea surface, these changes in pattern might be useful aids to landfall and navigation. It has also been found that even under cloud cover some homing pigeons can select the approximate homeward direction within a few minutes after release in unfamiliar territory. There is convincing evidence that the birds could not have seen the sun, suggesting that they oriented in some other fashion; perhaps their sensitivity to atmospheric pressure, which would help the birds to judge their altitude, could be a means by which they are able to determine the presence of updrafts or downdrafts and might provide directional guidance.

Finally, there is a structure (the pecten) in the avian eye that forms a large blind spot in the part of the visual field that usually views the sky. This structure might be useful for viewing the sun and perhaps for determining its altitude above the horizon. Because the pecten is heavily pigmented, it helps absorb the intense light of the sun; its rich blood flow may distribute the resulting heat, thereby avoiding any damage to the adjacent retina (the light-sensitive layer in the back wall of the eye).

Whatever the mechanisms birds employ for orientation and navigation, their performances on actual migratory and homing flights far surpass anything that has been revealed when their behaviour is subjected to laboratory experiments on latent learning, pattern recognition, perceptual organization, and exploratory learning. It is true, of course, that by simplifying the circumstances to which an animal is exposed in the laboratory beyond a certain point, it is impossible for that animal to show the real extent of its capabilities. To confine closely a highly organized animal may result in creating a moron. The principle of Ockham's razor, according to which the simplest explanation available is regarded as the most likely to be true, can be utterly misleading. Organisms often, perhaps one should say nearly always, turn out to be more complex than at first supposed.

Counting ability. The study of birds has also greatly enlarged man's understanding of the possibilities of abstraction and symbolization in animals. It is known that the human ability to symbolize in the sense of representing completely abstract or general ideas by words—which in themselves have nothing of the essential characteristics of the concepts that they denote—far exceeds in degree any similar capacity in animals below the level of the apes. It appears, nevertheless, that some animals, especially birds, are capable of some sort of numerical abstraction—*i.e.*, of behaving as if they understand number concepts. A raven (Corvus cornx), for example, learned to open a box that had the same number of spots on its lid as there were on a key card. Eventually, the bird was trained to distinguish among five groups of two, three, four. five, and six black spots on the lids of small boxes; the "key" was a group of objects lying on the ground in front of the boxes that were of the same number as the spots on the lids. The raven learned to raise only the lid that had the same number of spots as the "key" had objects. Despite efforts by the investigator to change various factors in a random manner from one experiment to the next—such as the positions of the five boxes and the key patterns as well as the size and form of the spots—the raven always chose the lid according to the only item that was not changed through all the experiments; *i.e.*, the number characteristic of the particular key pattern presented.

Sequential recall in birds

Birds also seem to have the ability to remember numbers of incidents in sequence, thus keeping in mind numbers presented successively in time, independent of rhythm or any other clue that might be helpful. Pigeons, for example, have been trained to eat only a specific number of grains out of many offered. They have also learned to eat only a specific number of peas rolled into a cup one after another at randomly varied intervals ranging from one to 30 seconds. Because the pigeon never sees more than one pea in the cup at a time, there is no visible clue for distinguishing the last "allowed" pea from rhe first "forbidden" one.

In another experiment birds have been taught to open the lids of boxes standing in a long row until a specific number of baits have been secured. Because the baits are arranged in the boxes in 20 or more different distributions that vary from one experiment to the next (some boxes were empty and some contained more than one bait), the number of lids to be opened constantly changed. Thus, a bird trained to take five baits (*e.g.*, peas) may have had to open any number of lids between one and seven in order to get the correct number of peas. Even more remarkable is the fact that birds can learn to master up to four problems of this kind at the same time; a jackdaw (Corvus *monedula*), for instance, learced to open black lids until it had secured two baits, green lids until it had three, red lids until it had four, and white lids until it had secured five.

Thinking unnamed numbers. Because all external clues seem to have been carefully excluded in the above experiment, some inner mechanism must have been responsible for the bird's stopping when the required number was reached. It would seem, therefore, as if the bird does some "inner marking"—*i.e.*, counting to itself—of the units it is acting upon, a possibility strengthened by the observation that supposed inward marks sometimes reveal themselves in external behaviour in the form of intention movements, such as nodding of the head once for the number 1, twice for the number 2, and so on. One investigator has called this phenomenon "thinking unnamed numbers."

A notable extension of these studies is an investigation of the number sense of a gray parrot (Psittacus *erithacus*); it was possible, after prolonged training, for the parrot to distinguish eight objects from seven objects. (Remarkably, it has not been demonstrated that any animal, including man, can immediately recognize the number of objects in a group beyond the point of about seven or eight.) The parrot learned to recognize that the successive presentation of a number of optic stimuli was a signal for a task involving the same number of actions. Thus, after having been shown four, six, or seven light flashes, the bird was able to take four, six, or seven pieces of irregularly distributed food out of a row of trays. Numerous random changes in the time sequence of the visual stimuli did not affect the percentage of correct solutions. After the bird learned this task, the signal of successive light flashes was replaced by successive notes on a flute. The parrot was able to substitute immediately without further training; the change from light flashes to flute notes had no effect on the number of correct solutions. The accomplishment was not hindered by completely arhythmic patterns or by a change of pitch. The parrot, however, was not able to accomplish a task that involved a combination of the two faculties of learning numbers; that is, it could not be trained to respond to visual numbers (*e.g.*, the number 5) when they were presented simultaneously with the same number of acoustic stimuli in series (*e.g.*, five beeps). Yet, when two different sounds were presented simultaneously (*e.g.*, a chord of two notes) or when a single note was presented, the parrot spontaneously opened a lid with two spots on it or a lid with one spot, according to the acoustic signal given. Although this work indicates that some species of birds have a counting ability in the form of two prelinguistic faculties—simultaneous and successive unnamed number sense—it is not true counting in the human sense.

Basic pre-linguistic faculties or "unnamed thinking"

In another area, however, the numerical ability of man and bird is approximately identical. If groups of objects are flashed on a screen long enough to be seen but too quickly to be counted, few persons will perceive as many as eight objects, and many perceive only five, which is the average for pigeons when given the same test. There thus seems to be no basis for expecting that man can achieve better results than birds if verbal counting (*i.e.*, counting by name) is excluded. The similarity in the limit of number perception in six bird species and man suggests that basic prelinguistic faculties, which may be described as "unnamed thinking," may be common to both birds and man. Because similar results have been achieved with squirrels and apes, it is clear that many birds and at least some subhuman mammals behave as if they can learn the concept of number even without being able to name numbers.

Mammals. The outstanding features of mammalian learning achievement are intimately related to the establishment and development of social life. Bodily contact—warmth, rocking, and body positioning, for example--enables the infant monkey to learn to identify its own mother from all other adults and to begin to understand the meaning of the mother's gestural communication. Although less is known about paternal affection—which expresses itself as protection against predators, protection of infants from aggression by others both without and within the social group, the social ordering of females and infants who are members of the in-group structure, and even a paternal interest in and play with infants—its effects appear to be important in the development of social behaviour.

Importance of play

Development of social behaviour. One important long-term socializing mechanism associated with early parental contact is the basic security and trust that it engenders. In all primates, including man, basic trust is often of crucial importance for the development of both exploratory and playful activity, particularly the latter. Play is the exercise of basically adaptive patterns of bodily action, either instinctive or learned or both combined, in circumstances where the normal objectives of such action (*e.g.*, hunting, food getting, aggressive and submissive display, etc.) are not sought. Thus the actions are incomplete in that they achieve no normal goal and therefore strike the observer as "not in earnest" (*e.g.*, the play of puppies, kittens, etc.). Play, particularly in young animals, leads to the development of motor skills and of perceptions, to the widening of perceptual horizons, and, thus, to the development of the exploratory drive. When placed in a secure environment, primate infants first explore and manipulate inanimate playthings and then turn their attention to social playmates, which are primarily other youngsters. Play automatically and inevitably results, both in man and monkeys, if the proper provisions are met—*i.e.*, associated playthings, agile and able playmates, and adequate protection. As the animals mature, play passes through increasingly complicated stages, stages that are obviously vastly more complex and more varied in humans than in other primates. One reason for this is the human capacity for speech.

Play appears to be the primary activity for successful social development in mammals. It involves, for example, the process whereby indiscriminate mingling with peers is transformed into heterosexuality. Homosexual play is practically universal in the early stages of life in mammals and in many birds. Among a great many mammals, and a few birds (*e.g.*, geese), such peer and playmate "love" patterns may continue into the heterosexual stage so that the animal behaves bisexually. The social–sexual bond uniting male and female members of a primate group may be profound and prolonged or perfunctory; there seems to be no consistent connection between the degree of evolutionary development and the length or intensity of heterosexual bonds. Indeed, among monkeys at least, the early peer-love relationship seems to be so important in the development of sexual behaviour in primates that its deprivation severely impairs adult heterosexuality.

Effects of social isolation. Social isolation, of which there are two qualitatively different types, is most devastating in its effect if instituted at birth before any affectional bonds have been formed. In studies of partial social isolation, individual rhesus monkeys have been placed in adjacent open cages so that they can see and hear but not touch each other. Total social isolation has been achieved by raising individual monkeys in enclosed cages in which all visual and manual contact with other animals is denied. Monkey infants subjected to partial social isolation exhibit excessive clinging and sucking behaviour. Moreover, locomotion and exploratory activity fail to develop normally; repetitive (stereotyped) behaviour, such as rocking, cage swinging, pacing, and circling, emerges instead. As such a monkey grows older, aggressive responses—both socially-directed and self-directed—develop, and eventually the frequency of both the abnormal and the normal patterns of locomotion and exploration decline. By the end of a decade, adult partially isolated monkeys do little but sit at the front of their cages and stare vacantly outward. If stressed by external stimuli, however, they may break into frantic frenzies of bizarre stereotyped activity or extreme self-aggression.

Sexual behaviour

Monkeys reared in partial social isolation for the entire first year of life show serious deficits in their social, sexual, and maternal behaviour. They rarely initiate interactions with others, and they become withdrawn and engage in disturbed irrelevant behaviour. If repeated social interactions are allowed after the first year, these monkeys ultimately display rudiments of play with other isolates; their sexual behaviour, however, is at best incompetent and often absent. Sexual drive may be evident (*e.g.*, through posturing and the rudiments of copulatory technique), but, even in the presence of a cooperative and experienced female, the behaviour of such males is little more than a caricature of normal sexual activity. Moreover, few female partial isolates become pregnant by natural means and, even then, very rarely by male partial isolates. If they do bear infants, they are hopelessly ineffective mothers, often indifferent or brutal, frequently to the point of killing the offspring.

By contrast, total social isolation only during the first three months of life merely leaves the monkey in a state of emotional shock. During this period the monkeys are denied both normal love by the mother and normal love for the mother. Yet, after three months of such isolation, the subjects make amazingly rapid and successful social adjustment to peers. When released to join cage mates at three months of age, they can still learn socialization because they have not yet reached the age at which most peer interactions normally begin.

If, after three months (from birth) of normal social living, monkeys are subjected to six months of total isolation, relatively little social impairment occurs, although those socially isolated in the last half of the first year tend to be unusually aggressive. This conforms to other data indicating that aggression begins to develop during the last quarter of the first year. Total social isolation during the first half year of life or longer, however, leaves monkeys almost completely unable to interact socially with age mates, impairs heterosexuality in all males and in most females, and eradicates all signs of normal maternal affection in females (which have to be impregnated by artificial means). These effects seem to be permanent; when such total isolates reach three or four years of age, they still show no positive interchange with either age mates or with monkeys half their age. Yet, despite this enormous social–sexual loss, there is no learning deficit as measured in the laboratory by standard learning test procedures, which have been designed for humans, not for monkeys. Even in monkeys totally isolated for nine to 12 months after birth, a procedure that permanently destroys sociability with age mates as well as all forms of sexuality and social communication, no "intellectual loss" has been detected.

Social psychotherapy among monkeys

When there is improvement in behaviour following the harmful effects of social isolation, it seems to come about by a process of social psychotherapy, in which some monkeys act as therapists and others as patients. It has been observed, for example, that the infants of isolate mothers continue to seek maternal attention and, unless actually killed by the mother, are surprisingly successful in forming maternal attachments. Moreover, after three to four months the brutal mothers, even though they still appear to ignore the infants, may begin to behave as if they enjoy the bodily contact with the infants and their sucking for milk. Surprisingly, most of these motherless-mother monkeys who subsequently have a second or third infant come to behave as normal or nearly normal mothers. Apparently, their first infants have psychiatrically rehabilitated them.

Because the first observations of this kind were more or less accidental, experimental psychotherapy was undertaken with a group of monkeys previously kept in total social isolation for six months (a period that had been found to be totally destructive socially if the isolates were then paired with age mates). In this experiment the previously isolated monkeys were intermixed with socially normal monkeys half the age of the former. The assumption was that the younger monkeys would be no threat to the isolates and could eventually re-educate them by initiating social contacts and play. The experiment was successful; gradually the isolate monkeys became progressively less fearful and more socially sophisticated, until they usually could not be distinguished from the normal monkeys.

Personality development. Mild deprivations among natural groupings (extended families) of rhesus monkeys in captivity yields more sophisticated and subtle information about monkey personality than can the more drastic techniques just described. By such means, monkeys can be used as substitutes for human social situations. In some experiments nothing more than an early and a very brief separation of the individual is employed, causing only mild behavioral disturbances. Even these can produce long-lasting personality defects which can be studied with a precision that is impossible with more violent techniques and, of course, is out of the question with humans.

The role of rhesus monkey mothers

Infant rhesus monkeys appear to learn to recognize their mother in the first week or two of life; perceptual and manipulative abilities continue to improve until there is some self-feeding at about three weeks and independent locomotion by about six weeks. The rhesus infants first leave their mothers very briefly when they are about one week old, after which each period of time spent away from the mother increases rapidly from the second to about the 20th week and again just before the end of the first year. During most of its first year the infant spends about 20 percent of the daylight hours awake and attached to the mother's nipple, yet only a small proportion of this time is actually spent sucking. Thus, the nipple serves as a way by which the infant can attach itself to its active mother; it is equally important as a pacifier. Such contact comfort supplied by the mother has been found to be the most important factor in the normal social development of the infant. Moreover, it appears that the increasing independence of the infant with age is the result of a change in the mother's behaviour rather than the infant's. The mother is not merely a guardian and passive provider of the infant's needs; she also plays an active part in promoting its independence. The infant spends more time away from the mother, investigating and exploring the environment, and playing with its peers. Because this play consists primarily of the approach–withdrawal and rough-and-tumble type, the younger infants gradually learn to avoid the playful attacks of their peers. Sex differences appear quite early; males not only initiate more rough-and-tumble play but also exhibit more social threat (*e.g.*, branch-shaking) and mounting behaviour from an early age. Under natural conditions mother and infant live in the complex social structure of a troop of monkeys. Other members in the troop display considerable interest in the infant: looking at, touching, grooming, or holding it; playing with it or behaving aggressively or sexually toward it. The mothers usually resent such attentions and protect their young either by restricting their movements, removing them, or threatening other monkeys.

The attentions of social companions may have a marked effect on the mother–infant relationship, as has been shown by a comparison between mother–infant pairs living in a social environment with mother–infant pairs living in social isolation. In the latter, the infants spent more time away from their mothers because the mothers of such pairs are more permissive. Indeed, in the isolate animals the infants were primarily responsible for maintaining proximity because, in the absence of peer playmates, the mother was the only social companion.

Monkey troop leadership

Effects of social organization. The social organization of the monkey troop also plays a predominant and basic role in controlling what the young animals learn and how they learn it. Females, for example, tend to remain in the centre of the group whereas, in the latter half of their second year, the males move toward the periphery. While the males are doing so, the mother–daughter relation continues, and the dependency on the mother acquired by the daughter in her infancy at the centre of the group seems to be preserved in adult life. As for the males, it is not always the most physically powerful who become leaders of a troop. In fact, a male monkey's chances of becoming a leader are vastly greater if he is born to a female in the troop's organization who is closely associated with the existing leader, even though the leader may not be the father. Because males, including the leader, share in caring for the infants, the children of favoured females, therefore, enjoy a privileged relationship with the leader that the children of other females do not have—a situation curiously reminiscent of patrician families in human societies.

In all monkey and ape societies that have been observed in the wild, clear differences in behaviour have been found from one group to another, even when genetic factors and the general environment are about the same. When Japanese investigators, for example, provided different groups with food, the habit of washing potatoes before eating them spread quite rapidly through one group but not through others. Such habits as swimming, readiness to eat candies, and the use of salt for seasoning provided further examples of new behaviour acquired by the same group that washed its potatoes. Moreover, it was also found that these habits were started by two three-year-old juveniles, after which the habits became popular with their brothers, sisters, and playmates. But, except for some mothers who learned the new habits from their own juveniles, the adults in general resisted adopting any of them. Evidently, it is through the younger ones that new behaviours become widely propagated, eventually being handed down from parent to infant. In fact, both monkey and ape societies show a kind of primitive culture that is acquired by individuals within the society and that constitutes a basic part of the process by which each member of the society develops its own distinctive personality.

Learning of sign language by chimpanzees

Development of "language." The observations described above make it clear that much information passes from one member to another in a troop of monkeys. It is also fairly clear, however, that vocalizations are not the major part of this process; rather, it seems that the chief mode of communication is by facial expression, gesture, posture, and bodily attitude. A number of attempts to teach chimpanzees to communicate information by the use of words have been complete failures. On the other hand, success has been achieved in teaching chimpanzees how to communicate by using a gesture language that is widely used by deaf people to communicate with each other. Two investigators made spectacular progress in understanding the communication of chimpanzees after five years of training a young female named Washoe to use many elements of the gesture language. A great advantage of this technique is that the animal's achievements can be compared directly with those of normal children in learning English and with those of deaf children of the same ages in learning this particular sign language.

After four years of experiment, Washoe had learned to use correctly more than 40 different signs for nouns (*e.g.*, bird, clothes, hammer). In addition, there were four signs of appeal (hurry, please, etc.), five for location (in, up, down, etc.), 24 indicating action (come, go, kiss, etc.), ten for agents or specific people (me, Roger, etc.), and ten for attributes (red, funny, sorry, etc.). Particularly interesting was her ability to use the pronoun "you" appropriately — that is, for any companion — and in combination with a wide variety of signs for actions and attributes. She began to use pronouns and proper names in the third year of teaching and later produced such sign language sentences as "you Roger Washoe out," "you me go out," and "you me go out hurry."

After four years of study, however, the chimpanzee seemed unable to use signs for such combining words as “and,” "for," “with,” or "to." It is significant, however, that words of this type are noticeably absent in the early sentences of young children. Hence, although Washoe’s achievements are not those of a fully articulate adult human being, her earliest two-sign combinations were comparable to the earliest two-word combinations of children.

Other experiments indicate that the linguistic achievements of chimpanzees may be even greater than the results with Washoe have shown. Instead of being taught gesture language, the animal (Sarah) in these experiments was supplied with movable tokens that represented words and that were treated by Sarah accordingly. Although the signs for words were presented to Sarah just as they were to Washoe, she did not have to learn to make the signs herself. Instead, she merely learned their significance and then moved the appropriate tokens on a board to indicate what she meant. In effect, Sarah learned to "write" sentences.

"Gentling." One other interesting phenomenon can with doubt be placed within the category of "learning." Nevertheless, it is significant in learning situations and, in fact, clearly plays a part in the organization of the monkey and ape societies described above. This phenomenon concerns the "gentling" of rats and its result on subsequent behaviour. When female rats are handled gently during their infancy and early life, they appear at maturity less emotional, more ready to leave their cages, and less fearful of strange stimuli than do other rats. In fact, the animal is able to respond more effectively when confronted with normal situations; in other words, its emotional response to novel but normal stimuli is not as intense as it is in rats raised in the usual manner. When such rats become mothers, the body weight and readiness to explore of their young are different from those of a standard controlled group. These effects appear to be mediated through both the prenatal mother–fetus and the postnatal mother–infant relationship. Not only are the young themselves of a different temperament as the result of the early experiences of their gentled mothers, but, when these young bear babies their patterns of mothering are also different from what they would have been normally. Because the effect of the gentling that their mothers received becomes apparent in their grandchildren, it has been called "the grandmother effect."

It appears, therefore, that experiences with both the inanimate and the social environment may affect subsequent fear, avoidance behaviour, and emotionality by a number of mechanisms. These effects in turn will have further ramifying consequences on nearly all other aspects of behaviour. Hence, when considering the effects of environmental manipulations on the development of behaviour, it is necessary to consider this chain of events.

(W.H.T.)

Learning, Perceptual

Perceptual learning refers to the effects of random experience or practice in modifying the way in which an individual processes sensory data. Some restrict this to mean an activity that enhances ability to extract information from external stimuli, permitting more accurate awareness of the environment. This implies the conventional view that learning is confined to improving performance. Nevertheless, practice or ordinary experience also can decrease perceptual efficiency.

For example, human adults are more likely than children to overestimate the size of an object as its distance from the observer increases. Also, many instances of illusory perceiving may result from specific past experience, as in misinterpreting the face of a stranger to be that of an acquaintance. Considering such examples, the term justifiably may be applied to any relatively enduring perceptual modification attributed to learning.

Theories: discovery versus enrichment

Historically, the perceptual role of learning was a source of controversy. Vigorous denials that perceiving is influenced by learning are found in arguments of early Gestalt psychologists (*e.g.*, Max Wertheimer, 1880–1943, a German), By contract, heavy reliance is placed on learning processes in the writings of the German philosopher and scientist H.L.F. von Helmholtz (1821–94). Today, there is virtually full agreement that perceiving is modified by learning. Disputes now focus on the process of perceptual learning itself. Most theoretical alternatives reflect two underlying themes: discovery and enrichment. The discovery thesis is reflected in Eleanor J. Gibson's view that perceptual learning is a process of discovering how to transform previously overlooked potentials of sensory stimulation into effective information. Enrichment theories depict perceptual learning as enriching sensory experience with specific associations and with rules for its interpretation that derive from past experience. Discovery theories propose that perceptual modification results from learning to respond to new aspects of sensory stimuli, while enrichment theories hold that such modification results from learning to respond differently to the same sensory stimuli.

Direct confrontations of these positions are rare, their advocates tending to differ in their selection of experimental procedures and learning situations. It may be that discovery and enrichment theories are compatible, simply accounting for different forms of perceptual learning.

General acceptance of the perceptual role of learning should not be taken to endorse the claim that perceiving originally depends on learning. Indeed, studies of human newborn and very young infants indicate highly organized and stable perceptual functions. Learning is to be regarded as supplementary to unlearned factors that mediate perceiving.

EFFECTS OF PRACTICE

The most direct examination of perceptual learning is provided by investigating the effects of practice.

Detection of stimuli

In so-called detection tasks the observer is required to detect the presence or absence of a selected stimulus. For example, effects of practice on visual acuity were studied by requiring observers to detect simple orientation (left or right) in a row of leaning letters; *e.g.*, E E E E. Practice tended to lower acuity thresholds, defined as the lowest intensity of illumination at which each observer could detect the orientation. Or, observers were asked to say when they just could see that an approaching pair of parallel bars was double. With practice they continued to report seeing the narrow space between the bars at increasing distances. Such improvements suggest that sensitivity to simple (unidimensional) stimuli is not immutable, being modifiable through practice.

Improvement is not limited to simple variables. In one visual-search procedure, subjects scanned a long list of letters to find a single letter that appeared only once. Search time was reduced by a factor of ten following extensive practice, after which ten different letters could be detected as quickly as a single letter. Practice effects with complex targets also have been studied. In one experiment, two rows of figures were displayed on each trial, one with four simple outlines of geometrical figures, the other containing three complicated figures. Subjects were to guess or detect which one of the simple figures was concealed (embedded) in all three of the complex figures. Again, ability to identify the correct simple figure improved with practice.

Tasks involving absolute judgment require much more of the observer than does simple or complex detection. For example, he may be asked to estimate the diameters of circular targets numerically (*e.g.*, in inches or centimetres). In a similar study, two groups of subjects made absolute judgments of widely varying distances outdoors, both before and after interpolated activity. One group spent the interpolated period estimating a large number of other distances, none the same as in the original series. The other group spent the interval on unrelated paper-and-pencil work. In the first (extra-practice) group, judgments became more accurate and less variable than among the pencil-and-paper workers. Increased precision following practice also has been reported for absolute judgments of odour intensities, and of multidimensional visual (colour) and auditory stimuli. Improvement with practice is observed even when the subject remains uninformed of his accuracy; correcting him seems to confer slight benefit.

Many studies have failed to establish a clear basis for observed improvements in altered perceptual sensitivity or discriminability. For example, better performance on an acuity test may result from adopting a new criterion of visual doubleness or from learning how to use characteristics of blur to infer slant among leaning Es. Such uncertainties cloud the theoretical and practical significance of much available data.

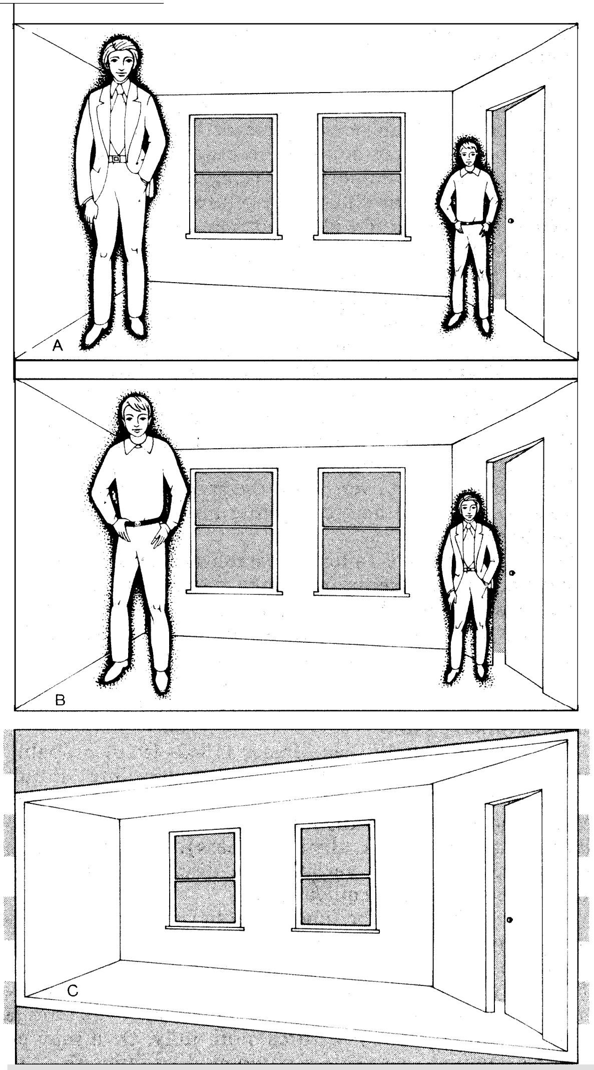
U.S. psychologist William James (1842–1910) probably introduced the notion that practice in labelling stimuli can alter their discriminability. Indeed, sometimes vague visual forms that are distinctively named are easier to discriminate (acquired distinctiveness). If several such stimuli have the same verbal label, discriminability may be reduced (acquired equivalence).

Labelling effects in the laboratory have been discouragingly fragile, however, and factors that favour them are poorly understood. Perhaps labelling affects one's efforts to discover distinguishing characteristics of stimuli. Having him learn distinctive labels may encourage him to analyze sensory features more fully. Or it may be that he begins to perceive a compound stimulus that includes the visual form and its associated label. If labels differ, the presumed compound stimuli are different, and discrimination should be enhanced. These hypotheses express both the discovery and enrichment theses.

EFFECTS OF PERCEPTUAL ASSUMPTIONS

According to one version of the enrichment thesis, exposure to recurrent regularities among stimuli prompts one to assume specific relationships between the environment and his sensory experience. For example, one learns that a continuous sequence of projective transformation (*e.g.*, the circular profile of a dinner plate seems to become eliiptical) is associated with changing positions of the object in view, or that continuous symmetrical expansion of the retinal image is associated with approach. In addition, one presumably learns to make assumptions about what is called reality; *e.g.*, despite alterations in retinal image, one perceives the plate to stay the same size. Psychologists Adelbert Ames, Jr., and Egon Brunswik proposed that one perceives under the strong influence of his learned assumptions and inferences, these providing a context for evaluating sensory data (inputs). In keeping with enrichment theory, Brunswik and Ames contended that sensory stimuli alone inherently lack some of the information needed for mature, adaptive perceiving; enrichment was held necessary to reduce ambiguity.

Much of the evidence for the contention that all perceiving is modified by one's assumptions comes from investigations in which most of the visual, everyday stimuli are eliminated. Often, the subject may view an isolated target in total darkness or look at a motionless display while keeping his head steady. To show that learned assumptions about physical size affect perceived distance, the observer may be asked to judge how far he is from a rectangle of light displayed against total darkness. He is



Perception modified by learned assumptions in a distorted room. The same men change places in A and B in a room modelled after C.

told at one time that the rectangle is a calling card; at another it is called a business envelope. His assumptions about these objects in relation to the size of his retinal image are invoked as prompting him to say that the "envelope" looks more distant than does the "calling card." Dramatic examples of this effect were invented by Ames, including his famous distorted room (see the Figure).

Ames held that perceiving under unusual conditions (*e.g.*, in a dark room) follows the same principles that govern more ordinary experience. The special conditions are said to permit experimental scrutiny of the same processes that are so difficult to examine under ordinary, uncontrolled conditions.

An opposing view is that such perceptual assumptions and inferences operate *only* under specific experimental conditions. It is asserted that only when commonly available sources of information are eliminated is the subject forced to rely on assumptions.

In the tradition of Helmholtz, Ames and Brunswik seemed to liken perceiving to reasoning, although not as a conscious process. They held that perceptual assumptions, once established, are influenced only slightly by logic. Although the floor and ceiling of the distorted room are sloped and all windows are of different size, it projects the same retinal pattern as a normal room; and a naïve subject will report that he sees an ordinary room. But even after he explores the room he remains likely to say it looks rectangular as before, despite his new information. Comparable observations have been reported for a variety of situations. Familiarization or instruction seems to have little effect on long-established perceptual assumptions.

Reasoning and perceiving

INFORMATION DISCREPANCY

Striking examples of perceptual learning are observed when one receives sensory data that contradict earlier experiences. For example, spectacles containing a wedge prism will bend light rays to displace images on the retina. An object thus will be seen as if it were somewhere other than its ordinarily perceived position. The subject's initial attempts to touch the target will be misdirected, and there is a discrepancy between its location as seen and as felt. A right-angle prism will tilt the visual scene to any desired degree, altering the customary direction in which retinal images move. Usually, images of stationary objects move parallel to the direction of head movement; now their motion is at an angle to the head's path.

However, if an observer wears such eyeglasses for an extended period, objects no longer seem displaced, nor does the scene continue to appear tilted. The observer has adapted to the prismatic distortions and comes to perceive the environment as he did pre-experimentally. Similarly adaptation to the perceptual aftereffects rapidly occurs after the prism is removed in such experiments.

Adaptation

Adaptation may be interpreted as perceptual learning that results from exposure to discrepancy. People who wear prism spectacles during active, self-initiated movement tend to show a greater degree of adaptation than do those who sit still or who are moved passively. Apparently conditions that heighten exposure to discrepancies facilitate adaptation. It seems likely that adaptation reflects a learning process during which the perceiver re-evaluates one or more sources of sensory information to reduce his experience of discrepancy. For example, information generated by receptors that respond to tension in skeletal muscles may be re-evaluated to resolve a discrepancy between felt and seen position.

It often is suggested that adaptation to prism eyeglasses may involve the same processes that serve perceptual development in infants. Indeed, some conditions that experimentally facilitate adaptation to prism distortion also seem necessary for everyday perceptual development (*e.g.*, active, self-initiated movement). In work reported by Richard Held (Scientific American, November 1965), actively moving kittens developed visually guided movements normally. When each of these was yoked to a littermate that was pulled passively over the same path, the passive partner failed to develop normal perceptual function. Yet both kittens apparently received identical visual stimuli.

The effects of learning on perceiving are varied. Most of these involve learning to respond to new stimuli or to make new responses to old stimuli. In one case, learning consists of differentiating previously neglected stimulus characteristics; in the other, it is a matter of re-evaluating stimuli and learning to respond to them differently.

BIBLIOGRAPHY. Descriptive reviews of the literature on perceptual learning have appeared at intervals in the *Annual Review of Psychology*, particularly the articles by J.D. DREVER (1960); E.J. GIBSON (1963); and J.F. WOHLWILL (1966). A more extensive review and evaluation of the diverse phenomena and theoretical formulations may be found in W. EPSTEIN, *Varieties of Perceptual Learning* (1967). A major publication is E.J. GIBSON, *Principles of Perceptual Learning and Development* (1969), an examination of the field from the viewpoint of the discovery theory of perceptual learning. This work includes an effort to show the relevance of principles of perceptual learning for a developmental theory of perception.

(W.E.)

Learning, Psychomotor

Human psychomotor skills are organized patterns of muscular activities guided by changing signals from the environment. Driving a car and eye–hand coordination tasks such as drilling a tooth, throwing a ball, typing, operating a lathe, and playing a trombone are behavioral examples. Also called sensorimotor and perceptual-motor skills, they are studied as special topics in the experimental psychology of human learning and performance. In research concerning psychomotor skills, particular attention is given to the learning of coordinated activity of the arms, hands, fingers, and feet; the role of verbal processes (see CONCEPT FORMATION) is not emphasized.

Whenever a person handles knife and fork, signs his name, or taps his foot to music, he is engaging in psychomotor behaviour; and these homely actions are no less perceptual and motor than the sophisticated behaviour of flying an airplane, running a printing press, executing a backhand stroke in tennis, or turning out a piece of ceramics. Some sensorimotor skills rest on eye–foot coordinations (*e.g.*, kicking a ball) or hand–foot coordinations (*e.g.,* playing an organ); others call for complex integrations of many parts of the body (*e.g.*, circus acrobatics, gymnastic routines). Arts and crafts, as well as scientific and technical abilities, require the skillful performance of motor acts under the guidance of sensory processes monitored by the brain.

Factors in performance

Although psychomotor skills are widely distributed—*e.g.,* in military, athletic, musical, and industrial settings—such complex situations typically do not lend themselves to rigorous experimental research. Most scientists have found it more analytically useful to study psychomotor learning under controlled laboratory conditions. Measures of proficiency obtained in the laboratory reflect increasing accuracy and decreasing variability in a learner's performance as training progresses. If there is sufficient genetic aptitude, a person's mastery of a skill depends on his motivation to improve, on his receiving continuous information or sensory feedback about the adequacy of his performance during training, and on such factors as the rewarding effects of corrections made during successive practice periods. Skills are susceptible to inhibitory influences. The full extent of gains in proficiency often is masked by temporary losses and emerges only later, without additional practice sessions.

Psychomotor habits are mediated primarily by the sensory and motor cortex of the brain and by the neural fibres (commissures) that connect the two cerebral hemispheres. According to the majority of theoreticians, learning proceeds (habit strength develops) as a mathematical function of the amount or duration of rewarded (reinforced) practice (see LEARNING THEORIES). The effects of associative and motivational factors are believed to combine mathematically by multiplying one another, while inhibitory and oscillation (variability) factors are thought to have subtractive effects. Despite theoretical and empirical progress, much remains to be discovered about the learning and performance of psychomotor skills, especially about the interrelationships among training variables, feedback contingencies, and human-factor variables.

LABORATORY RESEARCH IN PSYCHOMOTOR LEARNING

The pursuitmeter and the mathometer

Devices and tasks. Hundreds of electrical and mechanical instruments have been developed for research in psychomotor learning, but those commonly used number less than two dozen. In operating a device called a complex coordinator, the learner is instructed to make prompt, synchronized adjustments of handstick and foot-bar controls to match different combinations of stimulus lights. Another device, a discrimination reaction timer, requires that one of several toggle switches be snapped rapidly in response to designated distinctive spatial patterns of coloured signal lamps. In performing on a manual lever, a blindfolded subject must learn how far to move the handle on the basis of numerical information provided by the experimenter. With a so-called mirror tracer, a six-pointed star pattern is followed with an electrical stylus as accurately and quickly as possible, the learner being guided visually only by a mirror image. The operator of an instrument called a multidimensional pursuitmeter is required to scan four dials and to keep their indicators steady by making corrections with four controls of the type found in an airplane cockpit. On a rotary pursuitmeter the trainee's task is to hold a flexible stylus in continuous electrical contact with a small, circular metal target set into a revolving turntable.

Also employed in such research is a selective mathometer, on which the subject's problem is to discover, with cues provided by a signal lamp, which of 19 pushbuttons should be pressed in response to each of a series of distinctive images projected on a screen. While using a star discrimeter, a person receives information about his errors through earphones; his task is to learn to selectively position one lever among six radial slots in accordance with signals from differently coloured stimulus lights. A trainee on a two-hand coordinator has to manipulate two lathe crank handles synchronously to maintain contact with a target disk as it moves through an irregular course.

Measurements. The tasks required by the above devices produce a substantial range of psychomotor difficulty. The elements of skilled behaviour are expressed as numerical scores; *e.g.,* correct response and error percentages, amplitude and speed of movement, hand or foot pressures exerted, time on target, reaction time, rate of response, and indices of time-sharing activity. Most of the behaviour thus recorded lends itself readily to mathematical treatment. Laboratory devices for studying psychomotor learning characteristically exhibit high reliability (*i.e.*, intra-task consistency) and yield scores of useful validity (extra-task correlation) in predicting such behaviour as performance in factory work and the operation of motor vehicles and aircraft. In other words, it would appear that perceptual-motor devices reliably measure what they are designed to measure, and they also tap a significant proportion of the abilities required in real-life situations (see also MEASUREMENT, PSYCHOLOGICAL). When properly maintained and used under standardized conditions, and when the resulting measurements are treated by statistical methods, the above devices are prime choices for many applied and basic research programs.

PHENOMENA OF PSYCHOMOTOR LEARNING

Acquisition. Speed and accuracy in the majority of psychomotor tasks studied are typically acquired very rapidly during the early stages of reinforced practice, the average rate of gain tending to drop off as the number of trials or training time increases (Figure 1). Curves based on such measures as reaction time or errors reflect the learner's improvement by a series of decreasing scores, giving an inverted picture of Figure 1. Tracking scores from the two sexes are seen in Figure 1. Other devices have yielded more complicated functions—*e.g.*, S-shaped curves for complex multiple-choice problems on the selective mathometer (Figure 2). Most acquisition curves (whether the dependent response variable measured is positively or negatively related to the independent practice variable) obey a law of diminishing returns as high levels of skill are approached. Data such as those from tracking and multiple-choice tasks can be explained by rational mathematical equations derived from theoretical models (see formulas and captions in Figures 1 and 2). Between them, these two equations describe psychomotor acquisition curves from a wide variety of learning situa-

From Clyde E. Noble, "Acquisition of Pursuit Tracking Skill Under Extended Training as a Joint Function of Sex and Initial Ability," *Journal of Experimental Psychology*, vol. 86, pp. 360–373 (1970); Copyright (1970) by the American Psychological Association, and reproduced by permission

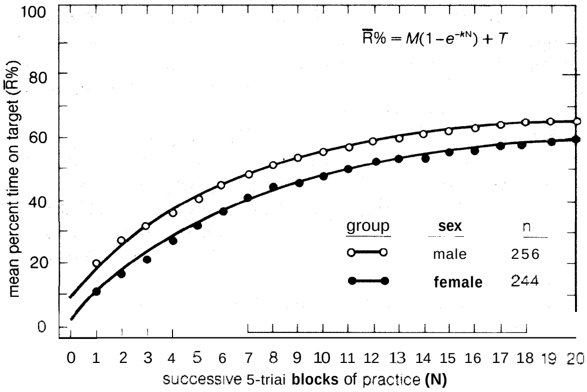


Figure 1: Rotary pursuit acquisition curves.
Average percent of response time on target ($\bar{R}\%$) while using a rotary pursuitmeter is plotted as a mathematical function of the number of successive 5-trial blocks of practice (N), with sex as the distinguishing factor, for 500 subjects. Both curves are predicted by the exponential equation shown in the figure, where T, k, and *M* represent origin, rate, and limit of theoretical response time, respectively.

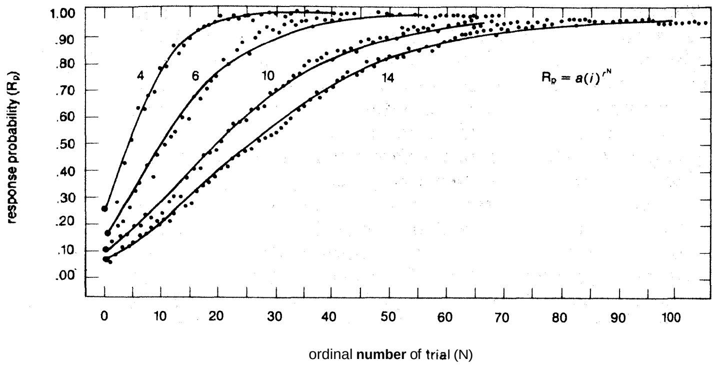

Figure 2: Selective mathometer acquisition curves. Response probability (R_p), or relative frequency of correct multiple choices, in a selective mathometer learning experiment is plotted as a mathematical function of the number of successive practice trials (N), with task length (4,6,10, or 14 units) as the experimental condition, for 192 male subjects. All four curves are predicted by the double-exponential equation shown in the figure, where I,r, and a represent origin, rate, and limit of theoretical response probability, respectively.

From Ciyde E. Noble, "The Length–Difficulty Relationship in Compound Trial-and-Error Learning" Journal of *Experimental Psychology.* vol. 54 (1957), pp. 246258 (1957); Copyright (1957) by the American Psychological Association, and reproduced by permission

tions and of trainees with less than a 2 percent average error of prediction. Contrary to lay opinion, stepwise plateaus of proficiency are seldom seen, not even in learning Morse code. The "natural plateau" is a phantom.

Similarity and performance

Generalization and transfer. The occurrence of the phenomenon of generalization is seen in the tendency of laboratory subjects (conditioned to respond to a particular stimulus—*e.g.*, a light) to respond as well to similar stimuli beyond the original conditions of training. As differences along a physical continuum (*e.g.*, brightness) between the stimuli used in training and those encountered on test trials increase, the effects of generalization decrease until there may be no transfer from one situation to another. Alternatively, the more the two situations have in common, the greater is the amount of predictable transfer. Generalization (or transfer) may be based on temporal patterns of stimuli (*e.g.*, rhythms), spatial cues (*e.g.*, triangularity), or other physical characteristics (see TRANSFER OF TRAINING).

The measured effects of prior training on the performance of a subsequent task define the transfer of psychomotor learning. Although similar, the latter task usually differs measurably from that originally practiced. A common example is the ability required of many automobile drivers to change easily from, say, a three-speed transmission with a horizontal gear lever on the steering wheel to a four-speed mechanism with a vertical floor-mounted gearshift. In laboratory tasks the amount and direction of transfer effects are accurately predicted. In practical skills, transfer is more likely between tennis and badminton than between swimming and football, between comet and trumpet than between piano and tuba. Similarity is not the only correlate of transfer, however, and empirical studies of these effects must take account of such factors as the amount of practice and the sequence of events in previous training.

Transfer effects may be positive, negative, or zero; *i.e.*, learning one task may facilitate, hinder, or have no observable influence upon performance of the next task. Flight simulators are designed to maximize the amount of positive transfer, often by ensuring high levels of behavioral similarity. Negative transfer effects (*e.g.*, reaching for the floor to shift gears when the lever is on the steering wheel) appear occasionally but tend to be rare, transitory, and easily overcome. Since transfer necessarily involves retention, the best schedules minimize forgetting by the inclusion of short time intervals between training and transfer.

The degree and amount of transfer are contingent upon such factors as number of common elements or principles, stimulus and response similarity, amount of predifferentiation training, the variety of learning-to-learn experiences, part–whole relationships, differences in intertask complexity, use of mnemonic aids, and the extent of proactive or retroactive interference, Transfer equations usually assume that the basic indices of performance for experimental and control groups will increase with practice, that the possible measures range from negative 100 percent through zero to positive 100 percent, and that the groups have been equated in aptitude or initial ability to learn before the experimental treatments are begun. Retroactive interference designs typically employ a sequence of original learning, interpolated learning, and relearning.

Effects of rest intervals

Retention. Learning is to acquisition as memory is to retention. Psychomotor retention scores indicate the percentage or degree of originally learned skill that is remembered or recalled as a function of elapsed time. Alterations of motor memory are reflected by changes in means, variances, and correlations between test results. In contrast to verbal behaviour, which is notoriously susceptible to forgetting through interference within a matter of seconds, mean scores for tracking and coordination skills recorded over periods ranging from two days to two years diminish scarcely at all. Yet, when intervals of three minutes to six weeks are interpolated between discrete responses on a manual lever device, performance remains stable for about two days and then becomes inconsistent; variabilities increase and correlations decrease as the subjects mis-recall more and more of their original skill. In the light of this evidence, motor memory may be viewed as a phenomenon of persistence, while forgetting is a case of inconsistence.

One hypothesis advanced to account for the greater retentivity of psychomotor behaviour, as compared to that of newly acquired verbal behaviour, is that nonverbal striped-muscle responses are more often overlearned and are less susceptible to proactive interference (*i.e.*, competition arising from things learned in the past). Distinctions between immediate, short-term, and long-term memory are also less prominent in studies of motor learning, possibly because of the devotion of skills specialists to efficient practice and feedback methods that ensure permanent storage of habits in the brain. This is not to say that motor skills are unforgettable; studies of short-term memory suggest that psychomotor forgetting can be swift indeed. Regardless of theoretical differences, however, psychologists generally agree that psychomotor behaviour is best remembered (and least forgotten) when overlearning is high, interference is low, reinforcing feedback is optimal, and interpolated activities are unrelated to the task being learned. Time is less important in the degradation of memory than are the events that fill the time (see also MEMORY: RETENTION AND FORGETTING).

Reminiscence. The phenomenon of reminiscence is a gain in performance without practice. Thus, when subjects performing trial after trial without rest (massed practice) are given a short break, perhaps midway through training, scores on the very next trial will show a significant improvement when compared with those of a massed group given no break. Reminiscence effects are most prominent in tasks demanding continuous attending and responding; they are least often observed with discrete-responding apparatus. The theoretical importance of this concept derives from its role in testing a hypothesis of reactive inhibition that asserts that a decremental process cumulates in the organism as a positive function of responding to stimulation and a negative function of resting time. That the phenomenon of reminiscence also manifests bilateral transfer of skill (*e.g.*, from the left to the right hand) suggests that the locus of the decrement is in the central nervous system rather than in the peripheral effector organs. Indeed, merely watching another subject practicing on a rotary pursuitmeter has an inhibitory effect on a person's performance; yet the cause is neither boredom nor fatigue.

Warm-up. Athletes and musicians often report that they get "cold" during a layoff (even for a rest period of a mere five minutes); when practice is resumed, the decrement in performance requires a warm-up before it is overcome. Similarly, on a rotary pursuitmeter, it is necessary to regain the optimal posture, grip the stylus correctly, begin the coordinated movements of eyes and hand, and recapture the proper whole-body rhythm. Warm-up produces a further gain in proficiency following the initial reminiscence effect. Mean scores continue to rise for several trials, reach a peak at the level found for distributed practice, and then fall more gradually until they merge with the curve for massed practice. When the duration of rest is extended, the amount of warm-up decrement first increases rapidly and then decreases; similar findings obtain for a succession of work and rest periods. Investigators who have tried to substitute warm-up activities other than actual pursuitmeter practice to offset or reduce the magnitude of the decrement have not been successful. At least for continuous psychomotor tasks of this sort, the need for proper, task-specific warm-up appears to be an intrinsic requirement of efficient performance. Wherever reminiscence goes, warm-up seems to follow; yet the converse does not always hold. The connection between warm-up and forgetting is uncertain.

Warm-up as a practice factor

Refractory period and anticipation. When required to make quick, discrete responses to two stimuli separated in time by one-half second or less, an operator's reaction time (latency) for executing the second response is typically longer than that of his first response. This difference in reaction time is called the psychological refractory period. At one time, it was thought possible that sensory feedback from the first response might stack up in the nerve centres to make the system refractory for a brief time, thereby delaying the processing of the second stimulus. Research findings that erroneous reactions could be corrected within one-tenth second would seem to negate the hypothesis. An alternative suggestion is that corrective movements are facilitated by feedback from the incorrect ones, and controlled observations appear to confirm that error-correcting responses have shorter latencies than those that are either correct or erroneous. Apparently, a false movement can be stopped on the basis of internal cues more promptly than on that of external stimuli.

Expectancy is a collateral factor with which researchers have had to reckon; *i.e.*, a subject may learn to accommodate himself to expect a delay between the first and second stimulus and thus be relatively unprepared should the second arrive earlier than usual. Further, people learn to be more expectant for particular kinds of stimuli than for others. When a person is uncertain about whether regularly occurring stimuli will be auditory or visual, or when their spatial direction is uncertain, performance is significantly degraded. This would suggest the possibility of divided attention; indeed, when pairs of stimuli are made perfectly predictable as to time and type, no impairment of response is observed.

Learning to divide attention

If a subject can acquire suitable expectancies via training and experience, then he can improve the skill of dividing his attention and, within physiological limits, simultaneously handle an increased range of stimuli without loss of proficiency. Results from extended practice on a task requiring successive choice and dual reaction indicate that. with learning, people can reduce the psychological refractory period. The ability to develop anticipatory responses to regularly occurring stimulus cues is well established. A military gunner scanning a distant fixed target for azimuth and elevation, for example, is engaging in a preview of receptor anticipation to maximize his score. An operatic tenor who rehearses covertly the opening notes of his cadenza while the orchestra finishes the introduction is employing perceptual anticipation to optimize his rendition. Anticipatory timing is learned, and reinforcing feedback is necessary.

FACTORS AFFECTING PSYCHOMOTOR SKILL

Amount of practice. It has been noted above (Figure 1) that the practice of sensorimotor tasks usually produces changes in scores that reflect diminishing returns. A major influence in learning generally, repetition is the most powerful experimental variable known in psychomotor-skills research. But practice alone does not make perfect; psychological feedback is also necessary. The consensus among theoreticians is that feedback must be relevant and reinforcing to effect permanent increments of habit strength. Once developed, habit never dies; it does not even fade away.

The effects of feedback and four other important performance variables (*i.e.*, task complexity, work distribution, motive-incentive conditions, and environmental factors) remain to be summarized.

Psychological feedback. Ranking prominently among experimental variables are so-called feedback contingencies (aftereffects, knowledge of results) that may be controlled by the experimenter so as to occur concurrently with or soon after a subject's response. A learner appears to improve by knowing the discrepancy between a response he has made and the response required of him; but, in experimental practice, the investigator manipulates behaviour by transforming functions of error. Since transformations are usually numerical or spatial, sensory returns from one's action may be informative, motivating, or reinforcing. Response-produced stimulation is intrinsic to most skeletal–muscular circuits; the neural consequences of bodily movement are fed back into the central nervous system to serve the organism's regulatory and adaptive functions. When this normal feedback is interrupted or delayed, psychomotor skill is often seriously degraded. Experimentally delayed auditory feedback of a subject's oral reading produces stuttering and other speech problems; delayed visual feedback in simulated automobile steering is a greater hazard under emergency conditions than is the driver's reaction time.

Generalizations about psychomotor learning

Laboratory investigations have supported the following generalizations about psychomotor learning: (1) without some kind of relevant feedback, there is no acquisition of skill; (2) progressive gains in proficiency occur in the presence of relevant feedback; (3) performance is disrupted when relevant feedback is withdrawn; (4) delayed feedback in continuous (but not discrete) tasks is typically decremental; (5) augmented or supplementary feedback usually results in increments; (6) the higher the relative frequency of reinforcing feedback, the greater is the facilitation of skill; and (7) the more specific the feedback (*e.g.*, in designating location, direction, amount), the better is the performance.

Experiments with a manual lever device, for example, suggest that when feedback is introduced and withdrawn at four stages of practice, the effect on error scores is profound. Knowledge of results given early and late has effects similar enough to reject any hypothesis that learning arises merely from repetition. These experiments indicate that practice makes perfect only if reinforced; the result of unreinforced practice is extinction of the correct response and a proliferation of errors. Studies employing a complex mirror-tracking apparatus have clarified the role of reinforcing feedback. Targeting performance was facilitated by presenting distinctive supplementary visual feedback cues previously associated with aversive (electrical shock) and nonaversive consequences. Moreover, the amount of facilitation grew curvilinearly with the number of cue conditioning trials. Work on human incentive learning thus demonstrates that the rate of gain in psychomotor proficiency can be regulated by stimuli that have been accompanied by positive or negative aftereffects. Persistence of the acquired reinforcing effects, considered with their cumulative quantitative properties, enhances the attractiveness of theoretical interpretations that emphasize continuity and reinforcement as contrasted with theories based on discontinuity and contiguity alone. Clark Hull's system (1943) is the classic model.

Human incentive learning

Task complexity. The complexity of discrete psychomotor tasks may be specified either as the number of response sequences a subject can make or as some measure of a subject's uncertainty about choices among stimuli. Still other factors that have been investigated as instances of complexity include variations in the number of possible responses at each choice point, different lengths of series, and regular versus unpredictable stimulus sequences.

Experimental procedures involving an increase of complexity produce more errors, require more trials to reach proficiency, and result in longer latencies per trial. Difficulty in psychomotor learning, therefore, generally increases with the complexity of the task to be mastered. An example of this phenomenon appears in Figure 2. Subjects exhibit continually altered probabilities of response during training sessions, and an average person with enough practice on a discrete sensorimotor task can learn to perceive, select, and react as fast to ten stimuli as he can to two. Apparently, it is not the number of choices among stimuli as much as it is the number of choices among responses that slows up a subject's processing activities and complicates his decision problems. Indeed, by limiting response alternatives (*e.g.*, circumscribing the physical range of a trainee's movements or providing supplementary auditory and visual indicators of error), a training device can facilitate the acquisition or transfer of skill.

Work distribution. Hazardous though generalizations about work and rest in psychomotor learning may be, a few guiding principles are notable: (1) massed practice is usually superior to distributed practice for simple discrete-trial tasks; (2) distributed practice is usually superior for complex continuous-action tasks; (3) short practice sessions are generally superior to long practice sessions; (4) long rest periods are generally superior to short rest periods, although forgetting must be counteracted; (5) for continuous-tracking tasks practiced under constant work sessions and variable rest periods, the final proficiency level grows curvilinearly as the intertrial interval is lengthened; (6) gains in proficiency under distributed practice, or with interpolated rest periods during massed practice, are usually in terms of performance rather than of learning; (7) losses in proficiency under massed practice, or with increased work load, usually pertain to inhibitory rather than motivational decrements; (8) under certain conditions (*e.g.*, "cramming" for examinations) it may be most efficient to mass practice as long as adequate rest can be obtained before criterion performance is demanded; (9) reminiscence increments and warm-up decrements are intimately related to schedules of work and rest; (10) decrement is not the same as fatigue.

Quite apart from the practical question of the optimal management of training programs (*e.g.*, in coaching oarsmen in racing shells), the aversive inhibitory consequences of sustained action that are recognized as subjective fatigue and behavioral decrement are clearly adaptive. By a reflex negative-feedback mechanism, inhibitory impulses may prevent an organism from working itself to exhaustion. With few exceptions, the presumption in favour of spaced practice can safely be taken out of the psychomotor-skills laboratory and applied in the gymnasium, lake, and playing field. Research on the skills involved in, for example, archery, badminton, basketball, golf, javelin throwing, juggling, marksmanship, rowing, and tennis supports the notion of distributing training by means of short workouts and frequent breaks (see also FATIGUE).

Distributed practice applications

Motive-incentive conditions. Motivational processes are states of the organism that serve to activate reaction tendencies. Such states are classified as primary (innate) or secondary (acquired, learned) motivation. Though common physiological needs (*e.g.*, for food, water, avoidance of pain) may evoke psychological drives (*e.g.*, hunger, thirst, pain), the concepts of need and drive are not perfectly correlated. Some needs (*e.g.*, oxygen demand) seem to have no specific behavioral drive, and for some drives, clear-cut biological needs remain to be identified (*e.g.*, curiosity). Despite this apparent discrepancy, there is a theoretical consensus that psychological drive arouses the body to action, energizes its latent responses, and supports its behaviour over time. Most theorists believe that motivation (drive) and learning (habit) interact (in a multiplicative — drive times habit equals action — manner) in generating response. In other words, to produce action both are theoretically indispensable, but neither is sufficient alone. A person is not likely to perform a skill if he does not want to and cannot do so if he does not know what to do. The multiplicative theory implies that the same level of psychomotor proficiency may arise from quite different combinations of learning and motivation. Moreover, the organism's temporary drive state seems clearly to affect the adequacy of reinforcing feedback (*e.g.*, offers of monetary reward do little to arouse one who is already trying his level best). While these theoretical interpretations often apply well to laboratory animals, their application to human acquisition of skill is complicated because incentive learning in man can become very abstract.

Physiological explanations of human behaviour that depend on the concept of primary motives (derived from research with rats and dogs) run into difficulties in view of the fact that primary motivation and reward do not appear to be critical in most studies of human skill acquisition. Thus, instead of giving food pellets (as to a rat), an experimenter delivers praise to a human subject; rather than receiving feedback by electric shock, the human can be guided by a needle moving on a dial or a buzzer signalling an error. At any rate, despite efforts to distinguish such motivational factors as general drives from selective incentives, attempts to demonstrate significant motivational effects in human psychomotor learning have met with only modest success. Among exceptions to the above are a few studies with standard apparatus (*e.g.*, the complex coordinator) and with special devices that have indicated that such incentives as money, verbal threats, electric shock, exhortations, and social competition may be relevant. Significant effects frequently fail to appear in experiments, and findings are often contradictory, so it has been suggested that the intrinsic challenge of the gadgetry, coupled with the subjects' already high pre-experimental motivation, leaves human volunteers unaffected by such weak laboratory manipulations of motive-incentive conditions as the foregoing (see also MOTIVATION).

Contradictory findings about motivation

Environmental factors. Many practical skills must be executed outside the laboratory under unfavourable conditions of temperature, humidity, illumination, and motion. It is generally found that below the limiting levels of extreme stress, such conditions affect psychomotor performance to a greater extent than they affect psychomotor learning. Representative findings have included the following: (1) isolation and sensory deprivation cause dramatic reductions in vigilance and monitoring skills within an hour; (2) environmental temperatures above or below 70° ± 5° F tend to lower scores on tracking apparatus but do not impair learning; (3) lack of oxygen slows reaction time, especially when the atmosphere corresponds to altitudes of 20,000 feet or higher; (4) accelerations of the body in a centrifuge or rotating platform disrupt postural coordination and produce systematic shifts in the perception of the vertical; (5) although such people as acrobats, dancers, pilots, and skaters can adapt well to high accelerations, even they lose equilibrium if deprived of the customary visual frame of reference; (6) rather mild centrifugal effects of slow, constant rotation may induce acute motion sickness and associated degradation of psychomotor proficiency in normal persons; (7) while some controlled work–rest schedules of crews during confinement in a small cabin upset daily sleep rhythms and lead to decrements in watchkeeping, memory, and procedural skills, a schedule of four-hours-on versus four-hours-off duty can be maintained for several months without significant impairment; (8) faulty identifications of visual displays on an eye–hand matching task have been produced in volunteer subjects exposed to controlled infectious diseases (*e.g.*, respiratory tularemia, phlebotomus fever, viral encephalitis).

Other environmental stress variables found to exert negative influences are vibration, low illumination, high atmospheric pressure, noise, glare, toxic gases, ionization, and subgravity. Certain drugs have positive effects on psychomotor performance (*e.g.*, amphetamines, magnesium pemoline, methyl caffeine, pipradrol); some have deleterious effects (*e.g.*, alcohol, barbiturates, diphenhydramine hydrochloride, lysergic acid, meprobamate, phenothiazines, scopolamine, tetrahydrocannabinol, tripelennamine); and others are either neutral or have inconsistent effects (*e.g.*, caffeine, nicotine).

INDIVIDUAL AND GROUP DIFFERENCES

Statistical indices of psychomotor ability (*e.g.*, means, variances, correlations) not only differ among individuals but may also serve to distinguish from each other groups of persons classified by such traits as age, sex, race, personality, and intelligence. Efforts to specify the relative contributions of heredity and environment to these individual and group differences are treated in GENETICS, HUMAN and HUMAN BEHAVIOUR, INNATE FACTORS IN. Comparative psychological studies of monozygotic (identical, one-egg) and dizygotic (fraternal, two-egg) twins have indicated that high coefficients of heritability—measured as a ratio of genotypic to phenotypic variance—exist for perceptual, spatial, and motor abilities.

Types of changes with age

Age. The most pervasive differences in human performance on psychomotor apparatus are associated with chronological age, and scores obtained from nearly all the devices mentioned above are sensitive to age differences. Researchers generally report a rapid increase in psychomotor proficiency from about the age of five years to the end of the second decade, followed by a few years of relative stability and then by a slow, almost linear decrease as the ninth decade is approached. For simple hand or foot reactions, complex discrimination-reaction time, and coordinated automobile steering, the peak of skill is attained between ages 15 and 20 on the average, and then performance at age 70 declines to about the level of age 10. This is a two-stage process: first, a developmental phase (*e.g.*, through maturation), followed by the more gradual deterioration of aging. Common athletic skills (*e.g.*, balancing, catching, gripping, jumping, reaching, running, and throwing) also improve through childhood, and it is well known that most athletes reach their prime before the end of the third decade. Olympic events requiring great muscular strength or stamina (*e.g.*, swimming) are dominated by athletes in their teens and 20s, whereas practitioners of more refined technical skills (*e.g.*, gymnastics) tend to be older. Self-paced, leisurely sports (*e.g.*, golf) are favoured over opponent-paced, combative activities (*e.g.*, tennis) as the aging process continues. Hereditary potentialities require several years to become established. It is probable that the genetic factors that underlie growth rates, and the age sequence in which different kinds of behaviour first appear, affect learning as well as performance.

Sex. Although the assessment of sexual differences in perceptual and reactive abilities is complicated by a number of factors (*e.g.*, age, race, and personality), girls and women tend to be more proficient than boys and men in such psychomotor skills as finger dexterity and inverted-alphabet printing. On the other hand, males generally do better than females at pursuit tracking, repetitive tapping, maze learning, and reaction-time tasks. On rotary pursuitmeter tests, women are not only less accurate but more variable than men of the same age and race (Figure 1). Although males appear to be superior to females in aptitude and capacity, these advantages disappear when subgroups are carefully matched for initial ability. In contrast, speed scores on discrimination-reaction tests reveal clearly diverging trends for college men and women trained intensively for several days (960 trials). This seems to be a genuine sex difference rather than an element of measurement or selection. Though both groups were equated for intelligence and had similar error scores, females began to suffer cumulative impairment on the fourth day of practice, whereas males kept improving. Sizable average differences in reaction latency as well as in movement time are characteristic of the sexes on other tasks.

Athletic skills

Whereas girls tend to attain their maximum proficiency in speeded tasks earlier in life than boys do, males continue to gain over a longer period and maintain their superiority over females for about half a century of the lifespan. After puberty, boys excel at most athletic skills demanding stamina and strength (*e.g.*, jumping, running, throwing). Thus, female Olympic swimming and track-and-field records are inferior to those of males and are achieved by girls who are noticeably younger than male champions in the same events. Sex has also been implicated in experiments employing complex coordinators, mirror tracers, and selective mathometers, with boys and men typically surpassing girls and women. Not all psychomotor differences associated with sex are intrinsically biological; unequal opportunities, distinctive social learning, role playing, and other culturally conditioned influences undoubtedly modulate the learning and execution of skills by males and females.

Race. All mankind is of one species. Zoologically, human races are all mutually interfertile subspecies—*i.e.*, breeding populations that differ in the relative frequencies of one or more genes (see ANTHROPOLOGY; HUMAN POPULATIONS; RACES OF MANKIND). Although the Variety of possible traits is practically limitless, random mating is not the case. Because of historical inbreeding tendencies, it is statistically improbable that any two human races have the same means and variances for all psychological traits. Not surprisingly, therefore, significant differences in psychomotor behaviour are foupd among ethnic groups throughout the world.

In one classic set of data (1904) on form-board skill (fitting nine geometric forms into correct holes), the average time in seconds for completing the task varied for different races—*e.g.*, seven African Pygmies (82.20), 12 Philippine Negritos (63.30), 55 American Indians and Eskimos (34.24), and 74 U.S. whites (27.80). Average error scores fell in the same order and, consistent with a genetic hypothesis, hybrid groups were appropriately ranked in between. These small samples were, however, not necessarily representative; *i.e.*, no effort was made to equate for differences in cultural values and psychomotor experiences found in different societies. Furthermore, since these were average differences, no conclusions about individual persons were warranted. It is interesting that the rankings were found to change for other psychomotor tasks; *e.g.*, on a test of tapping and aiming skill, Eskimos surpassed all others, followed by Filipinos, who were in turn trailed by Caucasians. A more recent study (1967) discovered that a sample of Mongoloid Chamorro people from Saipan and another of Indians from the U.S. exceeded white norms on a test of maze-tracing ability. In both studies, people of mixed races tended to make intermediate scores, a fact consistent with contemporary research in behavioral genetics and physical anthropology.

Absence of a superior race

No particular race is found to be uniformly superior in all psychomotor aptitudes and capacities, but environmental causes seem to be inadequate to explain differences in rate of acquisition and final level of performance on standard apparatus. For some tasks (*e.g.*, on the rotary pursuitmeter) psychologists report that the degree of initial hereditary determination seems to reach 90 percent, thus leaving little room for sociological variables to operate. Teams conducting research with infant tests have noted that Congoid babies in both Africa and the United States are more precocious in sensorimotor maturation than are Caucasoid babies in Africa, the United States, or Europe, and that this precocity lasts about three years, after which whites outperform the blacks. By adolescence, Negro subjects score significantly less well than whites on complex coordinator, rotary pursuitmeter, discrimination reaction, selective mathometer, and two-hand coordinator tasks. On the other hand, Chinese- and Japanese-American infants lag behind Caucasians in motor development but perform better than both whites and blacks on certain eye–hand coordination and dexterity tasks at later ages.

Many research workers believe that social, economic, educational, and attitudinal variables that might unequally influence minority groups are of little consequence in the psychomotor field. They point out, for instance, that Chinese, Jewish, Negro, and Puerto Rican children, when tested by members of their own cultures, show distinctive patterns of basic perceptual and motor abilities, and their particular skill profiles are unaffected by differences in socio-economic level. Malnutrition (*e.g.*, protein deficiency) is not believed to be a plausible explanation unless there has been severe deprivation during the perinatal period. According to much of the literature, blacks generally do better than whites on chemical taste tests, rhythmic discrimination, visual acuity, colour perception, and resistance to special optical illusions; Mongoloids show better taste sensitivity and less colour blindness than Caucasoids; and on certain physical-fitness tests male Afro-American athletes are not only superior to their white countrymen but their relative proficiency is inversely correlated with the degree of Caucasoid admixture.

Genetic behavioral differences among human populations—just as those of morphology—appear to be the rule rather than the exception. Tarahumara Indians far surpass other races in endurance at long-distance running contests; Andeans and Tibetans are superbly adapted to working at high altitudes; Eskimos excel on psychomotor tasks performed under low-temperature stress. It is plausible that the inherited factors underlying behavioral aptitudes and capacities have evolved from different selective pressures in different ecological niches. As is true for age and sex, however, hereditary and environmental variables are complexly intertwined in racial studies. Nevertheless, genetic determinants seem to be far more powerful in the etiology of original psychomotor aptitudes. It does not follow that learnability is weak. Quantitative experiments demonstate that heritabilities can be systematically altered by controlled practice; this is a theoretical discovery of broad implications for practical training programs. At the same time, it would appear that the hereditary control of several psychomotor abilities tends to be less pronounced at the end of training than at the beginning.

IQ correlations

Other factors. A number of other personal characteristics have been found to be of significance in psychomotor behaviour. For instance: (1) speed scores in reaction-time tasks are positively correlated with body temperature in adults, one of the many indices of variation within the individual; (2) psychotics show longer reaction times and poorer tracking scores than do people of normal personality; (3) right-handed operators are favoured on the rotary pursuitmeter, while left-handed persons tend to do better on the complex coordinator; (4) left-handed people are more variable in finger-dexterity and paper-cutting skills and also are more prone to show signs of ambidexterity; (5) intelligence quotients (IQ) are weakly related to physical strength or endurance yet are strongly associated with performance in such psychomotor activities as running the 35-yard dash, balancing on one foot, discrimination reaction, rotary pursuit, and selective mathometry—these correlations are especially high when based on groups that comprise a full range of IQs (from retardates to college students); (6) typically one's body build (somatotype) is associated with his athletic skills—the best fencers, oarsmen, and basketball players, for example, tend to be tall and lean (ectomorphic); top swimmers, divers, and pole-vaulters are likely to be broad-shouldered and slim-hipped (mesomorphic); champion wrestlers, shot putters, and weight lifters are apt to be thick-trunked and short-limbed (endomorphic). While these genetically determined somatotypes do not guarantee athletic prowess, they definitely do favour success in certain sports rather than others. Similar considerations apply to vocal and instrumental musical aptitudes wherein unique combinations of such anatomical structures as lips, teeth, larynx, tongue, eyes, ears, hands, and arms can facilitate the attainment of virtuoso skill.

In short, psychomotor abilities and learning underlie some of the most fundamental human activities, contributing to the full spectrum of work, play, creativity, love, and the very survival of individual and species.

Learning Theories

A common goal in defining any psychological concept is a statement that corresponds to common usage. Acceptance of that aim, however, entails some peril. It implicitly assumes that common language categorizes in scientifically meaningful ways; that the word learning, for example, corresponds to a definite psychological process. However. there appears to be good reason to doubt the validity of this assumption. The phenomena of learning are so varied and diverse that their inclusion in a single category may not be warranted.

Recognizing this danger (and the corollary that no definition of learning is likely to be totally satisfactory) a definition proposed in 1961 by G.A. Kimble may be considered representative: Learning is a relatively permanent change in a behavioral potentiality that occurs as a result of reinforced practice. Although the definition is useful, it still leaves problems.

The definition may be helpful by indicating that the change need not be an improvement; addictions and prejudices are learned as well as high-level skills and useful knowledge.

The phrase relatively permanent serves to exclude temporary behavioral changes that may depend on such factors as fatigue, the effects of drugs, or alterations in motives.

The word potentiality covers effects that do not appear at once; one might learn about tourniquets by reading a first-aid manual and put the information to use later.

To say that learning occurs as a result of practice excludes the effects of physiological development, aging, and brain damage.

Reinforcement as aid to learning

The stipulation that practice must be reinforced serves to distinguish learning from the opposed loss of unreinforced habits. Reinforcement objectively refers to any condition—often reward or punishment—that may promote learning.

However, the definition raises difficulties. How permanent is relatively permanent? Suppose one looks up an address, writes it on an envelope, but five minutes later has to look it up again to be sure it is correct. Does this qualify as relatively permanent? While commonly accepted as learning, it seems to violate the definition.

What exactly is the result that occurs with practice? Is it a change in the nervous system? Is it a matter of providing stimuli that can evoke responses they previously would not? Does it mean developing associations, gaining insights, or gaining new perspective?

Such questions serve to distinguish Kimble's descriptive definition from theoretical attempts to define learning by identifying the nature of its underlying process. These may be neurophysiological, perceptual, or associationistic; they begin to delineate theoretical issues and to identify the bases for and manifestations of learning.

The range of phenomena called learning. Even the simplest animals display such primitive forms of adaptive activity as habituation, the elimination of practiced responses. For example, a paramecium can learn to escape from a narrow glass tube to get to food. Learning in this case consists of the elimination (habituation) of unnecessary movements. Habituation also has been demonstrated for mammals in which control normally exercised by higher (brain) centres has been impaired by severing the spinal cord. For example, repeated application of electric shock to the paw of a cat so treated leads to habituation of the reflex withdrawal reaction. Whether single-celled animals or cats that function only through the spinal cord are capable of higher forms of learning is a matter of controversy. Sporadic reports that conditioned responses may be possible among such animals have been sharply debated.

At higher evolutionary levels the range of phenomena called learning is more extensive. Many mammalian species display the following varieties of learning.

Classical conditioning. This is the form of learning studied by Ivan Petrovich Pavlov (1849–1936). Some neutral stimulus. such as a bell, is presented just before delivery of some effective stimulus (say. food or acid placed in the mouth of a dog). A response such as salivation, originally evoked only by the effective stimulus, eventually appears when the initially neutral stimulus is presented. The response is said to have become conditioned. Classical conditioning seems easiest to establish for involuntary reactions mediated by the autonomic nervous system.

Conditioning of involuntary reactions

Instrumental conditioning. This indicates learning to obtain reward or to avoid punishment. Laboratory examples of such conditioning among small mammals or birds are common. Rats or pigeons may be taught to press levers for food; they also learn to avoid or terminate electric shock.

Chaining. In the form of learning called chaining the subject is required to make a series of responses in a definite order. For example, a sequence of correct turns in a maze is to be mastered, or a list of words is to be learned in specific sequence.

Acquisition of skill. Within limits, laboratory animals can be taught to regulate the force with which they press a lever or to control the speed at which they run down an alley. Such skills are learned when a reward is made contingent on quantitatively constrained performance. Among human learners complex, precise skills (*e.g.*, tying shoelaces) are routine.

Discrimination learning. In discrimination learning the subject is reinforced to respond only to selected sensory characteristics of stimuli. Discriminations that can be established in this way may be quite subtle. Pigeons, for example, can learn to discriminate differences in colours that are indistinguishable to human beings without the use of special devices.

Concept formation. An organism is said to have learned a concept when it responds uniquely to all objects or events in a given logical class as distinct from other classes. Even geese can master such concepts as roundness and triangularity; after training, they can respond appropriately to round or triangular figures they have never seen before.

Principle learning. A subject may be shown sets of three figures (say, two round and one triangular; next, two square and one round, and so on). With proper rewards, the subject may learn to distinguish any "odd" member of any set from those that are similar. Animals as low in the evolutionary scale as the pigeon can master the principle of this so-called oddity problem.

The oddity problem

Problem solving. Examples of human problem solving are familiar: finding the roots of a quadratic equation, solving a mechanical puzzle, and navigating by the stars. Among other animals, chimpanzees have been observed to solve problems requiring toolmaking.

This list only samples from the remarkable array of animal activities categorized as learning. Beginning with habituation, they range from the simple adjustments of single-celled animals up to the highest intellectual accomplishments of mankind. It would be wonderful indeed if a single theory of learning were enough to account for all this diversity. So far, however, no theory of learning adequately covers more than a small fraction of these phenomena.

THE STATE OF LEARNING THEORIES

Yet, at the start of the 20th century, vast psychological systems, such as behaviourism and Gestalt psychology, indeed were offered as explanations of learning (and of much wider ranges of behaviour as well). And as late as the 1940s, comprehensive theories of learning were still believed to be reasonably near at hand. But during the next three decades it grew clear that such theories are tenable only for very limited sets of data. By the 1970s, learning theory seemed to consist of a set of hypotheses of limited applicability.

Important earlier theorists. Beginning in the 1930s a number of general theories were advanced in attempts to organize most or all of the psychology of learning. The most influential of the contributing theorists are noted below.

E.R. Guthrie (1886–1959) wrote that learning requires only that a response be made in a changing situation. Any response was held to be linked specifically to the situation in which it was learned. Guthrie argued that learning is complete in one trial, that the most recent response in a situation is the one that is learned, and that responses (rather than perceptions or psychological states) provide the raw materials for the learning process.

For E.C. Tolman (1886–1959) the essence of learning was the acquisition by the organism of a set of what he called Sign-Gestalt-Expectations. These referred to propositions said to be made by the learner that his own specific response to given signs (or stimuli) would result in such and such circumstances later on. Tolman seemed to be saying that what the learner acquires is a specific knowledge of "what leads to what." In brief, his theory was that the learner develops expectations based on experience and that learning depends entirely on successions of events. Although less vocal on the point than others, Tolman implied that learning was a gradual process.

The theory offered by Clark L. Hull (1884–1952), over the period between 1929 and his death, was the most detailed and complex of the great theories of learning. The basic concept for Hull was "habit strength," which was said to develop as a function of practice. Habits were depicted as stimulus-response connections based on reward. According to Hull, responses (rather than perceptions or expectancies) participate in habit formation, the process is gradual, and reward is an essential condition.

Comparison of these theories yields major questions for empirical investigation. Is learning continuous or discontinuous; is it a gradual or sudden (one-trial) process? Is learning a matter of establishing stimulus–response (S–R) connections or does it depend on the learner's understanding of perceptual relationships? Is reward necessary for learning?

Are theories of learning necessary? Such major investigators of learning as B.F. Skinner and J.A. McGeoch maintained in the 1930s and 1940s that preoccupation with theory was misguided. For them the approach simply was to discover the conditions that produce and control learned behaviour. Beyond this, their interests diverged. Skinner studied instrumental conditioning (operant conditioning, as he called it) among rats; McGeoch specialized in human rote memory. Although study of rote verbal learning had become heavily theoretical by the 1970s, Skinner and his associates stuck to their empirical guns, guiding a variety of programs for the practical control of behaviour. Teaching machines and computer-aided instruction, behaviour modification (*e.g.*, the use of tokens to reward desired behaviour among psychiatric patients), and planned utopian societies (Walden II) all found scientific origins in Skinner's rejection of theory in favour of direct efforts to produce results.

Intervening variables and hypothetical constructs. Learning is a concept and not a thing, and the activity called learning is inferred only through behavioral symptoms. The distinction implicit here between behaviour and in-

Watson's reflex theory

ferred process is one of Tolman's major contributions and serves to reconcile influential views that might seem completely at odds. Classical behaviourism, as developed by John B. Watson (1878–1958), rejected every mentalistic account and sought to limit analysis to such physiological mechanisms as reflexes. Watson argued that these are objective in a way that so-called thoughts, hopes, expectancies, and images cannot be. The Opposing view holds that experiential (introspective) activity (exactly what Watson sought to dismiss) does require discussion.
