Antarctica, with an average height estimated at between 7,000 and 8,000 feet above sea level, is the world's highest continent. (Asia, the next, averages about 3,000 feet.) The vast ice sheets of East Antarctica reach heights of 11,500 feet or more in two main centres: one at about 80° S in western Wilkes Land, the other in a belt stretching southeastward from about 75° S in central Queen Maud Land. Without its ice, however, Antarctica would probably average little more than about 1,500 feet. It would then consist of a far smaller continent (East Antarctica) and a nearby island archipelago. A vast lowland plain between 90° E and 150° E (today's Polar and Wilkes subglacial basins) would be fringed by the ranges of the Transantarctic Mountains and of the Gamburtsev Mountains, 6,500 to 13,000 feet high. The rest might be a hilly to mountainous terrain. Relief in general would be great, with elevations ranging from 16,864 feet (5,140 metres) at Vinson Massif in the Sentinel Range, the highest point in Antarctica, to more than 8,200 feet below sea level in an adjoining marine trough to the west (today's Bentley Subglacial Trench). Areas that are now called "lands," including most of Ellsworth Land and Marie Byrd Land, would be beneath the sea.

Volcanoes Ice-scarred volcanoes, many still active, dot western Ellsworth Land, Marie Byrd Land, and sections of the coasts of the Antarctic Peninsula and Victoria Land, but principal activity is concentrated in the volcanic Scotia Arc. Only one volcano, Mt. Gaussberg (90° E), occurs along the entire coast of East Antarctica. Long dormant, Mt. Erebus, on Ross Island (see illustration), showed increased activity from the mid-1970s. Lava lakes have occasionally filled, but not overspilled, its crater, but the volcano's activity has been closely monitored because Antarctica's largest station (McMurdo Station, U.S.) lies on its lower flank. One of several violent eruptions of Deception Island, a volcanic caldera, in 1967–70, destroyed nearby British and Chilean stations. Whereas volcanoes of the Antarctic Peninsula and Scotia Arc are mineralogically similar to the volcanoes typical of the Pacific Ocean rim, the others in Antarctica are chemically like those of volcanoes along the East African Rift Valley. The differences are related to different styles of interaction between the Pacific and Antarctic crustal plates.

Climate. The unique weather and climate of Antarctica provide the basis for its familiar appellations—Home of the Blizzard and White Desert. By far the coldest continent, Antarctica has winter temperatures that range from –128.6° F (–89.2° C), the world's lowest recorded temperature, measured at Vostok Station on July 21, 1983, on the high inland ice sheet, to –76° F (–60° C) near sea level. Temperatures vary greatly from place to place, but direct measurements in most places are generally available only for summertime. Only at fixed stations operated since the IGY have year-round measurements been made. Winter temperatures rarely reach as high as 52° F (11° C) on the northern Antarctic Peninsula, which because of its maritime influences is the warmest part of the continent. Mean temperatures of the coldest months are –4° to –22° F (–20° to –30° C) on the coast, and –40° to –94° F (–40° to –70° C) in the interior, the coldest period on the polar plateau being usually in late August just before the return of the Sun. Whereas midsummer temperatures may reach as high as 59° F (15° C) on the Antarctic Peninsula, those elsewhere are usually much lower, ranging from a mean of about 32° F (0° C) on the coast to between –4° and –31° F (–20° and –35° C) in the interior. These temperatures are far lower than those of the Arctic, where monthly means range only from about 32° F in summer to –31° F in winter.

Winds Wind chill—the cooling power of the atmosphere—is the major debilitating weather factor of Antarctic expeditions. Fierce winds characterize most coastal regions, particularly of East Antarctica, where cold, dense air flows down the steep slopes off interior highlands. Known as katabatic

Ross Island seen across frozen McMurdo Sound. McMurdo Station is on the tip of the island at right with its aircraft runway in the foreground. The volcanic Mt. Erebus is in the upper centre.

By courtesy of the U.S. Navy

winds, they are a surface flow that may be smooth if of low velocity but that may also become greatly turbulent, sweeping high any loose snow, if a critical velocity is surpassed. This turbulent air may appear suddenly and is responsible for the brief and localized Antarctic "blizzards" during which no snow actually falls and skies above are clear. During one winter at Mirny Station, gusts reached more than 110 miles per hour on seven occasions. At the Adélie Coast camp of Douglas Mawson's Australasian Antarctic Expedition (1911–14), velocities in the winter of 1912–13 averaged 40 miles per hour for 64 percent of the time. Gusts estimated at between 140 and 155 miles per hour on Dec. 9, 1960, destroyed a Beaver aircraft at Mawson Station on the MacRobertson Land coast. Winds on the polar plateau are usually light, with monthly mean velocities at the South Pole ranging from about nine miles per hour in December (summer) to 17 miles per hour in June and July (winter).

The Antarctic atmosphere, because of its low temperature, contains only about one-tenth of the water-vapour concentration found in temperate latitudes. This atmospheric water largely comes from ice-free regions of the southern oceans and is transported in the troposphere into Antarctica mostly in the 140° sector (80° E to 140° W) from Wilkes Land to Marie Byrd Land. Most of this water precipitates as snow along the continental margin. Rainfalls are almost unknown. Despite the tremendous volume of potential water stored as ice, Antarctica must be considered as one of the world's great deserts; the average precipitation (water equivalent) is only about two inches (50 millimetres) per year over the polar plateau, though considerably more, perhaps 10 times as much, falls in the coastal belt. Lacking a heavy and protective water-vapour-rich atmospheric layer, which in other areas absorbs and reradiates to Earth long-wave radiation, the Antarctic surface readily loses heat energy into space.

Many factors determine Antarctica's climate, but the pri-

Cloud patterns around the South Pole as photographed by the U.S. satellite, ESSA 3, Jan. 28, 1967. At the top is the southern end of Africa and Madagascar.

Solar and
terrestrial
radiation

mary one is the geometry of the Sun-Earth relationship. The 23.5° axial tilt of the Earth to its annual plane of orbit, or ecliptic, around the Sun results in long winter nights and long summer days alternating between both polar regions and causing seasonal variations in climate. On midwinter day, about June 21, the Sun's rays reach to only 23.5° (not exact, due to refraction) from the South Pole along the latitude of 66.5° S, a line familiarly known as the Antarctic Circle. Although "night" theoretically is six months long at the geographic pole, one month of this actually is a twilight period. Only a few coastal fringes lie north of the Antarctic Circle. The amount of incoming solar radiation, and thus heat, depends additionally on the incident angle of the rays and therefore decreases inversely with latitude to reach a minimum at the geographic poles. These and other factors are essentially the same for both polar regions. The reason for their great climatic difference primarily lies in their reverse distributions of land and sea: the Arctic is an ocean surrounded by land, while Antarctica is a continent surrounded by ocean. The Arctic Ocean, a climate-ameliorating heat source, has no counterpart at the South Pole, the great elevation and perpetually reflective snow cover of which instead intensify its polar climate. Moreover, during Antarctic winters, freezing of the surrounding sea effectively more than doubles the size of the continent and removes the oceanic heat source to nearly 1,800 miles from the central polar plateau.

Outgoing terrestrial radiation greatly exceeds absorbed incoming solar radiation. This loss results in strong surface cooling, giving rise to the characteristic Antarctic temperature inversions in which temperature increases from the surface upward to about 1,000 feet above the surface. About 90 percent of the loss is replaced by atmospheric heat from lower latitudes, and the remainder by latent heat of water-vapour condensation.

Great cyclonic storms circle Antarctica in endless west-to-east procession, exchanging atmospheric heat to the continent from sources in the southern Atlantic, Pacific, and Indian oceans. Moist maritime air interacting with cold polar air makes the Antarctic Ocean in the vicinity of the Polar Front one of the world's stormiest. Few storms bring snowfalls to interior regions. With few reporting stations, weather prediction has been exceedingly difficult but is now greatly aided by satellite imagery.

A number of studies on the upper atmosphere of Antarctica have been leading toward solving problems that are worldwide in scope. Very low-frequency radio waves, called whistlers, which are generated by lightning at opposite, or conjugate, points in the Northern Hemisphere and received in Antarctica, are providing much information about the Earth's magnetosphere. Research in Antarctica has also made many contributions to knowledge of the ionosphere, geomagnetism, and solar cosmic radiation.

Glaciers and seas. *Glaciation.* Antarctica provides the best available picture of the probable appearance 20,000 years ago of northern North America under the great Laurentide Ice Sheet. Mountain glaciers, which formed on such highlands as the Sentinel Range perhaps as early as about 50,000,000 years ago, advanced down valleys to calve into the sea. Fringing ice shelves were built and later became grounded as glaciation intensified. Local ice caps developed, covering West Antarctic island groups as well as the mountain ranges of East Antarctica. The ice caps eventually coalesced into great ice sheets that tied together West and East Antarctica into the single continent that is known today. The continent has apparently been continuously glaciated since the first glaciers appeared.

Causal factors leading to birth and development of these continental ice sheets and then to their decay and death are, nevertheless, still poorly understood (see ICE AND

Evolution
of ice
sheets

ICE FORMATIONS). The factors are complexly interrelated. Moreover, once developed, ice sheets tend to form independent climatic patterns and thus to be self-perpetuating and eventually perhaps even self-destructing. Cold-air masses draining off Antarctic lands, for example, cool and freeze surrounding oceans in winter to form an ice pack, which reduces solar-energy input by increasing reflectivity and makes interior continental regions even more remote from sources of open oceanic heat and moisture. The East Antarctic Ice Sheet has grown to such great elevation and extent that little atmospheric moisture now nourishes its central part.

One hypothesis on the causes of continental glaciation ties periodic Northern Hemisphere ice ages, or glaciations, to periodic instability and surging of the Antarctic Ice Sheet. Instability is believed to occur when glacier buildup becomes so great as to cause pressure sufficient to melt the base of the ice sheet. Then, riding on water, the East Antarctic ice dome rapidly collapses, and, according to the hypothesis, the outflowing ice forms extensive ice shelves reaching perhaps to the Antarctic Convergence. The resulting increased reflectivity over such a large area would then cool the entire Earth. Once collapsed, the ice-dome base would no longer be at the pressure melting point, and the ice shelves, no longer fed, would soon disappear by calving and melting. Consequent decreased reflectivity over the Antarctic Ocean would then result in global warming and thus an interglacial period. The process could repeat itself many times.

The volume of South Polar ice must have fluctuated greatly at times since the birth of the ice sheets. Glacial erratics and glacially striated rocks on mountain summits now high above current ice-sheet levels testify to an overriding by ice at much higher levels. General lowering of levels caused some former glaciers flowing from the polar region through the Transantarctic Mountains to recede and nearly vanish, producing such spectacular "dry valleys" as the Wright, Taylor, and Victoria valleys near McMurdo Sound. Doubt has been shed on the common belief that Antarctic ice has continuously persisted since its origin by the discovery reported in 1983 of Cenozoic marine diatoms—believed to date from the Pliocene Epoch (about 7,000,000 to 2,500,000 years ago)—in glacial till of the Beardmore Glacier area. The diatoms are believed to have been scoured from young sedimentary deposits of basins in East Antarctica and incorporated into deposits of glaciers moving through the Transantarctic Mountains. If so, Antarctica may have been free or nearly free of ice as recently as about 3,000,000 years ago, when the diatom-bearing beds were deposited in a marine seaway; and the Antarctic Ice Sheet may have undergone deglaciations perhaps similar to those that occurred later during interglacial stages in the Northern Hemisphere. Evidence of former higher sea levels found in many areas of the Earth seems to support the hypothesis that such deglaciation occurred. If Antarctica's ice were to melt today, for example, global sea levels would probably rise about 150 to 200 feet.

Antarctic
ice budget

The Antarctic Ice Sheet seems to be approximately in a state of equilibrium, neither increasing nor decreasing significantly according to the best estimates. Snow precipitation is offset mainly by continental ice moving seaward by three mechanisms—ice-shelf flow, ice-stream flow, and sheet flow. The greatest volume loss is by calving from shelves, particularly the Ross, Ronne, Filchner, and Amery ice shelves. Much loss may also occur by bottom melting from ice shelves, but its importance is controversial and some glaciologists believe ice shelves actually gain mass by bottom accretion.

The Antarctic ice sheets are, in effect, settling tanks for atmospheric constituents and extraterrestrial material. They contain a record of climates and ancient atmospheres, of global volcanic activity, and of cosmic-particle bombardment extending back for thousands of years. Upper layers of ice, for instance, record the effects of high-latitude pollution by industrial wastes and of fallout of radioactive strontium (strontium-90) from the testing of nuclear weapons. This record in ice has been studied in cores from deep holes drilled through the ice sheet.

early 20th century has given way to an "extraterrestrial era" there, brought about by the discovery of thousands of meteorites on its ice sheets. Only five fragments had been found by 1969, but since then more than 7,000 have been recovered by Japanese and American scientists. In 1969 Japanese glaciologists began finding great numbers on blue-ice fields near their Syowa station, and an early recognition of the process by which the fragments are concentrated soon led to profitable searches in other areas, especially in the Transantarctic Mountains. Most specimens appear to have landed on Antarctic ice sheets between about 700,000 and 10,000 years ago. They accumulated and were carried by ice to areas near mountains where the ancient ice ablated and meteorites became concentrated on the surface. Probably only 1 to 10 percent of the finds, however, represent discrete meteorite falls. Most meteorites are believed to be from asteroids and a few from comets, but one found in 1982 is the first that is thought to be of lunar origin. Its composition and structure are like those of the soils on the Moon's surface collected by U.S. astronauts on the Apollo missions, and it seems likely that the meteorite came from material spalled off the Moon by some giant lunar impact and impelled into an Earth-crossing orbit. The discovery lends support to the hypothesis that meteorites from a rare class called shergottites had a similar origin from Mars; a few of the small handful known are from Antarctica. Antarctic ice is thus a rich storehouse of extraterrestrial samples. The cold, dry environment preserves them in a pristine state for great lengths of time, and they thus can provide much information about their parental bodies not available from meteorites collected elsewhere on Earth.

Meteorite
discoveries

The surrounding seas. The seas around Antarctica have often been likened to the moat around a fortress. The turbulent "Roaring Forties" and "Furious Fifties" lie in a circumpolar storm track and a westerly oceanic current zone commonly called the West Wind Drift, or Circumpolar Current. The three major oceans, Atlantic, Pacific, and Indian, are bounded on the south by Antarctic shores. Warm, subtropical surface currents move southward in the

Ocean
currents
and con-
vergences

western parts of these oceans and then turn eastward upon meeting the Circumpolar Current. The warm water meets and partly mixes with cold Antarctic water, called the Antarctic Surface Water, to form a mass with intermediate characteristics called Subantarctic Surface Water. Mixing occurs in a shallow but broad zone of approximately 10° latitude lying south of the Subtropical Convergence (at about 40° S) and north of the Antarctic Convergence (between about 50° and 60° S). The Subtropical Convergence generally defines the northern limits of a water mass having so many unique physical and biologic characteristics that it is often given a separate name, the Antarctic, or sometimes the Southern, Ocean; it contains about 10 percent of the global ocean volume.

The two convergences are well defined and important oceanic boundary zones that profoundly affect climates, marine life, bottom sedimentation, and ice-pack and ice-berg drift. They are easily identified by rapid changes in temperature and salinity. Antarctic waters are less saline than tropical waters because of their lower temperatures and lesser evaporational concentration of dissolved salts. When surface waters move southward from the Subtropical Convergence zone into the subantarctic climatic belt, their temperatures drop by as much as about 9° to 16° F (5° to 9° C). In crossing the Antarctic Convergence, from the subantarctic into the Antarctic climatic zone, surface-water temperature drops further, lowering from about 46° to 39° F (8° to 4° C) in summer, and from about 37° to 34° F (3° to 1° C) in winter.

Whereas the pattern of surface currents, controlled largely by the Earth's rotation, winds, water-density differences, and the geometry of basins, is relatively well understood, that of deeper water masses is more complex and less well known. North-flowing Antarctic Surface Water sinks to about 3,000 feet beneath warmer Subantarctic Surface Water along the Antarctic Convergence to become the Subantarctic Intermediate Water. This water mass, as well as the cold Antarctic Bottom Water, spreads far north beyond the Equator to exchange with waters of the Northern Hemisphere. The movement of the Antarctic Bottom Water is identifiable in the Atlantic as far north as the Bermuda Rise. Currents near the continent result in a circumferential belt of surface-water divergence accompanied by upwelling of deeper water masses.

Two forms of floating ice masses build out around the continent: (1) glacier-fed semipermanent ice shelves, some of enormous size, such as the Ross Ice Shelf, and (2) an annually frozen and melted ice pack that in winter reaches to about 56° S in the Atlantic and 64° S in the Pacific. Antarctica has been called the pulsating continent because of the annual buildup and retreat of its secondary ice-fronted coastline. Pushed by winds and currents, the ice pack is in continual motion. This movement is westward

in the coastal belt of the East Wind Drift at the continent edge and eastward (further north) at the belt of the West Wind Drift. Icebergs—calved fragments of glaciers and ice shelves—reach a northern limit at about the Subtropical Convergence. With an annual areal variation about six times as great as that for the Arctic ice pack, the Antarctic pack doubtless plays a far greater role in varying heat exchange between ocean and atmosphere and thus probably in altering global weather patterns. Long-term synoptic studies, now aided by satellite imagery, have been searching for long-period changes in the Antarctic ice-pack regimen and the possible relation of these changes to global climate changes.

As part of the Deep Sea Drilling Project conducted from 1968 to 1983 by the U.S. government, the drilling ship *Glo-mar Challenger* undertook several cruises of Antarctic and subantarctic waters to gather and study materials on and below the ocean floor. Expeditions included one between Australia and the Ross Sea (1972–73); one in the area south of New Zealand (1973); one from southern Chile to the Bellingshausen Sea (1974); and two in the Drake Passage and Falkland Islands area (1974 and 1979–80). Among the ship's most significant findings were hydrocarbons discovered in Tertiary sediments in the Ross Sea and rocks carried by icebergs from Antarctica found in late Oligocene sediments at numerous locations. Researchers inferred from these ice-borne debris that Antarctica was glaciated at least 25,000,000 years ago. A second long-term project that includes exploration of Antarctic waters, the Ocean Drilling Program, began operations in 1985.

Plant life. The cold-desert climate of Antarctica supports only an impoverished community of cold-tolerant land plants that are capable of surviving lengthy winter periods of total or near-total darkness during which photosynthesis cannot take place. Growth must occur in short summer bursts lasting only a few days, a few weeks, or a month or two, depending upon such diverse factors as latitude, seasonal snowpacks, elevation, topographic orientation, wind, and moisture, in both the substrate and the atmosphere. Moisture is the most important single variable and is provided mainly by atmospheric water vapour and by local melt supplies from fallen snow, drift snow, and permafrost. Stream runoff is exceedingly rare. Extreme cold, high winds, and aridity inhibit growth even in summer in most areas. There are, however, certain areas at high latitude and high elevation that have local microclimates formed by differential solar heating of dark surfaces, and these areas are able to support life. The importance of such microclimates was demonstrated by the second Byrd Antarctic Expedition (1933–35), which found that lichens in Marie Byrd Land grow preferentially on darker-coloured heat-absorbing rock.

Antarctic plants total about 800 species, of which 350 are lichens. Lichens, although slow growing, are particularly well adapted to Antarctic survival. They can endure lengthy high-stress periods in dormancy and almost instantly become photosynthetic when conditions improve. Bryophytes (mosses and liverworts), totaling about 100 species, predominate in maritime regions, but mosses can grow nearly everywhere that lichens grow. Liverworts are reported only from coastal and maritime regions. Numerous species of molds, yeasts, and other fungi, as well as freshwater algae and bacteria, complete the listing of Antarctic plants. These forms are extremely widespread and are reported as far as 87° S latitude. In addition, Antarctic seas are highly productive in plankton plant life, particularly in near-shore, nutrient-rich zones of upwelling. Diatoms, a type of algae, are especially abundant.

Although soils are essentially not of humic type, they commonly are not sterile either, in that they may contain such microorganisms as bacteria or a variety of blue-green algae. The blue-green algae *Nostoc* locally contribute minor organic compounds to soils.

Today's barren Antarctic landscape little resembles ancient Paleozoic and Mesozoic ones with their far greater floral displays. Antarctic glaciation, probably beginning 50,000,000 years ago, forced the northward migration of all vascular plants (ferns, conifers, and flowering plants). Only nonwoody forms have again populated subantarctic

Plant life
in the sub-
antarctic

regions and have scarcely repenetrated the Antarctic zone.

In contrast to Antarctica, lying south of the Antarctic Convergence, the islands north of the Convergence in the subantarctic botanical zone—including the South Georgia, Crozet, Kerguelen, and Macquarie islands—are characterized by an abundance of vascular plants of many species, at least 50 being identified on South Georgia alone. Thus, whereas plants reproducing by spores are characteristic of Antarctica, seed plants chiefly characterize subantarctic regions.

Humans have greatly influenced the natural ecosystem in many Antarctic and subantarctic regions. A number of alien species of vascular plants near whaling stations have been introduced, and doubtless many alien microorganisms exist near all Antarctic stations. Alien herbivores, chiefly sheep and rabbits, have decimated plant communities on many subantarctic islands. Rabbits have exterminated the native cabbage *Pringlea antiscorbutica* over wide areas on Kerguelen, and sheep have decimated tussock communities on South Georgia.

Animal life. Land fauna. The native land fauna is wholly invertebrate. Apparently climatically less tolerant and less easily dispersed, the fauna follows plant colonization of newly deglaciated regions and therefore is not as widely distributed. The Antarctic microfauna includes heliozoans, rotifers, tardigrades, nematodes, and ciliate protozoans. The protozoans dominate soil and freshwater communities. The terrestrial macrofauna consists entirely of arthropods, many species being parasitic on birds and seals. The principal arthropod groups represented include Acarina (mites), Mallophaga (biting lice), Collembola (springtails), Anoplura (sucking lice), Diptera (midges), and Siphonaptera (fleas). Two species of beetles, probably alien, are known from islands near the Antarctic Peninsula. The dominant free-living forms, mites and springtails, live under stones and are associated with spore-reproducing plants.

Birds. About 45 species of birds live south of the Antarctic Convergence, but only three—the emperor penguin, Antarctic petrel, and South Polar (McCormick's) skua—breed exclusively on the continent or on nearby islands. An absence of mammalian land predators and the rich offshore food supply make Antarctic coasts a haven for immense seabird rookeries. Penguins, of the order Sphenisciformes, symbolize this polar region, though they live on seacoasts throughout the Southern Hemisphere. Of the 18 living species (of which two may only be subspecies), only the Adélie and emperor live along the Antarctic coastline. The habitats of five other polar species—king, chinstrap, gentoo, rockhopper, and macaroni—extend only as far

south as the northern Antarctic Peninsula and subantarctic islands. The evolution of these flightless birds has been traced to the late Eocene Epoch, about 40,000,000 years ago, using fossils found on Seymour Island, off the northern tip of the Antarctic Peninsula, and at a few other places. The largest modern penguin, the emperor, standing between three and four feet in height, would be dwarfed by some of its extinct New Zealand and Seymour Island relatives, the fossil bones of which indicate that they reached heights up to five feet seven inches. Some authorities believe that penguins may have a shared ancestry with other birds of Antarctica, capable of flight, from the order Procellariiformes. Birds of that order, mainly species of petrels but also a few of albatrosses, make up more than half of the Antarctic and subantarctic breeding species. Other birds of the region include species of cormorants, pintails, gulls, terns, sheathbills, and pipits.

Banding and recovery studies show that some Antarctic birds travel throughout the world. One giant petrel caught alive at Fremantle, Australia, had been banded as a nestling only two months previously in the South Orkney Islands. In that time span, it had learned to fly and had traveled some 10,000 miles, about halfway around the world. Rare sightings of skuas and petrels far in the continental interior, even near the South Pole, suggest that these powerful birds may occasionally cross the continent. Experiments show that Antarctic birds, including the flightless penguin, have strong homing instincts and excellent navigational capability; they apparently have a highly developed Sun-azimuth orientation system and biological clock mechanism that functions even with the Sun remaining continuously high. Adélie penguins released as far as 1,900 miles from their nests, for example, are known to have returned within a year. The mechanism fails to explain, however, how emperor penguins living south of the Antarctic Circle in winter can navigate during the long polar night.

Feeding habits vary widely from species to species. Most depend on the abundantly provisioned larder of the sea. The seabirds feed mainly on crustacea, fish, and squid, mostly at the surface or, in the case of cormorants and penguins, at depths of up to about 150 feet. Shore birds forage for mollusks, echinoderms, and littoral crustacea. Sheathbills, the southern black-backed gull, giant petrels, and skuas feed occasionally, as allowed, on other birds' unguarded eggs. The voracious skua and giant petrel are even known to attack the young or weak of other species, particularly penguins. Low aircraft overflights of rookeries are now prohibited because frightened adults leave chicks and nests undefended from predators.

Dependent upon seafood, most birds leave the continent each autumn and follow Antarctica's "secondary" coastline as the ice pack builds northward. The emperor penguins, however, are unique exceptions and remain behind as solitary guardians (other than humans) of the continent through the long winter night. The emperors, once thought rare, are now estimated to number more than 1,000,000 in about 25 known colonies. They congregate in close-packed hordes, females each autumn laying a single egg that their mates incubate by carrying on their broad feet beneath a warm fold of abdominal skin. Whereas other penguins build pebble nests for summer use, the emperors, without nests, have uniquely adapted to violent winter conditions in which nest maintenance would be impossible in the driving snows of Antarctic blizzards.

Sea life. The prolific zooplankton of Antarctic waters feed on the copious phytoplankton and, in turn, form the basic diet of whales, seals, fish, squid, and seabirds. The Antarctic waters, because of their upwelled nutrients, are more than seven times as productive as subantarctic waters. The most important organism in the higher food chain is the small, shrimplike krill, *Euphausia superba*, only an inch or two in length when mature. But for their habit of congregating in vast, dense schools, they would have little food value for the large whales and seals. Their densities are great, however, and a whale, with built-in nets of baleen and hairlike fibres, can strain out meals of a ton or more in a few minutes. During the three to four months spent in Antarctic waters, the original population of baleen whales alone could consume an estimated

Krill

Fishes

150,000,000 tons of krill. Animals on the sea bottom of the near-shore zone include the sessile hydrozoans, corals, sponges, and bryozoans, as well as the foraging, crablike pycnogonids and isopods, the annelid worm polychaeta, echinoids, starfish, and a variety of crustaceans and mollusks. Winter and anchor ice, however, keep the sublittoral zone relatively barren to about 50 feet in depth.

Of the nearly 20,000 kinds of modern fish, no more than about 100 are known from seas south of the Antarctic Convergence. Nearly three-fourths of the 90 or so sea-bottom species belong to the superfamily Notothenioidea, the Antarctic perches. At sea bottom there are also the Zoarcidae, or eel-pouts; the Liparidae, or sea snails; the Macrouridae, or rat-tailed fishes; and the Gadidae, or codlike fishes. Rare nonbony types in the Antarctic zone include hagfish and skates. Many species of deep-sea fish are known south of the Antarctic Convergence, but only three, a barracuda and two lantern fishes, seem to be confined to this zone. Antarctic fishes are well adapted to the cold waters; the bottom fish are highly endemic, 90 percent of the species being found nowhere else. This supports other biologic and geologic evidence that Antarctica has been isolated for a very long time.

Seals

Antarctic native mammals are all marine and include seals (pinnipeds), porpoises, dolphins, and whales (cetaceans). Only one otariid, or fur seal, breeds south of the Antarctic Convergence; four species of phocids, or true seals—the gregarious Weddell seal, the ubiquitous crabeater seal, the solitary and aggressively carnivorous leopard seal, and the rarely seen Ross seal—breed almost exclusively in the Antarctic zone, and another, the southern elephant seal, breeds near the Convergence at South Georgia, Kerguelen, and Macquarie islands. The sea lion, an otariid, is plentiful in the Falkland Islands but probably never ventures into the cold Antarctic waters. The fur seal and the elephant seal are now regenerating after near extinction: the former have been estimated to number about 30,000 or more and the latter about 700,000. Weddell seals are thought to number about 500,000, the crab-eater about 5,000,000 to 6,000,000, and the Ross seals about 50,000. Weddell seals are unique in being able to survive under fast ice, even in winter, by maintaining open breathing holes with their teeth. The leopard seal, armed with powerful jaws and huge canines, is one of the few predators of adult penguins. A number of mummified seal carcasses, chiefly crab-eaters, have been found at distances of nearly 30 miles from the sea and elevations up to about 3,000 feet in the McMurdo dry valleys. Finding no food in such

E.E. Gless

Ross seal at Cape Hallett.

inland wanderings, the crab-eaters eventually died, and their leathery carcasses were preserved by the coldness and aridity of the climate.

Whales and their cetacean relatives, porpoises and dolphins, range widely from Arctic to Antarctic waters and are found in all oceans and seas. A number of species range to, but generally not across, the Antarctic Convergence and so are considered only peripheral Antarctic types. Among the fish- and squid-eating toothed whales, or odontocetes, are a few peripheral Antarctic porpoises and dolphins and the pilot whale. More typical of Antarctic waters are the killer whale, sperm whale, and rare bottle-nosed, or beaked, whale. Seven species of baleen, or whalebone, whales also inhabit Antarctic waters, subsisting on the plentiful krill; these include the southern right whale, humpback whale, and four kinds of rorqual—the blue whale, the fin whale, the sei whale, and the lesser rorqual, or minke. The pygmy right whale is endemic to Antarctic and subantarctic waters. The killer whale, one of the most intelligent of marine animals, hunts in packs and feeds on larger animals, such as fish, penguins and other aquatic birds, seals, dolphins, and other whales. Despite its name, there have been no authenticated accounts of attacks on humans near Antarctica. Excessive slaughter in the past has drastically decimated stocks of the larger whales, particularly the giant blue whales. Near extinction, the blue whales have been protected by international agreement.

Alien mammals that now reside semipermanently in Antarctic and subantarctic regions include sheep, rabbits, dogs, cats, rats, mice, and human beings. Effects on local ecosystems are great, from pollution of station areas by human wastes to erosion from overgrazing by sheep and to decimation of bird populations by dogs and cats and of whale and fur-seal stocks by humans. Even so, Antarctica remains by far the least contaminated land on Earth. Under the Antarctic Treaty, it is designated as a special conservation area, and many former human activities have been prohibited in an attempt to preserve the natural ecological system of the unique environment.

Conservation

ECONOMIC RESOURCES

Antarctica, it has been suggested, may have become a continent for science because it was useful for nothing else. Certainly, the great success of the Antarctic Treaty and of the political experiment in international cooperation is in no small way attributable to the fact that exploitable resources have not been found. Articles of the treaty do not exclude economic activities, but neither do they set up jurisdictional procedures in the event that any are undertaken (see below *History*).

Increasing economic pressures have forced mineral and petroleum exploration into more and more remote regions as resources have gradually become depleted in other, more accessible lands. It is likely that market and technological conditions will make it economically feasible to carry the search to Antarctica and its continental shelves. The political volatility of the resource question, especially the problems of rights of ownership and development, has prompted proposals that range from sharing any found mineral wealth equally among nations to establishing the continent as a world park; it is understood that any significant mineral discovery will provide a severe test for the Antarctic Treaty.

Most early Antarctic expeditions through the 19th century were directly or indirectly of economic incentive. For some, it was the search for new trading routes; for others, it meant the opening of new fur-sealing grounds; still others saw a possibility of mineral riches. The exploitation of natural resources has centered in the subantarctic and Antarctic seas, and virtually none has yet occurred on the continent. In one analysis of resource potentials, "Antarctic natural resources" were defined as "any natural materials or characteristics (in the Antarctic region) of significance to man." By this broad definition, the term includes not only biologic and mineral resources but also the land itself, water, ice, climate, and space for living and working, recreation, and storage. "Economic" resources are those that can be used or exported at a cost that is less than their value. Any attempted appraisal must therefore

Economics
of resource
develop-
ment

be continually reevaluated in terms of current market values, logistical costs, and technological developments. Few known Antarctic resources have any economic importance in terms of present-day estimates of these factors. The factors are complexly interrelated and difficult to assess for the present, let alone the future. For example, technological advances that could allow development in Antarctica might instead allow development of what are considered marginally economic resources in other regions. Moreover, by the time it might become feasible to develop an Antarctic resource, such as petroleum, other suppliers for the market might be found, such as, in this case, fusion reactors or solar or geothermal energy, which would greatly change cost factors.

Mineral resources. The geology of Antarctica is known sufficiently well to allow rather certain prediction of the existence of a variety of mineral deposits, some probably large. The fact that none of significant size, besides coal in the Transantarctic Mountains and iron near the Prince Charles Mountains of East Antarctica, is known to exist is largely the result of inadequate sampling. With the amount of ice-free terrain in Antarctica estimated at somewhere between 1 and 5 percent, the probability is practically nil that a potential ore body would be exposed. Moreover, whereas generations of prospectors have combed temperate and even Arctic mountains, Antarctic mountains have been visited mostly by reconnaissance parties since the IGY.

etween
Antarctica
and other
continents

The high degree of certainty that mineral deposits do exist is based on the close geological similarities that have been observed between areas of Antarctica and of mineral-rich provinces of South America, South Africa, and Australia and on the consensus that has been reached on the configuration of the Gondwanaland landmass during Mesozoic times. The gold-producing Witwatersrand beds of South Africa may correspond to the terranes of western Queen Maud Land. The young mountain belt of the copper-rich South American Andes continues southward, looping through the Scotia Arc into the Antarctic Peninsula and probably beyond into Ellsworth Land. The mostly ice-covered areas of Wilkes Land may parallel the gold-producing greenstone belts and platinum-bearing intrusions of southwestern Australia. The Dufek intrusion, an immense layered gabbroic complex in the northern Pensacola Mountains, is geologically similar to, though much

younger than, the Bushveld complex of South Africa, which is a leading producer of platinum-group metals, chromium, and other resources. Mineral occurrences have been found in some of these Antarctic areas, including antimony, chromium, copper, gold, lead, molybdenum, tin, uranium, and zinc. None approaches a grade or size warranting economic interest. Also noneconomic are the very large deposits of coal and sedimentary iron. Because of the high costs of polar operations, few conceivable resources—excepting those with high unit value such as platinum, gold, and perhaps diamonds—have any likelihood for exploitation.

Offshore resources of petroleum, however, are a different matter. The finding of gaseous hydrocarbons in cores drilled in the Ross Sea by the *Glomar Challenger* in 1973 aroused considerable international interest. Cruises of the U.S. research vessel *Eltanin* had by then made a number of reconnaissance geophysical studies investigating the nature of the Antarctic continental margin. Since the late 1970s oceanographic research ships of many nations, including those of France, West Germany, Japan, and the United States, have undertaken detailed studies of the structure of the continental margin, using the sophisticated geophysical techniques of seismic reflection and gravity and magnetic surveys. Thicknesses of sedimentary rock needed for sizable petroleum accumulations may occur in continental-margin areas of the Ross, Amundsen, Bellingshausen, and Weddell seas and perhaps near the Amery Ice Shelf; and some may also exist in inland basins covered by continental ice, particularly in West Antarctica. It seems unlikely, however, that fields of a size needed for exploitation are present. If they should be found, any petroleum extraction would be difficult but not impossible in the offshore areas, as technologies have been developed for drilling for and recovering petroleum in Arctic regions. Drill ships and platforms would be more severely affected by iceberg drift and moving ice packs than in the Arctic. Icebergs are commonly far larger than those in the Arctic and have deeper keels; they scour the seafloor at deeper levels and would be more likely to damage seafloor installations such as wellheads, pipelines, and mooring systems. These problems, even though great, are far fewer than those that would be encountered in developing inland mineral resources of any kind. Thus, although petroleum is generally considered to be the most likely prospect for exploitation in Antarctica, there is little potential for its development before reserves are consumed from more accessible areas throughout the world.

Biological resources. Resources of the sea first attracted men to Antarctica and provided the only basis for commercial activity in this region for many years. Commercial fur sealing began about 1766 in the Falkland Islands and rapidly spread to all subantarctic islands in the zeal to supply the wealthy markets of Europe and China. Immense profits were made, but the toll was equally immense. Early accounts relate that millions of skins were taken from the Falklands during the mid-1780s. Within a century, however, the herds of fur seals had disappeared. Elephant seals were then hunted for their oil, and as their numbers dwindled the sealers turned to whaling. During the 20th century herds of some whale species (notably blue, fin, and sei) were largely driven from Antarctic waters, but commercial whaling was not effectively curtailed until catch quotas were imposed in the 1970s and 1980s. Although populations of many species of seals and whales have been regenerating, it appears unlikely that they will again become an exploitable resource.

Commercial fishing, although little developed before 1970, has been rising in significance since then, especially with the increased use of factory ships, which can catch and process large quantities of fish. Catches of one species of Antarctic cod (*Notothenia rossii*) have been as high as 400,000 tons, prompting concerns about overfishing in Antarctic waters. Interest in fishing for Antarctic krill has also been growing. An almost unfathomable abundance of krill lives in the nutrient-rich coastal waters of Antarctica and the subantarctic islands. Predators (sea mammals, fish, and birds) take an enormous quantity of them annually, but their numbers are so great that there has been some

Offshore
petroleum
resources

Sealing and
whaling

activity, notably by the Soviet Union, toward establishing a krill-based fishing and processing industry.

Other resources. A rich imagination can see many possible uses of Antarctica and its materials. The continental ice sheet contains nearly 90 percent of the world's glacial ice—a huge potential supply of fresh water—but any economic value is precluded by delivery costs. Antarctica has been proposed as a long-term deep-freeze storage site for grain and other foods, but calculations show that such usage cannot be economic, because of excessive shipping, handling, and investment costs. The Antarctic Treaty prevents the continent from being used as a site for radioactive-waste disposal and storage. Antarctica and its nearby islands could play an important role in wartime, particularly in the Scotia Sea region and Drake Passage, for control of interocean shipping. In 1940–41, for example, German commerce raiders made considerable use of Kerguelen Island for this purpose. The Antarctic Treaty rules out military use, however, and the increasing capability of long-range aircraft, rocketry, and satellite surveillance and reentry decreases the possible military importance of Antarctica.

Tourism

Antarctica contains abundant scenic resources, and these have been increasingly exploited since the late 1950s. The tourist industry began in a modest way in January and February 1958, with tours to the Antarctic Peninsula area arranged by the Argentine Naval Transport Command. Since January 1966, yearly tourist ships have plied Antarctic coastal waters, stopping here and there for visits at scientific stations and at penguin rookeries. The number of visits by cruise ships has increased, and in the mid-1970s sightseeing flights by commercial airliners were inaugurated. Polar visionaries see an all-weather landing strip for wheeled jet aircraft at Marble Point near McMurdo Sound; one or more hotels nearby, perhaps in one of the McMurdo dry valleys and served by helicopter from the jet runway; and possibly even a centre for skiing and mountaineering. With such facilities, they believe, greatly increased numbers of tourists could be brought to the continent, and costs would be decreased accordingly. Many other problems, though, would be raised, including methods of sewage and waste disposal that would not affect highly sensitive local ecosystems; ways to ensure that Antarctic flora and fauna are not disturbed; provisions for search and rescue facilities; and a system for handling the civil and criminal cases that would inevitably arise.

History

A great many nations, large and small, played important roles in the discovery and exploration of Antarctica. Who first saw the continent is clouded in controversy. The Russian expedition leader Fabian Gottlieb von Bellingshausen, the Englishman Edward Bransfield, and the American Nathaniel Palmer all claim first sightings in 1820: Bellingshausen sighted a shelf edge of continental ice on January 20; two days later Bransfield caught sight of land that the British later considered to be a mainland part of the Antarctic Peninsula; and on November 18 Palmer unequivocally saw the mainland-peninsula side of Orleans Strait.

Terra Australis

In about AD 650, however, long before European geographers of the Middle Ages and the Renaissance were to conjecture about the mythical Terra Australis, Maori legend tells of a New Zealand Polynesian war canoe, under the command of one Ui-te-Rangiora, that sailed at least as far south as the frozen ocean. The legendary vast size of the continent shrank to nearly its present one when in 1772–75 the Englishman James Cook circumnavigated the globe in high southern latitude, proving that Terra Australis, if it existed at all, lay somewhere beyond the ice packs that he discovered between about 60° and 70° S.

The period from the 1760s to about 1900 was one dominated by exploitation of Antarctic and subantarctic seas, particularly along Scotia Ridge. Sealing vessels of many nations, principally U.S. and British but including Argentine, Australian, South African, New Zealand, German, and Norwegian, participated in hunting that eventually led to near extinction of the southern fur seal. Many also

hunted whales, but the less profitable whaling industry climaxed following World War I after the decline of sealing. Among the few geographic and scientific expeditions that stand out during this period are those of Bellingshausen, commanding the Russian ships *Vostok* and *Mirny*, in the first close-in circumnavigation of Antarctica in 1819–21; Bransfield, on a British expedition charting part of the Antarctic Peninsula in 1819–20; Dumont d'Urville, on a French expedition in 1837–40, when Adélie Land was discovered and claimed for France; Charles Wilkes, on a U.S. naval expedition in 1838–42 that explored a large section of the East Antarctic coast; and James Clark Ross, on a British expedition in 1839–43 that discovered the Ross Sea and Ross Ice Barrier (now called Ross Ice Shelf) as well as the coast of Victoria Land.

THE "HEROIC ERA" OF EXPLORATION

During the first two decades of the 20th century, commonly called the "heroic era" of Antarctic exploration, great advances were made in not only geographic but also scientific knowledge of the continent. The Englishmen Robert F. Scott and Ernest Henry Shackleton led three expeditions between 1901 and 1913, pioneering routes into the interior and making important geological, glaciological, and meteorological discoveries that provided a firm foundation for present-day scientific programs. This era was preceded by two events that proved the feasibility of Antarctic overwintering: (1) the Belgian ship *Belgica*, under command of Capt. Adrien de Gerlache, became the first vessel to winter in Antarctic waters when, from March 1898 to March 1899, it was trapped and drifted in pack ice of the Bellingshausen Sea; and (2) a scientific party under Carsten E. Borchgrevink spent the next winter camped at Cape Adare, for the first planned overwintering on the continent.

Sledge probes deep into the interior were made by Scott on the British National Antarctic *Discovery* Expedition (1901–04) and by Shackleton on the British Antarctic *Nimrod* Expedition (1907–09) from base camps on Ross Island. New southing records were set by Scott, in company with Shackleton and E.A. Wilson, who reached 82°17' S on Ross Ice Shelf on Dec. 30, 1902, and by Shackleton in a party of five, which reached 88°23' S, a point within 97 miles of the pole, on Jan. 9, 1909. The aerial age in Antarctica was presaged by Scott in 1902, who went aloft in a captive balloon for aerial reconnaissance, and the mechanical age by Shackleton in 1908, who used an automobile at Cape Royds, Ross Island. The experimental use of hardy Manchurian ponies and the pioneering of a route up the great Beardmore Glacier to the polar plateau by Shackleton paved the way for the epic sledging trip of Scott in 1911–12 to the South Pole.

National and personal prestige in attaining the Earth's poles, as well as territorial acquisition and scientific inquiry, provided strong motivation for polar exploration in the early 1900s. The south magnetic pole, the point of vertical orientation of a magnetic dip needle, which was predicted by the German physicist Carl Friedrich Gauss to lie at 66° S, 146° E, inspired the unsuccessful quest, in about 1840, of the seafarers Wilkes, d'Urville, and Ross (Ross had earlier discovered the north magnetic pole). The point was later reached, on Jan. 16, 1909, at 72°25' S, 155°16' E, on the high ice plateau of Victoria Land by T.W.E. David and Douglas Mawson on a sledge journey from Cape Royds. The pole has migrated more than 550 miles since then to its present location near the Adélie Land coast. The South Pole of the Earth's rotation was the unattained goal of Shackleton in 1908–09 but was eventually reached on Dec. 14, 1911, by Roald Amundsen of the Norwegian Antarctic Expedition of 1910–12 and, a month later, on Jan. 17, 1912, by Scott of the British Antarctic *Terra Nova* Expedition of 1910–13. Whereas Amundsen's party of skiers and dog teams, using the Axel Heiberg Glacier route, arrived back at Framheim Station at Bay of Whales with little difficulty, Scott's man-hauling polar party—Scott, E.A. Wilson, H.R. Bowers, L.E.G. Oates, and Edgar Evans—using the Beardmore Glacier route, perished during a blizzard on the Ross Ice Shelf on the return march.

The expeditions of Scott and Shackleton

Discovery of the Antarctic poles

Trans-Antarctic expeditions

Two other related discoveries were accomplished during the IGY. The south geomagnetic pole, the theoretical pole of the Earth's magnetic field, on the East Antarctic Ice Sheet at 78°28' S, 106°48' E, was reached by a Soviet IGY tractor traverse on Dec. 16, 1957. The pole of relative inaccessibility, the point most remote from all coasts, at 82°06' S, 54°58' E, was reached by a Soviet IGY tractor traverse on Dec. 14, 1958.

After Amundsen and Scott attained the South Pole, the idea that particularly haunted men's minds was that of an overland crossing of the continent. Conceived earlier by the Scotsman W.S. Bruce and the German Wilhelm Filchner to test the thought that a channel might exist connecting the Ross and Weddell seas, a trans-Antarctic expedition was finally organized in 1914 by Shackleton. His ship, the *Endurance*, was caught and crushed, however, in pack ice of the Weddell Sea, thus aborting one of the most ambitious polar expeditions hitherto planned. The idea lay dormant for several decades and came to fruition during IGY with the British Commonwealth Trans-Antarctic Expedition led by Vivian Fuchs. Using tracked vehicles and aided by aerial flights, the party left Shackleton Base on Filchner Ice Shelf on Nov. 24, 1957, and by way of the South Pole reached the New Zealand Scott Base on Ross Island on March 2, 1958. The continent was again crossed (1979–81) as part of the British Transglobe Expedition that undertook the first polar circumnavigation of the Earth.

FROM WORLD WAR I TO IGY

The period between World Wars I and II marks the beginning of the mechanical, particularly the aerial, age of Antarctic exploration. Wartime developments in aircraft, aerial cameras, radios, and motor transport were adapted for polar operation. On Nov. 16, 1928, the first heavier-than-air flight in Antarctica was made by the Alaskan bush pilot C.B. Eielson and George Hubert Wilkins in a wheel-equipped Lockheed Vega monoplane. This flight was quickly followed by the better-equipped, aircraft-supported expeditions of the American naval officer Richard E. Byrd (1928–30, 1933–35, 1939–41, and 1946–47), in which progressively greater use was made of ski-planes and aerial photography. Byrd, on Nov. 29, 1929, was first to fly over the South Pole (after having flown over the North Pole in 1926). His fourth expedition, called "Operation High Jump," in the summer of 1946–47, was the most massive sea and air exploratory assault hitherto attempted in Antarctica and involved 13 ships, including two seaplane tenders and an aircraft carrier, and a total of 25 airplanes.

The Byrd expeditions

Ship-based aircraft returned with 49,000 photographs that, together with those taken by land-based aircraft, covered about 60 percent of the Antarctic coast, nearly one-fourth of which had been previously unseen. Innovations by Byrd included the use of an autogiro in 1933–34 and six helicopters in 1946–47. Meanwhile, the courageous flight of Lincoln Ellsworth, an American, and Herbert Hollick-Kenyon, a Canadian pilot, across uncharted lands and icefields on the first aerial crossing of the continent from Nov. 23 to Dec. 5, 1935, clearly demonstrated the feasibility of aircraft landings and takeoffs for inland exploration. These early aerial operations and the extensive use of ship-based seaplanes in Norwegian explorations of coastal Queen Maud Land during the 1930s were forerunners of present-day aerial programs.

The early discoveries led to a few controversies not only for territorial claims but also in geographical nomenclature. The struggle for national influence was especially acute in the slender peninsular landmass south of Scotia Sea that became known as O'Higgins Land (Tierra O'Higgins) to Chileans and San Martín Land (Tierra San Martín) to Argentines, named for national heroes who helped in gaining independence from Spain. To the English it was known as Graham Land, for a former first lord of the admiralty, and to Americans as Palmer Peninsula, for the sealer and explorer Nathaniel Palmer. By interna-

National rivalries

Territorial Claims in Antarctica		
country	sector	date of claim
Norway (Queen Maud Land)	20°W–45°E	January 14, 1939, by Norwegian Order in Council (also claimed Bouvet Island on January 23, 1928, and Peter I Island on May 1, 1931)
Australia (Australian Antarctic Territory)	45°E–136°E, 142°E–160°E	February 7, 1933, by British Order in Council; and June 13, 1933, by Australian Antarctic Territory Acceptance Act
France (Adélie Land)	136°E–142°E	April 1, 1938, by official decree (placed under Governor of Madagascar in 1924)
New Zealand (Ross Dependency)	160°E–150°W	July 30, 1923, by British Order in Council
Chile (Antarctic Peninsula)	90°W–53°W	November 6, 1940, by official decree
Great Britain (British Antarctic Territory)	80°W–20°W	July 21, 1908
Argentina (Antarctic Peninsula)	74°W–25°W	1942

tional agreement, the region is now known simply as the Antarctic Peninsula, Graham Land its northern half and Palmer Land its southern half.

The first half of the 20th century is the colonial period in the history of Antarctica. Between 1908 and 1942, seven nations decreed sovereignty over pie-shaped sectors of the continent. Many nations—including the United States, the Soviet Union, Japan, Sweden, Belgium, and Germany—carried out Antarctic exploration without lodging formal territorial claims, even though claims may have been announced by some of their exploratory parties. The U.S. government, for example, has never taken up the claims made in 1929 by Richard Byrd's expedition in the Ford Ranges of Marie Byrd Land (an area presently unclaimed), nor those made by Lincoln Ellsworth on aerial landings on Nov. 23, 1935, in Ellsworth Land (an area now claimed by Chile) and on Jan. 11, 1939, in the American Highland near Amery Ice Shelf of East Antarctica (an area now claimed by Australia). The German Antarctic Expedition of 1939 aerially photographed an extensive segment of Princess Astrid and Princess Martha coasts of western Queen Maud Land and, dropping metal swastikas over the region, claimed it for the Hitler government (the area is now claimed by Norway). Other claims were transferred, such as that made in 1841 by James Ross, who, after discovering and naming the coastal Ross Sea region after Queen Victoria, claimed it for the British crown; the area was later transferred to, and is now claimed by, New Zealand.

After the French claim of Adélie Land caused Americans to demand retaliatory action, the United States' official position was announced in 1924 by the Secretary of State, Charles Evans Hughes:

It is the opinion of this Department that the discovery of lands unknown to civilization, even when coupled with a formal taking of possession, does not support a valid claim of sovereignty, unless the discovery is followed by an actual settlement of the discovered country.

This policy has been reiterated many times since.

Few combative activities have marred the history of Antarctica. World War II brushed the continent lightly, only in that its nearby seas were used by Nazi commerce raiders. The threat of increased activity, however, prompted British warships to keep the northern Antarctic Peninsula under surveillance. On one visit to Deception Island in January 1943, it was discovered that Argentine visitors had been there the year before, leaving a brass cylinder with notice of claim to the peninsular region. The British obliterated the Argentine signs, hoisted the Union Jack, posted a notice of crown ownership, and returned the cylinder to the Argentine government. Reaction was swift. In London, growing concern that the territory might possibly be lost and that a pro-German Argentine government might control both sides of the vital Drake Passage linking Atlantic and Pacific sea routes resulted in a secret military plan, code-named "Operation Tabarin," to establish a base on Deception Island for closer watch. When the British returned to the island in February 1944, they found their earlier sign gone and an Argentine flag painted in its place. This they soon replaced with their own flag, and their base was established to back up the British claims to the region. Several other stations were built, and, with the conclusion of the war, the United Kingdom decided to maintain a continued presence in Antarctica.

Argentina and Chile both were stimulated to increase activities to back up their claims to the Antarctic Peninsula as a result of the British occupancy. (Chile had expressed a claim in 1940.) The Argentines had maintained a weather station in the South Orkney Islands continuously since 1903, and after 1947 they and the Chileans constructed bases at several sites. With the coming of the U.S. Ronne Antarctic Research Expedition (RARE) in 1947–48 to the old U.S. Antarctic Service East Base camp on Marguerite Bay, the peninsula protagonists—British, Argentine, and Chilean—became concerned that the United States might rejuvenate its claims. Any antagonism was soon overcome, and the Americans and British joined forces for an arduous sledging journey down the east side of the peninsula.

Military violence has flared on two occasions in the re-

gion and in both instances has involved Argentina and the United Kingdom. The first incident took place in 1952, when Argentine navy small-arms fire chased a British meteorological party that had landed at Hope Bay (at the northern end of the Antarctic Peninsula) back to its ship. The matter was resolved when the Argentine government agreed not to interfere with the party. The second, much more serious confrontation took place in 1982 in the Falkland Islands, a British colony that is also claimed by Argentina (called the *Islas Malvinas* by the Argentines). Argentine forces invaded the Falklands and South Georgia Island in early April. The British responded by sending a military task force, reoccupying the islands, and forcing the Argentines to surrender on June 14.

By the mid-1950s, many nations had active Antarctic interests, some commercial and some scientific but generally political. In 1947–48, Australia had established stations on Heard and Macquarie islands and in 1954 built Mawson Station on the mainland coast of MacRobertson Land as a basis for its vast territorial claim. South Africans raised their flag over Prince Edward and Marion islands. France established permanent bases by 1953 in the Kerguelen and Crozet islands and surveyed much of the Adélie Land coast. In 1955, with icebreaker aid, Argentina established General Belgrano Station on the Filchner Ice Shelf. A profusion of British, Chilean, and Argentine bases had been built in such proximity to one another on the peninsula and nearby islands that their purpose seemed more for intelligence activities than for science. The international Norwegian-British-Swedish Expedition of 1949–52 carried out extensive explorations from Maudheim Base on the Queen Maud Land coast in the territory claimed in 1939 by Norway. The United States had shown little interest in Antarctica since the Ronne expedition and the U.S. naval "Operation Windmill," both in 1947–48 (the latter expedition was to obtain ground checks on the aerial photography of the previous season's "Operation High Jump"), but it continued its policy of nonrecognition of any claims. The Soviet Union had shown little interest, other than whaling, in Antarctica since Bellingshausen's pioneer voyage. On June 7, 1950, however, the Soviet government sent a memorandum to other interested governments intimating that it could not recognize any decisions on the regime for Antarctica taken without its participation. Such was the political climate on the continent during the organizational years for the coming International Geophysical Year of 1957–58.

IGY AND THE ANTARCTIC TREATY

The importance of coordinating polar science efforts was recognized in 1879 by the International Polar Commission meeting in Hamburg, Ger., and thus the 11 participating nations organized the First International Polar Year of 1882–83. Most work was planned for the better known Arctic, and, of the four geomagnetic and meteorologic stations scheduled for Antarctic regions, only the German station on South Georgia materialized. The decision was made at that time to organize similar programs every 50 years. In 1932–33 the Second International Polar Year took place, with 34 nations participating, but no expeditions were mounted to Antarctica.

The development of IGY. The idea for more frequent programs was born in 1950, when it was proposed that scientists take advantage of increasing technological developments, interest in polar regions, and, not the least, the maximum sunspot activity expected in 1957–58. (The earlier, second polar year was a year of sunspot minimum.) The idea quickly germinated and grew: a formalized version was adopted by the International Council of Scientific Unions (ICSU), and in 1952 ICSU appointed a committee that was to become known as the Comité Spécial de l'Année Géophysique Internationale (CSAGI) to coordinate IGY planning. Plans widened to include the scientific study of the whole Earth, and eventually 67 nations showed interest in joining. Plans were laid for simultaneous observations, at all angles, of the Sun, weather, the aurora, the magnetic field, the ionosphere, and cosmic rays. Whereas in the first polar year observations were confined to ground level and in the second to

about 33,000 feet by balloon, during IGY satellites were to be launched by the United States and the Soviet Union for exploration of space. Several international data centres were established to collect all observations and make them freely available for analysis to scientists of any nation.

Two programs, outer space and Antarctica, were especially emphasized at an ICSU committee meeting in Rome in 1954. Antarctica was emphasized because very few geophysical studies had yet been made on the continent, because the south geomagnetic pole focuses auroral and cosmic-ray activity in the Southern Hemisphere, and because on the eve of IGY almost half the continent had not yet even been seen by humans. The First Antarctic Conference was held in Paris in July 1955 to coordinate plans for expeditions, the advance parties of which were soon to set sail for the continent. Early tensions, due in part to overlapping political claims on the continent, were relaxed by the conference president's statement that overall aims were to be entirely scientific. Plans were laid for extensive explorations: 12 nations were to establish more than 50 overwintering stations on the continent and subantarctic islands; the first regular aircraft flights to the continent were to be inaugurated (by the United States); massive tractor traverses were to be run in order to establish inland stations in West Antarctica (Byrd Station for the United States), at the south geomagnetic pole (Vostok Station for the Soviet Union), and the pole of relative inaccessibility (also for the Soviet Union); and an airlift by giant cargo aircraft was to be established in order to set up a station at the South Pole itself (Amundsen-Scott Station for the United States). Several major scientific programs were scheduled for Antarctica, dealing with the aurora and airglow, cosmic rays, geomagnetism, glaciology, gravity measurement, ionospheric physics, meteorology, oceanography, and seismology. Biology and geology were not primary studies of IGY.

Coastal bases were established in the summer of 1955-56 and inland stations the next summer for the official opening of IGY on July 1, 1957. For 18 months, until the end of IGY on Dec. 31, 1958, a frenzy of activity not only in Antarctica but all over the world and in space resulted in a multitude of discoveries that revolutionized concepts of the Earth and its oceans, landmasses, glaciers, atmosphere, and gravitational and geomagnetic fields. Perhaps the greatest contribution was the political moratorium by the governments and the cooperative interchange between scientists of participating nations.

The Antarctic Treaty. With the ending of IGY the threat arose that the moratorium too would end, letting

the carefully worked out Antarctic structure collapse into its pre-IGY chaos. In the fall of 1957 the U.S. Department of State reviewed its Antarctic policy and sounded out agreements with the 11 other governments with Antarctic interests. On May 2, 1958, Pres. Dwight D. Eisenhower issued identical notes to these governments proposing that a treaty be concluded to ensure a lasting free and peaceful status for the continent. Preparatory talks by the 12 governments were held in Washington, D.C., beginning in June 1958 and continuing for more than a year. A final conference on Antarctica convened in Washington on Oct. 15, 1959. Agreement on the final draft was reached within six weeks of negotiations, and the Antarctic Treaty was signed on Dec. 1, 1959. With final ratification by each of the 12 governments (Argentina, Australia, Belgium, Chile, France, Japan, New Zealand, Norway, South Africa, Soviet Union, United Kingdom, and United States), the treaty was enacted on June 23, 1961.

The achievement of the Antarctic Treaty was an unprecedented landmark in political diplomacy: an entire continent was reserved for free and nonpolitical scientific investigation. Article I of the treaty provides for the peaceful use of Antarctica; Article II for international cooperation and freedom of scientific investigation; Article III for free exchange of plans, scientific results, and personnel; Article IV for the nonrenunciation of prior claim rights and for the prohibition of new claims and the citation of any activities during the treaty term as a basis for past or future claims; Article V for prohibition of nuclear explosions or waste disposal; Article VI for application of the treaty to all areas south of latitude 60° S, excluding the high seas, which come under international law; Article VII for open inspection of any nation's Antarctic operations by any other nation; Article XI for reference of disputes to the International Court of Justice if they cannot be settled by peaceful negotiation or arbitration by involved parties; and Article XII for a review of the treaty after it has been in force for 30 years, if such a review is requested by any contracting party.

As stated in Article IV, the many territorial claims that existed before the signing of the treaty were not abrogated by signatory nations. Multiple claims in some regions have never been resolved by international courts, and a number of countries, including the United States, recognize the validity of no claims in the absence of permanent habitation and settlements on the continent. An important provision of the treaty requires periodic meetings of representatives of signatory nations to take up occasional problems. Such meetings have agreed upon important

Research

measures for conservation of Antarctic flora and fauna and for the preservation of historic sites. The granting of consultative status within the Antarctic Treaty, permitting full participation in its operation with that of the original 12 contracting states, began in 1977 with the addition of Poland, followed by West Germany (1981), and Brazil and India (1983). Several other nations have also acceded to the treaty and have been granted partial status.

Post-IGY research. In order to continue and coordinate the international Antarctic scientific effort in the post-IGY period, ICSU in September 1957 organized the Special Committee on Antarctic Research, or SCAR. (In 1961 the word *Scientific* was substituted for *Special*.) The foundations for the committee were laid at its first meeting in The Hague in 1958. SCAR, a nonpolitical body, coordinates not only research activities in Antarctica itself but also, through ICSU, those Antarctic programs that relate to worldwide projects, such as the International Years of the Quiet Sun, the World Magnetic Survey, the Upper Mantle Project, the International Biological Program, and the International Hydrological Decade. Member nations send representatives to periodic meetings of "working groups" for the various scientific disciplines. International scientific symposia are organized by SCAR for exchange of latest research results, on a timetable depending upon progress in the discipline. The great success of the political venture of the Antarctic Treaty depends in no small way on the achievements of SCAR and of the scientific and support teams in the field and laboratory.

Scientific knowledge of Antarctica has increased steadily. Many important problems relating to knowledge of the entire Earth can be resolved only in the polar region. As pointed out by R.F. Scott's son Peter on an Antarctic visit in 1966, about half the topics of modern polar research could not even have been guessed at in his father's era only a half century earlier. Who at that time but a Jules Verne could have foreseen the advent of jet aircraft, turbine-powered helicopters, ski-planes, and of data-recording machines powered by radioactive isotopes and polar-orbiting satellites that automatically collect meteorologic and upper atmosphere data across the continent and transmit it to a base collection station? The polar knowledge gained in the decades during and after IGY far outweigh that learned in the preceding millennia. The incredible advances in modern Antarctic science have only been possible by adapting to polar operation the great technological advances in aircraft, oceanographic technique, and remote data acquisition and telemetry systems (unmanned weather stations, satellite surveillance, and the like).

Inter-
national
programs

During the period of the Antarctic Treaty there has been a steady growth in the number and nature of cooperative international scientific projects (the International Antarctic Glaciological Project, Dry Valley Drilling Project, Biomass [Biological Investigations of Antarctic Systems and Stocks], International Weddell Sea Oceanographic Expedition); of the various SCAR working groups; and, notably, of projects at the interface of astronomy and atmospheric physics (the International Magnetospheric Study, Antarctic and Southern Hemisphere Aeronomy Year).

In addition to these internationally supported programs, there have been major increases in individual national programs, mostly among those countries with territorial interests in the continent but also among countries that had not for decades (or never) supported programs there. This latter group includes Italy, which mounted its first expedition during 1975-76; Uruguay, which made its first land expedition in 1975; Poland, which established marine and land programs during 1976-77; West Germany, which first undertook large-scale operations in 1980-81; India, which began work in the early 1980s; and China, which established its first station in 1984.

Virtually all of the physical sciences are represented in the studies carried out under these programs, often having direct impact on such disparate fields as meteoritics and planetary geology, continental drift, hydrology and world water balance, meteorology and climate history, or biology and population studies. The biological programs reflect both the inherent interest of the Antarctic subjects themselves and the interest elsewhere in the world in ecol-

ogy and conservation. The history of Antarctic whaling had made apparent to scientists the necessity of conserving biological populations, and the area below 60° S had long contained nature reserves of greater or lesser extent, but the Convention on the Conservation of Antarctic Marine Living Resources (1982) gave especial impulse to the principle. One of the most unexpectedly fertile areas of research in the late 20th century was that of meteoritics, brought about by the Japanese meteorite discoveries in 1969. In less than a decade, the world's supply of meteorites available for study was doubled.

The gradual recognition by scientists of the extent of potentially exploitable mineral resources on Antarctica and on the seabed surrounding it, as well as the long, tortuous process that led to the final Law of the Sea Convention (1983), has induced consultative members of the treaty to initiate discussions that would eventually permit orderly exploitation of those resources within the conserving framework of existing agreements.

BIBLIOGRAPHY

General: The most complete guide to literature about the Antarctic is the U.S. LIBRARY OF CONGRESS, *Antarctic Bibliography* (irregular), which is continued monthly in *Current Antarctic Literature*. LOUIS O. QUAM (ed.), *Research in the Antarctic* (1971); and RICHARD S. LEWIS and PHILIP M. SMITH (eds.), *Frozen Future: A Prophetic Report from Antarctica* (1973), contain review articles by leading experts of most subjects of current research, the latter also with articles on resources, economics, politics, and the outlook for the future. A general review, RAYMOND PRIESTLEY, RAYMOND J. ADIE, and G. DE Q. ROBIN (eds.), *Antarctic Research* (1964), emphasizes British scientific achievements, particularly in the Antarctic Peninsula and Scotia Arc. *Атлас Антарктики*, 2 vol. (1966-69), is a comprehensive map collection in Russian, useful especially when complemented by the translation of legend matter and explanatory text from vol. 1, published as "Atlas of Antarctica," a special issue of *Soviet Geography: Review and Translation*, vol. 8, no. 5-6 (May-June 1967). Numerous folios of the AMERICAN GEOGRAPHICAL SOCIETY OF NEW YORK, *Antarctic Map Folio Series*, (1964-75); and volumes of the *Antarctic Research Series*, published by the AMERICAN GEOPHYSICAL UNION since 1964, provide modern maps and technical accounts of all phases of the research programs. Semitechnical to nontechnical reviews of current projects and exploration are in summary articles in the *Antarctic Journal of the United States* (five times per year); a general nontechnical review is provided by H.G.R. KING, *The Antarctic* (1969). F.M. AUBURN, *Antarctic Law and Politics* (1982), provides a comprehensive discussion of the legal aspects of the Antarctic Treaty, jurisdictional problems of crime, ecology, and tourism. J.F. LOVERING and J.R.V. PRESCOTT, *Last of Lands: Antarctica* (1979), examines resources, discovery and exploration, political geography, and future prospects. BARBARA MITCHELL, *Frozen Stakes: The Future of Antarctic Minerals* (1983), presents an account of polar politics and minerals and discusses possible regimes for regulating resource development. FRANCISCO ORREGO VICUÑA (ed.), *Antarctic Resources Policy: Scientific, Legal, and Political Issues* (1983), contains reports from the first symposium of its kind, a meeting of scientists, diplomats, and international lawyers at an Antarctic scientific station.

Geology and solid-earth geophysics: RAYMOND J. ADIE (ed.), *Antarctic Geology* (1964), and *Antarctic Geology and Geophysics* (1972); CAMPBELL CRADDOCK (ed.), *Antarctic Geoscience* (1982); and R.L. OLIVER, P.R. JAMES, and J.B. JAGO (eds.), *Antarctic Earth Science* (1983), are records of international symposia describing earth-science research by many nations. J.C. BEHRENDT and C.R. BENTLEY, *Magnetic and Gravity Maps of the Antarctic* (1968); and CAMPBELL CRADDOCK and V.C. BUSHNELL (eds.), *Geologic Maps of Antarctica* (1970), provide modern maps and texts, the latter work covering most mountain regions at 1:1,000,000 scale. SCRIPPS INSTITUTION OF OCEANOGRAPHY, *Initial Reports of the Deep Sea Drilling Project*, vol. 28 (1975), 35 (1976), and 36 (1977), contain results of drilling by the *Glomar Challenger* in Antarctic waters. A discussion of meteorite recovery through knowledge of glaciology is provided by WILLIAM A. CASSIDY and LOUIS A. RANCITELLI, "Antarctic Meteorites," *American Scientist*, vol. 70, no. 2, pp. 156-164 (March-April 1982).

Climate and meteorology: MORTON J. RUBIN (ed.), *Studies in Antarctic Meteorology* (1966); S. ORVIG (ed.), *Climates of the Polar Regions* (1970); and W.S. WEYANT, *The Antarctic Atmosphere: Climatology of the Surface Environment* (1967), include topical studies and a few general review articles.

Glaciology and oceanography: MALCOLM MELLOR (ed.), *Antarctic Snow and Ice Studies* (1964); and A.P. CRARY (ed.), *Antarctic Snow and Ice Studies II* (1971), are collections mainly

of topical studies of greatly varied scope; JOHN H. MERCER, *Glaciers of the Antarctic* (1967), provides a general review of Antarctica's glaciers. A.L. GORDON and R.D. GOLDBERG, *Circumpolar Characteristics of Antarctic Waters* (1970); and JOSEPH L. REID (ed.), *Antarctic Oceanology* (1971), describe features of South Polar water masses, their currents, and their interactions with subtropical and subantarctic waters, as well as of the ocean floor and sediment carpet.

Biology: ERIC HOSKING and BRYAN SAGE, *Antarctic Wildlife* (1982), is an authoritative discussion of the fauna of Antarctica. MILTON O. LEE, GEORGE A. LLANO, and I. EUGENE WALLEN (eds.), *Biology of the Antarctic Seas* (1964-), is a continuing series of technical accounts of Antarctic sea life; a more popular summary is ROBERT C. MURPHY, "The Oceanic Life of the Antarctic," *Scient. Am.*, vol. 207, no. 3, pp. 186-194 (Sept. 1962). Technical accounts of terrestrial life are in J. LINSLEY GRESSITT (ed.), *Entomology of Antarctica* (1967); and S.W. GREENE *et al.*,

Terrestrial Life of Antarctica (1967); a nontechnical review is provided by GEORGE A. LLANO, "The Terrestrial Life of the Antarctic," *Scient. Am.*, vol. 207, no. 3, pp. 212-218 (Sept. 1962). OLIVER L. AUSTIN, JR. (ed.), *Antarctic Bird Studies* (1968), is a technical publication, whereas JOHN SPARKS and TONY SOPER, *Penguins* (1967), comprehensively but nontechnically describes the characteristic flightless birds of subantarctic and Antarctic coasts. See also GEORGE GAYLORD SIMPSON, *Penguins Past and Present, Here and There* (1976), an authoritative, popularly written account of penguins and their fossil record.

History: A complete list of expeditions through the IGY is in BRIAN ROBERTS, *Chronological List of Antarctic Expeditions* (1958). A thorough general account is in C.H. GRATTAN, *The Southwest Pacific Since 1900* (1963); an account of early U.S. explorations is in KENNETH J. BERTRAND, *Americans in Antarctica, 1775-1948* (1971). An interesting and thorough history is WALTER SULLIVAN, *Quest for a Continent* (1957). (A.B.Fo.)

Antwerp

The second-largest city in the Kingdom of Belgium and the capital of the Belgian province of the same name, Antwerp (Flemish: Antwerpen; French: Anvers) is situated on the Schelde (Scheldt) River, about 55 miles (88 kilometres) from the North Sea. The Schelde, together with the Meuse and the Rhine, forms the biggest estuary in western Europe, and Antwerp is an essential part of an enormous harbour complex, one of the greatest in the world. The harbour installations of Antwerp grew especially after World War II. For many years this expansion took place on the right bank of the Schelde only, but during the 1970s and '80s there was much development

on the left bank, indicating that Antwerp's harbour facilities will ultimately extend on both banks of the river to the Dutch frontier, almost 13 miles downstream. Because Antwerp lies in the Dutch- (Flemish-) speaking part of Belgium, the city plays the role of unofficial capital of Flanders. Antwerpians generally take this role very seriously, conscious as they are of the great importance of their city in the past and present. The pride and competitive attitude thus exhibited by the residents has led to their being designated by the nickname *Sinjoren* (from the Spanish *señores*).

Physical and human geography

THE LANDSCAPE

The city site. Antwerp's site on the right bank of the generally south-north-flowing Schelde is a vast, flat alluvial plain. Since 1923, however, the city's territory also has included an area on the left bank of the river. Annexation of villages on the right bank north of Antwerp in 1929 and 1958 extended the city's territory to the Dutch frontier, and further annexation in 1983 of municipalities surrounding the original city added considerably to Antwerp's area and population. The total area of contemporary Antwerp measures 75 square miles (195 square kilometres), compared with 7 square miles before the beginning of the annexations. Only a part of this territory is completely built up. The extension of the agglomeration is continuing; many outlying villages have already lost their agricultural character and have grown in population as a result of emigration from the city.

The city layout. Until 1859 Antwerp lay surrounded by its 16th-century fortified walls, which were transformed in the latter half of the 19th century into broad avenues as a larger half circle of fortifications was built. This later encircling belt was replaced after World War II by another system of ring roads, which connect with a network of national and international highways. Several tunnels connect the right bank of the city with the left bank, where considerable residential and industrial development has taken place since World War II. The city centre, however, remains on the right bank; it stretches westward from the Central (railway) Station along the lively artery constituted by the Keyserlei and the Meir into the old city and thence to the terraced right bank of the Schelde.

The old city, within the arc once formed by the 16th-century fortifications, has many narrow, winding streets and old buildings. This area contains the Cathedral of Our Lady, begun in the 14th century and restored in the 19th and 20th centuries; it is one of the nation's finest Gothic buildings. The 19th-century city, with broader and substantially right-angled streets, stretches beyond the old city and merges with some of the suburban extensions annexed in 1983. A third right-bank area spreads beyond the 19th-century fortifications and is characterized by numerous modern buildings.

The largest part of Antwerp, however, is the essentially nonresidential northern seaport complex. Most of the agri-

cultural waterside villages incorporated by the city have been eliminated to make room for expanding, if somewhat bleak, areas of docks, industrial sites, and railway yards. Six locks connect this right-bank complex with the tidal Schelde River: the first, the Kattendijk, was opened in 1860; and the newest, the 1,640-foot (500-metre) Berendrecht, was when it opened in 1988 the largest lock in the world. Left-bank port and industrial facilities have access to the Schelde via the Kallo lock.

THE CHARACTER OF THE CITY

The unique flavour of Antwerp is derived from the combination of, and tensions between, the diverse aspects of its personality: a passionate commitment to commerce goes hand in hand with an abiding interest in the life of ideas and in the arts; respect and affection for the past are juxtaposed with a fervent desire to participate fully in the present and in the future; and awareness of being a truly European and cosmopolitan city, with a resulting openness and broad curiosity, coexists with a sense of tradition and of idiosyncratic particularity, which lend an almost provincial charm to life in the city. In its centre a lively social activity is conducted on the streets and in the countless cafés. The Schelde is the veritable heart and soul of Antwerp, the *raison d'être* not only of Antwerp's dynamic economic life but also of its sense of identity and of the deep attachment—touchingly expressed in many literary works—that Antwerpians tend to feel for their city.

THE PEOPLE

The residents of Antwerp generally speak the local Brabantian-Antwerp dialect of Dutch. Dutch as spoken in The Netherlands and by Dutch-speaking cultured Belgians, however, is taught in the schools and is gaining ground in economic life. Although French is still much used in commercial and industrial circles, it is losing steadily as a means of expression. This does not mean that Dutch-speaking Antwerpians do not know French or other languages, for the international character of the city implies a readiness of many of its residents to understand foreign languages.

Most of the foreigners living in Antwerp are Dutch, followed by Moroccans, Spaniards, French, and Germans; there are also small numbers of British, Americans, and Israelis. Unlike the other foreigners, the Moroccan and Spanish groups are largely unskilled workers who migrated

Spread of
the city

Dialects
and
languages

to Belgium during periods of labour scarcity after World War II. There have been associated social tensions, notably concerning discrimination in housing.

The prevalent religion in Antwerp is Roman Catholicism. There are also small groups of various Protestant churches and a sizable Jewish group of different tendencies. (By the 19th century, Antwerp already had a great number of Jewish residents, but many Jews died in World War II German concentration camps.) A large and growing part of the population is nonreligious.

THE ECONOMY

Industry and commerce. Antwerp's economic life has long been closely connected with its existence as a seaport, and as such it is inseparable from the city's favourable geographic location and from the port's facilities and functions. In the 16th century the city developed an important sugar-refining industry, in which partially worked sugarcane was brought in by ship, refined, and reexported. The first petroleum refineries were established during the 1920s and '30s, and they were soon joined by automobile assembly plants. After World War II, industry expanded at a rapid pace. Larger petroleum refineries, closely followed by petrochemical industries, were established, together with chemical plants in the 1960s, and the automotive industry was restructured on a larger scale.

Other important products include photographic and electronic equipment and cut diamonds, the latter for which Antwerp is world-famous. According to legend, the first diamond was cut in Antwerp in 1476. Since the 16th century, cutting and dealing establishments have thrived in the so-called diamond quarter adjacent to the Central Station, and Antwerp has become the international centre of the diamond industry.

Antwerp's complex of harbour and industrial activities is served by many commercial agencies, commission agents, import and export firms, banking establishments, insurance companies, road-transport enterprises, and railways.

Transportation. A dense network of railway lines and highways serves Antwerp's huge port and industrial complex, and the city is a rail and road centre for Belgian and international destinations. Antwerp is also well integrated into Europe's vast inland waterway network. The airport at Deurne is important for freight and passenger flights. On the local level, public transportation in the city consists of a network of bus lines and tramways; some of the tramways have been transformed into subway lines.

ADMINISTRATION AND SOCIAL CONDITIONS

Government. Like all Belgian municipalities, Antwerp is governed by an elected city council, which in turn elects a board of aldermen, headed by a burgomaster, nominated by the king on recommendation of the council. Generally the burgomaster is a member of the elected council, but this is not obligatory. Each alderman has a specified department to manage, but decisions and resolutions are always taken by the board as a whole. Under the board of aldermen is the town clerk, the chief official to whom the different administrative services report. The city is also the residence of the government of the province of Antwerp, headed by a governor appointed by the king; a provincial council, elected every four years; and its board of deputies, who have, in regard to the province, the same task as the city aldermen. The provincial recorder is the counterpart of the town clerk. A third kind of public service is the Commission for Public Relief. The members of the commission are appointed for six years by the city council.

Health and education. The Commission for Public Relief, responsible for public health and care of the aged and orphans, manages a series of institutions, among which are several large hospitals. Together with these official establishments, there are a number of independent, mostly Roman Catholic, institutions. This duality is also found in education. Besides the different schools of all grades (*i.e.*, kindergarten, primary and secondary schools, and technical institutions) managed by the city administration (and for a small part by the state), there exists an independent, essentially Roman Catholic, network. This is also the case at the university level: both an official (state) and an in-

dependent (Jesuit) institute were founded in 1965. Higher artistic training is given in the National Higher Institute and Royal Academy for Fine Arts (1663) and the Royal Flemish Conservatory of Music (1898).

CULTURAL LIFE

It is significant, in view of Antwerp's long-standing involvement with learning and with the arts, that two of the most important figures of its cultural past are still present in the modern city through the preservation of their homes and workshops as museums: the 16th-century humanist printer Christophe Plantin (Plantin-Moretus Museum) and the 17th-century painter Peter Paul Rubens (Rubens House). Rubens' works may be seen in the Royal Museum of Fine Arts, as well as in the Cathedral of Our Lady and many other Antwerp churches, such as the Church of St. James, where the painter is buried. Rubens united Italianate traits and an attachment to the Flemish artistic tradition to create a highly personal style. His students and coworkers included the three 17th-century Antwerpians Jacob Jordaens, Anthony Van Dyck, and Frans Snyders; their works also may be seen in the Royal Museum, which houses a vast collection from the 15th to the 20th century.

A number of other museums are located in historical buildings such as the Steen, the medieval riverside castle that is home to the National Maritime Museum; the 16th-century Butchers' Hall and Brewers' Hall, both of which house historic arts and artifacts; and the Maagdenhuis (Flemish: "Maidens' House"), a 16th-century charitable foundation for needy young women, where Renaissance art and furniture may be seen. Other small museums were established by 19th-century patrician families, such as the Mayer van den Bergh Museum, which contains sculpture, furniture, and paintings, notably Pieter Bruegel's famous "Dulle Griet" (or "Mad Meg"). Museums for folklore and for ethnography are located not far from the Schelde. For modern art, there is the Museum of Contemporary Art, installed in a 1920s Art Deco grain silo in the old dock area of the port, which is close to the Provincial Museum of Photography, housed in a former warehouse built in 1911. In the Middelheim Open-Air Museum of Sculpture, the permanent collection is displayed among the trees and lawns of a public park located south of the old city, and every other year a special exhibition features works by young contemporary sculptors. Antwerp's architecture ranges from Gothic to Postmodernism.

The performing arts in the city are represented by the Royal Flemish Opera House and by the Royal Dutch Theatre, and numerous theatrical and musical performances

Eric Carle—Shostal Assoc.

The Cathedral of Our Lady, Antwerp, with a statue of Peter Paul Rubens in the foreground.

Museums

The
diamond
industry

of traditional as well as modern works take place in the framework of Antwerp's monuments, such as in the courtyard of the Rubens House. The city's zoological garden is one of Europe's oldest as well as most modern zoos.

History

EARLY SETTLEMENT AND GROWTH

The site of Antwerp was probably already inhabited, as excavations on the right bank of the Schelde have proved, in Gallo-Roman times, in the 2nd and 3rd centuries AD. After the great Eurasian migrations of the 4th and 5th centuries, the region was occupied and Germanized by Franks and possibly Frisians, who gave it its present name, from the Germanic prefix *anda* ("against") and a noun derived from the verb *werpen* ("to throw"), indicating a structure—possibly a predecessor of Antwerp's 9th-century fortified castle, the Steen—erected against something or someone.

A more picturesque etymology for the name of the city involves the story of the evil giant Druon Antigoon, who severed the hands of the river's boatmen when they refused to pay his exorbitant tolls. The Roman soldier Silvius Brabo challenged him to a fight, cut off one of his hands, and flung it into the river, not far from the site of the present Steen, thus putting an end to the giant's extortion and giving the city its name: literally, "to throw a hand." Antwerp's coat of arms consists of a fortified castle with a hand on each side; and in the Great Market, in front of the 16th-century Town Hall, the Brabo Fountain (1887) depicts the legendary event.

The city probably developed from two nuclei: a southern one called Chanelaes—Caloes—Callo and a later northern nucleus grown around the Steen, which eventually became the more important of the two. Christianity was introduced in the 7th century. In the 9th century the region became a border county of the Holy Roman Empire. In 1124 the religious centre was transferred from Chanelaes to the northern nucleus. It was around the castle, built originally as a seat for the border county, that Antwerp developed, in the course of the centuries, in more or less concentric half circles.

Situated relatively far inland on the deep right bank of the Schelde, Antwerp was predestined to become a trade and shipping centre. This was already fully the case in the 13th century. At the end of that century and the beginning of the 14th, freedom of trade was given to the English, Venetians, and Genoese by the dukes of Brabant, who had made themselves masters of the county. The city of Antwerp became one of the duchy's capital cities, together with Louvain and Brussels, in Belgium, and the city of Hertogenbosch (Bois-le-Duc), in the Netherlands. In the first quarter of the 14th century, the Antwerp fairs began to flourish. These, together with the fairs of nearby Bergen op Zoom (now in The Netherlands) became one of the foundations of Antwerp's medieval economic growth.

FROM THE 15TH TO THE 19TH CENTURY

Antwerp succeeded in the 15th century in becoming the successor of Brugge (Bruges) in Flanders, which until then had been the mercantile metropolis of western Europe. At the end of the 15th century, when nearly all the Low Countries were united under the Burgundian and Habsburg dynasties, the economic preeminence of Antwerp over Brugge is indicated by the fact that the majority of foreign merchants transferred their residence from the old Flemish town to Antwerp. It quickly became the leading commercial centre of western Europe, profiting from the beginnings of colonial trade and stimulated by the great discoveries of the Portuguese and Spaniards. Toward the mid-16th century, the population totaled nearly 100,000, whereas there had been about 20,000 people in the city at the end of the 14th century. Extensive urbanization plans were developed to lodge the increasing population, who earned their livelihood in trade, transport, and industry.

The port underwent its first northward extension. New industries included breweries, malt factories, and bleaching works. Together with the already established finishing works of (English) cloth, tapestry, and silk factories, the

sugar refineries, and the diamond industry, they made Antwerp one of the greatest industrial centres of western Europe. Antwerp also became a financial centre: its Stock Exchange (inaugurated 1531), a model for the younger London and Amsterdam exchanges, was the scene of dramatic and momentous events, in which financial agents and bankers of the Habsburg, Tudor, and Valois monarchs played their part, together with Antwerpian, English, French, Portuguese, Italian, Spanish, and German merchants. Antwerp also became a great cultural centre: its school of painting began to flourish at the end of the 15th century; the city's printing houses became known throughout Europe; and humanism began to thrive.

State bankruptcies in Spain, Portugal, and elsewhere, together with religious troubles and ensuing wars (Antwerp early in the 16th century became a centre of Protestant activity), brought about a decline. Antwerp became involved in the revolt of the Netherlands and was taken, in 1585, by Alessandro Farnese, duke of Parma, governor general for the Spanish king. The consequences of this strife with Spain were severe: from 1585 to 1589 the population diminished from 80,000 to 42,000. The Schelde, gateway to the sea, was closed by the Dutch, maintaining their positions against King Philip II of Spain. Capital and enterprise emigrated from Antwerp, mostly northward. The economic greatness of Amsterdam in the 17th century was due in part to Antwerp emigrants and their financial support, as was the case, to a lesser extent, for Hamburg, Frankfurt am Main, and other mercantile cities.

Yet Antwerp was not reduced to the status of a nonentity. The city remained the dynamic economic centre of the Spanish (later, in the 18th century, the Austrian) Netherlands. Antwerp became a more famous art centre than ever before: this was the time of Rubens, Van Dyck, Jordaens, and other major artists. The French Revolution and the Napoleonic period, followed by Belgium's temporary union with The Netherlands (1815–30), reversed the general decline in trade of the 18th century. With the Schelde once more freely navigable (restored by the French in 1792), the attraction of Antwerp as a seaport became evident again. Population grew, and the city began to expand and modernize.

THE MODERN CITY

Since the second half of the 19th century, the growth of Antwerp's seaport has been interrupted only by the two world wars and associated German occupations; even the economic depression of the 1930s did not affect the expansion of port traffic and facilities. Immediately after liberation in 1944, Antwerp's nearly unharmed port was instrumental in the supply of the Allied armies aiming their final blow against Nazi Germany, although bombardment by German missiles devastated the city. Since World War II Antwerp, its suburbs, and its seaport have grown apace, spurred by a commercial, industrial, and maritime boom. Port facilities, highways, and inland waterways have all been extended and improved. Some of this expansion, however, has created ecological problems, which have been investigated and addressed to some degree.

BIBLIOGRAPHY. The economic history of the city is discussed by HERMAN VAN DER WEE, *The Growth of the Antwerp Market and the European Economy (Fourteenth–Sixteenth Centuries)*, 3 vol. (1963). F. SUYKENS *et al.*, *Antwerp, a Port for All Seasons*, trans. from Flemish (1986), gives the history of the harbour. Intellectual and cultural history is detailed in several books, among them THEODORE L. DE VINNE, *The Plantin-Moretus Museum: A Printer's Paradise* (1929); JOHN J. MURRAY, *Antwerp in the Age of Plantin and Brueghel* (1970); *Antwerp's Golden Age: The Metropolis of the West in the 16th and 17th Centuries* (1973?), an exhibition catalog with a large bibliography; and LÉON VOET, *Antwerp, the Golden Age: The Rise and Glory of the Metropolis in the Sixteenth Century* (1973; originally published in Dutch, 1973). JULIEN WEVERBERGH (ed.), *Museumgids voor Antwerpen* (1988), is a directory of Antwerp's museums.

Studies of Antwerp's history include WILFRID C. ROBINSON, *Antwerp: An Historical Sketch* (1904); JERVIS WEGG, *Antwerp, 1477–1559, from the Battle of Nancy to the Treaty of Cateau Cambrésis* (1916), with a good bibliography, and *The Decline of Antwerp Under Philip of Spain* (1924, reprinted 1979); and JAN VAN ACKER, *Antwerpen: van Romeins veer tot wereldhaven* (1975).

Arabia

Arabia is the name applied to the Arabian Peninsula (Arabic: Shibh al-Jazīrah al-'Arabiyyah), which is located in the extreme southwestern corner of Asia. The Arabian Peninsula is bounded by the Red Sea on the west and southwest, the Gulf of Aden on the south, the Arabian Sea on the south and southeast, and the Gulf of Oman and the Persian Gulf (also called Arabian Gulf) on the northeast. Geographically the peninsula and the Syrian Desert merge in the north with no clear line of demarcation, but the northern boundaries of Saudi Arabia and of Kuwait are generally taken as marking the limit of Arabia there.

The peninsula's total area is about 1,000,000 square miles (2,590,000 square kilometres). The length, bordering the Red Sea, is approximately 1,200 miles (1,900 kilometres) and the maximum breadth, from Yemen to Oman, 1,300 miles. The largest political division is Saudi Arabia; it is followed, in order of size, by Yemen, Oman, the United Arab Emirates, Kuwait, Qatar, and Bahrain. The island of Socotra, in the Indian Ocean about 200 miles southeast of the mainland, has strong ethnographic links to Arabia; politically it is a part of Yemen.

The geographic cohesiveness of the Arabian Peninsula is reflected in a shared interior of desert and a shared exterior of coast, ports, and relatively greater opportunities for agriculture. The fact that most of the peninsula is unfavourable for settled agriculture is of enormous significance. Competition for habitable land is keen, and efficient use of land is crucial to the welfare of each state. Social characteristics reinforce the geophysical factors that have created a somewhat similar physical environment throughout the peninsula: a homogeneity among the people is seen in a great degree of similarity in language, religion, culture, and political experience.

The vast majority of Arabians are ethnic Arabs, and many are able to trace their ancestry back through many generations living in the same area. Nearly all speak Arabic, and differences in dialects, though substantial, do not bar mutual intelligibility. Since the Islāmic expansion of the mid-7th century, most Arabians have been Muslim. Differences in sects are important locally, as in Bahrain and Yemen, but the historic commitment of the peninsula

to the faith of its son, the Prophet Muḥammad, has done more to unite than divide it.

Culture has found expression in forms that are the joint inheritance of all the peoples of the Arabian Peninsula, and that inheritance is shared with Arab and Muslim societies beyond the region. Poetry, religious laws and precepts, and values associated with tribal heroism permeated the culture of the past, but the innovations associated with Western culture have slowly reached the entire peninsula in the 20th century and have begun to influence art, mores, and behaviour.

Most of the states of the peninsula share common political and social goals. Nearly all are or have been monarchies, based in large part on principles of religious legitimacy. In the 20th century, and especially since World War II, they have aimed at conservative and gradual change in political life while diligently trying to achieve rapid economic and social advancement. Although the peninsula's available natural resources are not distributed equally among its states—those in the south and southwest deriving far less wealth from oil, for example—similar economic transformations have taken place, or are taking place, in all the societies. Urbanization, greater access to health care and education, secularization, and the settling of many nomads have changed the fabric of daily life throughout the area, and each community has experienced the slow weakening of tribal solidarity.

The various sections of the Arabian Peninsula have only seldom been united under one government. In the 16th century, for instance, the Ottoman Empire was able to conquer most of the coasts, but it could take neither the interior of the peninsula nor the southeast. In the 19th century Great Britain or the Ottomans controlled much of the peninsula, either directly or indirectly, but the central interior almost continually remained independent under the Saudis.

Despite the political disunity of the past, and the considerable variety of national experiences in the present, the Arabian Peninsula continues to share an underlying profound unity of environment, society, culture, and faith.

THE REGION

Physical and human geography

THE LAND

Arabia may be described as a vast plateau, edged with deeply dissected escarpments on three sides and sloping gently northeastward from the Red Sea to the eastern lowlands adjoining the Persian Gulf. The peninsula's highest peak, an-Nabī Shu'ayb, at 12,008 feet (3,660 metres), is located about 20 miles southwest of Ṣan'ā' in Yemen (Ṣan'ā').

Geology. The bulk of Arabia consists of two main geomorphological areas: the Arabian shield in the west; and sedimentary areas dipping away from the shield to the northeast, east, and southeast into the great basin consisting of lower Iraq, the Persian Gulf, and the eastern part of the Rub' al-Khali (the Empty Quarter) desert. The eastern edge of the shield curves eastward from the head of the Gulf of Aqaba, a northern extension of the Red Sea, to a point midway across the peninsula and then trends southwestward and southward to the Yemeni highlands. Extinct volcanoes overlie the shield; their eruptions, which ceased seven centuries ago, produced the broad black lava beds (*hārrahs*) characteristic of the western Arabian landscape.

The sedimentary areas, younger in age than the shield, represent the deposits of ancient seas. The surface sedimentary strata have been extensively eroded. The harder members, more resistant to erosion, now stand as westward-facing escarpments following the curve of the shield. The sedimentary province consists primarily of limestone, together with much sandstone and shale. The first deposits are early Paleozoic (570,000,000 to 395,000,000 years old), which in eastern Arabia dip to almost six miles below the surface. In the Jurassic and Cretaceous limestone (190,000,000 to 65,000,000 years old) oil and gas occur at depths of two miles or less. Some of the limestone strata take in rainfall at outcrops in the western highlands and carry it underground to the Persian Gulf coastal areas.

The Yemeni highlands are physiographically very different from those of the shield; they are not mountains but the deeply dissected edge of the Arabian plateau. From the west the formations rise abruptly from the narrow coastal plain in Yemen (Ṣan'ā'); they reach heights of about 10,000 to 12,000 feet above sea level, and eastward they decrease gradually in elevation. The highlands along the southern coast, in Yemen (Aden), are basically sedimentary in origin. The Omani highlands are geologically more closely related to the Zagros Mountains of western Iran than to other mountains in Arabia. (The sea is only about 50 miles wide at the Strait of Hormuz.)

Relief, drainage, and soils. *The Hejaz and Asir.* A virtually unbroken escarpment runs the length of the peninsula above the Red Sea. The stretch from the Gulf of Aqaba to a point about 200 miles south of Mecca is called the Hejaz (al-Hijāz, meaning "the Barrier"), and the higher stretch from there to the Najrān region near the Yemeni border has acquired the name of Asir ('Asīr; from the name, meaning "Difficult," of a prominent highland tribal confederation). In places the escarpment has two parallel ranges, with the lower range closer to the coast. In Midian (Madyan), the northernmost part of the Hejaz, the peaks have a maximum elevation of nearly 9,500 feet. The elevation decreases to the south, with an occasional upward surge such as Mount Raḍwā west of Medina (al-Madinah). Wadi al-Hamḍ, an intermittent river drawing water from the Medina Basin on the inner side of the escarpment, breaks through the mountains to reach the Red Sea. Another pass leads to Mecca and at-Ta'if in the highlands. The mountains become higher again in Asir, where some peaks rise to more than 9,000 feet. The passes there are particularly difficult. A lava field descending from the mountains and reaching the sea near Hali long formed the natural southern boundary of the Hejaz. The high plateau of Asir, within the area watered by the Indian Ocean monsoon, is more fertile than the rural Hejaz.

The Red Sea coastal plain is constricted throughout its

length, attaining its greatest widths, 40 to 50 miles, south of Medina and south of Mecca. The name Tihāmāh, used for the whole plain, is sometimes subdivided into Tihāmat al-Hijāz and Tihāmat 'Asir. There are no natural harbours adequate for large vessels, but the many inlets are well suited for sailing craft. Islands are particularly numerous along the southern part of the coast, where the Farasān Archipelago lies, and coral reefs are common.

In the northwestern interior the sandstone plateau of Hisma has an elevation of about 4,000 feet. South of it are great lava fields such as the 'Uwayrīd, while others ring Medina. Tongues of lava south of Medina, lapping over the mountains, descend almost to the coast. The sand plain of Rakbah unrolls south of the Kishb lava field, which is southeast of Medina. Among the lava fields east of Mecca is one surrounding the mountains of Ḥaḍan (Ḥiḍn), the traditional border area between the Hejaz and Najd.

Najd. The western part of Najd (Nejd, meaning "Highland"), known as Upper Najd, lies within the Arabian shield with an average elevation of 4,000 feet; the eastern part falls within the sedimentary province with the city of Riyadh (ar-Riyāḍ), near the eastern edge, having an elevation of about 1,950 feet. The principal drainage of Najd consists of a number of eastward-flowing wadi systems that carry water only seasonally.

In the north, the parallel ridges of Aja' and Salma tower above the plateau to form Jabal Shammar (named after the Shammar tribe), the northernmost district of Najd. Just south of the Mecca-Riyadh road are the Nir Hills. East of the Hejaz highlands and Mecca lie the Subay' sand dunes (named after the tribe of as-Subay'), which constitute the largest sand desert within the shield.

The broad mountain-studded plateau gives way in central and eastern Najd to a series of escarpments curving from north to south along the contour of the shield: al-Khuff, Jilh al-Ishar, the Tuwayq Mountains, and al-'Armah. Of these the longest and highest are the Tuwayq Mountains, which with their length of 800 miles constitute the backbone of the most densely settled part of Najd. The steep western face of the Tuwayq, rising about 800 feet above the plains to the west, is pierced by half a dozen wadis, of which the most spectacular is Wadi Birk, a tributary of Wadi as-Sahbā'. West of the Tuwayq a series of sand deserts (*irqs* and *nafūds*) forms an almost continuous link between the great desert known as an-Nafūd to the north and the Rub' al-Khali to the south; the sand deserts also conform to the curve of the shield.

An-Nafūd (Great Nafūd). The second largest sand desert in the Arabian Peninsula, an-Nafūd, marks the northern limit of Najd. Lying just beyond the shield, it occupies an area of about 25,000 square miles. Its sands almost reach the oasis towns of Taymā' (Taima) in the west, al-Jawf and Sakākā in the north, and Ḥā'il in the south. The sands are gradually moving toward the southeast, where they enter either the Mazhur sand dunes, the first of the deserts lying west of the Tuwayq Mountains, or ad-Dahnā'.

Northern Arabia. The Wadi as-Sirhān, a depression rather than a true wadi, is about 200 miles long and 1,000 feet below the adjacent plateau. Northeast of Wadi as-Sirhān are wide lava fields and chert plains belonging to the southern part of al-Hamād, the Syrian Desert. The basin containing an-Nafūd is rimmed on the north by escarpments, down the northern slope of which run the 'Anazah Wadis (the wadis of the tribe of 'Anazah), to empty into the Euphrates Valley; among the largest of these are Wadi 'Ar'ar and Wadi al-Khurr.

Ad-Dahnā'. The ad-Dahnā' belt, separating Najd from eastern Arabia, is a sand stream moving slowly over 800 miles from an-Nafūd to the Rub' al-Khali. Usually it is no more than 50 miles wide. The sands, often reddish in colour, vary greatly in form; particularly in the central stretches, long parallel ridges rise to heights of about 150 feet, while some dunes are three times that height. Ad-Dahnā' also provides pasture in winter and spring. In 1957 the Khurays oil field was discovered beneath its sands.

The Tuwayq Mountains

The Yemeni and Omani highlands

The Rub' al-Khali sand desert, most of which lies within Saudi Arabia.

Lynn Abercrombie

The Rub' al-Khali. The largest uninterrupted sand desert in the world, the Rub' al-Khali covers an area estimated at about 250,000 square miles. The name Rub' al-Khali is not commonly used by the few nomadic Bedouins who live there; they call it simply ar-Ramlah ("the Sand"). Shrub vegetation is widely spaced over the porous, sandy surfaces and is almost nonexistent on the occasional rock and salt surfaces. Only about 37 species have been identified, most of which are perennial. The desert has been intensively explored by oil companies since 1950.

Some areas of the Rub' al-Khali may have droughts of more than 10 years' duration, while others sometimes have thunderstorms or high summer humidity. In the west the gravel plains of Rayda' and Abu Bahr separate the Rub' al-Khali from the southern end of ad-Dahnā', while another gravel plain, al-Jaladah, lies within the Rub' al-Khali. What appears to be a northern extension of the Rub' al-Khali, al-Jāfurah, is regarded by the Arabs as an independent desert. Southeast of Qatar the sands give way before the vast salt flat of the Mati salt marsh, which runs north about 60 miles to the Persian Gulf coast. East of the Mati the oasis hamlets of al-Jiwa' (Liwa'; in the United Arab Emirates) lie among the dunes on the desert's north-eastern fringe. The largest dunes of the Rub' al-Khali are in the far east, where heights of more than 800 feet are reached and sand ridges extend for more than 30 miles, with salt flats as the usual floor in between. In the east, along the Oman edge of the desert, is the large salt flat of Umm as-Samīm. In the southwest, sand ridges reach a length of 150 miles.

Most of the Rub' al-Khali falls within Saudi Arabia, but boundaries with Oman in the south and Yemen (Ṣan'ā') in the southeast have been disputed. In 1974 Saudi Arabia and the United Arab Emirates reached an agreement over a disputed eastern boundary.

The Persian Gulf lowland. A low-lying region follows the Arabian shore of the Persian Gulf from Kuwait around to the al-Hajar mountains of Oman at the mouth of the gulf. The gravel plain of ad-Dibdibah lies inland southwest of Kuwait. Adjacent to ad-Dahnā' is the low plateau of aṣ-Ṣummān, between which and the coast scattered hills rise a few hundred feet. Broad patches of sand occur here and there and salt flats are numerous along the coast. The Persian Gulf on this side provides no good deep-draft natural harbours, but many inlets offer shelter to sailing craft, and modern ports have been built in Kuwait, Saudi Arabia, Bahrain, and Qatar. This lowland region is relatively well supplied with underground water from springs and wells. Deep in the sedimentary strata enormous accumulations of oil and gas are found.

The Yemen. Arabia's highest mountains occur in Yemen (Ṣan'ā'): Ḥaḍūr Shu'ayb, southwest of the capital, Ṣan'ā', reaches 12,336 feet. The Tihāmah in Yemen (Ṣan'ā'), broader and more habitable than the Tihāmah farther north in Saudi Arabia, supports some towns. Monsoon rains make the mountains and high plateaus of Yemen (Ṣan'ā') the most fruitful region in Arabia. The easy slope from the highlands to the southwestern corner

of the Rub' al-Khali was the principal home of the pre-Islāmic civilization of southern Arabia, and the ruins of the Ma'rib dam, the greatest monument of that age, still stand there. The seaward descent from the mountains of al-Kawr at the southern end of the Yemen is precipitous.

The harbour of Aden is formed by two volcanic peninsulas of the lowland below the southern mountain face of Yemen (Aden). The coastal plain, about 30 miles wide behind Aden, is narrower nearly everywhere else. Along this coast the stream of Wadi Hajr, perhaps the only truly perennial river in Arabia, flows about 60 miles to the sea.

Eastward the mountains of al-Kawr merge with the highlands of Hadhramaut known as the *jawl* ("plateau"). Hadhramaut, strictly speaking, is a great interior valley cleaving through the *jawl*, with its lower course reaching the sea under the name Wadi Masilah. In the interior the sand desert of Ramlat as-Sab'atayn lies on the slope descending from al-Kawr to the Rub' al-Khali, which is gentle both here and going down from the *jawl*.

Dhofar (Zufār). The Qarā' Mountains in Dhofar, the southern province of the Sultanate of Oman, are about 3,000 feet high, with one peak higher than 5,000 feet. The monsoon keeps the seaward (southern) side of the mountains, as well as the coastal plain, fertile. A gradual slope leads northward from the water divide to the Rub' al-Khali; valleys from the slope converge on Ramlat al-Mughshin at the desert's edge.

Oman. The al-Hajar mountain range is divided into Eastern al-Hajar and Western al-Hajar. The range, which exceeds a height of 9,000 feet in places, differs from other Arabian coastal highlands in being steep on both sides. Plains at the foot of the mountains fall away almost imperceptibly from the numerous towns of interior Oman to the Rub' al-Khali basin. No mountains bar Oman's outlet to the Arabian Sea in the south; the plateau along the coast has an average elevation of about 500 feet.

Climate. The Tropic of Cancer virtually bisects the Arabian Peninsula, passing just south of Medina. The summer heat is intense everywhere, reaching as high as 129° F (54° C) in places. Much of the interior is dry, but along the coasts and in some of the southern highlands and deserts the humidity is extreme in the summer. Fogs and dews occur in the humid areas, dew often serving as a substitute for rain. In the dry zones the sun blazes fiercely throughout the summer. Spring and autumn are pleasant seasons, and biting cold and snow are rare in winter, except at high elevations and in the far north.

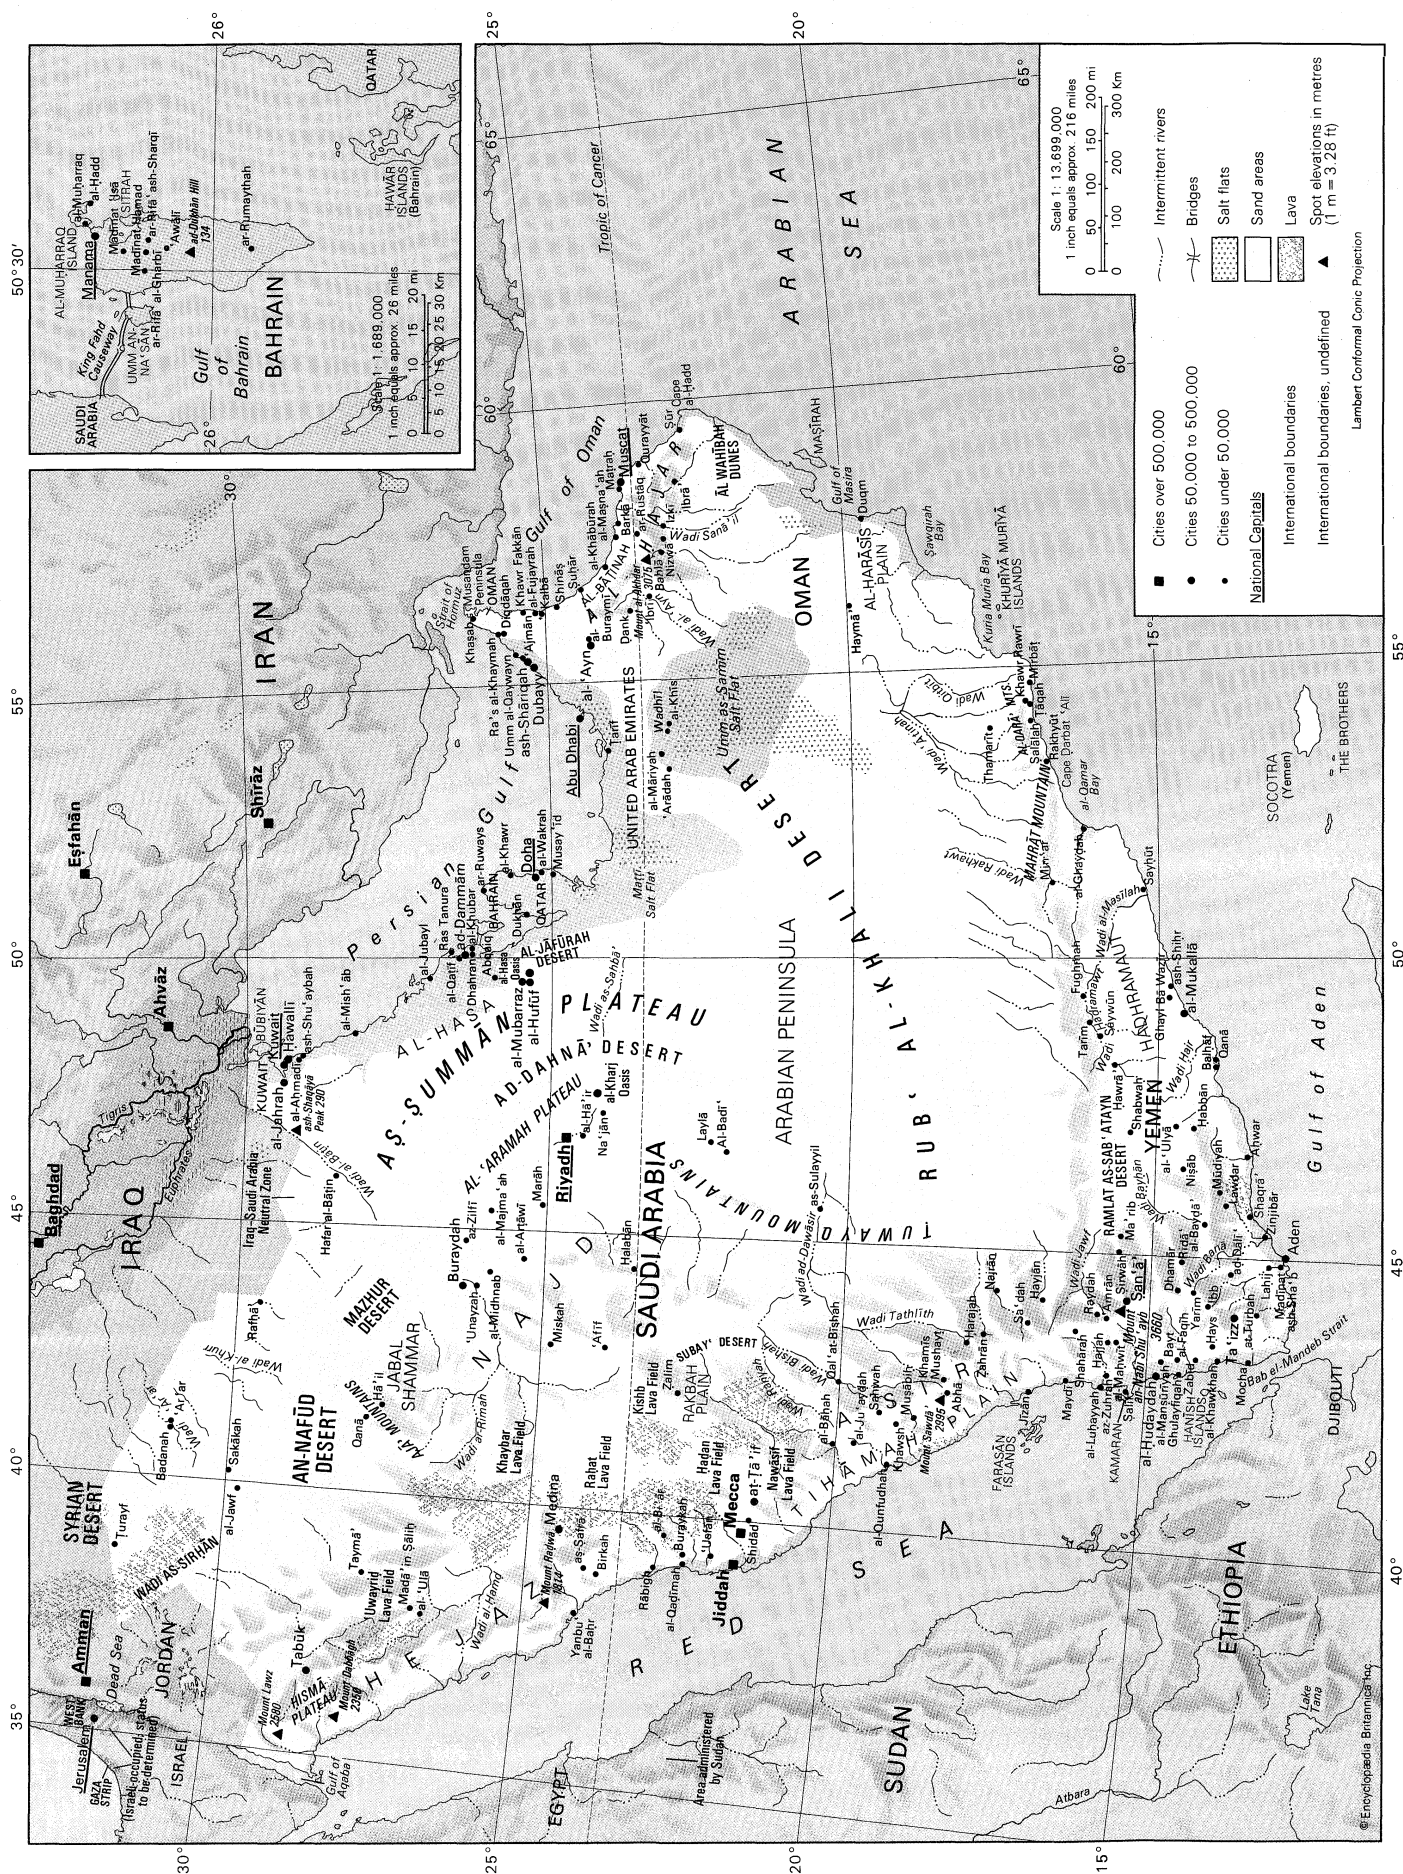

Rainfall is scanty in all parts beyond the reach of the Indian Ocean monsoon, averaging only three to four inches (77 to 102 millimetres) a year. The desert rains are torrential on occasion, causing flash floods in the wadis; sometimes these rains turn into hailstorms. It is not unusual for a drought to last several years. The monsoon increases the precipitation fourfold or more in the southwest and south. Lying within the trade wind belt, northern Arabia receives westerlies from the Mediterranean that blow toward the Persian Gulf and then south and southwest through the Rub' al-Khali toward the Yemen. The monsoon strikes Arabia from the opposite direction. In midwinter and again in early summer the Persian Gulf experiences seasonal winds laden with dust and sand similar to the Egyptian khamsin; in Arabia these are called *shamāl* ("north"), though the prevailing direction is actually from the north-northwest. In contrast to the *shamāl* is the less frequent *qaws* from the southeast. The wind regimes of Najd and the Rub' al-Khali are complex, particularly during spring. The winds may come from any point of the compass and vary in intensity from zephyr to gale.

Plant life. The date palm grows almost everywhere, except at very high elevations and in Dhofar, on the coast of which it is replaced by the coconut palm. The date is a source of food, and uses are found for the trunk, branches, and fibre of the date palm. Among places noted for high-quality date-palm production are Medina, Bishah, and al-Ḥasā. Alfalfa (lucerne), widely used as fodder, often fills the space between palms. The principal grains are wheat, sorghum, barley, and millet. Rice supplements wheat as a food, but little is raised locally. Cotton does well in a few places, such as Abyan near Aden. In general the

people of Arabia have a greater fondness for fruits than for vegetables. Melons, pomegranates, and the jujube are particularly favoured, and al-Buraymī is noted for its mangoes. Figs, grapes, bananas, prickly pears, and other fruits are also grown, and citron and Java almond flourish in the oases.

Although Arabia is no longer as renowned as formerly for its coffee, fair amounts are still cultivated on the terraced mountainsides of the Yemen. In places coffee has given way to the more profitable khat (*qāt*; *Caltha edulis*), the leaves of which produce a stimulant. Tobacco is a product of the Hadhramaut coast.

The world's chief source of incense in antiquity, Arabia still numbers various aromatics among its herbs, though the trade in frankincense and myrrh has long been languishing. Mimosas and acacias are widespread, but little advantage is taken commercially of their gums. Indigo and other native dyes are used in the south, both for cloth and for personal ornamentation. Cactus, cactiform *Euphorbia*, and the aloe grow profusely in some areas.

Arabia is not the most hospitable of lands for flowers, but the roses of at-Ṭā'if are well-known, the oleander thrives in a desert environment, and other flowers sometimes brighten the general bleakness of the landscape.

The peninsula is almost devoid of trees. Clumps of junipers in the southwestern highlands make the closest approach to true forests. The tamarisk, which grows well without much water, is often planted in rows to retard the encroachment of drift sand. Trees are so rare that the standard Arabic word for tree, *shajar*, is ordinarily used by the Bedouin for bushes in the desert that furnish grazing for his animals and firewood for his tent. The leaves of varieties called *hamd* have enough salinity to satisfy the camel's need for salt. The tough perennials are as essential to life as the tender annuals nourished by the rains of winter and spring. The rains also assist in growing the truffle, which the Bedouins dig out of the ground.

Importance
of the
camel

Animal life. The camel has traditionally been the chief support of nomadic life in Arabia. Without the camel the Bedouin could never have moved far from water fit for human beings; with the camel he could survive for months on its milk and penetrate deep into the deserts. The camel also furnished food, clothing, fuel (dung), transportation, and power for drawing water or for plowing. For the Bedouin the camel represented the best form of capital and the most valuable article of commerce. The noblest breeds of camel came from Oman, but some of the more plebeian breeds showed greater stamina. Today, the camel, which has been mostly supplanted as a means of transport by four-wheel-drive vehicles, is used mainly as livestock.

Sheep and goats, known collectively in Arabic as *ghanam*, are numerous, but they are kept in small numbers rather than in large herds. Mutton and lamb are the favourite meats, and goat's milk makes the best cheese. The Arabian horse, noted for its beauty and endurance, is a disappearing strain in Arabia, where only a few thousand remain, though the breed is now fostered in other countries. Many Bedouin own Salukis, a breed of speedy hunting dog; trained falcons are also used in the chase. Gazelles

once ranged the plains in large numbers, but unrestricted hunting decimated them. Very few oryx are left in the Rub' al-Khali, their last stronghold, and the ibex has also become rare. Other large wild animals are the hyena, wolf, and jackal. The lion is frequently mentioned in early Arabic literature, but lions seem now to be extinct in the peninsula. Baboons were once abundant in the southern highlands. Among the smaller animals are the fox, ratel, rabbit, hedgehog, and jerboa.

Deadly desert snakes are the horned viper and a species of cobra differing considerably from the Indian. The striped sea snakes are also poisonous. Lizards include the large desert monitor and the smaller sand-swimming skink.

Ostriches have become extinct. Eagles, vultures, and owls are common, and the lesser bustard is often hunted with falcons. Flamingos, pelicans, egrets, and other sea birds frequent the coasts. Smaller birds found in the towns and oases include the pigeon, cuckoo, swallow, and hoopoe, while the sand grouse, lark, and courser inhabit the desert.

Swarms of locusts periodically descend as a plague, devouring every green plant in their path. Other common insects are the fly, which appears even in the depths of the desert, mosquito, tick, beetle, scorpion, and ant. In some places bees are kept for their honey.

The seas around Arabia contain mackerel, groupers, tuna, porgies, and other food fish, as well as shrimps. Sharks and sardines are plentiful off the southern coast, and whales occasionally enter the Persian Gulf.

(G.Re./B.K.N.)

THE PEOPLE

In ethnographic terms, Arabs belong to the Mediterranean local race, a subgroup of the Caucasoid geographic race. According to tradition, Arabs are descended from a southern Arabian ancestor, Qaḥṭān, forebear of the "pure" or "genuine" Arabs (known as al-'Arab al-'Aribah), and a northern Arabian ancestor, 'Adnān, forebear of the "Arabicized" Arabs (al-'Arab al-Musta'ribah). A tradition, seemingly derived from the Bible, makes 'Adnān, and perhaps Qaḥṭān also, descend from Ismā'il (Ishmael), son of Abraham. The rivalry between the two groups spread, with the Muslim conquests, beyond Arabia; it even recurred in northern Yemen in the 1950s when the Zaydī imams, descendants of the Prophet Muḥammad, a "northern" Arab, were called "Adnānī."

A Veddoid, non-Mediterranean strain occurs in southern Arabia, where also are found the low-status groups called Akhdām and Ṣibyān. In the north are the Ṣulubah, known to the ancient Arabians as *qayn*, a low-status group regarded as being of non-Arab descent. In Oman the Zuṭṭ, a gypsy folk, seem to be descendants of Indian emigrants to the Gulf in the early 9th century, but the Baluchi, whose ancestors immigrated more recently, have formed a sort of warrior tribe there. In the border regions of Oman and Yemen (Aden) are the Mahra, Ḥarāsīs, Qarā, and others, speaking languages of the South Arabic group, and on the Musandam Peninsula are the Shihūḥ.

From ancient times African slaves were imported to Arabia; Saudi Arabia and the Yemen abolished slavery only in 1962. Some districts such as the oasis of Khaybar in the Hejaz and parts of the Tihāmah are largely populated by black cultivators. The ports always had a large element of Africans, Asians, and others. The oil era brought many Lebanese, Egyptians, Jordanians, and Iraqis with the education and skills the Arabians lacked, and great numbers of Yemenis moved into the oil-producing states as unskilled labourers. Palestinians make up between one-fifth and one-fourth of Kuwait's population, refugees from Yemen (Aden) occupy entire streets in Abu Dhabi, and so many Pakistanis, Indians, Sri Lankans, Koreans, and Filipinos have flocked to the Persian Gulf states that often they considerably outnumber the native inhabitants. By contrast, almost no Jews, long settled in western Arabia, now remain.

Throughout Arabian history, even during phases of foreign rule, it was the free, arms-bearing tribesmen who dominated other classes of society, be the tribes nomadic or oasis dwellers, settled farmers in the highlands, or sailors, traders, and pirates gaining their livelihood at sea.

Origin of
Arab tribes

Lynn Abercrombie

Bedouin woman with Arabian camels near Madā'in Ṣālīḥ, Saudi Arabia.

The sultans, emirs, and sheikhs were drawn from the tribes, whom they had to cosset to obtain backing. There are, however, descendants of the Prophet Muḥammad, sayyids and sharifs, regarded as superior in the social scale to all others, who have at times exercised a theocratic type of rule as spiritual leaders.

Bedouin

An age-old antagonism exists between the settled peoples, *al-ḥaḍār*, and the nomadic or pastoral tribes, known as Bedouin (*al-bādiyah*), but many settled tribes also have nomadic branches. In the Yemen, the fertile southwestern corner of Arabia containing more than one-third of its total population, the same antagonistic feelings exist between city dwellers and *qabilis*, arms-bearing tribes mostly settled in villages. Until after World War I the Bedouin of the northern deserts were able to keep the settled people in constant apprehension of their raiding; the tribes would even attack and plunder the pilgrim hajj caravans to the Holy Cities unless they were bought off or restrained by force. But modern weapons and airplanes, which can be used to search out tribesmen in their desert or mountain fastnesses, have altered the situation. Each tribe used to be at war or in a state of armed truce with others, and protection was required to enter another tribe's territory. Shortly before World War I Ibn Sa'ūd, the founder of modern Saudi Arabia, began to establish the Bedouin in military and agricultural colonies called *hijrah*, encouraging them to abandon pastoral life, and programs aimed at the "sedentarization" of the Bedouin have been adopted by states like Jordan and Kuwait.

Contrary to commonly held belief, the tribes are not egalitarian, and some have the quality of *sharaf* or nobility in greater degree than others; some, such as the Hutaym and Sharārāt of the north, are despised by the noble tribes. A father will not accept a suitor who belongs to an inferior tribe for his daughter's hand, far less a *ḥaḍārī* suitor. This is the key to social standing in Arabia.

The nomadic tribes of Arabia are herders of camels, sheep, and goats. They move from pasture to pasture, but they visit tribal markets to purchase dates and grain and to sell their animals, wool, and clarified butter (ghee). The mountain peoples depend more on donkeys than camels, and they raise cattle, which they use to power agricultural and irrigation work, as well as sheep and goats.

Oil and ancient culture

Oil's vast revenues, poured into Arabia, have transformed and are fast destroying ancient patterns of living. The population of the Arabian Peninsula as a whole is now incomparably better off in terms of nutrition, welfare, amenities, and education, but the rapidity of the cultural change is unsettling, as are the shifts in the native population. Throughout the peninsula, the new urban centres are drawing in labour from the countryside, and the presence of large numbers of foreigners, many of whom enjoy much higher incomes than the natives, is resented. (R.B.Se.)

THE ECONOMY

The mineral resource of greatest value is oil. The Arabian Peninsula has the largest oil reserves in the world. With the exception of deposits in the Yemen, the Arabian oil fields lie in the same great sedimentary basin as the fields of Iran and Iraq. Although oil was discovered in Iran in 1908, the first field on the Arabian side of the basin, in Bahrain, was not found until 1932. This inspired an intensive search in eastern Arabia that in time reached far into the interior. Oil was discovered in Saudi Arabia and Kuwait in 1938, in Qatar in 1940, on the mainland of the Saudi Arabia/Kuwait Neutral Zone in 1953, on the mainland of Abu Dhabi in 1960, in Oman in 1964, in Yemen (Aden) in 1983, and in Yemen (Ṣan'a') in 1984. In 1951 oil was discovered in the Persian Gulf off Saudi Arabia, in 1958 in Abu Dhabi offshore, and in 1960 in the Saudi Arabia/Kuwait Neutral Zone offshore.

In association with the oil are enormous amounts of natural gas. Making use of this gas commercially requires extremely large investments. Some gas is liquefied for local consumption or for export, and some is reinjected into the oil-bearing strata for storage and to help maintain pressure for oil production.

The Arabian countries are attempting economic diversification, though the abundance of oil is a disincentive.

Ancient mining sites bear witness to once-flourishing production of minerals: gold at the old mine of Maḥd adh-Dhahab in the Hejaz; silver at a mine in the mountains west of Ma'rib; and very large copper production in Oman (until deforestation exhausted the supplies of wood for on-site smelting). Deposits of iron have been found in the northern Hejaz and Najd. Other resources, some of which are being exploited, are barite, gypsum, salt, lime for cement, clay for bricks and pottery, shale, quartz sand for glass, marble, and building stone.

For many centuries the oyster beds of the Persian Gulf produced some of the world's finest pearls, and pearling was once a thriving and profitable occupation. Bahrain was the chief centre, and the Trucial States (now the United Arab Emirates), Qatar, and Saudi Arabia also participated. Since about 1931 the trade has declined continuously as a result of the world economic depression, the competition of Japanese cultured pearls, and the siphoning off of labour into other less onerous and more lucrative fields.

Decline of the oyster trade

Even in the southwest, where rainfall is heaviest, the water supply is not constant enough for the generation of power. The scarcity of water and the poor quality of the soil have hampered the development of an export trade in agricultural produce. Progress has been made by individual states in improving irrigation systems and expanding cultivated areas. (G.Re./B.K.N.)

History and cultural development

Some time after the rise of Islām in the first quarter of the 7th century AD and the emergence of the Arabian Muslims as the founders of one of the great empires of history, the name "Arab" came to be used by these Muslims themselves and by the nations with whom they came in contact to indicate all people of Arabian origin. The very name Arabia, or its Arabic name Jazīrat al-'Arab, has come to be used for the whole peninsula. But the definition of the area, even in Islāmic sources, is not agreed upon unanimously. In its narrowest application it indicates much less than the whole peninsula, while in ancient Greek and Latin sources—and often in subsequent sources—the term Arabia includes the Syrian and Jordanian deserts and the Iraqi desert west of the lower Euphrates. Similarly, "Arabs" connoted, at least in pre-Islāmic times, mainly the tribal populations of central and northern Arabia.

Arabia has been inhabited by innumerable tribal units, forever splitting or confederating; its history is a kaleidoscope of shifting allegiances, although certain broad patterns may be distinguished. A native system has evolved of moving from tribal anarchy to centralized government and relapsing again into anarchy. The tribes have dominated the peninsula, even in intermittent periods when the personal prestige of a leader has led briefly to some measure of tribal cohesion.

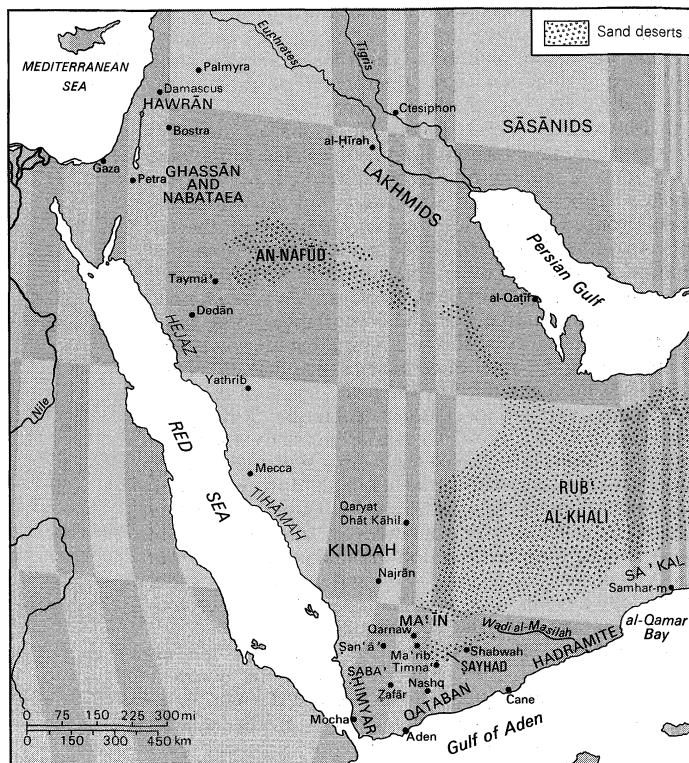

Arabian culture is a branch of Semitic civilization; because of this and because of the influences of sister Semitic cultures to which it has been subjected at certain epochs, it is sometimes difficult to determine what is specifically Arabian. Because a great trade route passed along its flanks, Arabia had contact along its borders with Egyptian, Greco-Roman, and Indo-Persian civilizations. The Turkish overlords of the Arabic-speaking countries affected Arabia relatively little, however, and the dominant culture of western Europe arrived late in the colonial era.

Arabian culture and the trade route

Arabia was the cradle of Islām, and through this faith it influenced every Muslim people. Islām, essentially Arabian in nature, whatever superficial external influences may have affected it, is Arabia's outstanding contribution to world civilization. (M.A.G./A.F.L.B.)

PRE-ISLĀMIC ARABIA, TO THE 7TH CENTURY AD

Prehistory and archaeology. At one time Arabia as a whole may have had greater rainfall and richer vegetation than it does today, as shown by the large dried-up watercourses intersecting the peninsula. But climatic conditions seem to have changed little in the past five millennia; human life—settled or nomad—has been a struggle to cope with the harsh realities of this vast subcontinent.

Principal sites in pre-Islamic Arabia.

Stone Age settlements of fishermen and shellfish eaters going back to the 3rd millennium BC have been found on the northeast coast and in the islands of Faylakah and Bahrain. Surface scatters of flint implements are seen in many places in the peninsula, as are undatable but probably ancient rock drawings for which affinities have been thought to exist with rock drawings in the Sahara.

Southern Arabia (comprising the Yemen and Oman) lies within the climatic zone of the Indian Ocean monsoons, which yield enough rainfall to make it potentially the most fertile part of Arabia. In the Yemen, sophisticated irrigation techniques go very far back indeed; soundings in the silt deposits around the great dam of Ma'rib attest intensive agricultural exploitation there from at least 2000 BC.

The racial affinities of the Arabian populations are not traceable. A theory by which Arabia was considered the birthplace and homeland of the nations of Semitic culture is not now regarded as tenable. Arabian peoples have been held to be related to a variety of groups, with homelands in almost all directions outside Arabia: the view that sought to visualize all Arabians as a single race has never been valid. The oldest evidence indicates the presence of Africans in the Red Sea coastal plain, Iranians in the southeastern tip of the peninsula, and peoples of Aramaean stock in the north. The racial affinities of the ancient Yemeni peoples remain unsolved; the marked similarity of their culture to the Semitic cultures that arose in the Fertile Crescent to the north of the peninsula can be attributed to cultural spread rather than to immigration.

Apart from pursuing the few prehistoric evidences, archaeological research centres mainly on sites of the historic period, which is also attested by written records beginning in the first half of the 1st millennium BC. Some sites in the northern Hejaz, such as Dedan (now al-'Ulā), al-Hijr (now Madā'in Šālih, barely six miles north of Dedan), and Taymā' to the northeast of the other two, have long been known but not fully explored. In south central Arabia, near as-Sulayyil, a town site at Qaryat Dhāt Kāhil (now Qaryat al-Fa'w) has yielded rich results from excavation. In northeast Arabia, inland from modern al-Qatif, a Danish expedition has revealed a hitherto unsuspected pre-Islamic walled town of large dimension.

The written records consist of a vast number of inscriptions (especially thickly clustered in the Yemen) on stone slabs, rock faces, bronze tablets, and other objects,

together with graffiti on rock, scattered widely through the peninsula. In all this material, only a handful of inscriptions can properly be called Arabic. In the north and centre the dominant linguistic form is Old North Arabian (subclassified into Lihyānic, Thamudic, and Safaitic); despite close connections between this group and Arabic, the latter cannot be regarded as lineally descended from it. The Yemenite inscriptions are in Old South Arabian (subclassified into Minaean, Sabaean, Qatabanian, and Hadhramautic), which is a wholly independent group within the Semitic family of languages. (The Old North Arabian and Old South Arabian inscriptions and graffiti are in scripts of a South Semitic type, of which Ethiopic is the only present-day survivor; modern Arabic script is of a North Semitic type.) Unscientific pillaging, however, has deprived many of the Yemeni inscriptions of a good deal of their value by removing them from their archaeological context. There are also inscriptions in extraneous languages: Aramaic, Greek, and Latin.

In the ancient Yemeni culture area are many great structures and monuments, such as dams, temples, and palaces, as well as a wealth of plastic art of extremely high quality. The motifs, such as the ubiquitous bull heads and ibex figures, are partly characteristic of the Yemen, but from the 3rd century BC onward the style is markedly Hellenistic.

Fresh data, both archaeological and epigraphic, appear every year and sometimes entail radical reappraisal of earlier hypotheses. Any attempt at a synthetic picture is therefore strictly provisional.

Pre-Islamic Yemeni kingdoms. The Greek writer Eratosthenes (3rd century BC) described "Eudaimon Arabia" (i.e., Yemen) as inhabited by four major peoples (*ethne*), and it is on the basis of his nomenclature for these groups that modern scholars are accustomed to speak of Minaeans, Sabaeans, Qatabanians, and Hadramites. The fourfold categorization does indeed correspond to the linguistic data (see above), but the political and historical facts are a good deal more complex. The capitals of the four peoples were not located in the centres of their respective territories but instead lay close together on the western, southern, and eastern fringes of a tract of sand desert known to medieval Arab geographers as the Šayhad (modern Ramlat as-Sab'atayn). This off-centre placing has been thought to originate from proximity to the trade route by which frankincense was conveyed from Hadhramaut first westward, then north to Najran, then up the west coast of Arabia to Gaza, and across the peninsula to the east coast. The territories attached to the latter three of the capitals spread out fanwise into the mountainous regions.

Sabaeans. The people who called themselves Saba' (biblical Sheba) are both the earliest and the most abundantly attested in the surviving written records. Their centre was at Ma'rib, east of present-day San'a' and on the edge of the sand desert. (In the indigenous inscriptions Ma'rib is rendered Mryb or Mrb; the modern spelling is based on an unjustified "correction" by medieval Arabic writers.) The town lay in a formerly highly cultivated area watered by the great Ma'rib Dam, which controlled the flow from the extensive Wadi Dhana basin.

Sabaean rulers—who are mentioned in Assyrian annals of the late 8th and early 7th centuries BC (although some scholars date Sabaean inscriptions to about the 6th century BC)—were responsible for impressive constructions both cultic and irrigational, including the greatest part of what is now visible of the dam; but there are traces of earlier dam works, and the silt deposits indicate agricultural exploitation far back in prehistory.

From the early historic period one ruler, named Kariba'il Water, has left a long epigraphic record of victories over peoples throughout the major part of the Yemen, most importantly the Awsanian kingdom to the southeast, but the victories did not lead to permanent conquest. Nor did his campaigns ever extend into the Hadhramaut region or to the Red Sea coastal area. At no period of their history as an independent people did the Sabaeans have real control of those two areas; in the Red Sea coastal area the sole indication of their presence is a small temple near Zabid, probably attached to a military outpost guarding a route down to the sea.

Ancient Yemeni art

Two secondary centres were Širwāh, on a tributary of the Wadi Dhana above the dam, and Nashq (now al-Bayḏā'), at the western end of Wadi al-Jawf.

From perhaps just before the Christian Era, however, the highland regions, both north and west of Šan'ā', played a much more active part in Sabaeen affairs, and some of the rulers belonged to highland clans. The early centuries of the Christian Era also saw the emergence of Šan'ā' as a government centre and royal residence (in its palace, Ghumdān) almost rivaling the status of Ma'rib. Nevertheless, Ma'rib (with its palace, Silhīn) retained its prestige into the 6th century AD.

Sabaeen
regnal style

Sabaeen rulers of the early period employed a regnal style consisting of two names, each chosen from a very short list of alternatives; possible permutations were thus limited, and the same style recurs several times over. In drafting their own texts, the rulers adopted the title *mukarrib*, now generally thought to mean "unifier" (with allusion to the process of expansion of Sabaeen influence over neighbouring communities). Persons other than the rulers never used this title in their texts but referred to the rulers by their regnal styles or occasionally as "king of Ma'rib." Later the title *mukarrib* disappeared, and the rulers referred to themselves, and were referred to by their subjects, as "king of Saba'."

As among the Minaeans, the early rulers were only one element in a legislature including both a council and representatives of the nation. The rulers' personal activity lay mainly in building and in leading wars. The first three centuries of the Christian Era have yielded a more ample documentation than any other period, but during those centuries the Sabaeans were facing a strong threat from the Himyarites to the south of them. The Himyarites succeeded at times in gaining supremacy over the Sabaeans, and at the end of the 3rd century they definitively absorbed the Sabaeans into their realm. In the wars of the 1st century onward, the kings (whether Sabaeen or Himyarite) were supported both by a national army (*khamīs*) under their own command and by contingents raised from the associated communities led by *qayls*, belonging to the aristocratic clans that headed each associated community. The oldest documents attest a number of other kingdoms. The most important was Awsān, which lay in the highlands to the south of the Wadi Bayḥān. An early Sabaeen text speaks of a massive defeat of Awsān, in terms that attest its high significance. Yet the kingdom had a brief resurgence much later, around the turn of the Christian Era, when it appears to have been wealthy and heavily influenced by Hellenistic culture. One of its kings of this period was the only Yemeni ruler to be (like the Ptolemies and Seleucids) accorded divine honours, and his portrait statuette is dressed in Greek garb, contrasting with those of his predecessors who are dressed in Arabian style, with kilt and shawl. Awsānian inscriptions are in the Qatabanian language (which might account for the fact that Eratosthenes gives no separate mention to Awsān in his list of the main *ethne*).

Minaeans. The Minaean kingdom (Ma'in) lasted from the 4th to the 2nd century BC and was predominantly a trading organization that, for the period, monopolized the trade routes. References to Ma'in occur earlier in Sabaeen texts, where they seem to be loosely associated with the Amir people to the north of the Minaean capital of Qarnaw (now Ma'in), which is at the eastern end of the Wadi al-Jawf and on the western border of the Ṣayḥad sands. The Minaeans had a second town surrounded by impressive and still extant walls at Yathill, a short distance south of Qarnaw; and they had trading establishments at Dedān and in the Qatabanian and Hadramite capitals. The overwhelming majority of Minaean inscriptions come from Qarnaw, Yathill, and Dedān, and there is virtually no evidence of territorial possessions apart from the immediate vicinities of these three centres, which have more the aspect of typical "caravan cities." A thin scattering of Minaean inscriptions has been found in places just outside Arabia, such as Egypt and the island of Delos, all manifestly resulting from far-flung trading activities; and texts from Qarnaw refer to a number of important points on the caravan routes, such as Yathrib (Medina)

Minaean
trading
activities

and Gaza, and also to interruption of trade by one of the several phases of warfare between Egypt and the Seleucids of Syria. An explicit mention of caravans is perhaps found in the expression *m'n mšm*, interpreted by the scholar Mahmud Ali Ghul as "the Minaean caravaneers."

Minaean social structure differed from that of the other three, predominantly agricultural peoples. The latter were federations of communities (often termed by modern scholars "tribes," though they were not genealogically based) grouped under a leading community, with the nation as a whole designated by the name of the hegemonial community, followed by the phrase "and the [associated] communities." The Minaeans, however, were subdivided into groups of varying size and importance, some quite small, with none exercising a dominating role over the others. Among the other three peoples the office of "elder" (*kabīr*) was normally filled by the head of one of the associated communities in a national federation. Among the Minaeans, however, the *kabīr* was a biennially appointed magistrate controlling one of the trading settlements or, in some cases, invested with authority in all of them. Legislative functions were exercised by the king acting together with a council and representatives of all the Minaean social classes. Minaean inscriptions make no mention of wars undertaken by the king or the state; this suggests that Ma'in may have enjoyed covenants of safe-conduct with their neighbours along the trade routes.

Qatabanians. The heartland of the Qataban people was Wadi Bayḥān, with the capital, Timna', at its northern end, and Wadi Ḥarīb, immediately west of Bayḥān. As in the case of Ma'in, the earliest references are in Sabaeen inscriptions; native Qatabanian inscriptions do not seem to antedate the 4th century BC. Timna' was destroyed by fire at a date not easy to fix; pottery evidence has been thought to suggest the 1st century AD, but epigraphy points to a survival of the kingdom at least until the end of the 2nd century. Its fortunes had fluctuated: In the earliest Sabaeen phase it was "liberated" by the Sabaeans from Awsānian domination in the above-mentioned defeat of Awsān. At some periods the Qatabanians themselves dominated a federacy similar to the Sabaeen one, and at a relatively late date a ruler whom his subjects called "King of Qataban" styled himself *mukarrib* of Qataban. Inasmuch as Eratosthenes says that this people extended to "both seas," i.e., the Red Sea and the Gulf of Aden, it might be inferred that there was some sort of Qatabanian presence in the southwest corner of the peninsula, an area later ruled by the Himyarites.

Hadramites. Inscriptions from the Hadramite kingdom are scantier in number than from the Sabaeen, Minaean, or Qatabanian. Yet the Hadramite was probably the wealthiest of them all. Hadhramaut and the Sa'kal area to the east (modern Dhofar province of the Sultanate of Oman) are the only places in Arabia where climatic conditions make production of frankincense possible, and Pliny wrote that the whole of the produce was collected at the Hadramite capital, Shabwah, on the eastern fringe of the Ṣayḥad sands, and taxed there before being handed over to the caravans that carried it to the Mediterranean and Mesopotamia. In addition, Hadhramaut was an entrepôt for Indian goods brought by sea and then forwarded by land. The caravan trade may have suffered to some degree from competition by Red Sea shipping, which, from the 1st century AD, began to sail through the Bab el-Mandeb Strait into the Indian Ocean. Nevertheless, as late as about AD 230 a king of Hadhramaut received missions from India and Palmyra (Tadmur), at the opposite ends of the long-standing trade route along which Hadhramaut occupied a central position. At Shabwah, French archaeological work begun in 1975 adjacent to the visible temple ruin has revealed a walled town of larger extent than any other ancient Yemeni site. The palace, on the opposite side of the town from the temple, was, according to the archaeological evidence, a truly magnificent building. The main port of Hadhramaut was at Cane on the bay of Bir 'Alī; and the Hadramites had a settlement at Samhar-m (now Khawr Rawri) on Qamar Bay in the Sa'kal region, founded around the turn of the Christian Era.

Himyarites. Himyar is the Arabic form of the name of

Frank-
incense
production

a people who appear in the inscriptions as Ḥmyr and in Greek sources as Homeritai. They occupied the extreme southwest of the peninsula and had their capital at Ṣafār, a site some nine miles southeast of present-day Yarim, on the motor road from Aden and Ta'izz to Ṣan'ā'. The first appearance of Ḥmyr in history is in Pliny's *Naturalis Historia* (latter half of the 1st century AD); a short time later the Greek document known to scholars as the *Periplus Maris Erythraei* mentions an individual who was "king of two nations, the Homerites and the Sabaeans." But this dual kingship was not definitive: throughout the 2nd and 3rd centuries there were phases of warfare between native Sabaeans rulers and Himyarite ones. Royal titulature in this period is confusing: alongside "kings of Saba'" are found "kings of Saba' and the Raydān," but the implications of the latter are still debated. A thesis advanced by the Arab scholar M.A. Bafaqih is that the former are native Sabaeans and the latter heads of a dual kingship over both peoples. Others have held that native Sabaeans rulers sometimes claimed the longer title even when there was little reality behind it. Moreover, the Himyarites, until the 6th century AD, used the Sabaean language for their epigraphic records, and there are no inscriptions or other monuments at Ṣafār or elsewhere in the true Himyarite area that can be confidently dated before AD 300.

In the last decades of the 3rd century AD a Himyarite ruler named Shammar Yur'ish ended the independent existence of both Saba' and Hadhramaut; and inasmuch as Qataban had already disappeared from the political map, the whole of the Yemen was united under his rule. Thereafter, the royal style was "king of Saba' and the Raydān and Hadhramaut and Yamnat." Arabic writers call him and his successors the Tabābi'ah (singular Tubba'), and, because in the centuries immediately preceding Islām the Yemen was dominated by the Himyarites, the Arabic writers (followed by many 19th-century Europeans) apply the term Himyaritic to all pre-Islāmic monuments of the Yemen, irrespective of date or location.

The Tubba' kings. A major break with the past was made in the 4th century AD, when the polytheistic religion of the earlier cultures was replaced by a monotheistic cult of "The Merciful (Raḥmān), Lord of heaven and earth." There was also an increasing interest, both friendly and hostile, in central Arabia. Already in the 2nd and 3rd centuries AD Sabaeans, Himyar-Sabaeans, and Himyarite rulers had employed central Arabian Bedouin mercenaries; and the first Tubba' king, Shammar Yur'ish, sent a diplomatic mission to the Sāsānian court at Ctesiphon.

The Kingdom of Aksum in Eritrea is mentioned in Sabaean texts of the 2nd century AD as having some not very definable link with Habashite ("Abyssinian") people settled in the Arabian coastal areas, who were throughout the 2nd and 3rd centuries a thorn in the flesh of both Sabaeans and Himyar-Sabaeans rulers, even at one point occupying Ṣafār. Tension between Aksum and Himyar reached a climax in AD 517 or 522, with a Jewish Himyarite king (traditionally said to have been a convert to Judaism) named Yūsuf As'ar Yath'ar. It seems that the conflict escalated from what had been (in one account) a trade dispute. Yūsuf massacred the entire Ethiopian population of the port of Mocha and of Ṣafār and, about a year later, the Christians of Najrān. Aksum retaliated with invasion, leading to the defeat and death of Yūsuf (who is known in Arabic tradition mostly by the nickname Dhū Nuwās) and the establishment of a puppet kingdom in the Yemen subject to Aksum. Somewhat later the Himyarite king Abraha regained some measure of independence, and he was responsible for major repairs to the Ma'rib Dam in the 540s. His reign was followed by a fairly brief Persian occupation of the Yemen. Early in the 7th century the Yemen accepted Islām peacefully, and its antique native culture merged into the Islāmic culture.

Central and north Arabia. The oasis of Taymā' in the northern Hejaz emerged briefly into the limelight when the Neo-Babylonian king Nabu-na'id (Nabonidus, reigned c. 556–539 BC) took up his residence there for 10 years and extended his power as far as Yathrib. A few important monuments of this time are known.

Dedān and al-Ḥijr. It is possible that the Minaean settlement at Dedān (see above) coexisted with a native Dedānite town. But only one "king of Dedān" is recorded. This kingdom seems to have been replaced quite soon by a kingdom of Liḥyān (Greek: Lechiēnoi). The entire area, however, was not long in coming under the rule of the Nabataean kings of a dynasty (centred at Petra) covering the 1st century BC and the 1st AD; and the ancient town of Dedān was eclipsed by a new Nabataean foundation just to the north at al-Ḥijr (Madā'in Ṣāliḥ). At the beginning of the 2nd century AD the Nabataean kingdom was annexed by Rome, the official decree of annexation being dated 111. The Nabataeans, like the Minaeans before them, had been involved in the caravan trade, and it would appear probable that for at least a time after the annexation they continued this role, under Roman aegis. Subsequent history of the area remains obscure.

Kindah. Kindah was a Bedouin tribal kingdom quite unlike the organized states of Yemen; its kings exercised an influence over a number of associated tribes more by personal prestige than by coercive settled authority. Its area of influence was south central Arabia, from the Yemeni border nearly up to Mecca. The discovery of the tomb of a king of Kindah (datable to perhaps the 3rd century AD) at Qaryat Dhāt Kāhil, on the trade route linking Najrān with the east coast, suggests that this was probably the royal headquarters. Sabaean texts of the 2nd and 3rd centuries contain a number of references to Kindah, attesting relations sometimes hostile (as when an assault was made on Qaryat Dhāt Kāhil) and other times friendly (as evidenced by the supply of Kindite troops for the Yemenite rulers). This pattern of relationship seems to have continued down to the early 6th century, when the Kindite hegemony collapsed, partly in consequence of tribal wars and partly perhaps as a result of the emergent power of the Meccan Quraysh at that time. The last Kindah king, the famous poet Imru' al-Qays, became a fugitive.

Al-Ḥirah. Al-Ḥirah was similarly a Bedouin tribal kingdom, the kings of which are commonly designated the Lakhmids. According to tradition, the founder of the dynasty was 'Amr, whose son Imru' al-Qays died in AD 328 and was entombed at an-Nimārah in the Syrian desert. His funerary inscription is written in an extremely difficult type of script. Recently there has been a revival of interest in the inscription, and a lively controversy has arisen over its precise implications. One thing that is certain is that Imru' al-Qays claimed the title "king of all the Bedouin" and claimed to have campaigned successfully over the entire north and centre of the peninsula, as far as the border of Najrān. In Muslim sources it is said that he was given by the Sāsānian king Shāpūr II a "governorship" over the Bedouin of northeast Arabia, being charged with the task of restraining their incursions into Sāsānian territory. Later kings of the dynasty settled themselves definitively in that area, at al-Ḥirah (near modern Kufah). They remained influential throughout the 6th century, and only in 602 was the last Lakhmid king, Nu'mān ibn al-Mundhir, put to death by the Sāsānian king Khosrow II (Parvīz) and the kingdom swept away. In the 6th century al-Ḥirah was a considerable centre of Nestorian Christianity.

Ghassān. The dynasty of the Ghassānids, though often called kings, were in fact Byzantine phylarchs (native rulers of subject frontier states). They had their headquarters well within the Byzantine Empire, a little east of the Sea of Galilee at Jābiyah in the Jawlān (Golan) area; but they controlled large areas of northwestern Arabia, as far south as Yathrib, serving as a counterpoise to the Sāsānian-oriented Lakhmids in the northeast. The Ghassānids were Monophysite Christians and played an important part in the religious conflicts of the Byzantine church. Their influence spanned the 6th century AD, and their most prominent member, al-Ḥārith ibn Jabalah (Greek: Aretas), flourished in mid-century. The last three phylarchs fell out with Orthodox Byzantium because of their Monophysite creed; in 614 the power of Ghassān was destroyed by a Persian invasion.

Quraysh. According to Muslim tradition, Mecca had at one time been in the hands of Jurhum, a people living on the central west coast recorded in Greco-Latin sources

The collapse of Kindite hegemony

Early Arabian monotheism

as Gorrhmites. But somewhere around AD 500 ("five generations before the Prophet Muḥammad") Quṣayy ibn Kilāb, called al-Mujammi' ("the Unifier"), is credited with having brought together scattered groups of Bedouin and installed them in Mecca. They took over a role that had long before been played by Minaeans and Nabataeans, controlling the west coast trade routes; they sent annual caravans to Syria and to the Yemen. Authority in Quraysh was not royal but was vested in a mercantile aristocracy, not unlike the Venetian Republic. Their trading contracts ensured them considerable influence, and, when in the opening years of the 7th century the collapse of Himyarites, Lakhmids, and Ghassānids had left a power vacuum in the peninsula, Quraysh remained the only effective influence. There is, however, little doubt that the ancient traditions of Yemenite civilization contributed substantially to the consolidation of the Islāmic empire. (A.F.L.B.)

ARABIA SINCE THE 7TH CENTURY

Quraysh
trade
agreements

Arabian and Islāmic expansion. In the 6th century Quraysh—the noble and holy house of the Kinānah confederation of the Hejaz controlling the sacred enclave (*haram*) of Mecca—contrived a chain of agreements with the northern and southern tribes that opened the highways of Arabia to commerce. Under Quraysh aegis, caravans moved freely from the Aden and Hadhramaut coasts in the south to Mecca and thence northward to Byzantium or eastward to Iraq. Another agreement made trade with Axum (in what is now Ethiopia) and the African coast secure, as was also the Arabian coastal sea route. Furthermore, members of the Quraysh house of 'Abd Manāf concluded pacts with Byzantium, Persia, and rulers of the Yemen and Ethiopia, promoting commerce outside Arabia. The 'Abd Manāf house could effect such agreements because of Quraysh's superior detached position with the tribes. Quraysh had some sanctity as lords of the Meccan temple (the Ka'bah) and were themselves known as the People of Allāh or the Protected Neighbours of Allāh; the tribes on pilgrimage to Mecca were called the Guests of Allāh, and Quraysh contributed to their entertainment.

In its *haram* Quraysh was secure from attack; it arbitrated in tribal disputes, attaining thereby at least a local preeminence and seemingly a kind of loose hegemony over many Arabian tribes. Temple privileges held by Quṣayy, who established the rule of Quraysh, passed to his posterity, the 'Abd Manāf house of which collected the tax to feed the pilgrims. The Ka'bah, through the additions of other cults, developed into a pantheon, the cult of other gods perhaps being linked with political agreements between Quraysh—worshippers of Allāh—and the tribes.

The life of Muḥammad. Muḥammad was born of the Hāshimite (Banū Hāshim) branch of the noble house of 'Abd Manāf; though orphaned at an early age and, in consequence, with little influence, he never lacked protection by his clan. Marriage to a wealthy widow improved his position, but he began to make his mark in Mecca through prophetic inspiration. He preached the oneness of Allāh—possibly reacting against the pantheon in favour of the Quraysh deity Allāh. Rejected by the Quraysh lords, Muḥammad sought affiliation with other tribes; he was unsuccessful until he managed to negotiate a pact with the tribal chiefs, the *naqibs*, of Medina, whereby he obtained their protection and became theocratic head and arbiter of the Median tribal confederation (*ummah*). Those Quraysh who joined him there were known as *muhājirūn* (refugees or emigrants), while his Median allies were called *anṣār* (supporters). The Muslim Era dates from the *hijrah* (hegira)—Muḥammad's move to Medina in AD 622. (For more detail about the life of Muḥammad and the rise of Islām, see ISLĀM, MUḤAMMAD AND THE RELIGION OF; and ISLĀMIC WORLD, THE.)

Beginning
of the
Muslim
Era

Muḥammad's men attacked a Quraysh caravan, thus breaking the vital security system established by the 'Abd Manāf house, and hostilities broke out against his Meccan kinsmen, who dubbed him "divider" (*muḥarriq*). Within Medina two problems confronted him—the necessity to enforce his role as arbiter and to raise supplies for his moves against Quraysh. He overcame internal opposition, removing in the process three Jewish tribes, whose prop-

erties he distributed among his followers. Externally, his ascendant power was demonstrated following Quraysh's failure to overrun Medina, when he declared it his own sacred enclave. He foiled Quraysh offensives and marched back into Mecca. After taking Mecca he became lord of the two sacred enclaves (*al-ḥaramayn*), but, although he broke the power of some Quraysh lords, his policy thenceforth was to conciliate his Quraysh kinsmen.

The rise of Islām. After Muḥammad's entry into Mecca the tribes linked with Quraysh came to negotiate with him and to accept Islām; this meant little more than giving up their local deities, already proved ineffective, and worshipping Allāh alone. They had to pay the tax, but this was not novel because the tribal chiefs had already been taxed to protect the Meccan *haram* from tribes that respected neither it nor the holy months of truce. Tribesmen probably regarded this as a typical Arabian family power squabble, and they waited to join the winner. Doubtless they cared little for Islām—many tried to break away (the so-called apostasy)—on Muḥammad's death.

Islām, however, was destined for a world role. Under Muḥammad's successors the expansionist urge of the tribes, temporarily united around the nucleus of the two sacred enclaves, coincided with the weakness of Byzantium and Persia. Tribes summoned to the banners of Islām launched a career of conquest that promised to satisfy their greed for booty and lands. With families and flocks, they left the peninsula. Population movements of such magnitude affected all of Arabia; in Hadhramaut they possibly caused neglect of irrigation works, resulting in erosion of fertile lands. In Oman, too, when Arab tribes evicted the Persian ruling class, its complex irrigation system seems to have suffered severely. Many Omani Arabs about the mid-7th century left for Basra (in Iraq) and formed the influential Azd group there. Arabian Islām replaced Persian influence in the Bahrain district and al-Hasa province in the northeast, and in the Yemen.

Islāmic ex-
pansionism

As the conquests far beyond Arabia poured loot into the Holy Cities (Mecca and Medina), they became wealthy centres of a sophisticated Arabian culture; Medina became a centre for Qur'anic study, the evolution of Islāmic law, and historical record. Under the caliphs—Muḥammad's successors—Islām began to assume its characteristic shape; paradoxically, outside the cities it made little difference to Arabian life for centuries. Shari'ah (Islāmic law), promoted often by the Prophet's own descendants, developed in the urban centres; but outside them customary law persisted, sometimes diametrically opposed to Shari'ah. In time the Hejaz and the Yemen came to make notable contributions to Islāmic culture, but Islām's basically Arabian nature shows in the early mosque, which resembles the pre-Islāmic temple, and in the pilgrimage rites, little altered from paganism.

Struggle for leadership. In Arabia offices were generally hereditary and elective; but on Muḥammad's death, Abū Bakr, the first caliph, abetted by his own eventual successor, 'Umar, seized the leadership that Quraysh might have lost to others. They were not of the house of Hāshim, which, from the outset, felt cheated of its rights. 'Alī, Muḥammad's cousin and son-in-law, became the focus of legitimist claims to succeed the Prophet. 'Uthmān, however, the third caliph, was descended from both the Umayyad and Hāshim branches of 'Abd Manāf. The latter half of 'Uthmān's reign coincided with a slackening in the tide of conquest and plunder. 'Uthmān was censured for diverting property, revenues, and booty in Iraq and Egypt to his Quraysh relatives, though Muḥammad had set precedents for so doing. Squabbles with the tribes resulted in 'Uthmān's murder at Medina by tribal malcontents from Egypt. 'Alī was proclaimed caliph by the *anṣār*, but he lost the political battle with 'Uthmān's powerful relative Mu'āwiyah, governor of Syria, who demanded retaliation against the murderers. 'Alī was later murdered by a Khārijite, a member of a dissident group that earlier as part of his army, had forced mediation on a reluctant 'Alī and willing Mu'āwiyah. 'Alī had quitted Medina for Iraq, and the political power centre of Islām left the peninsula, never to return. 'Alī's posterity, however, played an important part in subsequent Arabian history.

Departure
of the
caliphate

The Umayyad and 'Abbāsīd periods. Once Mu'āwīyah and the Umayyads had seized overlordship of the far-flung Islāmic empire, which they ruled from Damascus, the Holy Cities remained only the spiritual capitals of Islām. The Umayyad caliphs appointed governors over the Hejaz, the Yemen, and Oman, whose degree of authority was variable; but in Iraq occasional powerful governors managed to control the Persian Gulf provinces, the Gulf being an important maritime trade route, especially under the 'Abbāsīds. The brief unity Islām had imposed on the Arabians, however, was irrevocably broken; from primitive power struggles, the main Islāmic sects took shape—the "orthodox" Sunnites and the "legitimist" Shi'ites who were distinguished from the Sunnites principally by their tenet that the imam of the Muslim community must be descended from 'Alī by Muḥammad's daughter Fāṭimah).

Preservation
of the
Holy Cities

Umayyad forces defeated a Quraysh pretender, 'Abd Allāh ibn az-Zubayr, who had been proclaimed caliph in the Hejaz. Medina was captured; Mecca was besieged, the *ḥaram* bombarded, and the Ka'bah set on fire (the sacred Black Stone was split in three places). The harsh Umayyad general Ḥajjāj captured the city, and the pretender perished. The violation of the sacred enclaves by troops, including Arab Christians, was an act of sacrilege, but it broke any power remaining with the tribal "supporters" in Medina. The Prophet's original simple mosque in Medina, already enlarged by the early caliphs, was rebuilt by the Umayyad al-Walid (it has been much altered and restored since). The Umayyads spent lavishly on the Holy Cities and developed Hejaz irrigation.

The Umayyads collapsed before the 'Abbāsīds in 750, a fall to which rivalry between the tribes, nationally aligned as northern and southern Arabs, contributed materially. The 'Abbāsīds claimed adherence of the Legitimists, since their ancestor, the Prophet's uncle, was of the Hāshimite house. The 'Abbāsīds maintained a policy of strict adherence to religious observance, and they too devoted large sums to supporting and embellishing the Holy Cities, to which they sent annually a pilgrim caravan. Zubaydah, wife of the caliph Ḥārūn ar-Rashid, celebrated for her public works, is said to have ordered the construction of the *qanāt*, a tunneled conduit that still takes water to Mecca. The threat of insurrection by Legitimist pretenders of the 'Alid branch of the Hāshimite house—who denied 'Abbāsīd claims to the caliphate as they had with the Umayyads—was a constant danger to the 'Abbāsīd caliphs. The 'Alid family developed both Sunnite and Shi'ite branches; but the latter split into a multiplicity of sects, of which the most important are the "Twelvers" (Ithnā 'Ashariyah, or Imāmīs), who recognized 12 imams, and the "Seveners" (Ismā'īliyah, or Ismā'ilīs, for Imam Ismā'il ibn Ja'far), who acknowledged only seven.

The Yemen. To quell a rising in the Yemen, the 'Abbāsīd caliph Ma'mūn dispatched an Umayyad, Ibn Ziyād, who refounded in 820 the southern city of Zabid and became overlord of the Yemen, Najrān, and Hadhramaut. About a century later, the Najāhīds—Ethiopian slaves or local Afro-Asians—supplanted the Ziyādīds in Zabid; but, though independent, neither dynasty renounced vague 'Abbāsīd suzerainty. The Banū Ya'fur, lords north of Ṣan'ā', expelled the Ziyādīd governor and ruled independently from 861 to 997. Najāhīd rule ended when 'Alī ibn Mahdī captured Zabid in 1159.

Ismā'ili
threat
to the
'Abbāsīds

The Qarmaṭians. In the late 9th century an 'Alid revolt in Yamāmāh, in central Arabia, cut communications between Iraq and the Hejaz; but a more serious loss to 'Abbāsīd power in Arabia was occasioned by the appearance of Ismā'ili propaganda in the Yemen about 880, in eastern Arabia about 899, and even briefly in Oman. From the Yemen, Ismā'ili missionaries reached North Africa, where the Fāṭimid movement arose and conquered Egypt and for a time seriously threatened the 'Abbāsīds. The Qarmaṭians, an extremist offshoot of the Ismā'ilīs, founded a state in al-Hasa, in northeast Arabia. Careful planners and plotters, they set out to subvert orthodox Sunnite Islām. They were opposed to many of the teachings of the Prophet Muḥammad; they urged discarding of the prayer, the fast, and the pilgrimage, while encouraging wine drinking, sexual promiscuity, and music. In the Yemen the

Qarmaṭian 'Alī ibn al-Faḍl broke with the contemporary Fāṭimid missionary Maṣṣūr and in 912 entered Ṣan'ā'; but Qarmaṭianism was short-lived there.

In 1037 'Alī aṣ-Ṣulayhī of the Yām tribe proclaimed the Fāṭimid caliph al-Mustansir but set up a dynasty in Ṣan'ā'. The Ṣulayhīd dynasty ruled most of the upper Yemen and warred with the pro-'Abbāsīd Najāhīds. The Banū Ma'n (probably the 'Awlaqīs of today) had controlled Aden, apparently without submitting even to the Ziyādīds; the Ṣulayhīd expelled and replaced them with a section of the Yām tribe. From the latter stemmed the Shi'ite Zuray'ids, who ruled until the Ayyūbid Tūrān Shāh, brother of Saladin, invaded the Yemen in 1173–74 and took Aden.

In 930 the Persian Gulf Qarmaṭians plundered Mecca, carrying off the Black Stone to al-Hasa; they later returned it under Fāṭimid pressure. The Qarmaṭians were overthrown in 1077–78.

Oman. In the last decades of the 7th century the Ibādīyah, regarded as a moderate Khārījite sect, conquered southern Arabia, established a Kindite imam in Hadhramaut, occupied Ṣan'ā', and took Mecca and Medina, before the Umayyads drove them back to Hadhramaut. Oman had early become Khārījite; the first Ibādīte imam, al-Julandā ibn Mas'ūd, was elected at about the beginning of the 'Abbāsīd caliphate. After the Ibādīte invasion of southern Arabia in 893, Oman wavered between independence and subjection to the 'Abbāsīds and their Būyid or Seljuq supporters of western Asia. By the 12th century the Seljuq hold had become precarious and local imams existed. During periods when the Indian trade used the Persian Gulf, Omani ports flourished; but revenues diminished wherever trade was switched to the Red Sea. From the mid-12th century until 1406 the Nabhānī dynasty controlled the interior of Oman, but Turkic Oğuz (Ghuzz), Persians, and others variously possessed the coastal flank of the mountains.

The Zaydīs and 'Alawīs. In the Yemen lasting movements were being shaped by the close of the 9th century; the imam al-Hādī, a theocratic arbiter-ruler of traditional type, founded the 'Alid Zaydī dynasty in Ṣa'dah of the northern Yemen. About the mid-12th century a Zaydī imam extended his rule northward to Khaybar and Yanbu' (Yenbo) and southward to Zabid.

In the mid-10th century a refugee from disturbances in Iraq, Aḥmad ibn 'Isā al-Muhājir, arrived in Hadhramaut, then under Ibādī domination, and founded the 'Alawī Sayyid house, which was instrumental in spreading the Shāfi'i school of Islāmic law to India, Indonesia, and East Africa.

The Ayyūbids and Rasūlīds. The Ayyūbids, when they invaded the Yemen in 1173, found it parceled out among the Banū Mahdī in Zabid and in the Tihāmāh, the Aden Zuray'ids, the Zaydīs of Ṣa'dah, the Banū Ḥātim at Ṣan'ā', and the Sulaymānīs at Ḥaraḍ. Ayyūbid objectives were probably part political, to find themselves a haven and destroy the Ismā'ilīs, and part economic, to control the India trade route. They stayed in power until about 1229, generally controlling Aden, Hadhramaut, the Tihāmāh, and the districts south of Ṣan'ā'. They introduced an administrative centralization apparently adapted from Syro-Egyptian organization.

With the Ayyūbids arrived the emir 'Alī ibn Rasūl, probably of Oğuz origin, whose descendants, at first Ayyūbid governors, grasped independence (c. 1229) during the reign of al-Malik al-Kāmil. The Rasūlid period is the most brilliant era of Islāmic history in the Yemen. These monarchs embellished their capital, Ta'izz, and other cities with fine buildings; several kings had a literary bent and, besides belles lettres, wrote treatises of some originality on various subjects. A fiscal survey still surviving provides an account of the trade through ash-Shiḥr, Aden, and the Tihāmāh ports, with budgets for maintaining castles, troops, and hostages kept as surety of good tribal conduct. Aden served as an important trade centre in a flourishing period of Arab and Jewish commercial enterprise. The Rasūlīds kept the southern coast under loose control up to Dhofar, even holding Hadhramaut to some extent and maintaining a squadron against pirates.

The sharīfs of the Holy Cities. At Mecca in the mid-

The
Rasūlid
period

10th century commenced the 1,000-year ascendancy of the 'Alid sharifian families. Mecca now became capital of the Hejaz, replacing Medina, the centre from which it had been ruled since the Prophet's days. The sharifs, though at times subject to such foreign overlords as the rulers of Egypt and of other parts of Arabia, exercised virtual independence. Throughout the 'Abbāsīd-Fāṭimid struggle, however, the sharifs took the opportunist line of supporting the side in ascendancy. When Saladin, after deposing the Fāṭimids in 1171, brought back orthodoxy, the sharifs again recognized the 'Abbāsīds and Ayyūbīds, and from being Zaydīs turned Shāfi'ī.

In 1181 the French crusader knight Reynaud de Châtillon raided Arabia. He intended to attack Medina but, switching his plan, raided in 1182 the Red Sea ports as far south as Bab el-Mandeb; Saladin destroyed Reynaud's vessels and so ended the threat to Mecca.

By the early 13th century the Mūsāwī sharifs had conquered the Hejaz, extending their power southward to Hālī; but, when they sought support from Egypt, Syria, or the Yemen, the Rasūlīds managed temporarily to dispute the overlordship of Mecca with the Egyptians.

After Baghdad fell to the Mongols in 1258, the pilgrim caravan from Iraq lost all political significance for the Hejaz. As Iraq declined, Egyptian influence increased and the sharifs became steadily more dependent on the Mamlūks of Egypt.

Mamlūk and Ottoman influence. Although the Yemeni Rasūlīds sometimes disputed with the Mamlūks the overlordship of the Holy Cities, the Mamlūks generally prevailed. Egyptians and Meccans attacked al-Mujāhid the Rasūlīd on a pilgrimage in 1350, and he was held prisoner in Egypt though released later.

The Mamlūks. During the 14th and 15th centuries the Mamlūks became the dominant power, maintaining a political agent in the Hejaz and a body of cavalry in Mecca. Eventually they made or unmade the sharifian rulers, though the local Egyptian commander's policy sometimes ran counter to that of Cairo. From the mid-15th century the Mamlūks took charge of the customs at Jidda, Mecca's port, allotting a portion of the revenue to the pasha of that port. Sharif Muḥammad ibn Barakāt (ruled 1425-53), however, received one-quarter of the value of all wrecked ships, one-quarter of all gifts arriving from abroad for the Meccans, and one-tenth of all imported goods, including the cargo of the Indian ships destined for Jidda. About half his income was distributed among the leading sharifian families.

By the mid-15th century the foundering of the Rasūlīd dynasty in the Yemen made way for the Ṭāhirīds; about the same time the Kathirī tribe of southeastern Arabia controlled Hadhramaut on behalf of the new dynasty.

The beginning of the 16th century witnessed Portuguese penetration of the Indian Ocean and the Red Sea. Though they failed to capture Aden, the Portuguese blockaded the Indian trade routes to Europe via the Persian Gulf and Red Sea, causing severe, lasting damage to the economy of Muslim Middle Eastern countries.

The Ottomans. To counter the Portuguese, the Mamlūks found it imperative to occupy (c. 1516) the Yemen Tihāmah, using cannon and muskets, then new to South Arabia. In 1517, however, the Ottoman sultan Selim I conquered Egypt and proclaimed the Hejaz part of the Ottoman dominions. Sharif Barakāt II of Mecca sent his son to negotiate at the Ottoman court and was confirmed as lord of the Holy Cities and Jidda, subject to recognizing the Sublime Porte as overlord. Selim's successor, Süleyman I the Magnificent, at the zenith of Ottoman power, munificently subsidized the Holy Cities, devoting large sums to new building.

In the Yemen the Mamlūks of Zabīd and Ta'izz acknowledged Ottoman authority, and Turks took over naval operations against the Portuguese in the Red Sea and Indian Ocean. They seized Aden and forced the Yemenis into the mountains, capturing Ṣan'a' and Shahārah; ultimately, however, the Yemenis drove them back into the Tihāmah. The Turks adopted Mocha (al-Mukhā) in the southern Yemen as their base, and Aden declined in importance. After conquering Iraq in 1563, the Ottomans could oper-

ate in the Persian Gulf against the Portuguese, who had taken Hormuz and Muscat in 1507 and Bahrain in 1521 and freely harried the Arabian coasts.

Coastal Arabia was by then coming into direct contact with the Christian European maritime nations, which had begun their commercial penetration of the Orient. The Dutch and English followed the Portuguese; then came France and other nations. The Portuguese held Bahrain until 1602, Muscat until 1649. The Western nations traded with the Yemen through Mocha, whose coffee trade began in the 17th century; later the Dutch, British, French, and others opened factories there.

By 1635 the Zaydīs, supported by the northern tribes, had expelled the Ottomans from the Yemen, and the Zaydīs had their first great, if short-lived, expansion when their tribes moved into much of southern Arabia. The broken terrain made it impossible for them to maintain their supremacy, and local tribes drove out Zaydī garrisons by about the second decade of the 18th century.

In 1631 Turkish troops, dispatched to reinforce the hard-pressed Ottoman governor at Mocha, deserted in a body and, arriving by land at Mecca, sacked it; their drunkenness and their rape of members of noble families horrified Muslim sentiment. Security vanished, and the Bedouin again looted caravans freely until, with aid from Constantinople, Zayd, the new sharif of Mecca, was able to exterminate the rebels. Through his influence with the tribes, Zayd was also able to thwart the attempts of the Turks to control the Hejaz. In the late 17th and 18th centuries, however, there was confusion and civil war in Mecca, with disputes among the sharifian tribes and struggles at Jidda with Turkish officials, who, notwithstanding the virtual independence of the sharifs, still dabbled in Hejaz politics. A new element was introduced in Najd (in central Arabia) in the mid-18th century with the rise of the puritan Wāhhābīs, who, because the sharifs regarded them as dangerous heretics, for a time were refused permission to make the pilgrimage to Mecca.

Omani expansion. In Oman events took an independent course. The Ya'rubid dynasty—founded about 1624 when a member of the Ya'rub tribe (of the Azd group) was elected imam—expelled the Portuguese from Muscat and set to harrying Portuguese possessions on the Indian coast. Embarking on expansion overseas—to Mombasa in 1698, then to Pemba, Zanzibar, and Kilwa—the Omanis became the supreme power on all the coastal regions of the Indian Ocean, and European merchants feared marauding Omani fleets.

The Persians captured Muscat in 1743. The Ya'rubids dissolved into dynastic dispute, and a leader named Aḥmad ibn Sa'īd set to liberating Oman from the Persians. He became imam in 1749, founding the Āl Bū Sa'īd dynasty. This period in Oman is marked by the crystallization of the political alignment of the tribes of the Banū Ghāfir (Ghāfirī) against those of the Banū Hīnā (Hīnāwī).

During the 18th century the growth of the East India Company and British paramouncy in India began to affect Arabian politics in the Indian Ocean coastal region, though the interior was little concerned. A series of agreements paved the way to British control of the Gulf.

The Wāhhābīs. The Turks, clinging to the Hejaz for religious prestige and claiming to be custodians of the Holy Cities, had little power outside their garrisons in those cities and along the pilgrim route. The bribes they gave the Arabs for allowing the caravans to pass, and the need to keep supplies moving to Mecca and Medina, however, prevented their expulsion.

Religious reform. The Wāhhābī movement, which introduced a new factor into the pattern of Arabian politics, was founded by Muḥammad ibn 'Abd al-Wāhhāb, a reformer influenced by the writings of the 13th-14th-century pietist theologian Ibn Taymiyah, of the strict Ḥanbalī school of Islāmic law. Paganism still flourished in Arabia, and it was 'Abd al-Wāhhāb's intention to purify Islām of polytheism and to return it to an idealized primitive state. Expelled from his hometown in Najd, he moved to ad-Dir'iyyah, a village that had never been ruled by the Turks, and obtained the protection and the adherence of its chief, Muḥammad ibn Sa'ūd.

Mamlūk
domina-
tion

Resistance to the Ottomans. Propagating the doctrines of 'Abd al-Wahhāb, Ibn Sa'ūd and his son mastered all Najd. Late in the 18th century the Wahhābis began raiding Iraq and in 1801, despite Turkish attempts to suppress them, sacked the holy Shī'ite city of Karbalā'.

The Wahhābis then besieged Mecca, aided by Sharif Ghālib's brother-in-law, who defected to them. On Ghālib's withdrawal, the Wahhābis entered the city, where, though enforcing Wahhābī practice, they behaved in an orderly fashion. They failed before Jidda, however, and Ghālib reentered Mecca. In 1804 the Wahhābis took Medina and two years later, Mecca. The Ottomans became so alarmed at the Sa'ūdī-Wahhābī peril that the Sultan urged Muḥammad 'Alī, viceroy of Egypt, to act as his deputy and drive the Wahhābis from the Holy Cities. Egyptian troops invaded Arabia, and after a bitter seven-year struggle, with serious Egyptian reverses, the viceroy's forces recaptured Mecca and Medina. Forced to surrender his capital, the Wahhābī leader, 'Abd Allāh ibn Sa'ūd, was sent to Constantinople and there beheaded. Foreign occupation of northern Arabia continued some 20 years.

Extension
of Sa'ūdī-
Wahhābī
dominance

The second phase of Sa'ūdī-Wahhābī dominance began when Turkī, of a collateral Sa'ūdī branch, revolted and in 1824 captured Riyadh in Najd and made it his capital. He was succeeded by his son Fayṣal. By 1833 Wahhābī overlordship was generally recognized in the Persian Gulf, though the Turks and Egyptians remained in the Hejaz. A new Egyptian push, successful in reaching the Gulf, collapsed with the fall of Muḥammad 'Alī's empire.

After Fayṣal's death the fratricidal ambitions of his two eldest sons allowed Ibn Rashīd, ruler of Ḥā'il in Jabal Shammar to the north, to take Riyadh. Ibn Rashīd ruled northern Arabia until he died in 1897. Meanwhile, the Sa'ūdīs had lost the fertile al-Ḥasa to the Ottoman Turks, and the family ultimately took refuge in nearby Kuwait.

Ibn Rashīd's son and successor became involved in a struggle with the sheikh of Kuwait, which enabled the greatest of the Sa'ūdīs, Ibn Sa'ūd ('Abd al-'Azīz II), to retake Riyadh in 1902. By 1904, through raiding and skirmishing, Ibn Sa'ūd had recovered all the Sa'ūdī territory, though he had to campaign against Ibn Rashīd, the Ottomans, and disaffected tribes and relations. In 1912, to bring the nomads under control, he set up agricultural settlements (*hijrah*) colonized by Wahhābī warrior groups called Ikhwān, organized to fight and to farm the land. When World War I broke out, Kuwait renounced allegiance to Ottoman Turkey. Ibn Sa'ūd fought the pro-Turkish Ibn Rashīd but otherwise remained inactive.

The Hejaz. After Muḥammad 'Alī Pasha of Egypt deposed Ghālib in 1831, the Meccan sharifs were merely his nominees until 1840, when the Egyptians evacuated Arabia. Thereafter the sharifs were independent until the Turks began to reassert authority by force. Improved communications after the opening of the Suez Canal in 1869 allowed the Turks to send troops by sea to Arabia and to establish direct administration in the Hejaz. Ḥusayn ibn 'Alī, appointed grand sharif in 1908, traveled by the new Hejaz Railway from Constantinople to Medina.

British
control of
Aden

The Yemen. In 1839 the British took Aden, ruling it and the island of Socotra (at the entrance to the Gulf of Aden) from India, thus forestalling the Egyptians, who had aimed at capturing it for themselves. In 1849 the Ottoman Turks occupied the Tihāmah, compelling the Zaydī imam to sign a treaty whereby he would admit a small Turkish garrison to Ṣan'ā'. The Turks, however, could not enter Ṣan'ā' until 1872. They were never able to break the resistance of the Zaydī tribes completely and were forced to an accommodation with the imam a few years before World War I. Aden developed into a large town and port, especially after the Suez Canal opened. Protectorate treaties concluded with the independent tribes around Aden were extended to include Hadhramaut. Shortly before World War I an Anglo-Turkish commission partly settled differences over the protectorate's boundary with the Yemen.

The Gulf states. By the early 19th century the Qawāsim pirate tribes of the Gulf, conquered and largely inspired by the Wahhābī, had extended their depredations to India. In 1835 the pirate coastal chiefs were induced to bind themselves by a maritime truce to end hostilities by sea, and

the truce was made permanent in 1853. In Oman, Sulṭān ibn Aḥmad, revolting against his uncle the imam in 1793, gained mastery of the coastal towns and allied himself to the British to aid them against the French. Relations between the coastal sultans of Muscat and the British developed, and the British made Zanzibar, in East Africa, a protectorate in 1890. The extension of British influence over Bahrain culminated in 1900 with the opening of a British political agency. The British also persuaded the Gulf states and Zanzibar to help suppress the slave trade.

World War I. Turkey entered World War I holding all of western Arabia and supported in central northern Arabia by the Rashīdīs of Ḥā'il. Ottoman attempts to extend the empire to eastern Arabia, however, had been countered by the British, who were then paramount in the Gulf and in treaty relation with the Arab sheikhdoms there. Sharif Ḥusayn of Mecca had been corresponding with the British in Egypt before the war; with assurance of British support, he came out against the Turks in June 1916, taking Mecca but failing to capture Medina. The British also supported the Idrīsī in Asir against the Turks. The *modus vivendi* established in the Yemen had left the imam semi-independent in the north, while the Turks administered the rest; Turkish forces entered the Aden Protectorate, routing a small, badly organized British force at Lahij, but the war settled down to a gentlemanly stalemate.

The British sought to align Arab against Turk in eastern Arabia and in southern Iraq. Two sons of Sharif Ḥusayn of Mecca, Fayṣal and Abdullah, stirred up the tribes against the Turks and, assisted by British supplies and liaison officers, moved northward to Transjordan along the right flank of the British armies and into Damascus (1918). Fayṣal set up an Arab government there, only to be dislodged by the French in 1920. In 1921 he was made king of Iraq, Abdullah emir of Transjordan.

Wahhābī-sharifian dispute. During the war relations between Sharif Ḥusayn and Ibn Sa'ūd worsened. In 1919 the dispute broke into an open clash. The Wahhābis won so decisive a victory that they might have advanced unopposed into the Hejaz but for pressures on Ibn Sa'ūd by the British, who were supporting both him and Ḥusayn with subsidies. Instead, Ibn Sa'ūd concentrated his forces against Ibn Rashīd, mastering all Shammar territory and capturing Ḥā'il in 1921.

Meanwhile, the grand sharif refused the terms of a treaty with Britain, mainly because of the Balfour Declaration, which approved a national home in Palestine for the Jews. The Wahhābis marched into the Hejaz in 1924, and by October Ḥusayn was ruler no longer.

Saudi Arabia. Ibn Sa'ūd's zealous Wahhābī followers, arriving in the more lax atmosphere of Hejaz society, were now exposed to the world of Islām at large and to the modern world. Ibn Sa'ūd managed the resulting problems with firmness and tact. He had furthermore to enforce his rule over the tribes impatient of centralized government. His tough action with them won, and he set out to develop security, economic reform, and communications.

On Ibn Sa'ūd's southern border the Idrīsī sayyids of Asir had risen to power in the first decade of the 20th century. After the war the British handed them the Yemeni port of al-Ḥudaydah, to the intense annoyance of Imam Yaḥyā of the Yemen. When in 1926 and 1930 Ibn Sa'ūd concluded agreements with the Idrīsī, rendering Asir a virtual dependency of Saudi Arabia, Yaḥyā took al-Ḥudaydah and southern Asir. When negotiations with the imam failed to settle differences, Saudi troops swept into the Yemeni Tihāmah, but they withdrew after the Treaty of aṭ-Ṭā'if in 1934.

In the postwar years Britain and Saudi Arabia concluded agreements defining the frontiers with the British mandates of Jordan and Iraq, and by treaty in 1927 Ibn Sa'ūd was recognized as a sovereign, independent ruler.

The Yemen. Imam Yaḥyā had virtually to conquer the Yemen, in the Zaydī interest, after the Turkish departure; by measures often stern, he established security. He refused to recognize the Anglo-Turkish boundary, and his penetration eastward into tribal territory brought clashes with the British, who, in the later 1930s, made stirrings toward pacification and development of the protectorates.

Discovery
of oil

Postwar Arabia, to 1962. The post-World War I settlement and centralization of power in the hands of Yaḥyā, Ibn Sa'ūd, and the British gave Arabia a large measure of peace and security, which endured until 1962. A new factor in the 1930s was the discovery of immense quantities of petroleum in the deserts. In Bahrain oil was struck in June 1932. The U.S.-owned Arabian Standard Oil Company (later Aramco) discovered oil in the Dhahran area of Saudi Arabia, and the first shipments left al-Khubar in September 1938. The Kuwait Oil Company, a joint Anglo-U.S. enterprise, began production in June 1946. Thereafter oil was discovered in many other places, mostly in the Persian Gulf. Vast petroleum revenues brought enormous changes to Saudi Arabia and transformed the Gulf states. The market for labour brought migrants from the Yemen and Hadhramaut.

The Arab world began to ferment under an unending stream of nationalistic, revolutionary propaganda, first from Egypt, later from Syria and Iraq, utilizing resentment of Israel. In the late 1950s Egypt mounted a propaganda campaign to undermine "feudal" Arab kingdoms and remove "colonialism" from Arabia, with an eye to acquiring control of Arabian oil.

Arabia since 1962. In 1962 Egyptian-trained Yemeni officers engineered a coup d'état, forcing the imam, al-Badr, to leave Ṣan'ā', and Egyptian troops invaded the Yemen. Seeing the imminent peril of Egyptian thrusts toward its southern borders, Saudi Arabia backed the imam during five years of war against large Egyptian armies. King Ibn Sa'ūd of Saudi Arabia had died in 1953, and his ineffective heir, Sa'ūd, was replaced in 1964 by another son, Fayṣal. The imam's supporters, backed by Saudi aid, checked the Egyptian offensive, but Egypt's president, Gamal Abdel Nasser, did not withdraw his troops until Egypt's defeat in the Arab-Israeli Six-Day War of 1967.

Nasser then switched to political pressure to remove the British from Aden, but the British contained Egyptian-supplied terrorists until the Labour government in Britain suddenly decided to abandon the Aden base in 1966. Late in 1967 chiefs in treaty relation with Britain were packed off to Jidda. A violently leftist group, the National Liberation Front (NLF), proclaimed the People's Democratic Republic of Yemen (Yemen [Aden]), which became Communist and formed links with the Soviet Union.

After 1974 Yemen (Ṣan'ā') was ruled by a relatively liberal military government, with army officers as presidents, including 'Alī 'Abd Allah Ṣāliḥ, who in 1978 succeeded two murdered predecessors. Lip service was paid to a long projected union with Yemen (Aden), but the two states remained politically far apart, and the aggressiveness of Yemen (Aden) even escalated into an attempted invasion of Yemen (Ṣan'ā') in 1979. Over the next several years a struggle for control of Yemen (Aden) was waged between hard-line Communist leaders backed by the Soviet Union and more cautious politicians who sought aid from moderate Arab states and the West. A brief civil war broke out in January 1986 and prompted the Yemen Socialist Party to put together a more moderate leadership under Ḥaydar Abū Bakr al-'Aṭṭas.

In late 1989 the two Yemens finally agreed to a union, and formal merger took place in May 1990. Elections were scheduled to be held after a transition period of two and one-half years.

In Oman, after a palace revolution in 1970, the new sultan, Qābūs, opened a program of modernization, welfare, and reform. Much oil revenue initially had to be devoted

to repelling rebel attacks, supported from Yemen (Aden), but the rebels were defeated in 1975. A mutual accord was signed in 1982.

At the entrance to the Persian Gulf the Trucial States have acquired world importance from their vast oil riches and heightened strategic significance. Britain's Labour government of the 1960s reversed the policy of maintaining a protective presence there and, breaking long-standing treaties as in Yemen (Aden), resolved to abandon them. This shocked the Gulf rulers, but to refuse to accept the departure meant the loss of face before growing Arab nationalist sentiment. In the new alignments following Britain's withdrawal the former Trucial States—Abu Dhabi, Dubayy, ash-Shāriqah, 'Ajmān, al-Fujayrah, and Umm al-Qaywayn—proclaimed themselves the United Arab Emirates (UAE) in 1971. They were joined by Ra's al-Khaymah in 1972. Bahrain and Qatar became independent and acquired control of Western oil concerns operating in their territories. Their way of life was transformed and they could even subsidize poorer Arab States.

Though the eclipse of Nasser's encouragement of dissident groups in the peninsula removed an external danger to its security, a fresh potential threat arose with the revolution in Iran in 1978–79 and with the outbreak of the Iran–Iraq war in 1980. Earlier the Shah of Iran's forces had seized the strategic Tunb Islands in the Persian Gulf as the British departed. Islāmic fundamentalism in the ayatollah Khomeini's Iran struck an answering chord with malcontents, Shī'ite minorities, and Iranian workers in the Arabian states, which gave financial support to Iraq. The U.S. presidents Jimmy Carter and later Ronald Reagan pledged U.S. support to keep open the Strait of Hormuz, through which some 60 percent of the industrial world's oil supply was being transported. The involvement of the United States with Israel and Iran in the sale of weapons in the mid-1980s, however, heightened the Arabian states' suspicions of the West, so closely tied to their economies.

Common interests brought Saudi Arabia and Egypt together until the Saudis, with other Arab states, broke with Egypt over its peace negotiations with Israel in 1978–79. Saudi–Egyptian relations were fully restored, however, in the early 1980s.

In response to the tensions of the Iran–Iraq war, Saudi Arabia expanded its military power, setting up a naval base at al-Jubayl in the Persian Gulf. Another base was built at al-Wajh, north of Jiddah, to counter the Soviet naval presence in the Gulf of Aden. In 1979 religious militant extremists of the Wahhābī sect itself seized the Great Mosque of Mecca and had to be forcibly ejected, and in 1982 Iranians demonstrated in the Holy City. The fall in oil revenue from its 1981 peak has affected Saudi spending and had international economic repercussions, but Saudi Arabia has begun to develop new industries.

In March 1981 Kuwait, Bahrain, Qatar, Oman, Saudi Arabia, and the United Arab Emirates formed the Gulf Cooperation Council (GCC) to promote stability and cooperation in the Gulf region. The GCC coordinated economic and defensive efforts of the six countries. The expected rate of economic growth in the region was slowed by the fall in oil prices after 1983. The countries of Arabia made plans to diversify their economies and to institute austerity measures in the face of falling prices.

THE COUNTRIES OF ARABIA

Bahrain

The State of Bahrain (Arabic: Dawlat al-Baḥrayn), a small Arab state in the Persian (Arabian) Gulf, is an archipelago consisting of Bahrain Island—extending about 30 miles (48 kilometres) from north to south and 10 miles from east to west—and some 30 smaller islands. Its Arabic name, al-Baḥrayn, means "Two Seas." It is situated in a bay on the

southwestern coast of the Gulf between the northeastern coast of Saudi Arabia to the west and the Qatar peninsula to the east. The King Fahd Causeway, 15 miles long, links Bahrain with Saudi Arabia. Bahrain's total land area is 267 square miles (691 square kilometres).

From earliest times Bahrain has been an important commercial and shipping centre in the Gulf; its importance has increased since the discovery and development of the

oil resources of the region. Although only a small producer of oil itself, Bahrain is placed to take advantage of the vast oil production in Saudi Arabia, and its own early development of oil production and refining has provided opportunities for the creation of related industries and services. The chief town, port, and seat of administration is Manama (al-Manāmah), on the northeastern tip of Bahrain Island.

Bahrain became a fully independent Arab emirate in 1971. It is a member of the United Nations, the Arab League, and the Gulf Cooperation Council. The emir—the ruler of the state—is a member of the Khalifah family (Āl Khalifah), which has been paramount in Bahrain since 1783. The system of government might be described as a mixture of traditional Arab autocracy and a benevolent oligarchy much modified by Western influence.

PHYSICAL AND HUMAN GEOGRAPHY

The land. *Relief.* The state consists of two separate groups of islands. The 225-square-mile island of Bahrain is surrounded by smaller islands. Two of these—al-Muḥarraḡ and Sitrah, both to the northeast—are joined to it by causeways that have encouraged their development for residence and industry; other islands in the group are Nabī Šāliḡ, al-Muḥammadiyah (Umm aṣ-Šabbān), Umm Na'sān (linked by the King Fahd Causeway), and Jiddah. The second group consists of the Hawār Islands, which are situated near the coast of Qatar about 12 miles southeast of Bahrain Island; small and rocky, they are inhabited only by a few fishermen and quarry workers.

While all of the small islands in both groups are rocky and low-lying, rising only a few feet above sea level, the main island is more varied in appearance. Its arched layers of rock consist of limestone, sandstone, and marl (loose clay, sand, or silt containing calcium carbonate), which were formed during the Tertiary and Cretaceous periods (from 2,500,000 to 136,000,000 years ago). The central region rises to 440 feet (134 metres) above sea level at ad-Dukhān Hill and is rocky and barren. The southern and western lowlands consist of a bleak sandy plain with some salt marshes. The northern and northwestern coasts afford a striking contrast; they form a narrow belt of date and vegetable gardens irrigated from prolific springs and wells that tap artesian water.

Climate. Humidity is high throughout the year, and monthly mean temperatures from May until October exceed 83° F (28° C). Summer days can be distinctly hot and humid. Winters are cooler and more pleasant, with mean temperatures from December to March below 70° F (21° C). Rainfall, almost entirely confined to the winter months, averages only three inches (75 millimetres) per year. The predominant wind is the damp, northwesterly *shamāl*, but the *qaws*, a hot, dry wind from the south, occasionally brings sand and dust.

Plant and animal life. Some 200 different species of desert plants grow in the bare arid portions of the archipelago, while the irrigated and cultivated areas of the islands support fruit trees, fodder crops, and vegetables. The variety of animals is limited by the desert conditions. The gazelle and the hare are not yet extinct, and lizards and jerboas (desert rats) are common, while the mongoose—probably imported from India—is found in the irrigated areas. Birdlife is sparse except in spring and autumn, when many varieties of migratory birds rest temporarily in Bahrain.

Settlement patterns. The majority of the population now dwell in towns, but in the north and northwest of the main island, where irrigation has long been carried out using artesian water, there are numerous small villages and isolated dwellings where horticulture is the way of life. This area has an aspect of great fertility, which contrasts quite starkly with the bare desert appearance of much of the country. The villages consist, for the most part, of substantial houses built of stone or concrete with a flat roof. Some of the temporary settlements of fishermen and the very poor are still constructed of *barasti* (branches of the date palm). There is little permanent settlement in either the southern half of Bahrain Island or on the smaller islands.

About half of the population lives in the two principal towns, Manama and al-Muḥarraḡ. Manama, with its port of Minā' Salmān, is the principal town and contains the main government offices, the business and financial district, many large hotels, Western-style shops, and a traditional Arab souk. It has a distinctly modern appearance as compared with al-Muḥarraḡ, which is densely settled and has many narrow, winding streets. Other major settlements are 'Awālī, near the centre of Bahrain Island, which was built largely for expatriate employees of the Bahrain Petroleum Company; Madinat 'Isā' (Isa Town), a new town built by the government since 1968; the sizeable settlements of ar-Rifā' ash-Sharqī (East Rifā') and ar-Rifā' al-Gharbī (West Rifā'); and the new town at Hamad, completed in 1984.

The people. Some 70 percent of the population is Arab. Most of those are native-born Bahrainis, but some are Palestinians, Omanis, or Saudis. Foreign-born inhabitants are mostly Iranian, Indian, Pakistani, British, and American workers. The Muslim population is composed of both Sunnite and Shī'ite sects, with the latter in the majority. The ruling family and many of the wealthier and more influential Bahrainis are Sunnite, and this difference has been an underlying cause of local tension. Arabic is the official language of Bahrain, but English is widely understood.

The economy. The economy of Bahrain, like that of other Arab states in the Persian Gulf, has in recent times been based largely on the production of oil and natural gas and on refining petroleum products. It is therefore very sensitive to fluctuations in the demand for oil and in oil prices. With its long tradition of shipping and commerce, however, and because both its oil and gas reserves are relatively small, Bahrain has been more successful than some other states in the Gulf in diversifying its economy to include manufactures and both commercial and financial services.

Agriculture and fishing. The majority of Bahrain's food is imported, but agriculture contributes significantly to the local food supply. Dates, bananas, citrus fruits, mangoes, pomegranates, vegetables, and alfalfa (lucerne) are the main items. Cattle breeding and dairy and poultry farming are encouraged by the government, and camels and horses are bred for racing. The increasing pollution of the waters of the Gulf has almost killed off the fishing industry, particularly for shrimp.

Industry. The traditional industries of Bahrain were building dhows (Arab sailboats), fishing, pearling, and the manufacture of reed mats. Demand for the traditional products has decreased, however, as living standards have risen, and the traditional industries are now carried out only on a very small scale.

Tom Sheppard—Robert Harding Picture Library

Building a dhow in a boatyard on the coast of Bahrain.

Oil was first discovered in Bahrain in 1932. The country's oil reserves are expected to last only until the year 2000, but the offshore natural gas supplies may have a longer life. An aluminum smelter operated by Aluminum Bahrain (ALBA), in which the government has a majority share holding, began production in 1972 and is one of the largest non-oil industrial establishments in the Gulf.

The aluminum industry

The archipelago

As a further development of this industry, an aluminum rolling mill was opened in 1985 to manufacture aluminum products such as door and window frames. Ship repair is handled at Minā' Salmān, near Manama, and at a large yard operated on al-Azī Island. The yard can handle as many as 50 large tankers per year. Other industries include the production of building materials, furniture, soft drinks, plastics, and a wide range of consumer goods.

Finance and trade. The government has encouraged the growth of offshore banking, insurance, and other financial services, and consequently Bahrain has become an important financial centre. It has also been able to benefit from its long tradition as a commercial centre. Bahrain has good telecommunication with the rest of the Middle East and with the world.

Bahrain's major import is the crude petroleum brought in by underwater pipeline from Saudi Arabia to be refined. Other major imports are machinery, food, alumina, chemicals, and a wide range of manufactured goods. The major export is refined petroleum products, and other exports include aluminum goods, machinery, and transport services. Banking, insurance, and financial services are becoming important in the country's balance of payments.

Transportation. Bahrain Island has an excellent system of paved roads, and its causeway connections to al-Muḥarraḡ and Sitrah islands and to Saudi Arabia facilitate travel. The principal towns and villages are well served by bus and taxi services. A high percentage of residents own motor vehicles. Bahrain International Airport on al-Muḥarraḡ Island is one of the busiest airports in the Middle East and is used by most major international airlines. Manama is the headquarters of Gulf Air, owned by the governments of Bahrain, Oman, Qatar, and the United Arab Emirates. Steamers run scheduled service from Bahrain to other Gulf ports and to Karāchi, Pak., and to Bombay.

Administration and social conditions. The emir is assisted by a cabinet, or council of ministers, which consists of the heads of various government departments, many of whom are members of the royal family. A constitution promulgated in 1973 created a National Assembly composed of members of the Cabinet and elected members, but after a period of industrial unrest and political agitation the Assembly was dissolved by the emir in 1975. Public representation has reverted to the traditional Arab and Islāmic system of a *majlis*, through which citizens and other residents may present petitions to the emir. This system has survived subsequent sporadic outbursts of discontent fueled both by left-wing elements and by Shi'ite interests inspired by the 1979 Iranian revolution.

Public education is free for both boys and girls at the primary, intermediate, and secondary level. Private schools are available as well. Institutions of higher education include the University College of Arts, Sciences, and Education; the Gulf Polytechnic; and the College of Health Sciences. Medical care is extensive and free, and there is provision for most forms of social security: pensions, sick pay, compensation for industrial injury, unemployment benefits, and maternity and family allowance payments.

Cultural life. In spite of its rapid economic development, Bahrain remains, in many respects, essentially Arab in its culture. The state television and radio stations broadcast most programs in Arabic, although there are channels in English. Football (soccer) is popular, and the traditional sports of falconry and of gazelle and hare coursing are still practiced by wealthier Bahrainis. Horse and camel racing are popular public entertainments.

Several weekly and daily papers are published in Arabic, and a small number appear in English. The museum in Manama contains local artifacts from ancient times such as ivory figurines, pottery, copper articles, and gold rings, many of which reflect various external cultural influences.

For statistical data on the land and people of Bahrain, see the *Britannica World Data* section in the BRITANNICA WORLD DATA ANNUAL.

HISTORY

Bahrain has been inhabited from prehistoric times, and several thousand burial mounds in the north of the main island probably date from the Sumerian period of the

3rd millennium BC. The archipelago was mentioned by Persian, Greek, and Roman geographers and historians. It has been Arab and Muslim since the Muslim conquest of the 7th century AD, though it was occupied and ruled by the Portuguese from 1521 to 1602 and by the Persians from 1602 to 1783. Since 1783 it has been ruled by sheikhs of the Khalifah family, which originated in the Hasa province of Arabia.

Several times during the 19th century the British intervened in the government of the territory to suppress war and piracy and to prevent the establishment of Egyptian, Persian, German, or Russian influence. The first Bahraini-British treaty was signed in 1820; and Bahrain's British-protected status dates from 1861, with the completion of a treaty by which the sheikh bound himself to refrain from "the prosecution of war, piracy, or slavery." Until 1970 the government of Iran periodically advanced claims to sovereignty over Bahrain, but these were repudiated.

In August 1971 Bahrain proclaimed independence. A treaty of friendship was signed with the United Kingdom, terminating the British protectorate status, and Sheikh 'Isā was designated the emir. Bahrain then became a member of the United Nations and the Arab League. In 1981 Bahrain joined with five other Arab Gulf states in forming the Gulf Cooperation Council (GCC), which has led to freer trading and closer economic ties. The GCC is also concerned, however, with mutual interests in defense.

For later developments in the history of Bahrain, see the *Britannica Book of the Year* section in the BRITANNICA WORLD DATA ANNUAL. (C.G.S.)

Kuwait

The State of Kuwait (Arabic: Dawlat al-Kuwayt) is an independent Arabian state, lying at the upper northwestern corner of the Persian (Arabian) Gulf. It has an area of 6,880 square miles (17,818 square kilometres) and is bounded on the west and north by Iraq, on the east by the Persian Gulf, and on the south by Saudi Arabia. A territory of 2,200 square miles along the Gulf was shared by Kuwait and Saudi Arabia as a neutral zone until 1969, when a political boundary was agreed upon. Each of the two countries administers one-half of the territory, but, as before, they share equally the revenues from oil production in the entire area.

Kuwait is largely a desert, except for al-Jahrah Oasis, at the western end of Kuwait Bay, and a few fertile patches in the southeastern and coastal areas. The largest offshore islands are the uninhabited islands of Būbiyān and al-Warbah. The island of Faylakah, near the entrance of Kuwait Bay, has been populated since prehistoric times.

The capital city of Kuwait, a true desert metropolis, is located on the southern shore of Kuwait Bay and derives its name from the diminutive of *kūt*, meaning "fort." It is the most important city, even though several of the country's other cities are larger in population. Almost all of the population of the country is concentrated in the cities. Overall, Kuwait is one of the world's most highly urbanized states.

Oil dominates the economy of the country. Kuwait is one of the largest oil producers in the world and has one of the largest oil reserves of any producing country.

PHYSICAL AND HUMAN GEOGRAPHY

The land. *Relief.* The relief of Kuwait is generally flat or gently undulating, broken only by occasional low hills and shallow depressions. The elevations range from sea level in the east to 951 feet (290 metres) at ash-Shaqāyā peak, in the western corner of the country. The az-Zawr Escarpment, one of the main topographic features, borders the northwestern shore of Kuwait Bay and rises to a maximum height of 475 feet above sea level. Elsewhere in coastal areas large patches of salty marshland have developed. Throughout the northern, western, and central sections of Kuwait there are desert basins called playas, which fill with water after winter rains and form important watering places for the camel herds of the Bedouin.

Vegetation. True soils scarcely exist naturally in Kuwait. Except in the green belt of Kuwait city and some other

patches, where cultivation and irrigation are carried out, the vegetation consists of scrub and low bushes (and ephemeral grass in the spring). Salt-loving plants grow on the marshy stretches along the coast.

Climate. The climate is semitropical, tempered somewhat in the coastal regions by the warm waters of the Gulf. If there is enough rainfall, the desert turns green from the middle of March to the end of April. But during the dry season, between April and September, the heat is severe—the temperature ordinarily reaching 111° F (44° C) during the day and on occasion going as high as 130° F (54° C). The winter is more agreeable (even frost can occasionally occur in the interior, though never on the seacoast). Annual rainfall averages only from one to seven inches (25 to 180 millimetres), chiefly between October and April, though cloudbursts can bring more than two inches of rain in a day.

The frequent winds from the northwest are cool in winter and spring and hot in summer. Southeasterly winds, usually hot and damp, spring up between July and October; hot and dry south winds prevail in spring and early summer. The shamal, a northwesterly wind, causes sandstorms that are referred to as *tauz*.

Settlement patterns. The old city of Kuwait was located on one of the harshest spots on the Earth's surface. It is the exploitation of oil that has given rise to the extraordinary modern metropolis, which could never have grown so rapidly without exceptional impetus. The old city—oriented toward the sea and bounded landward from 1918 to 1954 by a mud wall, with gates that led out only into the endless desert—was compact, only five square miles in area; its typical dwelling was a courtyard house. The culture was one of a seafaring, desert-daring, pearl-diving patriarchal society guided by the Islamic religion. At one time drinking water was imported by barge from Iraq. Modern Kuwaitis drink distilled seawater and live and work in air-conditioned surroundings. In and around the city are schools, hospitals, and tall office buildings. Expansion of public and civic facilities has been rapid.

Up to 1951 Kuwait city consisted of little more than the area enclosed within the semicircular city wall. With the urban explosion of the years after 1951, the wall was demolished and new suburbs were formally laid out. Within the suburban blocks, building plots ranging in size from 8,100 to 11,000 square feet were allocated to Kuwaiti citizens who had been displaced from the old city, then in process of radical redevelopment.

Kuwaitis are now scattered at a relatively low density throughout the urban area, with minor concentrations in the suburbs of Dasmah, ash-Shāmiyah, and al-Udayliyah. Non-Kuwaitis, excluded from the restricted suburbs, live at higher densities in the old city and in the suburbs of Hawalli and as-Sālimiyah, mostly in apartments. Strong demographic contrasts have been introduced by the large-scale influx of migrants. Kuwait now has a cosmopolitan mixture, each ethnic group adding colour and contributions to the urban aspects of the country. Almost all of the British and Americans in Kuwait are connected with the oil companies or with government industrial projects.

The people. Native Kuwaitis make up only about 40 percent of Kuwait's total population. Other Arabs, primarily Palestinian, Egyptian, Iraqi, Syrian, and Lebanese, account for about 50 percent, and there are small percentages of Indians and Pakistanis. The Palestinians, some of them third-generation residents of Kuwait, account for between 20 and 25 percent of the total population and thus constitute the largest nonnative group. They, like other foreign workers, cannot enjoy the rights of citizenship, which are reserved for native Kuwaitis and for those who can prove Kuwaiti ancestry from before 1920. Naturalization is limited by strict residence and employment requirements and by annual quotas.

Unlike most Arab societies, Kuwaiti society was traditionally compact, united, and virtually classless. A definite class system, with all its traditions and conventions, has thus never developed among the native Kuwaitis.

Apart from small minorities of Arab and European Christians and of Indian Hindus, Kuwait's population is almost entirely Muslim. A law passed in 1981 confines

citizenship to Muslims. Among both the native and the foreign populations, the majority of Muslims are Sunni, but as many as one-third are Shi'ite. Most of the nonnative Shi'ites are from Iran and Iraq, and, in light of Iran's Shi'ite Islamic revolution of 1979, the presence of large numbers of Shi'ites in Kuwait has been seen by some as a threat to security.

The native and official language is Arabic, and fluency in Arabic is a requirement of naturalization. English is the second basic language taught in public schools. Hindi, Urdu, and Farsi also are widely spoken.

The economy. Virtually all of Kuwait's wealth is derived, directly or indirectly, from oil. Income from oil exports gives Kuwait one of the highest per capita incomes in the world. Although the downturn in the world oil market in 1983–85 reduced the income from oil exports by about half, Kuwait's economy did not suffer greatly. In part this was because the return on foreign investments, both in government holdings and in private hands, had become nearly as great as—and on occasion exceeded—the income from oil. Kuwait's foreign investments are mostly in the United States and include a variety of holdings. The Kuwait Fund for Arab Economic Development, established in 1961, extends generous loan assistance, although no longer at the levels achieved in the 1970s, when aid disbursements reached as much as 15 percent of the gross national product.

The most dramatic aspect of Kuwait's economic development since the 1970s has been the vertical integration of its oil industry. The integration has entailed an enormous expansion of refining and shipping capacity, marketing capabilities, and facilities for producing a range of petrochemical products. By 1983, for example, Kuwait could refine and sell a large portion of its daily petroleum output through its own refineries and gasoline stations in a number of western European countries.

Employment generated directly by oil production and export accounts for only a small percentage of the labour force. Almost one-half of all jobs are in the public administration, defense, and services sectors; about one-fifth are in construction; and the trade, manufacturing, transportation and communication, finance, and agriculture sectors all employ more than the oil sector.

Typically, Indians and Pakistanis hold clerical or skilled technical jobs while Iranians and some Arabs hold less desirable positions. Palestinians and Egyptians are well represented in professional positions and in the government bureaucracy. In all, more than 80 percent of the work force is non-Kuwaiti. The construction boom of the late 1970s and early '80s led to the arrival of large numbers of workers from East Asian countries. The general economic slowdown of the mid-1980s reduced development expenditures and prompted a corresponding reduction in the growth of the expatriate labour force. A lack of requisite skills and a cultural aversion to certain kinds of work among Kuwaitis, however, has ensured pronounced dependence upon foreign skilled and unskilled labour, despite the government's efforts to increase the number of native Kuwaitis in the work force.

Resources. Kuwait's proven, recoverable oil reserves are thought to be enough to sustain current levels of production for more than 250 years. Kuwait also has considerable reserves of natural gas, but almost all of it is in the form of associated gas—i.e., gas that is produced together with oil. The search for unassociated gas has been largely unavailing. There are no other minerals, and even the large expanses of sand, being very solid, are not economically exploitable. Naturally occurring fresh water is scarce.

Agriculture and fishing. The possibilities of agricultural development are severely limited. Only a very small percentage of the land is at all arable; and because of the scarcity of water, deficiencies of soil, and lack of manpower trained in agricultural skills, an even smaller percentage of the land area is under actual cultivation. Agriculture in Kuwait has remained a marginal activity, and its contribution to the output of the economy is insignificant.

Fish are plentiful in the Persian Gulf, and, before the discovery of oil, fishing in Kuwait was a leading and flourishing industry. It is assuming more importance again

Nature of

ization

The non-
Kuwaiti
work force

and is one of the sectors playing a significant role in the drive for diversification. The Kuwait United Fisheries, formed from the amalgamation of several major fishing companies, operates in territorial waters. Shrimps, the chief seafood exported, are being depleted by overfishing and pollution.

Development of oil production. *Industry.* In 1934 the Kuwait Oil Company (KOC), the ownership of which was divided equally between the British Petroleum Company and the Gulf Oil Corporation (of the United States), obtained a concession covering the whole territory except the Neutral Zone. Oil was struck in 1938, but World War II deferred development until 1946. Thereafter, progress was spectacular. In 1953 the American Independent Oil Company and the Getty Oil Company, which jointly held concessions for the Neutral Zone, struck oil in commercial quantities; and in 1955 oil was discovered in northern Kuwait. By 1976 Kuwait had achieved 100-percent control of the KOC, with the former owners retaining the right to purchase at a discount. The government also achieved full ownership of the Kuwait National Petroleum Company (KNPC), which it had formed in 1960 with private Kuwaiti investors. The KNPC, designed to serve as an integrated oil company, controlled distribution and petroleum products supplies within the country and began marketing operations abroad. In 1980 the government founded the Kuwait Petroleum Corporation as an umbrella organization overseeing the KOC and the KNPC as well as the Kuwait Oil Tanker Company, the Petrochemicals Industries Company, and the Kuwait Foreign Petroleum Exploration Company.

The relatively low cost of oil production in Kuwait stems from certain unique advantages. First, there are a number of highly productive wells, the output of which can be varied at short notice, thus eliminating the need for large numbers of storage tanks. Most of the storage tanks themselves are placed on a ridge set back a few miles from the seacoast at a height of some 300 feet; this enables loading operations to be carried out by gravity and not through the use of pumps. There are also extensive refineries and bunkers for tankers.

Natural gas and other industries. Massive volumes of natural gas are produced in association with crude oil. Although natural gas has great potential as a source of foreign exchange, its principal uses so far have been in reinjection in oil fields to maintain pressure, in the generation of electricity (as for water distillation), and in the production (as raw material) of petrochemicals and fertilizers.

Other industries in Kuwait include the production of cement, dry-cell batteries, electric cables, metal pipes, insulation materials, furniture, detergents, plastic tubes, woolen blankets, confections, paints, liquid gas, and lime bricks. Most of these industries are of small size.

A major industrial area has been developed at ash-Shu'aybah, between Kuwait city and Ahmadi, provided with a worker's town, a harbour and a dry dock for the repair of ships, a fertilizer plant, a desalinization plant, a seafood-packing plant, ammonia and urea plants, a cement factory, and a petrochemical complex.

The government encourages the development of industry by granting land at nominal rent, by subsidizing key inputs like the production of electricity and water, by offering exemptions from customs duty, tariffs, and import controls, by providing loans at low interest rates, by providing capital in exchange for owners' shares, by training labour, and by conducting technical studies designed to devise ways and means of increasing productivity. This policy to accelerate industrialization has produced results, but it is unlikely that manufacturing will ever account for more than a small proportion of the total domestic output. The difficulties of a small market and a lack of raw materials and manpower obviously limit the scope for industrialization.

For fresh water in earlier days people depended on a few artesian wells and on rainwater collected from the roofs of houses or from cisterns at ground level. Dhows manned by Kuwaiti seamen also brought fresh water from Shatt al-Arab near Basra, Iraq. With the rapid growth of population, however, the government of Kuwait built desalinization plants at Kuwait city, ash-Shu'aybah, and

several other locations. Important sources of fresh water have been discovered at Raudhatain and al-Shigaia, but desalinization still provides the great majority of Kuwait's daily consumption of potable water.

The expansion of electric facilities has also been remarkable. Production is concentrated in several large, natural-gas-fired power stations, including one at ash-Shuwaykh and another at ash-Shu'aybah.

Trade and finance. Oil and oil-derived products account for all but a very minor portion of Kuwait's exports, with Asia and Europe being the most important markets. Kuwait's imports, largely manufactured goods, are principally from Japan, the United States, and several western European nations.

In addition to its Central Bank, Kuwait has specialized banks operating in the areas of savings and credit, industrial loans, and real estate. There are also commercial banks. No foreign banks may operate, with the exception of the Bank of Bahrain and Kuwait, based in Bahrain and owned equally by the two states. An Islāmic bank has also been established. Since before independence an officially sanctioned stock exchange has operated, growing to become one of the largest in the world.

Transportation. Kuwait has a modern road system, linking it with its neighbours, and a large international airport. Kuwait Airways Corporation, a state-owned enterprise, serves a number of international routes. The country's port facilities and its fleet of oil tankers and general cargo ships have been expanded.

Administration and social conditions. Kuwait is a constitutional monarchy with a single parliamentary house, the National Assembly. Executive power is vested in the emir, who rules for life and exercises power through an appointed Council of Ministers. Under the constitution promulgated in 1962 only first-class male citizens—that is, literate males over 21 years of age who are natural-born Kuwaitis or whose families lived in Kuwait before 1920—are eligible to vote for members of the National Assembly. This provision limits the number of voters to less than 10 percent of the total population.

Government ministers are responsible to the emir, who can dissolve the Assembly. Legislation may be initiated by either the emir or the Assembly, and the latter approves the country's annual budget as well as foreign treaties. The Assembly was suspended, however, from 1976 to 1981 and again in July 1986.

The legal system of Kuwait is based upon a number of diverse sources. Matters of civil and personal status law are governed by the Shari'ah, the Islāmic religious law based on the Qur'an and the Hadith (collected traditions of the Prophet Muhammad). Commercial and criminal laws derive from Ottoman and several modern Arab sources and, through them, reflect elements of the French legal code and the English common law. There are several courts of first instance and courts of appeal at two levels. The emir acts as the final court of appeal.

Kuwait has a comprehensive scheme of social welfare. For the needy there is financial assistance; for the handicapped there are loans to start a profitable business; for the invalid and deformed there are treatment and training; and for adult illiterates there is education. A huge program called the Limited Income Housing Scheme, which provides adequate houses fully equipped with modern facilities for native Kuwaiti families with limited incomes, has been one of the chief projects of the Ministry of Social Affairs and Labour. Kuwait has established a Reserve Fund for Future Generations to provide for the welfare of its people. The fund receives 10 percent of the state's revenues annually, and both principal and interest are to remain untouched until the year 2001.

General education in Kuwait is compulsory for native Kuwaitis between the ages of six and 14. It is entirely free and includes not only tuition but also school meals, books, uniforms, transportation, and medical attention. Non-Kuwaiti students attend government schools as space permits or attend private schools. Kuwait University was founded in 1962. About three-fourths of the university students are Kuwaitis, and more than half are women. Several thousand students attend colleges and universities

Power

Social welfare services

overseas, principally in the United States, Britain, Egypt, and Lebanon.

The Ministry of Information runs the government press and the radio and television broadcasting stations. It also has undertaken the task of reviving some of the outstanding literary works in Arabic.

For statistical data on the land and people of Kuwait, see the *Britannica World Data* section in the BRITANNICA WORLD DATA ANNUAL. (D.A.Sa./J.D.An.)

HISTORY

The origin of the city of Kuwait—and of the State of Kuwait—is usually placed at about the beginning of the 18th century, when a number of families of the 'Anizah tribe in the interior of the Arabian Peninsula abandoned nomadism and migrated to the shores of the Persian Gulf. The foundation of the autonomous sheikhdom of Kuwait is dated from 1756, when the settlers decided to appoint a sheikh from the Šabāh family.

Kuwait first came to the attention of the European powers toward the end of the 19th century, at the time that Germany sought to extend the Berlin–Baghdad Railway to the port of Kuwait. Great Britain, eager to frustrate Germany's designs, and Kuwait's ruling sheikh, desirous of protecting himself against the Ottoman Empire's nominal suzerainty, concluded an agreement in 1899 whereby Britain assumed control of Kuwait's foreign affairs. Following the outbreak of war with the Ottomans in 1914, Britain established a protectorate over Kuwait.

Relations with Najd (later Saudi Arabia) were settled by the Treaty of al-Uqayr (1922), which involved the creation of the compromise Neutral Zone. The northern frontier with Iraq was agreed upon in 1923.

On June 19, 1961, the British government recognized the sheikhdom as independent. Six days later the Iraqi prime minister claimed Kuwait as an integral part of Iraq, his argument being that Kuwait had been a part of the Ottoman Empire and that ethnically, geographically, and socially Kuwait and Iraq were one country that had been arbitrarily divided by Britain. Threatened with invasion, the ruler of Kuwait appealed to Britain for military aid. In early July British troops landed in Kuwait, and on July 20 the Arab League admitted the sheikhdom to its membership, thus recognizing its independence and refusing to recognize the Iraqi claim. Almost two years later, on May 14, 1963, Kuwait was admitted to the United Nations. Relations with Iraq meanwhile improved, and in October 1963 Iraq recognized Kuwait's independence. Kuwaiti troops stationed along the Suez Canal fought during the Arab–Israeli war of 1973 (Yom Kippur War), and Kuwait has subsequently given strong financial and political support to Palestinian and other Arab causes. (D.A.Sa.)

Through the Kuwait Fund for Arab Economic Development and the Kuwait-based Arab Fund for Economic and Social Development (to which Libya as well as Saudi Arabia and other Gulf Arab countries also have contributed), important assistance has been rendered to a number of developing countries. The aid is directed primarily to Arab countries but has been made available to other Asian and African states as well.

Kuwait has long maintained good relations with almost all of its fellow Arab states, enjoying especially close and warm ties with those that share its own moderate stance on most issues and its conservative domestic political character. It has generally good relations with the European and Asian countries with which it has significant commercial dealings and with the United States, despite occasional strains arising largely from the U.S. position on Arab–Israeli issues. First among the Gulf Arab states to establish diplomatic relations with the Soviet Union (1963), Kuwait tries to steer a careful path between the superpowers.

The Iran–Iraq war, from its inception in September 1980, represented a serious threat to Kuwait's security. While Iraq remains a source of concern, periodically reviving its claim to Kuwaiti territory, Kuwait saw no alternative to providing the Baghdad government substantial financial support and serving as a vital conduit for military supplies. Iran attacked a Kuwaiti refinery complex in 1981 and

inspired terrorist acts of sabotage in 1983 and 1986, and in 1985 a member of the underground Iraqi radical group al-Dawa attempted to assassinate the ruler, Sheikh Jābir al-Ahmad Āl Šabāh.

In September 1986 Iran began to concentrate its attacks on Gulf shipping largely on Kuwaiti tankers. This led Kuwait to abandon its policy of trying to keep the superpowers out of the Gulf. Kuwait invited both the Soviet Union and the United States to provide protection for its tankers in early 1987. Several Kuwaiti tankers were reflagged with U.S. flags and were given U.S. naval escorts. In March 1987 three Kuwaiti tankers were reregistered under the flag of the Soviet Union.

The effect of the war has been to promote closer relations with Kuwait's conservative Gulf Arab neighbours, Saudi Arabia, Bahrain, Qatar, the United Arab Emirates, and Oman. With them, in 1981, Kuwait formed the Gulf Cooperation Council (GCC) to develop closer cooperation on economic and security issues. Steady, modest progress has been made in both areas.

For later developments in the history of Kuwait, see the *Britannica Book of the Year* section in the BRITANNICA WORLD DATA ANNUAL. (J.D.An.)

Oman

The Sultanate of Oman (Arabic: *Salṭanat 'Umān*) is an independent sultanate that occupies the southeastern coast of the Arabian Peninsula. It is bounded on the southwest by Yemen, on the south and east by the Arabian Sea, on the north by the Gulf of Oman, on the northwest by the United Arab Emirates, and on the west by Saudi Arabia. In addition, in the Ru'ūs al-Jibāl ("the Mountaintops") is a small enclave, occupying the northern tip of the Musandam Peninsula at the Strait of Hormuz; this territory gives Oman its only frontage on the Persian Gulf. Because the boundaries with Saudi Arabia are not fixed, the exact area of Oman cannot be determined; it is estimated to be about 120,000 square miles (300,000 square kilometres). Its offshore territories include al-Maṣīrah Island to the east and the five Khuriyā Muriyā Islands, 25 miles off the south coast. Muscat (Masqaṭ), a port on the Gulf of Oman, is the capital.

PHYSICAL AND HUMAN GEOGRAPHY

The land. *Relief.* Northern Oman is dominated by three physiographic zones. The long, narrow coastal plain of al-Bāṭinah stretches along the Gulf of Oman. The high, barren al-Hajar Mountains extend southeastward, parallel to the Gulf coast, from the Musandam Peninsula to a point near Cape al-Hadd, at the easternmost tip of the Arabian Peninsula; the great central divide of Wadi Sanā'il separates the al-Hajar into a western and an eastern range. An inland plateau falls away to the west of the al-Hajar Mountains into the great Rub' al-Khali (the Empty Quarter) desert, which the sultanate shares with Saudi Arabia. These zones are further subdivided into a number of unofficial provinces: al-Bāṭinah; the mountains and associated valleys of the Eastern al-Hajar and Western al-Hajar; Oman province, or al-Jawf (the central foothills and valleys on the inland side of the al-Hajar Mountains and the historic heartland of Oman); az-Zāhirah (west of Oman province, next to the United Arab Emirates, and including al-Buraymī oasis); ash-Sharqiyah (lying east of Oman province behind the al-Hajar Mountains); and Ja'lān (fronting the Arabian Sea south of Cape al-Hadd).

The fertile southern region of Dhofar (Zufār), incorporated into the sultanate only in the 19th century, is separated from the rest of Oman by several hundred miles of open desert. Three coterminous mountain ranges, rising to about 5,000 feet (1,524 metres), form a crescent in Dhofar around a long, narrow, coastal plain on which is located the provincial capital of Ṣalālah. Behind the mountains, gravel plains gradually merge northward into the southern reaches of the Rub' al-Khali.

Climate and plant and animal life. Generally, the climate is hot and dry in the interior and hot and humid along the coast. Summer temperatures in the capital of Muscat and other coastal locations often reach 97° F

Relations
with Arab
neighbours

Kuwaiti
independence

The
Dhofar
region

(36° C), with high humidity; winters are mild, with lows around 63° F (17° C). Temperatures are similar in the interior, although they are more moderate at higher altitudes. Dhofar is dominated by the summer monsoon that envelopes the mountains in fog and mist for up to four months. Šalālah's climate is more moderate than that of northern Oman and is relatively constant throughout the year. Rainfall throughout the country is minimal, averaging about four inches (104 millimetres) a year. There are no permanent bodies of fresh water in the sultanate.

Because of the low rainfall, vegetation is sparse except where irrigated. Irrigation is provided by an ancient system of water channels known as *aflāj* (singular, *falaj*). The channels, which often run underground, originate in wells near the bases of the mountains.

A.C. Waltham—Robert Harding Picture Library

A *falaj* in a date grove, Akhdar Mountains, Oman.

Acacia trees form most of what little natural vegetation exists, and the soil is extremely rocky. The government protects rare species, such as the Arabian oryx, mountain goats, foxes, and the loggerhead turtle.

Settlement patterns. Oman is fundamentally a rural country. Settlements are typically located near the foothills of the al-Ḥajar Mountains, where the *aflāj* provide irrigation. In addition to small villages, a number of sizable towns, including Nizwā, Bahlā', Izki, and 'Ibri, are found on the inland, or southwestern, side of the Western al-Ḥajar. The al-Bāṭinah coast provides opportunities for fishing, as well as irrigated cultivation. As a consequence it is rather more densely populated, with major towns at Shinās, Šuḥār, al-Khābūrah, al-Mašanna'a, and Barkā'. Traditional housing in the al-Bāṭinah often consists of palm-frond huts, in contrast to the mud-brick structures of the interior. Ar-Rustāq, al-'Awābī, and Nakhl are principal settlements on the al-Bāṭinah side of the Western al-Ḥajar.

At the eastern end of the al-Bāṭinah lie the twin cities of Muscat and Maṭrah; both are ancient ports, but they have been transformed into a booming metropolis. To the east, the only major town is Šūr, a well-protected port that is still the hub of fishing and boatbuilding industries. A nomadic population occupies the land between the irrigated valleys and the desert, but the nomadic proportion of the total population is quite small. Some of Dhofar's residents are concentrated in towns along the coast, and some are seminomadic cattle herders in the mountains. A small nomadic population inhabits the inland plateaus along the Rub' al-Khali. Khaṣab is the only significant town in the sparsely populated Musandam Peninsula.

The people. Oman's population is principally Arab, although large numbers of ethnic Baluchi live along the al-Bāṭinah; both groups are exclusively Muslim. The Ibādite branch of Islām, a moderate variant of the Khārijite sect, claims the largest number of adherents, perhaps slightly less than half of the total population. In belief and ritual, Ibādism is close to Sunnite Islām (the major or orthodox body of Muslims), differing in its emphasis on an elected imam as the spiritual and temporal leader of the Ibādite

community. Non-Ibādite Arabs and the Baluchi, who have migrated to Oman from Iran and Pakistan over the last several centuries, are Sunnites.

The Muscat-Maṭrah conurbation has long been home to significant numbers of merchants of Indian origin, some of whom also live along the al-Bāṭinah. Notable among these are the Liwāṭiyah (Khoja), originally from Sind but who have lived in Oman for about 400 years. The Indian communities are mainly Shī'ite, the most widespread Islāmic sect after the Sunnite, with a few Hindus. There are also several small Persian communities, and a number of Swahili-speaking Omanis born in Zanzibar and elsewhere in East Africa returned to Oman after 1970.

Several large Arab tribes predominate along Dhofar's coastal plain. The inhabitants of the Dhofari mountains are known as *jibālīs*, or "people of the mountains." They are ethnically distinct from the coastal Arabs and are related instead to the inhabitants of eastern Yemen (Aden). They speak South Arabic languages, which are largely unintelligible to speakers of modern standard (North) Arabic. Dhofaris are all Sunnite Muslims.

Since the influx of oil income and the palace coup of 1970, increasing numbers of expatriates reside in the country, particularly in the capital area. These include Western businessmen, government advisers, and army officers, as well as skilled and unskilled labourers from the Indian subcontinent, the Philippines, and elsewhere in Asia.

The economy. Oman is a rural, agricultural country, with fishing and overseas trading important for the coastal populations. Before 1970, thousands of Omanis left the country to find work in nearby oil-producing states. Oil in commercial quantities was discovered in Oman in 1964, however, and was first exported in 1967. Subsequently the production of oil rapidly came to dominate the country's economy. By the mid-1980s oil represented one-half of the gross domestic product and provided about 85 percent of the government's income.

Serious development planning began in 1976 with the first five-year plan (1976–80). The framework for the second five-year plan (1981–85) was laid in 1978. The plans included development of necessary social amenities, additional investment in the petroleum industry, and further economic diversification.

Natural resources. Several small copper mines and a smelter were opened in the early 1980s at an ancient mining site near Suhār, but copper reserves are not expected to last beyond the mid-1990s. Chromite is also mined in small quantities. Other mineral resources are insignificant.

Agriculture and fishing. Agriculture is mainly subsistence in nature and employs about one-half of the population. The *aflāj* irrigation system has long supported a three-tiered crop approach (three crops raised at different levels on the same plot), with date palms above; limes, bananas, or mangoes in the middle; and alfalfa, wheat, and sorghum on the ground. Dates (the country's leading crop) and limes grown in the interior oases have long been traded for fish from the coast as well as exported abroad. Grapes, walnuts, apples, and other fruits are grown in the high mountain plateaus. Dhofar also produces coconuts and papayas. Most rural families keep goats, as well as a few cows, and Oman is well known for camel breeding. Cattle are raised almost exclusively in Dhofar.

Labour migration has left fields to lie fallow and the irrigation systems to decay. Partly in an attempt to reduce food imports, the government has sought to stimulate agricultural production with the establishment of research stations and model farms along the Bāṭinah coast and in Dhofar, as well as date-processing plants at ar-Rustāq and Nazwā. The government has also sought to encourage commercial fishing by providing boats and motors, cold stores, and transportation; and fisheries production in the Gulf of Oman and Arabian Sea has increased.

Industry. Crude oil production averaged about 300,000 barrels per day through the 1970s. The government's response to declining oil prices in the 1980s was to increase production; by the middle of the decade, production had climbed to nearly 600,000 barrels per day, a larger figure than some OPEC countries produced but still far behind the ranks of the world's largest oil exporters.

Research
stations
and model
farms

Industrial development began only with the change of government in 1970 and is oriented to such infrastructural projects as electricity generators, desalinization complexes, and the cement plants outside Muscat and Ṣalālah. The five-year plans have stressed private-sector development as well as joint ventures with the government. Traditional handicrafts, such as weaving, leatherworking, boatbuilding, and gold and silver work, are declining.

Finance and trade. After registering annual economic growth rates of 10 percent or more in the early 1980s, the country began to suffer balance-of-payment deficits in 1986 as a result of declining oil prices. The low level of foreign reserves forced the government to introduce regular budget cuts, devalue the Omani riyal by 10 percent in 1986, and issue treasury bills for the first time. Defense spending, which had averaged between 40 and 50 percent of the total budget since 1970, was trimmed somewhat, and expensive arms purchases were postponed.

Crude oil accounts for most exports, while imports consist of consumer goods, foodstuffs, and industrial equipment. Among the country's major trading partners are Japan, the United Arab Emirates, and the United Kingdom. Most businesses are family-owned.

Transportation. There are two modern ports, Port Qabus in Maṭrah and Raysut near Ṣalālah, both built in the early 1970s. Significant intercoastal trade is carried on by traditional wooden dhows. The two principal airports are located at as-Sīb, about 30 miles from Muscat, and at Ṣalālah. The government is a major stockholder in the international carrier Gulf Air and also operates Oman Aviation Services domestically. Since 1970 a modern road network of asphalt and gravel roads linking all the country's main settlements has been built up from virtually nothing, and a 480-mile highway between Muscat and Ṣalālah was completed in 1984.

Administration and social conditions. *Government.* Oman's government is a monarchy (sultanate). Cabinet ministers are typically chosen from among Muscat merchants, informal representatives of interior tribes, and Dhofaris. The country has no written constitution and there are no political parties or elections, but the State Consultative Council, formed by the sultan in 1981, includes members representing the government, the chamber of commerce, and the various regions of the country. Local government is carried out by a combination of traditional *walis* (representatives of the sultan) and more recently established municipal councils.

The Sultan's Armed Forces, formed in 1958 from several smaller regiments, has grown since 1970 to about 21,500 personnel, spurred in part by the rebellion in Dhofar in 1964–76. The preponderance of Baluchi soldiers, many of whom had been recruited from the sultanate's former enclave of Gwādar in Pakistan, was reversed in favour of Arabs, and a policy of Omanization steadily reduced the numbers of British officers.

Education. Education has expanded dramatically since 1970, when only three primary schools existed. By 1985 there were almost 200 primary schools, 300 preparatory schools, and 36 secondary schools serving some 200,000 students. Sultan Qabus University was opened in September 1986.

Health and welfare. The post-1970 government also improved health care throughout the countryside. It has built hospitals, health centres, and dispensaries and equipped mobile medical teams to serve remote areas. The government also provides generous housing loans.

Cultural life. Oman is a tribal society and the individual Omani typically identifies foremost with his tribe. Women have been relatively freer in Oman than elsewhere in the Arab world. Attempts have been made to minimize the effect of development on the heavily traditional society through, for example, incorporating traditional elements of architecture in new buildings and a 1986 law forbidding Omani nationals to marry foreigners. The Ministry of National Heritage and Culture has been active in preserving historic buildings, excavating archaeological sites, and supporting traditional crafts.

Several Arabic-language newspapers are published on a daily and weekly basis, and there is an English-language

daily. A colour television system was opened in 1974–75, and radio stations broadcast in Arabic and English.

For statistical data on the land and people of Oman, see the *Britannica World Data* section in the BRITANNICA WORLD DATA ANNUAL.

HISTORY

There are three principal themes in Omani history: the tribal nature of its society, the traditional Ibāḍite Imamate form of government, and its maritime tradition. Archaeological evidence of civilization in Oman dates to the 3rd millennium BC, but Persian colonization in the 7th or 8th century BC seems to have been responsible for the creation of the *falaj* irrigation system, which has sustained Omani agriculture and civilization ever since.

The history of Dhofar followed a separate track. Ancient south Arabian kingdoms controlled the production of frankincense from Dhofar's port of Sumharum from the 1st century AD, and the province remained oriented toward south Arabia until it was absorbed into the Āl Bū Sa'īd state in the 19th century.

The Omani tribal system. The origins of the Omani tribal system can be traced to the immigration of Arab tribes from south Arabia into the Ja'lān region in the 2nd century AD. The tribes subsequently moved northward into the Persian-controlled area of Māzūn in Oman, where they were joined by tribes moving into Oman from the northwest. Arab dominance over the country began with the introduction of Islām in the 7th century.

The Ibāḍite Imamate. A semblance of national political unity emerged only with the introduction of the Ibāḍite Imamate in the mid-8th century. Oman's mountains and geographic isolation provided a refuge for then-extremist Ibāḍites, who proceeded to convert the leading tribal clans to their sect. The new Ibāḍite state was headed by an elected imam who served as both temporal and secular leader of the community. In actuality, selection of a new imam depended on agreement among the religious leaders and the heads of the major tribes, particularly the leaders of the two major tribal confederations, which came to be known as the Ghāfiris and the Hināwis.

A recurring pattern was established with the decline of the First Imamate, which reached its zenith during the 9th century. Elected imams tended to give way to hereditary dynasties, which then collapsed as a result of family disputes and the resurgence of Ibāḍite ideals.

The maritime tradition. Maritime trade, the third principal theme in Omani history, also contributed to dynastic decline. Virtually cut off from the rest of the Arabian Peninsula by vast deserts, Omani sailors plied the waters of the Indian Ocean, ranging as far as China in the medieval period. This maritime tendency was strongest when dynasties moved their capitals from the Ibāḍite heartland to the coast and focused their attention on acquiring territory elsewhere in the Gulf, along the Arabian Sea, and on the East African littoral.

Arrival of the Portuguese. The Portuguese sacked Muscat in 1507 and soon controlled the entire coast. A century later, the Ya'āriba dynasty drove the Portuguese from the Omani coast, recapturing Muscat in 1650, and then took over Portuguese settlements along the Persian and East African coasts. Their empire eventually crumbled in a civil war over succession in the early 18th century, enabling the Persian ruler Nāder Shāh to invade the country in 1737.

Aḥmad ibn Sa'īd, the governor of Ṣuḥār, drove out the Persian invaders and was subsequently elected imam about 1744, thus establishing the Āl Bū Sa'īd dynasty, which has ruled Oman ever since. His grandson, Sa'īd ibn Sulṭān (ruled 1807–56), reasserted Omani control over Zanzibar and eventually moved his residence there. Upon his death the Āl Bū Sa'īd empire was split between two sons, with one receiving Zanzibar, which remained under Āl Bū Sa'īd rule until 1964, and the other ruling Oman.

The fortunes of the Āl Bū Sa'īd state in Oman declined through the second half of the 19th century. The Āl Bū Sa'īd dynasty quite possibly would have collapsed if it had not been for the presence of the British, who propped up the Āl Bū Sa'īd sultans in Muscat against periodic revivals of the Ibāḍite Imamate in the interior.

Persian
coloniza-
tion

Tribal attacks in the name of the imam were made on Muscat and Maṭraḥ in 1895 and 1915. An agreement was negotiated by the British between the tribal leaders and Sultan Taymūr ibn Fayṣal (reigned 1913–32) in 1920. By its terms, the Sultan recognized the autonomy, but not the sovereignty, of the Omani interior.

This situation lasted until 1954, when Imam Muḥammad al-Khalīlī, who had become imam in 1920, died. His weak successor, Ghālib, was influenced by his brother Ṭālib and a prominent tribal leader, Sulaymān ibn Ḥim-yār, and the three enlisted Saudi Arabia's support against Sultan Sa'īd ibn Taymūr. The Saudis had occupied part of al-Buraymī oasis, jointly administered by Oman and neighbouring Abu Dhabi (now part of the United Arab Emirates), in 1952, apparently in hopes of finding oil. In 1955 an international arbitration tribunal on al-Buraymī broke down and the British engineered the ouster of the Saudi garrison.

At the same time a regiment led by British officers moved into the Omani interior and reunited the sultanate. Remnants of the imamate's supporters, however, held strongholds in the Mount al-Akhḍar Massif of the Western al-Ḥajar mountains until they were forced to surrender in early 1959.

In the early 1960s another threat to the sultanate emerged in Dhofar. Sultan Sa'īd ibn Taymūr had moved to Ṣalālah permanently in 1958. The mountain *jibālīs* began to rebel openly against Sultan Sa'īd's petty restrictions in the mid-1960s. The Marxist Popular Front for the Liberation of the Occupied Arab Gulf (later the Popular Front for the Liberation of Oman; PFO) gained control of the growing rebellion in 1968, with the help of neighbouring Marxist South Yemen (which gained independence from the British in late 1967) and first Chinese and then Soviet assistance. The seriousness of the Dhofar rebellion was a principal factor in the palace coup of July 23, 1970, which saw Sultan Sa'īd overthrown by his son, Qābūs ibn Sa'īd.

Qābūs, who had been trained in Britain at the Royal Military Academy, Sandhurst, quickly reversed his father's policy of isolation and set about to develop Oman. Additional British personnel and equipment were brought into the Sultan's Armed Forces to help put down the rebellion in Dhofar, and these efforts were aided by Jordanian and especially Iranian troops. The plain around Ṣalālah was gradually freed from the threat of attack, the mountains were cleared of rebel activity, and the rebellion was crushed by late 1975.

In late 1970 Sultan Qābūs appointed the country's first true cabinet and took steps toward building a modern government structure. Qābūs first appointed his uncle Ṭāriq ibn Taymūr as prime minister, but he subsequently served as his own prime minister and as minister of defense and foreign affairs also. The Āl Bū Sa'īd are less heavily represented in government positions than other ruling families elsewhere in the Gulf.

Oman joined the Arab League and the United Nations in 1971 but declined to join either the Organization of Petroleum Exporting Countries (OPEC) or the smaller Organization of Arab Petroleum Exporting Countries (OAPEC). It was one of six founding members of the Gulf Cooperation Council, established in 1981 to promote cooperation in economic, political, and security matters among its members. Oman has been closely linked to Britain since the early 19th century, and relations with the United States, established in 1833, have grown close since the early 1970s.

Diplomatic relations were established with neighbouring Yemen (Aden) in 1983 and the Soviet Union in 1985. Oman's location gives it a particular interest in the safety of traffic through the Strait of Hormuz, and Oman attempted to maintain neutrality in the Iran–Iraq war.

For later developments in the history of Oman, see the *Britannica Book of the Year* section in the BRITANNICA WORLD DATA ANNUAL.

Qatar

The State of Qatar (Arabic: Dawlat Qaṭar) is an independent emirate on the west coast of the Persian Gulf.

It occupies a desert peninsula that extends from the Arabian mainland north of southern Saudi Arabia and the United Arab Emirates. Its area is about 4,400 square miles (11,400 square kilometres), including a number of small islands nearby in the Persian Gulf. The capital is Doha (ad-Dawḥah) on the east coast, once a centre of pearling activity.

PHYSICAL AND HUMAN GEOGRAPHY

The land. The Qatar peninsula is about 100 miles (160 kilometres) from north to south and 50 miles from east to west. Most of its area is flat desert, but hills rise to about 130 feet (40 metres) along the western coast. Sand dunes and salt flats are the chief topographical features of the southern sector. Vegetation is found only in the north.

Doha, on the east coast, is Qatar's largest city and its commercial centre. It has a deepwater port and an international airport. The main oil port and industrial centre is Musay'id (Umm Sa'id), to the south of Doha on the eastern coast. Dukhān, on the western coast, is the country's third major urban area. These three cities and many smaller settlements are linked by road.

The climate is hot and humid from June to September, with temperatures as high as 104° F (40° C). The spring and fall months—April, May, October, and November—are temperate. Rainfall is scarce.

The people. Qatar was originally settled by nomads from the central part of the Arabian Peninsula. Native Qataris, most of whom are Sunnite Muslims, constitute only about one-fifth of the total population. About one-third of the population is of South Asian origin, largely Pakistani; almost one-fifth are Iranian (mostly Shi'ite Muslims); and about one-fourth are other Arabs. Few nomads remain, and only about 10 percent of the people live in rural areas. Of the total work force, some 90 percent is expatriate. Arabic is the official language, and the official religion is Islām.

The economy. Qatar's economic prosperity is derived from oil, which was discovered there in 1939 and was first produced in 1949. Before then, lacking any significant merchant class and any economic occupation apart from pearling, fishing, and some trade, Qatar's population was one of the poorest anywhere in the world. By the 1970s, however, the native Qataris enjoyed one of the highest per capita incomes in the world.

The original oil concession was granted to the Iraq Petroleum Company (IPC), comprising European and American companies. This and later concessions were nationalized in the 1970s. While the state-owned Qatar General Petroleum Corporation oversees oil operations, the private corporations continue to play an important role as service companies.

Resources. Qatar's oil reserves, found both onshore along the western coast and offshore from the eastern coast, are modest, especially by the standards set elsewhere in the region, and are expected to last only until the second or third decade of the 21st century (assuming a constant rate of production equal to that of the mid-1980s). By conservative estimate the country's gas reserves amount to 4 percent of the world's total.

Industry. To assure its future prosperity Qatar has sought to diversify its economy through industrialization. Most of the industrial sector comprises large firms of mixed state and foreign private ownership. For example, the Qatar Iron and Steel Company is co-owned by the Qatari government and two Japanese companies, which constructed the plant and took responsibility for production, marketing, and exporting. Flour milling and cement production have also been undertaken. Because the diversification is dependent for its success on the abundance of cheap energy to run the plants, it is tied to Qatar's hydrocarbon resources. Thus the future economic development and prosperity of the country are largely dependent upon exploitation of the enormous offshore natural gas reserves of the Northwest Dome, beneath the Persian Gulf.

Agriculture. The scarcity of fertile land and water imposes severe limitations on agriculture, and most food must be imported. Use of treated sewage effluent and desalinated water have helped expand production of fruits,

Saudi
occupation

National-
ization of
oil industry

such as dates and melons, and of vegetables, such as tomatoes, squash, and eggplants. Meat and milk production have grown, and some efforts at modernizing the fishing industry have been made. Food production generates only about 1 percent of the gross domestic product.

Trade and finance. In the mid-1970s Japan supplanted Britain as Qatar's chief source of imports. The chief purchasers of Qatari exports are Japan, France, and Singapore. Other major markets for and suppliers of goods include Italy, The Netherlands, the United States, and Australia. Machinery and transport make up the largest category of imports, and crude petroleum accounts for more than 90 percent of exports.

The Qatar National Bank provides banking functions for the state; other banks are authorized to operate. Qatar has been generous in its foreign aid disbursements, particularly to other Arab and Islāmic countries.

Administration and social conditions. *Government.* Qatar is ruled by a hereditary emir who presides over a patriarchal political system that resembles a traditional monarchy. In large measure the country's political stability is made possible by the homogeneous nature of the native Qatari population. Moreover, several hundred male members of the ruling family, the Āl Thānī, dominate politics, and the Āl Thānī make up perhaps as much as 40 percent of the native Qatari population. Succession is within the family but not necessarily from father to son, and the emir's power is constrained principally by the need to maintain the support of important members of the family.

The constitution, originally adopted in 1970 and revised since, formally divides the government into branches, explicitly naming the executive and the judiciary. The constitution includes the legislative process among the functions of the emir. The emir appoints a council of ministers to manage the affairs of state and an advisory council to assist him in drafting and promulgating laws. Civil and criminal codes were introduced in 1971, and all civil and criminal cases fall within the purview of a system of secular courts. The Islāmic (Shari'ah) courts are based on the interpretation of the Qur'an and the sunna (customs derived from the sayings and actions of the Prophet Muḥammad), which narrowly and rigidly defines the scope and application of the religious law. The jurisdiction of the Shari'ah courts in Qatar is now essentially confined to personal and family matters.

Qatar is a member of the Organization of Petroleum Exporting Countries (OPEC), the Organization of Arab Petroleum Exporting Countries (OAPEC), and the Arab League; membership in the Gulf Cooperation Council (GCC) links it closely to its fellow Arab Gulf states—Kuwait, Saudi Arabia, Bahrain, the United Arab Emirates, and Oman. In issues concerning the Gulf region and in wider issues, as in its foreign policy generally, Qatar maintains a low profile, generally steering a neutral political course and not taking a lead in regional issues. Although Qatar has a small defense force of about 6,000 men, for security against external threat it must depend on the protection of others. It follows very closely the lead of Saudi Arabia on most issues, in part because, like Qatar, Saudi Arabia adheres to the conservative Ḥanbali school of Islāmic jurisprudence.

Education. Education is free and compulsory for all residents, citizens and noncitizens alike. Six years of primary school, three years of intermediate school, and three years of secondary school are required in both government-run and private schools. Classes are segregated by sex.

Qatar spends generously on education, and its system has expanded rapidly. Two teacher-training colleges, one for men and one for women, were founded in 1973, and together they were given university status in 1977. The university has continued to expand, and a new campus was completed in 1985 in Doha.

The government also provides adult education classes in schools and centres throughout the country, with an emphasis on increasing adult literacy. The country's literacy rate is estimated to be about 50 percent.

Health and welfare. Health care and medical services are provided free to all residents through government

programs. The government also funds recreational and cultural clubs and facilities for young people as part of its extensive "youth welfare" campaign.

Cultural life. Several agencies and departments oversee literary, artistic, and cultural activities as well as recreation and tourism. The Qatar National Museum, in Doha, includes displays of the country's history and archaeology, a lagoon in which Qatari sailing and pearling vessels are displayed, and a museum of the sea.

The government sponsors the fine arts, traditional arts and crafts, theatre, music, publishing, and libraries through various programs. Government-owned radio and television stations broadcast in Arabic, English, French, and Urdu. Several local daily newspapers and weekly publications are available.

For statistical data on the land and people of Qatar, see the *Britannica World Data* section in the BRITANNICA WORLD DATA ANNUAL.

HISTORY

Up to the latter part of the 19th century the Khalifah family (Āl Khalifah), the ruling family of Bahrain, dominated Qatar. In 1868 leading families of the country requested negotiations with the British to end this relationship in exchange for an enlarged British protective role. In 1871 the son of the ruling sheikh invited the Ottoman Turks into Doha. He subsequently thwarted Turkish attempts to place Qatar under their administration, and in the Anglo-Turkish Convention of 1913 the Ottoman Empire gave up any rights to Qatar. In the course of the 19th century the Āl Thānī established their rule, and in 1916 they concluded a treaty with Britain that prohibited the ruler from entering into any relationships with other foreign governments without British consent. The British government in return was obliged to protect Qatar from maritime attack and to help the country to defend itself against an attack by land. A treaty signed in 1934 amplified the British guarantees of protection. Until independence in 1971, and after, British political, military, and financial advisers played a key role in the country's development.

Even before independence Qatar had begun to play a role in the international arena. It joined OPEC in 1961 and became a member of OAPEC in 1970. In 1968 the British government announced plans to withdraw from its defense commitments east of Suez, which meant that Britain would be ending its protective relationship with Qatar and its neighbours. Discussions were held to promote the concept of a union of nine states—the seven Trucial States, plus Bahrain and Qatar. Jealousies and suspicions prevented the realization of the union, though Qatar's constitution (with subsequent amendments) remains the one designed to serve a federation of nine. On Sept. 1, 1971, Qatar declared its independence, and the earlier agreements with Britain were replaced with a treaty of friendship. Later in that same month Qatar joined the Arab League and the United Nations. In 1981 it joined its five Arab Gulf neighbours in establishing the Gulf Cooperation Council, an alliance formed to promote economic cooperation and to enhance both internal security and external defense against the threats generated by the Islāmic revolution in Iran and the Iran-Iraq war.

For later developments in the history of Qatar, see the *Britannica Book of the Year* section in the BRITANNICA WORLD DATA ANNUAL. (J.D.An.)

Saudi Arabia

The Kingdom of Saudi Arabia (Arabic: al-Mamlakah al-'Arabiyyah as-Sa'ūdiyyah) has an estimated area of 865,000 square miles (2,240,000 square kilometres), occupying about four-fifths of the Arabian Peninsula. It is bordered by Jordan, Iraq, and Kuwait to the north; by the Persian (Arabian) Gulf, Qatar, the United Arab Emirates, and Oman on the east; by a portion of Oman on the southeast; by Yemen on the south and southwest; and by the Red Sea and the Gulf of Aqaba on the west. Portions of the borders with the United Arab Emirates, Oman, and Yemen are undefined. A territory of 2,200 square miles along the Gulf coast was shared by Kuwait and Saudi Arabia as a

The Āl
Thānī

Bahraini
dominance

neutral zone until 1969, when a political boundary was agreed upon. Each of the two countries administers one-half of the territory, but they equally share oil production in the entire area. The capital is Riyadh. Saudi Arabia is named for the house of Sa'ūd, the founding and ruling dynasty that dates from the 18th century.

Saudi Arabia is a Muslim and an Arab state, and these two attributes have had a fundamental influence on the country's foreign relations. It is a founding member of the Arab League (1945) and of the Organization of the Islamic Conference (1971). The kingdom exhibits a certain aloofness to outsiders: a foreigner can secure a visa to visit it only if invited by an individual or an organization within the country. Once inside, a visitor encounters a pervading sense of independence and pride. The extraordinary economic changes that occurred starting in the 1960s altered neither the government nor the centrality of religion.

Since the mid-20th century, however, the pace of life in Saudi Arabia has accelerated greatly. Mecca and Medina, the two holiest cities of Islām, have always provided the country with outside contacts, and such contacts have expanded with innovations in transportation technology and organization. More recently, petroleum has wrought irreversible domestic changes—educational and social as well as economic. Modern industrial skills, technology, and methods of organization have been superimposed on a traditional society by the introduction of millions of foreign skilled workers and by the employment of hundreds of thousands of Saudis in nontraditional jobs. In addition, tens of thousands of Saudi students have studied abroad, mostly in the United States. Television and radio have become common media of communication and education. Highways and airways have replaced traditional means of transportation, notably the camel caravan.

PHYSICAL AND HUMAN GEOGRAPHY

The land. *Relief.* The Arabian Peninsula is dominated by a plateau that rises abruptly from the Red Sea and dips gently toward the Persian Gulf. In the north the western highlands are upward of 5,000 feet (1,500 metres) above sea level, decreasing slightly to 4,000 feet in the vicinity of Medina and increasing southeastward to more than 10,000 feet. The watershed of the peninsula is only 25 miles (40 kilometres) from the Red Sea in the north, receding to 80 miles near the Yemen (Ṣan'ā') border. The coastal plain, known as Tihāmāh, is virtually nonexistent in the north, except for occasional wadi deltas, and it widens slightly toward the south. Wadis flowing to the Red Sea are short and steep, though one unusually long extension is made by Wadi al-Ḥamḍ, which rises near Medina and flows inland to the northwest for 100 miles before turning westward. The imposing escarpment that runs parallel to the Red Sea is somewhat interrupted by a gap northwest of Mecca but becomes more clearly continuous to the south.

Toward the interior, the surface gradually descends into the broad plateau area of the Najd, covered with lava flows and volcanic debris as well as with occasional sand accumulations; it slopes down from an elevation of about 4,500 feet in the west to about 2,500 feet in the east. There the drainage is more clearly dendritic (*i.e.*, branching) and is much more extensive than that flowing toward the Red Sea. To the east, this region is bounded by a series of long, low ridges, with steep slopes on the west and gentle slopes on the east; the area is 750 miles long and curves eastward from north to south. The most prominent of the ridges are the Ṭuwayq Mountains (Jabal Ṭuwayq), which rise from the plateau at an elevation of some 2,800 feet above sea level and reach a height of more than 3,500 feet southwest of Riyadh, overlooking the plateau's surface to the west by 800 feet and more.

The interior of the Arabian Peninsula contains extensive sand surfaces. Among them is the world's largest sand area, the Rub' al-Khali (the Empty Quarter), which dominates the southern part of the country and covers more than 250,000 square miles. It slopes from above 2,600 feet near the border with Yemen (Ṣan'ā') northeastward down almost to sea level near the Persian Gulf; individual sand mountains reach heights of 800 feet, especially in the eastern part. A smaller sand area of about 22,000 square

miles, called an-Nafūd (*nafūd* designating a sandy area or desert), is in the north central part of the country. A great arc of sand, ad-Dahnā', almost 900 miles long but in places only 30 miles wide, joins an-Nafūd with the Rub' al-Khali. Eastward, as the plateau surface slopes very gradually down to the Gulf, there are numerous salt flats (*sabkha*s) and marshes. The Gulf coastline is irregular, and the coastal waters are very shallow.

Drainage. There are virtually no permanent surface streams in the country, but wadis are numerous. Those leading to the Red Sea are short and deep, but those draining eastward are longer and more developed except in an-Nafūd and the Rub' al-Khali. Soils are poorly developed. Large areas are covered with pebbles of varying sizes. Alluvial deposits are found in wadis, basins, and oases. Salt flats are especially common in the east.

Climate. Climatically, the kingdom is almost entirely a desert. In winter, cyclonic weather systems generally skirt north of the Arabian Peninsula, moving eastward from the Mediterranean, though sometimes they reach eastern and central Arabia and the Gulf. Some weather systems move southward along the Red Sea trough and provide winter precipitation as far south as Mecca and sometimes as far as Yemen (Ṣan'ā'). In March and April some rain, normally torrential, falls. In summer the highlands of Asir (ʿAsīr), southeast of Mecca, receive enough rain from the monsoonal winds to support a steppelike strip of land.

Winters, from December to February, are cool, and frost and snow may occur in the southern highlands. Average temperatures for the coolest months, December through February, are 74° F (23° C) at Jiddah, 58° F (14° C) at Riyadh, and 63° F (17° C) at ad-Dammām. Summers, from June to August, are hot, with daytime temperatures in the shade exceeding 100° F (38° C) in almost all of the country. Temperatures in the desert frequently rise as high as 129° F (54° C) in the summer. Humidity is low, except along the coasts, where it can be high and very oppressive. Precipitation is low throughout the country, amounting to about 2½ inches (64 millimetres) at Jiddah, a little more than three inches at Riyadh, and three inches at ad-Dammām. These figures, however, represent mean annual precipitation, and large variations are normal. In the highlands of Asir more than 19 inches a year may be received, falling mostly between May and October when the summer monsoon winds prevail. In the Rub' al-Khali a decade may pass with no rain at all.

There are three climatic zones: (1) desert almost everywhere, (2) steppe along the western highlands, forming a strip less than 100 miles wide in the north but becoming almost 300 miles wide at the latitude of Mecca, and (3) a very small area of humid and mild temperature conditions, with long summers, in the highlands just north of Yemen (Ṣan'ā').

Plant and animal life. Much of Saudi Arabia's vegetation belongs to the North African–Indian desert region. Plants are xerophytic and are mostly small herbs and shrubs that are useful as forage. There are a few small areas of grass and trees in southern Asir. The date palm (*Phoenix dactylifera*) is widespread, though about one-third of the date palms grown are in ash-Sharqīyah province.

Animal life includes the wolf, hyena, fox, honey badger, mongoose, porcupine, baboon, hedgehog, hare, sand rat, and jerboa. Larger animals such as the gazelle, oryx, leopard, and mountain goat were relatively numerous until about 1950, when hunting from motor vehicles reduced these animals almost to extinction. Birds include falcons (which are caught and trained for hunting), eagles, hawks, vultures, owls, ravens, flamingos, egrets, pelicans, doves, and quail, as well as sand grouse and bulbuls. There are several species of snakes, many of which are poisonous, and numerous types of lizards. There is a wide variety of marine life in the Gulf. Domesticated animals include camels (now little used for transportation), fat-tailed sheep, long-eared goats, salukis, donkeys, and chickens.

Settlement patterns. Four traditional regions stand out—the Hejaz, Asir, Najd, and al-Ḥasa (transliterated more precisely as al-Hijāz, ʿAsīr, Najd, and al-Aḥsā'). The Hejaz, in the northwest, contains the two holiest cities of Islām, Mecca and Medina, as well as the kingdom's

the
Tihāmāh

the Empty
Quarter

Three
climatic
zones

primary port and diplomatic centre, Jiddah. Asir is the highland region south of the Hejaz; its capital, Abhā, lies at an elevation of about 8,000 feet. Subregions in Asir are formed by the oasis cluster of Najrān—a highland area north of Yemen (Ṣan'ā')—and by the coastal plain, the Tihāmah. Najd occupies a large part of the interior and includes the capital, Riyadh. Al-Hasa is in the east along the Persian Gulf; the region includes the principal petroleum-producing areas.

Nomadism, the form of land use with which the kingdom is traditionally associated, has become virtually nonexistent, and the pattern of extensive land use traditionally practiced by the nomadic Bedouin has been supplanted by the highly intensive patterns of urban land use. More than 70 percent of Saudi Arabia's total population lives in cities, and almost all of the rest lives in government-supported agricultural enterprises.

Irrigation

Less than 1 or 2 percent of the total land area is used for crops. Of the cultivated land about 45 percent is worked by rain-fed dry farming (mostly in Asir), 40 percent is in tree crops, and the remainder is irrigated. Most of the irrigated areas, in the districts of Riyadh and al-Qaṣīm, for example, and near al-Hufūf in ash-Sharqiyah province, utilize underground water.

The largest towns are cosmopolitan in character, and some are associated with dominant functions: Mecca and Medina are religious, Riyadh is political and administrative, and Jiddah is commercial and diplomatic. Dhahran (aḏ-Zahrān), near the Persian Gulf coast in ash-Sharqiyah province, is the administrative centre of the Arabian American Oil Company (Aramco), and nearby al-Khubar and ad-Dammām are important commercial coastal towns. Al-Jubayl on the Gulf and Yanbu' on the Red Sea are the terminus points of oil and gas pipelines, and large petrochemical industrial complexes are located there.

The people. *Language.* Arabic is a Semitic language. It originated in Arabia, where the language is presumed to be the "purest." Classical written Arabic is standard throughout the Arab world, while spoken Arabic varies considerably. Such colloquial variations are evident even within Saudi Arabia—in part because of the strength of traditional group allegiances and in part because of varying external influences in different parts of the kingdom. English is widely understood.

Ethnic homogeneity

Ethnic groups. Considerable ethnic homogeneity is evident. Saudi nomads are "pure" Arabs, or at least descendants therefrom. As in the case of language, variations have developed because of a long history of regionalism and tribal autonomy and because some localities have been subjected to important outside influences. Thus, the influence of black Africa is evident along the Red Sea littoral, and influences from Iran, Pakistan, and India in the east.

An increasing number of outsiders enter and leave Saudi Arabia. By the late 1980s the estimated number of foreign workers was between one-fourth and one-fifth of the country's total population. At first most of these were Arab, such as Yemenis, Egyptians, Palestinians, Syrians, and Iraqis. Increasing numbers of non-Arab Muslims such as Pakistanis have been employed, as have large numbers of non-Muslim Koreans and Filipinos who are hired in group contracts for specified periods. Among specialized technical workers, most are Europeans and Americans. Also of note is the number of people making the annual pilgrimage (hajj) to Mecca. By the late 1980s the number approached 2,500,000 a year, of whom about half traveled from Arab countries and half from African and Asian countries.

Religion. Saudi Arabia is the home of Islām, and its native population is almost entirely Sunnite Muslim (*i.e.*, adhering to the chief branch of Islām, Sunnism [Sun-nah], called traditionalist or orthodox). The Wahhābī interpretation of Sunnite Islām is the one officially used. Wahhābism, as it is called in the West, is a puritanical interpretation and is named after Muḥammad ibn 'Abd al-Wahhāb (1703–92). Islām is a political as well as a religious system, and it is the source of the government's legitimacy. The king upholds Islām, applies its precepts, and is subject to them.

Shī'ites, who are adherents of Shī'ism, the second major branch of Islām, make up about 4 percent of the population and are found mostly in the oases of al-Hasa and al-Qaṭīf. The only Christians are foreign industrial employees and businessmen. Public worship and display of non-Muslim faiths is prohibited.

Demography. Saudi Arabia's birth and death rates are, respectively, 42 per 1,000 and 12 per 1,000, giving an annual natural increase of about 3 percent. Infant mortality is about 110 per 1,000 live births, and life expectancy at birth is 61 years. About 45 percent of the population is under 15 years of age, and 4 percent is 60 years or older. The government's pro-natal policy prohibits the use of birth control measures.

The major areas of population are in the central Hejaz, in Asir, in central Najd, and near the Persian Gulf. The largest cities include Riyadh, Jiddah, Mecca, aṭ-Ṭā'if, Medina, ad-Dammām, al-Hufūf, Tabūk, Buraydah, al-Mubarrāz, Khamis Mushayt, al-Khubar, Najrān, Ḥā'il, Jizān, and Abhā.

The economy. Long-range economic development is directed through the implementation of five-year plans. In contrast to most developing countries, in Saudi Arabia there is an abundance of capital. The first two five-year plans (1970–80) established most of the country's basic transport and communications facilities. Subsequent objectives were to diversify the economy (including the development of agriculture-based industry, such as flour milling); to reduce dependence on foreign labour (especially at the management level); to increase domestic food production; to improve education, vocational training, and health services; and to further connect the different regions of the country. Industrial development is centred on the towns of al-Jubayl on the Persian Gulf and Yanbu' on the Red Sea coast, both of which are part of a plan to use natural gas to fuel industries.

Resources. The economy of Saudi Arabia is dominated by petroleum and its associated industries. In terms of oil reserves, Saudi Arabia ranks first, with almost one-fourth of the world's known reserves.

Oil deposits are located in the east, southward from Iraq and Kuwait into the Rub' al-Khali and under the waters of the Persian Gulf. Other mineral resources are known to exist, and the government has pursued a policy of exploration and production in order to diversify the economic base. Geologic reconnaissance mapping of the Precambrian shield in the west has revealed deposits of gold, silver, copper, zinc, lead, iron, titanium, pyrite, magnesite, platinum, and cadmium. There are also non-metallic resources such as limestone, silica, gypsum, and phosphorite. Forest and rangeland resources are limited, the former covering a total of only about 600 square miles, mostly in Asir.

Non-petroleum mineral resources

Agriculture. The Kingdom of Saudi Arabia inherited the simple, tribal economy of Arabia. Many of the people were nomads, engaged in raising camels, sheep, and goats. Agricultural production was localized and subsistent. Domestic food production has been given special attention in the kingdom's development planning, and the government has made subsidies and generous incentives available to the agriculture sector. In the mid-1980s more than 50 percent of the native Saudi work force continued to be employed in agriculture, and agriculture contributed about 4 percent of the gross domestic product.

The kingdom has achieved self-sufficiency in wheat, eggs, and milk, among other items, though it still imports about 70 percent of its food needs. Wheat is the primary cultivated crop, followed by sorghum, barley, and millet. Watermelons, tomatoes, dates, grapes, onions, and pumpkins and squash are also important crops.

Two major constraints to cultivation are poor water supply and poor soil. Concrete and earth-filled dams have been built, primarily in the southwest, to provide irrigation. Agricultural expansion has been great in irrigated areas, while the amount of land given to rain-fed farming has decreased. Substantial resources of subterranean water have been discovered in the central and eastern parts of the country. Desalinization of sea water is almost entirely for urban and industrial uses. Riyadh's water supply, for

example, is augmented by a pipeline from a desalinization plant in al-Jubayl on the Gulf.

Discovery
of oil

Industry. The discovery of oil changed the entire economic situation of Saudi Arabia. As early as 1923 Ibn Sa'ūd granted an oil-prospecting concession to a British company, but this concession was never exploited. Although oil was discovered in 1938, World War II curtailed activities until near its end. The Ras Tanura refinery was opened in 1945, and rapid expansion of the oil industry followed because of the increasing postwar demand.

In 1951 the Arabian American Oil Company (Aramco) discovered the first offshore field in the Middle East, at Ra's as-Saffāniyah, just south of the Saudi Arabia-Kuwait neutral zone, and oil was discovered in the zone itself in 1953. Al-Ghawār, just south of Dhahran and west of al-Hufuf, is the world's largest oil field. The first portion of the al-Ghawār oil field was discovered at 'Ain Dār in 1948. Intensive exploration of the Rub' al-Khali began in 1950, and oil fields were discovered there in the 1970s.

In 1950 Aramco put into operation the Trans-Arabian Pipe Line (Tapline), which ran from al-Qaysūmah in Saudi Arabia across Jordan and Syria to its Mediterranean terminal at Sidon, Lebanon. The line was in operation only sporadically during the 1970s, and in 1983 it ceased to function beyond supplying a refinery in Jordan. In 1981 Petroline, built to carry crude oil, was completed from al-Jubayl on the Persian Gulf to Yanbu' on the Red Sea, greatly shortening the distance to Europe and obviating navigation through the Gulf and the Strait of Hormuz. Petroline was built by the General Petroleum and Mineral Organization (Petromin), a government-owned corporation. Aramco constructed a massive gas-gathering system and, parallel to Petroline, a pipeline for transporting natural-gas liquids, which reached Yanbu' in 1981.

During the 1970s and early '80s Saudi Arabia gradually acquired complete ownership of Aramco, and in 1984 Aramco had its first Saudi president. In terms of production Saudi Arabia is surpassed only by the Soviet Union and the United States.

The manufacturing sector has expanded widely. Manufactures include rolled steel, petrochemicals, fertilizers, pipes, copper wire and cable, truck assembly, refrigeration, plastics, aluminum products, metal products, and cement. Small-scale enterprises include baking, printing, and furniture manufacturing.

Finance. The Saudi Arabian Monetary Agency (SAMA) was established in 1952 as the kingdom's central money and banking authority. It regulates commercial and development banks and other financial institutions. Its functions include issuing and regulating money supply, stabilizing the value of currency, acting as banker for the government, and managing foreign reserves and investments. As an Islāmic institution its status is nonprofit. Under Islāmic law banks cannot charge interest, but they do charge fees for lending and they pay commission on deposits. Money supply and the tempo of business are dominated by government economic activity, though the government favours expansion of the private sector. Saudi Arabia is one of the world's largest lenders in terms of foreign aid and development assistance.

Trade. Exports consist almost entirely of petroleum and petroleum products. Major imports are machinery and appliances, foodstuffs and tobacco, transport equipment, textiles and clothing, metals and metal articles, and chemicals. The principal destinations of exports are Japan, the United States, Italy, France, and The Netherlands. The principal sources of imports are the United States, Japan, West Germany, Italy, the United Kingdom, and Taiwan.

oads

Transportation. About one-third of the country's roads are paved. The first coast-to-coast road connection, from ad-Dammām on the Gulf to Jiddah on the Red Sea, by way of Riyadh, was opened in 1967; it includes a spectacular descent of the western escarpment from at-Tā'if to Mecca. Other important connections are from Riyadh northwestward through Najd to Hā'il, from Riyadh southwestward to the Najrān region, between central Najd and Medina, from Medina northwestward through Tabūk to Jordan, from Medina westward and southward to Yanbu' and Jiddah, along the length of the Red Sea coast between

the borders of Jordan and Yemen; from at-Tā'if southeastward along the edge of the plateau to the Najrān by way of Abhā, and from ad-Dammām on the Gulf northwestward along the Tapline to Jordan. A railroad passing through al-Hufuf connects Riyadh and ad-Dammām. A causeway, opened in 1986, connects the kingdom with the island nation of Bahrain.

Seaport capacity has been greatly expanded. Major cargo ports are Jiddah, Yanbu', and Jizān on the Red Sea and ad-Dammām and al-Jubayl on the Gulf. The country has many small airports, of which fewer than half have paved runways. The national airline, Saudia, provides both domestic and international service. The chief international airports are at Dhahran, Riyadh, and Jiddah.

Administration and social conditions. *Government.* Saudi Arabia's government is based on the law of Islām, the Shari'ah, derived from Muḥammad's pronouncements and practices and from the traditions of Islām's first adherents. Muslim law prescribes civil as well as religious rights, duties, obligations, and responsibilities for both ruler and ruled. Law is revealed and not created, and it is interpreted by the ulama, or learned religious men.

The person of the king combines legislative, executive, and judicial functions. As prime minister he presides over the Council of Ministers. This council is a legislative body, although it is also responsible for such executive and administrative matters as foreign and domestic policy, defense, finance, health, and education, which it administers through numerous separate agencies. Appointment to and dismissal from the council are prerogatives of the king. Major policy decisions are made by consensus, and opinion is sought primarily within the royal family (comprising the numerous descendants of the kingdom's founder, Ibn Sa'ūd). Many members of the royal family hold sensitive government posts.

Succession to the throne is not hereditary; the crown prince, who also serves as deputy prime minister, is designated by the royal family with the support of the ulama and the Council of Ministers. The same consultative process also designates the second deputy prime minister, who is the second heir apparent after the deputy prime minister.

The kingdom is divided into administrative regions, which in turn are divided into districts. Provincial governors are appointed and are responsible for such functions as finance, health, education, agriculture, and municipalities. The consultative principle operates at all levels of government, including the government of villages and tribes.

Justice. The Shari'ah law is the basis of justice. Judgment usually is according to the Ḥanbali tradition of Islām; the law tends to be conservative and punishment severe. In 1970 the Ministry of Justice was established; its work is assisted by a Supreme Judicial Council consisting of leading members of the ulama. There are more than 300 Shari'ah courts across the country. Rapid changes since the mid-20th century have produced circumstances—such as traffic violations and industrial accidents—not encompassed by traditional law, and these have been handled by the issuance of royal decrees. These decrees have evolved into a body of administrative law. Avenues of appeal are available, and the monarch is both the final court of appeal and the dispenser of pardon.

The armed forces. Military service is voluntary. The army accounts for about three-fifths of the total military force. It experienced rapid modernization especially after the Arab-Israeli war of 1967. Army officers are trained at King 'Abd al-Aziz Military Academy just north of Riyadh. The air force was equipped largely by the British until the 1970s, when the kingdom began to buy aircraft from the United States. Major air bases are at Riyadh, Dhahran, Ḥafar al-Bāṭin (part of the King Khālid Military City) near the border with Iraq and Kuwait, Tabūk in the northwest near Jordan, and Khamis Mushayṭ in the southwest near Yemen (Ṣan'ā'). All three armed services are directed by the defense minister, who is also the second deputy prime minister. The National Guard is essentially an internal security force, though it can support the regular forces for national defense. One of its primary peacetime tasks is to guard the country's oil fields. It is administered separately and its commander

The
monarchy

reports to the crown prince. The armed forces employ expatriate personnel in support and training positions.

Education. Education is free at all levels and is given high priority by the government. The school system consists of elementary (grades 1–6), intermediate (7–9), and secondary (10–12) schools.

Expansion
in higher
education

Higher education has expanded at a remarkable pace. Institutions of higher education include the King Sa'ūd University (formerly the University of Riyadh, founded in 1957), the Islāmic University (1961) at Medina, and the King 'Abd al-'Azīz University (1967) in Jiddah. Other institutes include the Higher Institute of Technology, the Higher Juridical Institute, the King 'Abd al-'Azīz Military Academy, the College for the Arabic Language, the Technical Institute, and the College of Islāmic Jurisprudence, all at Riyadh; the King Fahd University of Petroleum and Minerals at Dhahran; the School of Hadith (narrative traditions), the Shari'ah College of Islāmic Jurisprudence, and the Saudi Arabian Institute for Higher Education, all at Mecca; the School of Applied Arts and the Teacher Training Centre, both at Medina; and schools of industrial education at Riyadh, Jiddah, Medina, and ad-Dammām. Institutes for religious teaching are located in several towns. A college of medicine has been started in Jiddah. Many foreign teachers are employed, especially in technical and medical schools. Large numbers of students enroll in overseas universities.

Health and welfare. A great deal of attention has been given to health care since the 1970s. Between 1970 and 1980 the numbers of hospital beds, physicians, and nurses increased greatly. During the 1980s budgets made provision for the construction of many additional health institutes, hospitals, and health centres and the hiring of additional medical staff. A network of dispensaries serving communities of 10,000 or more persons is complemented by a system of mobile health services to reach small communities and the remaining nomadic populations. The government has also begun to train Saudis to replace foreign medical personnel. Of serious concern are a high rate of trachoma and occasional outbreaks of malaria, bilharzia, and cholera.

Nomads,
villagers,
and towns-
people

Saudi Arabia's population has traditionally been composed of nomads, villagers, and townspeople. Pervading this triad, however, is the patrilineal kinship principle, and superimposed on all is the administrative organization centred on the royal family. The kinship principle is pervasive in Saudi society, and the extended family is a strong social unit. Villages constitute local service centres and contain representatives from more than one tribal affiliation, though one group may tend to be dominant. Cities are not tribally organized, though the importance of kinship affiliation endures and local affairs tend to be dominated and administered by a few families. Social stratification is more clearly developed in the cities than elsewhere. Before the effects of oil were felt on the economy, status was a matter of lineage and occupation rather than of wealth; with the development of the oil industry, however, wealth and material position have acquired an additional social value. The new technology and industry have produced a growing middle-income economic group of technocrats that is increasingly aware of the widening gap between the ruling families and the rest of the population.

Cultural life. The cultural setting is Arab and Muslim. To preserve the country's purist religious position, many proscriptions of behaviour and dress are enforced. Alcoholic beverages are prohibited, for example, and the theatre and public cinema do not exist. Educated Saudis are well informed on issues of the Arab world, the Muslim world, and the world at large, but public expression of opinion about domestic matters is not encouraged. There are no public forums such as political parties or labour unions.

For a thousand years artistic expression usually perpetuated ancient forms. From the 18th century onward the strict Wāhhābī religious outlook discouraged intellectual deviation from accepted purist positions. With the advent of the petroleum industry came exposure to outside influences, such as housing styles, furnishings, and clothes, and at the same time local craftsmen found themselves in competition with imported goods.

Music and dance have always been part of Saudi life. Visual arts are dominated by geometric, floral, and abstract designs and by calligraphy, the latter a sophisticated and learned enterprise. Not much diversity is seen in traditional architecture; typical features are decorative designs on doors and windows and wide use of crenellated walls. The wave of change starting in the 1960s influenced architectural styles, and stark linear motifs became common in office and residential buildings. The spectacular airport terminals at Jiddah and Riyadh, however, are testimony to the persistence and worth of traditional styles.

Several daily and weekly newspapers are published in Arabic and in English. Radio and television broadcasting is operated by the Ministry of Information, and there is a modern system of telecommunications.

For statistical data on the land and people of Saudi Arabia, see the *Britannica World Data* section in the *BRITANNICA WORLD DATA ANNUAL*. (B.K.N.)

HISTORY

The Wāhhābī movement. *Origins and early expansion.* Muḥammad ibn 'Abd al-Wāhhāb, the founder of the Wāhhābī movement, was born in 'Uyaynah in 1703 to a family of religious judges and scholars and as a young man traveled widely in the Hejaz, Iraq, and other regions of the Middle East. It was upon his return to 'Uyaynah that he first began to preach his revolutionary ideas of religious reformation on fundamentalist lines. His teaching was influenced by that of the Ḥanbalī scholar Ibn Taymiyah, who had died in 1328.

The ruler of 'Uyaynah, 'Uthmān ibn Mu'ammār, gladly welcomed the returning prodigal and even adhered to his doctrines. But the temper of the people was less complaisant, and 'Abd al-Wāhhāb's preaching was put to a number of severe tests. 'Uthmān received threats from the Banū Khālīd chief of al-Hasa, demanding the death of the innovator on pain of withholding annual gifts from the province, and even of invasion.

'Uthmān, unable to face the risks of financial loss and actual danger but unwilling to kill his guest, decided to dismiss 'Abd al-Wāhhāb from his territory. The exiled 'Abd al-Wāhhāb went to ad-Dir'iyyah, some 40 miles away, which had been the seat of the local prince Muḥammad ibn Sa'ūd since 1726. In 1745 the people flocked to the teaching of the reformer, conducted at first discreetly on the outskirts of the capital. The alliance of theologian and prince, duly sealed by mutual oaths of loyalty, soon began to prosper in terms of military success and expansion.

One by one the enemies of the new dispensation were conquered. The earliest wars brought 'Uyaynah and al-Hasa under Wāhhābī control, but Riyadh and Manfuḥah maintained their stubborn resistance for 20 years before succumbing to the steady pressure of the new movement. By 1765, when Muḥammad ibn Sa'ūd died, much of central and eastern Arabia had fallen under more or less effective Wāhhābī rule.

Muḥammad ibn Sa'ūd's son and successor, 'Abd al-'Azīz I (reigned 1765–1803), who had been largely responsible for this extension of his father's realm by his exploits as commander in chief of the Wāhhābī forces, continued to work in complete harmony with Muḥammad ibn 'Abd al-Wāhhāb. It was indeed the latter who virtually controlled the civil administration of the country, while 'Abd al-'Azīz himself, later in cooperation with his warlike son, Sa'ūd I (reigned 1803–14), busied himself in the expansion of his empire far beyond the limits inherited by him. Meanwhile, in 1792, the venerable Muḥammad ibn 'Abd al-Wāhhāb died at the age of 89. Wāhhābī attacks had begun to attract the attention of the Ottoman government, and in 1798 a Turkish force invaded al-Hasa, though it was compelled to withdraw. Qatar fell to the Sa'ūdīs in 1797, and they also gained control through local allies over Bahrain, many of the Sunnites of coastal Oman, and, temporarily, Muscat.

Struggle with the Ottomans. In 1801 the Wāhhābīs captured and sacked the Shi'ite holy city of Karbalā' in Ottoman Iraq, and in the following year Sa'ūd led his father's army to the capture of Mecca itself in the Ottoman Hejaz. It was soon after his return from this expedition that his father was assassinated by a Shi'ite in the mosque

capture of
Medina

of ad-Dir'iyah in revenge for the desecration of Karbalā'.

The issue was now joined between the Ottomans and the Wahhābīs of Arabia. In 1804 Sa'ūd captured Medina, and the Wahhābī empire embraced the whole of Arabia down to Yemen and Oman. Year after year Sa'ūd visited Mecca to preside over the pilgrimage as the imam of the Muslim congregation. But the tide was soon to turn to his disadvantage. The Sultan of the Ottoman Empire, preoccupied in other directions, consigned to Muḥammad (Meḥmet) 'Alī Pasha, the virtually independent viceroy of Egypt, the task of crushing the "heretics." An Egyptian force landed on the Hejaz coast under the command of Tusun, the youthful son of Muḥammad 'Alī Pasha. Sa'ūd inflicted a severe defeat on the invaders, but reinforcements enabled Tusun to occupy Mecca and Medina in 1812. The following year Muḥammad 'Alī assumed command of the expeditionary force in person. In the east, Britain severely curbed the naval allies of the Wahhābīs in 1809.

Sa'ūd died at ad-Dir'iyah in 1814. His successor, his son 'Abd Allāh ibn Sa'ūd, was scarcely of his father's calibre, and the capture of ar-Ra's in al-Qaṣīm by the Egyptians in 1815 forced him to sue for peace. This was duly arranged, but the truce was short-lived, and in 1816 the struggle was renewed, with Ibrahim Pasha, another of Muḥammad 'Alī's sons, in command of the Egyptian forces. Gaining the support of the volatile tribes by skillful diplomacy and lavish gifts, he advanced into central Arabia. Joined by most of the principal tribes (Harb and 'Utaiba, Mutair and Banū Khālid), he appeared before ad-Dir'iyah in April 1818. Fighting among the palm groves of the Wahhābī capital ended in September with the surrender of 'Abd Allāh, who was sent to Istanbul and there beheaded. Local Wahhābī leaders were executed, ad-Dir'iyah was razed to the ground, and Egyptian garrisons were posted to the principal towns. The Sa'ūdī family had suffered heavy losses during the fighting. A few had managed to escape before the surrender; the rest were sent to Egypt for detention along with descendants of Muḥammad ibn 'Abd al-Wahhāb. The Wahhābī empire ceased to exist, but the faith lived on in the desert in defiance of the new rulers of the land.

The dynasty was restored and the second Sa'ūdī state began in 1824 when Turki (1823–34), a grandson of Muḥammad ibn Sa'ūd, succeeded in capturing Riyadh and expelling the Egyptian garrison. Thereafter, Riyadh remained the capital of the state. Turki tried to maintain friendly ties with the Ottoman governors of Iraq and the British as he accepted nominal Ottoman sovereignty. Al-Hasa and Ḥā'il fell again to the Sa'ūdīs by 1830, as the town militias of central Arabia, which formed the bases of the Sa'ūdī army, overcame the nomadic tribes. Literature, commerce, and agriculture flourished despite the crushing losses to society occasioned by the return of cholera.

In 1834 Turki was murdered by an ambitious cousin, who then was deposed and executed by Turki's son Fayṣal (1834–38; 1843–65). Fayṣal refused to pay the Egyptian tribute; in 1837 an Egyptian expeditionary force entered Riyadh, and Fayṣal was captured in 1838 and sent to Cairo. Khālid, son of Sa'ūd and brother of 'Abd Allāh, was installed as ruler of Najd by the Egyptians. Both Fayṣal and Khālid had been carried away into captivity in Egypt after the fall of ad-Dir'iyah, but the former had escaped in 1828 to rejoin his father and to play a prominent part in the reestablishment of the Wahhābī regime. Khālid had been released from prison to accompany the expeditionary force sent to restore Egyptian rule in Arabia as the ruler designate, on his undertaking to recognize the control by Egypt. So Fayṣal returned to Cairo for a second period of incarceration until his second escape and return to Najd in 1843.

Meanwhile the subservience of Khālid to his Egyptian and Ottoman masters was increasingly resented by his Wahhābī subjects; and in 1841 his cousin, 'Abd Allāh ibn Thunayan, raised the standard of revolt. Riyadh was captured by a bold coup, its garrison was expelled, and Khālid, who was in al-Hasa at the time, fled by ship to Jiddah. 'Abd Allāh resisted when Fayṣal reappeared in 1843, only to be overpowered and slain. So Fayṣal resumed his reign after an interruption of five years, to rule

basically unchallenged, despite occasional tribal uprisings and friction with the townspeople of al-Qaṣīm, until his death in 1865. The Hejaz remained in Ottoman hands, while northern Arabia (the province of Jabal Shammar) was locally autonomous but acknowledged the supremacy of Riyadh. Fayṣal reestablished Sa'ūdī authority in Bahrain for a short time, however, and for a longer time in al-Buraymī and the Oman hinterland. He extended his influence as far as Hadhramaut and the frontiers of Yemen. Only British intervention stopped the extension of direct Sa'ūdī power over the western shore of the Gulf.

Administration under Fayṣal was simple and involved few people, mostly members of the royal family and descendants of Muḥammad ibn 'Abd al-Wahhāb. Justice in the provinces was enforced by officials appointed by Riyadh, even the tribes paid taxes, and the writing of poetry and history flourished.

In 1865, when his power was an acknowledged factor in Arabian politics, Fayṣal died. His sons disputed the succession. His eldest son, 'Abd Allāh, succeeded first, maintaining himself uneasily on the throne against the rebellion of his brother Sa'ūd II for six years until his defeat at the Battle of Judah in 1871. 'Abd Allāh's flight from that field left Sa'ūd in possession, but the next five years saw the throne change hands no fewer than seven times in favour of different members of the Sa'ūdī family. Drought in 1870–74 exacerbated the civil war's effects, as the unity of the Wahhābī community disintegrated. Meanwhile 'Abd Allāh had appealed to the Ottomans in Baghdad, who came to his assistance but took advantage of the situation to occupy the province of al-Hasa for themselves in 1871—an occupation that lasted for 42 years.

The Rashidīs. Sa'ūd II died of wounds in 1875, and after a brief interval of chaos 'Abd Allāh II returned to the throne the following year, only to find himself powerless against Muḥammad ibn 'Abd Allāh ar-Rashīd, whose capital was at Ḥā'il (and of whom Charles Doughty left a brilliant picture in his *Travels in Arabia Deserta*). Ibn Rashīd had succeeded to the throne of his father, the founder of the Rashīdī dynasty, after a short period of anarchy; his accession was marked by the spilling of royal blood on an impressive scale, but he made amends for the bloodbath by the smooth and efficient administration that he succeeded in imposing on his realm.

Ibn Rashīd was undoubtedly the dominant figure in Arabian politics when 'Abd Allāh II ibn Sa'ūd returned to Riyadh for his third spell of authority. At first the Rashīdīs refrained from any forward action, but they soon intervened in the chaotic affairs of the Wahhābī state. And it was not long before 'Abd Allāh was "invited" to be the "guest" of Ibn Rashīd at Ḥā'il, while a representative of the Rashīdīs was appointed governor of Riyadh in 1887. 'Abd Allāh's health began to show serious signs of deterioration, and he was allowed to return to Riyadh and even was named governor of the city in 1889. 'Abd Allāh did not live long in enjoyment of his restoration, however; he died in the same year, leaving to his youngest brother, 'Abd ar-Rahmān, the almost hopeless task of saving the realm of their ancestors.

But 'Abd ar-Rahmān was soon embroiled in senseless hostilities with the Rashīdīs. The Battle of al-Mulaida (in al-Qaṣīm) settled the issue between them decisively in 1891, and for the second time in the space of 70 years the Wahhābī state seemed to be complete destroyed. 'Abd ar-Rahmān fled with his family to take refuge in Kuwait as the guest of its rulers.

At the death of Muḥammad ibn ar-Rashīd in 1897 the throne passed to his nephew, 'Abd al-'Azīz ibn 'Abd Miṭ'ab, who by the turn of the century had alienated the sympathies of all Najd. Meanwhile the son of 'Abd ar-Rahmān, 'Abd al-'Azīz ibn 'Abd ar-Rahmān, was taking full advantage of his enforced sojourn in Kuwait to gain from his host, Sheikh Mubārak aṣ-Ṣabāḥ, a useful knowledge of world politics. In 1901 the young 'Abd al-'Azīz ibn 'Abd ar-Rahmān (he was about 22 to 26 years old) sallied out with a small force of 40 followers on what must have seemed a forlorn adventure. On Jan. 15, 1902, with a select body of only 15 warriors, he scaled the walls of Riyadh, surprised and defeated the Rashīdī governor

and his escort before the gate of the Mismak fort, and was hailed by the population as their ruler.

Ibn Sa'ūd. Thus began a reign destined to be one of the most famous in Arabian history. The following years witnessed the development of the struggle between the Rashidis, whose power was by no means spent and who received substantial help from the Ottomans in men and material, and the restored Sa'ūdī dynasty. In 1904 the combined Rashidī and Ottoman forces were defeated by Ibn Sa'ūd (as 'Abd al-'Azīz ibn 'Abd ar-Rahmān ibn Fayṣal ibn Turkī ibn 'Abd Allāh ibn Muḥammad Al Sa'ūd became generally known outside Arabia); but in agreement with him the Ottomans placed garrisons in central Arabia for one year. Ibn Rashid continued the struggle, but he was killed in battle in 1906, and thenceforth Ibn Sa'ūd, who secured the withdrawal of Ottoman troops from al-Qaṣīm in 1906, remained the undisputed master of Arabia. Ibn Sa'ūd bent himself to the task of regaining the whole realm of his ancestors. He was cautious enough to keep the fiction of acknowledging Ottoman overlordship, and by contacts with Britain he hoped to balance each power against the other.

Meanwhile he busied himself with the reorganization of the country's administration, including the inception of a plan designed to ensure the stability and permanence of his military force. It was the foundations of Arab society that needed examination and strengthening; and it was to this task that he set his hand in 1912 with the establishment of the first Ikhwān (Brethren) colony on the desert wells of al-Aṭṭāwiyah, peopled entirely by Bedouin. The colony formed a militant cantonment dedicated to the service of God and prince. Within the next decade nearly 100 similar colonies organized around tribal group identity were founded on suitable sites throughout the country, providing Ibn Sa'ūd with a formidable force. The Sa'ūdī military also included, however, soldiers recruited from the towns and nomadic tribes.

Ibn Sa'ūd's first spectacular conquest was the taking of al-Hasa province from the Ottomans in 1913, although he was compelled to reaffirm Ottoman sovereignty over all of his territory in 1914. During World War I he was aided by British subsidies, but he managed by adroit diplomacy to be relatively quiescent, though surrounded by enemies. In 1919, however, he struck his first blow, against Sharif Ḥusayn ibn 'Alī of the Hejaz, whose army was annihilated at Turabah by the Ikhwān. In 1920 Ibn Sa'ūd's son Fayṣal captured the province of Asir between the Hejaz and the Yemen. In 1921 Ibn Sa'ūd defeated the forces of Muḥammad ibn Talal, the last Rashidī emir, and annexed the whole of northern Arabia, occupying al-Jawf and Wadi Sirhan in the following year. Kuwait experienced border raids and a Sa'ūdī blockade over payment of customs duties. Meanwhile Fayṣal and Abdullah, the sons of Sharif Ḥusayn of Mecca, king of the Hejaz, had been placed on the thrones of Iraq and Transjordan, respectively, by the British government. These territories with the Hejaz served as a formidable British-protected cordon around the northern and western borders of the Wahhābī state, with the inevitable result of frequent border incidents.

In 1923 the British government invited all the rulers concerned in these sporadic hostilities to attend a conference at Kuwait and if possible to agree on a settlement of their differences. The British also made it clear that the subsidies hitherto paid to Ibn Sa'ūd and Sharif Ḥusayn would be terminated from the end of that financial year.

The conference ended in complete disagreement on all points, and in September 1924 the Wahhābīs attacked the Hejaz. They captured at-Tā'if after a brief struggle but with an accompanying massacre of male civilians, and then they occupied Mecca without opposition. Ibn Sa'ūd then laid siege to Jiddah and Medina, while Sharif Ḥusayn abdicated his throne in favour of his son 'Alī, whose situation was virtually hopeless from the beginning. By the end of 1925 both Medina and Jiddah had surrendered to the Sa'ūdīs. The Aqaba-Ma'an district of the northern Hejaz was occupied by Transjordan, to prevent its falling into Wahhābī hands. On Jan. 8, 1926, Ibn Sa'ūd, who had adopted the title of sultan of Najd in 1921, was proclaimed king of the Hejaz in the Great Mosque of Mecca. In 1927

he also changed his title of sultan to king of Najd and its dependencies, the two parts of his dual kingdom being administered for the time being as separate units. In the same year the Treaty of Jiddah, negotiated by him with Sir Gilbert Clayton, placed his relations with Great Britain on a permanent footing as the British fully acknowledged Sa'ūdī independence. The results of Muslim conferences sponsored by the Sa'ūdīs in the Hejaz were to legitimize their presence as rulers.

Ibn Sa'ūd found himself in difficulties with the more religious elements of Najd because of his association with Christian powers and his alleged complaisance in regard to the British-protected regimes in Iraq and Transjordan, which were still the objects of Ikhwān desire for conquest. Incidents on their frontiers created a state of virtual though undeclared war, in which British aircraft played a part in discouraging Wahhābī incursions. Ibn Sa'ūd also on several occasions violently suppressed political and military opposition by the Ikhwān.

In 1928 and 1929 Fayṣal ad-Dawīsh, Sulṭān ibn Bijād, and other leaders of the Ikhwān, accusing Ibn Sa'ūd of betraying the cause for which they had fought and opposing the taxes levied upon their followers, resumed their defiance of the king's authority. The rebels sought to maintain their grazing lands in Iraq, stop the centralization of power in the hands of the king, and keep the purity of Wahhābī practices against the innovations advocated by Ibn Sa'ūd. The majority of the population rallied to the King's side and this, with the support of the Najdī ulama, enabled him to defeat the rebels. The civil war, however, dragged on into 1930, when the rebels were rounded up by the British in Kuwaiti territory and their leaders were handed over to the King. With their defeat, power passed definitively into the hands of townspeople rather than the tribes.

Ibn Sa'ūd was at last free to give his undivided attention to the development of his country and to the problems of foreign policy which beset him on all sides. Above all he was concerned to assert and maintain the complete independence of his country and in it the exclusive supremacy of Islām. The ban on music was progressively stifled by the radio, which was also used as a tool to unite the kingdom and increase military efficiency. And so on until the latitudinarian spirit, slowly at first but with ever-increasing momentum, dispersed the inhibitions of the puritan regime.

On the other hand Ibn Sa'ūd had rigorously set his face against any foreign intervention whatever in the internal politics of the regime. Aside from members of the royal family, and Najdī and Hejazi merchants, many of the King's chief advisers were foreign Muslims. Many of the foreign advisers were political refugees from their homelands and served Ibn Sa'ūd for a very long time.

(H.St.J.B.P./W.L.O.)

The Kingdom of Saudi Arabia. The history of the Kingdom of Saudi Arabia begins properly on Sept. 18, 1932, when by royal decree the dual kingdom of the Hejaz and Najd with its dependencies, administered since 1927 as two separate units under slightly different systems, was unified under the name of the Kingdom of Saudi Arabia. The chief immediate effect was to increase the unity of the kingdom and to decrease the possibility of Hejazi separatism. No attempt was made to change the supreme authority of the king as the absolute monarch of the new regime; indeed, his power was emphasized in 1933 by his choice of his son Sa'ūd as heir apparent.

Foreign relations, 1932-53. From the date of its establishment in September 1932, Saudi Arabia enjoyed full international recognition as an independent state, although it did not join the League of Nations.

In 1934 Ibn Sa'ūd was involved in war with the Yemen over a boundary dispute. An additional cause of the war was the Yemen's support of a rising by an Asiri prince against Ibn Sa'ūd. In a seven-week campaign the Saudis were generally victorious, advancing as far south as the Yemeni port of al-Hudaydah. Hostilities were terminated by the Treaty of at-Tā'if, by which the Saudis gained the disputed district. The rebel Asiri prince was given up by the Yemenis, and normal relations were renewed. Diplomatic relations with Egypt, severed in 1926 because of

Unification
of the
kingdom

King of the
Hejaz and
Najd

an incident on the Meccan pilgrimage, were not renewed until after the death of King Fu'ad of Egypt in 1936.

Fixation of the boundaries of the country remained a problem throughout the 1930s. In tribal society, where a considerable proportion of the population was nomadic, sovereignty was traditionally expressed in the form of suzerainty over certain tribes rather than in fixed territorial boundaries. Hence Ibn Sa'ud regarded the demarcation of land frontiers with suspicion. Nevertheless the majority of the frontiers with Iraq and Jordan had been demarcated by 1930. In the south and east no agreement was reached on the exact site of the frontiers with the Trucial States and with Muscat and Oman.

During World War II Saudi Arabia declared its neutrality. Britain and the United States subsidized Saudi Arabia, and they sent food from India and Egypt to the Hejaz, where, because of fewer pilgrims and thus less revenue, the losses caused by the war were severe. In 1945, however, Ibn Sa'ud declared war on Germany, a purely formal action that enabled Saudi Arabia to enter the United Nations as a founder member. Ibn Sa'ud also, after some hesitation, joined the Arab League, but he did not play a leading part in it. The religious and conservative element in Saudi Arabia still acted as an obstacle to integration with other Arab states, even when Saudis shared common views, as in opposition to Zionism. In the Arab-Israeli war of 1948 Saudi Arabia contributed only one battalion to the Arab cause; it fought as an auxiliary of the Egyptian army.

Internal affairs, 1932-53. Although oil had been discovered in al-Hasa near the shores of the Persian Gulf before World War II, it was not exploited energetically until after the entry of the United States into the war. Revenues before the war were based primarily on the pilgrimage, customs duties, and taxes—much of which decreased as a result of the world economic depression of the 1930s. After 1944 a considerable number of employees of the oil company, known thereafter as Aramco (the Arabian American Oil Company), arrived in Saudi Arabia. The resulting sudden access of wealth from increased production was a mixed blessing. The country was itself unable to supply the oil company with sufficient skilled workers, and as a result a flood of employees entered the country from other Arab states, materially influencing the thought and behaviour of the Saudis. Cultural life flourished, primarily in the Hejaz, which was the centre for newspapers and radio. Much to the annoyance of the Saudi leadership, in 1949 Aramco paid more taxes to the U.S. government than the yield to Saudi Arabia in royalties. As production dramatically increased, the Saudis pushed for a revision of the 1933 concession. The new agreement of 1950 required Aramco to pay an income tax of 50 percent of the net operating income to the Saudis.

The disturbance of traditional patterns caused by the new wealth and the movement of the population to the major cities was reflected in the government. Inexperience and the advent of fortune hunters from neighbouring countries encouraged extravagance. The poor became rich overnight, but prices soared and those who were not paid by the oil company became poorer than ever. Despite the new wealth, extravagant spending led to governmental deficits and foreign borrowing in the 1950s.

Ibn Sa'ud viewed this flood of wealth and the consequent changes in morality with distaste and bewilderment. He died on Nov. 9, 1953.

Reign of King Sa'ud ibn 'Abd al-'Aziz. Ibn Sa'ud was succeeded by his eldest surviving son, Sa'ud, his second son, Fayṣal, being declared heir apparent. The two brothers were remarkably different. Sa'ud had been heir apparent since 1933; he had many ties among the desert tribes. Fayṣal, who had lived chiefly in the cities of the Hejaz, had often been abroad in his post as Saudi foreign minister. Sa'ud thus represented the ancien régime, while those advocating modernization supported Fayṣal.

As urbanization increased, the character of Riyadh and Jiddah was enormously changed. Roads, schools, hospitals, palaces, apartment buildings, and airports replaced the old alleyways and mud-built houses. Weaving and other crafts continued, but they were modified by the use of new patterns and materials.

At the royal court there was constant rivalry between Sa'ud and Fayṣal. In March 1958, as a result of pressure, Sa'ud issued a decree transferring all executive power to Fayṣal. In December 1960, however, Fayṣal was obliged to resign as prime minister and the King himself assumed the office. In 1962-63 Fayṣal was once more given executive powers. Finally, on Nov. 2, 1964, King Sa'ud was deposed and Fayṣal was proclaimed king. The National Guard, the royal princes, and the ulama supported Fayṣal in the struggle for power against Sa'ud. Fayṣal was more competent than the King; it was he who developed the ministries of government and established for the first time an efficient bureaucracy.

Foreign affairs under Sa'ud and Fayṣal. The frontier between Saudi Arabia and Muscat and Oman had never been demarcated. In the late 1940s this problem assumed importance because of the possibility of discovery of oil in the area. In 1952 Saudi Arabia occupied the oasis of al-Buraymī and in January 1953 Britain and Oman reoccupied the oasis. In July 1954 the British and the Saudis agreed to arbitration, but upon the failure of this process Oman and Abu Dhabi reoccupied the oasis.

After World War II the United States became the most influential foreign power in Saudi Arabia. American interest was directed toward the oil industry, which was owned by U.S. companies. In 1960 Saudi Arabia became a founding member of the Organization of Petroleum Exporting Countries (OPEC), which in the 1970s sharply limited U.S. dominance in the Middle East.

As a result of the rise to power of Egypt's Pan-Arab nationalist and socialist president, Gamal Abdel Nasser, Saudi relations with Egypt were often strained. Egyptian propaganda made frequent and sometimes venomous attacks on the Saudi royal family and system of government. When Egyptian troops were sent to Yemen (Ṣan'ā') in 1962, tension between Saudi Arabia and Egypt became more acute. The Saudis helped the Yemeni royalists against the Egyptian-backed republic, and Egyptian aircraft bombed towns in Saudi Arabia near the border with Yemen. In the Arab-Israeli war of 1967 Saudi Arabia sent troops to Jordan, but they did not go into action, and Fayṣal ultimately agreed to assist Egypt with financial aid provided Nasser withdrew his troops from Yemen.

Fayṣal, leader of the largest conservative Arab state, continued to warn against the danger of Communist influence in Arab and Muslim countries. Saudi Arabia also acted against the United States, however, as a result of U.S. assistance to Israel during the Arab-Israeli war of 1973. The Saudis and other Arab oil producers organized a short-lived oil boycott; production was progressively curtailed in late 1973 and early 1974, and the price of oil quadrupled.

The Saudi government gained direct ownership of one-quarter of Aramco's crude oil operations in 1973. This interest was increased to 60 percent in 1974. Ultimately, the Saudis achieved complete control of the company and, therefore, over their chief economic resource. By 1984 the president of Aramco was a Saudi citizen.

(H.St.J.B.P./J.B.GI./W.L.O.)

Reigns of Khālid and Fahd. On March 25, 1975, King Fayṣal was assassinated by his nephew Prince Fayṣal ibn Muṣā'id 'Abd al-'Aziz. Fayṣal was succeeded by his half-brother, Crown Prince Khālid, and Prince Fahd was made crown prince. During the new king's reign economic and social development, guided by Islāmic law, continued at an extremely rapid rate, revolutionizing the infrastructure and educational system of the country. Despite this, Khālid exerted a conservative influence among the Arab and Muslim nations.

After the signing of the Egyptian-Israeli peace agreement on March 26, 1979, Saudi Arabia joined the other Arab nations in severing diplomatic relations with Egypt and imposing economic and political sanctions. Saudi Arabia stated that the primary conditions for peace were full Israeli withdrawal from all territories occupied in the 1967 Arab-Israeli war and the recognition of the Palestinian right to self-determination. The overthrow of the Shah of Iran in 1979 and the establishment of the Islāmic Republic of Iran caused the Saudi monarchy serious concern. Foreign policy also was orientated toward oil policy.

Disputes
with Egypt

Assassi-
nation of
Fayṣal

The only serious domestic challenge to the monarchy since World War II took place when the Haram mosque (Great Mosque) in Mecca, the holiest site in the world for Muslims, was seized by followers of a Saudi Sunni extremist. Holding hostages, the rebels occupied the mosque for two weeks before they were defeated. The takeover was religiously and politically motivated as the rebels called for the overthrow of the dynasty and for a stricter Muslim society and polity. Domestic unrest continued with rioting by Shi'ite Muslims in eastern Saudi Arabia in November 1979 and February 1980. The Saudi Arabian government announced plans for the reorganization of the political system to include a consultative council and a written constitution. No real changes took place, however, and political power remained exclusively in the hands of the king and the royal family.

On June 13, 1982, King Khālid died and Crown Prince Fahd, who had long been influential in the administration of affairs, succeeded to the throne. Fahd maintained Saudi Arabia's foreign policy of close cooperation with the United States and increased purchases of sophisticated military equipment from the United States and Great Britain. Saudi Arabia in general attempted to lessen disputes among the Arab states. Beginning in the 1980s the Saudi government played a major role in determining OPEC policy on oil production and pricing. Oil revenues have been crucial to Saudi society as its economy and ways of living have been revolutionized by the extraordinary wealth channeled through the government and derived from oil operations. Urbanization, mass public education, the presence of numerous foreign workers, and access to new media have all affected Saudi values and mores. While society has changed profoundly, however, political processes have not. The political elite has come to include more bureaucrats and technocrats, but real power continues in the hands of the dynasty.

For later developments in the history of Saudi Arabia, see the *Britannica Book of the Year* section in the BRITANNICA WORLD DATA ANNUAL. (W.L.O.)

United Arab Emirates

Seven tiny emirates along the eastern Persian (Arabian) Gulf coast of the Arabian Peninsula together form the United Arab Emirates (Arabic: Ittiḥād al-Imārāt al-'Arabiyyah). Formerly known as the Trucial States, Trucial Oman, or the Trucial Sheikdoms, they are bordered by Qatar on the northwest, by Saudi Arabia on the west, south, and southeast, and by Oman on the southeast and northeast. Most of the union's area of 30,000 square miles (77,700 square kilometres) is occupied by Abu Dhabi, which stretches along the Persian Gulf coast. The six other emirates are clustered on the Musandam Peninsula, which separates the Persian Gulf from the Gulf of Oman; they are Dubayy, 'Ajmān, ash-Shāriqah, Umm al-Qaywayn, and Ra's al-Khaymah on the Persian Gulf side, and al-Fujayrah on the Gulf of Oman side. The population is concentrated in cities along both coasts, although the interior oasis settlement of al-'Ayn has grown into a major population centre as well. 'Ajmān, ash-Shāriqah, and Dubayy have enclaves in al-Fujayrah. Upon formation of the union, in 1971, the city of Abu Dhabi was chosen as the national capital for a period of five years (later extended).

PHYSICAL AND HUMAN GEOGRAPHY

The land. Nearly the entire union is desert, containing broad patches of sand and numerous salt flats. Along the eastern portion of the Musandam Peninsula, the northern extension of the al-Hajar Mountains offers the only other major relief feature. Steep on all sides, the mountains rise to 5,000 feet in some places. The Persian Gulf coast is broken by shoals and dotted with islands that offer shelter to small vessels. There are, however, no natural deepwater harbours. The coast of the Gulf of Oman is more regular and has three natural harbours—Dibā al-Ḥiṣn, Khawr Fakkān, and Kalbā.

The climate is hot and humid along the coast and is hotter still, but dry, in the interior. Rainfall averages only three to four inches (75 to 100 millimetres) annually. The

average January temperature is 65° F (18° C), while in July the temperature averages 92° F (33° C). Summer temperatures can reach 115° F (46° C) on the coast and 120° F (49° C) or more in the desert. In midwinter and early summer winds known as the shamal blow from the north and northwest, bearing dust and sand.

Because of the desert climate, vegetation is scanty and largely limited to the low shrubs that offer forage to nomadic herds. In the oases date palms are raised together with alfalfa. Food grains include wheat, barley, and millet. Fruits are grown, and al-'Ayn oasis in Abu Dhabi is known for its mangoes. Animal life is largely restricted to domesticated goats, sheep, and camels, together with cattle and poultry, which were introduced in modern times. The Gulf waters offer schools of mackerel, grouper, tuna, and porgies, as well as sharks and occasional whales.

The people. Only one-fifth of the union's residents are native and enjoy the rights of citizenship. The remainder are the mostly male foreign workers and their dependents, with South Asians, mainly Indians and Pakistanis, accounting for as much as half of the total population by some accounts. Arabs from countries other than the United Arab Emirates account for more than 10 percent, as do Iranians. Southeast Asians, including many Filipinos, have immigrated in increasing numbers to work in various capacities. The official language is Arabic.

Most of the population resides in the coastal cities. Al-'Ayn, part of a grouping of oases on the Omani border (known in Oman as al-Buraymi), is a rapidly growing city in the interior.

The economy. The union's economy is dominated by the oil produced in the Abu Dhabi and Dubayy emirates. The richest of the emirates, Abu Dhabi, contributes more than three-fifths of the national budget.

Oil was first discovered in Abu Dhabi in 1958. The government of Abu Dhabi owns a controlling interest in all oil company operations in the emirate. The largest concessions are held by Abu Dhabi Marine Operating Company (Adma-Opco), which is partially owned by British, French, and Japanese interests. One of the main offshore fields is located in Umm ash-Shayf, 80 miles into the Persian Gulf and 20 miles from the island of Dās. Al-Bunduq offshore field is shared with neighbouring Qatar but is operated by Adma-Opco. A Japanese consortium operates an offshore rig at al-Mubarrāz, 70 miles west of Abu Dhabi city, and other offshore concessions are held by U.S. companies.

Onshore oil concessions are held by the Abu Dhabi Company for Onshore Oil Operations (ADCO), which is partially owned by U.S., French, and British interests. Other concessions are held by Japanese companies.

The production of oil in Dubayy began in 1969. There are offshore oil fields at al-Fath, Fallah, and Rashid, all located between 30 and 80 miles northwest of Dubayy. Dubayy owns a controlling interest in all oil companies in the emirate. Ash-Shāriqah began producing oil in 1974, and in 1980 another field, predominantly yielding natural gas, was discovered. In 1984 oil production began off the shore of Ra's al-Khaymah, in the Persian Gulf.

Agricultural production, largely centred in Ra's al-Khaymah emirate, al-Fujayrah emirate, the enclaves of 'Ajmān, and al-'Ayn, has undergone a considerable expansion through the increasing use of wells and pumps to provide water for irrigation. Dates are a major crop, and the United Arab Emirates is close to self-sufficiency in much fruit and vegetable production. The country must import most of its grains, however. It has also greatly increased its production of eggs, poultry, and dairy products. The Arid Lands Research Centre, moved from as-Sa'diyāt Island to al-'Ayn, experiments with raising crops in a desert environment. Most fishing is at Umm al-Qaywayn.

The emirates have attempted to diversify their economy so as not to be completely dependent on oil. Abu Dhabi has begun to harness energy from natural gas for local use as well as for export. A petroleum industrial complex has opened in ar-Ruways, 140 miles southwest of Abu Dhabi city, with a petroleum refinery, a gas fractionation plant, and an ammonia and urea plant. Dubayy's revenues have been invested in projects such as a dry dock and a trade centre; its airport has been expanded, and additional ho-

Oil reserves

Desert
climate

tels have been built. The free trade zone of Minā' Jabal Ali, 20 miles southwest of Dubayy city, was developed during the 1970s and early '80s. Ash-Shāriqah has built a cement plant, a plastic-pipe factory, and paint factories.

Finance. The United Arab Emirates Central Bank was established in 1980, with Dubayy and Abu Dhabi depositing one-half of their revenues in the institution. There are also commercial and foreign and domestic banks.

Trade
patterns

Trade. Trade has long been important to Dubayy and ash-Shāriqah. Even before the discovery of oil, Dubayy's prosperity was assured by its role as the Gulf's leading entrepôt. It was known especially as a route for smuggling gold into India. Dubayy's Port Rāshid, adjacent to the city, is a large, modern port with a vast shipyard. Ash-Shāriqah city's more modest port is located a few miles north of the city on the Persian Gulf coast. Ash-Shāriqah's port of Khawr Fakkān, in an enclave on the Gulf of Oman coast, specializes in container shipping.

Exports are dominated by oil, primarily to Japan, the United States, and western Europe. Imports include machinery and transport equipment, basic manufactures, foodstuffs and live animals, mineral fuels, chemicals, and crude minerals. Major trading partners include Japan, western European countries, the United States, Bahrain, Australia, and Singapore.

Transportation. An excellent road system, developed in the late 1960s and '70s, carries vehicular traffic throughout the emirates and links the union to its neighbours. The addition of a tunnel to the bridge connecting Dubayy city and Dayrah facilitates the movement of traffic across the small saltwater inlet that separates them. The cities of Abu Dhabi, Dubayy, ash-Shāriqah, and Ra's al-Khaymah have international airports.

Administration and social conditions. *Government.* The highest governmental authority is the Supreme Council, which is composed of the rulers of the seven emirates. The president and vice president of the union are elected by the Supreme Council from among its members. The president appoints a prime minister and a cabinet. The Federal National Council, an advisory body, is made up of members appointed by the emirates for two-year terms.

Justice. A provisional constitution was ratified in 1971 and has been extended periodically by the Federal National Council. The provisional constitution blends Western and Islāmic legal principles and calls for a legal code based on Shari'ah (Islāmic law). At the federal level the judicial branch consists of a supreme court and several courts of first instance; the former deals with emirate-federal or inter-emirate disputes and crimes against the state, and the latter cover administrative, commercial, and civil disputes between individuals and the federal government. Other legal matters are left to local judicial bodies.

The armed forces. The Abu Dhabi and Dubayy defense forces have been merged with those of the other emirates as the Federal Defense Force; in practice, however, Dubayy's forces have remained independent of those of the other emirates. The Supreme Council has made the right to levy armed forces a power of the national government.

Alain le Garsmeur—CLICK/Chicago

Young boys preparing for a camel race in Dubayy, United Arab Emirates.

Education. Education in the emirates is free. Both boys and girls attend public school, and women constitute more than half of the student body at the United Arab Emirates University, opened in 1977. The literacy rate has reached about 70 percent.

Health. Medical services are concentrated in Dubayy, which has several hospitals and child-welfare clinics, and in Abu Dhabi, which has a large maternity hospital and other health facilities. Hospital services are free; there is little private medical practice, and most people are treated in hospital outpatient clinics.

Cultural life. The cultural life of the United Arab Emirates remains largely traditional. It is rooted in Islām and identifies with the wider Arab world, but it maintains ties especially with the neighbouring conservative, patriarchal states. Tribal identities remain fairly strong, despite urbanization, and the family is still the strongest and most cohesive social unit. The United Arab Emirates has experienced the impact of Islāmic resurgence, though Islām in the emirates is generally less austere than in Saudi Arabia. Camel racing remains a popular sport, with prize racers often selling for hundreds of thousands of dollars.

In a number of ways change is apparent in the nation's cultural life. Changes in attitudes toward marriage and employment of women are discernible. Some women are now given more opportunity for choice in a marriage partner, and education and some types of professional work have become available to women. New forms of entertainment, ranging from soccer matches to videotape recorders, have begun to alter patterns of taste and behaviour.

The news media are concentrated in Abu Dhabi, Dubayy, and ash-Shāriqah. Several daily newspapers are published, in both Arabic and English. Daily radio and television programs are broadcast from Abu Dhabi, Dubayy, and Ra's al-Khaymah, in Arabic and English.

For statistical data on the land and people of the United Arab Emirates, see the *Britannica World Data* section in the BRITANNICA WORLD DATA ANNUAL.

HISTORY

In the late 18th and early 19th centuries the dominant tribal faction was the Qawāsim, whose ships controlled the maritime commerce of the lower Persian Gulf and much of the Indian Ocean. Attacks on British and Indian shipping led to a British naval action in 1819 that defeated the Qawāsim forces.

The effect of this was not only to lessen the power of the Qawāsim but to favour the Bani Yās tribal confederation of Abu Dhabi. The Bani Yās were centred on the al-Liwa' oases of Abu Dhabi, and their strength was land-based and largely Bedouin. Under the leadership of the Āl Nuḥayyan, members of the Āl Bū Falah tribe, they were the dominant element in the Trucial States from the mid-19th century. The sheikhs signed in 1820 a general treaty of peace, in 1853 the perpetual maritime truce, and in 1892 exclusive agreements restricting their foreign relations to Britain. In January 1968, after the British government announced that its forces would be withdrawn from the Persian Gulf by the end of 1971, Trucial Oman and the sheikhdoms of Qatar and Bahrain initiated plans to confederate. After three years of negotiations, however, Qatar and Bahrain decided on independent sovereign status. The former Trucial States, excluding Ra's al-Khaymah, announced the formation of the United Arab Emirates in December 1971. Ra's al-Khaymah joined the federation in February 1972.

A movement toward centralization was initiated by Abu Dhabi in December 1973, when after a change in Cabinet membership several of its former Cabinet members took positions with the federal government. In May 1976 the seven emirates agreed to merge their armed forces, and the constitution was amended in November limiting to the federal government the right to form an army and purchase weapons. Conflicts in 1978 prompted Dubayy and Ra's al-Khaymah to refuse to submit their forces to federal command, and Dubayy began purchasing weapons independently. A proposal to form a federal budget, merge revenues, and eliminate internal boundaries was rejected by Dubayy and Ra's al-Khaymah, despite strong domestic support. Dubayy's opposition was curtailed, however,

The
federation

when its ruler, Sheikh Rashid, was offered the premiership of the federal government; he took office in July 1979.

The Khomeini regime in Iran and the Iran–Iraq war created significant danger for the United Arab Emirates. The resurgence of Islāmic fundamentalism posed a double threat to the union's stability by generating unrest among the many Iranian Shī'ites living in the emirates and by providing inspiration to the growing numbers of young activist Sunnites who found the existing political order to be insufficiently committed to Islāmic values. The Iran–Iraq war was brought within a few miles of the United Arab Emirates' coast when Iran and Iraq began to attack tankers in the Persian Gulf.

The intensity of such threats moved the United Arab Emirates to join with Oman, Qatar, Saudi Arabia, Bahrain, and Kuwait to form the Gulf Cooperation Council (GCC). The council, which held its first summit meeting in 1981, was designed to strengthen the security of its members and to promote economic cooperation.

For later developments in the history of the United Arab Emirates, see the *Britannica Book of the Year* section in the BRITANNICA WORLD DATA ANNUAL.

Yemen, South

South Yemen, formerly the People's Democratic Republic of Yemen, also known as Yemen (Aden), merged with its neighbour North Yemen in 1990 to form the Republic of Yemen. The present article treats the two regions individually.

South Yemen is situated in the southeastern part of the Arabian Peninsula. To the west and northwest lies North Yemen. In the north the frontier is undemarcated and runs through the great desert of the Arabian Peninsula, the Rub' al-Khali (the Empty Quarter). In the east lies Oman, and on the south the country is bordered by the Gulf of Aden, a part of the Arabian Sea. The territory of South Yemen also includes the island of Socotra, which lies in the Indian Ocean about 600 miles (965 kilometres) due east of Aden and about 200 miles from the Horn of Africa; the Brothers, small islets near Socotra; the island known as Perim (Arabic: Barīm), in the Bab el-Mandeb Strait, which separates the Arabian Peninsula from the African continent; and, technically, Kamaran Island, located just off the coast of North Yemen in the Red Sea. Kamaran was occupied in 1972 by North Yemen, which insisted that the original treaty assigning the island to South Yemen was illegitimate.

Because a major frontier is undemarcated, there is variation in the estimates of the land area of South Yemen. The government claims a total of about 80,000 square miles (about 208,000 square kilometres). Other sources estimate an area as large as 130,066 square miles.

The history, culture, economy, and population of South Yemen have all been influenced by its strategic location at the southern entrance to the Red Sea and at a crossroads of both ancient and modern trade and communications routes. The same routes that carried goods from India to the Mediterranean via the Red Sea also carried Europeans to Asia, where they sought trade, ports, and colonies. Eventually, after attempts by numerous Middle Eastern and European powers to take over the areas around Aden, it fell to the British in 1839.

Aden as
entrepôt

Originally, the British East India Company had been interested in Aden as an entrepôt and coal-bunkering facility for steamships using the Indian Ocean trade routes. The opening of the Suez Canal in 1869, however, restored the Red Sea route to its former prominence and further enhanced the value of Aden. By the time oil became a major export of the Middle East, in the 1950s, Aden was one of the world's busiest and most important commercial ports.

In time, British interests and concerns led to a more aggressive policy with respect to Aden's hinterland. Between 1882 and 1914 the British government entered into treaties with the many principalities there, and in 1937 the principalities were given formal protectorate status. In the following year the protectorate was divided into the Western Aden Protectorate and the Eastern Aden Protec-

torate. In 1967, after a bitter conflict, the country became independent and took the name People's Republic of South Yemen; this was changed in 1970 to the People's Democratic Republic of Yemen. The generally poor economy, the lack of exploitable natural resources (with the exception of the oil discovered in the 1980s), and the long conflict with Britain (and the West in general) produced a slow but steady drift to an association with the Soviet Union. The country continued to be closely tied to the Eastern-bloc states until the democratic reforms of 1989 called Marxist Yemen's own viability into question.

(M.A.G./M.W.W./Ed.)

PHYSICAL AND HUMAN GEOGRAPHY

The land. *Relief, soils, and drainage.* South Yemen is divided into two distinct physical zones: the coastal plain and the inland mountains. The coastal plain runs for about 700 miles along the shore of the Gulf of Aden, from the Bab el-Mandeb Strait in the west to Cape Dharbat 'Alī in the east, on the frontier with Oman. The coastal plain ranges in width from about five miles to as many as 40, and its composition varies from gravelly in the west to sandy in the east. The plain is intersected at irregular intervals by wadis (seasonal watercourses). Their source of water is the occasional precipitation that falls on the inland mountain ranges. The range nearest the coast is relatively low (about 1,000 to 2,000 feet, or 305 to 610 metres), and the range farther inland, with an average height of more than 6,500 feet, has numerous peaks of 8,000–9,000 feet. Between them is a plateau with an average altitude of about 3,000–3,500 feet, which contains a sizable portion of both the population and the arable land.

Nearly all of the wadis drain southward into the Gulf of Aden; some of the more important are Wadi Tuban, the most westerly; Wadi Mayfa'ah, which formed a part of the old Incense Road; and Wadi Ḥaḍramawt (Ḥaḍramaut Valley), which has been known since antiquity for its frankincense trees. Two wadis drain northward into the Ramlat as-Sab'atayn, a desert extension of the Rub' al-Khali. One of these, Wadi Bayhān, was the site of one of the Yemen's major ancient city-states. Over the centuries, the wadis have created alluvial fans, which are the other major concentration of arable land.

With the exception of Socotra, the island possessions of South Yemen have few people and few resources. Perim is a waterless, low-lying, almost featureless island with no permanent population (since an old quarantine station was abandoned); and the Brothers are rocky islets with no inhabitants. Only Socotra, with its 1,400 square miles and some 12,000 inhabitants, is of any importance. Although its renown today rests primarily on the allegation that it has become a major Soviet naval base, in the past it was noted as a source of such valuable commodities as civet musk, ambergris, frankincense, tortoiseshell, aloes, and dyestuffs. Its population is ethnically and linguistically distinct from the majority of the inhabitants of South Yemen.

Island
possessions

Climate. The climate varies with respect to the major mountain range. Along the Gulf of Aden coast the climate is tropical; it is fiercely hot, with summer temperatures regularly exceeding 100° F (38° C), and with very high humidity. The winter months are milder, but in the city of Aden (and on Socotra and Perim) the seasonal difference is not significant. In the mountain areas, however, the effect of altitude is quite dramatic: the summer months are characterized by fairly pleasant temperatures with moderate humidity, while the winter months often produce frost and occasional snowfalls.

The climate of South Yemen is influenced by regional wind patterns, especially the monsoons, which bring the only reasonably regular rainfall. Although in the far west and in North Yemen rains fall in late winter and early spring, most of South Yemen gets no rainfall until the summer months and then rarely gets more than about 12 inches (304 millimetres). Averages conceal the fact that the coastal plain may not get rain for more than a year at a time, while some of the mountain regions may get as much as 22 inches per year.

Plant and animal life. The generally arid conditions that characterize South Yemen are reflected in the prevail-

ing flora: euphorbias, aloes, tamarisks, acacias, and similar drought-resistant species. Among the tropical plants that are successfully cultivated are the date palm, citrus fruits, bananas, and plantains. Although there is evidence that many areas had considerable forest cover as recently as 100 years ago, there are no extensive stands of trees.

The oryx, a large antelope, and the ibex, a mountain goat, have been hunted into virtual if not complete extinction; as recently as 100 years ago there were colonies of panthers, ostriches, and numerous other larger species. Wildlife now consists primarily of small mammals (rabbit, fox, hyena), various reptiles, and other species well adapted to the varied ecological niches to be found in South Yemen. Perhaps the largest variety of wildlife is the bird population: the mountains, as well as the coastal marches and wetlands, of South Yemen are major stopovers on migration routes. Socotra has retained a considerable variety of flora and fauna, many of which bridge the types found in Africa and the Arabian Peninsula. Nevertheless, the increased use of land for grazing (for sheep, goats, and the indigenous cattle) has eroded the ecological base of many of these species. Perhaps the greatest variety of fauna is found in the surrounding seas, where tuna, shark, sardines, lobster, squid, and mackerel abound.

Settlement patterns. Aden is the country's major urban and commercial centre. The many years of administration by the British and their Indian associates is reflected in the city's design and architecture, a combination of modern European and Asian styles. There are very few settlements of any size besides Aden; the most important other towns with a measure of modern facilities are Lahij to the northwest of Aden; al-Mukallā to the east, on the Gulf of Aden; and the towns of Tarim and Say'un in the Hadhramaut. Most of the population is rural and lives in small villages, which are widely dispersed.

Towns and villages in the mountain areas north, northwest, and northeast of Aden are characterized by a striking architectural style similar to that found in the highlands of North Yemen. Its most obvious feature is the height of the houses; the typical residential structure is four to six stories tall. Upon a base of cut stone blocks, additional courses of mud or baked brick are added. Windows are often highlighted in plaster, and the practice of adding windows between floors produces the impression of multi-storied skyscrapers. Although buildings in the Hadhramaut Valley are constructed with the same techniques, their decorative motifs and stylistic variations have been influenced by Indonesian and Indian designs, brought home by Yemeni emigrants.

The people. *Ethnic and linguistic composition.* The population of South Yemen is overwhelmingly of Mediterranean stock, with Arabic as its mother language. Although Arabic is the official language, it is heavily influenced by the ancient South Semitic language, and it is not the only language spoken within the country. The most important and visible minority is the Mahra people, resident in the area around Qishn in the eastern border area and on the island of Socotra. (They were formerly united in the Mahra Sultanate of Qishn and Socotra before being melded into the South Yemen state.) The Mahra are a Vedoid (Australoid) people. According to linguists, their dialect, Maḥri, is a variant of the ancient Himyaritic language, which was used by ancient empires in the region about two millennia ago. There are also a few isolated, predominantly African communities, made up of descendants of slaves taken to the peninsula decades ago, and there are remnants of the large Indian, Somali, and Jewish communities that once were a part of the Aden urban area. The fierce nationalism that characterized the late 1960s, as well as the aggressive nationalizations of the 1970s, drove most members of these minority groups from the country.

Most of the population is divided into tribal groupings and confederations, "tribe" in this context referring to a social, political, and economic unit whose members sometimes number in the thousands and which is the primary basis for personal identification and often for group activity. These tribal confederations, among which the most important are the 'Aulaqi, Yafa'i, and Dathina, were the basis for the principalities that existed in the

area before independence. A larger part of the population of the eastern region is detribalized, though the basis for authority for the major polities in the old Eastern Aden Protectorate, such as the Kathiri sultanate and the Wahidi sultanates, was tribal.

The government of independent South Yemen, as part of its determined program of secularization and modernization, undertook numerous measures to de-emphasize the importance of the tribe in all areas of domestic life (including eliminating the names of the old principalities). It also sought somewhat successfully to decrease the relative importance of the old social classes and categories.

Religions. In religious terms, the overwhelming majority of the population are Sunnite Muslims of the Shāfi'i school of law (one of the four major schools of Sunnite Muslim jurisprudence). There is a significant minority of the Zaydiyyah, a Shī'ite sect that is predominant in the highlands of North Yemen. The Mahra people, especially those living on the island of Socotra, seem to have been Christian at one time, but they are now Muslim. The Jews, Hindus, and Zoroastrians, who were formerly important in the commerce and trade of Aden, are now almost entirely gone.

Demographic trends. In some respects, the most important characteristic of the population is the emigration of large numbers of males seeking higher-paying employment. This is not purely a modern phenomenon: South Yemenis, especially those from the Hadhramaut, have been emigrating for centuries, especially in the 18th and 19th centuries to Indonesia, Malaysia, and India. The high rate of emigration has had an important impact on the economy and demography of the country. It has been estimated that in the late 1970s, when emigration was at a peak, perhaps as many as 200,000 South Yemenis were abroad, primarily in the Persian Gulf states, and that their remittances were the single largest source of foreign exchange. As the price of oil fell and the economy of the labour-importing states leveled off, both the flow of emigration and the income from remittances declined.

The economy. Independent South Yemen was one of the world's poorest countries: the region has little industry, and the amount and variety of its natural resources are limited. The economy is centred on Aden, but the city's dramatic decline since independence, as well as the service nature of its economic base, mean that it does not add significantly to the overall standard of living, especially of the rural majority.

Resources. There are deposits of a few ores, predominantly in the Hadhramaut region and in some of the mountains of the north and northwest, but these are not commercially viable. Oil was discovered in the Shabwah region on the edge of the Ramlat as-Sab'atayn in 1983, and the first well began production in 1987. Salt is mined in the Shabwah region also, from which it has been obtained since antiquity. Salt also is extracted from the sea in extensive salt pans near Aden.

Agriculture. Less than 1 percent of the total land area is arable. As a result, the country is not self-sufficient in foodstuffs, and a large portion of the population is engaged in subsistence farming, typically in the alluvial fans of the wadis, along the banks of the wadis themselves, or in the upland areas that have sufficient soil for effective cultivation. The limited soil and poor rainfall have combined to produce some of the most highly sophisticated methods of water conservation anywhere in the world, most visible in the terracing of the northwestern mountains. Irrigation is necessary for almost all cultivation. Livestock includes goats, sheep, and cattle (with an unusual variety found on Socotra). Camels and donkeys are used primarily for transportation, though their value has declined as the network of roads has expanded and more people are able to afford motor vehicles.

The most common crops are cereals, such as millet, corn (maize), wheat, and barley; vegetables; some fruits, such as bananas and melons; sesame (primarily for oil); and the date palm. For many years the main cash crop was cotton (Abyan long-staple), but high production costs as well as low market prices have combined to send this sector into decline.

Fishing. An important sector of the contemporary economy of Yemen is the commercial fishing industry. The waters of the Gulf of Aden and surrounding areas teem with a wide variety of commercially desirable fish. With extensive assistance from the Soviet Union, this sector of the economy has expanded to become a significant source of foreign exchange.

Industry. Most industry is located in the Aden region. The nation's oil refinery—its major industrial enterprise—is in an industrial zone known as Little Aden, to the west of the city. The refinery, originally built by British Petroleum in 1954, has been expanded and upgraded a number of times and was nationalized in 1977. Industries, typical of a developing state, are predominately the manufacture of foodstuffs (particularly fish and fish products), soft drinks, cement, plastics, paints, aluminum ware, and furniture, mostly for local use. A small handicrafts sector produces goods such as the *jambiya* (the traditional Yemeni dagger) and its various accessories.

Trade. Trade was for centuries the major source of wealth for Aden, as well as the ancient city-states of the hinterland. The port of Aden has always been highly valued because of its deep-water anchorage and protection from winds and seas; these features allowed it to become an entrepôt and transshipment emporium for goods going to and from North Yemen, which has poor natural harbours, and Somalia and Ethiopia (Eritrea), as well as goods eventually moving on to Egypt and the Mediterranean Basin. In the 1950s and '60s, the heyday of the Suez Canal and the European-Far East trade, Aden was one of the busiest ports in the world. With the closure of the canal, the development of supertankers, and the conflicts in the area, its position and importance declined. Today's shipping, trade, and other traffic is a small fraction of that in the early 1960s.

South Yemen imports large amounts of crude petroleum, especially from Iran, for refining and exports petroleum products (which make up the bulk of its total exports) to Iran, Japan, France, The Netherlands, and other countries. Fresh fish also are exported. Nonpetroleum imports include machinery and transport equipment, food and live animals, and manufactured goods. The Soviet Union, Japan, Australia, and the United Kingdom are the major sources of nonpetroleum imports.

Transportation. Because Britain's primary interest lay in Aden and because the British government was com-

mitted for many years to a policy of noninterference in the internal affairs of the protectorate states, little was done to improve communications in these areas. Most of the mountain areas of the west, northwest, and north are connected only by rudimentary tracks, often impassable even for four-wheel-drive vehicles. The nation's most important overland trade route for many decades has been the link with North Yemen, from Aden to Ta'izz. This was the first track to be paved. Since independence the government has built paved roads to most of the major coastal towns east of Aden. Aden remains the transportation hub, however.

Coastal sea traffic is essentially limited to small ships carrying fish and other local commodities between Aden and, for example, al-Mukallā. The most dramatic improvement in domestic transportation is probably the development of extensive domestic air services. An international airport is located near Aden.

Administration and social conditions. *Government.* Prior to the merger with North Yemen in 1990, South Yemen had an avowedly Marxist government. Its political system and economy reflected many of the goals and principles of Marxism, and its domestic and foreign policies provided further evidence of this orientation. On the other hand, some characteristics of the country remained essentially as they were during the pre-independence period, and some marked deviations from rigid Marxism were made in the government's priorities and policies.

Before independence the territory of South Yemen was divided into more than 20 "statelets," and different sections of the country had different statuses within the British Empire. For example, Aden, with its more sophisticated economy, population, and global orientation, was administered as a Crown Colony (*i.e.*, directly from London) from 1937 to 1967. At the same time, the statelets were given the status of protectorates, which meant that Britain did not directly intervene in their domestic affairs (although it often gave "advice" on policy) but committed itself to the defense of their given frontiers in return for their commitment not to undertake any foreign policies that would be detrimental to Britain's interests. The principalities were administered by the Bombay Presidency, in India. One result of this fragmentation was a considerable difference in the political sophistication as well as economic development between Aden and the hinterlands.

In order to break down the old tribal affiliations, as well as the economic and political factionalism and loyalties associated with them, the postindependence government abolished the traditional borders and reorganized the country into six numbered governorates. (The numbering system was later abandoned, and the governorates were given names to promote identification with them by their respective inhabitants.) Tribal affiliations and loyalties were not eliminated, however, by the creation of the new administrative subdivisions, which deliberately cut across the lines and associations of the old ones. Abundant evidence of this was provided by the events of January 1986, when a brief civil war broke out: the alliances that coalesced during this time clearly resurrected traditional tribal loyalties and enmities.

The formal governmental framework of South Yemen was laid out in the constitution of 1970. The major institutions were the Presidium, an 11- to 17-member collegial executive body, whose chairman was the formal head of state; the Council of Ministers, which was the main focus of executive authority and policy-making; and the Supreme People's Council, a 111-member body, which was the equivalent of a national legislature and the source of authority of the government and the state. Its membership was elected by universal adult suffrage.

The constitution expressly stated that the formal goals of the republic were to be achieved through the Yemen Socialist Party (YSP), the only legal political organization. Its major institutions were the General Congress, which met briefly once every few years, at which time it selected the party's secretary-general, the Central Committee, and the Politburo. The Central Committee ran the party between congresses; its most influential and powerful members were also selected to the Politburo, which was headed by

Yemeni
"statelets"

the secretary-general. Although the Politburo made most important decisions, it remained accountable to the Central Committee, which removed presidents of the republic from office in 1975 and 1986. All other government bodies, including the armed forces, were subordinate to the party.

Justice. During the years preceding independence, different systems of law were used in the Crown Colony of Aden and in the various protectorates. In Aden the local courts applied laws enacted by the legislative and executive authorities in civil and criminal matters. The Muslim law (Shari'ah) was applied in matters of personal status (such as birth, marriage, divorce, and inheritance), and the other religious communities were similarly allowed their own religious regulations. In the rural areas traditional judges applied the Shari'ah, and in cases that involved civil actions they often acted as intermediaries or mediators (the role usually played by the sayyids in the more settled areas and by the *manqads* in the remoter reaches of the Ramlat as-Sab'atayn, for example). The legal system used in these areas often had little to do with the more formal provisions of the Shari'ah; in fact, these adjudicators often administered or used tribal law.

The Marxist government of South Yemen sought to introduce a secular and regularized administration of justice throughout the country and pledged to introduce family, labour, criminal, and even civil law through a nationwide system of courts. Some progress in this direction was made by establishing a supreme court and magistrate's courts, but there were clear remnants of the old system, especially in the rural areas.

Health and welfare. Many tropical diseases are endemic in the country, especially in the coastal belt, and the standard of health is generally low, with high infant mortality rates and widespread malnutrition. An important goal of the government has been to decrease the consumption of the khat (*qāt*) plant, the leaves of which contain a mild alkaloid. The chewing of khat leaves is an important part of the social life of all Yemenis, however. Most of the khat consumed in South Yemen is grown in North Yemen, and an active trade has continued despite the efforts of the government of the south to eliminate it.

Education. The government has also sought to secularize and to improve access to public education. The school system offers eight years of elementary education to all students. Secondary education varies from two to five years, depending on the specialty. Secondary education is divided into academic, technical, and skilled labour programs. The country's only university was founded at Aden in 1975. Many students study abroad.

Cultural life. South Yemen is a part of the Islamic world and as such participates in and identifies with many of the trends therein. The country also contains, however, the remnants of many past empires and political systems that played important roles in the world centuries before the appearance of Islam. The best known of these were associated with the ancient world's dependence upon southern Arabia for its highly prized supply of frankincense and myrrh. Furthermore, the mariners and traders of these ancient states had a monopoly on trade between India and the Mediterranean due to their knowledge of the trade winds and monsoons. The result was the rise of extremely wealthy and powerful states and empires. The ruins of their temples and cities are an important draw to archaeologists and scholars and are a matter of intense pride for the South Yemenis.

In more recent times the asceticism of the Marxist government, especially from 1970 to 1990, severely restricted the participation of the population in global cultural trends. Because education, broadcasting, and the press were all under governmental control, cultural life was neither particularly varied nor cosmopolitan. There was, however, a growing system of higher education, as well as an active antiquities and archaeology department, and their publications and activities were varied. Aden has archaeology and ethnology museums.

For statistical data on the land and people of South Yemen, see the *Britannica World Data* section in the BRITANNICA WORLD DATA ANNUAL.

HISTORY

Before the arrival of Islam, the Yemen was claimed by the various city-states and empires that arose in the southwestern corner of the peninsula. Their wealth and power were based in their exclusive trade of frankincense and myrrh and in their control over the trade of a number of other highly prized commodities drawn from trading partners in India, Southeast Asia, and East Africa: ivory, ostrich plumes, various spices, and other goods.

With the development of Roman shipping in the Red Sea and the consequent loss of exclusive knowledge concerning the trade winds and monsoons, and with the conquest of the Arabian Peninsula by Islam, the centre of economic and political activity moved from southern Arabia to the Hejaz (the area around Mecca and Medina in modern Saudi Arabia). The Yemen fell prey to an unending series of factional, dynastic, and local rulers of more or less despotic tendencies.

Southern Arabia reemerged as an important area with the cultivation of the coffee shrub (*Coffea arabica*), beginning in the 15th century, and with the vastly increased demand for the goods of Asia among Europeans emerging from the Middle Ages. The Red Sea region became an arena of conflict between the Egyptians, the Ottomans, and, later, various European powers seeking to gain some measure of control over the trade in condiments and spices from India to Europe, as well as over the coffee trade. The conflict occupied most of the 16th and 17th centuries; by the beginning of the 18th century, with the route to Europe around Africa having become the standard one, Arabia once again lost Europe's interest (as well as its own primary source of wealth). With the exception of Mocha in the western Yemen, which continued to play a role in the coffee trade, Aden and other ports in the region became backwaters. Aden's population sank dramatically as its trade moved elsewhere: by the early 19th century what had been a thriving town with a population of more than 10,000 had become a village of fewer than 500.

Developments in the 19th century, however, began to change this: first, there was the determination of the French to establish footholds in the Middle East; second, there was the determination of the British to stop them; third, there was the bipartisan effort to limit the influence and power of Muhammad 'Ali's Egypt; and, fourth, there was the decision of the Ottoman Empire to reestablish its presence in the Yemen, which it had abandoned centuries earlier. Most of these interests intensified as a result of the opening of the Suez Canal in 1869 and the reemergence of the Red Sea route between Europe and the Far East as the most economical and commercially important one.

In the interim, primarily to establish a presence in southern Arabia from which to resist the advances of the Ottoman Empire, the British had, in 1839, taken the city of Aden. In succeeding decades, as the Ottoman Empire's presence became firmer and more widespread, the British presence expanded: the British obtained nearby islands and additional areas on the mainland (from malleable sheikhs). Under British administration the role of Aden as an entrepôt and coaling station began to grow; its population and its economic importance in the region similarly increased. To protect Aden's hinterland from the designs of the Ottomans as much as from the predation of local Yemeni leaders, the British signed a series of treaties with the sheikhs, *naqibs*, sultans, and other rulers of the small principalities into which the area's population was divided.

By the early 20th century the confrontations between the British and the Ottomans required an agreement; in 1904 a border commission and a subsequent treaty established the frontier between North and South Yemen. The treaty was regarded by both Yemens as an instance of non-Arab interference in Yemeni affairs.

British policy with respect to the Aden hinterland remained essentially unchanged throughout the decades following the treaty: noninterference in the internal affairs of most sheikhdoms, and assistance or guarantees with respect to their frontiers and the continuation in office of the main families. In effect, this made the protectorates a cordon sanitaire around Aden. By the early 1930s British influence began to make itself felt in the Hadhramaut

The decline of economic activity

The secular legal system

British and Ottoman conflict

area. Under the skillful diplomacy and negotiating skills of Harold Ingrams, a British resident adviser, the more than 1,400 tribes and clans of the Hadhramaut region were persuaded, in 1937, to participate in a truce, ending years of intertribal feuding and bloodshed. With that, the Eastern Aden Protectorate became another chink in the armour of the Aden Crown Colony.

At about the same time, it became increasingly clear that Britain had to reach agreement with the imam of Yemen. Because many of the disagreements over frontiers and similar matters could not be permanently settled, the Treaty of 1934 was essentially a papering over of most of the essential rifts, including sovereignty over the statelets of the protectorate. After World War II the problem grew apace: the imams of Yemen had the advantage of offering an indigenous Muslim regime as an alternative to the secular British government (for such it was in many areas, where advice had more or less become administration).

By the 1950s Imam Ahmad's aggressive policies in the Western Protectorate alarmed some of the ruling families there, who presumed, correctly, that if North Yemen were to take over, their positions would probably be severely curtailed if not eliminated. They therefore thought it in their interest to cooperate more closely with Great Britain, which after all paid most of them a subsidy. By 1959 an earlier proposal to federate some of the smaller and weaker statelets had grown into a much broader scheme to include all of the principalities, as well as a design for eventual independence.

In order to strengthen the federation, Britain insisted that Aden join it, thus creating the anomaly that eventually brought an end to the whole scheme: the sophisticated business community, the activist labour organizations, and similar modern associations in Aden feared their future at the hands of what they perceived to be a group of largely illiterate and unsophisticated tribal leaders. The tribal leaders, on the other hand, feared their overthrow at worst, and a considerably diminished political and economic role at best, at the hands of the overly sophisticated Aden population, which included many non-Muslims and non-Arabs. The British continued to insist upon their chosen course of action, and by 1965 all but four of the protectorate states had joined the federation—a total of 17 states. Shortly thereafter Britain announced that the federation would become independent no later than 1968. This announcement unleashed the political conflict and the bloodshed that characterized Aden and much of the protectorates for the next two years.

Two major groupings emerged: the Front for the Liberation of South Yemen (FLOSY), more or less dependent upon Egyptian support, and the National Liberation Front (NLF), which drew its support almost solely from indigenous sources. As the time for independence grew nearer, the conflict between the two developed into open warfare for the right to succeed the British. By late 1967 it was clear that the NLF was going to emerge as victor, as it had already established its control in all of the protectorate statelets. When the South Arabian Federation's army declared its allegiance to the NLF, Britain acceded to the inevitable and arranged the transfer of sovereignty to the NLF on Nov. 30, 1967.

The new government, which at first changed the name of the country to the People's Republic of South Yemen, was not warmly received. Short of resources and unable to obtain any significant amounts of aid or development assistance from the Western states, the new government began to drift toward the Soviet bloc, which was ready to welcome an Arab state into the ranks of "liberated states," especially after other Arab states had rebuffed Soviet overtures and aid programs. At the same time, also an outgrowth of the fact that its neighbours had supported its rival FLOSY, the NLF began to adopt aggressive policies toward these states, particularly Oman.

Relations with North Yemen were only marginally better even though many of South Yemen's leaders were from the north and were interested in unity between the two states (as reflected in the name adopted at independence). For most of the 1970s the movement of people between the two was marked: former leaders of South Yemen, such

as 'Abd Allah al-Asnaj, moved north and took government positions, and northerners such as 'Abd al-Fattāḥ Ismā'īl moved to the south.

Both states claimed to be in favour of unification; furthermore, some other Arab states (notably Libya) supported and subsidized various meetings and efforts to bring about unification. Yet unification clearly faced major obstacles: there were important differences in ideology, as well as domestic and foreign policy, between the two states, and some Arab states, such as Saudi Arabia, opposed the idea. Furthermore, in their effort to expand their influence in North Yemen, which was seen as a Western client state, the South Yemenis helped to found and fund a broad-based opposition movement, the National Democratic Front.

The desperation of their cause, and the desire to spread their vision of the future of the peninsula as soon as possible, led the NLF leadership in 1978 to assassinate North Yemen's president, Major Aḥmad ibn Hussayn al-Ghashmī. The aftermath in South Yemen was the summary trial and execution of the president there, Sālim 'Alī Rubayyī. Shortly thereafter, 'Abd al-Fattāḥ Ismā'īl became president.

Ismā'īl was the major ideologue and driving force behind the NLF's movement into the Soviet camp. Ultimately found to be too dogmatic and rigid in his analyses as well as his policies and methods of implementation, he was deposed in 1980 and went into voluntary exile in the Soviet Union. His successor, 'Alī Nāṣir Muḥammad, instituted a far less dogmatic political and economic order.

Nevertheless, the factionalism within the YSP continued; some supporters of the more ideologically pure viewpoint of the past resented the compromises of the Muḥammad regime. In February 1985, based upon their support, Ismā'īl returned to South Yemen from the Soviet Union. In party councils and other political bodies, many of the old disagreements on theory and policy reemerged.

In January 1986 these conflicts surfaced in a brief and violent civil war that left Ismā'īl dead and 'Alī Nāṣir Muḥammad exiled to North Yemen. Leadership of the government fell to Ḥaydar Abū Bakr al-Aṭṭas, who had served in previous governments as a technocrat.

Late in 1989, echoing the transformations occurring among its European allies, the government of South Yemen joined the government of North Yemen in announcing approval of a draft constitution for a unified democratic Yemen. Actual merger followed on May 22, 1990, some six months earlier than originally planned. Ṣan'ā' became the political capital and Aden the economic capital. The former North Yemen president, 'Alī 'Abd Allāh Ṣāliḥ, was elected president, and 'Alī Salem al-Baidh, former secretary general of the Socialist Party of South Yemen, was named vice president by the two countries' parliaments. All-Yemeni elections were scheduled to follow a two-and-a-half-year transition period.

For later developments in the history of South Yemen, see the *Britannica Book of the Year* section in the *BRITANNICA WORLD DATA ANNUAL*. (M.W.W./Ed.)

Yemen, North

The former Yemen Arab Republic, also known as North Yemen and as Yemen (Ṣan'ā'), merged with the People's Democratic Republic of Yemen (see above *Yemen, South*) in 1990 to form the Republic of Yemen. The present article treats the two regions individually.

North Yemen is situated in the southwestern corner of the Arabian Peninsula. It is bounded on the north and east by Saudi Arabia, on the south by South Yemen, and on the west by the Red Sea. Its eastern border with Saudi Arabia, marked by the desert region known as the Rub' al-Khali (the Empty Quarter), remains, however, undemarcated. Its seacoast, from the mouth of Wadi Maydī in the north to the Bab el-Mandeb Strait in the south, is about 280 miles (450 kilometres) long. Because of the indefinite boundaries, the area of North Yemen cannot be precisely determined. The former central government estimated an area of 77,200 square miles (199,950 square kilometres), but unofficial sources estimate about 52,210 square miles. The former capital,

Assassination of Yemeni presidents

British accession

Present-day boundaries

San'a', is now the political capital of the new republic.

Historically and geographically, North Yemen extended far beyond the boundaries of the present state. In ancient times it was successively the centre of the first Minaean (13th to 7th century BC), the Sabaeen (from about the 9th century to 115/110 BC), and the Himyaritic (from 115/110 BC to AD 525) civilizations. It was known to the Greeks as Eudaimon Arabia, to the Romans as Arabia Felix, and to medieval Arab scholars as al-Yaman as-Saida, all of which mean "Fortunate Yemen." Such geographic names invariably designated the whole of southern or southwestern Arabia, from latitude about 20° N southward to the Arabian Sea and from the Red Sea coast eastward to the vast sandy desert of the Rub' al-Khali and the ancient kingdom of Hadhramaut (now the Hadhramaut region in South Yemen). The political boundaries of North Yemen were established early in the 20th century by a variety of non-Yemeni governments. The government of North Yemen did not recognize these boundaries in their entirety.

PHYSICAL AND HUMAN GEOGRAPHY

The land. With sufficient periodic rainfall to permit systematic cultivation, North Yemen is quite unlike any other part of Arabia. It is a surprisingly fertile region in contrast to the generally arid character of the Arabian Peninsula. Because of its volcanic origin, high relief, and abundant rainfall, the country is characterized by a remarkable diversity of physical geography varying from lowlands to highland ranges.

Relief. North Yemen may be divided into four major regions, each extending from north to south. From west to east these are the Tihāmah, Upper Tihāmah, Yemen Highlands, and eastern plateau and valley area.

The Tihāmah consists of an arid, level strip of coastal land extending eastward from the Red Sea until the land reaches an altitude of 660 feet (200 metres). Intermittent patches of cultivated fields alternate with extensive chains of sand dunes. Wadis (seasonal watercourses) frequently end in the sands before reaching the sea.

In Upper Tihāmah, to the east, the flat plains of the Tihāmah change into canyonlike jagged valleys and low plateaus that run parallel to the coast. The region is sometimes known as Mountain Tihāmah. Its eastern slopes lie between 1,500 and 4,500 feet above sea level. The plains are crowned by several hills and peaks, while vigorous stream erosion has carved the crystalline, volcanic, and limestone rocks into a variety of formations.

The Yemen Highlands run through the centre of the country. They consist of high mountains between about 5,000 and 11,000 feet above sea level, although some peaks reach even higher. Valleys and plateaus give the region a very rugged and complicated topography. There are ancient volcanic structures, rolling plateau surfaces, high ridges separated by seasonal river valleys, and many natural or man-made terraces. These highlands form the best cultivated part of North Yemen and support some three-quarters of the country's population.

To the east of the highlands the land gradually slopes down toward the undefined eastern borders of the country. This region consists of larger and more extensive plateaus separated by well-defined and longer valleys. It lies roughly between 3,000 and 6,000 feet above sea level. The whole belt may be regarded as a transitional zone, where temperate conditions give way to semiarid and arid desert conditions.

Drainage. Innumerable wadis radiate in almost all directions from the highlands. There are perennial streams and rivers in the highlands, but they do not reach the coast. Their volume is limited by the seasonal character of the rainfall and its annual variations in volume, by the high rate of evaporation, and by the downward passage of water through the permeable rocks of some riverbeds. The orientation of the main drainage systems is toward the west and south, with a minor system draining to the east. Although many of the rivers flow in short, uninterrupted beds, the drainage of the highlands displays a branching pattern similar to that of a tree.

Soils. Most of the Tihāmah region is composed of transported material. The wadis deposit gravel and silt,

while the wind deposits sand and loess (a brown mixture of clay, silt, and sand). Poor white salt soils are quite common and can be utilized only if extensive irrigation is undertaken. In Upper Tihāmah, alluvial fans provide soils more favourable for agriculture. In the flood season, however, the loesslike soils occasionally become waterlogged, while in the dry season the land is susceptible to wind erosion.

On the highlands soils of the terraced fields are largely the result of weathering. Because of their high nutrient content and their texture, such weathered products are valuable agricultural lands. They are extremely vulnerable to water erosion, however, and may become rapidly exhausted under an intensive system of cultivation that employs little or no fertilization. Extensive highland areas are covered by lithosols—shallow soils consisting of nearly unweathered rock fragments, with few or no fine particles.

Climate. North Yemen lies at the border zone of two main air masses—the regular northerly winds and the southwest monsoon winds. These divide the climate into a fairly well-defined seasonal rhythm. Over the highlands, northerly winds predominate in the winter season, while in the summer the southwest monsoons bring considerable rain from July to September.

Seven climatic regions are generally recognized. Semiarid conditions extend along the Red Sea coast, where the average annual rainfall is less than three inches (75 millimetres), occurring in limited areas mostly during the winter months. Temperatures are high throughout the year, with an annual average of 86° F (30° C). Between the coastal region and Upper Tihāmah these conditions become more arid because of heat currents along the edge of the foothills, which often give rise to dust storms. Strong winds blow almost daily, reducing visibility to a few feet and inducing a high rate of evaporation.

In Upper Tihāmah precipitation is considerably higher, reaching an annual average of some 20 inches. The valleys, plains, and depressions provide easy access for air exchanges between the Tihāmah and the highlands that are characterized by twice-daily changes of wind direction. On the western slopes, between 2,200 feet and the frost line at 6,700 feet, precipitation occurs throughout the year. Yearly rainfall averages vary, according to altitude, from eight inches to 39 inches; there are two main rainy seasons. The southern mountain slopes receive rains generally in the summer. The eastern slopes form a transitional zone, where summer precipitation decreases eastward until desert conditions prevail. Winter rainfall is confined to the upper slopes. The average annual temperature is about 64° F (18° C).

As a climatic region, the highlands extend upward from the frost line. This is the coldest and wettest region. Precipitation, often accompanied by thunderstorms, ranges between 16 inches and 32 inches annually. Much of the rain falls in the summer, from July to December, while in the winter a secondary rainy season occurs, in March and April. The temperature can drop below freezing in the early hours of winter mornings; the annual maximum temperature is 82° F (28° C) and the minimum is 18° F (−8° C).

Plant life. The distribution of vegetation roughly follows variations in both elevation and precipitation. Three vegetational regions can be distinguished: the arid-to-semiarid Tihāmah, the steppe (treeless plain) and wooded region of Upper Tihāmah, and the mountain vegetation of the Yemen Highlands.

The damp coastal salt steppe is covered with dense salsola scrub, while low prickly grass (*Panicum turgidum*) merges into the more arid Bokar zone. In the wadis, acacias are the dominant species. Near the foothills of the western slopes, thorn trees form a discontinuous belt, which is interrupted by Upper Tihāmah. Other woody associations include sycamores, tamarind, pandanus, and acacias.

Between 600 and 4,000 feet above sea level, mountain vegetation includes such natural and cultivated plants as myrrh, carob, fig trees, date palms, and mango trees. The evergreen zone between 4,000 and 6,700 feet is characterized by the dominance of euphorbia, which grows to a height of 12 or 15 feet. Other plants include eucalyptus,

Seven
types of
climate

Four
physical
regions

The
direction of
drainage

acacia, buddleia (shrubs or trees with yellow or violet flowers), primula (perennial herbs), *Cleome arabica*, and aloes. Terrace cultivation and overgrazing have resulted in serious deforestation, and forest areas are confined to small, inaccessible or useless patches.

The treeless uplands above 6,700 feet are equivalent to the Alpine pastures of grassland and bushes. Thorn shrub vegetation is the dominant form; other species include *Euphorbia officinalis*.

The people. North Yemen has a generally homogeneous population, apparently formed from a mixture of two groups. The pre-Qaḥṭānian Mediterranean type, which originally inhabited the area, is believed to have been absorbed into a composite stock, in which Armenoid (Middle Eastern Alpine) elements predominate. In the highlands the population shows an even balance between the two types. Negroid characteristics introduced about the 5th or 6th century AD, however, are increasingly to be seen in the Tihāmah and toward the south but are almost entirely absent in the highlands. A further admixture of early Indo-Aryan traits occurs in some parts of the highlands, where the population is characterized by fair complexion, blue eyes, and blond hair. Virtually all the people are Arabic-speaking Muslims, and they are divided more or less equally into the two traditional Islāmic sects—Sunnism and Shī'ism. Sunnism is represented in North Yemen by the Shāfi'is in the south and southwest and Shī'ism by the Zaydis and the Ismā'ilis in the north, centre, and east. Yemeni Jews have mostly migrated to Israel.

Sunnism
and
Shī'ism

Demography. The demographic trends, life expectancy, and age structure of the population display characteristics typical of the less-developed world. The high birth rate in North Yemen is primarily the result of early marriages, poverty, and the fact that Yemenis take pride in having many children. The high death rate is generally the result of poor medical facilities, hygiene, and sanitation as well as high infant mortality. While immigration is almost negligible, emigration has been a constant characteristic of the Yemeni population since ancient times. In the late 20th century a steady stream of male migration, attributed to both economic and political causes, has resulted in the establishment of important Yemeni settlements in neighbouring countries, particularly in Saudi Arabia. Between one-third and one-half of the total male labour force was estimated to be working outside of the country in the early 1980s.

The bulk of the population lives in the western two-thirds of the country—that is, in the central highlands, the western slopes, and in parts of the Tihāmah where sufficient water is available for cultivation. There are important regional differences in population density. Thus the Tihāmah and the steppe regions have comparatively lower densities than the highlands. In eastern North Yemen the density is much lower than the national average.

Settlement patterns. Most agricultural villages of the highlands are spread out along the windward-facing slopes, where rainfall can support cultivation. The populous western and southern slopes present a sharp contrast to the dry eastern plateaus. In both the Tihāmah and eastern North Yemen the rural settlement pattern is one of nucleation, or clustered settlements, while on the wetter highlands the pattern is one of dispersion. The frost line at 6,700 feet marks the upper limit of dense rural settlement.

The average village is a fairly compact settlement with houses huddled close together. Some, especially in eastern North Yemen, represent relics of more prosperous, ancient settlements. In the highlands the average house is built of stone or brick, often to a height of three to five stories, while in the Tihāmah mud-brick and mud-grass houses with thatched or straw-covered roofs are fairly common. Kinship provides the basis of village social organization, and many of the smaller villages are inhabited by joint families.

The cities of North Yemen are primarily communities of traders and manufacturers. Other associated groups include an aristocracy, servants, the religious nobility, civil servants, and the unemployed. Some cities, such as Ṣan'ā', Zabid, Ta'izz, Ibb, and Bayt al-Faqih, can claim a long history stretching back to biblical times. Almost all the

urban settlements are scattered in the belt of denser population along the western slopes of the central highlands. The largest and most important city is Ṣan'ā', the capital. For centuries it has been a manufacturing centre, famous for its metalwork and high-quality steel as well as for its architecture and its numerous mosques. Ta'izz, located in a predominantly Shāfi'i area, is the major city of the south. Its position near South Yemen has made it an entrepôt for Yemeni trade through Aden. Of numerous ancient ports—such as Ṣalif, Mocha, Maydī, and al-Luḥayyah—only al-Ḥudaydah survives as a seaport of major commercial significance, the growth of Aden having stifled the maritime trade of North Yemen. Even al-Ḥudaydah was of little significance until 1961, when the construction of port facilities was completed.

Only a small percentage of the total population occupies the desert margins of the north and east. The people are largely seminomadic cultivators, living in tents.

The economy. Oil was discovered in North Yemen in 1984, and the country's participation in the oil market was expected to radically transform its basically agricultural economy. Foreign aid, mainly from Saudi Arabia and Kuwait, was substantially reduced after the fall of oil prices on the world market in 1985.

Resources. Although little scientific surveying has been conducted in North Yemen, the country is generally considered to be rich in minerals. Deposits of oil have been found in the northeast in the Ma'rib-al-Jawf basin and elsewhere in the country. Iron ore, already mined and smelted on a small scale at Jabal Nuqum, has also been discovered in the older sandstone region in the north, at Sa'ada and Najrān. Other mineral deposits include coal, copper, sulfur, lead, zinc, nickel, silver, gold, and uranium. Salt is mined at Ṣalif in the Tihāmah.

Agriculture. The economy of North Yemen is primarily agricultural; the country is not, however, self-sufficient in foodstuffs. Subsistence farming predominates, and agricultural methods have remained almost unchanged through the centuries. The peasant tribesmen still work their land with ox-drawn plows, and they have retained the traditional method of fertilizing with manure and alternating the growing of the principal crops with vegetables, legumes, and clover. Tractors, chemical fertilizers, and modern irrigation methods, however, are used increasingly. About 90 percent of all agricultural land is given to cereal crops, including sorghum, millet, barley, and corn (maize).

The country's extremes of altitude and variations in soil and climate make it possible to grow a wide variety of crops. Coffee, khat (*qāt*; an evergreen shrub with leaves that act as a stimulant when chewed), and cereals are grown in the highlands; citrus fruits, grapes, and other Mediterranean fruits are grown on the slopes; while millet, bananas, cotton, dates, tobacco, mangoes, and tropical fruits are produced on the coastal plain. On the dry eastern slopes terracing is less common, and the fields are confined to areas into which rainwater is channeled or where springs can be used for irrigation.

Coffee, khat, and cotton are of particular importance to the country's economy as cash crops. Coffee for centuries has been the most important and renowned export of North Yemen. Internationally known as mocha because Mocha (al-Mukhā) was the main export port, it is still among the most prized and expensive of the world's coffees. The choicest variety is grown in the area around Ṣan'ā', and the four best kinds are Matari, Sanani, Sherki, and Haymi. Coffee is generally grown under irrigation at an altitude between 4,300 and 6,700 feet. Exports, sold chiefly in the United States and Europe, are an important source of the foreign exchange of North Yemen.

Coffee cultivation, however, has been steadily yielding to the more profitable growing of khat. Yemeni khat, like Yemeni coffee, is considered to be of superior quality; the government's measures to limit its production and consumption have had little effect. Its local use, however, is largely confined to urban centres.

In the Tihāmah, cotton cultivation has decreased substantially since the mid-1970s as a result of adverse weather conditions and generally low prices. The chief cereal is millet, and other crops of the area (grown with irrigation)

Traditional
farming

include sugarcane, dates, tobacco, flax, sesame, olives, watermelons, and a variety of market-garden produce. In the subtropical zone of Upper Tihāmah, wadi beds are often terraced, and the principal crops include corn, bananas, citrus fruit, papaya, and aromatic herbs. The agricultural development of the Tihāmah is being funded by the United Nations, the International Development Association, the Kuwait Fund for Arab Economic Development, and other international organizations.

Cattle breeding is practiced, but old methods are still in use, and the livestock industry in general is still in its infancy. The indigenous cattle are mainly of the Asiatic zebu variety, which produces little milk. The Frisian, a European dairy breed, was introduced but without much success. Sheep of three varieties are bred. The predominance of sheep rearing over the raising of all other livestock except goats is due to the triple yield of meat, milk, and wool. Sheepskin exports are significant.

Fishing. Fishing is a relatively small industry. Small boats known locally as *sunbuk* are used; they are based in the Red Sea ports of al-Luḥayyah, al-Ḥudaydah, al-Ghulayfiqah, and Mocha. The catch is consumed locally; dried fish is sold in the interior, while oysters and clams are marketed on the coast. A fish-processing plant, however, was built near al-Ḥudaydah.

Industry. The handicraft industry is known for its high degree of skill and artistry. Notable products include fine textiles, jewelry, indigo dyes, carpets, sheepskins and leatherwork, glass, domestic utensils, swords and shields, and a variety of ornaments. Modern industry, however, is still in its infancy. There are small industrial plants at al-Ḥudaydah, Bājil, and Ṣan'ā'. Al-Ḥudaydah has a cotton gin, cotton-cleaning plants, and a cigarette plant, among others. Bājil has a cotton-spinning and cotton-weaving factory and a number of light industries, including a cement factory. In Ṣan'ā' an integrated cotton-textile factory was completed in 1967, and its products account for a large percentage of the country's exports.

The almost-unexploited mineral and industrial potential of North Yemen has attracted local and foreign interest. Industrial concerns include the Yemen Petroleum Company in Ṣan'ā', the Yemen General Electricity Corporation, the Yemen Textile and Weaving Corporation in Ṣan'ā', and the Yemen Company for Industry and Trade. The Yemen Hunt Oil Company, a subsidiary of the U.S. Hunt Oil Company, has developed the oil wells in the Alif field, in the Ma'rib-al-Jawf basin, and opened a refinery there in 1986. Construction was completed in 1987 on a pipeline linking the Alif field with the Red Sea terminal of 'Isā Point, near the port of Ṣalif.

Finance. The Central Bank of Yemen, founded in 1971, is responsible for issuing currency and for managing gold and foreign exchange reserves. The Yemeni Bank for Reconstruction and Development, founded in 1962, has several branches in the country. Foreign banks include the British Bank of the Middle East, the Arab Bank Ltd. (Jordanian), and two Pakistani banks, the Habib Bank Ltd. and the United Bank Ltd.

Trade. Until 1961 about 75 percent of the international trade of North Yemen passed through Aden. Following the attainment of independence in 1962, however, nearly all trade passed through the port of al-Ḥudaydah. The export trade, however, was insufficiently organized and did not match the import trade in quantity, value, or variety. In the mid-1980s exports covered only about one-fifth of the value of imports. The principal agriculture-based exports are cotton, cotton fabrics, and yarn; cereals; hides and skins; and coffee. Crude petroleum is also exported. Imports include food and live animals, manufactured goods, machinery and transport equipment, and chemical products.

Transportation. Road development has been promoted by considerable foreign aid. The People's Republic of China constructed the mountainous road from al-Ḥudaydah to Ṣan'ā', the United States built the road from Mocha to Ṣan'ā' via Ta'izz, the Soviet Union built the road from al-Ḥudaydah to Ta'izz, and West Germany provided aid to asphalt the Ṣan'ā'-Ta'izz road. The road from Ṣan'ā' east to Ma'rib was completed in 1984. The mountain-

ous roads, especially the al-Ḥudaydah-Ṣan'ā' road, built by imported Chinese labour and rising to more than 11,000 feet above sea level, represent technical achievements. Goods are transported by modern trucks that are often overloaded. Passenger buses make regularly scheduled trips among Ṣan'ā', Ta'izz, and al-Ḥudaydah. There are also innumerable tracks and trails radiating in many directions; Ṣan'ā' is the central focus of most of them.

The major port is at new al-Ḥudaydah, to the north of old al-Ḥudaydah. It is equipped with cranes, a power station, repair docks, and storage facilities. All large ships dock at new al-Ḥudaydah, which is frequently congested, while only small boats continue to use Mocha.

The Yemen Navigation Company runs passenger and cargo shipping services to many ports in the Red Sea and on the east coast of Africa. Smaller companies have cargo boats that ply between al-Ḥudaydah, Djibouti, and Aden.

Yemen Airways (Yemenia) operates domestic flights among al-Ḥudaydah, Ṣan'ā', and Ta'izz airports and international flights to Arab countries in the Middle East and Africa.

Administration and social conditions. *Government.* Independent North Yemen had a republican form of government under the provisional constitution of 1974. The legislative body was the Constituent People's Assembly, appointed in 1978 to replace the Military Command Council. The head of state and government was the president, who was elected to a five-year term of office by the Assembly. The Cabinet, headed by the prime minister, was the executive body. The General People's Congress, consisting of 700 elected members and 300 presidential appointees, provided representation for the people at large. In 1979 North Yemen and South Yemen agreed to unite. A draft constitution was prepared in 1981, but was not approved until late 1989. The merger formally took place on May 22, 1990.

North Yemen is divided into *liwā* (province), *qaḍā'* (district), and *nāhiyah* (subdistrict) levels. Ṣan'ā' is the most populous province and the most economically developed. Each *nāhiyah* is composed of about 30 or 40 villages.

Justice. Justice and laws are in accordance with Islam, and where constitutional meaning is unclear the principles of the Shari'ah are applied. Early in 1964 a Shari'ah court was established in Ṣan'ā' to deal with political cases and the trials of senior government officials; it is the country's highest court. Judges must be well acquainted with Islamic law, and members of the government must "uphold the Qur'an, the teachings of the Prophet, and his religion."

Armed forces. The Supreme Defense Council, headed by the president, is charged with the nation's defense and creation of a popular army. The air force flies bombers and fighters as well as transports and helicopters.

Health and welfare. Despite the generally healthy climate of the Yemen Highlands, where most of the population lives, health conditions are poor. Since the 1960s, the number of hospitals and other health facilities, as well as the number of doctors, has greatly increased. The most prevalent communicable and endemic diseases are gastroenteritis and malaria.

Education. Education was largely provided by traditional Qur'anic schools until secularization was begun in the late 1930s. A modern graded school system has been in operation since 1962, providing for a six-year primary stage, a three-year intermediate stage, and a three-year secondary course. Although education is free, only a small percentage of children attend school. Despite the government's increasing attention to education, North Yemen has a low level of literacy.

Higher education within the country is limited to Ṣan'ā' University, founded in 1970, and a small number of colleges. There is an agricultural college, founded at Ṣan'ā' in the late 1930s, and there are several vocational and polytechnic schools, including one for aviation and another for radio telecommunications. Of the theological colleges—often attached to mosques or to their libraries—those at Zabid, Ta'izz, and Dhamār are the most important.

Cultural life. In spite of its apparent cultural unity, the Yemen was a meeting place for many ancient cultures and civilizations. Similarities have been drawn between

Handicrafts

Road construction

Modernization of education

marriage institutions in India and Yemen and between religious music in Yemen and Byzantine masses.

Tribal dances, some of which are of pre-Islāmic origin, are performed by men and boys alone or by girls alone. At weddings and other festivities, males dance slowly around in a circle, each pirouetting as he advances to the accompaniment of drums; each holds his traditional dagger (*jambiya*) aloft, with the point downward.

Local oral literature is rich in proverbs, popular stories, superstitions, mysticism, and poetry. Written literature, though not as rich, deals mainly with Yemeni history, Islāmic theology, biography, and poetry. Modern Arabic literature from the neighbouring countries has a direct impact on Yemeni cultural life.

There are daily newspapers and several weekly and other magazines. A national television network was established in 1980. Both press and broadcasting are largely controlled by the government.

For statistical data on the land and people of North Yemen, see the *Britannica World Data* section in the *BRITANNICA WORLD DATA ANNUAL*. (Y.T.T./Ed.)

HISTORY

For several centuries before the Muslim conquest the Himyarites (Homeritae) were dominant in the Yemen, but in AD 525 the last Himyarite king, a Jewish convert named Yūsuf As'ar Yath'ar and called Dhū Nuwās, was overthrown by the Ethiopians (Aksumites) in revenge for his massacre of the Ethiopian population of Mocha. Under the Aksumite Abraha (Abreha), who established himself as an independent ruler, the country prospered, but foreign rule was unpopular and a Himyarite prince asked for Persian help. The Persians expelled the Ethiopians c. 575 but stayed on to establish their own rule. The last Persian viceroy embraced Islām in 628.

The Muslim conquest. The Yemen easily accepted the new religion. 'Alī, Muḥammad's son-in-law, was named governor of the country, but after the Prophet's death dissidents rose in revolt. The first caliph, Abū Bakr (632–634), united the whole of Arabia, including the Yemen, under his rule, but neither then nor in the Umayyad or 'Abbāsīd periods were the caliphs able to exercise really effective control.

Members of the Shi'ite sect, who wanted 'Alī's descendants to rule, became a menace to the caliphate, and the 'Abbāsīd caliph Ma'mūn sent Muḥammad ibn Ziyād to subdue them. Ibn Ziyād established his own dynasty (c. 822) and founded Zabīd in the lowlands as his capital. In 861 another local dynasty, the Banū Yūfir, established itself in the highlands with the capital at Ṣan'ā'. The 'Abbāsīds had to acknowledge both dynasties.

A group known as Zaydis, Shi'ite followers of Zayd, grandson of the Prophet's grandson Ḥusayn, arrived in the 9th century from Iraq and the Hejaz and later ruled much of the northern highlands. The 10th and 11th centuries are thus a confused tale of contesting local dynasties. The (Ismā'īlī) Ṣulayḥīds aided by the Fāṭimid caliphs of Egypt were dominant from 1063 for about 50 years, while the 'Abbāsīds supported the Sunnites of the coast.

The 12th to 19th centuries. After overthrowing the Fāṭimids, Saladin sent his brother Tūrān-Shāh to annex the Yemen in 1173. He made Ta'izz his capital and ruled most of the Yemen except for the area north of Ṣan'ā'. As Saladin's Ayyūbid dynasty gradually succumbed to the Mamlūks, his Kurdish and Turkish representatives in the Yemen became independent; they set up the brilliant Rasūlid dynasty in about 1230, with its capital at Zabīd. The Rasūlids ruled nearly all of the Yemen, including the thriving port of Aden, and administered the land through fiefs (*iqṭā'*). On their decline in the 15th century, Sunnites continued to flourish for a while, as the Ṭāhirids (from 1453, capital Ta'izz) dominated most of the area. From 1538 Ottoman Turkish armies overran the country, aided immeasurably by their use of artillery. The Zaydis of the north were based on a tribal army as they established their local rule, but it was their leader Qāsim the Great—who was imam from 1597 to 1620—and his son Muḥammad who expelled the Ottomans by 1636.

The English, under the auspices of the East India Com-

pany and with a firman from the Ottomans, built a trading post at Mocha (al-Mukhā) in 1618; coffee was the major commodity traded. The imam Ismā'il (1644–76) reestablished Zaydī control over all of the Yemen and fought the rising power of Oman for control of the southern coastal ports. After the death of Ismā'il, the Yemen subsided into chaos, and the lowlands became independent under various chiefs. Al-Mahdī 'Abbās (1748–75) temporarily revived the power of the imamate, but after 1835 his descendants lost effective power.

Wahhābī influence made some advance in the area of the Red Sea coast from 1803, but that was checked during 1816–18 when Ibrahim Pasha invaded the Yemen from the Hejaz on behalf of his father, Muḥammad 'Alī, viceroy of Egypt. The English capture of Aden in 1839 and the return of the Turks in 1849 ended this Egyptian control. In 1872 the Ottomans captured Ṣan'ā'.

The Zaydī imamate was elective, but in 1891 the new imam, Muḥammad ibn Yaḥyā Ḥamīd ad-Dīn, virtually transformed the 1,000-year-old imamate into a hereditary dynasty that survived until 1962. Resistance to the Ottoman Empire continued until 1911, when the Ottomans made an agreement with Imam Yaḥyā (ruled 1904–48) conceding in substance most of his demands for local authority. The agreement was observed by both parties, and Yaḥyā supported the Ottomans in World War I.

Independence. After the Ottoman defeat, imamic independence meant the resuscitation of Zaydī claims to the historic Yemen, including Aden and the protectorate; Imam Yaḥyā did not recognize the Anglo-Ottoman boundary agreed upon in 1914. The Yemen lost the war of 1934 with Saudi Arabia and had to yield its claims on Asir to the Saudis. In the same year, the Imam concluded a treaty with the British providing for the preservation of the status quo of the frontiers. Yaḥyā strengthened the imamate by extending government power to the Shāfi'is, and he sent military cadets to Iraq and Egypt. Although generally the Yemen was kept isolated from the rest of the world, many Yemenis left to work in Aden or abroad, where they came to see alternatives to the existing order. Dissatisfaction with Zaydī rule and the conservatism of the dynasty led to Yaḥyā's assassination in 1948, and his son Aḥmad succeeded to the imamate. An attempt to depose him in 1955 was foiled, and Aḥmad beheaded two of his brothers for their share in the conspiracy.

Revolution. Imam Aḥmad died on Sept. 19, 1962, and was succeeded by his son Muḥammad al-Badr. Al-Badr's first act was to appoint 'Abd Allāh as-Sallal as chief of staff, and it was as-Sallal, who had functioned as al-Badr's trusted aide, who ultimately came to lead the revolution against the Imam. The revolutionaries falsely claimed to have killed al-Badr when the fighting began on September 26. The new Yemen Arab Republic was announced, and Egyptian troops soon arrived by sea and by air. The appointment of a new Cabinet consisting of as-Sallal as president and 18 ministers made it clear that the new republic was very largely dependent upon the Yemeni army and upon strong Egyptian support. The republic continued to be dominated by Zaydis as the imamate had been, but many of the sayyids (the descendants of the Prophet) lost their power and their lives.

Even though the Imam was alive and support for him was increasing in the north (encouraged by help from Saudi Arabia), the new revolutionary government was recognized by the Communist countries, the Arab republics, and the United States.

Attempts by the United Nations to mediate and to effect a withdrawal of Egyptian and Saudi Arabian aid were unsuccessful. By early 1965 the Imam and his tribal supporters appeared to be winning in much of the country. Internal political disorder was augmented on the emergence of a "third force" between republicans and royalists. In April 1965 a "third force" leader, Aḥmad Nu'mān, became premier, and a presidency council of six was set up, including as-Sallal as chairman.

Yemen was in effect divided into a republic and a kingdom. The latter probably covered two-thirds of the country, though much of it was less densely populated than the area of the republic. The roots of the revolution were in

Dynasty

Dynasty of
Ibn Ziyād

the towns rather than among the northern tribes or in the countryside. It was in the towns that evidence of social and material change—such as the abolition of slavery and the creation of banks—largely due to Egyptian and other foreign influence, was mostly to be found.

One of the results of an Arab summit meeting held at Khartoum from Aug. 28 to Sept. 3, 1967, was an agreement between the Egyptians and the Saudis to withdraw all support from the republicans and the royalists. Saudi Arabia was anxious that this should coincide with the British evacuation from Aden. The date agreed for the withdrawal from Yemen was fixed for Dec. 15, 1967. By early October the first transports of Egyptian troops had left Yemen and by the end of November the British had evacuated Aden.

As-Sallal was dismissed from the republican presidency on Nov. 5, 1967, by the Yemeni army with the encouragement of Egypt. He was replaced by a three-man presidency council headed by Qadi 'Abd ar-Rahmān al-Iryāni, a former member of the republican government who had been under house arrest in Cairo the previous year.

The eight-year civil war finally came to an end in 1970 with the reconciliation of the moderates among the republicans and the royalists, and the latter were integrated into the republican regime. The first elections for the members of the Consultative Council, as provided in the December 1970 constitution, were held in March 1971. In 1972 fighting broke out along the border with South Yemen. A cease-fire in October led to negotiations that produced a surprising agreement to unite the two countries, signed on Oct. 28, 1972. Although sentiment was strong for unity, the vast differences in political systems, foreign alliances, and economies precluded any substantive steps toward actually uniting the two Yemens.

On June 13, 1974, the government of President al-Iryāni was overthrown by a seven-man junta, led by Colonel Ibrāhīm al-Ḥamdī. The constitution and the Consultative Council were suspended. The change in government discouraged efforts toward unification of the pro-Saudi North Yemen with the pro-Soviet South Yemen. North Yemen developed increasingly closer relations with Saudi Arabia, which provided important budget and development assistance.

Negotiations between the heads of state of the two Yemens on unification were held in February 1977 and were scheduled to continue through the year. Colonel al-Ḥamdī was assassinated on Oct. 11, 1977, however. Forces opposed to unification and to military reform were believed responsible. Major Aḥmad ibn Ḥusayn al-Ghashmī, elected by the appointed Constituent Assembly on April 22, 1978, was killed two months later. The Constituent Assembly elected Colonel 'Alī 'Abd Allah Ṣāliḥ president on July 17, 1978. Ṣāliḥ conciliated nearly all factions and foreign states and managed to extend his rule as the military became the only institution that held the country together. Foreign policy and military purchases were designed to balance the influence of the Soviet Union with that of the United States and Saudi Arabia.

Border fighting with South Yemen that broke out in July intensified into full-scale war in February 1979. In North Yemen the National Democratic Front (NDF), an opposition group, also engaged in fighting in the border area and claimed to capture several towns. In March a cease-fire was agreed on, with the withdrawal of troops of both North Yemen and South Yemen from the border area and a reopening of unification talks. The talks, however, led to no real change in the relations between the two states. The Yemeni economy and government rested largely on the prosperity of Saudi Arabia, where hundreds of thousands of Yemenis worked.

In late 1989, the two Yemeni governments announced their approval of a draft constitution for a unified, democratic Yemen. The actual merger was formalized on May 22, 1990. Ṣan'ā' was made the political capital of Yemen, with Aden designated the economic capital. 'Alī 'Abd Allah Ṣāliḥ was elected president, and 'Alī Salem al-Baidh, former secretary general of the Socialist Party of South Yemen, was named vice president by the two Yemeni parliaments. Nationwide elections were scheduled

to follow a transition period of two and a half years.

For later developments in the history of North Yemen, see the *Britannica Book of the Year* section in the *BRITANNICA WORLD DATA ANNUAL*. (W.H.I./W.L.O./Ed.)

BIBLIOGRAPHY

Introductions to the area include SHEILA A. SCOVILLE (ed.), *Gazetteer of Arabia: A Geographical and Tribal History of the Arabian Peninsula*, (1979–), 1 vol. of which had appeared by 1987; ROBERT W. See also M.W. DEMPSEY (comp.), *Atlas of the Arab World* (1983). Early explorations are chronicled in DAVID GEORGE HOGARTH, *The Penetration of Arabia: A Record of the Development of Western Knowledge Concerning the Arabian Peninsula* (1904, reprinted 1981); R.H. KIERNAN, *The Unveiling of Arabia: The Story of Arabian Travel and Discovery* (1937, reprinted 1975); ROBIN BIDWELL, *Travellers in Arabia* (1976); and ZAHRA FREETH and H.V.F. WINSTONE, *Explorers of Arabia: From Renaissance to the End of the Victorian Era* (1978). First-hand accounts include H.S.T.J.B. PHILBY, *Arabia of the Wahhabis* (1928, reprinted 1977), *Sheba's Daughters: Being a Record of Travel in Southern Arabia* (1939), and *Arabian Highlands* (1952, reprinted 1976). The people of the peninsula are described in PETER MANSFIELD, *The New Arabians* (1981); H.R.P. DICKSON, *The Arab of the Desert*, 3rd ed. rev. and abridged by ROBERT WILSON and ZAHRA FREETH (1983); MAX FREIHERR VON OPPENHEIM, *Die Beduinen*, 2 vol. (1939, reprinted 1983); and WALTER DOSTAL, *Die Beduinen in Südarabien*. (1967). Religious life and history are detailed in GONZAGUE RYCKMANS, *Les Religions arabes préislamiques*, 2nd ed. (1951); J. SPENCER TRIMMINGHAM, *Christianity Among the Arabs in Pre-Islamic Times* (1979); and A.J. ARBERRY (ed.), *Religion in the Middle East*, vol. 2, *Islam* (1969, reprinted 1976). Articles on the geography, history, and religion of the Arabian Peninsula may be found in *The Encyclopaedia of Islam*, 4 vol. and a suppl. (1913–36), with a new edition in progress, of which 5 vol. were issued from 1960 to 1986; and *The Shorter Encyclopaedia of Islam* (1953, reprinted 1974), with articles taken from the larger work. A useful index to publications is *Index Islamicus, 1906–1955* (1958), with supplements covering publications to 1980, and, for later materials, continued by *The Quarterly Index Islamicus*. Periodicals include *Arabian Studies* (annual); *The Middle East and North Africa* (annual); *The Middle East Journal* (quarterly); and *Proceedings of the Seminar for Arabian Studies* (annual).

Archaeology and early history are described in RICHARD LE BARON BOWEN, JR., and FRANK P. ALBRIGHT, *Archaeological Discoveries in South Arabia* (1958); G. LANKESTER HARDING, *Archaeology in the Aden Protectorates* (1964); F.V. WINNETT and W.L. REED, *Ancient Records from North Arabia* (1970); and BRIAN DOE, *Southern Arabia* (1971). General historical studies include J. WELLHAUSEN, *The Arab Kingdom and Its Fall* (1927, reprinted 1973; originally published in German, 1902), covering the Islamic empire, AD 622–750, still useful though some views are now disputed; HERMANN V. WISSMANN, *Zur Geschichte und Landeskunde von Alt-Südarabien* (1964); PHILIP K. HITTI, *History of the Arabs from the Earliest Times to the Present*, 10th ed. (1970, reprinted 1977); ZAMIL MUHAMMAD AL-RASHID, *Su'ādi Relations with Eastern Arabia and 'Uman, 1800–1870* (1981); R.B. SERJEANT, *Studies in Arabian History and Civilisation* (1981); WILLIAM OCHSENWALD, *Religion, Society, and the State in Arabia: The Hijaz Under Ottoman Control, 1840–1908* (1984); GEORGE ANTONIUS, *The Arab Awakening: The Story of the Arab National Movement* (1938, reissued 1981); and IAN RICHARD NETTON (ed.), *Arabia and the Gulf: From Traditional Society to Modern States* (1986). More specialized works include NIGEL GROOM, *Frankincense and Myrrh: A Study of the Arabian Incense Trade* (1981); M.J. KISTER, *Studies in Jāhiliyya and Early Islam* (1980); GUNNAR OLINDER, *The Kings of Kinda of the Family of Akil al-Murār* (1927); R.B. SERJEANT, *The Portuguese off the South Arabian Coast: Hadrami Chronicles, with Yemeni and European Accounts of Dutch Pirates off Mocha in the Seventeenth Century* (1963, reprinted 1974); and NELSON GLUECK, *Deities and Dolphins: The Story of the Nabataeans* (1965), a study of early Arab traders and seafarers.

Comparative coverage of the five Persian Gulf states—Bahrain, Kuwait, Oman, Qatar, and the United Arab Emirates—is provided by RICHARD F. NYROP (ed.), *Persian Gulf States: Country Studies*, 2nd ed.; JOHN BULLOCH, *The Persian Gulf Unveiled* (U.K. title, *The Gulf*, 1984); and ALVIN J. COTRELL (ed.), *The Persian Gulf States: A General Survey* (1980). Discussions of early history include PENELOPE TUSON, *The Records of the British Residency and Agencies in the Persian Gulf* (1979); AHMAD MUSTAFA ABU-HAKIMA, *History of Eastern*

PETERSON, *Defending Arabia* (1986); and HUSAIN M. ALBAHARNA, *The Arabian Gulf States: Their Legal and Political Status and Their International Problems*, 2nd rev. ed. (1975).

Overviews of the peninsula's southern region are given in RICHARD F. NYROP (ed.), *The Yemens: Country Studies*, 2nd ed. (1986); ROBIN BIDWELL, *The Two Yemens* (1983); and HAROLD INGRAMS, *Arabia and the Isles*, 3rd. ed. (1966). The prehistory of the area is studied in *Archäologische Berichte aus dem Yemen*, 2 vol. (1982–83); and JACQUELINE PIRENNE, *Le Royaume sud-arabe de Qatabân et sa datation d'après l'archéologie...* (1961). Historical explorations include HENRY CASSELS KAY (trans.), *Yaman: Its Early Mediaeval History* (1892, reissued 1968); JOSEPH CHELHOD et al., *L'Arabie du sud: histoire et civilisation*, 3 vol. (1984–85); and ERIC MACRO, *Yemen and the Western World, Since 1571* (1968). For modern history and politics, see B.R. PRIDHAM (ed.), *Contemporary Yemen: Politics and Historical Background* (1984), and *Economy, Society, & Culture in Contemporary Yemen* (1985); and STEPHEN PAGE, *The Soviet Union and the Yemens: Influence on Asymmetrical Relationships* (1985). A useful bibliography is G. REX SMITH (comp.), *The Yemens: The Yemen Arab Republic and the People's Democratic Republic of Yemen* (1984).

Bahrain: Good general accounts include JOHN WHELAN (ed.), *Bahrain* (1983); ANGELA CLARKE, *The Islands of Bahrain: An Illustrated Guide to Their Heritage* (1981); and JAMES H.D. BELGRAVE, *Welcome to Bahrain*, 9th ed. (1975), a detailed guidebook that includes the geography, history, and customs of Bahrain, together with a bibliography of works in Arabic, English, and French. The islands' history is surveyed in CURTIS E. LARSEN, *Life and Land Use on the Bahrain Islands: The Geoarchaeology of an Ancient Society* (1983); ABBAS FAROUGHY, *The Bahrain Islands, 750–1951: A Contribution to the Study of Power Politics in the Persian Gulf: An Historical, Economic, and Geographical Survey* (1951); and M.G. RUMAIHI, *Bahrain: Social and Political Change Since the First World War* (1976). Politics and social conditions are addressed in JEFFREY B. NUGENT and THEODORE THOMAS (eds.), *Bahrain and the Gulf: Past Perspectives and Alternative Futures* (1985); and FUAD I. KHURI, *Tribe and State in Bahrain: The Transformation of Social and Political Authority in an Arab State* (1980). Further bibliographic information can be found in P.T.H. UNWIN (comp.), *Bahrain* (1984).

Kuwait: For the geography and history of the country, see AHMAD MUSTAFA ABU-HAKIMA, *The Modern History of Kuwait, 1750–1965* (1983); DAVID SAPSTED, *Modern Kuwait* (1980); and VIOLET DICKSON, *Forty Years in Kuwait* (1971). On the economy, see JACQUELINE S. ISMAEL, *Kuwait: Social Change in Historical Perspective* (1982); RAGAEI EL MALLAKH, *The Absorptive Capacity of Kuwait: Domestic and International Perspectives* (1981), and *Kuwait: Trade and Investment* (1979); and Y.S.F. AL-SABAH, *The Oil Economy of Kuwait* (1980).

Oman: For the geography of Oman, see numerous travel accounts, beginning with J.R. WELLSTED, *Travels in Arabia*, 2 vol. (1838, reprinted 1978), by one of the first Europeans to venture into the Omani interior. Classic accounts by 20th-century explorers include BERTRAM THOMAS, *Alarms and Excursions in Arabia* (1931), by the first Westerner to cross the Rub' al-Khali; and WILFRED THESIGER, *Arabian Sands* (1959), a lyrical description of the desert by an Englishman who crossed it repeatedly. General works include DONALD HAWLEY, *Oman & Its Renaissance*, 4th ed. (1987); and LIESL GRAZ, *The Omanis: Sentinels of the Gulf* (1982). Anthropological studies include JÖRG JANZEN, *Nomads in the Sultanate of Oman: Tradition and Development in Dhofar* (1986; originally published in German, 1980); and FREDRICK BARTH, *Sohar: Culture and Society in an Omani Town* (1983). The role of women is the subject of CHRISTINE EICKELMAN, *Women and Community in Oman* (1984); and UNNI WIKAN, *Behind the Veil in Arabia: Women in Oman* (1982). A fascinating collection of old photographs is found in W.D. PEYTON, *Old Oman* (1983).

JOHN DUKE ANTHONY, JOHN PETERSON, and DONALD SEAN ABELSON, *Historical and Cultural Dictionary of the Sultanate of Oman and the Emirates of Eastern Arabia* (1976); and S.B. MILES, *The Countries and Tribes of the Persian Gulf*, 2 vol. (1919, reissued in 1 vol., 1966), are general introductions.

PATRICIA RISSO, *Oman & Muscat: An Early Modern History* (1986); and ROBERT GERAN LANDEN, *Oman Since 1856: Disruptive Modernization in a Traditional Arab Society* (1967), are scholarly treatments of the first and second halves of the 19th century, respectively. J.E. PETERSON, *Oman in the Twentieth Century: Political Foundations of an Emerging State* (1978), gives a political history of the sultanate; and JOHN C. WILKINSON, *The Imamate Tradition of Oman* (1987), outlines the background of the events leading to the demise of the Ibādi Imamate in the 1950s. The period before the 1970 coup d'état is described in IAN SKEET, *Muscat and Oman: The End of an Era* (1974, reprinted 1985); and JOHN TOWNSEND, *Oman: The Making of a Modern State* (1977), gives a general assessment of the challenges facing the state after the coup. See also B.R. PRIDHAM (ed.), *Oman: Economic, Social, and Strategic Development* (1987), for an overview. Further research information may be found in FRANK A. CLEMENTS (comp.), *Oman* (1981); and BRUNO LE COUR GRANDMAISON and COLETTE LE COUR GRANDMAISON (comps.), *Contribution to a General Bibliography of Oman* (1980).

Qatar: JOHN WHELAN (ed.), *Qatar* (1983); and P.T.H. UNWIN (comp.), *Qatar* (1982), provide introductions to the geography and culture of the country. HELGA GRAHAM, *Arabian Time Machine: Self-Portrait of an Oil State* (1978), is an introduction to the people of Qatar. For a discussion of Qatar's economic history, policies, and prospects, see RAGAEI EL MALLAKH, *Qatar: Energy and Development* (1985). The history of Qatar from 1766 to 1949 is discussed in ROSEMARIE SAID ZAHLAN, *The Creation of Qatar* (1979).

Saudi Arabia: Overviews are provided by NORMAN ANDERSON et al., *The Kingdom of Saudi Arabia*, 7th ed. rev. (1987); MIDDLE EAST RESEARCH INSTITUTE, *MERI Report: Saudi Arabia* (1985); RICHARD F. NYROP (ed.), *Saudi Arabia: A Country Study*, 4th ed. (1984); TREVOR MOSTYN (comp.), *Saudi Arabia*, 2nd ed. (1983); and ISMAIL I. NAWWAB, PETER C. SPEERS, and PAUL F. HOYE (eds.), *Aramco and Its World: Arabia and the Middle East* (1980). HUSSEIN HAMZA BINDAGI, *Atlas of Saudi Arabia* (1978), includes thematic, regional, and city maps. Two major cities are the subject of GERALD DE GAURY, *Rulers of Mecca* (1951, reissued 1980); and ANGELO PESCE, *Jiddah: Portrait of an Arabian City*, rev. ed. (1977). Sociological studies include SORAYA ALTORKI, *Women in Saudi Arabia: Ideology and Behavior Among the Elite* (1986); and WILLIAM LANCASTER, *The Rwala Bedouin Today* (1981), a case study. See also G.R.D. KING, *The Historical Mosques of Saudi Arabia* (1986), a study of mosque architecture; and SAFEYA BINZAGR, *Saudi Arabia: An Artist's View of the Past* (1979), a pictorial perspective of Saudi Arabia's culture and people.

The economy is examined in ALI D. JOHANY, MICHEL BERNE, and J. WILSON MIXON, JR., *The Saudi Arabian Economy* (1986); ADNAN M. ABDEEN and DALE N. SHOOK, *The Saudi Financial System, in the Context of Western and Islamic Finance* (1984); A. REZA S. ISLAMI and ROSTAM MEHRABAN KAYOUSSI, *The Political Economy of Saudi Arabia* (1984); JOHN R. PRESLEY, *A Guide to the Saudi Arabian Economy* (1984); ARTHUR N. YOUNG, *Saudi Arabia: The Making of a Financial Giant* (1983), a historical survey of the impact of oil; TIM NIBLOCK (ed.), *State, Society, and Economy in Saudi Arabia* (1982); FOUAD AL-FARSY, *Saudi Arabia: A Case Study in Development*, 2nd ed. rev. (1980); and DONALD M. MOLIVER and PAUL J. ABBONDANTE, *The Economy of Saudi Arabia* (1980). Policy studies are found in RAGAEI EL MALLAKH, *Saudi Arabia, Rush to Development: Profile of an Energy Economy and Investment* (1982); HASSAN HAMZA HAJRAH, *Public Land Distribution in Saudi Arabia* (1982), on transformation of land ownership; ROBERT E. LOONEY, *Saudi Arabia's Development Potential: Application of an Islamic Growth Model* (1982); WILLIAM B. QUANDT, *Saudi Arabia in the 1980s: Foreign Policy, Security, and Oil* (1981), a diplomatic study; and ROBERT D. CRANE, *Planning the Future of Saudi Arabia: A Model for Achieving National Priorities* (1978), with a summary of the five-year plans. Further bibliographic information can be found in HANS-JÜRGEN PHILIPP, *Saudi Arabia: Bibliography on Society, Politics, Economics* (1984), in English and German; and FRANK A. CLEMENTS, *Saudi Arabia* (1979).

The most important historical sources include KAMAL SALIBI, *A History of Arabia* (1980); ABDELGADIR MAHMOUD ABDALLA, SAMI AL-SAKKAR, and RICHARD T. MORTEL, *Sources for the History of Arabia*, 2 vol. (1979); and H.ST.J.B. PHILBY, *Sa'udi Arabia* (1955, reprinted 1972). For a more interpretive discussion, see JOSEPH KOSTINER, "Tracing the Curves of Modern Saudi History," *Asian and African Studies*, 19(2):219–244 (July 1985). R. BAYLY WINDER, *Saudi Arabia in the Nineteenth Century* (1965, reprinted 1980), remains the definitive work on that period. The life of Ibn Sa'ūd, the founder of the modern Saudi state, is discussed in a sympathetic fashion in MOHAMMED ALMANA, *Arabia Unified: A Portrait of Ibn Saud* (1982); DAVID HOLDEN and RICHARD JOHNS, *The House of Saud* (1981), a detailed history of the years 1902–80; HAFIZ WAHBA, *Arabian Days* (1964);

and AMEEN RIHANI, *Ibn Sa'ud of Arabia: His People and His Land* (1928, reprinted 1983). The work of CHRISTINE MOSS HELMS, *The Cohesion of Saudi Arabia: Evolution of Political Identity* (1981), combines political geography, history, and diplomacy for the early 20th century. Works covering the same time include JOHN S. HABIB, *Ibn Sa'ud's Warriors of Islam: The Ikhwan of Najd and Their Role in the Creation of the Saudi Kingdom, 1910-1930* (1978); JACOB GOLDBERG, *The Foreign Policy of Saudi Arabia: The Formative Years, 1902-1918* (1986); and CLIVE LEATHERDALE, *Britain and Saudi Arabia, 1925-1939: The Imperial Oasis* (1983). Histories of Aramco and U.S.-Saudi foreign policy include IRVINE H. ANDERSON, *Aramco, the United States, and Saudi Arabia: A Study of the Dynamics of Foreign Oil Policy, 1933-1950* (1981); and AARON DAVID MILLER, *Search for Security: Saudi Arabian Oil and American Foreign Policy, 1939-1949* (1980). Two important internal issues in the post-World War II period are analyzed in AYMAN AL-YASSINI, *Religion and State in the Kingdom of Saudi Arabia* (1985); and ALEXANDER BLIGH, *From Prince to King: Royal Succession in the House of Saud in the Twentieth Century* (1984). See also SUMMER SCOTT HUYETTE, *Political Adaptation in Saudi Arabia: A Study of the Council of Ministers* (1985).

United Arab Emirates: For general works, see MALCOLM C. PECK, *The United Arab Emirates: A Venture in Unity* (1986); TREVOR MOSTYN (ed.), *UAE* (1982); ALI MOHAMMED KHALIFA, *The United Arab Emirates: Unity in Fragmentation* (1979); and MICHAEL TOMKINSON, *The United Arab Emirates* (1975). LINDA USRA SOFFAN, *The Women of the United Arab Emirates* (1980), discusses changes in the status of women. See also RAGAEI EL MALLAKH, *The Economic Development of the United Arab Emirates* (1981). Historical works include FRAUKE HEARD-BEY, *From Trucial States to United Arab Emirates: A Society in Transition* (1982); MUHAMMAD MORSY ABDULLAH, *The United Arab Emirates: A Modern History* (1978); and CLARENCE MANN, *Abu Dhabi: Birth of an Oil Sheikdom*, 2nd ed. (1969). See also CLAUD MORRIS, *The Desert Falcon: The Story of H.H. Sheikh Zayed Bin Sultan Al Nahiyah, President of the United Arab Emirates* (1974).

South Yemen: Introductions are given in TAREQ Y. ISMAEL and JACQUELINE S. ISMAEL, *The People's Democratic Republic of Yemen: Politics, Economics, and Society: The Politics of Socialist Transformation* (1986); HELEN LACKNER, *P.D.R. Yemen: Outpost of Socialist Development in Arabia* (1985); and ROBERT W. STOOKEY, *South Yemen: A Marxist Republic in Arabia* (1982). *People's Democratic Republic of Yemen: A Review of*

Economic and Social Development (1979), is a country study published by the World Bank. Historical analysis is presented in R.J. GAVIN, *Aden Under British Rule, 1839-1967* (1975); MANFRED W. WENNER, "People's Republic of South Yemen," in TAREQ Y. ISMAEL et al., *Governments and Politics of the Contemporary Middle East* (1970), pp. 412-429, and "South Yemen Since Independence: An Arab Political Maverick," in B.R. FRIDHAM (ed.), *Contemporary Yemen: Politics and Historical Background* (1984); MICHEL TUCHSCHERER, "La Formation d'un état: la république démocratique et populaire du Yémen, 1939-1981," in PAUL BONNENFANT (ed.), *La Péninsule Arabique d'aujourd'hui*, vol. 2 (1982); and KENNEDY TREVASKIS, *Shades of Amber: A South Arabian Episode* (1968).

North Yemen: Specialized studies include R.B. SERJEANT and RONALD LEWCOCK (eds.), *San'a': An Arabian Islamic City* (1983); CHRISTIAN ROBIN, *Les Hautes-Terres du Nord-Yémen avant l'Islam*, 2 vol. (1982), a study of antiquities; C. MYNTTI, *Women and Development in Yemen Arab Republic* (1979); and HANS STEFFEN and OLIVIER BLANC, "La Démographie de la République Arabe du Yémen," in PAUL BONNENFANT (ed.), *La Péninsule arabe d'aujourd'hui*, vol. 2 (1982), pp. 73-106. Politics and the economy are analyzed in ROBERT BURROWES, *The Yemen Arab Republic: The Politics of Development* (1986); RAGAEI EL MALLAKH, *The Economic Development of the Yemen Arab Republic* (1986); JON C. SWANSON, *Emigration and Economic Development: The Case of the Yemen Arab Republic* (1979); and *Yemen Arab Republic: Development of a Traditional Economy* (1979), a country study published by the World Bank. The most useful surveys of history are HUSAYN B. 'ABDULLAH AL-'AMRI, *The Yemen in the 18th & 19th Centuries: A Political and Intellectual History* (1985); and ROBERT W. STOOKEY, *Yemen: The Politics of the Yemen Arab Republic* (1978), which covers a wide historical range. Recent developments are analyzed in J.E. PETERSON, *Yemen: The Search for a Modern State* (1982); MANFRED W. WENNER, *Modern Yemen, 1918-1966* (1967); and MOHAMMED AHMAD ZABARAH, *Yemen, Traditionalism vs. Modernity* (1982). The civil war of the 1960s is discussed in EDGAR O'BALLANCE, *The War in the Yemen* (1971); and DANA ADAMS SCHMIDT, *Yemen: The Unknown War* (1968). For foreign policy and politics since 1970, see ROBERT D. BURROWES, "The Yemen Arab Republic and the Ali Abdallah Salih Regime: 1978-1984," *The Middle East Journal*, 39(3):287-316 (Summer 1985).

Arachnids

The class Arachnida, part of the invertebrate phylum Arthropoda, includes forms such as spiders (Araneida), harvestmen (daddy longlegs; Opiliones), scorpions (Scorpionida), mites and ticks (Acari), and a few lesser known groups. Only a few species are of economic

importance, including the acarids that transmit diseases to humans, other animals, and plants. For coverage of related topics in the *Macropædia* and *Micropædia*, see the *Propædia*, section 313. This article is divided into the following sections:

ARACHNIDS

GENERAL FEATURES

Size range and diversity of structure. Arachnids range in size from mites that measure 0.08 millimetre (0.003 inch) to the enormous scorpion *Hadogenes troglodytes* of Africa, which may be 21 centimetres (eight inches) or more in length. In appearance, they vary from the small rounded mites to the long-legged opilionids and the crab-like spiders.

Like all arthropods, the arachnids have a segmented body, a tough exoskeleton, and jointed appendages. Most are carnivorous. Arachnids lack jaws and, with only a few exceptions, inject digestive fluids into their prey before sucking the liquefied remains into their mouths. Except among the acarids (mites and ticks), in which the entire body forms a single region, the arachnid body is divided into two distinct parts: the cephalothorax, or prosoma, and the abdomen, or opisthosoma. The sternites (ventral plates) of the lower surface of the body show more variation than those of the upper surface. The arachnids have simple eyes.

The cephalothorax is covered dorsally with a rigid cover (the carapace) and contains six pairs of appendages, the first of which are the chelicerae; these are the only appendages that are preoral in position; and in many forms they are chelate, or pincerlike, and are used to hold and crush prey. Among spiders the chelicerae contain venom sacs, and the second segment, the fang, can inject venom. The second pair of appendages are the pedipalps, or palps, which in arachnids function as an organ of touch. In spiders and harvestmen the pedipalps are elongated structures; in scorpions they are large, chelate, prehensile organs. Among spiders the pedipalps are highly modified as sexual intromittent organs. The basal segment is frequently modified for crushing or cutting food. The remaining four pairs of appendages are walking legs, though the first of these pairs serves as tactile organs among the amblypygids, or tailless whip scorpions, while it is the second of these pairs that functions as such among the opilionids. Among the ricinuleids special copulatory organs are located on the third pair of legs. Some mites, particularly the immature individuals, have only two or three pairs of legs.

In many arachnids the cephalothorax and abdomen are broadly joined, while in others (such as spiders) they are joined by a narrow, stalklike pedicel. The abdomen is composed of a maximum of 13 segments. The first of these may be present only in the embryo and absent in

the adult. In some orders a mesosoma consisting of seven segments and metasoma of five may be distinguished; in others a few posterior segments may form a pygidium, or postabdomen. In general, except for the spinnerets of the spiders, the opisthosoma has no appendages. In some groups the abdomen is elongated with free tergites; in others it may be shortened with indistinct segmentation. Postanal structures vary in both appearance and function. The scorpions have a short stinger with a swollen base enclosing a poison gland; the orders Uropygi (whip scorpions) and Palpigradi (palpigrades) have long whiplike structures of unknown functions.

Distribution and abundance. With the exception of a few groups that have secondarily become aquatic, the arachnids are terrestrial predators. Spiders, harvestmen, false scorpions (order Pseudoscorpiones), and mites and ticks are nearly worldwide in distribution. Scorpions, solpugids (wind scorpions, including sun spiders; order Solpugida), tailless whip scorpions (order Amblypygi), and vinegar-rooms, or whip scorpions (order Uropygi), are widespread within the tropical and subtropical areas of the world, only occasionally being encountered in northern areas. Of more sporadic distribution, but more common in tropical areas, are the palpigrades, or microwhip scorpions (order Palpigradi), the schizomids (Schizomida), and the ricinuleids (Ricinulei). In northern areas mature spiders and harvestmen are particularly conspicuous during the early autumn, though they are abundant throughout the year. Most, however, are seldom observed, for they inhabit leaf mold or soil and form an important part of the cryptozoic fauna. Most abundant of the arachnids are the acarids found in soil, in fresh and marine waters, and as parasites of animals and humans.

Importance. The numbers and predaceous habits of arachnids make them important to humans. Free-living mites play an important role in the conversion of leaf mold to humus. Many mites are parasitic. Many ticks are intermediate hosts for organisms that cause serious diseases. Though all spiders possess poison that can be utilized for catching prey, only a few have a poison sufficiently powerful to affect humans. A bite of the black widow spider (*Latrodectus mactans*) may result in discomfort or serious illness; that of the brown recluse spider (*Loxosceles reclusa*) may result in a severe local reaction. The sting of some species of scorpions may cause a severe reaction and even death in humans.

NATURAL HISTORY

Reproduction and life cycle. In most cases the male does not transfer the spermatozoa directly to the female but rather initiates courtship rituals in which the female is induced to accept the gelatinous sperm capsule (spermatophore). During mating the sperm are transferred to a sac within the female reproductive system, the spermatheca. The eggs are fertilized as they are laid. Mating in solpugids is more active, occurring at dusk or during the night; during courting the male seizes the female, lays her on her side, massages her undersurface, opens her genital orifice, and forces a mass of sperm into her spermatheca. Reproductive behaviour in mites is highly variable; sperm usually are produced in a spermatophore and transferred to the female either by the chelicerae or by the third pair of legs of the male. In the ricinuleids the third legs rather than the pedipalps are modified for the transfer of sperm into the female genital opening.

The harvestmen appear to be the only arachnids in which sperm transfer is direct. There is little or no courtship among the members of this class; rather, mating occurs whenever a male and female encounter one another. The male has a chitinized penis that is inserted into the genital opening of the female as the partners face one another.

Many arachnids simply deposit their eggs in the soil or in a protected site, and no further care is given to them;

others, particularly tropical species, guard the eggs by remaining with them during the period of development. Some spiders place their eggs in cocoons, and the eggs of some tailless whip scorpions, schizomids, whip scorpions, and false scorpions are attached beneath the abdomen.

Among scorpions the fertilized eggs develop inside the mother, and the young are born alive. In scorpions whose eggs contain much yolk, the eggs develop within the oviduct; in those with little yolk, the eggs remain in place and each embryo lies in a diverticulum (hollow outpouching) with a tubular extension through which nutrient fluids pass from the wall of the maternal intestine. When the young are sufficiently developed, they are expelled and carried about on the mother's back until after the first molt. False scorpions carry their eggs in a brood sac attached to the genitalia. The embryos develop and grow within this brood sac and are nourished by the female.

Details of early development are not known for all forms, but that of egg-laying spiders is considered typical. The two major divisions of the body (the cephalothorax and the abdomen) appear at an early stage, and the appendages first appear as knobs. In many arachnids the organism is wrapped around the yolk, a situation altered by a process termed inversion or reversion, after which hatching usually occurs.

Growth occurs by molting, or ecdysis. In many, the first molt occurs while the animal is still within the egg. The newly hatched arachnid is small and the exoskeleton less sclerotized (hardened) than the adult. With the exception of the acarids and ricinuleids, which have three pairs of legs when hatched, the hatchlings have four pairs of legs. The number of molts required to attain maturity varies; some spiders, for example, have 12. Before molting, arachnids seek protected sites; spiders, false scorpions, and some mites produce a cocoon to protect themselves.

Mites differ in both development and growth. In the life cycle of the mite, unlike other arachnids, an egg hatches into the six-legged, or hexapod, larva, which passes through one or several immature (nymphal) stages before becoming an adult. Most mites lay eggs, though some are ovoviviparous; *i.e.*, the eggs develop within the body of the female and hatch within or immediately after extrusion. Acarids are also able to reproduce from unfertilized eggs (parthenogenesis). The life cycle of ticks is similar to that of mites.

The life span of arachnids in temperate areas is usually a single season; they rely upon their eggs to perpetuate the species. In warm regions some groups (*e.g.*, whip scorpions, tailless whip scorpions, scorpions, solpugids, and tarantulas) appear to live more than a single year.

Ecology and habitats. Although most arachnids are inconspicuous free-living terrestrial forms, some acarids are parasitic, a few spiders live on or near water, and some mites are aquatic. Most arachnids lead solitary lives, coming together only briefly for mating. Even though they possess a chitinous exoskeleton, most arachnids are subject to damage by desiccation. Many arachnids, especially small, little-known forms, (ricinuleids, for example), are found only in well-protected niches. The favourable environment of the relatively constant, moisture-containing microclimate provided by soil litter, burrows, or caves is the reason these species constitute a high proportion of the cryptozoic fauna. Cave-dwelling species often have special adaptations—for example long extremities, light colour, and no eyes. Most arachnids, even those adapted to desert areas, avoid excessive heat by adopting a cryptozoic habitat and by being active only during the cooler parts of the day.

A few arachnids (*e.g.*, some scorpions, solpugids, spiders, and harvestmen) are capable of producing rasping sounds by rubbing together horny ridges or other special sound-producing structures. Sound may be used in general to warn predators or by males during courtship. Preening is common among arachnids. This consists of cleaning the legs by passing them through the chelicerae. A method of protection and escape from predatory enemies consists of the quick dropping of a captured limb.

Locomotion. Locomotion among arachnids involves a sequence of movements of the legs: the first and third legs

Molting

Life span

Spermatophore

Care for eggs

Phoresy

of one side and the second and fourth legs of the other side are brought forward nearly simultaneously. Most arachnids are not great travelers. Those that do travel long distances rely upon methods other than walking or running; for example, a spider about to migrate scales a vertical object, releases a strand of silk, and relies upon the wind to carry it away (ballooning). Pseudoscorpions often rely on an activity termed phoresy, in which they cling to the legs of more mobile animals, such as flies or harvestmen, and are carried about. Mites may use phoresy or gusts of air to carry them to new sites.

Food and feeding. As carnivores, most arachnids feed chiefly upon smaller arthropods; exceptions are among parasitic acarids and plant-feeding harvestmen. Acarids are nourished principally by fluids obtained either from living animal or plant material or from decaying organic matter. Parasitic forms have mouthparts modified for sucking blood or juice. Harvestmen appear to be the only arachnids capable of ingesting small particles. More commonly the prey is torn into small pieces as digestive fluids flow over it—or a hole is made in the body of the prey, and digestive fluids are injected—and the digested contents are sucked up.

While many arachnids actively seek their prey, the more common method is that of lying in wait. Active arachnids, such as the solpugids, use both tactile and visual responses in prey recognition as they run at random. The American whip scorpion (*Mastigoproctus giganteus*) hunts mostly at night, moving slowly with pedipalps extended and touching objects with the extended first leg. Harvestmen run rapidly over bushes, herbs, and other vegetation in pursuit of prey.

Communal spiders

Associations. Though most arachnids are solitary animals, some spiders live in enormous communal webs housing males, females, and spiderlings. Most of the individuals live in the central part of the web, with the outer part providing snare space for prey shared by all of the inhabitants. In some cool and dry areas harvestmen often gather in enormous numbers, probably protecting themselves against extremes of temperature or desiccation. Mimicry is seen among some spiders that are found in ant colonies. These spiders resemble the ants in appearance and habit, are tolerated by the ants, and actually feed upon the ant pupae.

FORM AND FUNCTION

General features. Though arachnids are easily recognized by the division of the body into two parts (the cephalothorax and abdomen) and their possession of six pairs of appendages, they are extremely diverse in form. The dorsal region of the prosoma has a solid covering, the carapace, and the underside has one or more sternal plates or the coxal segments of the six pairs of appendages. The opisthosomal segments do not bear appendages. The soft body is protected by an exoskeleton composed of chitin, and the somites are united by a soft membrane. Eyes, if present, are simple, and their number varies with the species. Sexes are always separate, but it is often difficult to distinguish between them. At times, however, either males or females, but especially males, may develop special structures, brighter colour, larger spines, or larger size.

External features. There are many modifications of the cephalothorax and abdomen. Among the scorpions the abdomen is subdivided into the mesosoma, or preabdomen, and the metasoma, or postabdomen; the latter is mobile and more slender. Similar arrangements are found among whip scorpions, schizomids, and ricinuleids. Among the harvestmen the division between the two parts is only partial, and among most acarids the body is rounded and shows no segmentation. Spiders exhibit the greatest variation in body shape.

Function of chelicerae

The form and function of the six pairs of appendages is variable. The first pair, the chelicerae, often have claws. They transport spermatophore (solpugids, some acarids), produce sounds (solpugids, some spiders), cut strands of silk (web-dwelling spiders), and produce silk (pseudoscorpions). The pedipalps, the second pair, likewise are often highly modified. Among the scorpions and pseudoscorpions the pedipalps are large; among the tailless whip

Figure 2: Anatomy of a pseudoscorpion.

From A. Petrunkevitch, *Treatise on Invertebrate Paleontology*, part P (1955), courtesy of the Geological Society of America and the University of Kansas Press

scorpions and some harvestmen they are elongated and equipped with many heavy spines. Among some arachnids they are prehensile, serving both to capture and hold prey. In spiders they serve to transfer sperm, and for the scorpions, pseudoscorpions, and tailless whip scorpions they play an important role during courtship.

There are typically four pairs of walking legs, each of which usually has seven segments of variable lengths, with the last segment often bearing claws. The legs serve chiefly for locomotion but may be modified to serve as tactile organs (harvestmen), for capturing and immobilizing prey (running spiders), and for producing sound (harvestmen, spiders, solpugids, and scorpions).

Internal features. *Support, skeleton, and exoskeleton.* The arachnid exoskeleton is formed of chitin, a nitrogen-containing carbohydrate associated with a protein. This complex is tough but pliable. The exoskeleton consists of two parts: the thin outer epicuticle, which is usually a wax and is impermeable to water, and the thicker endocuticle. Membranes, flexible portions of the cuticle, are present wherever there are movable articulations.

Growth can occur only by shedding the old skeleton, a process termed molting, or ecdysis. This process is under hormonal control and involves the secretion of a new cuticle below the old one. Sclerotization, or hardening, may be accompanied by pigmentation.

While the exoskeleton provides both support and protection, the arachnids have an endoskeleton, the endosternite, which provides a surface for muscle attachment.

Tissues and muscles. The muscles of the cephalothorax are well developed, while those of the abdomen are reduced. The muscles are striated, similar to those of vertebrates; those of the legs have their origin either on the endosternite or on the body wall and extend to the basal segments of the appendages. Muscles within the appendages make possible the movements of the individual segments. Within the opisthosoma, muscles consist primarily of bundles that connect the various segments. Most of the space between the digestive tract and the body wall, the hemocoel, is filled with blood.

Nervous system and organs of sensation. The arachnid nervous system is similar to that of other arthropods in that it consists of a brain and a chain of paired ganglia. The nervous system has been highly modified by ganglionic fusion and migration forward toward the head region. The

Striated muscles

large ganglion above the esophagus is considered the brain and gives rise to the nerves of the eyes and chelicerae. It is joined to a ganglion located below the esophagus. Nerves from this latter ganglion extend to the pedipalpi and legs. An unpaired nerve runs along the esophagus and stomach; it is connected to the brain by paired nerves.

There are commonly three types of sense organs: tactile hairs called trichobothria (Figure 3), simple eyes (ocelli), and slit sense (lyriform) organs. Specialized structures, possibly serving as tactile organs or for the detection of air movements, include malleoli (racket organs) of solpugids and comblike appendages (pectines) of scorpions. The number of simple eyes found on the carapace varies; scorpions, for example, may have as many as five pairs of simple eyes on the sides of the carapace in addition to a median pair, while opilionids have only median eyes, and many cryptic or cave-dwelling species have either reduced eyes or none at all. The most abundant sense organs, tactile hairs, are scattered over the body. The slit sense organs, which appear as slits in the cuticle, may function to detect odours; slit organs on the legs of harvestmen, however, function in the reception of internal stimuli (proprioception). Tarsal organs are small, round holes in the upper surface of the last segment of the leg that may act as chemoreceptors.

Figure 3: Trichobothrium of a spider with only the lower part of the hair showing.

Digestion and nutrition. With the exception of some harvestmen and mites, arachnids are predators, relying upon smaller arthropods for their food. The harvestmen may be the only arachnids capable of ingesting food particles; most species partially digest their prey as it is held in the chelicerae. The digestive system is a tube that begins with the mouth situated below the chelicerae, leading into the pharynx, then into the esophagus, and from there into the sucking stomach, which has heavy muscles and serves to pump the partially digested food into the midgut, where special enzymes digest the food. The absorptive surface of the midgut is increased by a series of blind sacs. Fecal material accumulates in the hindgut and is voided through the anus.

Excretion. Two main types of excretory organs occur in arachnids: coxal glands and Malpighian tubules. The coxal glands consist of three parts: a large excretory sac lying opposite the coxal segment of the first pair of legs; a long coiled tubule; and a short exit tube that opens to the exterior through orifices behind the first and third coxal leg segments. The nitrogen-containing waste material usually is the organic compound guanine.

Respiration. Two types of respiratory organs are found among arachnids: book lungs and tracheae. Book lungs are found in hardened pockets; diffusion of gases occurs between the blood circulating within thin leaflike structures (lamellae) stacked like pages in a book and the air in spaces between these thin structures (Figure 4). The tracheal system consists of a number of tubes that open to the exterior by paired respiratory pores (spiracles) and is similar to that of insects; diffusion of gases occurs within small fluid-filled tubes that ramify over the internal organs. Scorpions, the tailless whip scorpions, and the whip scorpions rely upon book lungs; the pseudoscorpions, solpugids, ricinuleids, harvestmen, and acarids have only tracheae;

Figure 4: Diagrammatic section through a book lung.

From R.D. Barnes, *Invertebrate Zoology*, 4th ed., (1980), Saunders College, Philadelphia

most spiders have both; and the small palpigrades and acarids have only cutaneous respiration.

Circulatory system. The circulatory system of the arachnids is an open system; that is, blood circulates in tissue sinuses. Special venous channels conduct blood from the tissues to the heart, from which it is pumped through a series of blood vessels back to the sinuses. The respiratory pigment usually is hemocyanin and is in solution in the hemolymph; cells are present but do not carry oxygen.

Reproductive system. There is considerable variation in the number and appearance of both ovaries and testes. In general, the ovaries are associated with oviducts; and the testes have vasa deferentia. The genital orifice of both sexes (except mites) is on the undersurface of the second abdominal segment; in mites it may be dorsal. Sperm are usually transferred to a special structure of the female, the spermatheca.

Glands and hormones. The glands of arachnids are usually peculiar to individual orders. In spiders, silk is stored as a viscous liquid in the silk glands, which are found at the end of the abdomen; the number of spinnerets is variable. The viscous liquid, a protein, passes through minute tubes at the tips of the spinnerets; the change from liquid to solid thread occurs by a structural rearrangement of the protein molecules after the silk is drawn from a silk droplet. The silk of the pseudoscorpions is produced by a spinneret located on a movable finger of the chelicera; the few mites that produce silk have glands in the area of the mouth.

Toxic substances are secreted by special glands found in the chelicerae of spiders, in the pedipalps of false scorpions, and in the poison glands of scorpions. The poisonous substances (and their effects) differ even within species of the same order. The strongly alkaline poison of spiders is much less poisonous to mammals than to arthropods; bites of spiders of the genera *Loxosceles* (brown recluse) and *Latrodectus* (black widow) may cause human discomfort; those of the latter may cause serious illness. The venom of most scorpions, sufficiently toxic to kill most invertebrates, usually is not dangerous to humans; the venoms of some genera (*Androctonus* and *Buthus* of Africa, various species of *Centruroides* of Mexico, Arizona, and New Mexico), however, are highly toxic nerve poisons. The toxicity of the venom of the pseudoscorpions is not known. The paired glands of whip scorpions located near the anus secrete specific acids (formic, acetic) that serve as irritants and apparently are used for defense. The openings of paired odoriferous glands are found on the cephalothorax of harvestmen; when irritated these animals secrete a fluid containing cyanic acid that probably serves to repel predators.

Toxic substances

EVOLUTION AND PALEONTOLOGY

While arachnid fossils are abundant, it is extremely difficult to trace the evolution of individual groups. The earliest forms recognizable as arachnids include a scorpion that dates from the Silurian Period (about 430,000,000–395,000,000 years ago) and an acarid from the Devonian Period (about 395,000,000 to 345,000,000 years ago). Spiders with segmented abdomens and presumably four

Book lungs and tracheae

pairs of spinnerets are known to have existed during the Carboniferous Period (345,000,000 years ago). Palpigrades have been described as fossils only from the Jurassic Period (190,000,000 years ago) in Europe, and the schizomids are known from the late Cenozoic Era in Arizona (about 7,000,000 years ago). The Mesozoic Era (about 225,000,000–65,000,000 years ago) is poor in arachnid fossils; while the Cenozoic Era (from about 65,000,000 years ago to the present) is rich in them. A. Petrunkevitch (1953) concluded that all orders of arachnids were either already extant or in the process of evolving by the Silurian Period. Since the Silurian scorpion closely resembled modern forms, the hypothetical arachnid ancestor must antedate any known fossil forms. The stem group of the chelicerates is believed to be among the members of the trilobite-like Olenellinae. These date from the Cambrian Period (about 570,000,000 years ago). During Paleozoic times the eurypterida, large animals resembling modern scorpions, were abundant, and both groups can be traced to a common ancestor.

It is impossible to reconstruct an exact phylogeny of the arthropods, but possibly they arose from some simple segmented worm prior to the Cambrian Period. Two divergent lines (other than the trilobites) appeared early among the marine forms; one group remained aquatic, the other gave rise to the terrestrial arachnids.

Invasion of
land

The invasion of the land probably started in moist habitats, such as under leaf-litterlike material. Many changes in anatomy and reproductive behaviour had to occur before the arthropods were successful in their transfer to terrestrial life.

A major characteristic of arachnid evolution is that segments were fused or lost. The five posterior segments of the scorpions were retained as a tail. Among the spiders, primitive families had abdomens composed of 12 distinct segments, which were reduced to five or six in other families and completely fused in adults. Among the acarids, abdominal segmentation was lost and the body showed no external segmentation. In general, scorpions have the largest number of primitive arachnid features, and spiders and mites are the most highly evolved.

CLASSIFICATION

Distinguishing taxonomic features. In classifying arachnids, taxonomists rely mostly upon external structures, including such features as general body form, the degree of visible external segmentation, structural modifications of prosoma and opisthosoma, characteristics of appendages, and special structures involved in sperm transfer. Internal anatomical features, developmental traits, and serological characteristics are used to a limited extent; conceivably, however, as information becomes available, traits such as these could play a more important role in arachnid classification.

Annotated classification. The following classification of arachnids is based chiefly on work by L. Störmer (1944) and by A. Petrunkevitch (1949). In the classification below, the groups marked with a dagger (†) are wholly extinct and known only from fossils.

CLASS ARACHNIDA (arachnids)

Chelicerate arthropods with adult body composed of 18 somites, divided into anterior prosoma (6 somites) and posterior opisthosoma (12 somites); prosoma with 6 pairs of appendages, 1st pair preoral, last 2 pairs secondarily lost in some mites; genital opening in both sexes on 2nd abdominal somite (except some mites); heart usually in abdomen; respiration by means of book lungs, tracheal tubes, a combination of the two, or cutaneous (some cryptozoic forms); excretion by coxal glands and/or Malpighian tubules; digestive system with a pumping foregut, midgut with blind sacs, and a short hindgut opening with an anus on ventral side of opisthosoma; nervous system with a tendency to fuse; not more than 12 simple eyes (ocelli); sexes dimorphic; courtship frequent before sperm transfer; usually terrestrial, carnivorous, nocturnal, and cryptozoic; social organization rare; instinctive behaviour highly developed; distribution variable; about 70,000 species described.

Order Scorpiones (or *Scorpionida*; scorpions). Prosoma compact, opisthosoma subdivided, taillike portion ending in stinger; chelicerae chelate (pincerlike), 3-jointed; size 14–210 mm; ovoviviparous; earliest fossil records from Silurian; widespread in

tropical and subtropical regions; about 1,200 to 1,300 species described.

Order Pseudoscorpiones (or *Pseudoscorpionida*; false or book scorpions). Length 1–7.5 mm; carapace entire, abdominal somites often subdivided dorsally; chelicerae chelate, movable finger with spinneret; oviparous; worldwide distribution; about 2,000 species described.

Order Opiliones (harvestmen or daddy longlegs). Size 1–22 mm; 3 to 8 opisthosomatic dorsal regions of segments (tergites) fused with carapace, remainder free; single pair of eyes, usually on median tubercle; oviparous; worldwide distribution; about 4,500 species described.

†**Order Architarbi**. Fossil forms with segmented opisthosoma; carapace complete, with 2 to 6 eyes; chelicerae chelate; Upper Carboniferous of Europe, Pennsylvanian of North America.

†**Order Haptopoda**. Fossil forms with carapace complete; chelicerae 3-jointed, chelate, from Upper Carboniferous, England.

†**Order Anthracomarti**. Fossil forms with complete carapace; abdomen with 10 segments; from Upper Carboniferous of Europe, Pennsylvanian of North America.

†**Order Trigonotarbi**. Fossil forms with complete carapace, chelicerae 2-jointed, pedipalps leglike, arrangement of coxae as in spiders; from Devonian of Scotland, Upper Carboniferous of Europe, Pennsylvanian of North America.

Order Palpigradi (palpigrades). Size 0.8–2.6 mm; carapace subdivided into 3 parts; eyes absent; coxae movable; chelicerae chelate; 3-jointed pedipalps leglike; telson a many-segmented flagellum; no book lungs or tracheae; sporadic distribution; about 60 species described.

Order Uropygi (whip scorpions or vinegaroons). Size to 130 mm; carapace complete; coxae movable, pedipalps predatory; 1st tarsus tactile; long, whiplike telson; order coextensive with 1 family, Thelyphonidae; fossils nearly identical with living forms; known from Carboniferous of Illinois, Czechoslovakia, and England; widespread in tropical and subtropical regions; about 85 species described.

Order Schizomida (schizomids). Size 2–15 mm; prosoma with segmented carapace; chelicerae 2-segmented; telson short; sporadic distribution; about 80 species described.

†**Order Kustarachnae**. Fossil forms known only from Pennsylvanian of North America; sternum small, coxae radiate from it.

Order Amblypygi (tailless whip scorpions). Size 8–45 mm; prosoma broader than long, covered with carapace; 8 eyes; chelicerae not chelate; pedipalps very long, strong; 1st pair of legs tactile; members widespread in tropical and subtropical regions; about 70 species described.

Order Araneida (*Araneae*; spiders). Size 0.5–90 mm; carapace complete; chelicerae 2-jointed, with ducts of poison glands; pedipalps leglike in males, with special copulatory apparatus; opisthosoma nonsegmented, bearing spinnerets; group large and variable in appearance and habits; worldwide distribution; about 34,000 species described.

Order Solpugida (*Solifugae*; solpugids [wind scorpions]). Size 10–50 mm; anterior part of 3-part prosoma swollen into head; chelicerae powerful; opisthosoma 10 or 11 segments; widespread in tropical and subtropical regions; about 900 species described.

Order Ricinulei (ricinuleids). Size 8–10 mm; carapace complete, with cucullus; abdomen of 9 segments, last 3 forming caudal region pygidium, development with a 6-legged larval form; of sporadic distribution; about 33 species described.

Subclass Acari (*Acarina* or *Acarida*; mites and ticks)

Size from 0.08 to 30 mm in some fully engorged ticks; prosoma and opisthosoma fused, somites not apparent; mouthparts adapted to piercing, sucking, biting, grating, or sawing; highly variable in appearance; many parasitic and economically important forms; worldwide distribution; about 30,000 species described.

Order Opilioacariformes (or *Opilioacarida*). Body divided into hairy anterior portion bearing 2 to 3 pairs of simple eyes and nude posterior portion, with 4 pairs of stigmata and 12 secondarily developed segments; terminal palpal apotele a pair of claws; terrestrial; 1 family; 12 species.

Order Parasitiformes (mites and ticks). Small to large in size; usually heavily sclerotized mites; 1 to 4 pairs of stigmata on posterior portion of body; peritremes, or grooves, present or absent; palpal apotele present or absent; tarsi of first pair of legs with sensory organs.

Order Acariformes (mites). Weakly sclerotized with few plates; eyes present or absent; stigmata, when present, at or between bases of chelicerae or on anterior portion of body; chelicerae styletlike, chelate (pincerlike), or reduced; habitats from aquatic to terrestrial, predatory to parasitic.

Critical appraisal. Many schemes for the classification of the Arachnida have been proposed. The system used here recognizes the name Arachnida as that of a terrestrial class of the subphylum Chelicerata. Members of this class differ from those of the aquatic class Merostomata (the horseshoe crabs) in the absence of gill books and compound eyes, while resembling them in possession of six pairs of prosomatic appendages. This definition of Arachnida results in the exclusion of the pycnogonids from the class (consequently establishing them in their own chelicerate class, the Pycnogonida) and is in accord with

taxonomic practices of subdividing and separating groups in order to clarify relationships.

A systematization of arachnids based upon the work of P. Weygoldt and H.F. Paulus (1979) reflects the phylogeny of the group and is known as cladistic. This systematization is the result of a careful comparative study of structures of ancient origin (*i.e.*, segmentation) as well as the modifications occurring on more recently inherited structures. Thus, a well-constructed cladogram will indicate not only the phylogeny of the group but also its relationships to other forms. (M.L.Go.)

MAJOR ARACHNID ORDERS

Scorpions

Scorpions (order Scorpiones) often play the role of evil-doers in fables and legends; Greek respect for scorpions prompted the naming of the constellation Scorpio, a sign of the zodiac. A long, curved tail tipped with a venomous stinger and grasping, fingerlike first appendages are typical scorpion features.

GENERAL FEATURES

Size range and diversity of structure. Scorpions are relatively large arachnids, with an average size of about six centimetres (about 2½ inches). Only some spiders and myriapods and a few insects rival the size of larger scorpions. Larger scorpion species are larger than almost all terrestrial invertebrates and 33 to 50 percent of all terrestrial vertebrate species (*e.g.*, frogs, lizards, rodents). Giants among scorpions include the black species from tropical Africa—*Pandinus imperator* of Guinea attains a body length of about 18 centimetres and a mass of 60 grams. The length of the smallest scorpion, the Caribbean *Micrctityus fundorai*, is 12 millimetres. Although many were of average size, a few precursors of modern scorpions were comparative giants; some early scorpions (*Gigantoscorpio willsi*, *Brontoscorpio anglicus*) measured 35 centimetres to one metre or more; an undescribed species is estimated to have been 90 centimetres. Most species from deserts and other arid regions are yellowish or light brown in colour; those scorpions that are found in moist or mountain habitats, however, are brown or black.

Distribution and abundance. Modern scorpions live on all major landmasses except Greenland and Antarctica (they were accidentally introduced into New Zealand and England). They range from Canada and central Europe to the tips of South America and Africa. Scorpions have radiated into all non-boreal habitats, including deserts, savannas, grasslands, and temperate, tropical, and rain forests.

The most diverse scorpion faunas occurs in temperate and subtropical deserts. Scorpions live at altitudes that range from sea level to 2,000 metres (6,000 feet) in the Alps, 3,000 metres in the mountains of southwestern North America, and 4,000 to 5,000 metres in the Andes. Only 14 species are reported in all of the Soviet Union, while more than 40 species occur in California and 62 in Baja California. In North America only one species occurs as far north as southern Canada (*Paruroctonus boreus*) and one as far south as Tierra del Fuego (*Bothriurus burmeisteri*). In Europe one species of scorpion is known as far north as southern Germany, but none is found in Scandinavia. Diversity at one location in the tropics ranges from five to seven species in Trinidad and Venezuela to three species in Brazil.

NATURAL HISTORY

Reproduction and life cycle. Scorpions exhibit few sexual differences, although males usually are more slender and have longer tails than females. In order to survive on land, scorpions evolved mating behaviours that prevent eggs and spermatozoa from drying out.

The breeding season almost always occurs during the warm months (late spring through early fall). At this time males become vagrant and may travel hundreds of metres to find receptive females. It appears that males find

females by localizing a pheromone that the female emits from the end of her metasoma. Mating in scorpions is preceded by a complicated and characteristic courtship; it is initiated by the male, who faces and grasps the female by appendages called pedipalps. The pair, directed by the male, moves sideways and backward in a dancelike motion called *promenade à deux*. Many of these actions actually result from the efforts of the pair to find a smooth surface on which the male can extrude and attach the spermatophore by its stalk. The spermatophore bears spermatozoa at the tip of the stalk. His maneuvers also serve to bring the spermatophore near the open genital opercula of the female. Once the female is positioned over the spermatophore, physical contact with it causes spermatozoa to be ejected into the genital opening (gonopore) of the female. Males that remain near females after mating sometimes are killed and eaten by them.

Males can mate more than once with a certain amount of time between matings (probably the period necessary to produce a new spermatophore). Females also mate repeatedly. Some females in the family Buthidae mate even while carrying newborn scorpions. Some female buthids produce multiple (two to seven) litters from a single insemination. At least two species are parthenogenetic. Scorpion reproduction is uncharacteristic of terrestrial arthropods.

The mother invests a great amount of time and energy in her offspring. Further, unlike almost all other animals except mammals, scorpions are viviparous, with embryos nourished in utero by the mother. Once fertilized, eggs are retained in the female's body for periods varying from several months to a year before the young are born alive. Birth lasts several hours to several days. Temperate species usually give birth in spring and summer. Tropical species, as a group, give birth throughout the year, although many restrict parturition to a few months. Litter size averages 25, with a range of one to 105.

Each young scorpion, white in colour, is still enveloped in a membrane, or chorion, at birth; after freeing itself, the immature scorpion crawls onto the mother's back, where it remains for a period ranging from one to 50 days. During this time the young scorpions are defenseless, receive water transpired through the mother's cuticle and taken up through their own, and utilize food reserves in their bodies. Newborns then molt their soft embryonic cuticle for one that is fully functional when they assume independence. This early mother-young association is obligatory for newborns; without it, they do not molt successfully and usually die. The young usually leave the mother soon after this first molt.

As in all arthropods, growth is accompanied by ecdysis (molting). Scorpions molt an average of five times, with a range of four to nine times, before reaching maturity. The number in some species is variable; in others, males reach maturity after a different number of molts. For example, in some *Centruroides* small males mature after four molts and large males after five. There are no reports of molting occurring after reproductive maturity has been reached.

Food and feeding. Scorpions are opportunistic predators that eat any small animal they can capture. Common prey include insects, and spiders and other arachnids. Scorpions often prey on other scorpions. Less common, but regular, prey include terrestrial isopods, snails, and small vertebrates (lizards, snakes, rodents). The only known

Courtship rituals

Mother-young interaction

Common prey

reatest concentration

specialist scorpion is the Australian *Isometroides vescu*, which feeds solely on burrowing spiders.

Scorpions are largely nocturnal and hide during the day in the confines of their burrows, in natural cracks, or under rocks or bark. Individuals become active at the beginning of the night and cease activity some time before dawn.

Most scorpions are sit-and-wait predators that remain motionless until a suitable prey moves into an ambush zone. Airborne vibrations of flying prey are detected. Scorpions also sense substrate vibrations of prey walking on the surface. These behaviours are sophisticated enough that scorpions can determine the precise distance and direction of their prey. Once the prey is detected, the scorpion orients, runs to the prey, and seizes it. The prey is stung if it is relatively large, aggressive, or active; otherwise, it is simply held in the pedipalps while it is eaten.

Many buthids, however, actively search for prey. These species usually have long, slender bodies and chelae. Many have powerful venoms to offset their small chelae.

Scorpions lack conventional jaws, and their feeding habits are unusual; a pair of toothed pincerlike appendages (chelicerae) and sharp edges of adjacent jawlike structures (maxillae and coxae) macerate the prey, as quantities of digestive fluids secreted from the small intestine pour over it. The victim's soft parts are broken down, liquefied, and sucked into the scorpion's stomach by a pumping action. The victim is gradually reduced to a ball of indigestible material, which is cast aside. Eating is a slow process, often taking many hours. (W.J.G./G.A.Po.)

Ecology and habitats. Because scorpions fluoresce under ultraviolet light, biologists can study their natural behaviour and ecology. Portable camping lights equipped with black light bulbs are used to detect scorpions at night. On a moonless night, scorpions can be seen at distances of 10 metres.

Scorpions' habitats range from the intertidal zone to snow-covered mountains. Several species live in caves, with one species, *Alacran tartarus*, found at depths more than 800 metres below the surface.

Some species are specific in habitat and substrate re-

quirements. For example, psammophilic species exhibit a morphology that both adapts and restricts them to sand. Setae form combs on the legs that increase the surface area and allow them to walk on sand without sinking or losing traction. Lithophilic species occur only on rocks. They possess stout, spinelike setae that operate in conjunction with highly curved claws to provide the legs with a strong grip on rock surfaces. The longest scorpion in the world, *Hadogenes troglodytes*, in which a South African female averages 210 millimetres, is a lithophile that can move rapidly on any spatial plane, even upside down.

Other species show adaptability in habitat use. The European *Euscorpium carpathicus* occurs in caves, above ground, and in the intertidal zone. *Scorpio maurus* occurs from sea level in Israel to above 3,000 metres in the Atlas Mountains thousands of kilometres to the west.

In some habitats scorpions are one of the most successful and important predators in terms of density, diversity, population biomass, and role in community energetics and structure. Many species occur locally at densities up to one or more individuals per square metre. *Vaejovis littoralis*, an intertidal scorpion from Baja California, exhibits the highest density, two to more than 12 per square metre along the high-tide mark. Since adult scorpions commonly weigh from 0.5 to five grams, the population biomass of the denser species is high. In some desert areas the population biomass of scorpions exceeds that of all other animals except termites and ants.

Several factors contribute to scorpions' success. Although they are morphologically conservative, scorpions are quite adaptable in terms of ecology, behaviour, physiology, and life history. They continue to thrive in extreme environmental conditions. Some species can be supercooled below the freezing point for weeks, yet return within hours to normal levels of activity. Others survive total immersion under water for as long as one to two days. Desert scorpions can withstand warm temperatures (45°–47° C), several degrees higher than the lethal temperatures for other desert arthropods.

Associations. Scorpions are a valuable prey because many are relatively large and quite dense. Vertebrate predators include birds (mostly owls), lizards, a few small snakes, mammals (some rodents and carnivores), and frogs and toads. Some vertebrates specialize on scorpions, at least seasonally. Scorpions are a major predator on other scorpions as well; both cannibalism and predation on other species is frequent. Such predation can be a major mortality factor and may limit the abundance and distribution of some species. A few large arthropods (spiders, solpugids, centipedes) also eat scorpions.

Scorpions exhibit several antipredator adaptations. The most obvious are the stinger and venom. Venom has a dual function: one of its chemical components is directed at arthropods (prey capture) and one at vertebrates (predator deterrence). An injection of potent neurotoxin is an overkill for most insects. Nocturnal activity and the low levels of surface activity may have evolved to avoid predation (most species are active only a few hours on 20 to 50 percent of all nights in the year).

Many predators exhibit typical behaviours that enable them to handle scorpions safely. Most vertebrate predators bite or break off the scorpion's tail and stinger. Some vertebrates and arthropods are immune to scorpion venom, even from those species that are lethal to humans.

The vast majority of scorpions are nonsocial, solitary animals that interact only at birth, courtship, or cannibalism. They are often aggressive and are usually considered "inveterate cannibals." A few, however, exhibit social behaviour. Some form overwintering aggregations with individuals of their own species, usually under bark or in fallen trees. A few extend the mother-offspring association for weeks to months or even years. In some cases (e.g., *Pandinus imperator*) offspring may remain with the family group even as adults, and some family groups cooperate in prey capture.

FORM AND FUNCTION

General features. The anatomy of scorpions has changed little from the Paleozoic Era. Consequently, their

Specificity
to habitat

Adapt-
ability

Anti-
predator
adaptations

Figure 5: (A) Dorsal and (B) ventral views of a scorpion.

body plan is relatively primitive. Segments and associated structures were lost or fused during evolution from ancestral arthropods and arachnids to more highly evolved descendants. Scorpions have more segments (18) than any other arachnids and are strongly segmented in the design of the heart and nervous system. The possession of book lungs, rather than a trachea, for respiration is also primitive.

External features. The three major regions that form the body are the anterior prosoma, the medial mesosoma, and the posterior metasoma. The mesosoma and the metasoma form the opisthosoma. The prosoma has six segments, each with a pair of appendages. The three-segmented chelicerae that arise from the first segment are chelate (pincerlike) and serve to masticate food. The pedipalps originate in the second segment and terminate in chelate pincers (chela). Pedipalps are used for a variety of purposes, including prey capture, defense, courtship, and burrow excavation. Four pairs of legs arise from segments three through six. The pedipalps and legs are composed of segments: (basal) coxa, trochanter, femur, patella, tibia, basitarsus, and tarsus. Legs end in tarsal claws used to grasp the surface during walking. The coxae of the pedipalps and the first two pairs of legs are expanded ventrally to form a gnathobase that encloses a preoral cavity where food is masticated, squeezed, and transferred from the chelicerae to the mouth. One medial and from zero to five lateral pairs of eyes are set into the dorsal carapace that covers the prosoma.

The mesosoma has seven segments: the first (pregenital) segment is reduced and bears the sternum; the second (genital) bears the ventral gonopore covered by a pair of small genital opercula. The unique comblike pectines arise from the genital segment. Four pairs of book lungs are on the ventral side of mesosomal segments three through six. The seventh mesosomal segment marks the end of the "body." The mesosoma is covered dorsally by seven tergites and ventrally by five sternites; these plates are separated from each other and laterally by a flexible pleural membrane. The tail is composed of the five-segmented cylindrical metasoma and a posterior telson bearing the stinger. The anus exits at the end of the fifth metasomal segment.

The exoskeleton is composed of chitinous cuticle overlain by impermeable epicuticular waxes. Growth is accompanied by ecdysis. Scorpions increase in weight until the exoskeleton becomes too small to allow further growth and a new exoskeleton is secreted by the epidermis under the old. During this process, some materials are resorbed from the old cuticle. Scorpions, like other arachnids, probably increase blood pressure just before molting. The cuticle ruptures at the side and front margins of the carapace. The chelicerae, pedipalps, legs and body are withdrawn from the old cuticle over a period of 12 hours. Scorpions then probably change blood pressure to expand body volume temporarily while the new cuticle hardens. This allows room for future growth in mass. As the cuticle tans, it hardens, darkens, and gradually acquires the ability to fluoresce under ultraviolet light.

Internal features. Muscles attach to the inner cuticle. Scorpion muscles are striated with individual fibres innervated by several neurons. A single neuron can attach to several muscle fibres. The strength of muscular contraction is a function of the rate of impulse delivery rather than of the number of fibres contracting (as is the case in vertebrates). The neuromuscular system has fast (phasic) neurons that produce rapid movement and slow (tonic) neurons that produce the prolonged contractions necessary in posture or slow movement.

The central nervous system consists of a brain and ventral nerve cord. The brain is composed of two large ganglia that surround the esophagus. The supraesophageal ganglion is bilobed: the protocerebrum processes optic information and is the origin of complex behaviours; the tritocerebrum mainly controls the normal body functions. The subesophageal ganglion innervates the chelicerae. Locomotion is controlled by both ganglia. A pair of circumesophageal connectives links the two ganglia. The nerve cord, which runs posteriorly along the length of the ani-

mal, consists of seven ganglia connected by pairs of fibres.

Scorpions perceive the world through visual, tactile, and chemical sense organs. Their eyes cannot form sharp images; however, their medial eyes are among the most sensitive to light in the animal kingdom. Evidently they can navigate at night using shadows cast by starlight. Lateral ocelli sense only changes in light intensity and are used to entrain circadian cycles. Light receptors occur in the tail in some species.

Scorpions interpret vibrations transmitted through the air and substrate. Long, thin trichobothria are deflected best by air vibrations originating perpendicular to one plane. These hairs are situated on the pedipalps along different planes, thus allowing scorpions to detect the direction of air movement—*e.g.*, to catch aerial prey, detect predators, and navigate using prevailing winds. Tarsal slit sense organs are used by some species to detect substrate vibrations produced by prey, potential predators, and mates. These thin areas in the cuticle are deformed by mechanical energy transmitted up the leg from the substrate.

Chemoreceptors are located in the oral cavity (for taste) and the pectines. Receptors in the pectines are used by some species to locate some prey. Males use their pectines to detect pheromones produced by receptive females. Pectines are sexually dimorphic in that males have larger pectines with more and larger teeth.

Digestion by all arachnids, including scorpions, begins outside the mouth. The preoral cavity is supplied with digestive juices from the gut that semi-digest the food before it enters the mouth. Setae in the preoral cavity filter undigestible material such as prey exoskeleton. These particles are matted together and expelled. Food passes from the mouth to the pharynx to the esophagus to the midgut to the hindgut and is expelled through the anus. The muscular pharynx acts as a pumping organ drawing food into the body. Several pairs of cecal glands arise in the hepatopancreas and enter the midgut. These glands produce the amylases, proteases, and lipases used to digest food in the midgut and preoral cavity. Absorption occurs in the midgut and hindgut. The hepatopancreas is a large organ constituting about 20 percent of the total body mass, where food is stored as glycogen.

Scorpions are extremely efficient eating machines. They can increase their body weight by one-third when feeding. Metabolic rates and energy needs are low—10 times lower than that of insects. Further, they are extremely efficient at transferring energy from prey tissue to their own. The ability to consume large quantities of food at one time, high transfer efficiency, extremely low metabolic rates, and an efficient food-storage organ combine to allow scorpions to live without food for up to 12 months. It is possible that scorpions feed from only five to 50 times a year. The proportion observed feeding in nature is always low (2 to 7 percent).

Excretion and water balance are interlinked in all terrestrial arthropods, including scorpions. Nitrogenous wastes from protein metabolism are collected by two pairs of Malpighian tubules. They enter the gut at the hindgut-midgut connection. Excretory wastes are expelled through the anus with feces. The scorpion excretory system is one reason desert scorpions are so efficient at water conservation. Nitrogenous wastes (xanthine, guanine, and uric acid) are nearly insoluble to water. Feces are likewise extremely dry. Further, minimal water is lost through either the spiracles or waxed integument. Some scorpions live indefinitely without drinking water; sufficient water is normally contained in their food or is produced internally from food as water of metabolism.

The open circulatory system is typical of arthropods. The dorsal tubular heart runs the length of the mesosoma. A pacemaker contracts the heart rhythmically. Hemolymph (blood) flows via the anterior aorta to the prosoma and from the posterior aorta to the metasoma. The anterior aorta branches into the cephalic and cerebral arteries and to smaller arteries that carry blood to each limb and to the nerve cord. Arteries branch further and eventually empty into blood sinuses. Blood sinuses are extensive and bathe most tissues. Most gas and material exchange occurs there. Blood returns via sinuses and veins into a pericardial sac

process of
molting

Open
circulatory
system

surrounding the heart, entering the heart through seven pairs of slitlike ostia. Blood is a colourless fluid containing proteins and salts. There are no blood cells.

Book lungs consist of a cavity and internal parallel leaves (lamellae) of thin cuticle across which gas exchange occurs. A sinus surrounds the book lungs, and blood is pumped in and out indirectly by the heart; the cardiac pulse is transmitted by ligaments attached to the sinus. Ventilation occurs passively when individuals move.

The paired gonads are a network of tubules that superficially appear similar in both sexes. Males possess seminal vesicles, and large paraxial organs produce the spermatophore. The spermatophore is produced in two parts that fuse during extrusion. Sperm enters the female's gonopore, and fertilization is internal. Eggs (from ovarian follicles within the ovariterus) undergo two types of embryologic development. Apoikogenic scorpions have ova with various amounts of yolk; katoikogenic scorpions have smaller, yolkless ova. Both are viviparous but differ in the amount of nutrition derived directly from the mother. Apoikogenic embryos primarily use yolk and receive only some nourishment from the mother, possibly by diffusion across embryonic membranes. Katoikogenic embryos are nourished via a specialized oral feeding apparatus that develops early. They use their chelicerae to grip the nipple of a specialized, stalked diverticulum that branches from the mother's ovariterus. This "teat" receives and transports nutrients from the hepatopancreas to the embryo, which uses its pharyngeal musculature to pump nutrients into its body.

Hazards
to humans

Venoms. About 25 species in eight genera possess potent venoms capable of killing humans. With the exception of snakes and bees, scorpions cause more deaths than any other nonparasitic group of animals. More than 5,000 people are thought to die each year from scorpion stings. In Mexico alone, five species of *Centruroides* caused an average of 1,696 deaths per year during the 1950s.

Scorpions are major health hazards in parts of India (*Buthotus tamulus*), North Africa and the Middle East (*Androctonus*, *Buthus occitanus*, *Buthus minax*, *Leiurus quinquestriatus*), South America and the West Indies (*Tityus*, *Rhopalurus*), and South Africa (*Parabuthus*). All these species are members of the family Buthidae. Buthids produce a complex neurotoxin that causes local and systemic effects. Severe convulsions, paralysis, and cardiac irregularities precede death. Death can be avoided if antivenoms are administered (now available against most lethal species).

The venoms of more than 1,200 other species are not deadly. These species produce hemotoxins that cause mild to strong local effects, including edema, discoloration, and pain. (The sting is often far less painful than that of a bee.) Victims fully recover in minutes or in a matter of days.

EVOLUTION AND PALEONTOLOGY

Scorpions first appeared in the Silurian Period (430,000,000 to 395,000,000 years ago). Some believe that they almost certainly evolved from the Eurypterida (water scorpions). Paleozoic scorpions and eurypterids share several features: external book gills, flaplike abdominal appendages, large compound eyes, and similar chewing structures on the coxae of the first legs.

Earliest
scorpions

Like many of the modern crabs, early scorpions were marine or amphibious. The earliest scorpions not only apparently possessed gills but also had legs adapted to a benthic (bottom-dwelling) existence. The fact that many of the earliest scorpions were relatively large also strongly suggests that these species needed water for support. Finally, the earliest fossils are associated with marine organisms.

Marine and amphibious scorpions probably persisted well into the Carboniferous Period (345,000,000 to 280,000,000 years ago). The first decidedly terrestrial scorpions probably appeared during the Upper Devonian or Lower Carboniferous periods (350,000,000 to 325,000,000 years ago). The evolution of enclosed book lungs in place of external book gills was the major change associated with the transition from water to land. Although the arrangement of early scorpions into categories is uncertain, they radiated into several extinct families and superfamilies.

Several other terrestrial arthropods were on land before scorpions appeared. Fossils of other arachnids, myriapods, and possibly even insects occur in the Devonian Period (380,000,000 years ago). Thus, land was colonized repeatedly by arthropods, and scorpions were probably not the first arthropods to establish successfully.

The presence of these fossils along with differing interpretations of embryologic and morphological data have produced a controversy over the origin of the arachnids and the relationship of scorpions to other arachnids. One view considers that scorpions are a group in the phylum Arachnida and may even be the ancestor of other arachnids. The alternate view contends that scorpions are not arachnids at all but modern, terrestrial merostomes: the horseshoe crab *Limulus* is the closest living relative, and the Merostomata, including scorpions, are a group distinct from the arachnids. Whatever their exact taxonomic relationship, it is clear that scorpions form a distinct group consistently separated by taxonomists from other arachnids.

Except for changes in locomotion and respiration necessitated by the migration to land, the basic scorpion body plan is similar to that of scorpions that lived 430,000,000 years ago. The earliest scorpions possessed a segmented opisthosoma with the mesosoma and metasoma clearly differentiated, well-formed chelate pedipalps and chelicerae, eight walking legs, pectines, and a terminal stinger. This body plan was a particularly successful one; no great architectural revolution in external morphology accompanied the taxonomic diversification of scorpions, and there has not been extensive modification during radiation into different habitats. Although some species show ecomorphological adaptation to different substrates, similarities among scorpions far overshadow morphological differences. (G.A.Po.)

CLASSIFICATION

Distinguishing taxonomic features. Eight extant families and about two dozen subfamilies are identified by the structure of the sternum, gnathobase, legs, cheliceral dentation, venom gland, and number and distribution of lateral eyes and pedipalpal trichobothria. Embryologic patterns and the anatomy of the reproductive system are also important diagnostic traits.

Annotated classification.

ORDER SCORPIONES (or SCORPIONIDA; scorpions)

Chelicerate arachnids with single carapace over cephalothorax; pair of 3-jointed chelicerae; large chelate pedipalps; 4 pairs of walking legs; comblike pectines; 4 pairs of book lungs; tropics to warm temperate zone; about 1,200–1,300 species described.

Family Buthidae (buthids)

Oldest living family; in tropics to warm temperate zones; triangular sternum; often with spine under stinger; worldwide distribution; about 600 species, including those most dangerously venomous.

Family Scorpionidae (scorpionids)

Mostly in tropics and subtropics of Eastern Hemisphere; pentagonal sternum; single spur at base of tarsus; worldwide except North America; includes the largest scorpions (*Pandinus* and *Hadogenes*); about 175 species.

Family Diplocentridae (diplocentrids)

Warm regions of Middle East, Mexico, and the Antilles; pentagonal sternum, single tarsal spur, and tubercular spine under stinger; about 50 species.

Family Chactidae (chactids)

Tropical to warm temperate zones, mostly in South America; a few species in Australia, Mexico, and Mediterranean region; pentagonal sternum and 2 lateral eyes on each side; about 75 species.

Family Vaejovidae (vejovids)

Mostly in warm temperate region of western North and South America, Middle East to eastern Asia; sternum with nearly parallel sides; 3 lateral eyes; about 125 species.

Family Bothriuridae (bothriurids)

Tropical and subtropical South America; 1 Australian genus; broad, inconspicuous sternum consists of 2 narrow, transverse plates; 3 lateral eyes on each side; about 80 species.

Family Chaerilidae (chaerilids)

Pedipalpal femur with 9 trichobothria; gnathobases expanded to broad lobes anteriorly; female reproductive system including an ovariterus, with yolk-rich ova developing in the lumen; moist habitats in the Malay Peninsula; 15 species.

Family Iuridae (iurids)

Pedipalpal femur with 3 trichobothria; female reproductive system including an ovariterus, with yolk-poor ova developing in the lumen; arid regions of the Americas and the Aegean region of Europe; *Hadrurus* the largest in the United States; 20 species.

(W.J.G./G.A.Po.)

Acarids (mites and ticks)

Mites and ticks, close relatives of spiders, scorpions, and harvestmen, constitute the subclass Acari (Acarina, Acarida), which is part of the arthropod class Arachnida. The acarids may be separated into three orders, Opilioacariformes, Parasitiformes, and Acariformes, consisting of six suborders and about 428 families.

GENERAL FEATURES

Size range and diversity of structure. Some mites are 0.1 millimetre in length; the largest ticks are slightly more than 30 millimetres. Nymphs and adults generally have four pairs of legs, the larvae three. Members of some families have a dense covering of stiff hairs, or setae, while others are almost nude. Soft-bodied mites and ticks have only a few hardened plates, or shields; others that are strongly sclerotized have numerous hardened plates. Acarids range in shape from minute, soft-bodied, elongated or circular individuals to large, hard-bodied, spiderlike ones. Some are flattened; others assume grotesque body shapes as they become engorged with food or filled with eggs.

Distribution and abundance. Mites and ticks are distributed throughout the world in almost every conceivable habitat and frequently occur in large numbers. They are recorded as high as 5,000 metres on the slopes of Mount Everest and as deep as 5,200 metres in the northern Pacific Ocean. More than 50 terrestrial species are known from the Antarctic. A few mites have been found drifting high in the atmosphere.

Acarids have been found in diverse habitats that include hot springs, caves, harsh deserts, and tundras. Although many of the approximately 35,000 species described are free-living, some are parasites of animals. The total number of species of mites and ticks has been estimated at more than 500,000.

Importance. The Acari are an economically important arachnid group; the ticks (suborder Ixodida), for example, surpass all other arthropods (except mosquitoes) in the number of diseases they transmit to humans. Many mites also are intermediate hosts of diseases transmissible to humans, domesticated animals, and crops. Others are pests as a result of their biting or feeding habits or the damage they cause to food and related products.

In the mite suborder Holothyrima (order Parasitiformes), one species of *Holothyrus* is known to secrete an irritant substance that is toxic to fowl and humans. The house-mouse mite (*Liponyssoides sanguineus*) transmits rickettsialpox to humans. Widespread species such as the tropical fowl mite (*Ornithonyssus bursa*), northern fowl mite (*O. sylviarum*), and chicken mite (*Dermanyssus gallinae*) also are pests of poultry and humans.

Eriophyid and tetranychid mites (Prostigmata), widespread plant-feeding species, frequently seriously injure or kill the host plant; the former are the only phytophagous Acari known to transmit plant viruses. The mange, itch, or scab mites (Astigmata) occur on many different animals including humans. House-dust allergy is caused by species of *Dermatophagoides*, a common arthropod.

The beetle mites (Oribatida), among the most numerous soil arthropods, are important in the development of soil fertility and also act as intermediate hosts for important tapeworm parasites of domestic animals.

Lyme disease of humans and some animals is caused by a spirochete transmitted by *Ixodes dammini* or related species. Rocky Mountain spotted fever, a rickettsial disease that occurs in the United States, is transmitted to humans by the bite of several species of hard ticks (Ixodidae), especially the Rocky Mountain wood tick (*Dermacentor andersoni*) and the American dog tick (*D. variabilis*). Relapsing fever, an important bacterial disease throughout the world, is transmitted to humans by certain species of soft ticks (Argasidae) of the genus *Ornithodoros*. Texas cattle fever is a widespread protozoan disease transmitted by cattle ticks (*Boophilus*); the disease, no longer prevalent in the United States because the tick has been eliminated, remains important in many tropical and subtropical countries. Various other diseases transmitted to animals by ticks include anaplasmosis, tularemia, Q fever, Colorado tick fever, hemorrhagic fever, and tick-borne encephalitis.

The chiggers (Prostigmata), important pests of humans, also transmit scrub typhus (tsutsugamushi disease), a rickettsial disease occurring in the Asiatic-Pacific region.

NATURAL HISTORY

Reproduction and life cycle. The sexes occur separately in acarids; i.e., there are both males and females. Most species lay eggs (oviparity), but in some parasitic ones the eggs hatch within the female, and the young are born alive. Many species also can reproduce by parthenogenesis; i.e., by the development of unfertilized eggs.

The actual process of sperm transfer occurs directly or in packets called spermatophores. The male spermatozoa may be introduced by the male copulatory structure (aedeagus) directly into the female genital opening or, as in some Astigmata, into a special female copulatory structure called a bursa copulatrix. The males of species that use the latter method may have special copulatory structures (e.g., suckers, spurs, or enlarged legs) for grasping the female. Some males produce a sealed packet contain-

Carriers of disease

Fertilization

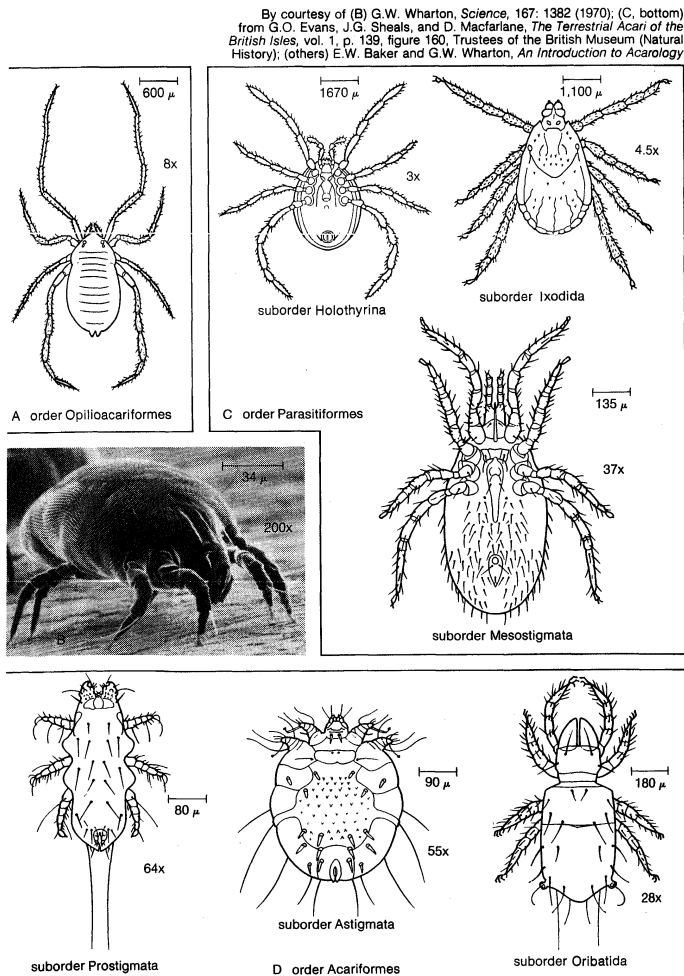

Figure 6: Diversity of Acari.

ing spermatozoa (spermatophore) that is transferred to the female genital opening, either directly by the mouthparts of the male or indirectly by deposition on a surface, after which the female places it in her genital opening. Eggs begin to develop after mating and fertilization; although only a few eggs develop simultaneously in many acarids, large numbers develop at the same time in ticks and some mites. Eggs are deposited haphazardly on food material by many plant- and grain-feeding species and are hidden in the soil by predatory soil-inhabiting species. One predatory mite, *Cheyletus eruditus*, broods her small cluster of eggs and drives other arthropods from them.

The primitive life cycle among species that lay eggs has four active immature stages—hexapod larva, protonymph, deutonymph, and tritonymph. There are many deviations from this primitive type of life cycle, which is found only in the Oribatida and some Prostigmata. The hexapod larva, characterized by three pairs of legs, is common to all families of acarids except Eriophyidae (Prostigmata), whose members have only two pairs of legs in all active stages. Among the Parasitiformes the Mesostigmata lack the tritonymphal stage; the Ixodida may have only one nymphal stage (Ixodidae) or as many as eight (Argasidae). Some Prostigmata (Podapolipidae) develop directly from egg to larviform adults; others have from one to three nymphal stages. Many Astigmata (order Acariformes) have a nonfeeding, or hypopal, stage between the protonymphal and tritonymphal stages; it frequently occurs during adverse environmental conditions.

Free-living
acarids

Ecology. The free-living acarids include species from all of the suborders except Ixodida (ticks). The beetle mites (Oribatida), largely fungal feeders, are extremely numerous in the surface layers of soil; it is estimated that as many as 6,000,000 members of one species occur in an acre of pasture soil.

Some families of free-living mites have specialized stylet-like feeding organs (chelicerae), which can pierce plant cells and are used to suck out their contents; feeding by members of the family Eriophyidae (Prostigmata), for ex-

ample, causes the formation of galls, dwarfing of shoots, and malformation of fruits and leaves. The family Tetranychidae (Prostigmata) contains the spider mites, which are foliage feeders; several species capable of producing silk spin a light web over plant leaves.

The families Acaridae and Glycyphagidae (Astigmata), pests of stored grain and cereal products, have blunt, toothed chelicerae that enable them to scrape and gouge their food material; certain species of these two families frequently increase to tremendous numbers in foodstuffs, causing "grocers' itch" or "copra itch" in humans. A large group of free-living predatory mites lives in soil, humus, other organic matter, and water; these mites prey on small arthropods, their eggs, and other small invertebrates.

Many free-living mites utilize insects or other arthropods to disperse themselves; this nonparasitic association is known as phoresy. Adults of the genus *Dinogamasus* (Laelapidae), for example, live in a special mite pouch on an abdominal segment of certain carpenter bees.

Parasitic species are known in all acarid groups except Opilioacariformes, Holothyrida, and Oribatida. The majority are external parasites, including those most important to humans and domesticated animals. A few species are internal parasites of animals. One ecological group contains families found only on the skin surface or feathers of the host. Psoroptidae (Astigmata), or scab mites, for example, attack the skin surface of mammals and feed on skin scales; the continuous abrasion of the skin causes a lesion over which a protective scab eventually forms. A second ecological group contains several families of mites that burrow into skin, hair follicles, or quills of the host and feed on fatty secretions, lymph material, or, occasionally, blood. The families Sarcoptidae (Astigmata) and Psorergatidae (Prostigmata), for example, contain species that burrow just beneath the skin of a mammalian host, causing mange or itch. A third ecological group contains species that pierce the skin and suck up tissue fluid or blood without actually invading the tissues. These species may spend either short or long intervals on the host.

Parasitic
acarids

The larvae of Trombiculidae (Prostigmata), the chiggers, parasitize many vertebrates and a few invertebrates, feeding on host tissues; chigger nymphs and adults, however, are free-living and predatory. Species of Dermatomyssidae, Macronyssidae, and many Laelapidae (Mesostigmata) feed on blood or tissue secretions of mammals, birds, and reptiles. Some species, which spend much of their time off the host and in the nest, frequently are referred to as nest parasites, or nidicolous species. The protonymph of one species of Macronyssidae, found in the mouth of a long-nosed bat, causes destruction of tissues; and a species of Spinturnicidae (Mesostigmata) is found in the anal opening of certain species of cave-dwelling bats. Most members of the tick families Argasidae and Ixodidae (Ixodida) are obligate blood-sucking parasites of vertebrates; most Argasidae nymphs and adults feed on the host for only a few minutes, but Ixodidae in most stages in the life cycle remain attached to the host for several days.

A few families of mites are found in additional parasitic associations with vertebrates. Rhinonyssidae, Entonyssidae, and Halarhynidae (Mesostigmata), for example, are respiratory parasites of birds, snakes, and mammals, respectively. Several families of mites have established a parasitic relationship with invertebrates. Larvae of Trombiculidae and Erythracidae (Prostigmata) and other families, for example, are parasitic on insects; in later stages the mites are free-living. In contrast, in the aquatic family Unionicolidae (Prostigmata), nymphs and adults parasitize mollusks and sponges, and larvae are free-living.

FORM AND FUNCTION

External features. The subclass Acari is distinguished by the lack of body segmentation (secondarily developed in a few families), a characteristic shared only with the spiders among the arachnids. An anterior region called the gnathosoma contains the mouth, specialized feeding appendages (chelicerae), and segmented structures called palps, or pedipalps. The mouth or buccal cavity joins the pharynx internally; paired salivary glands may discharge into the mouth or in front of its opening. The chelicerae

Major
body
regions

Figure 7: Life cycle of a hard tick (*Ixodes dammini*). The cycle requires two years for completion. Eggs are deposited in the spring and larvae emerge several weeks later and feed once during summer, usually on the blood of small mammals. Larvae molt the following spring into eight-legged nymphs and feed once during the summer on mammals before molting into adults in the fall. Adults attach to a host, where they mate; the male dies but the female continues to feed until she lays her eggs and dies. The cycle is then repeated.

are basically three-segmented pincerlike appendages; as a result of the diverse feeding habits of some mites, however, chelicerae sometimes are modified as piercing organs or stylets. The pedipalps, which may be simple sensory structures or predatory organs modified for grasping or piercing, usually have five free segments—trochanter, femur, genu, tibia, tarsus; frequently there also is a clawlike apotele (modified sixth distal segment of appendage).

Behind the gnathosoma is a large region (idiosoma) that bears the legs, the genital and anal openings, and an assortment of tactile and sensory structures; respiratory pores (stigmata) and sclerotized shields of various shapes and sizes usually are present. The functions of the idiosoma parallel those of the abdomen, thorax, and portions of the head of insects. Although nymphs and adults commonly have four pairs of legs, some Prostigmata (Eriophyidae, Podapolipidae, Tenuipalpidae) and Astigmata (Evansacariidae, Teinocoptidae) have one to three pairs. Legs have the same basic segmentation as pedipalps plus a basal coxa; fusion or division of segments frequently occurs. The tarsus may be terminated either by several sensory hairs (setae) or by a clawlike or suckerlike apotele. The legs, which frequently bear ridges and spurs, always have tactile and sensory setae that follow a fixed pattern in position and number; the arrangement of leg setae is helpful in establishing systematic relationships. The first pair of legs usually functions in locomotion but sometimes is modified as a sensory or predatory structure.

The genital opening, usually located on the underside between the legs, frequently is protected by one or more shields or flaps and has two or three pairs of disks; in some Prostigmata (Cloacaridae, Demodicidae, Myobiidae, Ophioptidae, Podapolipidae), however, the male genitalia (aedeagus) is located on the dorsal side. The anal opening, also generally on the underside, is surrounded by a shield in the Mesostigmata and is always closed by a pair of valves; in some Prostigmata (Penthaleidae) and Astigmata (Chirorhynchobiidae, Knemidocoptidae) the anal opening is located on the dorsal side. As in all arthropods, the cuticle of acarids is secreted by an outer cell layer called the epidermis, which contains numerous pore canals. The cuticle of many acarids absorbs water from the air, enabling them to avoid desiccation.

There are many different types of sensory receptors, most of which are setal. The setae, of many shapes and sizes, may be hollow chemoreceptors or solid, tactile structures. Other specialized setae, known as trichobothria, pseudostigmatic organs, eupathidia, or famuli, occur only in the Acariformes. A sensory pit called Haller's organ contains sensory setae and is found on the tarsal segment of the first pair of legs of all ticks (Ixodida). One to three pairs of eyes are present on the anterior of the idiosoma in Opilioacariformes, a few Astigmata, and many Ixodida and Prostigmata. A single median eye also may be present in some Prostigmata.

Internal features. The digestive system consists of an anterior muscular pharynx, long narrow esophagus, ventriculus (stomach), short intestine, hindgut, and posterior rectal cavity. The ventriculus may have several paired gastric cecae (blind sacs), which function partly as food-storage organs and enable some acarids to go for long periods without feeding. One or two pairs of excretory organs (Malpighian tubules), which may open into the hindgut, absorb waste material from the body cavity and transform it into an organic compound called guanine, which passes into the hindgut, is mixed with other residues, and eventually is excreted from the anal orifice. Some Ixodida and Prostigmata have no connection between the ventriculus and hindgut, and the latter serves as an excretory organ.

The idiosomal body cavity contains various organ systems bathed in blood, or hemolymph. Circulation of blood carrying the products of digestion and excretion may be by the movement of muscles or by a heart, which is present in some suborders. The blood of some soft ticks (Argasidae) differs from that of other acarids biochemically, although similar morphologically.

One to four pairs of stigmata are present in the idiosomal region of all acarid orders except Astigmata and some Prostigmata and Oribatida, which respire through

Figure 8: Internal features of a mite. (Top) Dorsal internal aspect. (Bottom) Midsagittal section through the anterior region.

From G.W. Krantz, *A Manual of Acarology*, 2nd ed.

the cuticle or have other types of respiratory organs. The stigmata open internally into a system of tubes (tracheae) that radiates throughout the body. Tracheae function in the exchange of oxygen and carbon dioxide and help to control water loss in certain species.

A well-developed central nervous system surrounds the esophagus in the idiosoma. A series of nerves radiating from one part of the brain innervates the legs, digestive system, musculature, and genitalia. The mouthparts are innervated by another part of the brain.

The male and female reproductive systems vary in structure and position. The gonads may be paired (primitive condition), united, or multiple (testes in some Prostigmata). There usually are accessory glands associated with the reproductive systems, especially in males.

Pheromones of four types (alarm, assembly, attachment, and sex) have been reported in acarids, with those of ticks (Ixodida) best known.

CLASSIFICATION

Distinguishing taxonomic features. Features that distinguish the orders and suborders of Acari include the presence or absence of stigmata—if present, the type, relative position, and structures associated with the stigmata are important—the position and form of the palpal apotele (modified distal segment of palpus) when present, the type and location of sensory organs, the type of mouthparts, and the presence or absence of eyes.

Annotated classification. The ordinal classification presented here is after Donald E. Johnston in Sybil P. Parker (1982). The process of evolution in mites and ticks has resulted in a degree of specialization and morphological diversity not found in any other group of arachnids. Acarids, believed to be derived from two lines of descent, have a long, though meagre, fossil history dating from the Devonian Period (about 395,000,000 years ago).

SUBCLASS ACARI (ACARINA, ACARIDA; mites and ticks)

Arachnids usually without visible segmentation; mostly minute in size; larvae usually with 3 pairs of legs, adults usually with 4 pairs; diverse habitats include plants, soil, animals, stored foods, fresh and marine water; parasitic forms may transmit diseases; worldwide distribution; about 35,000 described species.

Order Opilioacariformes (mites)

Weakly sclerotized mites superficially resembling members of arachnid subclass Opiliones; 1–2.5 mm in size; body divided into hairy anterior portion bearing 2 or 3 pairs of simple eyes and nude posterior portion with over 200 pores, 4 pairs of stigmata, and 12 secondarily developed segments; terminal palpal apotele a pair of claws; rutellae (hypertrophied setae) present; all coxae of legs movable; first 2 pairs of legs with 6 segments, last 2 with divided trochanter, 7 segments; tritosternum paired base divided; terrestrial, under stones and other debris in semiarid habitats; recorded from southwestern United States, Puerto Rico, South America, Central Asia, Africa, and the Mediterranean region; carnivorous and possibly omnivorous; of no economic importance; 1 family and about 12 species.

Order Parasitiformes (mites and ticks)

Small to large in size; usually heavily sclerotized mites; 1 to 4 pairs of stigmata on posterior portion of body; peritremes, or grooves, present or absent; palpal apotele present or absent; tarsi of 1st pair of legs with sensory organs.

Suborder Mesostigmata

Generally with a number of sclerotized plates; 0.2–2 mm in size; eyes absent; pair of stigmata between coxae of 2nd, 3rd, or 4th pair of legs; usually associated with elongated peritremes; palpal apotele present; tritosternum usually well developed but reduced to absent in some parasitic families; majority free-living in soil or decaying organic matter; many parasites of vertebrates (except amphibians and fishes) and invertebrates; some economically important; cosmopolitan; about 76 families, and 5,050 species.

Suborder Holothyrida

Heavily sclerotized; 2–7 mm in size; eyes absent; pair of coxal glands opening at base of coxae of 1st pair of legs; pair of stigmata behind coxae of 3rd and 4th pair of legs, peritremes present; palpal apotele present; tritosternum absent; terrestrial, under stones and decaying vegetation; recorded from Indo-Pacific region, southeastern United States; carnivorous; of minor economic importance; 3 families and about 13 species.

Suborder Ixodida (ticks)

Largest Acari; adults 2–30 mm in size, eyes present or absent; pair of lateral stigmata enclosed in stigmatal plate (modified peritreme) anterior or behind coxae of 4th pair of legs; palpal apotele and tritosternum absent; sensory organ on tarsus of 1st pair of legs a pit (Haller's organ); mouthparts modified to form hypostome (holdfast organ) with teeth turned backward; active stages mostly external parasites (some nonfeeders), feeding primarily on blood of vertebrates (except fishes); many members economically important as disease carriers; cosmopolitan; 3 families and about 825 species.

Order Acariformes (mites)

Small to large in size; generally weakly sclerotized mites (except most Oribatida); palpal apotele and posterior body stigmata absent; anterior portion of body with or without sensory organs that are specialized setae.

Suborder Prostigmata

Most heterogeneous order includes chiggers; 0.1–16 mm in size; weakly sclerotized with few plates; eyes present or absent; stigmata, when present, at or between bases of chelicerae or on anterior portion of body; chelicerae styletlike, chelate (pincerlike), or reduced; diverse in habitat and habits—terrestrial, aquatic, marine, parasitic, predatory, phytophagous; many species economically important; cosmopolitan; about 135 families and 14,100 species.

Suborder Oribatida (oribatid or beetle mites)

Usually strongly sclerotized and slow moving, 0.2–1.5 mm in size; eyes and stigmata absent; pseudostigmata generally present, palps without claws, 3–5 segments; chelicerae usually chelate; rutella present; tarsi with 1–3 claws; ventrally with various shields; majority terrestrial in forest humus and soil, a few aquatic; feed on algae, fungi, or decaying material; of some economic importance; cosmopolitan; about 145 families and 8,500 species.

Suborder Astigmata

Homogeneous group includes mange, itch, or scab mites; weakly sclerotized and slow moving; 0.2–1.5 mm in size; eyes rarely present, stigmata absent; palps single segmented (sometimes with 2 false segments); chelicerae chelate; true claws absent; rodlike sensory setae on tarsus of 1st pair of legs; wide range of terrestrial habitats; parasitic, predatory, or feed on

decaying material; some species economically important; cosmopolitan; about 65 families and 6,500 species.

Critical appraisal. Acarologists are not in total agreement as to the classification of mites and ticks. Much of the disagreement concerns the levels at which taxonomic divisions should be made and the use of ordinal names; consequently, seemingly different classifications are actually more alike than they may initially appear to be. Knowledge of Acari systematics is so incomplete that any classification proposed below the ordinal level is difficult and may quickly become obsolete.

Three major classifications, including that used above, have been proposed since 1978 for the mites and ticks. The suborders listed above are treated as orders in other classifications, with the choice of ordinal names differing in some cases. (N.A.W.)

Spiders

Spiders (order Araneida) are common terrestrial members of the invertebrate arthropod class Arachnida. They differ from the insects, another arthropod group, in having eight legs rather than six and in having the body divided into two parts rather than three. The use of silk is highly developed among spiders. About 34,000 species of spiders have been described; the world's spider fauna outside of northern Europe, Japan, and North America, however, has not been thoroughly collected and studied.

Spiders are predators, feeding almost entirely on other arthropods, especially insects. Many spiders that are active hunters and overpower their prey have a well-developed sense of touch or sight. Others construct silk snares, or webs, to capture prey, sometimes in larger numbers than can be consumed; webs, constructed instinctively, effectively trap flying insects. Many spiders are able to inject venom into their prey to kill it; others use silk to overpower prey.

GENERAL FEATURES

Size range. Spiders range in body length from 0.5 to about 90 millimetres (0.02–3.5 inches). The largest spiders, hairy mygalomorphs (tarantulas), are found in warm climates and are most abundant in the Americas; the largest, *Theraphosa leblondi*, is found in Guyana. The smallest spiders belong to several families found in the tropics, and information about them became known only in the 1980s.

Distribution. Spiders are found on all continents except Antarctica (though spider fragments have been reported there) and at elevations as high as 5,000 metres (16,400 feet) in the Himalayan ranges. Many more species occur in the tropics than in temperate regions. Though most spiders are terrestrial, one Eurasian species is aquatic and lives in slow-moving fresh water; a few species live along shores or on the surface of fresh water or saltwater.

Small spiders and the young of many larger species secrete long silk strands that catch the wind and can carry the spiders great distances. This ballooning behaviour occurs in many families and expedites distribution. Ballooning spiders drift through the air at heights that range from three metres or less to more than 800 metres.

Importance. Spiders are predators and because of their abundance are the most important predators of insects. The impact of spider predation is difficult to assess. One reason for this is that the web of a spider may catch many more insects than the spider can use as food. Spiders have been used to control insects in apple orchards in Israel and rice fields in China. Spiders also have been observed feeding on insects in South American rice fields and in fields of various North American crops. Modern pest management uses insecticides that do the least damage to natural predators of insect pests.

Some spiders attract their insect prey by secreting substances that mimic the odour attractants (pheromones) of female insects. A male moth in search of a female, for example, is attracted to the spider and is caught by a sticky globule on a silk line thrown by the spider. If synthesized commercially, the odoriferous substances might have importance in pest control.

Pest
control

iders
rmful to
mans

A few spiders are toxic to humans. The venom of the black widow spider and others of the *Latrodectus* genus acts as a painful nerve poison. The bite of the brown recluse and others of the *Loxosceles* genus may cause localized tissue death. Other venomous spiders include the mygalomorph funnel weaver (*Atrax*) of southeastern Australia and some members of the family Theraphosidae (tarantulas) of Africa and South America. In North America *Cheiracanthium mildei*, a small, pale, clubionid spider introduced from the Mediterranean, enters houses in late fall and is responsible for some bites; rarely, the site of the bite becomes necrotic. Some American theraphosids, or tarantulas, throw off abdominal hairs as a defense against predators. The hairs have tiny barbs that penetrate skin and mucous membranes and may cause temporary itching and allergic reactions.

NATURAL HISTORY

Reproduction and life cycle. *Courtship.* In male spiders the second pair of appendages (pedipalps) is modified to form a complex structure for holding sperm; the enlarged tips of the pedipalps form copulatory organs. When the time for mating approaches, the male constructs a special web, called the sperm web. The silk comes from silk glands and emerges from the spinnerets; epigastric silk glands also supply silk, which emerges from spigots in the epigastric area (between the book lungs). A drop of fluid containing sperm is deposited onto the sperm web through an opening (the gonopore) located on the underside of the abdomen. The male draws the sperm into his pedipalps; the process of charging the pedipalps, known as sperm induction, may require minutes or hours for completion. Sperm induction may occur before a male seeks a mate or after the mate is found; if more than one mating occurs, the male charges his pedipalps between copulations.

The way in which a male finds a female varies among species. The males of many species wander more extensively than the females, and males of the relatively sedentary web weavers generally have longer legs than females. The wandering males of some species follow silk threads; some may recognize both the threads produced by a female of his own species and the female's condition—*i.e.*, whether she is mature and receptive. Pheromones are involved. Other species (*e.g.*, jumping spiders) also use visual senses to recognize mates.

Males in a few species locate a female and then unceremoniously run to her and mate. In most species, however, elaborate courtship patterns have evolved, probably to protect the male from being mistaken for prey. The male web spider courts by rhythmically plucking the threads of a web; after the female approaches, he pats and strokes her before mating. When male wolf spiders or jumping spiders see a female, they wave the pedipalps, conveying a visual message characteristic of the species; an appropriate response from a female encourages the approach of the male. Some male wolf spiders tap dry leaves, perhaps to attract a female; an aggregation of tapping males produces sound that can be heard some distance away. A crab spider male quickly and expertly wraps his intended mate with silk. Although the female is able to escape, she does not do so until mating is completed. After the male of the European nursery web spider locates a suitable mate, he captures a fly, wraps it in silk, and presents it to the female; while the female is occupied with eating the fly, the male mates with her. If no fly is available, the male may wrap a pebble. Some male spiders use specialized jaws or legs to immobilize the jaws of the female during mating.

Mating. After a male has successfully approached a female and mounted her, in most groups he inserts his left pedipalp into the left opening of her genital structure and the right pedipalp into her right opening.

The female genital structure, or epigynum (epigyne), is a hardened plate on the underside of the abdomen anterior to the gonopore. After the sperm are transferred into the epigynum, they move into receptacles (spermathecae) that connect to the oviducts; eggs are fertilized as they pass through the oviducts and out through the gonopore. In some primitive spiders (*e.g.*, haplogynes, mygalomorphs) and some Tetragnathidae lacking an epigynum, the male

inserts both pedipalps simultaneously into the female's genital slit, the left pedipalp on her right side and the right pedipalp on her left side.

The force that causes the injection of sperm from the pedipalp of the male into the receptacle of the female has not been established with certainty but may involve blood pressure. Increases in blood pressure expand a soft vascular tissue (hematodocha) between the hard plates of pedipalps, causing a bulbous structure containing a duct to twist and to hook into the epigynum of the female.

Mating may require seconds in some species, hours in others. Some males recharge their pedipalps and mate again with the same female. After mating, the males of some species smear secretion over the epigynum; called an epigynal plug, the secretion prevents the female from mating a second time. Male spiders usually die soon after, or even during, the mating process. The female of one European orb weaver species bites into the abdomen of the male and holds on during mating. Although some females eat the male after mating, the practice is not common. The male of the black widow, *Latrodectus mactans*, for example, usually dies days after mating; occasionally he is so weak after mating that he is captured and eaten by the female.

Females of some species mate only once; others accept several males, one after another. The long-lived females of mygalomorph spiders must mate repeatedly because they shed their skins once or twice a year, including the lining of the sperm receptacles.

Eggs and egg sacs. Female spiders produce either one egg sac containing several to a thousand eggs or several egg sacs with successively fewer eggs. Females of some species die after producing the last egg sac or after the young have been taken care of; these females live one or, at most, two years. On the other hand, the females of the mygalomorph spiders may live up to 25 years, and those of the primitive haplogyne spiders, 10.

fertiliza-
tion

Fate of the
egg sac

The protective egg sac surrounding the eggs of most spiders is made of silk. Although a few spiders tie their eggs together with several strands of silk, most construct elaborate sacs of numerous layers of thick silk; the colour of the silk may vary. Eggs, which often have the appearance of a drop of fluid, first are deposited on silk and then wrapped in silk and covered, so that the finished egg sac is spherical or disk-shaped. The females of many species place the egg sac on a stalk, attach it to a stone, or cover it with smooth silk before abandoning it. Other females guard the egg sac or carry it either in their jaws or attached to the spinnerets. If a female loses an egg sac, she makes searching movements and may pick up a pebble or a piece of paper and attach it to the spinnerets. The European cobweb spider, *Achaearanea saxatile*, lowers its egg sac from a protective thimble-shaped structure or pulls it inside, depending on the temperature. Female wolf spiders carry their egg sacs attached to the spinnerets and instinctively bite the egg sac to permit the young to emerge after a certain length of time has elapsed.

Maturation. After hatching, young wolf spiderlings, usually numbering from 20 to 100, climb onto the back of their mother and remain there about 10 days before dispersing. If they fall off, they climb back up again, seeking contact with bristlelike structures (setae) or something similar in texture. Some female spiders feed their young; the female of one European species dies at the time the young are ready to feed, and they eat her carcass. When food has been sufficiently liquefied by females of other species (in spiders, digestion occurs outside the mouth), the young also feed on their mother's prey. The mother of one web spider species plucks threads of the web to call her young, both to food sources and to warn them of danger. The young of many species are independent when they emerge from the egg sac.

Molting

Young spiderlings, except for size and undeveloped reproductive organs, resemble adults. They shed their skins (molt) as they increase in size. The number of molts varies among species, within a species, and also among related young of the same sex. Males have fewer molts than females and mature earlier; females may molt six to 12 times, males two to eight. Males of some species may emerge mature from the egg sac, one or two molts having occurred before emergence. Some spiders mature a few weeks after hatching, but many overwinter in an immature stage. Mygalomorph spiders require three to four years (some authorities claim nine years) to become sexually mature in warm climates.

Before molting, many spiderlings hang by the claws in some inconspicuous place; mygalomorph spiders turn on their side or back. The carapace surrounding the cephalothorax breaks below the eyes or the opposite end, and the spider laboriously extracts its legs from their casings as the old abdominal cuticle (skin) shrinks. The cast-off cuticle, or exuviae, remains hanging, and the newly emerged spider dangles on a thread, helplessly soft. Molt-

ing is hazardous for spiderlings: they may dry out before emerging from the old cuticle or fall victim to a predator while defenseless. Even a small injury during a molting period usually is fatal. Emergence from the exuviae is accompanied by wide fluctuations of blood pressure; these raise and lower the setae and gradually force the legs free. The first break around the carapace edge also is caused by increased blood pressure. Growth and molting are believed to be under the control of hormones; some spiderlings fail to molt, others undergo delayed molts, perhaps because of faulty hormone balance, and may die. Many spiderlings eventually disperse by ballooning, usually in the fall.

Feeding behaviour. *Stalking prey.* Most hunting spiders locate prey by searching randomly or by responding to vibrations; wolf spiders and jumping spiders have keen eyesight. The latter stalk their prey within five to 10 centimetres (two to four inches), then pounce when it moves. Many crab spiders wait for prey on flowers similar in colour to their own; they use their legs to grasp an unsuspecting insect and then give it a lethal bite.

Unique among the hunters are the spitting spiders (family Scytodidae). When these spiders encounter an insect, they touch it, back off, and shoot a zigzag stream of sticky material over it. The sticky material, produced by modified venom glands in the cephalothorax, emerges from pores near the tips of the fangs, which are located on the chelicerae; as the victim struggles, the spider approaches cautiously and bites the entangled insect.

Trapping prey. Spiders that use silk to capture prey utilize various techniques. Ground-dwelling trap-door spiders construct silk-lined tubes, sometimes with silk trapdoors, from which they dart out to capture passing insects. Other tube-dwelling spiders place silk trip threads around the mouth of the tube and trip insects; vibrations of the threads inform the spider of a victim's presence. Funnel-weaving spiders live in silk tubes with a narrow end that extends into vegetation or into a crevice and an expanded sheetlike end that vibrates when an insect walks across it. Many web spiders construct silk sheets in vegetation, sometimes one above the other, and often add anchor threads, which trip unsuspecting insects. The irregular three-dimensional web of cobweb spiders (Theridiidae) has anchoring threads of sticky silk. An insect caught in the web or touching an anchor line becomes entangled, increasingly so if it struggles; if a thread breaks, the force of elasticity in it pulls the insect toward the centre of the web.

The most elaborate webs (orb webs), which are conspicuous on mornings with dew, are constructed by several spider families, suggesting that they are efficient traps, covering the largest area with the least possible silk. The web acts as an air filter, trapping weak-flying insects that cannot see the fine silk. The orb web is usually rebuilt every day. The web may be up only during the day or only at night. A web is damaged during capture of prey, and most spiders construct new web-parts frequently. The ways by which spiders keep from becoming entangled in

their own webs are not completely understood nor is their mechanism for cutting the extremely elastic silk threads used in web construction.

To begin orb web construction the spider releases a silk thread that is carried by wind. If the free end does not become attached to an object, the spider may pull it back and feed on it; if it becomes firmly attached—for example, to a twig—the spider secures the thread and crosses the newly formed bridge, reinforcing it with additional threads. The spider then descends from the centre of the bridge, securing a thread on the ground or on a twig. The centre, or hub, of the web is established when the spider returns to the bridge with a thread, carrying it part way across the bridge before securing it; this thread is the first radius, or spoke. After all of the spokes are in place, the spider returns to the hub and constructs a few temporary spirals of dry silk toward the outside of the web. The spider then reverses direction, deposits ensnaring silk, and removes the spiral. The ensnaring threads form a dense spiral. Some species attach a signal thread from the hub to a retreat in a leaf so that they are informed (by vibrations) of trapped insects; others remain head down in the centre of the web, locating prey by sensing tensions or vibrations in individual spokes. To build radii and orb takes only about an hour. Webs of the family Uloboridae have a woolly (cribellate) ensnaring silk; those of the families Araneidae and Tetragnathidae have spirals constructed of a sticky material that dries after several days and must be rebuilt.

Spiders usually cover a captured insect in silk and turn it efficiently, as on a spit, before biting it and carrying it either to a retreat or to the hub of the web for feeding or storage. Although the scales on butterfly and moth wings facilitate their escape from the web, spiders have evolved a counterstrategy: they bite the moths before wrapping them, rather than afterward.

The webs of uloborid spiders of the genus *Hyptiotes* consist of only three sections of the orb web. The spider, attached by a thread to vegetation, holds one thread from the tip of the hub until an insect brushes the web; then the spider alternately relaxes and tightens the thread, and the struggling victim becomes completely entangled. Tiny theridiosomatid spiders also control web tension. Ogre-faced spiders of the family Deinopidae build small flat webs during the evening hours and then cut the attachments and spread the web among their four long anterior legs. During the night the web is thrown over a passing insect. The spider abandons or eats the web in the morning and passes the day resting on a branch before constructing a new web. The bolas spider, *Mastophora*, releases a single thread with a sticky droplet at the end (bolas) and holds it with one leg; some species swing the bolas, and others throw it when a moth approaches. Only male moths are attracted to the spider by emanations of odours that mimic those of female moths. Many other examples of web specializations have been described.

Some tropical species of spiders are social and live in large communal webs containing hundreds of individuals, most of them female. They cooperate to build and repair the web. A pack of spiders overpowers and kills insects that have been caught in the communal web. Feeding is communal.

FORM AND FUNCTION

External features. The bodies of spiders, like those of other arachnids, are divided into two parts, the cephalothorax (prosoma) and the abdomen (opisthosoma). The legs are attached to the cephalothorax, which contains the stomach and brain. The top of the cephalothorax is covered by a protective structure, the carapace; the underside is covered by a structure called the sternum, which has an anterior projection, the labium. The abdomen contains the gut, the heart, the reproductive organs, and the silk glands. Spiders (except the primitive suborder Mesothelae) differ from other arachnids in lacking external segmentation of the abdomen and in having the abdomen attached to the cephalothorax by a narrow stalk, the pedicel. The gut, the nerve cord, the blood vessels, and sometimes the respiratory tubules (tracheae) pass through the narrow pedicel,

Usinger, copyright © 1957 by the McGraw-Hill Book Company, Inc., used with the permission of McGraw-Hill Book Company.

which allows the body movements necessary for efficient use of the spinnerets during web construction. Among arachnids other than spiders, the tailless whip scorpions (order Amblypygi) have a pedicel but lack spinnerets. Spiders, like other arthropods, have an outer skeleton; inside the cephalothorax is the endosternite, to which some jaw and leg muscles are attached.

Spiders have six pairs of appendages. The first pair, the jaws, or chelicerae, have a fang containing the opening of a poison gland near the tip. The chelicerae move forward and down in the orthognathans (mygalomorph spiders), sideways and together in the labidognathans (araneomorph spiders). The venom ducts pass through the chelicerae, which sometimes also contain the venom glands. The second pair of appendages, the pedipalps, are modified in the males of all adult spiders to carry sperm (see above *Reproduction and life cycle*). In females and immature males, however, the leglike pedipalps are used to handle food and also function as sense organs. The pedipalpal proximal segment (coxa) attached to the cephalothorax usually is modified to form a structure (endite) that is used in feeding.

The pedipalps are followed by four pairs of walking legs. Each leg consists of eight segments—the coxa, attached to the cephalothorax; a small trochanter; a long, strong femur; a short patella; a long tibia; a metatarsus; a tarsus, which may be subdivided in some species; and a small pretarsus, which bears two claws in running spiders and an additional median claw in web-building ones. The young of two-clawed running spiders often have three claws. The legs, covered by setae, contain several types of sense organs and may have accessory claws. A few species use the first pair of legs as feelers. Spiders can amputate their own legs (autotomy); new but shorter legs appear at the next molt.

Internal features. *Nervous system and sense organs.* The nervous system, unlike that of other arachnids, is completely concentrated in the cephalothorax. The masses of nervous tissue (ganglia) are fused with a ganglion found under the esophagus and below and behind the brain (subesophageal ganglion). The shape of the brain, or epipharyngeal ganglion, somewhat reflects the habits of the spider; i.e., in the web weavers, which are sensitive

/rapping
ie prey

ommunal
iders

to touch, the posterior part of the brain is larger than in spiders that hunt with vision.

Eyes The simple eyes of spiders, which number eight or less, consist of two groups, the main or direct eyes (called the anterior medians) and the secondary eyes, which include anterior laterals, posterior laterals, and posterior medians. The rhabdoms, which receive light rays, face the lenses in the main eyes; in the other eyes the rhabdoms turn inward. Both the structure of the secondary eyes and eye arrangement are characteristic for each family.

Other sense organs are long fine hairs (trichobothria) on the legs, which are sensitive to air currents and vibrations. Slit sense organs are minute slits, or several parallel slits, located either near the leg articulations (or hinges) or scattered over the body. The slit is closed toward the outside by a thin membrane and on the other side by a delicate membrane that may be penetrated by a nerve. Slit sense organs are sensitive to stresses on the cuticle; others act as vibration receptors or hearing organs. Internal receptors (proprioceptors) provide information about body movement and position. Olfactory organs of spiders are specialized hollow hairs found at the tips of pedipalps and legs.

Ceca *Digestion and excretion.* The mouth leads into a narrow passage, the pharynx, which leads to a stomach. The midgut has a variable number (usually four pairs) of blind extensions, or ceca, that extend into the coxae. Additional ceca and a branched digestive gland are located at the front of the abdomen. At the end of the gut a cecum (stercoral pocket, or cloaca) connects with the hindgut before opening through the anus.

Food is digested outside the mouth (preorally). Some spiders chew their prey as they cover it with enzymes secreted by the digestive tract; others bite the prey and pump digestive enzymes into it before sucking up the nutrient liquid.

The excretory system includes large cells in the prosoma that concentrate nitrogen-containing wastes (nephrocytes); a pigment-storing layer (hypodermis); the ends of the abdominal gut ceca, which are filled with a white excretory pigment (guanine); coxal glands; and tubular glands (Malpighian tubules) in the abdomen. The excretory compounds include various nitrogen-containing compounds—e.g., guanine, adenine, hypoxanthine, and uric acid. Silk may have evolved from an excretory product.

Respiration. The respiratory system, located in the abdomen, consists of book lungs and tracheae. Book lungs are paired respiratory organs composed of 10 to 80 hollow leaves that hang into a blood sinus, are separated by small hardened columns, and open into chambers (atria), which open to the outside through one or several slits (spiracles). Book lungs frequently transform into tracheae, which are tubes that conduct air to various tissues. The two respiratory organs at the very front end of the abdomen usually are book lungs; the posterior two are tracheae; in some groups, however, both pairs are book lungs (orthognathans—mygalomorph spiders) or tracheae (some minute araneomorph spiders). Because book lung covers, which are hardened plates, may be present in species in which the book lungs have transformed into tracheae, it is impossible to determine from surface structure whether a spider has lungs, tracheae, or both.

Circulation. The circulatory system is best developed in spiders with book lungs and is least developed in spiders with bundles of tracheae going to various parts of the body. The abdomen of all spiders contains a tube-shaped heart, which usually has a variable number of openings (ostia) along its sides and one artery to carry blood forward and one to carry it backward when the heart contracts. The ostia close during contraction. The forward-flowing artery, which goes into the cephalothorax, is branched in spiders with book lungs; the blood eventually empties into spaces, flows into the lung sinus, and travels into a cavity (pericardial cavity) from which it enters the heart through ostia. The blood, or hemolymph, contains various kinds of blood cells and a respiratory pigment, hemocyanin. Changes in blood pressure function to extend the legs and break the skin at molting time.

Reproductive system. The sex organs (gonads) of male and female spiders are in the abdomen. The eggs are

fertilized as they pass through the oviduct to the outside from sperm stored in the seminal receptacles after mating. The fertilized egg (zygote) develops in the manner typical of arthropod eggs rich in yolk.

Specialized features. *Venom.* Venom glands, present in most spiders but absent in the family Uloboridae, are located either in the chelicerae or under the carapace; venom ducts cross the chelicerae and open near the tips of their fangs. A muscle layer covers the venom glands in *Latrodectus*. Venom glands probably originated as accessory digestive glands whose secretions aided in the external digestion of prey. Although the secretions of some spiders may consist entirely of digestive enzymes, those of many species effectively subdue prey, and venoms of a few species are effective against predators, including vertebrates. The spitting spiders (*Scytodes*, Scytodidae) secrete a sticky substance that glues potential prey to a surface. The high and domed carapace of the spitting spiders is modified as a result of the large glands it contains.

Characteristics of the venom of widow spiders, especially the black widow, have been determined. The various protein components of the venom affect specific organisms; i.e., different components affect mammals and insects. Widows exhibit a warning coloration in the red hourglass-shaped mark on the underside of the abdomen and often have a red stripe; because the spider hangs upside down in its web, the hourglass mark is turned conspicuously upward. The venom, a nerve toxin, causes severe pain in humans, especially in the abdominal region, but is usually not fatal. There are widow spiders in most parts of the world, except central Europe and northern Eurasia. Some areas have several species. Although all appear superficially similar, each species has its own habits.

In southeastern Australia the funnel weaver, *Atrax* (family Hexathelidae), a mygalomorph spider, is considered dangerous to humans. There are also venomous theraphosid spiders (tarantulas) in Africa and South America.

The bite of the brown recluse (*Loxosceles reclusa*) results in a localized region of dead tissue (necrotic lesion) that heals slowly; the larger *Loxosceles laeta* of South America causes a more severe lesion in humans. The bites of several other species belonging to different families may occasionally cause necrotic lesions; e.g., *Lycosa raptoria*, *Mastophora*, *Phidippus formosus*, *P. sicarius*, *Cheiracanthium mildei*, and other species of *Cheiracanthium*. Knowledge of the effects of spider bites on humans is limited because the bite is not noticed at the time it occurs or because the spider is never identified.

Silk. Although silk is produced by some insects, centipedes, and millipedes, and a similar substance is produced by mites, pseudoscorpions, and some crustaceans (ostracods and amphipods), only the spiders are true silk specialists. Spider silks that have been studied are proteins called fibroin, which has chemical characteristics similar to those of insect silk. The silk is produced by more than seven different types of glands in the abdomen. Ducts from the glands traverse structures called spinnerets, which open to the outside through spigots. Abdominal pressure forces the silk to flow outward; the rate of flow is controlled by muscular valves in the ducts. The primitive Mesothelae have only two types of silk glands, but orb weavers have at least seven, each of which produces a different kind of silk; e.g., aciniform glands produce silk for wrapping prey, ampullate glands produce the draglines and frame threads, and cylindrical glands produce parts of the egg sac. Epigastric silk glands of male spiders produce silk that emerges through spigots in the abdomen between the book lung covers; silk from these glands provides a surface for the sperm drop in sperm induction.

Threads of *Nephila* silk have a high tensile strength and great elasticity. Silk probably changes to a solid in the spigot, or as a result of tension forces. Strands usually are flat or cylindrical as they emerge and are of surprisingly uniform diameter. The glob of silk that binds or anchors strands emerges from the spigot as a liquid.

The movable spinnerets, which consist of telescoping articles, are modified appendages; two pairs are from the 10th body segment, two pairs from the 11th. *Liphistius*, of the suborder Mesothelae, is the only spider with a full

Spider bites

Silk glands

complement of four pairs of spinnerets in the adult. Most spiders have three pairs; usually the anterior median pair is lost or reduced either to a nonfunctional cone, called the colulus, or to a flat plate, the cribellum, through which open thousands of minute spigots. Spiders with a cribellum also have a comb, the calamistrum, on the metatarsus of the fourth leg. The calamistrum combs the silk that flows from the cribellum, producing a characteristically woolly (cribellate) silk.

CLASSIFICATION

Distinguishing taxonomic features. The Araneida are separated into three suborders—Mesothelae, Orthognatha (mygalomorph spiders), and Labidognatha (araneomorph spiders)—on the basis of the type of movement of the two jaws; i.e., movement forward and down is orthognath (paraxial), movement sideways and together is labidognath (diaxial). Other features that distinguish suborders include the structure of the male pedipalps, presence or absence of an epigynum in the female, presence and number of book lungs, number of small openings (ostia) in the heart, and extent of fusion of nerve ganglia in the prosoma. Families are distinguished on the basis of such characteristics as number and spacing of simple eyes, number of tarsal claws, number of spinnerets, habits, structure of chelicerae, and specialized (apomorph) characters such as glands, setae, and teeth and peculiarities of the external genitalia. Species and also genera of araneomorph spiders are usually separated by specializations in their external genitalic morphology, that of the female epigynum and male pedipalp.

Annotated classification. Of the numerous classification schemes published in the 1930s, most of them in response to one of Alexander Petrunkevitch, none is acceptable and up-to-date. All classifications have relied heavily on the work of Eugène Simon, who published in France in the late 19th century. Although newer tools, such as scanning electron microscopy, molecular methods, and cladistics, remain little tried for spiders, they have changed traditional classification schemes. In addition, many new spiders have been found in the Southern Hemisphere that do not readily fit into established families, prompting the proposal of new ones, but without the overall view for a new system. Less than 30 percent of the large neotropical spiders are known (and probably less of the small neotropical spiders), while in north and central Europe, northern North America, Korea, and Japan 80 percent or more of the species are known. The known species are placed into about 90 families, only the most important of which are discussed below.

ORDER ARANEIDA (or ARANEAE; spiders)

Members of the class Arachnida; unsegmented abdomen (opisthosoma) attached to cephalothorax (prosoma) by pedicel; prosoma with poison glands whose ducts open through large chelicerae with a movable fang, no pincers; leglike pedipalps usually with modifications (endites) on coxae to aid in feeding, modified as copulatory organs in males; abdomen usually with 2 pairs of respiratory organs, anterior book lungs and posterior tracheae; spinnerets at posterior end of abdomen; 4 pairs of walking legs; 1 or 2 pairs of coxal glands; about 34,000 species described; worldwide distribution.

Suborder Mesothelae

Abdomen clearly segmented dorsally from 7th segment (pedicel) to 18th; 8 spinnerets at middle of abdomen; chelicerae orthognath (paraxial), attached in front of carapace; pedipalpal coxae without endites; male pedipalps relatively complicated; epigynum absent in females; 18 ganglia in prosoma more distinctly separated than those in other suborders; heart with 5 pairs of ostia in segments 8 to 13; 2 pairs of book lungs; a few species from Japan to Southeast Asia; inhabit trapdoor tubes in ground; family Liphistidae.

Suborder Orthognatha (mygalomorph spiders)

Chelicerae orthognath (paraxial), attached in front of carapace; pedipalpal coxae without endites (except in Atypidae); 2 pairs of book lungs; heart with 4, rarely 3, ostia; bulb of male pedipalps simple; female without epigynum; 13th through 18th ganglia lost, others fused; most species large and long-lived in warm climates; about 2,000 to 3,000 species.

Family Ctenizidae (ctenizid trap-door spiders). Chelicerae with structure (rake or rastellum) used to dig; 3 tarsal claws; labium and sternum separate; eyes closely grouped; most

species at least 3 cm or more in length; inhabit silk-lined tubes in ground, with entrances covered by hinged silk lids.

Family Dipluridae (diplurid funnel-web mygalomorphs). No cheliceral rastellum; 3 tarsal claws; 4 to 6 spinnerets, posterior (lateral) pair very long; body hairy; web similar to funnel webs of Agelenidae.

Family Hexathelidae. Arched, glabrous carapace differentiates it from Dipluridae. *Atrax* found in southeastern Australia is venomous.

Family Atypidae (purseweb spiders). No cheliceral rake; 3 tarsal claws; pedipalpal coxae with endites; 6 spinnerets; less than 3 cm long; live in closed silk tubes partly below ground; bite prey through tube and pull it in; found in Europe, North America, Japan, Burma, and Java.

Family Theraphosidae (hairy mygalomorphs, "tarantulas" of North America; monkey spiders of South Africa; bird-eating spiders of Australia). No cheliceral rake; 2 tarsal claws; labium not fused to sternum; large, hairy, nonsocial, nocturnal; some burrow, others inhabit trees; mostly tropical; *Aphonopelma hentzi* in south-central United States; *Theraphosa* of Amazon River Basin up to 9 cm long with 28 cm leg spread; about 800 species.

Suborder Labidognatha (araneomorph spiders)

Chelicerae labidognath (diaxial), attached below carapace; pedipalpal coxae with endites; usually 1 pair of book lungs, sometimes replaced by tracheae; heart with 3, sometimes 2, ostia; 13th through 18th ganglia lost, others fused; 31,000 to 32,000 species.

Family Dysderidae. Respiratory tracheae with 4 spiracles (openings) in 2 pairs, one behind the other.

Family Scytodidae (spitting spiders). Six eyes arranged in 3 groups; high, domed carapace, slopes anteriorly; catch prey with well-aimed squirt of saliva; mostly in tropical and subtropical regions; about 200 species.

Family Loxoscelidae (brown spiders). Six eyes arranged in 3 groups; carapace low; overpower web-entangled prey; *Loxosceles reclusa* (brown recluse) and *Loxosceles laeta* venomous to humans; about 20 other species found in North and South America and Mediterranean region.

Family Sicariidae (6-eyed crab spiders). Large, six eyes, low carapace; legs extended toward sides; burrow in sand in deserts of Southern Hemisphere; about 40 species.

Family Pholcidae (harvestmen). Tarsi of legs with many false articulations; no tracheae; web loose and tangled; *Pholcus* of Europe and America; about 500 species.

Family Uloboridae (uloborids). Cribellum; lack poison glands; 3 tarsal claws; eyes in 3 rows; anal tubercle large; make orb webs; *Hyptiotes*, triangle spiders; about 300 species; worldwide.

Family Deinopidae (ogre-faced spiders). Cribellum; three tarsal claws; eyes in 3 rows; anal tubercle large; *Dinopis*, huge anterior eyes, holds web, throws it over prey; about 60 species, found throughout tropics.

Family Tetragnathidae (long-jawed orb weavers). Males with long chelicerae; epigynum often secondarily lost; worldwide; about 500 to 700 species.

Family Araneidae (orb weavers). Legs with strong setae; chelicerae strong, truncated proximally, with 6 to 8 teeth; colulus always present; paracymbium fused to cymbium of male pedipalp; usually construct orb webs; *Araneus* widespread; *Mastophora*, the bolas spider, probably venomous to humans; many species make no webs; wait for prey to stumble into them; more than 3,000 species; worldwide.

Family Theridiosomatidae (ray spiders). Globular abdomen; high clypeus (area below eyes); chelicerae lack boss; orb webs; about 50 species.

Family Theridiidae (cobweb weavers or comb-footed spiders). Has comb on each 4th leg, used to throw silk over prey (attack wrap); chelicerae pointed on proximal end under carapace, few teeth; male pedipalp with accessory arm (paracymbium) absent or present as a small hook on side of cup-like modification of tarsus (cymbium); no stridulating (sound-producing) structures on side of chelicerae; web irregular; sometimes hunt on ground; *Latrodectus* (widows) poisonous to mammals; more than 2,500 species; worldwide.

Family Linyphiidae (sheet-web weavers and dwarf spiders). Chelicerae with many teeth, blunt on proximal end, often with stridulating file on side; legs with many strong setae; colulus always present; paracymbium a separate sclerite in male pedipalp; about 3,500 species; worldwide.

Family Dictynidae (dictynids). Cribellum; three tarsal claws; tarsi lack trichobothria and brush of setae; small in size; make irregular webs under leaves or in branches of herbs; common in temperate areas; about 500 species.

Family Amaurobiidae (amaurobiids). Cribellum, three tarsal claws without brush of setae; tarsi with dorsal row of trichobothria; resemble Agelenidae; make an irregular funnel web between stones; common; about 350 species; worldwide.

Family Agelenidae (funnel weavers). Eyes in 2 rows; anterior (lateral) spinnerets long; most make funnel web (flat web in vegetation with a tube-shaped retreat at the side); *Argyroneta*, the Eurasian water spider, constructs an air bell beneath surface of slow-moving waters; in its own family but related to agelenids; about 1,000 species; worldwide.

Family Lycosidae (wolf spiders). Eyes in 3 rows; anterior row with 4 eyes; hunting spiders; females carry egg sac attached to spinnerets and carry young on abdomen; may dig tubes in soil; numerous species in the Arctic and on high mountains; true tarantula, *Lycosa tarentula* of southern Europe, probably not poisonous to humans; about 2,500 species throughout world.

Family Ctenidae (wandering spiders). Eyes in 3 rows; median eyes face same direction, form a trapezoid wider behind than in front; eyes of posterior row largest, anterior laterals smallest; 1st 2 legs armed with strong ventral setae; some adults with only 2 tarsal claws; aggressive *Phoneutria fera* of South America venomous to humans; mainly large tropical spiders; about 400 species.

Family Gnaphosidae (gnaphosids). Anterior (lateral) spinnerets cylindrical and separated; posterior median eyes often oval and diagonal; nocturnal hunters; common and widespread; about 2,000 species.

Family Clubionidae (sac spiders). Anterior pair of spinnerets conical and touching; *Cheiracanthium* species may be venomous to humans; common and widespread hunting spiders; about 2,000 species.

Family Oxyopidae (lynx spiders). Eyes arranged in a hexagon; hunt on vegetation, pounce on prey; worldwide; about 500 species.

Family Sparassidae (*Heteropodidae*) (huntsman spiders, tarantulas in Australia). Eyes in 2 rows; legs extended sideways; large, slightly flattened body; found in most tropical regions; about 1,000 species.

Family Thomisidae (crab spiders). May sit on flowers awaiting insects; some change colour; some live on or under bark; many species; common; worldwide; about 3,000 species.

Family Salticidae (jumping spiders). Hunt during daylight hours by stalking and jumping on prey; best vision of all spiders; more than 4,000 species; mostly tropical, but many species also found in northern and Arctic regions; the largest family.

KASTON, *How to Know the Spiders*, 3rd ed. (1978), with keys to identifying North American spiders; HERBERT W. LEVI and LORNA R. LEVI, *A Guide to Spiders and Their Kin* (1968, reprinted with title *Spiders and Their Kin*, 1987), coloured illustrations of spider families; WOLFGANG NENTWIG (ed.), *Ecophysiology of Spiders* (1987), summaries of research by more than 30 specialists; VINCENT D. ROTH, *Spider Genera of North America: With Keys to Families and Genera and a Guide to Literature* (1985); WILLIAM A. SHEAR (ed.), *Spiders—Webs, Behavior, and Evolution* (1986), in which specialists report on the results of recent research; EUGÈNE SIMON, *Histoire Naturelle des Araignées*, 2nd ed., 2 vol. (1892–97), one basis for the classification system used in this article; and PETER N. WITT, CHARLES F. REED, and DAVID B. PEAKALL, *A Spider's Web: Problems in Regulatory Biology* (1968), an excellent introduction to orb-web-building spiders.

(H.W.L./L.R.L.)

Archimedes

Archimedes, the most famous ancient Greek mathematician and inventor, was born c. 290–280 bc in Syracuse, the principal city-state in Sicily. He probably spent some time in Egypt early in his career, but he resided for most of his life in Syracuse, where he was on intimate terms with its king, Hieron II. Archimedes published his works in the form of correspondence with the principal mathematicians of his time, including the Alexandrian scholars Conon of Samos and Eratosthenes of Cyrene. He played an important role in the defense of Syracuse against the siege laid by the Romans in 213 bc by constructing war machines so effective that they long delayed the capture of the city. But Syracuse was eventually captured by the Roman general Marcus Claudius Marcellus in the autumn of 212 or spring of 211 bc, and Archimedes was killed in the sack of the city.

Far more details survive about the life of Archimedes than about any other ancient scientist, but they are largely anecdotal, reflecting the impression that his mechanical genius made on the popular imagination. Thus, he is credited with inventing the Archimedes screw, a device for raising water, and he is supposed to have made two “spheres” that Marcellus took back to Rome—one a star globe and the other a device (the details of which are uncertain) for mechanically representing the motions of the Sun, Moon, and planets. The story that he determined the proportion of gold and silver in a wreath made for Hieron by weighing it in water is probably true, but the version that has him leaping from the bath in which he supposedly got the idea and running naked through the streets shouting “Heurēka!” (“I have found it!”) is popular embellishment. Equally apocryphal are the stories that he used a huge array of mirrors to burn the Roman ships besieging Syracuse; that he said, “Give me a place to stand and I will move the Earth”; and that a Roman soldier killed him because he refused to leave his mathematical diagrams—although all are popular reflections of his real interest in catoptrics (the branch of optics dealing with the reflection of light from mirrors, plane or curved), mechanics, and pure mathematics.

According to Plutarch, Archimedes had so low an opinion of the kind of practical invention at which he excelled and to which he owed his contemporary fame that he left no written work on such subjects. While it is true that—apart from a dubious reference to a treatise, “On Sphere-Making”—all of his known works were of a theoretical character, nevertheless his interest in mechanics deeply influenced his mathematical thinking. Not only did he write works on theoretical mechanics and hydrostatics, but his treatise *Method Concerning Mechanical Theorems* shows that he used mechanical reasoning as a heuristic device for the discovery of new mathematical theorems.

His works. There are nine extant treatises by Archimedes in Greek. The principal results in *On the Sphere and Cylinder* (in two books) are that the surface area of any sphere is four times that of its greatest circle (in modern notation, $S = 4\pi r^2$) and that the volume of a sphere is two-thirds that of the cylinder in which it is inscribed (leading immediately to the formula for the volume, $V = \frac{4}{3}\pi r^3$). Archimedes was proud enough of the latter discovery to leave instructions for his tomb to be marked with a sphere inscribed in a cylinder. Cicero found the tomb, overgrown with vegetation, a century and a half after Archimedes’ death.

Measurement of the Circle is a short work in which π (pi), the ratio of the circumference to the diameter of a circle, is shown to lie between the limits of $3\frac{1}{7}$ and $3\frac{10}{71}$. The approach to this problem devised by Archimedes, which consists of inscribing and circumscribing regular polygons with large numbers of sides, was the one followed by all those who subsequently dealt with the problem of deter-

mining π until the development of series expansions in the late 17th century. This work also contains accurate approximations (expressed as ratios of integers) to the square roots of 3 and several large numbers.

On Conoids and Spheroids deals with determining the volumes of the segments of solids formed by the revolution of a conic section (circle, ellipse, parabola, or hyperbola) about its axis. In modern terms, these are problems of integration. *On Spirals* develops many properties of tangents to the spiral of Archimedes—i.e., the locus of a point moving with uniform speed along a straight line that itself is rotating with uniform speed about a fixed point.

On the Equilibrium of Planes (or *Centres of Gravity of Planes*; in two books) is mainly concerned with establishing the centres of gravity of various rectilinear plane figures and segments of conics. The first book purports to establish the “law of the lever” (magnitudes balance at distances from the fulcrum in inverse ratio to their weights), and it is mainly on the basis of this treatise that Archimedes has been called the founder of theoretical mechanics. Much of this book, however, is undoubtedly not authentic, consisting as it does of inept later additions or reworking, and it seems likely that the basic principle of the law of the lever and—possibly—the concept of centre of gravity were established on a mathematical basis by scholars earlier than Archimedes. His contribution was rather to extend these concepts to conic sections.

Quadrature of the Parabola demonstrates, first by “mechanical” means (as in *Method*, below) and then by conventional geometrical methods, that the area of any segment of a parabola is $\frac{4}{3}$ of the area of the triangle having the same base and height as that segment. This is, again, a problem in integration.

The Sand-Reckoner is a small treatise that is a *jeu d’esprit* written for the layman—it is addressed to Gelon, son of Hieron—that nevertheless contains some profoundly original mathematics. Its object is to remedy the inadequacies of the Greek numerical notation system by showing how to express a huge number—the number of grains of sand that it would take to fill the whole of the universe. What Archimedes does, in effect, is to create a place-value system of notation, with a base of 100,000,000. (This was apparently a completely original idea, since he had no knowledge of the contemporary Babylonian place-value system with base 60.) The work is also of interest because it gives the most detailed surviving description of the heliocentric system of Aristarchus of Samos and because it contains an account of an ingenious procedure that Archimedes used to determine the Sun’s apparent diameter by observation with an instrument.

Method Concerning Mechanical Theorems describes the process of discovery in mathematics. It is the sole surviving work from antiquity and one of the few from any period that deals with this topic. In it Archimedes recounts how he used a “mechanical” method to arrive at some of his key discoveries, including the area of a parabolic segment and the surface area and volume of a sphere. The technique consists of dividing each of two figures, one bounded by straight lines and the other by a curve, into an infinite but equal number of infinitesimally thin strips, then “weighing” each corresponding pair of these strips against each other on a notional balance, and summing them to find the ratio of the two whole figures. Archimedes emphasizes that, though useful as a heuristic method, this procedure does not constitute a rigorous proof.

On Floating Bodies (in two books) survives only partly in Greek, the rest in medieval Latin translation from the Greek. It is the first known work in hydrostatics, of which Archimedes is recognized as the founder. Its purpose is to determine the positions that various solids will assume when floating in a fluid, according to their form and the

The

medes
crew

Extant
works

Archimedes' principle

variation in their specific gravities. In the first book various general principles are established, notably (in Proposition 7) what has come to be known as Archimedes' principle, which is that a solid denser than a fluid will, when immersed in that fluid, be lighter by the weight of the fluid it displaces. The second book is a mathematical tour de force unmatched in antiquity and rarely equalled since. In it Archimedes determines the different positions of stability that a right paraboloid of revolution assumes when floating in a fluid of greater specific gravity, according to geometric and hydrostatic variations.

Archimedes is known, from references of later authors, to have written a number of other works that have not come down to us. Of particular interest are treatises on catoptrics, in which he discussed, among other things, the phenomenon of refraction; on the 13 semiregular (Archimedean) polyhedra (those bodies bounded by regular polygons, not all of the same type, that can be inscribed in a sphere); and the "Cattle Problem" (preserved in a Greek epigram), which poses a problem in indeterminate analysis, with eight unknowns. In addition to these, there survive several works in Arabic translation ascribed to Archimedes but that cannot have been composed by him in their present form, although they may contain "Archimedean" elements. These include a work on inscribing the regular heptagon in a circle; a collection of lemmas (propositions assumed to be true that are used to prove a theorem) and a book, "On Touching Circles," both having to do with elementary plane geometry; and the "Stomachion" (parts of which also survive in Greek), dealing with a square divided into 14 pieces for a game or puzzle.

Archimedes' mathematical proofs and presentation exhibit great boldness and originality of thought on the one hand and extreme rigour on the other, meeting the highest standards of contemporary geometry. While *Method* shows that he arrived at the formulas for the surface area and volume of a sphere by "mechanical" reasoning involving infinitesimals, in his actual proofs of the results in *Sphere and Cylinder* he uses only the rigorous methods of passage to the limit that had been invented by Eudoxus of Cnidus in the 4th century BC. These methods, of which Archimedes was a master, are the standard procedure in all his works on higher geometry that deal with problems of integration. Their mathematical rigour stands in strong contrast to the "proofs" of the first practitioners of integral calculus in the 17th century, when infinitesimals were reintroduced into mathematics. Yet Archimedes' results are no less impressive than theirs. The same freedom from conventional ways of thinking is apparent in the arithmetical field in *Sand-Reckoner*, which shows an understanding of the nature of the numerical system unparalleled before the modern era.

Archimedes as astronomer

In antiquity Archimedes was also known as an outstanding astronomer: his observations of solstices were used by Hipparchus, the foremost ancient astronomer. Very little is known of this side of Archimedes' activity, although *Sand-Reckoner* reveals his keen astronomical interest and practical observational ability. But there has been handed down a set of numbers attributed to him giving the distances of the various heavenly bodies from Earth, which has been shown to be based not on observed astronomical data but on a "Pythagorean" theory associating the spatial intervals between the planets with musical intervals. Surprising though it is to find these metaphysical speculations in the work of a practicing astronomer, there is good reason to believe that their attribution to Archimedes is correct.

His influence. Given the magnitude and originality of Archimedes' achievement, the influence of his mathematics in antiquity was rather small. Those of his results that could be simply expressed—such as the formulas for the surface area and volume of a sphere—became mathematical commonplaces, and one of the bounds he established for π , $22/7$, was adopted as the usual approximation to it in antiquity and the Middle Ages. But his mathematical work was not continued or developed, as far as is known, in any important way in ancient times, despite his hope expressed in *Method* that its publication would enable others to make new discoveries. It was not until some of his mathematical treatises were translated into Arabic in the late 8th or 9th century that attempts were made to extend his results, particularly in the determination of the volumes of solids of revolution. Several meritorious works by Arabic mathematicians of the early medieval period were inspired by their study of Archimedes.

But the greatest effect of his work on that of later mathematicians came in the 16th and 17th centuries with the printing of texts derived from the Greek, and eventually of the Greek text itself, the *editio princeps*, in Basel in 1544. The Latin translation of many of Archimedes' works by Federico Commandino in 1558 contributed greatly to the spread of knowledge of them, which was reflected in the work of the foremost mathematicians and physicists of the time, including Johannes Kepler and Galileo. David Rivault's edition and Latin translation (1615) of the complete works, including the ancient commentaries, was enormously influential in the work of some of the best mathematicians of the 17th century, notably René Descartes and Pierre de Fermat. Without the background of the rediscovered ancient mathematicians, amongst whom Archimedes was paramount, the development of mathematics in Europe in the century between 1550 and 1650 is inconceivable. It is unfortunate that *Method* remained unknown to both Arabic and Renaissance mathematicians (it was only rediscovered in the late 19th century), for they might have fulfilled Archimedes' hope that it would prove of use to his successors in discovering theorems. (G.J.T.)

BIBLIOGRAPHY. The standard edition, in Greek and Latin, of the works of Archimedes, with the ancient commentaries, is that of JOHAN LUDVIG HEIBERG (ed.), *Archimedis Opera Omnia cum Commentariis Eutocii*, 3 vol. (1910–15, reprinted 1972). To the reprint was added *Über einander berührende Kreise* (1975), a translation into German by YVONNE DOLDSAMPLONIUS, HEINRICH HERMELINK and MATTHIAS SCHRAMM of the Arabic text "On Touching Circles." An English translation is THOMAS L. HEATH (ed.), *The Works of Archimedes* (1897), with a supplement, *The Method of Archimedes* (1912; both reprinted in 1 vol., 1953). Unfortunately Heath, by paraphrasing Archimedes' mathematics in modern notation, misrepresents him. For those wishing to get the flavour of the original, a much better translation is the French one by PAUL VER EECHE, *Les Oeuvres complètes d'Archimède* (1921). The best detailed discussion of the contents of Archimedes' work is EDWARD J. DIJKSTERHUIS, *Archimedes* (1956), which also assembles most of the biographical data. Valuable too is the article "Archimedes" by MARSHALL CLAGETT, in the *Dictionary of Scientific Biography*, vol. 1 (1970), particularly for its bibliography and discussion of the influence of Archimedes. On the textual tradition and knowledge of Archimedes in Europe in the Middle Ages and early Renaissance, an indispensable work is MARSHALL CLAGETT (ed.), *Archimedes in the Middle Ages*, 4 vol. in 8 (1964–80). A particularly useful guide to the modern literature is IVO SCHNEIDER, *Archimedes* (1979), in German. The basis of Archimedes' numbers for the planetary distances was explained satisfactorily for the first time by CATHERINE OSBORNE in "Archimedes on the Dimension of the Cosmos," *Isis*, vol. 74, no. 272, pp. 234–242 (June 1983).

The Art of Architecture

Architecture is the art and the technique of building, employed to fulfill the practical and expressive requirements of civilized people. Almost every settled society that possesses the techniques for building produces architecture. It is necessary in all but the simplest cultures; without it, man is confined to a primitive struggle with the elements; with it, he has not only a defense against the natural environment but also the benefits of a human environment, a prerequisite for and a symbol of the development of civilized institutions.

The characteristics that distinguish a work of architecture from other man-made structures are (1) the suitability of the work to use by human beings in general and the adaptability of it to particular human activities; (2) the stability and permanence of the work's construction; and (3) the communication of experience and ideas through its form.

All these conditions must be met in architecture. The second is a constant, while the first and third vary in relative importance according to the social function of buildings. If the function is chiefly utilitarian, as in a factory, communication is of less importance. If the function is chiefly expressive, as in a monumental tomb, utility is a minor concern. In some buildings, such as churches and city halls, utility and communication may be of equal importance.

The present article treats primarily the forms, elements, methods, and theory of architecture. For treatment of the architecture of particular cultures and regions, see, for example, *AFRICAN ARTS*; *ARCHITECTURE, THE HISTORY OF WESTERN*; *EAST ASIAN ARTS*; and *SOUTHEAST ASIAN ARTS*.

For coverage of related topics in the *Macropædia* and *Micropædia*, see the *Propædia*, section 626, and the *Index*.

Use

The types of architecture are established not by architects but by society, according to the needs of its different institutions. Society sets the goals and assigns to the architect the job of finding the means of achieving them. This section of the article is concerned with architectural typology, with the role of society in determining the kinds of architecture, and with planning—the role of the architect in adapting designs to particular uses and to the general physical needs of human beings.

ARCHITECTURAL TYPES

Architecture is created only to fulfill the specifications of an individual or group. Economic law prevents architects from emulating their fellow artists in producing works for which the demand is nonexistent or only potential. So the types of architecture depend upon social formations and may be classified according to the role of the patron in the community. The types that will be discussed here—domestic, religious, governmental, recreational, welfare and educational, and commercial and industrial—represent the simplest classification; a scientific typology of architecture would require a more detailed analysis.

Domestic architecture. Domestic architecture is produced for the social unit: the individual, family, or clan and their dependents, human and animal. It provides shelter and security for the basic physical functions of life and at times also for commercial, industrial, or agricultural activities that involve the family unit rather than the community. The basic requirements of domestic architecture are simple: a place to sleep, prepare food, eat, and perhaps work; a place that has some light and is protected from the weather. A single room with sturdy walls and roof, a door, a window, and a hearth are the necessities; all else is luxury.

"Vernacular" architecture. In much of the world today, even where institutions have been in a continuous process of change, dwelling types of ancient or prehistoric origin are in use. In the industrialized United States, for instance, barns are being built according to a design employed in Europe in the 1st millennium BC. The forces that produce a dynamic evolution of architectural style in communal building are usually inactive in the home and farm. The life of the average person may be unaltered by the most fundamental changes in his institutions. He can be successively a slave, the subject of a monarchy, and a voting citizen, without having the means or the desire to change

The essential components of a domestic building

Palace of Versailles, France, built chiefly by Louis Le Vau and Jules Hardouin-Mansart during the last half of the 17th century.

Aerofilms, Ltd., London

his customs, techniques, or surroundings. Economic pressure is the major factor that causes the average individual to restrict his demands to a level far below that which the technology of his time is capable of maintaining. Frequently he builds new structures with old techniques because experiment and innovation are more costly than repetition. But in wealthy cultures economy permits and customs encourage architecture to provide conveniences such as sanitation, lighting, and heating, as well as separate areas for distinct functions, and these may come to be regarded as necessities. The same causes tend to replace the conservatism of the home with the aspirations of institutional architecture and to emphasize the expressive as well as the utilitarian function.

"Power" architecture. As wealth and expressive functions increase, a special type of domestic building can be distinguished that may be called power architecture. In almost every civilization the pattern of society gives to a few of its members the power to utilize the resources of the community in the construction of their homes, palaces, villas, gardens, and places of recreation. These few, whose advantages usually arise from economic, religious, or class distinctions, are able to enjoy an infinite variety of domestic activities connected with the mores of their position. These can include even communal functions: the palace of the Flavian emperors in ancient Rome incorporated the activities of the state and the judicial system; the palace of Versailles, a whole city in itself, provided the necessities and luxuries of life for several thousand persons of all classes and was the centre of government for the empire of Louis XIV. Power architecture may have a complex expressive function, too, since the symbolizing of power by elegance or display is a responsibility or a necessity (and often a fault) of the powerful. Since this function usually is sought not so much to delight the patron as to demonstrate his social position to others, power architecture becomes communal as well as domestic. In democracies such as ancient Greece and in the 20th-century Western

world, this show of power may be more reserved, but it is still distinguishable.

Group housing. A third type of domestic architecture accommodates the group rather than the unit and is therefore public as well as private. It is familiar through the widespread development of mass housing in the modern world, in which individuals or families find living space either in multiple dwellings or in single units produced in quantity. Group housing is produced by many kinds of cultures: by communal states to equalize living standards, by tyrants to assure a docile labour force, and by feudal or caste systems to bring together members of a class. The apartment house was developed independently by the imperial Romans of antiquity to suit urban conditions and by the American Indians to suit agricultural conditions. Group architecture may be power architecture as well, particularly when land values are too high to permit even the wealthy to build privately, as in the 17th-century Place des Vosges in Paris, where aristocratic mansions were designed uniformly around a square, or in the 18th-century flats in English towns and spas. Although most domestic architecture of the 20th century employs the style and techniques of the past, the exceptions are more numerous and more important for the development of architecture than ever before. This is because the distribution of wealth and power is widespread in parts of the world where architecture is vital and because the modern state has assumed responsibility for much high-quality housing.

Religious architecture. The history of architecture is concerned more with religious buildings than with any other type, because in most past cultures the universal and exalted appeal of religion made the church or temple the most expressive, the most permanent, and the most influential building in any community.

The typology of religious architecture is complex, because no basic requirements such as those that characterize domestic architecture are common to all religions and because the functions of any one religion involve many

Cultures in which group housing has been produced

George Holton—Photo Researchers, Inc.

different kinds of activity, all of which change with the evolution of cultural patterns.

The temple or church. Temples or churches serve as places of worship and as shelters for the images, relics, and holy areas of the cult. In the older religions, the temple was not always designed for communal use. In ancient Egypt and India it was considered the residence of the deity, and entrance into the sanctum was prohibited or reserved for priests; in ancient Greece it contained an accessible cult image, but services were held outside the main facade; and in the ancient Near East and in the Mayan and Aztec architecture of ancient Mexico, where the temple was erected at the summit of pyramidal mounds, only privileged members of the community were allowed to approach. Few existing religions are so exclusive. Beliefs as dissimilar as Christianity, Buddhism, Judaism, and Islam are based on communal participation in rites held inside the temple or church. The buildings have even evolved into similar plans, because of a common requirement that the maximum number of worshippers be able to face the focal point of the service (the mosque's "point" is the wall facing the direction of Mecca, the city of Muhammad's birth and therefore the most sacred of all Islamic religious sites). Consequently, the Muslims were able to adopt the Byzantine church tradition, modern synagogues are often scarcely distinguishable from churches, and early Protestantism absorbed Catholic architecture with only minor revision (elimination of subsidiary chapels and altars, repositories of relics, and some symbolic decoration).

Shelter is not always required for worship. Primitive rites are often practiced outdoors with some monument as a focus, while the altar of Pergamum and the Ara Pacis Augustae (Augustan Altar of Peace) in Rome are evidences of the open-air religious observances of the classical world. The atrium of early Christian architecture and the cloister were isolated areas for prayer.

The complex programs of later religions made the place of worship the focus for varied activities demanding architectural solutions; for example, the baptistery, bell towers, and chapter houses of Christian architecture, the minarets of the Muslims, and the holy gates of Buddhism. Most modern sects demand space for religious education ad-

joining the community church or temple. Catholicism and the religions of Asia have produced monasteries, convents, and abbeys—connected to places of worship—that accommodate the organized practice of religion, adding domestic and often industrial, agricultural, and scholarly functions to the religious.

Shrines and memoria. Shrines consecrate a holy place for its miraculous character or for its association with the life of the founder, gods, or saints of a cult. Since the importance of such structures is usually proportionate to the antiquity of their tradition and associations with cult origins, they have had little importance in later architectural history. The major commemorative buildings of Christianity are those connected with the life of Jesus Christ (Church of the Nativity in Bethlehem) and the apostles or early Church Fathers (St. Peter's in Rome) or with the medieval cult of relics (Santiago de Compostela in Spain). No single formal design characterizes this type, but the theme of the domed or central-plan structure (round, square, polygon, Greek cross, etc.) connects the *memoria* of Asia (the Indian stupa, Chinese pagoda), pagan antiquity (the Pantheon in Rome), and Christianity (the Church of the Holy Sepulchre in Jerusalem). The significance of the form is discussed below under *Content*.

Funerary art. Expressing man's relationship to the afterlife, funerary art is not always architectural, since it may be purely symbolic and therefore suitable to sculptural treatment, as in the classic Greek, medieval, and modern tomb. Funerary architecture is produced by societies whose belief in the afterlife is materialistic and by individuals who want to perpetuate and symbolize their temporal importance. Monumental tombs have been produced in ancient Egypt (pyramids), Hellenistic Greece (tomb of Mausolus at Halicarnassus, which is the source of the word mausoleum), ancient Rome (tomb of Hadrian), Renaissance Europe (Michelangelo's Medici Chapel, Florence), and Asia (Taj Mahal, Agra, Uttar Pradesh, India). Modern tomb design has lost vitality, though it remains as elaborate (Monument to Victor Emmanuel II, Rome) or as meaningful in terms of power (Lenin Mausoleum, Moscow) as before. The exceptional examples are partly sculptural in character (e.g., Louis Sullivan's Wainwright

Tomb, St. Louis, Missouri; Walter Gropius' war memorial, Weimar, Germany).

Since the 18th century much of religious architecture has lost individuality and importance through the weakening of liturgical traditions. But today, as in the past, outstanding architects have met new demands of use and expression with superior solutions.

Governmental architecture. The basic functions of government, to an even greater extent than those of religion, are similar in all societies: administration, legislation, and the dispensing of justice. But the architectural needs differ according to the nature of the relationship between the governing and the governed. Where governmental functions are centralized in the hands of a single individual, they are simple and may be exercised in the ruler's residence; where the functions are shared by many and established as specialized activities, they become complex and demand distinct structures. There are, however, no basic formal solutions for governmental architecture, since the practical needs of government may be met in any sheltered area that has convenient space for deliberation and administration. A distinct type is created rather by expressive functions arising from the ideology of the different systems of political organization (monarchy, theocracy, democracy, etc.) and from the traditions of the various offices of government (law courts, assembly houses, city halls, etc.). Governments that exercise power by force rather than by consent tend to employ the expressive functions of architecture to emphasize their power; they tend to produce buildings of a monumentality disproportionate to their service to the community. Those in which the ruler is given divine attributes bring religious symbolism into architecture. Democratic governments have the responsibility of expressing in their architecture the aims of the community itself, a difficult task in the modern world, when the community may be neither small enough to express itself easily nor homogeneous enough to agree on how to do so.

The simple democratic processes of the Greek city-states and the medieval free towns produced governmental architecture on a domestic scale, while the Roman Empire and later monarchies seldom made important distinctions between the palace and the seat of state functions. The

widespread growth of representative government and the increase in the size and functions of the state in the 19th century created a great variety of buildings, some for entirely new uses. Some examples are: first, capitols, court-houses, parliament buildings, printing offices, and mints and, later, post offices, embassies, archives, secretariats, and even laboratories, when the work, the increased personnel, and the complexity of mechanical aids demanded specialized architectural solutions. Bureaucracy, for better or for worse, has made governmental architecture more important than at any time in history.

In the first rapid expansion from about 1780 to 1840, Neoclassical architects found impressive solutions to the new problems, but afterward governmental architecture lapsed into a century of conservatism, following at a safe distance behind private building. After World War II, governmental architecture showed new vitality. Outstanding are Le Corbusier's work at Chandigarh, Punjab, India, the United Nations Educational, Scientific and Cultural Organization headquarters in Paris, and the program of the U.S. Department of State for building American embassies.

Military architecture is closer to the governmental type than to others, but its expressive function is so much subordinated to the practical that it is usually regarded as a class of engineering (see WAR, TECHNOLOGY OF: *Fortifications*).

Recreational architecture. Few recreations require architecture until they become institutionalized and must provide for both active and passive participation (athletic events, dramatic, musical performances, etc.) or for communal participation in essentially private luxuries (baths, museums, libraries). Throughout history, recreational architecture has been the most consistent in form of any type. Diversions may change, but, as in domestic architecture, the physical makeup of the human being provides consistency. If his participation is passive he must be able to hear and to see in comfort. If his participation is active, he must be given spaces suited to the chosen activity. In most cultures, recreational institutions have their origins in religious rites, but they easily gain independence, and religious expression is reduced or eliminated in their architecture.

Theatres. Theatres originated in ancient Greece with the rites of the god Dionysus, first as temporary installations and later as outdoor architecture using the natural slope and curves of hillsides to bring the spectator close to the stage and to avoid the need for substructures. The Greek theatre was monumentalized and modified by the Romans, whose arches and vaults allowed construction of sloping seats from level foundations. In the Middle Ages churches and temporary structures were used for dramatic purposes, and in the Renaissance the form of the Roman theatre was occasionally revived (Andrea Palladio's Teatro Olimpico in Vicenza, Italy). The 17th-century development of opera, drama, and ballet in Europe brought about a revival of theatre building but in a new form conceived to satisfy class and economic distinctions (e.g., the Teatro Farnese in Parma, Italy; Residenztheater, in Munich). A flat or inclined pit accommodated standing patrons, tiers of boxes rose vertically above in a horseshoe plan, and permanent covering (for both acoustics and comfort) made artificial lighting an important feature in theatrical performances. While the modern theatre has been greatly improved in efficiency by new acoustical methods and materials, it also has kept much of the Baroque form. However, it provides seating throughout and usually substitutes sloping galleries (into which the unprivileged have been moved) for boxes. The motion picture has had little effect on theatre design (see THEATRICAL PRODUCTION).

Auditoriums. The auditorium is distinguished by the absence of stage machinery and by its greater size. The development of large symphony orchestras and choirs and of the institution of lectures and mass meetings combined with growing urban populations to produce this modification of the theatre.

Athletic facilities. Sport arenas, racetracks, and public swimming pools of the present day owe their origin to the ancient Romans (though certain precedents can be found in Crete and Greece). Although the classical tradition of

Importance of Roman prototypes

sports was broken from the early Middle Ages to the 19th century, even the design of arenas and tracks has been scarcely altered from the Colosseum and Circus Maximus, though the construction of large grandstands has inspired magnificent designs in reinforced concrete (stadiums at Florence, Helsinki, and the Universidad Nacional Autónoma de México). Sports that have no precedents in antiquity, such as baseball, have required modifications in design but have not been important for architecture.

Museums and libraries. Museum and library architecture was also an innovation of classical antiquity (library architecture appears independently in ancient China and Japan). Early examples are found on the acropolis of Hellenistic Pergamum and in Roman Ephesus. Museums were not cultivated in the Middle Ages, and libraries were incorporated into monasteries. In the Renaissance and Baroque periods, library construction like Johann Bernhard Fischer von Erlach's Hofbibliothek in the Hofburg, Vienna, was rare, but important civic buildings were designed within religious institutions (Michelangelo's Biblioteca Laurenziana in Florence) and universities (Sir Christopher Wren's Trinity College Library, Cambridge; James Gibbs' Radcliffe Camera, Oxford). This type of architecture became truly communal for the first time in the 19th century, when the size of library collections and the number of visitors inspired some of the finest architecture of the modern period (Michael Gottlieb Bindesbøll's Thorvaldsen Museum, Copenhagen; Sir Robert Smirke's British Museum in London; Henri Labrousse's Bibliothèque Sainte-Geneviève in Paris; Alvar Aalto's library in Viipuri, Finland; Frank Lloyd Wright's Solomon R. Guggenheim Museum in New York City). (See MUSEUMS; LIBRARIES AND LIBRARY SCIENCE.)

Architecture of welfare and education. The principal institutions of public welfare are those that provide facilities for education, health, public security, and utilities. Some

of these functions are performed by the church and the state, but, since their character is not essentially religious or political, they may require independent architectural solutions, particularly in urban environments. A consistent typology of this architecture, however, cannot be established throughout history, because the acceptance of responsibility for the welfare of the community differs in degree in every social system.

Buildings for the specific purposes of public welfare were seldom considered necessary in antiquity, in most of Eastern architecture, or in the early Middle Ages. But in ancient Greece health facilities were included in precincts of Asclepius, the god of healing, and in the East within Buddhist precincts. The Romans produced a highly developed system of water supply and sewerage, of which their monumental aqueducts are an impressive survival.

In the later Middle Ages consistent forms began to emerge. With the separation of the university from a purely religious context, a concept of planning developed (particularly at Oxford, Cambridge, and Paris) that still influences educational architecture. Hospitals designed as large halls were established as adjuncts to churches, convents, and monasteries (Hôtel-Dieu, Beaune, France) and gained architectural independence in the Renaissance (Ospedale degli Innocenti, Florence). Ancient and medieval prisons and guardhouses were occasionally isolated from military architecture (e.g., Tower of London; Bargello in Florence), but the prison did not become an important architectural type until the late 18th and 19th centuries (e.g., George Dance's Newgate Prison, London; Henry Hobson Richardson's Allegheny County Jail, Pittsburgh).

The expansion of education and health facilities beginning in the 19th century created a widespread and consistently growing need for specialized architectural solutions. Schools, from the nursery to the university, now demand not only particular solutions at all levels but structures for a variety of purposes within each level; advanced education demands buildings for scientific research, training for trades and professions, recreation, health, housing, religious institutions, and other purposes. Most of the countries of the Western world have produced educational architecture of the highest quality; this architectural type is more important than in any past age.

Commercial and industrial architecture. Buildings for exchange, transportation, communication, manufacturing, and power production meet the principal needs of commerce and industry. In the past these needs were mostly unspecialized. They were met either within domestic architecture or in buildings distinguished from domestic types chiefly by their size. Stores, banks, hostels, guildhalls, and factories required only space for more persons and things than houses could accommodate. Bridges, warehouses, and other structures not used for sheltering people were, of course, specialized from the beginning and survived the Industrial Revolution without basic changes. The Industrial Revolution profoundly affected the typology as well as the techniques of architecture. Through the introduction of the machine and mass production, economic life moved out of the domestic environment into an area dominated by devices and processes rather than by individuals, creating the need for buildings more specialized and more numerous than the total accumulation of types throughout history. All the types cannot be discussed here, but a categorical listing into which they can be fitted will illustrate their importance for architecture: exchange (office buildings, stores, markets, banks, exchanges, warehouses, exhibition halls); transportation (roads, bridges, tunnels; stations for rail, sea, and air transport and the dispensing of fuel; garages, hangars, and other storage facilities; hotels); communication (structures for the transmission and reception of telephone, telegraph, radio, television, and radar communication; for the printing and distribution of newspapers, magazines, books, and other reading matter; for motion-picture production; and for advertising functions); production (mines, factories, laboratories, food-processing plants); power (dams, generating plants; fuel storage, processing, and distribution installations). (See PUBLIC WORKS.)

Each of these functions demands its own architectural

Specialized solutions demanded since the 19th century

Effect of the Industrial Revolution

machine-
centred
buildings

solution, but in general they may be divided into two classes according to whether the plan must give greater attention to the size and movement of machinery or of persons. Wherever human activity is the chief concern, there has been less departure from traditional expression; banks in the form of Roman temples are an obvious example. The demands of machines have no tradition and have encouraged a search for greater, simpler, and more flexible spaces; but frequently the practical function has entirely eliminated the expressive, so that with some distinguished exceptions (*e.g.*, Frank Lloyd Wright's S.C. Johnson & Sons, Inc., building, Racine, Wisconsin; Eero Saarinen's General Motors Technical Center, Warren, Michigan), most modern factories are not architecture. Where both men and machines must be given equal attention, as in railroad stations, architecture of the 19th and 20th centuries has vacillated between creating new forms and grasping for irrelevant traditions.

ARCHITECTURAL PLANNING

The architect usually begins to work when the site and the type and cost of a building have been determined.

The site involves the varying behaviour of the natural environment that must be adjusted to the unvarying physical needs of human beings; the type is the generalized form established by society that must be adjusted to the special use for which the building is required; the cost implies the economics of land, labour, and materials that must be adjusted to suit a particular sum.

Thus, planning is the process of particularizing and, ultimately, of harmonizing the demands of environment, use, and economy. This process has a cultural as well as a utilitarian value, for in creating a plan for any social activity the architect inevitably influences the way in which that activity is performed.

Planning the environment. The natural environment is at once a hindrance and a help, and the architect seeks both to invite its aid and to repel its attacks. To make buildings habitable and comfortable, he must control the effects of heat, cold, light, air, moisture, and dryness and foresee destructive potentialities such as fire, earthquake, flood, and disease.

The methods of controlling the environment considered here are only the practical aspects of planning. They are treated by the architect within the context of the expressive aspects. The placement and form of buildings in relation to their sites, the distribution of spaces within buildings, and other planning devices discussed below are fundamental elements in the aesthetics of architecture.

Orientation. The arrangement of the axes of buildings and their parts is a device for controlling the effects of sun, wind, and rainfall. The sun is regular in its course; it favours the southern and neglects the northern exposures of buildings in the Northern Hemisphere, so that it may be captured for heat or evaded for coolness by turning the axis of a plan toward or away from it. Within buildings, the axis and placement of each space determines the amount of sun it receives. Orientation may control air for circulation and reduce the disadvantages of wind, rain, and snow, since in most climates the prevailing currents can be foreseen. The characteristics of the immediate environment also influence orientation: trees, land formations, and other buildings create shade and reduce or intensify wind, while bodies of water produce moisture and reflect the sun.

Architectural forms. Planning may control the environment by the design of architectural forms that may modify the effects of natural forces. For example, overhanging eaves, moldings, projections, courts, and porches give shade and protection from rain. Roofs are designed to shed snow and to drain or preserve water. Walls control the amount of heat lost to the exterior or retained in the interior by their thickness and by the structural and insulating materials used in making them. Walls, when properly sealed and protected, are the chief defense against wind and moisture. Windows are the principal means of controlling natural light; its amount, distribution, intensity, direction, and quality are conditioned by their number, size, shape, and placement and by the characteristics

of translucent materials (*e.g.*, thickness, transparency, texture, colour). But the planning of fenestration is influenced by other factors, such as ventilation and heating. Since most translucent materials conduct heat more readily than the average wall, windows are used sparingly in extreme climates. Finally, since transparent windows are the medium of visual contact between the interior and exterior, their design is conditioned by aesthetic and practical demands.

Colour. Colour has a practical planning function as well as an expressive quality because of the range of its reflection and its absorption of solar rays. Since light colours reflect heat and dark colours absorb it, the choice of materials and pigments is an effective tool of environmental control.

Materials and techniques. The choice of materials is conditioned by their own ability to withstand the environment as well as by properties that make them useful to human beings. One of the architect's jobs is to find a successful solution to both conditions; to balance the physical and economic advantages of wood against the possibility of fire, termites, and mold, the weather resistance of glass and light metals against their high thermal conductivity, and many similar conflicts. The more violent natural manifestations, such as heavy snow loads, earthquakes, high winds, and tornadoes, are controlled by special technical devices in regions where they are prevalent.

Any number of these controls may be out of reach of the planner for various reasons. The urban environment, for example, restricts freedom of orientation and design of architectural forms and creates new control problems of its own: smoke, dirt, noise, and odours.

Interior control. The control of the environment through the design of the plan and the outer shell of a building cannot be complete, since extremes of heat and cold, light, and sounds penetrate into the interior, where they can be further modified by the planning of spaces and by special conditioning devices.

Temperature, light and sound are all subject to control by the size and shape of interior spaces, the way in which the spaces are connected, and the materials employed for floors, walls, ceilings, and furnishings. Hot air may be retained or released by the adjustment of ceiling heights and sources of ventilation. Light reflects in relation to the colour and texture of surfaces and may be reduced by dark, rough walls and increased by light, smooth ones. Sounds are transmitted by some materials and absorbed by others and may be controlled by the form of interiors and by the use of structural or applied materials that by their density, thickness, and texture amplify or restrict sound waves.

Conditioning devices played only a small part in architecture before the introduction of mechanical and electrical systems in the 19th century. The fireplace was almost the only method of temperature control (though the ancient Romans anticipated the modern water system for radiant heating); fuel lamps and candles had to be movable and were rather in the sphere of furnishings than of architecture; the same is true of the tapestries and hangings used for acoustical purposes and to block drafts.

Today, heating, insulation, air conditioning, lighting, and acoustical methods have become basic parts of the architectural program. These defenses and comforts of industrialization control the environment so efficiently that the contemporary architect is free to use or to discard many of the traditional approaches to site and interior planning.

Planning for use. While environmental planning produces comfort for the senses (sight, feeling, hearing) and reflexes (respiration), planning for use or function is concerned with convenience of movement and rest. All activities that demand architectural attention require unique planning solutions to facilitate them. These solutions are found by differentiating spaces for distinct functions, by providing circulation among these spaces, and by designing them to facilitate the actions of the human body.

Differentiation. The number of functions requiring distinct kinds of space within a building depends not only upon the type of building but also upon the requirements of the culture and the habits and activities of the indi-

determin-
ing a
building's
axis

The role of
fenestration

Early
temper-
ature
condition-
ing devices

vidual patrons. A primitive house has a single room with a hearth area, and a modern one has separate areas for cooking, eating, sleeping, washing, storage, and recreation. A meetinghouse with a single hall is sufficient for Quaker religious services, while a Roman Catholic cathedral may require a nave, aisles, choir, apse, chapels, crypt, sacristy, and ambulatory.

The planning of differentiated spaces involves as a guide to their design (placement, size, shape, environmental conditions, sequence, etc.) the analysis of use (number of uses and character, duration, time of day, frequency, variability, etc., of each), users (number, behaviour, age, sex, physical condition, etc.), and furniture or equipment required.

Circulation. Communication among differentiated spaces and between the exterior and the interior may be achieved by openings alone in the simplest plans, but most buildings require distinct spaces allotted to horizontal and vertical circulation (corridors, lobbies, stairs, ramps, elevators, etc.). These are designed by the procedure of analysis employed for differentiating uses. Since their function is usually limited to simplifying the movement of persons and things toward a particular goal, their efficiency depends on making the goal evident and the movement direct and easy to execute.

Facilitation. The convenience of movement, like the comfort of environment, can be increased both by planning and by devices. Planning methods are based on analysis of the body measurements, movements, and muscular power of human beings of different ages and sexes, which results in the establishment of standards for the measurements of ceilings, doorways, windows, storage shelves, working surfaces, steps, and the like and for the weight of architectural elements that must be moved, such as doors, gates, and windows. These standards also include allowances for the movement of whatever furnishings, equipment, or machinery are required for the use of any building. Devices for facilitating movement within buildings replace or simplify the labours of daily life: the

Thomas Airviews

Rockefeller Center, New York, by Reinhard & Hofmeister, Corbett, Harrison & MacMurray, and Hood & Foulhoux, 1929–40; an example of urban planning using skyscrapers.

traditional pumps, plumbing, and sewerage systems and the innumerable modern machines for circulation, food preparation and preservation, industrial processing, and other purposes.

Economic planning. Major expenses in building are for land, materials, and labour. In each case they are high when the commodity is scarce and low when it is abundant, and they influence planning more directly when they become restrictive.

The effect of high land values is to limit the amount of space occupied by any building as well as the amount of expenditure that can be reserved for construction. When land coverage is limited, it is usually necessary to design in height the space that otherwise would be planned in breadth and depth, as in the ancient Roman *insula* (apartment houses) or the modern skyscraper. When the choice of materials is influenced by cost, all phases of architectural design are affected, since the planning procedure, the technique, and the form of buildings are dependent on materials. High labour costs influence the choice of techniques and, consequently, of materials. They encourage simplification in construction and the replacement of craftsmanship by standardization. The development in the 19th and 20th centuries of light wood-frame construction and methods of prefabrication were largely the result of the rising cost of labour.

Planning involves not only the control of cost in each area but also the proportioning of expenditures among land, materials, and labour in order to produce the most effective solution to an architectural problem.

Techniques

The techniques of architecture in the sense that they will be considered here are simply the methods by which structures are formed from particular materials. These methods are influenced not only by the availability and character of materials but also by the total technological development of society, for architecture depends on an organized labour force and upon the existence of the tools and skills necessary to secure, manufacture, transport, and work durable materials.

The evolution of techniques is conditioned by two forces. One is economic—the search for a maximum of stability and durability in building with a minimum of materials and labour. The other is expressive—the desire to produce meaningful form. Techniques evolve rapidly when economic requirements suggest new expressive forms or when the conception of new forms demands new procedures. But they remain static when architects avoid the risk of pioneering with untried and possibly unsuccessful methods and depend instead on proved procedures or when the need for the observance of tradition, for the communication of ideas, or for elegance and display is best fulfilled by familiar forms.

The ultimate purpose of building techniques is to create a stable structure. In mechanical terms, structures are stable when all their parts are in a state of equilibrium, or rest. Walls and roofs can buckle, crack, or collapse if they are not properly designed. These movements are caused by forces that tend to push or pull bodies in a given direction. Forces acting on any member (part) of a building are, first, its own weight and, second, the loads it carries, principally from other members but also from persons, furnishings, wind, etc. Their action encounters a reaction in opposing forces that hold the member in place by resisting at its joints. These forces may be active in all directions, and they must be balanced for stability. They tend to crush, pull apart, and bend the member—in other words, to change its size and shape.

Within the member itself there are forces, too, that tend to resist any deformation. They are called stresses, and they vary according to the strength of materials and the form of the member. The kinds of stress under consideration are compression, which resists crushing; tension, which resists pulling apart; and bending, which occurs when one part of a member is in compression and the other is in tension. A column is put into compression by the loads it carries; in a trussed roof the piece that forms the base

Cost of land, materials, and labour as planning factors

The influence of economic and expressive forces in the development of technique

of the triangle is put into tension by the outward-pushing forces in the sides; and a lintel or beam (the member that spans a space) is put into bending by loads and forces that push down on its top and encounter a reacting force at its ends. Some materials are strong only in compression (*e.g.*, stone, brick, cast iron, concrete) and others in tension as well (*e.g.*, wood, steel, reinforced concrete), so the latter are more efficient in resisting bending forces.

Finally, the stability of the total structure whose single members are all in equilibrium is achieved by diverting the loads from all of them downward so that they may be resisted by the upward-supporting forces of the ground.

Techniques will be discussed in terms of the characteristics of building materials and the methods by which they are used in architecture (see BUILDING CONSTRUCTION).

MATERIALS

Stone. In most areas where stone is available, it has been favoured over other materials for the construction of monumental architecture. Its advantages are durability, adaptability to sculptural treatment, and the fact that it can be used in modest structures in its natural state. But it is difficult to quarry, transport, and cut, and its weakness in tension limits its use for beams, lintels, and floor supports.

The simplest and cheapest stonework is rubble; *i.e.*, roughly broken stones of any shape bounded in mortar. The strongest and most suitable stonework for monumental architecture is ashlar masonry, which consists of regularly cut blocks (usually rectangular). Because of its weight and the precision with which it can be shaped, stone masonry (in contrast with brick) does not depend on strong bonding for stability where it supports only direct downward loads. The entablatures (the upper sections of a classical order that rest on the capital of a column) of an ancient Greek temple, for example, were bonded by small bronze dowels. But the weight creates problems of stability when loads push at an angle; stone vaults and arches require more support and buttressing than equivalent forms in other materials.

The best stone (and brick) bonding is that in which blocks are placed so that the vertical joints in one course are not above the joints in the courses above and below, since the stone resists deformation better than any bonding material. Many stones are strong enough to provide monolithic supports (columns and piers) and beams (lintels); and in some styles stone slabs are employed even for roofing (ancient Egyptian temples, early Christian basilicas in Syria). But this roofing requires so many columns that unvaulted masonry buildings are almost always combined with floors and covering in wood. Stone has been consistently used for building since the Stone Age, as exemplified by Stonehenge, in England. Although it has generally been replaced as a structural material by cheaper and more efficient manufactured products, it is still widely used as a surface veneer for its practical and expressive qualities.

Brick. Brick compares favourably with stone as a structural material for its fire- and weather-resisting qualities and for the ease of production, transportation, and laying. The size of bricks is limited by the need for efficient drying, firing, and handling, but shapes, along with the techniques of bricklaying, have varied widely throughout history. Special shapes can be produced by molding to meet particular structural or expressive requirements (for example, wedge-shaped bricks are sometimes employed in arch construction and bricks with rounded faces in columns). Bricks may be used in construction only in conjunction with mortar, since the unit is too small, too light, and too irregular to be stabilized by weight. Each course must be laid on an ample mortar bed with mortar filling the vertical joints. The commonest ancient Roman bricks were cut into triangles and laid with the base out and the apex set into a concrete filling that provided additional strength. Rectangular bricks are bonded either as headers (short side out) or stretchers (long side out). Standard modern types provide a ratio of width to length of slightly less than 1:2 to permit a wide variety of bonding patterns within a consistent module, or standard of measurement. Brick, which has been used since the 4th millennium BC,

was the chief building material in the ancient Near East. The versatility of the medium was expanded in ancient Rome by improvements in the manufacture of both bricks and mortar and by new techniques of laying and bonding. Employed throughout the Middle Ages, brick gained greater popularity from the 16th century on, particularly in northern Europe. It is widely used in the 20th century, often for nonbearing walls in steel frame construction.

Wood. Wood is easier to acquire, transport, and work than other natural materials. All parts of a building can be efficiently constructed of wood except foundations; its disadvantage is susceptibility to fire, mold, and termites. The strength of wood in both tension and compression arises from its organic nature, which gives it an internal structure of longitudinal and radial fibres that is not impaired by cutting or long exposure. But like all organisms it contains moisture and is not uniformly strong, so it must be carefully selected and seasoned to prevent warping, splitting, and failure under loads. Wood is used in building both solid and skeletal structures. The principal solid system, called log construction, is employed when only primitive cutting tools are available. Four walls must be built up together in horizontal layers of single hewn or uncut logs and jointed at the corners. The stability of the log building depends entirely on the mutual support of the walls, and the method is suitable only for simple structures of limited size. The skeletal system requires precise cutting and shaping of lumber. It provides a rigid framework of jointed or nailed members independent of the walls, which are attached to the exterior and interior surfaces after completion.

Almost all masonry buildings of the past had wood floors and coverings, since wood is the lightest, the most practical, and the most inexpensive material for spanning spaces.

The monumental architecture of the West has typically employed materials rarer than wood for expressive purposes, but the history of wood construction can be traced consistently in China, Korea, and Japan and in the domestic architecture of northern Europe and North America. Wood continues to be used in a growing number of techniques and products: heavy framing systems with compound beams and girders, interior and exterior facing with plywood and other composite panels, and arch and truss systems with laminated members that can be designed to meet particular structural demands (see FORESTRY AND WOOD PRODUCTION).

Iron and steel. The development of construction methods in iron and steel was the most important innovation in architecture since ancient times. These methods provide far stronger and taller structures with less expenditure of material than stone, brick, or wood and can produce greater unsupported spans over openings and interior or exterior spaces. The evolution of steel frame construction in the 20th century entirely changed the concept of the wall and the support.

In architecture before 1800, metals played an auxiliary role. They were used for bonding masonry (dowels and clamps), for tension members (chains strengthening domes, tie rods across arches to reinforce the vaults), and for roofing, doors, windows, and decoration. Cast iron, the first metal that could be substituted for traditional structural materials, was used in bridge building as early as 1779. Its ability to bear loads and to be produced in an endless variety of forms, in addition to its resistance to fire and corrosion, quickly encouraged architectural adaptations, first as columns and arches and afterward in skeletal structures. Because cast iron has much more compressive than tensile strength (for example, it works better as a small column than as a beam), it was largely replaced in the late 19th century by steel, which is more uniformly strong, elastic, and workable, and its high resistance in all stresses can be closely calculated.

Steel structural members are rolled in a variety of shapes, the commonest of which are plates, angles, I beams, and U-shaped channels. These members may be joined by steel bolts or rivets, and the development of welding in the 20th century made it possible to produce fused joints with less labour and materials. The result is a rigid, continuous structure in which the joint is as firm as the member and

Organic
nature
of wood
structures

Durability
of stone

Advantages
of steel
construction

which distributes stresses between beams and columns. This is a fundamental change in architectural technique, the effect of which cannot yet be estimated.

Normally, steel must be protected against corrosion by surface coverings, but alloys such as stainless steel have been developed for exposed surfaces. Aluminum and other light metal alloys have come to be favoured for exterior construction because of their weather resistance.

Concrete. Concrete is a manufactured mixture of cement and water, with aggregates of sand and stones, which hardens rapidly by chemical combination to a stonelike, water- and fire-resisting solid of great compressive (but low tensile) strength. Because it can be poured into forms while liquid to produce a great variety of structural elements, it provides an economical substitute for traditional materials, and it has the advantages of continuity (absence of joints) and of fusing with other materials.

Concrete was employed in ancient Egypt and was highly developed by the ancient Romans, whose concrete made with volcanic-ash cement (pozzolana) permitted a great expansion of architectural methods, particularly the development of domes and vaults (often reinforced by brick ribbing) to cover large areas, of foundations, and of structures such as bridges and sewerage systems where waterproofing was essential. The technique of manufacture declined in the Middle Ages and was regained in the 18th century, but concrete had only a limited importance for architecture until the invention of reinforced concrete in the 1860s.

Reinforced concrete was developed to add the tensile strength of steel to the compressive strength of mass concrete. The metal is embedded by being set as a mesh into the forms before pouring, and in the hardened material the two act uniformly. The combination is much more versatile than either product; it serves not only for constructing rigid frames but also for foundations, columns, walls, floors, and a limitless variety of coverings, and it does not require the addition of other structural materials. Although the making of forms is a slow and costly process, the technique competes economically with steel frame construction because the mesh, composed of thin, bendable metal rods or metal fabric, employs far less steel, and concrete is itself inexpensive.

The steel reinforcement is employed to take full advantage of the plastic, or sculptural, character of concrete. It can be jointed or bent to unify supporting members with the floors and the coverings they carry. Furthermore, stresses produced in floors, domes, and vaults may be distributed within the slabs themselves to reduce load, and the diminished load may be concentrated at desired points so that the number and size of supports is greatly reduced.

Three 20th-century developments in production are destined to have a radical effect on architecture. The first, concrete-shell construction, permits the erection of vast vaults and domes with a concrete and steel content so reduced that the thickness is comparatively less than that of an eggshell. The second development, precast-concrete construction, employs bricks, slabs, and supports made under optimal factory conditions to increase waterproofing and solidity, to decrease time and cost in erection, and to reduce expansion and contraction. Finally, prestressed concrete provides bearing members into which reinforcement is set under tension to produce a live force to resist a particular load. Since the member acts like a spring, it can carry a greater load than an unstressed member of the same size.

METHODS

Wall. The two types of wall are load bearing, which supports the weight of floors and roofs, and nonbearing, which at most supports its own weight.

Load-bearing wall. The load-bearing wall of masonry is thickened in proportion to the forces it has to resist: its own load, the load of floors, roofs, persons, etc., and the lateral forces of arches, vaults, wind, etc., that may cause it to crack or buckle. Its thickness often can be reduced at the top, because loads accumulate toward the base; in high buildings this is done by interior or exterior setbacks at the floor level of upper stories. Walls that must resist lateral forces are thickened either along the whole length

or at particular points where the force is concentrated. The latter method is called buttressing. Doors and windows weaken the resistance of the wall and divert the forces above them to the parts on either side, which must be thickened in proportion to the width of the opening. In multistory buildings, windows—unless they are very small—must be placed one above the other so as to leave uninterrupted vertical masses of wall between them to transfer loads directly to the ground. The number of openings that can be used depends on the strength of the masonry and the stresses in the wall. Walls in light, wood-framed structures and in reinforced-concrete construction may have a bearing function also. But the nature of the material admits other means of resisting forces than the increase of mass.

The placement of walls is determined by the type of support for floors and roofs. The commonest support is the beam, which must be jointed to walls at both ends; consequently, its maximum permissible length establishes the distance between bearing walls. All floors and coverings are most easily supported on straight, parallel walls except the dome (see below *Dome*).

Nonbearing wall. Excluding the independent garden variety, the nonbearing wall appears only where loads are carried by other members, as in heavy timber and other skeletal structures. Modern steel and reinforced-concrete frames require exterior walls only for shelter and sometimes dispense with them on the ground floor to permit easier access. Since the wall rests or hangs upon members of the frame, it becomes a curtain or screen and admits treatment in any durable, weather-resisting material. Traditional materials are often used, but light walls of glass, plastic, metal alloys, wood products, etc., can be equally efficient. This freedom of choice extends also to the form of walls and offers greatly expanded opportunities for creative expression.

Post-and-lintel. The simplest illustration of load and support in construction is the post-and-lintel system, in which two upright members (posts, columns, piers) hold

up a third member (lintel, beam, girder, rafter) laid horizontally across their top surfaces. This is the basis for the evolution of all openings. But, in its pure form, the post-and-lintel is seen only in colonnades and in framed structures, since the posts of doors, windows, ceilings, and roofs are part of the wall.

The job of the lintel is to bear the loads that rest on it (and its own load) without deforming or breaking. Failure occurs only when the material is too weak or the lintel is too long. Lintels composed of materials that are weak in bending, such as stone, must be short, while lintels in materials that are strong in bending, such as steel, may span far greater openings. Masonry lintels are inefficient because they must depend on the cohesiveness of mortar, which is weaker than the blocks it bonds; so, in masonry construction, lintels of monolithic (single-slab) stone, wood, and stronger materials are employed.

The job of the post is to support the lintel and its loads without crushing or buckling. Failure occurs, as in lintels, from excessive weakness or length, but the difference is that the material must be especially strong in compression. Stone, which has this property, is more versatile as a post than as a lintel; under heavy loads it is superior to wood but not to iron, steel, or reinforced concrete. Masonry posts, including those of brick, may be highly efficient, since the loads compress the joints and add to their cohesiveness. Although monolithic stone columns are used, they are extravagant to produce for large structures, and columns are usually built up of a series of cylindrical blocks called drums.

From prehistoric times to the Roman Empire, the post-and-lintel system was the root of architectural design. The interiors of Egyptian temples and the exteriors of Greek temples are delineated by columns covered by stone lintels. The Greeks opened their interior spaces by substituting wooden beams for stone, since the wood required fewer supports. The development of the arch and vault challenged the system but could not diminish its importance either in masonry construction or in wood framing, by its nature dependent on posts and beams.

Ancient uses of the post-and-lintel were refined but not fundamentally altered until the production of cast-iron columns, which, offering greater strength and smaller circumference, greatly reduced the mass and weight of buildings. Much construction in modern materials is based on the post-and-lintel system of the past. Steel and concrete skeletons restore to modern architecture the formal simplicity of the oldest structures known. But, because they are rigid frames, they abandon the fundamental concept of the duality of post-and-lintel by fusing them into a unit throughout which stresses are distributed. The "mushroom" column is a further departure, since the unit can be extended into a covering slab and becomes a ceiling as well as a support.

Arch. The arch can be called a curved lintel. Early masonry builders could span only narrow openings because of the necessary shortness and weight of monolithic stone lintels. With the invention of the arch, two problems were solved: (1) wide openings could be spanned with small, light blocks, in brick as well as stone, which were easy to transport and to handle; and (2) the arch was bent upward to resist and to conduct into its supports the loads that tended to bend the lintel downward. Because the arch is curved, the upper edge has a greater circumference than the lower, so that each of its blocks must be cut in wedge shapes that press firmly against the whole surface of neighbouring blocks and conduct loads uniformly. This form creates problems of equilibrium that do not exist in

lintels. The stresses in the arch tend to squeeze the blocks outward radially, and loads divert these outward forces downward to exert a resultant diagonal force, called thrust, which will cause the arch to collapse if it is not properly buttressed. So an arch cannot replace a lintel on two free-standing posts unless the posts are massive enough to buttress the thrust and to conduct it into the foundations (as in ancient Roman triumphal arches). Arches may rest on light supports, however, where they occur in a row, because the thrust of one arch counteracts the thrust of its neighbours, and the system will remain stable as long as the arches at either end of the row are buttressed by walls, piers, or earth.

The size of arches is limited only by economy; large arches exert large thrusts, and they are hard to buttress and to build. The form may be varied to meet specific problems; the most efficient forms in masonry are semi-circular, segmental (segment of a circle), and pointed (two intersecting arcs of a circle), but noncircular curves can be used successfully.

Arches were known in Egypt and Greece but were considered unsuitable for monumental architecture. In Roman times the arch was fully exploited in bridges, aqueducts, and large-scale architecture. New forms and uses were found in medieval and particularly Gothic architecture (flying buttress, pointed arch), and Baroque architects developed a vocabulary of noncircular forms for expressive reasons. Steel, concrete, and laminated-wood arches of the 20th century have changed the concept and the mechanics of arches. Their components are completely different from wedge-shaped blocks; they may be made entirely rigid so as to require only vertical support; they may be of hinged intersections that work independently, or they may be thin slabs or members (in reinforced concrete) in which stresses are so distributed that they add the advantages of lintels

to those of arches, requiring only light supports. These innovations provide a great freedom of design and a means of covering great spans without a massive substructure.

Vault. The evolution of the vault begins with the discovery of the arch, because the basic "barrel" form, which appeared first in ancient Egypt and the Near East, is simply a deep, or three-dimensional, arch. Since the barrel vault exerts thrust as the arch does, it must be buttressed along its entire length by heavy walls in which openings must be limited in size and number. This is a disadvantage, since it inhibits light and circulation.

But Roman builders discovered that openings could be made by building two barrel vaults that intersected at right angles to form the groin vault, which is square in plan and may be repeated in series to span rectangular areas of unlimited length. This vault has the additional advantage that its thrusts are concentrated at the four corners, so that the supporting walls need not be uniformly massive but may be buttressed where they support the vault.

Two disadvantages of the groin vault encouraged Gothic builders to develop a modification known as the rib vault. First, to build a groin vault, a form must be made to pour or lay the entire vault, and this requires complex scaffolding from the ground up; second, the groin vault must be more or less square, and a single vault cannot span extended rectangular areas. The rib vault provided a skeleton of arches or ribs along the sides of the area and crossing it diagonally; on these the masonry of the vault could be laid; a simple centring sufficed for the ribs. To cover the rectangular areas, the medieval mason used pointed arches, which, unlike round arches, can be raised as high over a short span as over a long one. Thus, the vault could be composed of the intersection of two vaults of different widths but the same height.

To reduce further the thickness of the wall (to the point

Vaults in antiquity and the Middle Ages

of substituting large areas of glass for masonry), Gothic builders developed the flying buttress, which counteracts vault thrust not by continuous wall mass and weight but by counterthrust created by exterior half-arches placed at the height of the vaults at the points of greatest stress. These buttresses conduct stresses to heavier wall buttresses below the window level.

Modern
methods of
vaulting

The next important development in vaults, as in arches, came with 19th-century materials. Great iron skeleton vaults were constructed as a framework for light materials such as glass (Crystal Palace, London). The elimination of weight and excessive thrust, the freedom in the use of materials, and the absence of centring problems favoured the simple barrel vault and made more complex types obsolete. But in many of the modern frame systems the vault itself loses its structural function and becomes a thin skin laid over a series of arches.

While the arch is supplanting the vault in one area of technique, the vault has abandoned the arch principle in another. The reinforced-concrete shell vault, based on the principle of the bent or molded slab, is one of the most important innovations in the history of architecture. It has all the advantages of load distribution of the concrete floor slab, plus the resistance to bending provided by its curved form. The shell is reinforced in such a way that it exerts no lateral thrust and may be supported as if it were a beam or truss; hence, the form no longer necessitates the conducting of loads into the wall, and the vault may be designed with great freedom.

Dome. Domes appeared first on round huts and tombs in the ancient Near East, India, and the Mediterranean region but only as solid mounds or in techniques adaptable only to the smallest buildings. They became technically significant with the introduction of the large-scale masonry hemispheres by the Romans. Domes, like vaults, evolved from the arch, for in their simplest form they may be thought of as a continuous series of arches, with the same centre. Therefore, the dome exerts thrusts all around its perimeter, and the earliest monumental examples required heavy walls. Since the walls permitted few openings and had to be round or polygonal to give continuous support, early domes were difficult to incorporate into complex structures, especially when adjacent spaces were vaulted.

Develop-
ment of
penden-
tives

Byzantine architects perfected a way of raising domes on piers instead of walls (like groin vaults), which permitted lighting and communication from four directions. The transition from a cubic plan to the hemisphere was achieved by four inverted spherical triangles called pendentives—masses of masonry curved both horizontally and

Interior showing dome on pendentives, Hagia Sophia, Istanbul, by Anthemius of Tralles and Isidore of Miletus, completed 537.

Hirmer Fotoarchiv, Munich

vertically. Their apexes rested on the four piers, to which they conducted the forces of the dome; their sides joined to form arches over openings in four faces of the cube; and their bases met in a complete circle to form the dome foundation. The pendentive dome could rest directly on this foundation or upon a cylindrical wall, called a drum, inserted between the two to increase height.

The dome was unsuited to the lightness and verticality of late-medieval styles but was widely used in the Renaissance and Baroque periods. Renaissance builders adapted the Gothic rib system to dome construction and found

Buckminster Fuller

Climatron, geodesic dome, Missouri Botanical Garden, St. Louis, by R. Buckminster Fuller, opened 1960.

new means to reduce loads and thrust (concentric chains, etc.) that permitted high drums and variations in the curvature of the dome. The awkward, tunnellike effect produced on the interior by high domes was often hidden by an internal shell built on the same foundations (as at Florence Cathedral and St. Paul's Cathedral, London).

The effort and ingenuity devoted to doming rectangular buildings can be explained principally by the symbolic character of the form, since vaulting is a simpler alternative. So it was chiefly the desire to observe tradition that preserved the dome in the early era of iron and steel construction, and, with rare exceptions (Halle aux Blés, Paris; the Coal Exchange, London), 19th-century examples retained masonry forms without exploiting the advantages of metal.

Modern
techniques
of vault
construction

Newer techniques, however, have added practically to the expressive advantages of domes. The reinforced-concrete slab used in vaulting can be curved in length as well as width (like an inflated handkerchief or a parachute). And in this development the distinction between vaults and domes loses significance, being based on nothing but the type of curvature in the slab. Geodesic domes, developed in the 20th century by R. Buckminster Fuller, are spherical forms in which triangular or polygonal facets composed of light skeletal struts or flat planes replace the arch principle and distribute stresses within the structure itself, as in a truss. Geodesic domes can be supported by light walls and are the only large domes that can be set directly on the ground as complete structures.

Truss. By far the commonest covering throughout history is the trussed roof, constructed upon a frame composed of triangular sections spaced crosswise at intervals and made rigid in length by beams. Trusses formerly were principally of wood and were used to cover masonry as well as framed structures, even when these were vaulted. The variety of trusses is so great that only the general principle of the form can be given here.

The truss is based on the geometric law that a triangle is the only figure that cannot be changed in shape without a change in the length of its sides; thus, a triangular frame of strong pieces firmly fastened at the angles cannot be deformed by its own load or by external forces such

as wind pressure. These forces, which in a vault thrust outward against the walls, are contained within the truss itself, because the piece (chord) at the base of the triangle resists by tension the tendency of the two sides to behave like a vault. With its forces in equilibrium, the truss exerts only a direct downward pressure on the walls, so that they need not be thickened or buttressed. This explains why most roofs are triangular in cross section.

In trusses that are too large to be constructed of three members of moderate size, a complex system of small triangles within the frame replaces the simple triangle.

Not all peaked roofs are trusses, for in primitive building, in ancient Greece, and in much Chinese and Japanese wood architecture the chord is omitted and the sides exert thrust. Nor are all trusses triangular, since the principle may be modified (as in modern steel and heavy timber construction) to apply to arches and vaults if chords of sufficient strength can be found.

Framed structures. A framed structure in any material is one that is made stable by a skeleton that is able to stand by itself as a rigid structure without depending on floors or walls to resist deformation. Materials such as wood, steel, and reinforced concrete, which are strong in both tension and compression, make the best members for framing. Masonry skeletons, which cannot be made rigid without walls, are not frames. The heavy timber frame, in which large posts, spaced relatively far apart, support thick floor and roof beams, was the commonest type of construction in eastern Asia and northern Europe from prehistoric times to the mid-19th century. It was supplanted by the American light wood frame (balloon frame), composed of many small and closely spaced members that could be handled easily and assembled quickly by nailing instead of by the slow joinery and dowelling of the past. Construction is similar in the two systems, since they are both based on the post-and-lintel principle. Posts must rest on a level, waterproof foundation, usually composed of masonry or concrete, on which the sill (base member) is attached. Each upper story is laid on crossbeams that are supported on the exterior wall by horizontal members. Interior walls give additional beam support.

The
American
balloon
frame

In the heavy-timber system, the beams are strong enough to allow the upper story and roof to project beyond the plane of the ground-floor posts, increasing the space and weather protection. The members are usually exposed on the exterior. In China, Korea, and Japan, spaces between are enclosed by light screen walls and in northern Europe partly by thinner bracing members and partly by boards, panels, or (in half-timbered construction) bricks or earth.

The light frame, however, is sheathed with vertical or horizontal boarding or shingling, which is jointed or overlapped for weather protection. Sheathing helps to brace as well as to protect the frame, so the frame is not structurally independent as in steel frame construction. The light-frame system has not been significantly improved since its introduction, and it lags behind other modern techniques. Prefabricated panels designed to reduce the growing cost of construction have not been widely adopted. Modern heavy-timber and laminated-wood techniques, however, provide means of building up compound members for trusses and arches that challenge steel construction for certain large-scale projects in areas where wood is plentiful.

Steel framing is based on the same principles but is much simplified by the far greater strength of the material, which provides more rigidity with fewer members. The load-bearing capacity of steel is adequate for buildings many times higher than those made of other materials. Because the column and beam are fused by riveting or welding, stresses are distributed between them, and both can be longer and lighter than in structures in which they work independently as post-and-lintel. Thus, large cubic spaces can be spanned by four columns and four beams, and buildings of almost any size can be produced by joining cubes in height and width. Since structural steel must be protected from corrosion, the skeleton is either covered by curtain walls or surfaced in concrete or, more rarely, painted. The steel frame is used also in single-story buildings where large spans are required. The simple cube then can be abandoned for covering systems employing arches,

trusses, and other elements in a limitless variety of forms in order to suit the functions of the building.

Differences between reinforced-concrete and steel framing are discussed in the section on materials. The greater rigidity and continuity of concrete frames give them more versatility, but steel is favoured for very tall structures for reasons of economy in construction and space. An example is the system called box frame construction, in which each unit is composed of two walls bearing a slab (the

other two walls enclosing the unit are nonbearing curtain walls); this type of construction extends the post-and-lintel principle into three dimensions. Here, again, concrete crosses the barriers that separated traditional methods of construction.

Expression

Expression in architecture is the communication of quality and meaning. The functions and the techniques of building are interpreted and transformed by expression into art, as sounds are made into music and words into literature.

The nature of expression varies with the character of culture in different places and in different times, forming distinct modes or languages of expression that are called styles. Style communicates the outlook of a culture and the concepts of its architects. The boundaries of a style may be national and geographical (*e.g.*, Japanese, Mayan) or religious (*e.g.*, Islamic) and intellectual (*e.g.*, Renaissance), embracing distinct linguistic, racial, and national units, and different expressions within each of these boundaries are produced by the particular style of regions, towns, groups, architects, or craftsmen. The lifespan of styles may be long (ancient Egyptian, over 3,000 years) or short (Baroque, less than 200 years) according to the changeability of cultural patterns. The principal forces in the creation of a style are tradition, the experience of earlier architecture; influence, the contribution of contemporary expressions outside the immediate cultural environment; and innovation, the creative contribution of the culture and the architect. These forces operate to produce an evolution within every style and ultimately to generate new styles that tend to supplant their predecessors.

The components of expression, which communicate the particular values of style, are content and form. Since content can be communicated only through form, the two are organically united, but here they will be discussed separately in order to distinguish the specific and concrete meaning (content) from the abstract expression of qualities (form).

CONTENT

Content is the subject matter of architecture, the element in architectural expression that communicates specific meanings that interpret to society the functions and techniques of buildings.

Symbols of function. Society requires that architecture not only communicate the aspirations of its institutions but also fulfill their practical needs. Differences in expres-

form

sion, apart from differences in planning, distinguish the forms of architectural types (the house from the church, etc.), the kinds of use (the Catholic from the Protestant church), and the traditions and customs of users (the English from the Swiss Protestant church). When architectural forms become the vehicles of content—in plan, elevation, and decoration—they are symbolic. Their symbolism can be understood consciously or unconsciously, by association (e.g., spire = church) to a building one has seen before and by the fact that it suggests certain universal experiences (e.g., vertical forms “rise”; low roofs “envelop”). One comprehends the meaning of symbols that are new, as well as those that are known, by association, because the laws of statics restrain builders from putting them into forms so completely unfamiliar that they do not suggest some tradition, just as the structure of language permits endless new meanings but retains a fairly constant vocabulary. The meaning of architectural symbols—or of words—may even change, but the process must be both logical and gradual, for, if the change is irrational, the purpose—communication—is lost.

The architectural plan, when used symbolically, communicates through its shape. From prehistoric times and in many cultures, the circle, with its suggestion of the planets and other manifestations of nature, gained a symbolic, mystical significance and was used in the plans of houses, tombs, and religious structures. By slow processes it came to be employed for *memoria* and shrines and for hero cults in both the East and the West. When building techniques permitted, its symbolism often merged with that of the dome. In Hindu temples, the square (and the cross plans developed from it) expressed celestial harmony. The central-plan Christian church (circle, polygon, Greek cross, ellipse) fascinated the architects of the Renaissance by its symbolic and traditional values, and it is found in their drawings and treatises to the virtual exclusion of the more practical longitudinal basilicas that the architects were often commissioned to build.

Plan symbolism remained almost exclusively in the sphere of religion after antiquity, and its traditions gradually disappeared in the course of the 19th century. The modern plan is determined by problems of form (space-mass relationships, etc.) and by the practical demands of use rather than by symbolic communication.

Symbolic
forms in
elevation

In elevation the most consistent symbolic forms have been the dome, the tower, the stairway, the portal, and the colonnade. Domes imply the meanings of the circle and more, since a dome is a covering. Long before masonry domes could be built, the hemisphere was associated with the heavens as a “cosmic canopy,” and throughout history domes have been decorated with stars and astrological symbols.

In ancient Rome and among Christians and Indian Buddhists the dome came to mean universal power. During the Renaissance it spread from religious structures to palaces and government buildings, retaining some of its implications of power. In the United States the national capitol is domed and there are few state capitols without domes; the symbol has survived the loss of its original meanings.

The tower, with origins in primitive nature rites, has consistently symbolized power. The Chinese pagoda extends central-plan symbolism into towers; many towers and spires rose from the northern European Gothic cathedral and the medieval Italian city was a forest of towers erected by nobles in constant competition to express their supremacy. This meaning survives in modern skyscrapers; their height is more frequently boasted of than their efficiency or beauty.

Functional
archi-
tectural
elements
as symbols

Architectural elements conceived to facilitate the use of buildings may also take on symbolic significance. The stairway, employed in the past to give “monumentality” to important buildings, frequently became more expressive than convenient, especially in Baroque palaces. Portals, from the time of ancient Egyptian temple pylons and Babylonian city gates, became monuments in themselves, used to communicate a heightened significance to what lay behind them. In the Gothic cathedral they became the richest element of the facade—a translation of biblical doctrine into stone. Since the classic development of the

Baroque staircase, Residenz (1719–44), Würzburg, West Germany, by Balthasar Neumann.

Erich Müller

ancient Greek temple, the colonnade on the exterior of buildings has borne similar implications.

Such symbols have become archaic in modern culture and appear as a sign of resistance to new forms. This resistance is especially evident in the popular symbolism of domestic architecture, where the atmosphere of the home is often expressed by cottage-like roofs, shutters, trellises, mullioned windows, grilles, and other associations with a more peaceful past.

Decoration, the most easily recognized medium of content, communicates meaning either through architectural elements or through the figural arts (sculpture, painting, mosaic, stained glass, etc.). The architectural elements used decoratively, such as the classical orders, usually originate in technique and in time lose their structural significance to become symbols. In Rome and from the Renaissance to the 20th century, the formal Grecian orders were applied to buildings of many different techniques as expressions of the continuing influence of Greek institutions. Similarly, the new vocabulary of Gothic architecture, developed with new building techniques (the pointed arch, the flying buttress, etc.), became in later periods a source for religious and romantic symbolism. The Art Nouveau of the turn of the 20th century, a system of ornament based on floral and other organic forms, survived for only two decades, perhaps because its symbols were neither drawn from a tradition nor derived from a structural system. (The role of architectural ornament will be further treated below).

The function of the figural arts in conveying content is a subject outside the scope of this article, but its importance for architecture must be mentioned. The figural arts not only offer the means of expressing more specific ideas than any architectural symbols, but in many architectural styles they define the character of mass and space. The sculptures of the Hindu temple, the mosaics of the Byzan-

Foto Marburg

tine church, and the stuccoes of Moorish palaces are not ornamental applications; they determine the form of the building itself.

The virtual absence of traditional symbols in modern architecture is evidence of the failure of these symbols to express the cultural patterns of the 20th century. In these times, architecture, like painting, sculpture, and other arts, has tended to be abstract, to emphasize qualities of form rather than the communication of familiar ideas through symbols.

Expression of technique. The second aspect of content is the communication of the structural significance of materials and methods. Its purpose is to interpret the way in which architecture is put together. The characteristics of materials that are important in expressing design techniques are the properties of their composition (e.g., structure, weight, durability) and the way they are used in structure. Their properties may be expressed and interpreted by the treatment of the surface, and their use may be expressed by emphasis on the dimensions and joining of the building units into which they are formed.

The hardness, weight, and crystalline composition of stone masonry traditionally have been emphasized by devices not necessarily connected with structural methods: rustication (finishing in rough, uneven surfaces), drafting (more refined, linear cutting), and polishing. Niches and other indentations, projecting courses, or frames around openings suggest massiveness. In nonbearing walls, a smooth, unbroken surface implies thinness. The use of stone or brick masonry in construction is emphasized by clarifying the limits of each block and by the amount of mortar used and by distinguishing lintels, arches, and other specific members from the construction of the wall. The properties of wood are suggested by revealing and emphasizing its texture in load-bearing members and by treating the sheathing of light wood frames in patterns (of shingling or boarding) that communicate thinness. The plasticity of concrete is shown by freedom in modelling and its use in construction by emphasizing the impressions of the wooden forms in which it is cast. The sections of light metal curtain walls are frequently stamped into geometric patterns to illustrate their nonbearing character. Materials that must be covered for protection, such as unfired brick and the steel used in framing, are not adaptable to this type of communication.

Interpre-
tive
expression
of
structural
method

At times building methods are demonstrated simply by exposing the structure, as in the heavy timber frame, but in many styles the functions of structural systems have been interpreted by designing their members in forms that often are more explanatory than efficient. The Greek column, which is narrower at its summit than at its base, is

diminished by a curve beginning slightly below the mid-point, giving it an effect of an almost muscular power to resist loads. The expression is more explicit in the caryatid, a human figure that replaces the column, and in the burdened animals and dwarfs that support the columns of Romanesque portals. Many elements in the Gothic cathedral serve as diagrams of structure: the supporting piers are clusters of shafts, each of which extends upward without interruption to become the rib of the vault, and the ribs themselves are an elucidation of technique; the flying buttress and the window tracery are elegant interpretations of their functions. In the modern steel-frame building, the hidden forms of the skeleton are often repeated on the facade to enable one to “see through” to the technique, but the system also permits the alternative of expressing the lightness and independence of the curtain wall by sheer surfaces of glass and other materials. The work of the concrete slab is made explicit by projecting indications of the placement of reinforcement or of the distribution of stresses.

The expression of technique is characteristic not of all architectural styles but only of those such as the Gothic and modern, in which new techniques excite a search for the interpretive design of their materials and methods. More often than not, both materials and methods have been disguised by decorative forms or surfacing such as veneers, stucco, or paint, because of emphasis on the expression of content or of form. Most early stone architecture in Egypt, Greece, and India retained as decoration the forms developed in wooden forerunners. The precious marble of Greek temples was disguised under painted stucco; Roman brickwork was hidden by slabs of coloured marble; and 19th-century cast-iron columns were molded into classic or Gothic forms. The history of domes is filled with examples of the successful disguising of method, of giving the ponderous mass the effect of rising from the exterior and of floating from within.

Technical content has been one of the foundation stones of 20th-century architectural theory, particularly in its early phases, and has represented a reaction against 19th-century symbolic content. It is essential for the understanding of modern architecture that the expression of technique be seen as an art—a creative interpretation that heightens awareness of the nature of architecture.

FORM

In the sphere of function and technique, the architect is responsible to the patterns of his culture on one hand and to the patterns of technology on the other; but, in the expression of form, he is free to communicate his own personality and concepts. Not every architect has the

Oswaldo Bohm EB Inc.

gift to exercise this prerogative to the fullest. As in other arts and sciences, a few individuals generate new styles, and others follow, interpreting these styles in original and personal ways. But the majority accepts styles as given and perpetuates them without leaving its mark. The architect's principal responsibility in the formation of style is

to create meaningful form. When form is spoken of in the arts, not only the physical shape, size, and mass of a work are meant but also all the elements that contribute to the work's aesthetic structure and composition. Many of these may be without a fixed form of their own—a rest in music, a line in painting, a space in architecture—and gain significance only as they are organized into the finished product. The basic formal elements of architecture in this sense are space and mass. The process of organizing these elements into an ordered form is called composition, and the principal means by which they are given expressive quality are scale, light, texture, and colour.

Space and mass. Space, that immaterial essence that the painter suggests and the sculptor fills, the architect envelops, creating a wholly human and finite environment within the infinite environment of nature. The concept that space can have a quality other than emptiness is difficult to grasp. When a building is entered, floor, supports, walls, and a ceiling are seen, all of which can be studied and perhaps enjoyed, while the space, in the sense that one is accustomed to think of it, is void: the absence of mass, filled by air.

But spatial experiences that express something are common to everyone, though they are not always consciously grasped. One feels insecure in a low cave or a narrow defile, exhilarated and powerful on a hilltop; these are psychological and motor reactions that result from measuring one's potential for movement against the surrounding spaces, and the same reactions take root even in language ("confining" circumstances and "elevating" experiences are spoken of). An infinite variety of such reactions may be summoned by the architect, because he controls the limits above, below, and on all sides of the observer. As a person enters the architect's space he measures it in terms of the degree and the quality of his potential for movement. The concept of potentiality is important, first, because the observer can anticipate where he may move merely looking about him and, second, because he can conceive movements that he cannot execute. Thus, in the nave of a Gothic cathedral the high walls closely confining the observer on two sides restrict his possible movements, suggesting advance along the free space of the nave toward the altar; or their compression forces him to look upward to the vaults and the light far overhead, there to feel a sense of physical release, though he is earthbound. The experience of Gothic space is called uplifting because it urges one to rise.

Experiencing space

Alinari—Art Resource

St. Peter's, Vatican City, colonnade and piazza designed by Gian Lorenzo Bernini, begun 1656.

Renaissance space, on the other hand, attempts to balance its suggestion of movement, to draw the observer to a focal point at which he can sense an equilibrium of movement in all directions, a resolution of the conflict of compression and release. At this point one feels physically at rest, at the opposite extreme from the elevating sensation of the cathedral.

Of course, one does not use his eyes alone to feel spatial quality, because only the simplest spaces—a cubic room, for example—can be wholly experienced from one standpoint. In a complex of spaces, such as that of the cathedral, the observer walks about, gaining new sensations, seeing new potentials for movement at every step. Most modern architecture, in its free organization of space sequences, demands mobility; its techniques have made it possible to remove the heavy walls and supports of the past, reducing the sense of compression. Walls become membranes to be arranged at will for spatial experience, and some are transparent and so extend one's potential for movement into the limitless out-of-doors.

Spatial experience is not restricted to the interiors of buildings. The sensations one has in nature's open spaces may be re-created by art. City squares and streets, even gardens, achieve a variety of expression comparable with that of interiors. The Baroque piazza of St. Peter's in Rome, which directs the observer along its great embracing arcs toward the entrance, is at least as moving as the church interior.

The exterior of a single building, particularly one that is isolated from other architecture, does not create a space. It occupies the space of nature. Thus, it may be experienced as sculpture, in terms of the play of masses in a void. The aesthetics of masses, like that of spaces, is rooted in one's psychology. When a tall tree or a mountain is called majestic and a rocky cliff menacing, human attributes are being projected. Man inevitably humanizes inert matter and so gives the architect the opportunity to arouse predictable patterns of experience.

Appreciating mass

The appreciation of mass, like that of space, depends on movement, but this movement must be physical. It cannot be experienced in anticipation, because, no matter where one stands to observe even the simplest building, part of it is out of sight. The mass of a complex building is differently composed from every point of view. The 20th-century art critic Sigfried Giedion, emphasizing the need for movement in experiencing modern architecture, suggested that architecture may be four-dimensional,

since time (for movement) is as meaningful as the spatial dimensions.

Some architecture depends much more on mass expression than on space expression. The Egyptian pyramid, the Indian stupa, and the dagoba of Sri Lanka have no meaningful interior spaces; they are architectural in function and technique, sculptural in expression. The interior of a Greek temple is of little interest compared with the wonderful play of forms on its colonnaded exterior, while early Christian and Byzantine architecture reverse the emphasis, making the simple exterior a shell for a splendid and mystical space. Gothic architecture balances the two, partly in order to express a dual content: earthly power over the world outside, spiritual power inside. Modern techniques permit a reduction of the contrast between space and mass expressions by reducing the mass of walls and the size and number of supports and by allowing the interpenetration of interior and exterior space.

Composition. Space and mass are the raw materials of architectural form; from them the architect creates an ordered expression through the process of composition. Composition is the organization of the whole out of its parts—the conception of single elements, the interrelating of these elements, and the relating of them to the total form.

The simplest architectural element is a plane, the flat, two-dimensional surface that limits masses and spaces. The simplest plane is a rectangular one without openings or decoration—the wall of a room, for example. This wall is given quality solely by the proportion of its width to its height. Now a door is put into the wall; the door itself has a certain proportion, and a third element is injected, the relation of two proportions. A window is added, and the composition becomes more complex; then a row of windows, and sequence becomes a factor in addition to the elements of proportion and relation. Sequence again involves the concept of motion; the row of windows is said “to run along” the facade or is “rhythmically” designed.

Finally, this wall may gain rich subtleties of composition within its proportions and rhythms. It can be modelled—into a complex of planes or irregular or curved surfaces—to provide the dimension of depth to its proportions; or symbols of use or of technique can become part of its expressive form.

No architectural planes stand alone, of course; they always intersect other planes. The room wall meets two other walls, the floor, and the ceiling, and a facade wall

Paul Popper Ltd.—Publix

The Ruanveli dagoba at Anurādhapura, Sri Lanka, 2nd century.

meets the ground, the roof, and two other walls. So the total composition of a wall must be harmonized with the composition of other planes in a three-dimensional whole.

systems
of proportions

The means of achieving this harmony differ in every style. Greek architects developed a system of proportions based on the lower diameter of the temple column, from which spatial intervals and the measurement of masses were derived by multiplication and division. Medieval architects first used arithmetical modules based on the measurements of areas in the cathedral plan and, in the Gothic period, changed to a geometric system that employed chiefly the equilateral triangle and the square, figures that had symbolic and mystical values. In Renaissance theory, proportions and harmonies were developed from systems of musical composition, since architects believed that relationships in all the arts depended on an all-pervading celestial harmony. Several modular and proportional systems have been evolved by modern architects (e.g., Le Corbusier's "Modulor"), but none has been widely adopted.

Behind these changing theoretical methods, however, there seems to be a constant human reaction to spatial relationships that distinguishes harmony from cacophony, that makes one bored with a perfectly cubic room or prefer certain rectangular forms to others. This psychological response to form probably is connected to one's mechanisms of balance, movements, and stature—in short, to one's own composition—but the scientific analysis of the process is still at an early stage of development.

"The Interior of the Pantheon," oil painting by Gian Paolo Pannini (1691/92–1765). In the National Gallery of Art, Washington, D.C.

Some buildings have only a single, simple interior space (the Pantheon in Rome) or exterior mass (the pyramids of Egypt) and are not less expressive on this account. But composition carries on into a richer dimension as soon as two or more spaces or masses are organized into the whole. Such a complex composition must give a coordinated form to connecting spaces and masses, each of them

in itself a unique harmony. The observer must be made to feel, in moving through the spaces and around the masses, not only that each is related to the one that precedes and follows it but that each one is contributing to a concept of the whole: a form that is greater than the sum of its parts. In the Gothic cathedral, the nave, the aisles alongside it, the transept that crosses it toward one end, the choir, and apse beyond may each be experienced separately for its own quality. But the experience gains its full meaning only when the form of the total expression is realized: the low aisles giving grandeur to the high nave, the three together leading to the confluence of the two transept arms at the crossing in a vast climax that prepares for the resolution or finale at the altar. In the same way, the significance of a total mass composition unfolds as one moves about its separate parts. At St. Peter's in Rome, the three projecting apses are gathered into a unity by the undulating walls; they prepare for the cylindrical drum, the drum for the dome, the form of which leads to the culminating lantern, which is harmonized with the drum. Toward the facade, two little domes frame and prophesy the great one, as the cathedral aisles do the nave. While these particular examples from the past illustrate symmetrical compositions with a climax, other buildings that are of equal quality might be chosen to show irregular unity that is no less expressive (e.g., the Erechtheum in Athens; the abbey of Mont Saint-Michel in France).

In modern architecture, as in modern painting, Renaissance laws of composition, which emphasized the symmetry and balance of semi-independent units, have been supplanted by principles that imply the continuity of the whole and remove distinctions between parts. The biological term organic is sometimes used to describe a process of composition that seeks to develop interdependent spaces and masses that function expressively as members of an organism.

If composition were merely a matter of organizing a certain number of relationships, the process would be mechanical, not creative, and all architecture would be equally good or, more likely, bad. The purpose of composition is to express particular concepts and experiences, and it is successful only when these are fully communicated to the observer.

Scale. When the proportions of architectural composition are applied to a particular building, the two-termed relationship of the parts to the whole must be harmonized with a third term—the observer. He not only sees the proportions of a door and their relationship to those of a wall (as he would in a drawing of the building), but he measures them against his own dimensions. This three-termed relationship is called scale.

A well-scaled building such as a Greek temple will serve for illustration. If it were to be magnified to the size of St. Peter's in Rome, with its proportions remaining unchanged in their own relationships, the temple would be out of scale, and the result would appear monstrous. If the columns were to be doubled in width while the temple remained the same size, they would be out of scale and out of proportion with the whole. The proportions of the temple are satisfactory as they are because they are based on certain aesthetic principles established by the Greeks, principles that are partly rooted in human psychological makeup and partly accepted by custom (e.g., as are musical consonances). It is difficult to understand, however, why the scale of these temples is so successful within a certain range of size, for neither the ancient Greeks nor anyone else established laws to relate scale to size. They found their solution by experiment and subjective judgment.

It may be that the success of scale depends upon man's ability to comprehend proportions in relation to some unit or module that is roughly human sized and close enough to a person in a building to permit him to measure it against himself. The Greeks, in employing the base of the column as a module for all the proportions of a temple, found a unit of a size that can be grasped easily and one that is close to eye level as a person approaches the temple. This module is a key to relationships among elements too far away to measure. This can be done in much larger buildings, too, where the elements close to the

Perception
of both the
whole and
its parts

Compre-
hension
of propor-
tions

observer are too massive to be measured easily. Roman and Renaissance architecture retained the ancient Greek orders as decoration partly for this reason, using them to break up huge masses into more comprehensible parts. In entirely different styles of architecture, such as the Gothic, where the expressive function requires immeasurable proportions, there is still a measurable module given in the base of the pier. But piers and columns are not always a source of the module. In masonry construction, the single block can serve the same purpose. In frame construction, the bay (distance between floors or columns) or doors and windows may make a better key. The most successful modern skyscrapers retain a comprehensible scale, in spite of their size, by the repetition of some such module, and this is one reason why the skeleton is so often expressed on the exterior even when it is hidden behind walls.

Light. Light is a necessity for sight and, in architecture, a utility. But light is also a powerful, though ephemeral, vehicle of expression. Because it moves, changes character, and comes and goes with its source, light has the power to give to the inert mass of architecture the living quality of nature. The architect, though he does not quite control it, can predict its behaviour well enough to catch its movements meaningfully. He channels it through openings into his spaces and molds it on the surfaces of his masses by changes of plane, making it enliven his forms by contrast with shadow (see LIGHTING AND LIGHTING DEVICES).

The sunlight that falls on the exteriors of buildings cannot be directed or changed in quality, but it can be reflected or absorbed in a wide range of modulation by the relief and texture of surfaces. The planes and decoration of a facade, therefore, are not just the lines the architect makes on his working drawings but receptacles of light and shadow that change in character, even in form, as the Earth moves about the Sun.

Because of this link between nature and art, an important part in the formation of local architectural styles is played by the variation in the quality and intensity of light in different climatic regions.

The architect controls interior light better than exterior light, since he can select the position, size, and shape of its source. With glass and other transparent materials he transforms even its colour and intensity and so gives light a meaning independent of that which it imparts to the structure. One realizes this most powerfully in the Gothic cathedral, where the stained-glass windows transform the rays of the sun into a mystical diffusion that descends from above like a supernatural vision.

Furthermore, light may be illusory, dissolving rather than clarifying form. When it comes out of darkness in great intensity it seems to spread outward from its architectural channel. This illusion may be employed to express meanings, as at Hagia Sophia in Istanbul, where the light from the base of the dome hides the supports, giving the impression that the canopy floats on air.

Texture. Texture plays a dual role in architecture: it expresses something of the quality of materials, and it gives a particular quality to light. Although one absorbs both qualities simultaneously by eye, the first has tactile, the second visual associations.

Specific tactile textures are peculiar to every material by virtue of its manufacture or natural composition, but they may be altered to produce a variety of expressive qualities. Any stone may be used in its natural, irregular state, or it may be chiselled in a rough or smooth texture or highly polished to convey a range of meanings from vigour to refinement.

Visual textures are produced by the patterns given to the lighting of the surface both through the way the materials are worked (e.g., vertical or horizontal chiselling of stone) and through the way they are employed in building (e.g., vertical or horizontal boarding, projection and recession of courses of brick). Like all patterns, visual textures create associations of movement, giving rhythm to the surface.

A single texture is rarely employed in building. The variety of materials and treatments typically produces a complex of textures that must be composed and harmonized like the forms and spaces of architecture into a consistent expressive whole.

Colour. Since colour is a characteristic of all building materials, it is a constant feature of architecture. But building materials are selected primarily for their structural value, and their colours are not always suited to expressive requirements; thus, other materials chosen for their colour are frequently added to the surface. These include pigments, which usually preserve the texture of the original surface, and veneers of stone, wood, and a variety of manufactured products that entirely alter the surface character.

But colour, regardless of how it is produced, is the most impermanent element in architecture. It changes with the weathering and staining of materials (the white Gothic cathedrals are now deep gray), or, if it is superficial, it can easily be altered or removed (as the coloured stucco veneers of ancient Greek temples or the bright marble facing on Roman brickwork).

The values that are associated with colour (yellow and red, for instance, are called "gay," black and deep blue "sombre") are independent of materials and forms, and they give the architect a range of expression not provided by other means at his disposal. A different expressive device is provided by the great range of light reflection in the colour scale. Colours that reflect light brilliantly appear to advance toward the viewer, and those that absorb light appear to recede; the degree of projection and recession of architectural forms may be altered, emphasized, or subdued by the colours of their surfaces.

Environment. Architecture, unlike most of the other arts, is not often conceived independently of particular surroundings. The problems of design extend beyond the organizing of space and mass complexes to include the relating of the total form to its natural and architectural environment.

In site planning, a primary function of architectural design, the architect aims to create harmonies with preexisting elements in the landscape and "townscape."

But the province of the architect is not limited to the conception of single structures in harmony with a given setting. Throughout history, architects have been employed in giving a new form to the environment itself: planning the natural surroundings by the design of parks, roadways, waterways, etc.; designing complexes of related buildings; and organizing the urban environment into areas of residence, recreation, assembly, commerce, etc., both to increase their utility and to give them unique expressive qualities through the interrelationship of groups of buildings to the open areas about them. (J.S.Ac.)

ORNAMENT

Although it would be difficult to cover in any single definition all conceptions, past and present, of what constitutes ornament in architecture, three basic and fairly distinct categories may be recognized: mimetic, or imitative, ornament, the forms of which have certain definite meanings or symbolic significance; applied ornament, intended to add beauty to a structure but extrinsic to it; and organic ornament, inherent in the building's function or materials.

Mimetic ornament. Although it is still found in the 20th century, mimetic ornament is by far the commonest type of architectural ornament in primitive cultures, in Asian civilizations, and generally throughout antiquity. It grows out of what seems to be a universal human reaction to technological change: the tendency to reproduce in new materials and techniques shapes and qualities familiar from past usage, regardless of appropriateness. This tendency may be called the principle of mimesis. Most common building types in antiquity, both East and West (e.g., tombs, pyramids, temples, towers), began as imitations of primeval house and shrine forms. An obvious example is the dome, which developed as a permanent wooden or stone reproduction of a revered form originally built of pliable materials. In the mature stages of early civilizations, building types tended to evolve beyond primitive prototypes; their ornament, however, usually remained based on such models. Decorative motifs derived from earlier structural and symbolic forms are innumerable and universal. In developed Indian and Chinese architecture, domical and other originally structural forms occur often

Attempts
to control
light for
expressive
effect

Traditional
nature of
mimetic
ornament

and lavishly as ornament. In ancient Egypt, architectural details continued to preserve faithfully the appearance of bundled papyrus shafts and similar early building forms. In ancient Mesopotamia, brick walls long imitated the effect of primitive mud-and-reed construction. In the carved-stone details of the Greco-Roman orders (*e.g.*, capitals, entablatures, moldings), the precedent of archaic construction in wood was always clearly discernible.

The prevalence of mimetic ornament in architecture may be explained in two ways. Some (perhaps most in primitive cultures) is religious in origin. Certain forms and shapes, through long association with religious rites, became sacred and were preserved and reproduced for their symbolic value. These forms continued to be understood even though they were often stylized into abstract or geometric patterns, unrecognizably removed from their naturalistic models. Much mimetic ornament, however, even in early times, can be ascribed simply to inertia or conservatism. People have generally tended to resist change; they find it reassuring to be surrounded by known and familiar forms. Reproducing them as ornament on newly introduced forms is a common reaction to the vague feeling of uneasiness that rapid social and technological change induces; it provides a satisfying sense of continuity between the past and the present. This resistance was a factor in the 19th- and early-20th-century practice of disguising new techniques of construction in metal and glass by an overload of ornament imitating earlier styles.

Applied ornament. Architectural ornament in the 19th century exemplified the common tendency for mimetic ornament, in all times and places, to turn into mere applied decoration, lacking either symbolic meaning or reference to the structure on which it is placed. By the 5th century BC in Greece, the details of the orders had largely lost whatever conscious symbolic or structural significance they may have had; they became simply decorative elements extrinsic to the structure. The Doric frieze is a good case: its origin (*i.e.*, an imitation of the effect of alternating beam ends and shuttered openings in archaic wood construction) remained evident, but it came to be treated as a decorative sheath without reference to the actual structural forms behind. In losing their mimetic character, the details of the Greek orders acquired a new function; they served to articulate or unify the building visually, organizing it into a series of coordinated visual units that could be comprehended as an integrated whole, rather than as a collection of isolated units. This concept of applied decoration was passed on through the Greco-Roman period. The triumphal arch of Rome, with its system of decorative columns and entablature articulating what is essentially one massive shape, is a particularly good illustration; the Colosseum is another. Most of the great architecture of the Renaissance and Baroque periods depends on it; to a large extent, the difference between these styles is the difference in decoration. The characteristic serenity and balance of Filippo Brunelleschi's architecture in the 15th century, for example, is very largely effected by his treatment of pilasters (rectangular ornamental columns with bases and capitals) and entablatures applied to them, whereas, in 16th-century wall-surface designs such as Michelangelo's Medici chapel or the dome of St. Peter's, the same elements are used in different combinations to create a quite opposite effect of tension and release.

Judicious and intelligent use of applied ornament remained characteristic of most Western architecture until the 19th century, when the rationale of applied ornament frequently broke down, and an often indiscriminate and inappropriate use of decoration became characteristic. The reasons for this development are complex. In part it was a reaction to an overly rapid pace of social change during the period; partly, also, it was a logical outgrowth of the increasingly lavish decoration of late Baroque and Rococo architecture in the 18th century. Also, there was an overemphasis on the purely literary and associative values attached to the ornament characteristic of historical architectural styles. But compounding all these factors was the development of machinery, such as multiple lathes and jigs, which provided builders with cheap prefabricated ornament to give their often shoddy and ill-proportioned

structures an illusion of elegance. Architectural ornament and architectural forms proper tended to part company and to be designed quite independently of each other.

Organic ornament. By the early 20th century a preoccupation with the proper function of architectural ornament was characteristic of all advanced architectural thinkers; by the mid-20th century a concept of architectural ornament had been formulated that has been called organic ornament. This concept, however, is by no means peculiar to the 20th century. Its essential principle is that ornament in architecture should derive directly from and be a function of the nature of the building and the materials used. This principle is characteristic of both Christian and Islamic religious architecture of the medieval period. In the architectural ornament of Muslim India or Persia, as in early Christian and Byzantine work, there is a strong mimetic element. The proscription of representational forms in the Qur'an and the tendency of both Muslim and early Christian artists to borrow and adapt their formal vocabulary from preceding cultures led inevitably to their transforming what had been meaningful forms into systems of abstract ornament. But basically this ornament was neither mimetic nor applied. Throughout the Middle Ages, church buildings were conceived primarily as tangible symbols of heaven. Their architectural ornament, no matter how various or lavish, was consistently designed to promote this symbolism; whether by gilt, intricacy, or multiplicity, it all contributed to an overall effect of glory and so was integral to the architectural form.

Twentieth-century concepts of the function of architectural ornament, generally speaking, began with an understanding of this medieval usage that grew out of the 19th-century writings of the English art critic John Ruskin and the French Gothic Revival architect Viollet-le-Duc, as well as through the interpretations and applications of the British designer William Morris. The immediate influence of these men proved rather unfortunate. The first result of Viollet-le-Duc's disciplined and scholarly investigations into the principles of medieval architecture was a school of slick archaeological architects, capable of decorating all manner of collegiate, civic, and domestic buildings with frigidly correct reproductions of the details of medieval cathedrals and châteaux. Out of Ruskin's demonstration of the origins of medieval decoration in natural forms there grew the so-called Art Nouveau movement toward exaggerated floral and curvilinear ornament; and out of Morris' insistence on handicrafts, inspired by infatuation with the medieval guild system, developed the Arts and Crafts movement.

As early as the 1870s the U.S. architect H.H. Richardson adopted the Romanesque style, less for its historical associations than for the opportunities it afforded him to express the nature and texture of stone. In mature examples of his architecture from the mid-1880s, ornament in the older, applied sense had virtually disappeared, and his buildings depend for their aesthetic effect mainly on the inherent qualities of their materials. The generation following Richardson saw a further international development of this principle.

In Great Britain Sir Edwin Lutyens and Charles Rennie Mackintosh, in The Netherlands Hendrick Petrus Berlage, and in the United States Louis Sullivan were among many architects who contributed to the new ornamental expression. It was largely based on intrinsic texture and pattern but with interspersed bands and patches of naturalistic ornament, applied with studied discipline. With the general reaction against 19th-century eclectic principles of ornamentation after World War I, however, leading designers rejected even this kind of applied ornament and relied for ornamental effect on building materials alone. The so-called International Style, in which the German architect Walter Gropius and the Swiss-French architect Le Corbusier were the chief figures, dominated advanced design during the late 1920s and 1930s. The barrenness that resulted from their reliance on such materials as concrete and glass, however, along with other factors, resulted in a reaction in the 1940s in favour of the neglected precedent set by the U.S. architect Frank Lloyd Wright in his early-20th-century work, which emphasized more visually in-

teresting materials, intricate textural patterns, and natural settings as the proper basis of architectural ornament. This trend continued in later decades; the style known as the New Brutalism was related to it. (Al.Go.)

Theory of architecture

The term theory of architecture was originally simply the accepted translation of the Latin term *ratiocinatio* as used by Vitruvius, a Roman architect-engineer of the 1st century AD, to differentiate intellectual from practical knowledge in architectural education; but it has come to signify the total basis for judging the merits of buildings or building projects. Such reasoned judgments are an essential part of the architectural creative process. A building can be designed only by a continuous creative, intellectual dialectic between imagination and reason in the mind of each creator.

A variety of interpretations has been given to the term architectural theory by those who have written or spoken on the topic in the past. Before 1750 every comprehensive treatise or published lecture course on architecture could appropriately be described as a textbook on architectural theory. But, after the changes associated with the Industrial Revolution, the amount of architectural knowledge that could be acquired only by academic study increased to the point where a complete synthesis became virtually impossible in a single volume.

The historical evolution of architectural theory is assessable mainly from manuscripts and published treatises, from critical essays and commentaries, and from the surviving buildings of every epoch. It is thus in no way a type of historical study that can reflect accurately the spirit of each age and in this respect is similar to the history of philosophy itself. Some architectural treatises were intended to publicize novel concepts rather than to state widely accepted ideals. The most idiosyncratic theories could (and often did) exert a wide and sometimes beneficial influence; but the value of these influences is not necessarily related to the extent of this acceptance.

Analysis of
historical
buildings

The analysis of surviving buildings provides guidance that requires great caution, since, apart from the impossibility of determining whether or not any particular group of buildings (intact or in ruins) constitutes a reliable sample of the era, any such analyses will usually depend on preliminary evaluations of merit and will be useless unless the extent to which the function, the structure, and the detailing envisaged by the original builders can be correctly re-established. Many erudite studies of antique theories are misleading because they rest on the assumption that the original character and appearance of fragmentary ancient Greek and Hellenistic architectural environments can be adequately deduced from verbal or graphic "reconstructions." Even when buildings constructed before 1500 remain intact, the many textbooks dealing with antique and medieval theories of architecture seldom make qualitative distinctions and generally imply that all surviving antique and medieval buildings were good, if not absolutely perfect.

Nevertheless, the study of the history of architectural philosophy, like that of the history of general philosophy, not only teaches what past generations thought but can help the individual decide how he himself should act and judge. For those desirous of establishing a viable theory of architecture for their own era, it is generally agreed that great stimulus can be found in studying historical evidence and in speculating on the ideals and achievements of those who created this evidence.

DISTINCTION BETWEEN THE HISTORY AND THEORY OF ARCHITECTURE

Emergence
of two
disciplines
in the 18th
century

The distinction between the history and theory of architecture did not emerge until the mid-18th century; indeed, the establishment of two separate academic disciplines was not even nominal until 1818, when separate professorships with these titles were established at the École des Beaux-Arts in Paris. Even then, however, the distinction was seldom scrupulously maintained by either specialist. It is impossible to discuss meaningfully the buildings of

the immediate past without discussing the ideals of those who built them, just as it is impossible to discuss the ideals of bygone architects without reference to the structures they designed. Nevertheless, since any two disciplines that are inseparably complementary can at the same time be logically distinguishable, it may be asserted that this particular distinction first became manifest in *Les Ruines des plus beaux monuments de la Grèce* ("The Ruins of the Most Beautiful Monuments of Greece"), written in 1758 by a French architecture student, Julien-David LeRoy. Faced with the problem of discussing Athenian buildings constructed in the time of Vitruvius, he decided to discuss them twice, by treating them separately under two different headings. Before this date, "history" was of architectural importance only as a means of justifying, by reference to classical mythology, the use of certain otherwise irrational elements, such as caryatids. Even Jacques-François Blondel, who in 1750 was probably the first architectural teacher to devote a separate section of his lecture courses to "history," envisaged the subject mainly as an account of the literary references to architecture found in antique manuscripts—an attitude already developed by the 15th-century Renaissance architect Leon Battista Alberti.

The modern concept of architectural history was in fact simply part of a larger trend stimulated by the leading writers of the French Enlightenment, an 18th-century intellectual movement that developed from interrelated conceptions of reason, nature, and man. As a result of discussing constitutional law in terms of its evolution, every branch of knowledge (especially the natural and social sciences) was eventually seen as a historical sequence. In the philosophy of architecture, as in all other kinds of philosophy, the introduction of the historical method not only facilitated the teaching of these subjects but also militated against the elaboration of theoretical speculation. Just as those charged with the responsibility of lecturing on ethics found it very much easier to lecture on the history of ethics, rather than to discuss how a person should or should not act in specific contemporary circumstances, so those who lectured on architectural theory found it easier to recite detailed accounts of what had been done in the past, rather than to recommend practical methods of dealing with current problems.

Moreover, the system of the Paris École des Beaux-Arts (which provided virtually the only organized system of architectural education at the beginning of the 19th century) was radically different from that of the pre-revolutionary Académie Royale d'Architecture. Quatremère de Quincy, an Italophile archaeologist who had been trained as a sculptor, united the school of architecture with that of painting and sculpture to form a single organization, so that, although architectural students were ultimately given their own professor of theory, the whole theoretical background of their studies was assimilated to the other two fine arts by lecture courses and textbooks such as Hippolyte Taine's *Philosophie de l'art*, Charles Blanc's *Grammaire des arts du dessin*, and Eugène Guillaume's *Essais sur la théorie du dessin*.

Similarly, whereas before 1750 the uniformity of doctrine (the basic premises of which were ostensibly unchanged since the Renaissance) allowed the professor of architecture to discuss antique and 16th-century buildings as examples of architectural theory and to ignore medieval buildings completely, the mid-19th-century controversy between "medievalists" and "classicists" (the "Battle of the Styles") and the ensuing faith in Eclecticism turned the studies of architectural history into courses on archaeology.

Thus, the attitudes of those scholars who, during the 19th and early 20th centuries, wished to expound a theory of architecture that was neither a philosophy of art nor a history of architecture tended to become highly personal, if not idiosyncratic. By 1950 most theoretical writings concentrated almost exclusively on visual aspects of architecture, thereby identifying the theory of architecture with what, before 1750, would have been regarded as simply that aspect that Vitruvius called *venustas* (i.e., "beauty"). This approach did not necessarily invalidate the conclusions reached; but many valuable ideas then put forward as theories of architecture were only partial

century

theories, in which it was taken for granted that theoretical concepts concerning construction and planning were dealt with in other texts.

DISTINCTION BETWEEN THE THEORY OF ARCHITECTURE AND THE THEORY OF ART

Before embarking on any discussion as to the nature of the philosophy of architecture, it is essential to distinguish between two mutually exclusive theories that affect the whole course of any such speculation. The first theory regards the philosophy of architecture as the application of a general philosophy of art to a particular type of art. The second, on the contrary, regards the philosophy of architecture as a separate study that, though it may well have many characteristics common to the theories of other arts, is generically distinct.

The first notion (*i.e.*, that there exists a generic theory of art of which the theory of architecture is a specific extension) has been widely held since the mid-16th century, when the artist and writer Giorgio Vasari published in his *Le vite de' più eccellenti pittori, scultori ed architettori italiani . . .* (*The Lives of the Most Eminent Italian Painters, Sculptors and Architects . . .*) his assertion that painting, sculpture, and architecture are all of common ancestry in that all depend on the ability to draw. This idea became particularly prevalent among English-speaking theorists, since the word design is used to translate both *disegno* ("a drawing") and *concetto* ("a mental plan"). But its main influence on Western thought was due to Italophile Frenchmen, after Louis XIV had been induced to establish in Rome a French Academy modelled on Italian art academies.

As a result of the widespread influence of French culture in the 17th and 18th centuries, the concept of the *beaux arts* (literally "beautiful arts" but usually translated into English as "fine arts") was accepted by Anglo-Saxon theorists as denoting a philosophical entity, to the point where it was generally forgotten that in France itself the architectural profession remained totally aloof from the Académie Royale de Peinture et de Sculpture until they were forced to amalgamate after the French Revolution.

This theory of fine art might not have been so widely adopted but for the development of aesthetics, elaborated after 1750. Thus, when academies of fine art were being established successively in Denmark, Russia, and England on the model of the French Academy in Rome, German philosophers were gradually asserting (1) that it was possible to elaborate a theory of beauty without reference to function (*Zweck*); (2) that any theory of beauty should be applicable to all sensory perceptions, whether visual or auditory; and (3) that the notion of beauty was only one aspect of a much larger concept of life-enhancing sensory stimuli.

The alternative theory (*i.e.*, that a philosophy of architecture is unique and can therefore be evolved only by specific reference to the art of building) will be dealt with below with reference to the traditional triad usually cited in the formula coined, by the English theorist Sir Henry Wotton, in his book *The Elements of Architecture*, namely "commodity, firmness, and delight."

Generally speaking, writers on aesthetics have been noticeably reluctant to use architectural examples in support of speculations as to the nature of their general theories; but references to buildings have been used in most "philosophies of art" ever since the German philosophers Immanuel Kant and G.W.F. Hegel first popularized the philosophical discipline. Kant, in his *Kritik der Urteilskraft* (1790; Eng. trans., *Critique of Judgment*, 1951), distinguished between what he termed free beauty (*pulchritudo vaga*) and dependent beauty (*pulchritudo adhaerens*). He classified architecture as dependent beauty, saying that in a thing that is possible only by means of design (*Absicht*)—a building or even an animal—the regularity consisting in symmetry must express the unity of the intuition that accompanies the concept of purpose (*Zweck*), and this regularity belongs to cognition. Nevertheless, he claimed that a flower should be classified as free beauty (where the judgment of taste is "pure") "because hardly anyone but a botanist knows what sort of thing a flower ought

to be; and even he, though recognizing in the flower the reproductive organ of the plant, pays no regard to this natural purpose if he is passing judgment on the flower by taste." What Kant's reaction would have been to a modern plastic imitation flower is impossible to guess; but it will readily be perceived (1) why those who, in the 19th century, accepted the notion that beauty in architecture is *pulchritudo adhaerens* felt such antipathy toward "shams," (2) how the distinction between "pure art" and "functional art" (*Zweckkunst*) became confused, and (3) why there arose a tendency to pursue definitions of "pure beauty" or "pure art" without specifically referring to the function and structure of any particular class of beautiful or artistic objects, such as buildings.

This latter tendency was reinforced when the French philosopher Victor Cousin, writing in 1835, classified the history of philosophy under three distinct headings: the true, the beautiful, and the good. The ensuing acceptance of the idea that beauty was to be studied independently of truth and goodness produced a tendency not merely to regard beauty as something added to a building (rather than conceptually inseparable from the truth and goodness of its structure and function) but to regard beauty as limited to visual and emotional qualities.

In the first half of the 20th century, philosophers grew less dogmatic about aesthetics. But its influence on theories of architecture became stronger because of the popular view that sculpture was essentially nonrepresentational. Thus, although the assertion that "aesthetically, architecture is the creation of sculpture big enough to walk about inside" is meaningful in the 20th century, it would have seemed nonsensical to any architectural theorist living before 1900, when sculpture was invariably thought of either as representational or as a carved refinement of load-bearing wood or stone.

FUNCTIONALISM

The notion of functional art, most actively promoted by German writers and termed by them *Zweckkunst*, is most appropriately related to architectural theory under three headings, namely (1) the idea that no building is beautiful unless it properly fulfills its function, (2) the idea that if a building fulfills its function it is ipso facto beautiful, and (3) the idea that, since form relates to function, all artifacts, including buildings, are a species of industrial, or applied, art (known in German as *Kunstgewerbe*).

The first proposition will be dealt with later under the heading *utilitas*. The second proposition, though widely popularized through the publication of the French architect Jean-Nicholas-Louis Durand's lectures delivered during the economic depression of the beginning of the 19th century, has had little influence except during similar periods of economic depression. The third proposition has, however, had a wide influence, since, unlike the second proposition, it is closely akin to (rather than antagonistic toward) the theory of aesthetics, in that it regards all the visual arts as generically related.

This last theory seems to have been popularized, if not originated, by Gottfried Semper, an architect from Dresden who, after finding political asylum in England (where he then helped to organize the Great Exhibition of 1851), published a book in German on arts and crafts that seems to have been influential not only in Germany but also in areas of the United States heavily populated by German-speaking immigrants, such as Chicago. Later, in 20th-century Germany, the Bauhaus (officially Hochschule für Gestaltung; Academy for Form Giving) was ostensibly intended to train students in separate creative disciplines, but its didactic method was based on the assumption—implied by the general introductory courses—that, if one could design anything, one could design everything. In the explanatory words of its founder, the architect Walter Gropius, "The approach to any kind of design—a chair, a building, a whole town or a regional plan—should be essentially identical."

THE ART OF BUILDING

The notion that architecture is the art of building was implied by Alberti in the first published treatise on the

Influence of aesthetics in 20th-century theory

Bauhaus functionalism

theorists' reluctance to use specific buildings as examples

theory of architecture, *De re aedificatoria* (1485; Eng. trans., *Ten Books on Architecture*, 1955); for, although he was a layman writing for other lay scholars, he rejected, by his title, the idea that architecture was simply applied mathematics, as had been claimed by Vitruvius. The specific denotation of architecture as "the art of building," however, seems to be a French tradition, deriving perhaps from the medieval status of master masons, as understood by the 16th-century architect Philibert Delorme. This definition occurs in most French treatises published before 1750; and, although the humanistic and antiquarian aspects of fine building were rarely questioned after the Renaissance, the distinction between "architecture" and "building" never had any appreciable significance before Renaissance ideas succumbed to the combined assault of "aesthetics" and the Gothic Revival movement.

Before the 18th century it was generally accepted that the theory of architecture was concerned mainly with important private or civic buildings such as palaces, mansions, churches, and monasteries. Buildings such as these required the superior skill that only book learning could provide, and so relatively little attention was given, in theoretical writings, to simple and straightforward buildings that could be competently built in accordance with local traditions by unlettered craftsmen. But, with the expansion of the architectural profession, with the perversion of the idea that social prestige was symbolized by ornamentation, with the wider distribution of wealth, and with the growing urge toward individualism in an increasingly egalitarian society, the real distinction between these two kinds of buildings was obscured, and in its place was substituted an antithesis. Henceforth, "building" was associated with the notion of cheapness, whereas "architecture" was associated with what John Ruskin would have called "sacrifice" (but which his antagonists would have called conspicuous waste). A distinction was made between the respective attitudes of "art architects" and practical-minded civil engineers. This distinction persisted because of the different methods of training candidates for the two professions. Whereas a fledgling engineering student is seldom asked to design a whole structure (such as a bridge), architectural students begin by designing whole structures and proceed with structures of increasing size and complexity, either graphically or by means of small-scale models.

It was doubtless the difference in educational methods that prompted Le Corbusier to state:

The engineer, inspired by the law of economy and led by mathematical calculation, puts us in accord with the laws of the universe. He achieves harmony. The architect, by his arrangement of forms, achieves an order which is a pure creation of his spirit . . . it is then that we experience beauty.

Yet some 80 years previously the English critic James Fergusson had felt obliged to qualify, with a comparable distinction, his enthusiasm for the new architecture of the Crystal Palace, by observing that "it has not a sufficient amount of decoration about its parts to take it entirely out of the category of first-class engineering and to make it entirely an object of fine art." The distinction between architecture and "mere building" was stated by Nikolaus Pevsner in the opening paragraph of his *Outline of European Architecture* (1942): "a bicycle shed is a building; Lincoln Cathedral is a piece of architecture . . . the term architecture applies only to buildings designed with a view to aesthetic appeal." Whatever the justification for such assertions, it must nevertheless be recognized that neither of these authors suggests that aesthetic appeal or art are synonyms for superfluity. Although adjustment in proportions or refinement of profiles may increase the thickness of short-span structural members beyond the structural analytical minima, this does not necessarily imply any radical decrease in real economy but simply indicates a concept of economy that takes into account the assembly and amenity of spatial enclosures and admits that there is value in environmental harmony. It is thus as misleading to imply (as Fergusson implied) that architecture is civil engineering plus ornament as it is to imply (as Le Corbusier did) that the status of the two professions is to be distinguished by the relative superiority of beauty over harmony.

It is important to insist that the theory of architecture is concerned primarily with the attainment of certain environmental ideals rather than with their cost; for these two problems are philosophically distinct, as is clear if one considers such a concept as, for example, that of standardization. The financial saving made by standardizing rolled-steel sections or by casting concrete in reusable formwork is so obvious that it requires no elaboration with respect to Vitruvius' demand for *oeconomia*. But such standardization also fulfills Vitruvius' concurrent demand for order, arrangement, eurythmy, symmetry, and propriety.

The Place Vendôme in Paris is adorned with over 100 identical pilasters and half columns, all carved with the same Corinthian capitals under the supervision of a member of the Académie Royale de Peinture et de Sculpture. Whether or not the resultant uniformity was or still is both pleasing and desirable is certainly open to discussion; but it will be perceived that any argument about architectural standardization must primarily be a question of value, rather than of cost, and it is with values that architectural theory has always been predominantly concerned.

"COMMODITY, FIRMNESS, AND DELIGHT": THE ULTIMATE SYNTHESIS

It has been generally assumed that a complete theory of architecture is always concerned essentially in some way or another with these three interrelated terms, which, in Vitruvius' Latin text, are given as *firmitas*, *utilitas*, and *venustas* (i.e., structural stability, appropriate spatial accommodation, and attractive appearance). Nevertheless, a number of influential theorists after 1750 sought to make modifications to this traditional triad (1) by giving its components a radically different equilibrium (such as the primacy given by the 18th-century French architect Étienne-Louis Boullée to the effects of geometric forms in light or the claim made by J.N.L. Durand that the fulfillment of function was the sole essence of architectural beauty), (2) by adding ethical values (such as Ruskin's "sacrifice" and "obedience"), or (3) by introducing new scientific concepts (such as Giedion's "space-time").

Furthermore, it has been argued that the traditional concept of *firmitas*, *utilitas*, and *venustas* ceased to have any real value after 1800, when engineers began creating structures that seemed so ostentatiously to defy the stonemasons' laws of gravity, when scientific studies were creating more and more doubts as to the economical, sociological, psychological, acoustical, thermal, or optical determinants of appropriate spatial accommodation and when beauty was "altogether in the eye of the beholder."

Clearly, one must be wary of attributing too much importance to the sequence, since a slight variation occurs in the writings of even the most traditional theorists. Vitruvius gives these terms in the sequence *firmitas*, *utilitas*, *venustas*, whereas both Alberti and, following him, the 16th-century Venetian architect and theorist Andrea Palladio reverse the order of the first two. Thus, Sir Henry Wotton's sequence (which is normally used in English-language texts) does not, as so often stated, derive directly from the Latin text of Vitruvius but from the Italian text of Palladio's *I quattro libri dell' architettura* (i.e., *comodità*, *perpetuità*, *bellezza*). But it does seem worth noting that *venustas* generally comes last, implying that *firmitas* and *utilitas* are to be regarded as essential logical prerequisites of architectural beauty.

On the other hand, the practical advantages, in academic treatises, of giving priority to *venustas* are evident. Jacques-François Blondel, in his nine-volume *Cours d'architecture* (1771–77) used this sequence because he observed that considerations of "decoration" are almost entirely within the domain of the theory of architecture, whereas neither distribution (*utilitas*) nor construction (*firmitas*) can be explained properly without practical experience. The growing emphasis on aesthetics, combined with developments in psychology and the influence of art-historical methods, added weight to this argument, while the corresponding independence of scientific techniques of structural and spatial analysis led many teachers of architecture to consider *utilitas* and *firmitas* as totally separate academic disciplines. Important exceptions can be found to this gen-

theory

eralization. At the end of the 19th century, Julien Guadet, in reaction against the creation of a chair of aesthetics at the Paris École des Beaux-Arts, considered it his duty, as professor of architectural theory, to devote his lectures to the study of architectural planning, and this method, which achieved prestige as a result of his keen mind and wide historical knowledge, was pursued by many later scholars. But Guadet's approach became unfashionable, and since the 1960s the predominant methods of teaching architectural theory have ranged from a return to the synthesis of structural, spatial, and formal values espoused by Robert Venturi to the exploration of the architectural implications of general theories of linguistics advanced by Christian Norberg-Schulz.

Venustas. This Latin term for "beauty" (literally, the salient qualities possessed by the goddess Venus) clearly implied a visual quality in architecture that would arouse the emotion of love; but it is of interest to note that one of the crucial aspects of this problem was already anticipated by Alberti in the 15th century, as is made clear by his substitution of the word *amoenitas* ("pleasure") for Vitruvius' more anthropomorphic term *venustas*. Alberti not only avoids the erotic implications of the term *venustas* but, by subdividing *amoenitas* into *pulchritudo* and *ornamentum*, gives far more precise indications as to the type of visual satisfaction that architecture should provide. *Pulchritudo*, he asserts, is derived from harmonious proportions that are comparable to those that exist in music and are the essence of the pleasure created by architecture. *Ornamentum*, he claims, is only an "auxiliary brightness," the quality and extent of which will depend essentially on what is appropriate and seemly. Both *pulchritudo* and *ornamentum* were thus related to function and environment in that, ideally, they were governed by a sense of decorum; and, since the etymological roots of both "decoration" and "decorum" are the same, it will be understood why, before 1750, the term decoration had in both English and French a far less superficial architectural implication than it often does today.

After the German philosopher and educator Alexander Gottlieb Baumgarten had introduced the neologism aesthetics in about 1750, the visual merits of all artifacts tended to be assessed more subjectively than objectively; and, in the criticism of all those sensory stimuli that, for want of a better term, critics somewhat indiscriminately lumped together as the fine arts, the visual criteria were extended to include not only beauty but also sublimity, picturesqueness, and even ugliness. Now it is clear that, once ugliness is equated with beauty, both terms (being contradictory) become virtually meaningless. But ugliness, after the mid-19th century, was not only one of the most important themes of many popular dramas and novels; ugliness was also often considered the most appropriate architectural expression for all sorts of virtues—especially those of manliness, sincerity, and so on.

Before 1750, architects had expressed these qualities more subtly (e.g., by slight modifications of proportions or by unobtrusive ornament). In later years, when the value of proportion and ornament became highly controversial, architectural theorists tended to avoid committing themselves to any criteria that might be subsumed under the heading *venustas*. In the last resort, however, some concept of beauty must be essential to any theory of architecture; and, whether one considers Le Corbusier's buildings beautiful or not, his most stabilizing contribution toward the theory of modern architecture was undoubtedly his constant reiteration of this term and his insistence on the traditional view that beauty in architecture is essentially based on harmonious proportions, mathematically conceived.

In the 20th century the main obstacle to an acceptance of Alberti's notions of *pulchritudo* and *ornamentum* resulted from the influence of nonrepresentational sculpture after 1918, whereby ornament was no longer conceived as an enrichment of proportioned structure but as an integral, all-pervading part of each building's totality. This ideal of the fusion between good proportions and "auxiliary brightness" was expressed by Walter Gropius in *The New Architecture and the Bauhaus* when he wrote in 1935:

Our ultimate goal, therefore, was the composite but inseparable work of art, the great building, in which the old dividing-line between monumental and decorative elements would have disappeared for ever.

The idea was accepted in most schools of architecture by the mid-20th century; but one may question whether it fully justified the expectations of its protagonists, once it had been exemplified and proliferated in so many urban environments. It is by no means certain that Gropius' concept of the fundamental interdependence of architectural proportion and architectural ornament was irrevocably established by the Bauhaus theorists or that future architectural theorists need only concentrate on such minor modifications to the concept as may be required by sociological and technological developments.

Utilitas. The notion that a building is defective unless the spaces provided are adequate and appropriate for their intended usage would seem obvious. Yet the statement itself has been a source of controversy since the 1960s. The main reasons for the controversy are: first, whereas there are seldom exact statistical means of computing spatial adequacy or appropriateness, there are many building types or building elements for which one cannot even establish the optimum forms and dimensions with any confidence that they will be generally accepted. Second, edifices are frequently used for purposes other than those for which they were originally planned. Furthermore, there is some doubt as to whether "form follows function" or "function follows form," since, although, in general, it can reasonably be assumed that an architect's task is to construct specific spaces for the fulfillment of predetermined functions, there is plenty of historical evidence to suggest that many important social institutions have resulted from spaces already built. No better example could be found than the evolution of parliamentary systems. The British system, based on the concept of legislatures in which the sovereign's government and the sovereign's opposition confront each other, originated in the fact that the earliest parliaments met in the medieval palace chapel. The French system, created concurrently with the Greek and Roman revivals, was based on the concept of legislatures addressed by orators, and its environment was that of an antique theatre. In the former system the seating was designed in accordance with the liturgical requirements of a Christian church; in the latter, with the evolution of Greek drama. Neither had anything to do with preconceived notions regarding the most effective environment for parliamentary debate, yet both have had divergent influences on constitutional procedures, thereby deeply affecting the whole theory of government.

Third, the exact significance of what is meant by "adequate appropriate spaces" becomes far more complex in buildings requiring a large number of interrelated spaces than it is in single-cell buildings. The emotional effect of transitions from spacious to constricted volumes and vice versa transcends in architectural importance the statistical evaluation of floor areas; a fact which explains the attractiveness of theories that have tacitly adopted places of worship as spatial paradigms and bolstered their arguments by historical reference to temples and churches. This bias is perceptible not only in the most influential theories enunciated before 1900 (when the prototypes were either primeval, antique, or medieval) but also in the most influential ideas promulgated by such great architectural leaders of the 20th century as Frank Lloyd Wright and Ludwig Mies van der Rohe.

The idealization of monumental single-cell spaces is sometimes justified, but the difficulty of evolving theories of planning by the use of historical prototypes should be emphasized. It is in this branch of architectural theory that the influences of historicism have been most insidious, precisely because they are less obvious here than in systems of construction, of proportions, and of ornamentation. Such influences persist mainly because of art-historical indifference to the essential distinction between building types, since such distinction conflicts with the chronological sequence of particular architects' stylistic evolution; but it is for this reason that Julien Guadet's greatest contribution to the theory of architecture may well

Alberti's
theory

have been his decision to evolve a history of architecture in which all buildings were classified solely in accordance with their function.

Firmitas. Two plausible reasons can be given for according logical primacy in the Vitruvian triad to *firmitas*. The first is the notion that architecture is essentially the "art of building." The second is that, since the uses or functions of a building tend to change, the structures serving such functions may be considered as taking logical precedence over them. This idea was expressed with characteristic lapidary vigour by the 20th-century French architect Auguste Perret when he asserted that

architecture is the art of organizing space; but it is by construction that it expresses itself... Functions, customs, and building regulations and fashions impose conditions which are only transitory.

Some later architectural theorists have become so concerned with the rapid obsolescence of modern buildings that they have envisaged edifices that express the temporary nature of these transitory qualities and are therefore built in such a way as to enable the structures themselves to be discarded completely after a few years. On the other hand (since the economic feasibility of this technique is questionable), there are still many architects who believe in the inevitability of permanent buildings and who therefore hold views more compatible with this belief.

The issue of revealing the structural system to the observer

From the time of the Renaissance to the mid-18th century—as also before the decline of the ancient Roman Empire on which the culture of this era was modelled—little concern seems to have been given to the idea that there was any virtue in manifesting the actual structural system of a building. Alberti recommended a distinctive articulation of the skeleton frame in conformity with the antique concept of *trabeation*, or the post-and-lintel system (and hence the independence of the "infilling" elements, such as arches or solid walling); but the more commonly accepted notion seems to have been that, provided a *trabeated* system was expressed externally, the relationship of this visual expression to the actual system of construction was relatively unimportant. Theoretical pronouncements on this matter depended of course on the architectural traditions of each country. In Italy (where the traditional technique of building had, even during the Middle Ages, assumed that structure was independent of appearance and where it was common to complete a building in brick before adding its marble facades) the idea that there could be any theoretical dilemma regarding the union between these two elements was virtually inconceivable. Palladio and his generation seem to have generally accepted the idea that, in regions where masonry was scarce, the use of stuccoed, painted, or veneered brickwork, with plastered timber beams, was architecturally as "genuine" as the use of stone, provided it was all of one colour. But in the Île-de-France region around Paris, on the contrary, the medieval traditions of French masonry construction, combined with the abundance of good freestone, caused theorists from the Renaissance to the time of the French Revolution to favour a less tenuous relationship between the external appearance of a building and the system by which it was constructed. Nevertheless, it is probably fair to say that in all European countries before the end of the 18th century, as well as in their American colonies, the only problem concerned with *firmitas* (other than technical problems) was the problem of the relationship between "real and apparent stability"; and, when theorists pronounced on this problem, it was usually to assert that a building should not only be structurally stable but should also appear to be so.

A violent assault upon this point of view was launched by the Gothic Revivalists, who, in the mid-19th century, contended that the breathtaking counterpoise of a cathedral's flying buttresses was far more dramatically expressive of *firmitas* than the ponderous massiveness of its sturdy western towers. It was in this era that the term *daring* (which Ruskin had frequently used with reference to the paintings of the English Romantic artist Joseph Mallord William Turner) became popular as a laudatory epithet, thereby indicating an ideal of structural expression that was to be increasingly exploited when steel and reinforced

concrete permitted higher buildings with fewer and more slender supports.

But the most controversial issue concerning *firmitas* in the 19th century—which also arose through the influence of the Gothic Revival movement—concerned the extent to which a building should manifest its structural system and the materials used. The attraction of this particular interpretation of the concept of truthful architecture was probably due to the popularity of new attitudes toward experimental science and to the disrepute into which mythology had been cast by the philosophers of the Enlightenment. Presumably, truth was no less prized in the 17th or 18th centuries than in the 19th century (though shams may have been less rife), while hypocrisy was regarded with as much contempt. Moreover, although the 19th century was a period of growing realism in literature, it was also a period of growing expressiveness in painting and music. Whatever the reason for this change of attitude, the 19th century saw a general acceptance of the notion that buildings were "true" only insofar as their structural form and appearance corresponded to the structural systems and materials employed, and this dogma was developed by means of many elaborate biological and mechanical analogies.

This particular doctrine had a highly beneficial influence on architectural evolution during the 20th century, since it helped to demonstrate why the radical changes in building technology rendered earlier concepts of architectural form (based on load-bearing masonry construction) theoretically untenable. For, while it may readily be admitted that a building can express many other things besides its function and structure, failure to express the latter in some manner, however remote, must always lead to arbitrariness. This would not only be harmful to the evolution of architectural form but would inevitably result in a somewhat cynical concept of building as "pure form"—a concept that only those who regard architecture as nothing more than large-scale packaging or abstract sculpture could accept. (Pe.C.)

The History of Western Architecture

Architecture, the art of building, is perhaps the best example of the partnership and basic identity of a fine and a useful art, beauty and utility, form and function. A building—whether a temple, church, factory, office complex, exhibition hall, or domestic dwelling—must demonstrate the solution of the practical problems associated with its purpose. In addition, the building must show the careful manipulation of structural and ornamental materials, used to express aesthetic, cultural, or symbolic ideas.

The primary concern of the architect is the definition and articulation of exterior space and the spanning and enclosure of interior space. The moment a square or circle has been described on the ground, one area has been physically and intellectually separated from another and the architectural process has begun. As the architect spans the space—on the ground as with a wall or road or in the air as with an arch or bridge—he encounters not only the complex technical problems of the craft but aesthetic factors as well. Materials must be molded with an eye for the proportions of masses and voids; for the interaction of qualities, textures, colours, and capacities of these materials; for the harmonious relationship of open windows and doors to closed wall space; for the control and flow of lighting; and above all for architecture in action—that is, for the shelter, comfort, and movement of the people who will be living, working, and carrying on their various activities within the building.

The history of architecture may be read in the progressive changes in the solution of structural problems. The transition from the most primitive shed roof and simple truss construction to the vertical posts, or columns, supporting horizontal beams, or lintels, covers the period from the beginning of civilization through ancient Greek culture. Greek architecture also formalized many structural and decorative elements into three of the classical orders—Ionic, Doric, and Corinthian—which, to a greater or lesser

extent, have influenced architectural style since that time. The Romans exploited the arch, vault, and dome and made broader use of the load-bearing masonry wall; and in the late medieval period the pointed arch, ribbing, and pier systems gradually emerged. At this point all the problems of brick and stone masonry construction had been solved, and little innovation except in decoration was achieved until the Industrial Revolution. Not until the 19th century, with the advent of cast-iron and steel construction, did a new architectural age dawn and higher, broader, and lighter buildings become possible. With the advances of 20th century technology, new structural methods such as cantilevering received more extensive use.

Building materials evolved in much the same way from simple, often perishable materials such as primitive grass thatch, stick frame, and wattle and daub to more durable materials such as clay, adobe, brick, stone, and cement. The modern use of reinforced and pre-stressed ferroconcrete and of various metals, including steel, copper, and aluminum, as well as of glass and structural fabrics and plastics, has led not only to more daring structural innovations but also to much beauty through the realization of the inherent qualities of such materials and their use in novel decorative schemes.

In postmodern architecture the classical orders have been reintroduced as one of a number of contrasting design methods, so that late 20th-century architecture attempted to include historical references in its design approach and was characterized by a new aesthetic pluralism.

European Metal Age cultures

AEGEAN AND EASTERN MEDITERRANEAN

The islands of the eastern Mediterranean and the Aegean Sea form a natural link between the landmasses of the Middle East and Europe. A westward expansion from the civilizations of western Asia and Egypt began about 3000 bc and led to settlements in Crete, the Cyclades, and mainland Greece. The fundamental difference between these and the earlier, Neolithic cultures is that stone tools and weapons were replaced by those made of copper and, later, bronze. The Chalcolithic (Copper-Stone) Age, lasting in the Aegean area from the early 3rd millennium bc to the beginning of the 2nd, is usually considered a part of the greater Bronze Age, which was superseded by the Iron Age from about 1200 bc.

The hallmark of the Aegean civilizations was the facility with which Asiatic motifs and techniques were adapted to form original local styles. In architecture, by far the most important achievements were those of the civilizations of Minoan Crete and Mycenaean Greece.

Minoan Crete. The great maritime civilization of Crete crystallized around palaces such as those at Knossos, Phaestus, Ayía Triáda, Mallia, and Tylissos. The immensely important Palace of Minos at Knossos, excavated and reconstructed early in the 20th century by Sir Arthur Evans, offers evidence of unbroken architectural and artistic development from Neolithic beginnings, culminating in a brilliant display of building activity during the third phase of the Middle Minoan period (1700–1580 bc) and continuing until the invasion of the Achaeans in the 12th century. The palace, however, is essentially a structure of the late two Middle Minoan periods (1800–1580 bc). It no doubt rivaled Middle Eastern and Egyptian palaces in monumentality. As in these, a quadrangular complex of rooms and corridors is grouped around a great central court, at Knossos roughly 175 × 100 feet (50 × 30 metres). At the northern end, toward the sea, a grand portico of 12 pilasters gave access to the central court. At this end, also, is situated the grand theatrical area, a rectangular open-air theatre perhaps used for ritual performances. The east wing of the palace is divided into two parts by a long corridor running on an east–west axis; originally it rose four or five stories above the slope of the valley. The southeast portion of the palace contains domestic apartments, elaborately supplied with plumbing and flushing facilities, as well as a sanctuary. A wide stairway led to an upper story, which no longer exists. The northeast portion of the palace is occupied by offices and storerooms. The west portion is again divided by a main corridor, more than 200 feet long, running north and south. Behind this corridor, along the western side, was discovered a series of long narrow storerooms containing great numbers of pithoi, or human-size storage vessels for oil. On the other side of the corridor, facing toward the central court, are

the rooms of state, including the throne room with its unique gypsum throne and world-famous griffin frescoes.

Light was supplied from above by an ingenious system of light wells, and several colonnaded porticoes provided ventilation during the hot Cretan summers. Brilliantly hued frescoes played an important part in both the interior and the exterior decoration of the palace.

The development of the other Minoan palaces (Phaestus, Mallia, Ayía Triáda, Tylissos) roughly parallels that of Knossos. Each has its special interest, and Phaestus is particularly fascinating, due to extensive Italian excavations. Maritime hegemony enabled the Cretan sea kings to build these palaces in low and unprotected places; consequently there is a conspicuous absence of fortification walls, as contrasted to the great walls of Mesopotamian palaces. Since Cretan worship seems to have been conducted largely in the open air, there are no real temples as in the Middle East. Yet, the disposition of the various parts of the palace around the central court and the avoidance of outside windows as much as possible are characteristics that seem to indicate an early contact with the Middle East. A taste for long, straight palace corridors, as well as a highly developed water-supply system, may also have been inherited from older civilizations to the east. The column made its first European appearance in the Cretan palace, where it is often employed individually to divide an entranceway.

The development of funerary architecture in Crete proceeds from the old chamber ossuaries of the Early Minoan period (2750–2000 bc) to the developed tholoi, or beehive tombs, of the Mesara plain and the elaborate temple-tombs of Knossos that appeared at the end of the Middle Minoan period.

On the crest of Minoan prosperity came the great crash. An invasion from the mainland about 1400 bc destroyed the palaces and resulted in the removal of power to Mycenaean Greece. Architectural remains in Crete of structures that are pre-Greek in design and yet were built subsequent to this catastrophe are very rare. Several country shrines belong to this post-destruction period, and at Prinias a unique temple building may date from as late as 700 bc. The doorway of this temple, now in the Archaeological Museum at Iráklion, has low reliefs on its architectural members. The opening above the lintel is flanked by seated figures, while the lintel itself is carved on its underside with figures of a goddess and of animals. That the Minoan tradition was not entirely extinct is indicated by the column that seems to have stood in the middle of this doorway, as at the Palace of Minos.

Mycenaean Greece. The sudden architectural awakening of the Mycenaean Greek mainland is intimately connected with the zenith and decline of Minoan Crete and can only be understood against the background of a long Cretan development. Unlike Minoan Knossos, the archaeological remains on the mainland are fragmentary.

Palace of
Minos

Figure 1: Cross sections and plan of the Treasury of Atreus, Mycenae.

Redrawn after Fig. 5 in Alan J.B. Wace, *Mycenae: An Archaeological History and Guide* (copyright 1949 by Princeton University Press). Reprinted by permission of Princeton University Press.

Knowledge of at least three sites, Mycenae, Tiryns, and Pylos, suggests a picture of Mycenaean architecture. The important architectural monuments visible today date largely from Late Helladic times (1580 to c. 1100 BC), and little earlier architecture is preserved.

Fortification. The tremendous building activity of the 14th century BC reflects an age of warfare, when powerful Greek-speaking kings built fortresses in key defensive positions on the mainland. The cyclopean walls (*i.e.*, walls in which great blocks of irregular untrimmed stone fitted together without mortar were employed) of Mycenae and Tiryns and the strategically placed Lion Gate at Mycenae were constructed in this period. The latter consists of two colossal doorjambs that support a monolithic lintel. The wall above the gate is so constructed as to form a relieving triangle over the lintel, and this space is blocked with the famous relief panel of two heraldic lions, which has given the gate its name. This method of construction provides an ingenious substitute for the arch, which was unknown to the Mycenaean.

Also justly famed are the concealed galleries of Tiryns, where the primitive corbel vault (constructed of rows of masonry placed so that each row projects slightly beyond the one below, the two opposite walls meeting at the top) makes its first appearance in mainland Europe.

Palaces. Mycenaean palaces have been unearthed at Mycenae, Tiryns, Pylos, Gla, and Phylakopi (Cyclades). The palace at Pylos is a typical mainland palace of the Heroic Age as described in the poetry of Homer. The characteristic plan comprises four elements: (1) a narrow court on which the structure fronts; (2) a double-columned entrance portico; (3) a vestibule (*prodomos*); and (4) the richly frescoed *domos*, or hall proper. The latter had a fixed throne at one end and a central fixed hearth between four wooden columns that supported an open towerlike structure rising above the roof for light and ventilation. Archives, comparable to those of the Hittite kings at Boğazköy, were associated with this palace. Private houses, such as have been discovered at Mycenae, exhibit similar features as well as the basement storage magazines mentioned by Homer.

Tombs. The earliest royal burials known from Mycenae are those of the two grave circles, the first discovered by Heinrich Schliemann in 1876 and the second by Alan J.B.

Wace in 1951. These grave circles have no architectural character, consisting essentially of vertical shafts cut into the bedrock.

More important architecturally are the tholoi. The evolution of these family sepulchres began in Minoan Crete but culminated in the so-called Treasury of Atreus at Mycenae, now believed to have been constructed as late as about 1250 BC (Figure 1). This most impressive monument of the Mycenaean world is a pointed dome built up of overhanging (*i.e.*, corbeled) blocks of conglomerate masonry cut and polished to give the impression of a true vault. The diameter of this tomb is almost 50 feet; its height is slightly less. The enormous monolithic lintel of the doorway weighs 120 tons and is 29½ feet long, 16½ feet deep, and three feet high. It is surmounted by a relieving triangle similar to that over the Lion Gate and decorated with relief plaques carved in a variety of coloured stones. A small side chamber hewn out of the living rock contained the burials, whereas the main chamber was probably reserved for ritual use. Two engaged half columns (*i.e.*, attached to the wall and projecting from it for about half their diameter) of Cretan type (now in the British Museum, London) were secured to the facade, which was approached by a dromos, or ceremonial passageway, revetted with cyclopean blocks of masonry and open to the sky. Other tholoi, not as well preserved, exist at Mycenae and Orchomenos. (H.Hn./Ed.)

WESTERN MEDITERRANEAN

Bronze Age cultures. Metalworking improved and promoted the progress of the western Mediterranean lands, which developed maritime relations joining them to one another and binding them to the eastern Mediterranean. Several great centres displayed considerable architectural activity, of which some splendid evidence remains.

Iberia. The Bronze Age was a brilliant stage of culture in the Iberian Peninsula and was designated El Argar, honouring the name of a great site of southeastern Spain. El Argar, which stood well fortified on a plateau about 1,000 feet long and about 330 feet wide, enjoyed, from 1700 BC, several centuries of prosperity and exerted an influence that spread over the eastern coasts of Spain and over southern Portugal. A necropolis of about 1,000 burials has yielded goods of quality from the graves. The El

Lion Gate

El Argar
culture

Argar culture had continuing contacts with the Balearic Isles, Malta, and Sardinia.

Balearic Isles. In the Balearic Isles the Bronze Age corresponds to the 2nd millennium BC and is designated "talayotic" from the name of the talayot, a megalithic monument in the form of a round or quadrangular tower. Majorca still has about 1,000 talayots, and Minorca has more than 300. These high numbers indicate the amplitude of construction activity, implying precise architectural planning and the coordination of the efforts of human groups. Their intended purpose varies: they may be defensive towers, places of worship, or funerary monuments. There are also other types of megalithic monuments in the Balearic Isles; for example, navetas, or collective tombs built in the form of ships, and Minorcan taulas, composed of a monolithic column topped by a slab and today recognized as places of worship. This megalithic architecture, which is imposing in conception and skilled in execution, continued into the 1st millennium BC, the early Iron Age, and made the Balearic Isles an exceptional ground for the study of the structures of the pre-Roman era.

Malta. Malta had experienced a magnificent flourishing of underground burial chambers, or hypogea, and megalithic temples in the Neolithic period (Figure 2). These Neolithic temples are among the first instances in Europe

Figure 2: One of the chambers of a megalithic temple at Tarxien, Malta, Late Neolithic (2300–1900 BC).

of buildings erected for a particular functional purpose. They have a trefoil plan and a roof construction of corbelled stone that is the earliest known example of its kind. The arrival of Cycladic and Cretan influences in Malta stimulated the birth of a stone and terra-cotta statuary representing the deities and their worshipers. This continued brilliantly in the Copper Age, but the beginning of the 2nd millennium witnessed the appearance of a new people who conquered and destroyed, which is well known from the cremation burial ground of Tarxien. Small terra-cotta female idols recall contemporary figurines of Cyprus, but the culture was rapidly impoverished.

Sardinia and Corsica. It is necessary to go farther north—Sardinia and Corsica—to find an original and prosperous Bronze Age, the creations of which continue to pose certain problems of interpretation. The Sardinian bronze civilization is characterized by the nuraghi, round towers that may occur alone or form the centre of complex fortified arrangements. About 7,000 of them, dating from about 1500 to 1100 BC, have been discovered on different parts of the island. They are efficiently and skillfully constructed defensive fortresses, the interior arrangements of which give evidence of an art developed out of military

architecture. Around the nuraghi press the round huts of villagers, which are, in turn, surrounded by solid ramparts. The complex thus constitutes an architectural unity, which arose from a patriarchal society in which families fearfully gathered around their clan chief. There is a kind of rough beauty in these true fortified castles, with their compact and severe appearance. Tribal battles and the Phoenician conquest in the 7th century BC led to the decline and disappearance of the nuraghic civilization.

On neighbouring Corsica, fine megalithic structures, such as dolmens and isolated or grouped menhirs, were made during the Neolithic Period. This megalithic architecture continued in the Copper Age and throughout the Bronze Age. Populated centres were provided with a fortified arrangement; Filitosa, for example, with its elliptical surrounding wall, its menhir statuary erected in a place of worship, and its defensive towers.

Italy. From 1500 BC there developed in Emilia, in northern Italy south of the Po River, the Terramare culture, a curious world of *terramare*, habitations built on pilings and protected by a vallum, or defensive wall, which screened them from floods in a flat countryside where seasonal rains are violent. Their name (singular *terramara*) comes from the word *terra-marna* ("rich land") in the dialect of Emilia and results from the considerable archaeological deposit that these dwellings left behind. These villages, whose dead were cremated, lasted until the Early Iron Age. The society was peasant, and, once again, its art was limited to the construction of dwellings and to the production and ornamentation of weapons and vases.

Iron Age cultures. Iberia. Highly interesting artistic flowerings occurred in Spain at the end of the protohistoric era. First, in the southwest of the peninsula, near the town of Cadiz, there developed at the extreme end of the 2nd millennium BC a civilization, still poorly understood, that tradition attributes to the semi-historic, semilegendary state of Tartessus. Archaeology has not yet revealed the splendour ascribed by the ancients to the Tartessian culture, which was strongly influenced by early Phoenician commercial contacts from the southern coast of Spain. Along the coasts of the Levant and penetrating deeply into the interior of the peninsula, an indigenous population, the Iberians, developed a truly original art under combined Grecian, Carthaginian, and Phoenician influences.

Many Iberian dwelling sites have been discovered on the eastern coasts of Spain, where they were established on such high places as steep-sloped plateaus and protected by surrounding walls with round and square towers and doors. The street network does not seem to follow a regular plan. Great temples such as those of Castellar de Santisteban and Despeñaperros in the Sierra Morena have sacred storerooms where a great number (about 6,000 for the two sites) of votive statuettes have been discovered.

Italy. The fate and art of the Etruscan people—who made their appearance in the heart of Italy between the Arno and Tiber rivers about 700 BC and vanished, under the legions' blows, in the last centuries of the Roman Republic—must be mentioned here because in the early years of their existence they were deeply involved in Italic protohistory. In antiquity the Etruscans were regarded as skillful architects and excellent builders. Precise ritual rules of town planning made it possible for them to construct cities on regular plans, the most beautiful remains of which are those of Marzabotto, near Bologna, and of Capua, in Campania. Nothing much remains of the Tuscan cities, which were, nevertheless, very splendid. On the other hand, there remain thousands of tombs that reveal the structure of the vanished houses. The tomb was the dwelling of the dead and simulated the appearance of one or several rooms, constructed in bedrock and built of stone. Thus well protected, Etruscan grave goods and artistic creations were preserved. (R.Bl./D.J.Wa.)

What little remains of Etruscan stonework has survived by virtue of its massiveness. Foundations of city walls survive at Volterra, Volsinii, and Cortona, but those of Perugia are more complete and have surviving vaulted gates. The tombs, themselves replicas of house interiors, show something of moldings, arches, and vaults. True vaulting and arching were known, and these enabled buildings

Iberian
dwelling
sites

nuraghic
civiliza-
tion

larger than those of Greece to be constructed. Wood was the chief building material for domestic purposes and for temples, from which the terra-cotta decorations alone survive. Blocks of houses in carefully paved streets are known only from Marzabotto, although the layout of the tombs with paved streets in the Banditaccia at Caere and the Cuccumella at Vetulonia makes them veritable cities of the dead. The Latian hut urns show that houses of the Villanovan period (8th century BC) were circular in plan with conical roofs, but a stone urn from Clusium is modeled in the form of a rectangular Etruscan house erected on a tall, stepped platform. The roof is a hipped gable and has a gabled gallery over it. In this connection it is interesting that the Romans attributed to the Etruscans the construction of the atrium house. Temples were rectangular in plan and divided into three cellae (chambers); ground plans and nothing more are known from Rome and Bolsena. Etruscan temples, such as those of which remains survive at Bolsena and Orvieto, were built of wood and brick upon high platforms of dressed stone and were consequently more perishable than their Greek equivalents. They were crowned and decorated by brightly painted statues and revetments of terra-cotta, many of which have survived.

(W.Cu./D.J.Wa.)

Ancient Greek

The increased wealth of Greece in the 7th century BC had been promoted by overseas trade and by colonizing activity in Italy and Sicily that had opened new markets and resources. Athens did not send out colonists and did not engage in vigorous trade, and it declined as a cultural and artistic centre. Corinth, Sparta, the islands, the cities of eastern Greece, and Crete came to the fore with their diverse artistic interests and means of expression. At no other time were there such strongly differentiated regional schools of art in the Greek world. The cities demonstrated their wealth and power, particularly in temple building, which was to foster new architectural forms, and also in the decoration of the temples and of the national sanctuaries. These architectural arts in turn encouraged imaginative and ambitious forms in sculpture and painting.

THE EARLY PERIODS

Throughout the history of Greek art, the architect's main role was to design cult buildings, and until the Classical period it was virtually his only concern. The focus of worship in Greek religion was the altar, which for a long time was a simple block and only much later evolved into a monumental form. It stood in the open air, and if there was a temple, generally the altar was positioned to the east of it. The temple was basically a house (*oikos*) for the deity, who was represented there by his cult statue. Temple plans, then, were house plans—one-room buildings with columnar porches (Figure 3). To distinguish the divine house from a mortal one, the early temple was given an elongated plan, with the cult statue placed at the back, viewed distantly beyond a row of central pillar supports. The exterior came to be embellished by a peristyle, an outer colonnade of posts supporting extended eaves. This colonnade provided a covered ambulatory (roofed walkway), and it was also a device to distinguish the building

from purely secular architecture. This plan can be seen in buildings on Samos and at Thermum in central Greece. The construction remained simple: well-laid rubble and mud brick, with timbering and a thatched or flat clay roof. By about 700 BC, fired-clay roof tiles made possible a lower pitched roof, and by the mid-7th century, fired- and painted-clay facings were being made to decorate and protect the vulnerable wooden upperworks of buildings. As yet, nothing had been constructed in finished stone.

The Orientalizing period. From about 650 on, the Greeks began to visit Egypt regularly, and their observation of the monumental stone buildings there was the genesis of the ultimate development of monumental architecture and sculpture in Greece. The first step in architecture was simply the replacement of wooden pillars with stone ones and the translation of the carpentry and brick structural forms into stone equivalents. This provided an opportunity for the expression of proportion and pattern, an expression that eventually took the form of the invention or evolution of the stone "orders" of architecture. These orders, or arrangements of specific types of columns supporting an upper section called an entablature, defined the pattern of the columnar facades and upperworks that formed the basic decorative shell of the Greek temple building.

The Doric order was invented in the second half of the 7th century, perhaps in Corinth. Its parts—the simple, baseless columns, the spreading capitals, and the triglyph-metope (alternating vertically ridged and plain blocks) frieze above the columns—constitute an aesthetic development in stone incorporating variants on themes used functionally in earlier wood and brick construction. Doric long remained the favourite order of the Greek mainland and western colonies, and it changed little throughout its history. Early examples, such as the temple at Thermum, were not wholly of stone but still used much timber and fired clay.

The Ionic order evolved later, in eastern Greece. About 600 BC, at Smyrna, the first intimation of the style appeared in stone columns with capitals elaborately carved in floral hoops—an Orientalizing pattern familiar mainly on smaller objects and furniture and enlarged for architecture. This pattern was to be the determining factor in the full development of the Ionic order in the 6th century.

The Archaic period (c. 750–500 BC). About 750 BC there began a period of consolidation of the diverse influences that had been entering Greek art at a rapid rate over the previous 100 years; it is known as the Archaic period. It was an age of preoccupation with domestic troubles brought on by the new prosperity rather than an age of reaching out to other cultures. It was also the age of the tyrant, whose individual rule was often supported by arms and by the allegiance of the merchant classes. The courts of these tyrants became the significant cultural centres, and there was an increase in the demand for art of all kinds; demonstration of the rulers' wealth and power took the form of temple building more ambitious than in almost any other period of Greek art, while in sculpture there was a growing use of expensive and elaborate statuary for dedication and for marking tombs. In contrast to the previous relation of Greece to the outside world in art, there developed for the first time a substantial production of bronzes and pottery for export; sometimes styles or motifs were even deliberately conceived with the foreign customer in view.

During this period the arts of sculpture, vase painting, and bronze working reached a level of technical mastery and imaginative freedom that brought narrative action and even emotion under the command of figural representation. Simultaneously, out of extensive experimentation with the architectural innovations of the later 7th century, the Classical Doric and Ionic orders were fully established and largely standardized.

In the 6th century the western Greek colonies claimed a position of importance in the history of Greek art. The colonies in southern Italy and Sicily had grown as strong and rich as many cities in the motherland and had made similar demonstrations of wealth by the dedication of treasures in the national sanctuaries and by lavish temple building at home. The temples were generally in the Doric

style, but they often bore Ionic details. In their sculpture and architecture the colonies were handicapped by the lack of local sources for fine white marble, and they relied more on painted and stuccoed limestone; the lack of marble, however, stimulated their production of major sculptural works in fired clay to a degree not matched at home. The colonial art centres seem to have been Syracuse, Selinus, and Agrigento in Sicily and Poseidonia, or Paestum (Figure 4), Sybaris, and Tarentum in Italy. Although the Greek colonies seem to have attracted artists from the homeland, all their art tends to a largeness of scale and of detail that often contrasts with popular notions of Greek monumental art. For example, the most striking ancient building on Sicily is the colossal Doric temple of Olympian Zeus at Agrigento, begun in about 500 BC and left unfinished a century later. To carry the weight of the massive entablature, the outer columns were not freestanding but were half-columns engaged against (that is, partially attached to) a continuous solid wall. An earlier Sicilian variant of this use of the plastically molded wall mass with the orders applied decoratively can be seen in the columnar curtain walls of Temple F at Selinus, begun about 560 BC. The engaged columns of Agrigento were echoed in the late 5th century by the architect Ictinus in the cella of the Temple of Apollo at Bassae and half a century later by the sculptor Scopas in the Temple of Athena at Tegea. All these buildings suggest that the 18th-century Enlightenment idea of Greek architecture as a system based solely on post-and-lintel construction, in which the columns carried the load, was erroneous.

Because temples constructed entirely of stone were expensive, they were not replaced without a compelling reason; in many central and southern Greek cities, therefore, the robust Archaic forms of the Doric temples dominated the townscape through the Classical and later periods. The forms were heavy, with plump columns and capitals and brightly coloured upperworks. Although little change was made in the basic order in the 6th century, there was a gradual refinement of detail and proportion approaching the Classical form of the order (Figure 5). At this time also the place of sculpture in Doric architecture was once and for all established.

The more exotic Ionic order of eastern Greece was slower to determine its forms; the order developed through the so-called Aeolic capital with vertically springing volutes, or spiral ornaments, to the familiar Ionic capital, the volutes of which spread horizontally from the centre and curl downward. There were also several distinctive local methods of treating bases or entire plans. The order was always fussier and more ornate, less stereotyped than Doric, yet it was still limited to monumental plans, and the Ionic temples of the 6th century exceed in size and decoration

even the most ambitious of their Classical successors. Such were the temples of Artemis at Ephesus in Asia Minor and the successive temples of Hera on the island of Samos, all of which were more than 300 feet long and set with forests of more than 100 columns standing in double and triple rows around the central rectangular room (cella), where the cult image stood. At the same time, masons developed and refined the carved cyma (double curve) and ovolo (convex curve) moldings, which are two profiles that have remained part of the grammar of Western architectural ornament to the present day.

THE CLASSICAL PERIOD

Early Classical (c. 500–450 BC). The only significant architectural work of the early Classical period was at Olympia, where a great Temple of Zeus was built in about 460. This temple was the first statement of Classical Doric in its canonical form and one of the largest Doric temples of the Greek mainland.

High Classical (c. 450–400 BC). By far the most impressive examples of Greek architecture of the high Classical

order

The buildings of the Acropolis

cal period were the buildings constructed under Pericles for the Athenian Acropolis. The Acropolis architecture, which is in several ways a clear display of civic pride, also exhibits considerable subtlety of design in the use of the Doric and Ionic orders. The ensemble of the major buildings—the Parthenon, a temple to Athena; the Erechtheum, a temple housing several cults; and the monumental gateway to the Acropolis, the Propylaea—shows the orders used in deliberate contrast: the Erechtheum provides a decorative Ionic counterpart to the severe Doric of the Parthenon, which itself has an Ionic frieze; and in the Propylaea, columns of both orders complement each other.

The Parthenon, designed by the architect Ictinus, is a broader, more stately building than most Doric temples, with an eight-column facade instead of the usual six. With the four-square Doric style there had always been the possibility of giving an impression of dull immobility, a danger that in the Archaic period was partially avoided through the use of bulging columns and capitals. In the Classical period—and best observed in the Parthenon—a subtle deviation from strict linearity accomplishes the same correction. The Parthenon was the display place for a great statue of Athena by the sculptor Phidias, a statue that honoured the city goddess but not the oldest cult of Athena, which was housed in the Erechtheum. The obvious implications of civic pride are enhanced by the unparalleled portrayal of a contemporary event on the frieze of the building: the procession of citizens in the yearly festival in honour of Athena. The Erechtheum was a more complicated building than the Parthenon; built on an awkward site, it also had to serve different cults, which meant that its architect had to design a building with three porches and three different floor levels. Its Caryatid porch, with figures of women for columns, makes use of an old Oriental motif that had appeared earlier, in Archaic treasuries at Delphi. The Propylaea was designed by Mnesicles, who had to adapt the rigid conventions of colonnade construction to a steeply rising site. In the precision and finish of their execution, which complements the brilliant innovation of their design, these three buildings had no rival in the Greek world.

Other architecture of the high Classical period

By this time use of the orders was no longer confined to temple buildings. The marketplace at Athens was adorned with various public buildings in which the orders were applied to structures of different plans: the colonnade stoa, or portico, a council house, and even a circular clubhouse for state officials. The stage buildings of theatres began to receive monumental treatment as well, although the action still took place on the flat circular orchestra and the seats were for the most part still wooden (or were missing—the audience sitting upon the bare hillside that was usually chosen for theatre sites) rather than stone. Several new Doric temples were also built in the lower city of Athens and in the Attic countryside. The Ionic order was used only for the smaller temples, as for the Temple of Athena Nike on the Acropolis; but even though the Ionic was never to be used as the exterior order for major buildings on the Greek mainland, Athens did contribute new forms of column base to the order.

At Bassae in remote Arcadia in the mountains of the Peloponnese, a Doric temple was built for Apollo incorporating unusual variants on the Ionic column in the interior and a new type of capital, which had two rows of acanthus leaves curling below the volutes—the first recorded Corinthian capital. This type was reputedly invented by the sculptor-architect Callimachus to provide an alternative for the Ionic order that could be viewed from any side and so placed at corners or in interiors. It was difficult to carve, however, and slow to win favour in Greece.

Late Classical (c. 400–323 BC). With growth now concentrated in outlying areas, there was understandably less temple building in mainland Greece in this period than there had been in the 5th century, but the Doric temples at Tegea and Nemea in the Peloponnese were important, the former for admitting Corinthian capitals to columns engaged on its interior walls. In eastern Greece, on the other hand, there began a series of new temple constructions rivaling those of the Archaic period but consciously copying the Archaic in their plan and elaboration of detail.

Some are simply replacements, such as that at Ephesus replacing an earlier temple destroyed by fire, or the rather later one at Didyma. Similarly, the town of Priene in Ionia, although built on a new foundation after the mid-4th century, was laid out as a grid of streets on a principle developed by the 5th-century architect Hippodamus, who had applied the same scheme to his home city, Miletus, and to the port of Athens, Piraeus. The new Athena Temple at Priene is the best example of classic Ionic known, with no eccentricity of plan or detail. The eastern Greeks had long worked for their neighbours in the Persian towns of Lycia and Caria, supplying monumental tombs of native pattern decorated with sculpture in Greek style. At Xanthus, the capital of Lycia, a tomb resembling a Greek temple raised high on a platform had been built by the end of the 5th century; and similar structures were made there in the 4th century, culminating in the great tomb built in mid-century at Halicarnassus for King Mausolus of Caria, a king who has given his name to all such monumental mausoleums. The fine architectural detail and the sculpture (British Museum, London) executed by Greek artists of the first rank show a total Hellenization of local taste and exemplify the high quality that Greek art in foreign lands had attained at this time.

The 4th century saw much greater diversity of architectural forms than ever before. Theatres received marble seats and elaborate stage buildings. Circular temples (tholoi) appeared in mainland Greek sanctuaries—Doric in style but with the new Corinthian columns within. A small-scale tholos with Corinthian columns was also used for the choragic monument of Lysicrates in Athens (Figure 6). The two-storied stoa became an essential element in the planning of marketplaces or administrative areas. Architects were at pains to adapt the rigid orders to architectural forms and needs more complicated than those of the basic Greek temple plan.

HELLENISTIC PERIOD

The successors to Alexander's empire split the new Greek world, which now ran to the borders of India in the east and the Sudan in the south, into separate kingdoms. The generals who ruled them established dynastic control and created a court life that provided a type of stimulus to the arts that had not been experienced in Greece since the Bronze Age. The Attalids, who had become the rulers of Pergamum in northwest Asia Minor, constructed there a new capital city in which influential schools of sculpture and architecture flourished. The Seleucids ruled the Eastern world as far as Persia, and under them the art of architecture in particular evolved in near-Baroque forms that were to have their effect on Roman architecture. In Egypt the Ptolemies, at the new capital city that bore Alexander's name and was founded by him, built the famous lighthouse and library; and there another important sculptural school developed. In the Aegean world, Rhodes proved an important centre and so, of course, did the Macedonian homeland in the north. By comparison, the great cities of central Greece declined in importance; but Athens in particular had a hold on the imagination of Greeks everywhere for its former role against the Persians and the achievements of the Classical period, and as a result it benefited from the gifts of the new kingdoms, especially in building.

Alexander's aspirations and closer knowledge of Eastern and Egyptian ways led the new rulers to take more seriously their roles of near divinity. This gave considerable impetus to the art of portraiture, since these rulers thus deserved commemoration as much as any god; in fact, even private citizens aspired now to some heroic status after death, so that portrait monuments for tombs and honorific statues became more common. Except for this growth of portraiture, however, the mood in the arts during the Hellenistic period was to intensify and elaborate styles developed by Classical Greece. Palatial architecture aimed at effects never contemplated hitherto; and even domestic architecture for the first time had palatial pretensions. Trade and the newly acquired resources of the East opened up new possibilities for the artist, in both materials and inspiration; the results, however, generally tended to elaboration and grandeur such that the finer qualities of balance and precision characteristic of earlier periods are often difficult to discern in later works.

The Classical form of the Doric temple was out of favour in the new age, and the few that were built are elaborate in plan and detail, impairing the sober quality of the order. This age appreciated the Ionic and the more flamboyant Corinthian forms, and at any rate most new temple building was done in the new eastern areas of the Greek world, where Ionic had been the usual idiom. The 3rd-century architect Hermogenes of Priene codified the Ionic order in his books, and his buildings popularized new features in plan, notably the broad flanking colonnades ("pseudo-dipteral"), where the earlier Ionic temples of eastern Greece had set ranks of columns. For the first time the Corinthian order was used for temple exteriors, and work was resumed on the great Temple of Olympian Zeus at Athens, financed by an Eastern king, Antiochus IV Epiphanes. The two-storied stoa became an architectural form of importance, serving as hotel, emporium, or office block, and the design of central market and administrative areas depended largely on the disposition of such buildings. An Attalid king paid for a fine stoa for Athens' marketplace, recently restored; and his city of Pergamum seems to have been important in developing stoa design.

Monumental tombs were naturally still required for ruling families, but nobles and the nouveaux riches could also aspire to them now, designing some as minor sanctuaries for the heroized dead. The finest Macedonian tombs of the period displayed a painted architectural facade below ground, leading to a painted and elaborately furnished vaulted underground chamber. The variety of administrative and court requirements for buildings led to original designs that broke still more decisively with the colonnade orders of Classical temples. A few important examples of particularly original designs are the famous lighthouse (Pharos) of Alexandria with its tiers of masonry 440 feet

high; the library of Alexandria; the clock house Tower of the Winds at Athens; monumental fountains and assembly halls; and a new elaboration of stage architecture for theatres, in which for the first time the acting took place on a raised stage. To the established decorative repertory of moldings and carved ornament was added a variety of floral and animal forms that enriched the surface decoration of buildings. In the East especially these forms were combined in original ways that, together with compositions that defied the logic of the Classical orders, tended to a style that in many respects anticipates the Baroque. Slowly, too, the advantages of arch and vault, avoided hitherto by Greek architects, were exploited; but architecture was still basically that of mass on mass, and it was left to Rome to make significant progress in construction methods. (Jo.Bo./D.J.Wa.)

Roman and early Christian

Rome before the Etruscan advent was a small conglomeration of villages. It was under the new masters that, according to tradition, the first public works such as the walls of the Capitoline Hill and the Cloaca Maxima were constructed. Considerable evidence of the Etruscan period in Rome's history has come to light in the region of the Capitol. That there were rich tombs in Rome itself cannot be doubted—tombs similar to those in the Latin town of Praeneste. Meanwhile, by the beginning of the 6th century BC the Etruscans had included Fiesole and Volterra in their northern limits and at the same time began to push southward into Campania. Capua became the chief Etruscan settlement in this region and Nola a second; a necropolis has been found in the Salerno region and Etruscan objects in low levels at Herculaneum and Pompeii. The coastal region was still, however, in Greek hands. (W.Cu.)

REPUBLIC AND EMPIRE

Roman architecture was almost as complex as the Roman Empire itself; it was influenced by a multitude of geographic, climatic, political, economic, social, and cultural factors. The cohesive factor through all the differences was the Roman character, which possessed the talent and felt the necessity to organize in large and complex terms, politically, architecturally, or otherwise.

Modern knowledge of Roman architecture derives primarily from extant remains scattered throughout the area of the empire. Some are well preserved, and others are known only in fragments and by theoretical restoration. Another source of information is a vast store of records, including dedicatory and other inscriptions on public works. Especially important is a book on architecture by the architect Vitruvius, who lived about the time of Christ. His book *De architectura* (c. 27 BC) is a handbook for Roman architects and covers almost every aspect of architecture, but it is limited because it was based on Greek models and was written at the beginning of a more creative phase of Roman architecture, in the period of the empire.

Building materials. The material employed in the earliest buildings constructed around Rome was tuff, a volcanic rock of varying hardnesses, some soft enough to be worked with bronze tools. Later, other harder volcanic stones were used, such as peperino and albani stone from the nearby Alban hills. Under the later republic and the empire the most important stone for building was travertine, a limestone quarried mainly at Tivoli. An example of the use of travertine is the exterior of the Colosseum in Rome. The use made by the Romans of marble was mainly decorative. It was set in cement and applied in slabs to brick and concrete walls. It was used for pavements either in slabs cut and arranged in patterns or as mosaic. Under the empire a great demand arose for coloured marbles and such stones as porphyry, granite, and alabaster, which were imported from various parts of the empire. The abundant use of these marbles is well illustrated by the remains of the Flavian palace on the Palatine Hill in Rome and of Hadrian's Villa at Tivoli.

Unburned bricks faced with stucco were used especially for private houses during the republic. Of these, naturally,

Sources of modern knowledge about Roman architecture

first
major
se of the
Corin-
thian order

very few remain. Under the empire, kiln-baked bricks and tiles were the most common facing for concrete. They were never used to build a whole wall in the modern manner but merely as a protective skin. These bricks or tiles were almost always used in triangular shapes. Large tiles about two feet square called *bipedales* were also employed.

Use of
stucco and
concrete

The use of stucco over unbaked brick and over coarse stone was prevalent from the earliest times in Greece, Sicily, and Italy. It served as a protection against the weather and also as a finish. Later it was used over brick and concrete. It was often made of lime, sand, and fine marble dust, and some forms would take a high polish or fine molding. Thus, it became the usual ground for decoration especially in the interiors of houses, examples of which abound at Pompeii and Rome. Bronze was another material primarily used in a decorative manner; doors, grilles, panels of ceilings, and other details were made of it.

For their concrete the Romans used pozzolana, of which there are extensive beds at Pozzuoli, near Naples, and around Rome. It is a fine, chocolate-red volcanic earth, which when mixed with hydrated lime forms an excellent cement that will set well even under water. With this cement was mixed an aggregate of broken tuff, travertine, brick, or even marble, with pumice stone being used in vaults after the 1st century AD to lighten the weight of the structure. Concrete was used in all great imperial buildings (for example, the Pantheon, Baths of Caracalla, and Basilica of Maxentius in Rome). New forms of architecture that were developed by the use of this material spread throughout the Roman Empire, although in the provinces other, often weaker, kinds of concrete were used.

Construction. Walls were built of ordinary masonry or of concrete (faced or unfaced). There are several examples of early stone walling without courses (continuous layers), especially in such Italian towns as Norba and Praeneste. Most of the stone walls existing, however, were built of fairly large squared blocks laid in regular courses as headers (stone or brick laid with its end toward the face of the wall) and stretchers (stone or brick laid with its length parallel to the face of the wall). This type of masonry was called *opus quadratum*.

Kinds of
facing for
concrete

Concrete walls, except below ground, were always faced. They are divided into types according to the kind of facing used. (1) *Opus quadratum*—that is, ordinary stone walling—was used as a facing especially for important public buildings under the earlier empire (for example, the exterior of the Colosseum). (2) *Opus incertum* was the most common facing for ordinary concrete walls of the 2nd and 1st centuries BC. The face of the concrete was studded with three- to four-inch irregularly shaped pieces of stone, usually tuff. (3) *Opus reticulatum* came into vogue in the 1st century BC and remained until the time of Hadrian (AD 117). The construction was like that of *opus incertum* but the pieces of stone were pyramid-shaped with square bases set diagonally in rows and wedged into the concrete walls. (4) Brick- and tile-faced concrete (so-called *opus testaceum*) was by far the most common material for walling during the empire. Triangular tiles were used with their points turned into the concrete and their long sides showing, thus giving the appearance of a wall built of thin bricks. Bonding courses of *bipedales* were employed at intervals of two or three feet. (5) Mixed brick and stone facing, called *opus mixtum*, was popular under the later empire and especially under Diocletian (AD 284–305).

Other kinds of supports included columns and piers. Columns were usually of stone and often monolithic; occasionally, small columns were of brick covered with stucco. Piers (solid blocks of masonry supporting either an arch or a lintel) were often of stone, but those serving as primary support for large vaults were usually of concrete.

Arches occurred in gates, bridges, and aqueducts, as well as in colonnades and doors. Not only round but also segmental (part of a circle but less than a semicircle) and flat arches were used freely. The discovery of concrete enormously facilitated the spread of arch construction. Concrete arches were faced with wedge-shaped stones or tiles called *voussoirs*.

Vaults and
domes

The vaults used by the Romans were simple geometric forms: the barrel vault (semicircular in shape), the inter-

secting (groined) barrel vault, and the segmental vault. By the 1st century BC, extensive systems of barrel vaulting were employed. The surfaces of the vaults were tile-faced or covered with stucco. A fine example of Roman vaulting is the Basilica of Maxentius in Rome. The construction of the dome naturally follows that of the vault. Characteristic of imperial Roman design was the elaboration of complex forms of domes to fit multilobed ground plans.

Most monumental buildings were erected for public use, and income, if any, from rents or fees went to the public treasury. Many of these buildings, however, were erected by wealthy individuals and given to the community in a form of voluntary income tax. Construction was done by state agencies or private contractors, employing slave or free labour. Techniques and crafts were highly developed, though machines were simple and powered by men or animals.

Design. The pervasive Roman predilection was for spatial composition—the organization of lines, surfaces, masses, and volumes in space. In this the Romans differed from their predecessors in the ancient Mediterranean world, and, however freely they used the elements of earlier styles, in Rome or in the provinces they recast them according to their own taste.

Their most conspicuous inheritance was the order. These were taken directly from Greek tradition, with little alteration of their major form, although the Romans did use them with little attention to their internal logic. There were five orders of Roman architecture: Doric, Ionic, Corinthian, Tuscan, and Composite. Tuscan and Composite were modifications of the Greek Doric and Corinthian orders, respectively. In general, the proportion of the Roman order was slenderer than that of the corresponding Greek order, and there was a tendency toward greater elaboration. Columns were often unfluted, but the faces of the entablature, left plain in Greek work, were covered with decoration.

Unlike the Greek Doric, the Roman Doric order almost invariably had a base molding that was probably taken from the Etruscan Doric or Tuscan column. Examples of Roman Doric are to be found in the Tabularium (78 BC), Rome, and in the lowest order of the Colosseum (AD 80), where it was used in conjunction with the arch. The Temple of Hercules at Cori, Italy (c. 80 BC), is one of the few known Roman Doric temples.

The Ionic order was used in some temples and public buildings, and the number of isolated capitals found suggests that it had a certain vogue in private homes. Notable examples of this order are the Temple of Fortuna Virilis and Trajan's Forum at Rome.

Because of its richness, the Corinthian order was by far the most popular with the Roman builder. Columns removed by the conquering Roman general Sulla in about 86 BC from the Temple of Olympian Zeus at Athens were the model, but the whole order became progressively elaborated in detail and showed a tendency toward sharp contrasts of light and shadow. Examples of this order are seen at the temples of Mars Ultor and of Castor and Pollux in Rome and the Temple of Vesta at Tivoli.

The Composite capital is formed from a Corinthian capital and an Ionic volute (spiral, scroll-shaped ornament) at each of the four corners. Examples of this capital are found in Rome on the triumphal arches of Titus and Septimius Severus and in the Baths of Diocletian.

Although the orders were taken bodily from the Greeks, in Roman architecture columns carried arches as well as entablatures, permitting more varied linear patterns, wider intercolumniations, and greater freedom in articulating spatial forms. Moreover, as a development of Greek practice in temples at Acragas, Selinus, Bassae, and Tegea, columns were used not only as primary supports but also decoratively as detached columns and pilasters (flattened columns), together with other projecting elements and recessed niches of all kinds, so as to modulate the sheer face of a wall or pier into a composition of mass and volume in depth, supplementing the larger forms of the main volumes. Realistic or fanciful architectural compositions were even painted on some walls to give an illusion of the same effect.

tural
orders

Compar-
ison of
Greek and
Roman
use of the
orders

In terms of primary architectural forms, Roman design from its first emergence from Italic and Etruscan traditions favoured temples with spacious porches, like the Temple of Apollo at Pompeii. In imperial architecture the design of the temple precinct, forum, *thermae* (baths), and other public buildings was normally conceived as a complex of variously formed spaces related to variously formed masses. Even landscaping was incorporated, as at the imperial Roman villas at Tivoli and Capri. Interiors of smaller houses as well as of grand structures were designed around vistas through variously shaped rooms of varying qualities of illumination. There was a powerful, even rigid, final dominant of axial symmetry, but against this was exploited richly every kind of spatial form in a highly developed system of organization.

Characteristics of the Roman temple

Types of public buildings. Roman temples differed in many important respects from those of the Greeks. For a comparatively low stylobate (the foundation on which a colonnade rests) with three steps all around the structure, the Romans substituted a high platform or podium with a flight of steps on the entrance facade. Greek temples were isolated from other buildings and almost always faced east and west; those of the Romans were turned to all points of the compass, their orientation governed by their relation to other buildings. This resulted in the entrance facade being emphasized and the entrance portico being deepened. The cella was wider, and the colonnade that surrounded the Greek temple was often reduced to a row of engaged, or applied, columns or pilasters along the cella walls, except on the entrance facade. In some cases the cella was vaulted in concrete and might have an apsidal (semicircular) end, such as in the so-called Baths of Diana at Nîmes, France, and especially the double Temple of Venus and Rome in Rome. The best preserved example of a Roman temple now existing is that known as the Maison-Carrée at Nîmes. Among the most important temples of which remains exist are those of Fortuna Virilis, Mars Ultor, Castor and Pollux, Concord and Antoninus, and Faustina in Rome; in Italy, the Temple of Minerva at Assisi and the temples at Pompeii; and in Syria, the Temple of Bacchus at Baalbek (now in Lebanon) and the Temple of the Sun at Palmyra.

Circular temples

The Romans built many circular temples. Among the most important remaining examples of these are the temples of Vesta and Mater Matuta in Rome, Vesta at Tivoli, and Venus at Baalbek (Figure 7). The greatest surviving circular temple of antiquity, and in many respects the most important Roman building, is the Pantheon in Rome. It consists of a rotunda about 142 feet in diameter surrounded by concrete walls 20 feet thick, in which are alternate circular and rectangular niches. Light is admitted through a central opening, or oculus, about 28 feet across, at the crown of the dome. In front is a porch with an inscription commemorating an earlier building of Marcus Agrippa (12 BC–AD 14) but built with the existing rotunda (AD 120–124) under the emperor Hadrian. The rotunda and dome are among the finest examples of Roman concrete work. The interior was lined with precious marbles, the coffers (decorative recessed panels) of the dome were ornamented with bronze rosettes, and the dome itself once was covered externally with bronze plates.

The large Roman tomb consisted of an earth mound or tumulus, surrounded by a ring of masonry rising usually to a considerable height. Few of the type now exist, the most notable being the Tomb of Caecilia Metella on the Via Appia and Hadrian's Tomb, now Castel Sant'Angelo. Smaller tombs, in particular those of the columbarium type (a structure of vaults with recesses for cinerary urns) are usually underground, though there is sometimes an upper story built of brick, from which steps lead down to the tomb proper. There is a line of such tombs just outside Rome along the Via Appia and also along the Via Latina, and such a cemetery has been found under St. Peter's in Rome. Examples of Roman funeral monuments of various kinds exist along the Street of Tombs at Pompeii and in the provinces (for example, at Jerusalem; Palmyra, Syria; and Petra, Jordan).

The basilica was a large covered hall used as a court of justice and for banking and other commercial transactions.

Figure 7: Temple of Venus at Baalbek, 3rd century AD.
Fototeca Unione, Rome

In the Forum at Rome are the Basilica Julia on the south side and the Basilica Aemilia on the north side, both of which had a central hall and side aisles. The Basilica Ulpia in Trajan's Forum was similar in plan but had at either end semicircular halls (apses), which served as law courts. The fourth and greatest of the basilicas was that begun by Maxentius (AD 306–312) and finished by Constantine about AD 313. This huge building covered 63,000 square feet (5,850 square metres) and followed in construction and plan the great hall of the Roman baths (Figure 8). Vaults over the bays on the north side are still overhanging without support, a striking testimony to the marvelous cohesion and enduring strength of Roman concrete (Figure 9). A hall at Pompeii is an example of the simpler type of basilica generally constructed in the provinces.

The Roman basilica

By the end of the republic, baths (*balneae*) had become a recognized feature of Roman life. Under the empire

GEKS

their numbers increased, until at the beginning of the 4th century AD they numbered 1,000 in Rome alone. Like the 20th-century Turkish baths, Roman steam baths had rooms heated to different temperatures. Remains of these establishments are common throughout the empire. The Stabian Baths at Pompeii are the best preserved of such structures.

Imperial *thermae* were more than baths. They were immense establishments of great magnificence, with facilities for every gymnastic exercise and halls in which philosophers, poets, rhetoricians, and those who wished to hear them gathered. The earliest of these *thermae* were those built in Rome by Agrippa about 21 BC. Others were built by Nero, Titus, Trajan, Caracalla, Diocletian, and Constantine. The best preserved are the Baths of Caracalla (begun c. AD 217), which covered an area about 1,000 feet square, and those of Diocletian (c. AD 298–306), with accommodation for 3,200 bathers. Parts of the latter are now occupied by the church of Santa Maria degli Angeli and by the Roman National Museum.

Roman theatres differed in several respects from those of the Greeks. The auditorium was not excavated and the walls surrounding stage and seating were continuous, entrance to the orchestra being by vaulted passages. As the chorus played no part in the Roman theatre, the orchestra or dancing space became part of the auditorium. The facade behind the stage was elaborately adorned with architectural fantasies.

The only theatre in Rome of which any remains exist is that of Marcellus, built by Augustus (c. 11–10 BC), but there are numerous examples throughout the Roman Empire, especially in Asia Minor. The theatre at Orange, Fr., and Leptis Magna (near Tripoli, Libya) are among the best-preserved examples. The Odeum of Agrippa in Athens is a good example of a completely enclosed music hall.

Amphitheatres were arenas in which spectacles were held. The largest and most important amphitheatre of Rome was the Colosseum, built by the emperors Vespasian, Titus, and Domitian in about AD 70/72–82 (Figure 10). Covering six acres (2.4 hectares), it had seating for about 50,000 spectators, and its 80 entrances were so arranged that the building could be cleared quickly. The whole is built of concrete, the exterior faced with travertine and the interior with precious marbles that have long since disappeared. Other important amphitheatres are those at Verona, Italy; Pula, Yugos.; and Arles, Fr.

The circus was essentially a racecourse, lined, ideally, with tiers of seats along each side and curving around one end, with the opposite end squared off and provided

with arrangements for chariots to enter and draw up for the start. Down the middle ran a barrier, on which judges and referees might perform their functions. Since it was the largest facility for watching a function, the circus was also used for spectacles other than racing, such as, traditionally, the burning of the Christians by Nero. There are remains of one of these circuses at Perga, near the southern coast of Turkey.

Triumphal arches were sometimes erected to commemorate an important event or campaign. They were often isolated rather than built to span a roadway. The triumphal arch was usually decorated with columns and bas-reliefs of the chief events it commemorated and was frequently surmounted by sculpture. The most important of these arches are the Arch of Titus (c. AD 81), commemorating the capture of Jerusalem (Figure 11), and the arches of Septimius Severus (c. AD 203) and Constantine (c. AD 315) all in Rome, and Trajan's arches at Benevento and Ancona. There are several other triumphal arches in the provinces, notably those of Tiberius at Orange, of Augustus at Susa, and Caracalla at Tébessa.

A monumental city gate, while sometimes serving a commemorative purpose, differs from an arch in being part of the defenses of the city. Of these gates the most famous are the Porta Nigra at Trier in Germany and the gate from Miletus in Turkey (Pergamon Museum, East Berlin).

The bridges and aqueducts of the Romans rank among their greatest monuments. The most famous surviving examples of Roman aqueducts are the Pont du Gard at Nîmes and the aqueduct at Segovia in Spain.

There are not many of the larger Roman bridges now remaining. The best preserved is that built by Augustus and Tiberius at Rimini, and perhaps the finest is that across the Tagus River at Alcántara in Spain.

Residential architecture. Private houses, even palaces, were usually of the style that emphasized interior courts and gardens rather than external facade; this tradition was even maintained so far as possible in Roman settlements in northern Europe and Britain, where elaborate arrangements for heating had to be added. In the native Mediterranean climate, however, construction tended to be light and open rather than compact and imposing.

Even the palaces of the Caesars in Rome consisted essentially of series of gardens and, considering their purpose, relatively unmonumental buildings, spread somewhat casually over the Palatine Hill. Augustus himself bought and enlarged the house known as the House of Livia, which still exists. Tiberius built a palace on the northwest side of the hill. Another palace was built on the southeast corner of the hill by Claudius or Nero. The central space

was covered by the palace of the Flavians, Domitian with his architect Rabirius being responsible for a magnificent suite of state apartments and for the sunken garden called the *hippodromus*. Hadrian extended the palace toward the Forum, and Septimius Severus raised a huge structure overlooking the Circus Maximus. Very little remains of the famous Golden House of Nero, which originally occupied an area of more than 300 acres on the site now covered by the Baths of Titus, the Colosseum, and the Basilica of Maxentius.

Hadrian's Villa at Tivoli, begun about AD 123, was a sumptuous residence with parks and gardens on a large scale. The unevenness of the site necessitated large terraces and flights of steps. There are remains of great brick and concrete structures. All the buildings are Roman in style and method of construction, though with Greek names.

The Palace of Diocletian at Spalato (Split) in Yugoslavia, to which he retired on his abdication in AD 305, combined a palace with a fortress. It consisted of an immense rectangle surrounded on three sides with walls guarded by towers; on the fourth it was protected by the sea. The palace itself was on the south side with a great gallery 520 feet long with 51 windows overlooking the sea.

The Latin word *villa* pertained to an estate, complete with house, grounds, and subsidiary buildings. Relatively modest villas were found around Pompeii; descriptions in literature, such as that of Pliny the Younger of his villa at Laurentum, and remains of the palatial residence of the 4th century at Piazza Armerina in Sicily, might represent the most opulent class. Hadrian's Villa at Tivoli is too elaborate and extensive to be taken as typical (Figure 12).

In Roman architecture there were two types of houses, the *domus* and the *insula*. The *domus* consisted of suites of rooms grouped around a central hall, or atrium, to which were often added further suites at the rear, grouped around a colonnaded court, or peristyle. The atrium, a rectangular room with an opening in the roof to the sky, and its adjoining rooms were peculiarly Roman elements; the peristyle was Greek or Middle Eastern. There were few windows on the street, light being obtained from the atrium or peristyle. The *domus*, as exemplified by those remaining at Pompeii and Herculaneum, has long been regarded as the typical Roman house. In Rome itself, however, very few remains of the *domus* have come to light, the chief examples being the House of the Vestals in the Forum and that of Livia on the Palatine Hill.

From Latin writers it has long been known that there

were in Rome great blocks of flats or tenements to which the term *insulae* was applied. Excavations at Ostia, Italy, have revealed the design of these blocks. Planned on three or four floors with strict regard to economy of space, they depended on light from the exterior as well as from a central court. Independent apartments had separate entrances with direct access to the street. Since Ostia was a typical town of the 1st and 2nd centuries AD and was almost a suburb of Rome itself, it is supposed that *insulae* at Rome would have similar features. Shops might line the street front of either *domus* or *insula*.

Town planning. Vitruvius clearly indicated that the Romans were keenly aware of the fundamentals of town planning. When a new town was established, such considerations as its function, climate, and geographic environment were examined.

A characteristic Roman plan, either inherited from early Italic towns or developed in the discipline of army camp engineering, was used. The overall plan was square, with main avenues bisecting the sides and intersecting at the centre. The rest of the streets were in checkerboard grid.

At or near the centre of the Roman town was the forum, the principal focus of Roman life. This was a space in which important business might be conducted. Gradually buildings were built on the periphery for particular civic, commercial, and religious activities, as at Pompeii or in the Forum in Rome. In late republican or imperial times a forum might be laid out as a single comprehensive architectural design including all the facilities, as in the Imperial Forums at Rome. In a very large and old city, such as Rome itself, there might be several forums, some devoted primarily to administrative, legal, or financial affairs, others to trade in particular commodities, including meat and vegetables. For the latter kind of commerce, however, structures architecturally distinct from the forum though superficially similar were developed. One is the *macellum*, which was not essentially an open square but a market building consisting of shops around a colonnaded court. Great warehouses, called *horrea*, served in wholesale commerce.

Long-established communities, which had developed by accretion rather than by plan, were often gradually brought, under Roman influence, within some approximation of this scheme, sometimes with considerable subtlety. Often, however, as in Rome itself, the scale and topography prevented the achievement of any fully logical order. In general, colonnades lined the important streets;

Alinari—Art Resource/EB Inc.

water was conveyed to spectacular ornamental fountains or to practical neighbourhood basins from reservoirs fed by aqueducts (in some climates cisterns were necessary); many large sewers collected waste water from the street, if not from private homes; and building codes were devised and enforced.

The layout of a whole town can be most easily seen in some of the towns in North Africa (for example, Timgad, Tébessa, Thuburbo Majus), where there has been little or no subsequent building to modify the original lines of the plan.

Stylistic development. Roman monumental architecture emerged about the 6th century BC as an Italic style, closely related to that of the Etruscans. The Temple of Jupiter Capitolinus in Rome, built about this time, resembled Etruscan buildings in central Italy—at Signia, Orvieto, Veii, and elsewhere—in its podium (base or platform on which it rests), its triple cella, its broad low Etruscan porch, and its characteristic terra-cotta adornment. The Capitulum Temple at Cosa, a Roman foundation located northeast of Rome, was similarly conceived in the 3rd century BC. The forms, sculptural and spatial, had evolved locally in a tradition of wood and terra-cotta, though even at this time there was a slight Greek influence.

From about 200 BC to about AD 50, the rise of republican Rome and the increasing contacts with Greece resulted in a Greek influence strong enough to control the sculptural forms and even to modify the spatial effects. A temple at Gabii, perhaps of the 3rd century, and the Temple of Apollo at Pompeii, of about 120 BC, had approximately the Greek single-cella, peripheral (having a single row of columns surrounding the building) plan; the latter retained the Italic podium and open porch, and it had pronounced modifications of the Greek Ionic order. Buildings such as the temple under the present church of San Nicola in Carcere (c. 31 BC) and the Temple of Fortuna Virilis (c. 40 BC), both in Rome, show the height of Hellenistic influence. But the slightly later Augustan temples of Concord, Castor and Pollux in the Roman Forum, and Mars Ultor in the Forum of Augustus in Rome had a native freedom of arrangement of space and highly elaborated moldings, particularly in the entablature, where new forms, mostly floral, were lavishly displayed in finely worked, full masses, and consoles (projecting ornamental brackets) became increasingly important.

During this period the more peculiarly Roman concepts developed chiefly in secular architecture. The Stabian Baths at Pompeii, built perhaps as early as 120 BC, were already composed of vaulted spaces, though quite compactly and with little of the later freedom and spaciousness. In some buildings—such as the Carcer and Tullianum (prisonlike structures of about 100 BC or earlier) and the Tabularium of about 78 BC, all just west of the Forum in Rome—arches and concrete were basic, though orders influenced

by Hellenistic architecture were used for ornament. The Theatre of Marcellus (c. 11–10 BC) was built with a high exterior facade where orders and arches blended—a type of theatrical design that became standard.

The beginning of Roman influence outside Italy is evident in theatres and amphitheatres at Arles and Nîmes (perhaps as early as 30 BC), in a temple built about 12 BC at Nîmes called the Maison-Carrée (Figure 13), and in small buildings in Greece and Syria built shortly thereafter.

About the middle of the 1st century AD there was a surge of development of spatial composition. The orders and other ornament inherited from Greece were increasingly modified and elaborated in nonfunctional perspective effects, and other kinds of ornament and spatial configurations gained importance. Buildings such as the Colosseum (AD 80) in Rome preserved a more conservative character, but with the baths and palaces of Nero began the series of imperial compositions of grand, elaborate spaces. The movement came to a climax under Trajan and Hadrian (c. 98–138), with Trajan's Forum at Rome, the great complex of buildings at Baalbek in Syria, the Pantheon in Rome, and Hadrian's Villa at Tivoli.

Through the 2nd and 3rd centuries countless buildings were erected in cities and towns throughout the empire, in part under imperial patronage and in part by local enterprise. Provincial buildings had great individuality, but the more ambitious usually followed the influence of the capital. Forms evolved by about AD 140 were followed conventionally for the next 50 years (and longer), but from about AD 200 to the age of Constantine, there was a growing trend toward increased majesty and less emphasis on the material substance or appearance of a building. Even before the end of the 2nd century, deep cutting with sharply contrasting light and shadow had begun to detract from the impression of the solid forms in carved ornament. In the arches of Septimius Severus (c. AD 200), for instance, light and shadow alone formed the design—not the masses of the forms of the motifs. Especially in Africa, illogical composition of the elements of entablatures robbed them of structural significance. In the Palace of Diocletian (c. AD 300), extensive use of arched colonnades emphasized movement rather than mass. The sheer faces of some wall surfaces, like those of towers flanking the gates, became austere geometric forms. Experimentation and elaboration in vaulting, as in the so-called Temple of Minerva Medica (c. AD 260) at Rome, was directed toward making the supports lighter structurally and aesthetically. Compared with the Baths of Caracalla (c. AD 217), the Basilica of Maxentius (c. AD 310–320) was simpler in design and more concentrated, increasing its sense of elemental vastness and permanence, whereas in contrast to the Pantheon its shape and ornament are less tangible.

Finally, evolving into the early Christian art to come, the

Constantinian mausoleum of Santa Costanza (Figure 15), with its dome resting on a drum supported on arches on a circle of pairs of slender columns, already was striving to suggest the independence of roof and space from material support.

(R.L.S./D.J.Wa.)

EARLY CHRISTIAN

Early in the 20th century it was thought that Christian art and architecture began after the death of Christ or, at least, in the second half of the 1st century AD. But later discoveries and studies showed that a truly Christian style did not exist before the end of the 2nd or beginning of the 3rd century. The terminal date of this period is even more difficult to establish; it may be placed in the 4th, 5th, or 6th century. Early Christian architecture penetrated all the provinces of the Roman Empire, adapting itself to existing pagan architecture. It subsequently created its own forms, which varied according to local stylistic evolution. The new capital at Constantinople (ancient Byzantium), founded by the emperor Constantine the Great (306–337), was to be an important centre. The art and architecture of this city henceforth became known as Byzantine and extended throughout the entire Christian East. It is customary to distinguish early Christian architecture of the West, or Latin part of the Roman Empire, from the Christian architecture of regions dominated by the Greek language and to consider the latter as proto-Byzantine, while acknowledging, however, a certain latitude in the initial date of this separation: 330, the foundation of Constantinople; 395, the separation of the Greek part of the empire from its Latin sector; or, finally, the reign of Justinian (527–565). For the purposes of this article, monuments shall be treated as early Christian mainly on the basis of their style, as distinct from the genuine Byzantine style of Constantinople; since the transition from the earlier to the later architecture discussed in the next section took place at different times in different locations, this section has no precise chronological boundary. Only after Justinian's reign did many Eastern regions submit to the ascendancy of Constantinople, following until the 6th and even the 7th century the paths traced by Christian architecture in its beginnings. In the West the end of early Christian architecture is easier to determine. Closely tied to Roman architecture, it finished with the collapse of the empire at the end of the 5th century. Then, transformed into a multitude of regional styles, it assimilated various influences from the East and from the barbaric peoples who superseded their Roman masters.

Early Christian architecture is divided into two periods, quite unequal in length and in importance. During the first—which preceded the Edict of Milan, by which Constantine the Great in 313 decreed official tolerance of open practice of the Christian religion—Christianity was often persecuted, while in the second it soon became the state religion. The monuments of the first period were modest and few in number, those of the second phase were numerous and splendid.

First period, to AD 313. Little is known about Christian places of worship before 313. By bringing together the relevant texts and the results of excavations, one can, however, succeed in forming an idea of them. These *domus ecclesiae* (“meeting houses”; *ecclesia*, “assembly, meeting”) were private homes placed at the disposal of communities by well-to-do members. A spacious room, already existing or fitted out for the occasion, served as chamber of worship, while others were allotted for various activities of the community: charity work, study, funeral services, and living quarters for the clergy. This was the arrangement of the only extant *domus ecclesiae* from the 3rd century, that in the Syrian caravan city of Doura-Europus, on the west bank of the Euphrates. A Syrian home of the common type, it contained a longitudinal sanctuary, a baptistery, and four smaller rooms grouped around an interior courtyard. The sanctuary, stripped of decoration, was distinguished only by a small dais at the western end, probably the seat of the bishop, and by a small cupola, the use of which is unknown, set in the ground near this platform. The general character of these meeting houses seems to have been the same everywhere. They must have been rather numerous; the *tituli* (“titles”) of the 25 Christian basilicas in Rome today are, in fact, the names of the private houses in which these congregations were first established.

First
Christian
church:
the *domus
ecclesiae*

The double Church of Bishop Theodore of Aquileia marks a step toward the creation of a monumental edifice of the Christian religion. Standing within the enclosure of a Roman villa, it occupied all the space of the earlier building and more. Two sanctuaries of considerable size, 121 by 66 feet and 121 by 56 feet, were rectangular rooms subdivided by pillars into three longitudinal aisles that outlined the naves of the standard Christian basilica plan.

Second period, after AD 313. It was this kind of plan that architects adopted when Constantine officially recognized the church in 313 and was converted to Christianity. Whether in Rome or in other cities of the empire, his architects took their inspiration not from pagan temples,

Figure 13: Maison-Carrée, Nîmes, Fr., c. 12 BC.

Wayne Andrews

old-fashioned in the 4th century, but, rather, from a secular building type of utilitarian character, the basilica, which had served as a hall of assembly, commerce, reception, or law-making. Of Hellenistic origin both in form and in name (*stoa basileōs*, or “royal room”), the basilica under the Romans varied in plan and size according to use and to the importance of the social group to which it belonged. It could be either a simple hall or one divided by columns into three longitudinal aisles, or surrounded on three sides by one- or two-story arcades with a dais on a short or long side.

The first Christian basilicas, built in Rome, were variations of secular basilicas adapted to the new cult. St. John Lateran, superficially transformed in the 17th and 19th centuries, is the oldest, begun about 313. It was followed by St. Peter's (replaced in the 16th century by the present church) in the last years of the reign of Constantine and his sons (Figure 14). San Clemente, Santa Pudenziana, St. Paul's Outside the Walls, San Sebastiano, Santa Sabina, and others belong to the late 4th and to the 5th century.

These were, in most cases, halls with five longitudinal aisles, the central one raised and lit directly by windows piercing the high walls. A semicircular protrusion of the wall, or apse, on the short side opposite the entrance, first on the west side but later on the east side, was covered over with a half-dome vault, while the so-called hall itself usually had a wooden frame roof. The side aisles were separated from the central nave by rows of columns. These supported a rectilinear entablature, or solid horizontal section; later this entablature was replaced by a series of arches resting on capitals (San Clemente, 360; St. Paul's Outside the Walls, 385; Santa Sabina, 422–432), but at Santa Maria Maggiore, still intact under its 17th-century Baroque facing, Pope Sixtus III (432–440) returned to the classical form of the straight entablature.

Whereas St. John Lateran and San Clemente were used entirely for the eucharistic service, St. Peter's and St. Paul's Outside the Walls were also martyria, buildings commemorating the martyrdom of their titular saints. This commemorative function influenced the plan: in front of the apse a large transept, sheltering the site of the relics, facilitated the presentation of the liturgy and the circulation of the faithful around the sacred place.

The churches built under Constantine at Constantinople and in Palestine were more complex in plan and structure. The destroyed Church of the Holy Apostles at

Constantinople, known only through a description by Eusebius of Caesarea, was begun in 333 and completed by Constantius II (337–361). It was cross-shaped, and a drum (i.e., a cylindrical or polygonal wall that usually supports a dome) rose above the crossing, probably covered by a conical wooden roof. The sarcophagus of Constantine stood in the centre, surrounded by memorials to the 12 Apostles. It was less a church than a mausoleum in honour of the first Christian emperor, who was made to appear in that church as the 13th Apostle. In the sanctuaries in Jerusalem and in the church of Bethlehem, the commemorative building and the hall of worship (basilica) were united. At Jerusalem several structures combine to form the Church of the Holy Sepulchre. The Anastasis (the Resurrection), a rotunda approximately 131 feet in diameter whose foundations and remains of the walls have been discovered under later additions, was built about 340 on the “tomb” of Christ, the funeral place hewn into the rock and surmounted by a small temple. Two levels of galleries surrounded the rotunda, and the whole was covered by a wooden cupola. The site of Golgotha, open to the sky, was preceded toward the east by a martyrium, a five-aisled basilica with tribunes, or raised platforms, intended for gatherings of the faithful. It probably terminated at the west with a rotunda, open to the nave and surrounded by 12 columns marking the place where it was thought that Helena, mother of Constantine, had found Christ's cross. The Church of the Holy Sepulchre and the court of Golgotha were surrounded by porches aligned along the exterior aisles of the basilica (martyrium) and on the galleries of an atrium (forecourt), which preceded the martyrium. The Constantinian basilica at Bethlehem, still partly intact, having five aisles without tribunes, the central aisle raised, was preceded on the west by an atrium and terminated in the east by an octagon built above the Grotto of the Nativity. Justinian had it replaced by a triconch (three-apsed building), which still stands.

The considerable dimensions of all these complexes (657 by 230 feet including the atrium in the case of St. Peter's, the largest) and the richness of their decoration (marble columns and inlay; mosaics on the vaults; *opus sectile*, or inlaid stone, in the pavements; and sometimes gold coffered ceilings, as at the Martyrium in Jerusalem) lent to these structures a sumptuousness that made them the equals in scale and splendour of the imperial palaces. Moreover, the liturgical ceremony became progressively

assimilated with that of the court; the image of Christ standing or enthroned in the apses of the basilicas evoked the emperor presiding over reception ceremonies in his palace.

The differences of plan between the Greek and the Latin Constantinian churches have been a subject of controversy. One hypothesis explains them on the grounds of the Greek traditions—differing from those of the Romans—of the cult of heroes and of the dead. Since the churches of Palestine commemorate the earthly appearances of Christ, his Birth, and his Resurrection, they are comparable in function to the Greek *hērōa*, which are commemorative temples. In the West, however, the churches enclose actual graves, the focus of a funerary cult, completely different from the cult of the Greek heroes.

The central-plan building, round, polygonal, or cruciform in design, gathered considerable momentum in the West as well as in the East in the course of the 4th and 5th centuries. The deconsecrated church of Santa Costanza in Rome, built between 337 and 350 for members of the imperial family, was a rotunda with ambulatory or circular walkway separated from the central area by columns (Figure 15); the mausoleum of Centcelles (Tarragona) in Spain, likewise a rotunda, was probably the burial place of Constans, son of Constantine, assassinated in 350. Both are somewhat related in type to the Tomb of Diocletian (c. 300) at Split in Yugoslavia.

Milan, which had been the imperial residence several times since 350 and seat of the bishop St. Ambrose since 374, has preserved the remains of some centrally planned churches of the 4th century. San Lorenzo Maggiore, begun about 370, is a quadrifoil room with four niches and ambulatory; an octagon adjoining it (today Sant'Aquilino) was formerly an imperial mausoleum or baptistery. The Church of the Holy Apostles, the present San Nazaro Maggiore (begun in 382), is cruciform in plan with an apse in the east, built in imitation of the church of the same name at Constantinople. At Cologne, the oval plan of St. Gereon (built about 380) is enriched by eight smaller

apses (apsidioles), an apse in the east, and a narthex, or large rectangular room placed before the west entrance. At Antioch in Syria an octagonal structure, called the Golden House because of its gilded roofing, was begun as early as 327 by Constantine. Near this city at Kaussich are preserved the foundations of a cruciform church, built between 378 and the end of the 4th century; it served both the normal cult and the commemoration of three martyrs whose sarcophagi were found in the transept.

Since most of these churches were not consecrated to the cult of a martyr, the mausoleum could not be the only source of inspiration for their plans. Imperial reception rooms may have been models. The octagonal church at Antioch and that of San Lorenzo in Milan were probably palace churches, and the transfer of plan from one to the other seems perfectly plausible.

Central-
zied Greek
church
plan

In the 5th century, as local schools formed, the unity of Christian architecture with that of the empire ceased to exist. In Italy, although basilicas of the classical type continued to be built, they assimilated Eastern influences. North Africa modified the basilica plan only by multiplying the number of side aisles (Damous-el-Karita in Carthage has eight) or by adding apses.

The ecclesiastical architecture of the East is more varied, partly as a result of differences in the liturgies. The ruins of St. John Studios in Constantinople (463) and the Church of the Acheiropoietos at Thessalonica (470) were basilicas with tribunes and narthexes, which, in their proportions, approached those of centrally planned structures. The large central aisle, inaccessible to the faithful, was reserved for the service of the eucharist, the side aisles for the men, the tribunes for the women, and the narthex for those who for some reason could not participate in the communion. Later, this form of basilica spread into the Greek countries and gave birth to an essentially Byzantine type of church, the "domed basilica." Nevertheless, the ordinary basilica plan, of three or five aisles with an apse in the east, remained no less popular in Greece, on the islands, in the Balkans (Stobi in Serbia), and in the Middle East. In Asia Minor the Church of St. John of Ephesus (450), later replaced by a building of Justinian, was cruciform in plan, inspired by the Church of the Holy Apostles in Constantinople. Extending from the square ciborium (a canopy over the altar supported by columns) placed at the crossing were four wings, the eastern one having an apse and five aisles, the others having three aisles.

In Syria, Israel, and Jordan a particularly large number of 5th-, 6th-, and 7th-century churches are preserved. The triple influence of the Greek countries, Constantinople, and the imperial sanctuaries of the Holy Land resulted in many plans, whereas the materials and construction methods remained in the tradition of the region. At Qa'at as-Sim'an near Aleppo, Syria (Figure 16), lies the ruin of a martyrium built about 470 around the column on which the ascetic St. Simeon Stylites spent the last years of his life. The precious relic was enclosed by a central octagon of considerable dimensions, adjoined by four arms of a cross in the form of basilicas. At Jarash in Jordan the Church of the Apostles and Martyrs (465) is a cross inscribed in a square, heralding a typically Byzantine plan of later centuries. Also at Jarash, the triple church dedicated to Saints Cosmas and Damian, to St. John the Baptist, and to St. George consists of two basilicas flanking a rotunda with an ambulatory (528–533) and an apse in the east. Other rotundas are at Buṣrā ash-Shām and Izra' in Syria, as well as the octagonal Church of the Theotokos (484) on Mount Gerizim (now in the occupied West Bank territory). The sanctuaries of Egypt were also influenced by those of Constantinople, the Greek countries, and Italy. The cathedral of Hermopolis (al-Ashmūnayn), built about 430–440 in southern Egypt, and the martyrium-church of

St. Menas, nearer the coast (first half of the 5th century), combine the influences of Constantinople and Italy in the three-lobed sanctuary, the transept, and the long basilica room with three aisles. The ties between the Latin West and the Greek East, particularly strong in the 4th and 5th centuries, relaxed in the 6th. Beginning with the reign of Justinian, a true Byzantine architecture developed from the new capital. In the western Mediterranean, the end of the ancient world and of early Christian architecture came with the fall of the Roman Empire in 476. (He.S.)

Eastern Christian

THE EARLY BYZANTINE PERIOD (330–726)

When Constantine began to build his new capital on the Bosphorus, a mass of artisans was assembled for the purpose. The majority of them were drawn from Rome, so that, at first, official art was early Christian in style and was, in fact, virtually Roman art: the classical basilica was adopted as the usual type of Christian church; portrait statues of emperors were set up as in pagan times, and sarcophagi were elaborately sculptured; floor mosaics of classical character were widely used; and works in ivory and metal retained a basically Roman character. Change was in the air, however, even before the capital had been moved from Rome. In architecture the post-and-lintel style in stone, which had been taken over from the Greeks, was already giving place to an architecture of arches, vaults, and domes in brick, whereas sculptural ornament was becoming more formal and less naturalistic. These changes were accelerated at Constantinople partly because of the proximity of the city to Asia Minor and Syria, both fertile centres of new artistic ideas that had developed independently of Rome. Indeed, church architecture in those areas progressed considerably between the 4th and the 6th centuries, while in the visual arts a style that favoured formality and expression rather than the idealized naturalism of classical art had begun to find approval at an early date.

Constantine's new capital was carefully laid out and boasted an important series of secular buildings—walls, hippodrome, forums, public buildings, arcaded streets, and an imperial palace—all of great magnificence. The religious structures he set up were of two principal types: longitudinal basilicas and centralized churches. The former, usually with three aisles, were intended for congregational worship; the latter, which were circular, square, or even octagonal, were for burial or commemorative usage. Both types were to be found over a very wide area, though there were, of course, numerous local variations. It was through a subtle combination of the two types that the characteristic Byzantine church emerged, thanks to some experiments made in the eastern Mediterranean area in the 5th century. The progress cannot be followed exactly because so much has been destroyed, but the earliest sur-

Develop-
ment of

Figure 16: South facade of the martyrium at Qa'at as-Sim'an near Aleppo, Syria, c. 470.

living church in Constantinople, that of St. John of the Studium (Mosque of İmrahor), shows that this process had already gone quite far by the year it was built, 463. It is a basilica in that it has an eastern apse and three aisles, but in plan it approaches a centralized building, for it is nearly square, in contrast to the long basilicas in vogue in Rome. A similar change characterizes the sculptures that adorn its facade, for they are in low relief, in contrast with typical Roman high-relief sculpture, and the motifs are treated formally, as pieces of pattern, rather than as depictions of natural forms.

The process of development that can be seen here in

embryo had greatly advanced by the end of the century, as recently discovered remains of the Church of St. Polyuktos show. The church was founded by the princess Juliana Anicia (granddaughter of Valentinian III), whose name is known from an illuminated manuscript dated 512. The change was advanced still further some 30 years later, thanks to the patronage of the emperor Justinian, one of the greatest builders of all time. He was responsible for four major churches in Constantinople: SS. Sergius and Bacchus, a centralized building; the Church of St. Eirene (Irene), a basilica roofed by two domes in echelon (*i.e.*, parallel-stepped arrangement); the Church of the Holy

Hagia
Sophia

Apostles, which was cruciform, with a dome at the crossing and another on each of the arms of the cross; and, finally, the great cathedral of Hagia Sophia, where the ideas of longitudinal basilica and centralized building were combined in a wholly original manner (Figure 17). The distinctive feature of all these structures was the form of roof, the dome. In SS. Sergius and Bacchus it stood on an octagonal base, so that no great problems were involved in converting the angular ground plan to a circle on which the dome could rest. But in the others the dome stands above a square, and the transition from the one to the other was complicated. Two separate processes of doing this had evolved: the squinch, a niche or arch in the corner of the square, which transformed it into an octagon, over which the dome could be placed without great difficulty; and the pendentive, a spherical triangle fitted into the corners of the square, its vertical sides corresponding to the curves of the arches supporting the dome and its upper side corresponding to the circular base of the drum. This served to brace and support the weight and to transfer it downward to the ground at the same time. The squinch served its purpose well enough and continued in use for many centuries, but it had certain weaknesses; the pendentive was one of the great architectural inventions of all time, transforming what had been mere building, where stress was counteracted by mass, into organic architecture, where thrust was compensated by thrust and strength depended on balance. So far as is known, the squinch was first used in Persia and the pendentive in Syria.

Though Justinian's domed basilicas are the models from which Byzantine architecture developed, Hagia Sophia remained unique, and no attempt was thereafter made by Byzantine builders to emulate it. In plan it is almost square, but looked at from within, it appears to be rectangular, for there is a great semidome at east and west above that prolongs the effect of the roof, while on the ground there are three aisles, separated by columns with galleries above. At either end, however, great piers rise up through the galleries to support the dome. Above the galleries are curtain walls (non-load-bearing exterior walls) at either side, pierced by windows, and there are more windows at the base of the dome. The columns are of finest marble, selected for their colour and variety, while the lower parts of the walls are covered with marble slabs. Like the elaborately carved cornices and capitals, these survive, but the rest of the original decoration, including most of the mosaics that adorned the upper parts of the walls and the roof, have perished. They were all described in the most glowing terms by early writers. But enough does survive to warrant the inclusion of Hagia Sophia in the list of the world's greatest buildings. It was built as the result of the destruction in a riot of its predecessor, the basilica begun by Constantine, and the work of rebuilding was completed in the amazingly short period of five years, 10 months, and four days, under the direction of two architects from Asia Minor, Anthemius of Tralles and Isidorus of Miletus, in the year 537.

Early
secular
architec-
ture

From the little known it would seem that similar changes were taking place in secular architecture. The walls of the city, which still in greater part survive, were set up under Theodosius II (408–450) early in the 5th century, and already the method of construction (where a number of courses of brick alternate with those of stone) and the forms of vaulting used to support the floors in the numerous towers show several innovations. The walls themselves, a triple line of defense, with 192 towers at alternate intervals in the inner and middle wall, were far in advance of anything erected previously; they were, indeed, so well conceived that they served to protect the city against every assault until the Turks, supported by cannon, attacked with vastly superior odds in 1453. Also distinctive were the underground cisterns, of which more than 30 are known in Constantinople today. They all took on the same character, with strong outer walls and roofs of small domes supported on tall columns. Some are of great size, some comparatively small. In some, like the great cistern near Hagia Sophia called by the Turks the Yerebatan (Underground) Palace, old material was reused; in others, like the even more impressive Binbirdirek (Thousand and

One Columns) cistern, new columns of unusually tall and slender proportions and new capitals of cubic form were designed specially. These cisterns assured an adequate supply of water even when the aqueducts that fed the city were cut by an attacking enemy. Many of them were still in use at the end of the 19th century. Contemporary texts show that the houses were often large and elaborate and had at least two stories, while the imperial palace was built on enormous terraces of masonry on the slopes bordering the upper shores of the Sea of Marmara. The palace was founded by Constantine, but practically every subsequent emperor added to it, and it eventually became a vast conglomeration of buildings extending over more than 100 acres. Many of the buildings were of a very original character, if the descriptions that survive are to be believed; unfortunately, nearly all have been destroyed in the course of time.

THE ICONOCLASTIC AGE (726–843)

In spite of the ban on the representation of saintly or divine personages, and the reduced prosperity of the state during this period, churches continued to be built, including the Church of the Assumption at Nicaea and Hagia Sophia at Salonika. The emperors were not necessarily opposed to all building and art, however. It is known from texts that Theophilus (829–842) was responsible for numerous additions to the Great Palace.

THE MIDDLE BYZANTINE PERIOD (843–1204)

The most understanding of the emperors in the years immediately succeeding iconoclasm was Basil I (867–886). Like many of his predecessors, he built in the area of the Great Palace, his most interesting contributions being two churches, the New Church and the Church of the Theotokos of the Pharos. These set a fashion in church building and decoration that was to exercise an influence for many centuries. Neither survives, but something is known of them from written descriptions, and it would seem that both were typical of what was to be the mid-Byzantine style. Broadly speaking, the churches of this age conform to a single type, usually termed the cross-in-square. It is made up of three aisles, each one terminating in an apsidal chapel at the east, with a transverse nave, known as the exonarthex, at the west. Invariably, there was a dome over the central aisle, supported on four columns, with four vaults radiating from it to roof the central aisle to the west, the sanctuary to the east, and the central portions of the side aisles to the north and south. These vaults rose above the roofs of the other portions of the building, so that the church was cruciform at roof level. Excluding the exonarthex, the churches were usu-

ally almost as broad as they were long, making the basic plan virtually a square. Occasionally, additional columns were used to extend the nave westward, producing a type known as the domed basilica; sometimes the walls separating the eastern ends of the side aisles from the central presbytery were extended westward as substitutes for the two eastern columns upholding the dome, but the essentials of the plan were always retained. Subsidiary domes were sometimes added, either in place of the vaults on the arms of the cross, producing a true five-domed type, like

St. Mark's Cathedral at Venice, or placed above the eastern and western extremities of the side aisles, producing a type called the quincunx (Figure 18). These domes were usually comparatively small and were set on drums, which tended to become narrower and taller with the progress of time. The eastern extremities of the side aisles formed chapels which played an important part in the liturgy, that to the north being termed the prothesis and that to the south the diakonikon. Both the chapels and the main sanctuary were separated from the body of the church by a screen, which also became taller and heavier until it developed into the massive iconostasis that constitutes such a characteristic feature of Orthodox churches today. As in earlier periods, the lower portions of the walls were, in the richer churches, covered with marble slabs; and there were elaborately carved cornices and capitals, though ornament was always rather formal and in low relief. The main church at the monastery of St. Luke near Delphi, in Greece (c. 1050), is the most complete surviving example of the type (Figure 19).

The quincunx type

THE LATE BYZANTINE PERIOD (1204–1453)

Quite a number of buildings from the late Byzantine period survive in Constantinople, Salonika, and throughout Greece and the Balkans (Figure 20). In general they are on a small scale and follow the plan of those of the middle Byzantine period. But their appearance changed quite considerably, the domes becoming smaller and higher, while the wall surfaces of the exterior were usually elaborately decorated, either with intricate patterns in brickwork or by setting glazed pottery vessels into the wall to form friezes similar to work in tile. In Constantinople elaborate blank arcading also played an important role, as, for example, in the Church of the Pammakaristos Virgin (Mosque of Fethiye; c. 1315). The building material varied with the locality, though generally brick was preferred to stone. In the details of planning and in the handling there was considerable regional variation, and numerous local styles may be distinguished. Grandeur was generally lacking—except perhaps in the churches set up for the Comnene emperors of Trebizond, a state on the south side of the Black Sea, ruled by Greeks (1204–1461)—but all the buildings have considerable charm and deserve fuller consideration than they have sometimes received. Good work was done even after the Turkish conquests, especially on Mount Athos, Greece, and in the Romanian region of Moldavia (Figure 21), where the large-scale painted churches, which mostly date from the 16th and 17th centuries, are often both magnificent and very beautiful.

Smaller scale of buildings with elaborate brickwork

Even at this period, little is known of secular architecture,

J. Powell, Rome

but a portion of the Blachernae Palace at Constantinople may be noted (Figure 22), as well as the monasteries, particularly those on Mount Athos; though they have been much restored or even wholly rebuilt, the general layout of most follows a Byzantine scheme. (D.T.R.)

KIEVAN RUS AND RUSSIA

Kievan Rus was converted to Christianity in 988, and in Kiev, its dominant political and cultural centre, mosaics, which date from about 1045, were the work of Byzantine

craftsmen. Other Byzantine artists and artisans worked intermittently in the area from that time onward, so that Russian art as a whole was founded on a Byzantine basis. Architecture and icon painting grew up as important independent arts, both having their beginnings during this period.

From Kiev the Byzantine style of architecture soon spread throughout the principalities of Novgorod and Vladimir-Suzdal. The emphasis of the Byzantine church on the physical splendour of its edifices was a cardinal factor

in determining the characteristics of Russian ecclesiastical architecture. Everything connected with the design and decoration of the new churches followed the Byzantine pattern; and the standard scheme of the Greek church—the cross inscribed in a rectangle and the dome supported on piers or on pendentives—became the accepted type for Orthodox churches. The design and support of the central dome or cupola, together with the number and disposition of the subsidiary cupolas, remained for a long time the principal theme of Russian architecture.

The main monuments of Kiev were the Church of the Tithes (989–996), the Cathedral of St. Sophia (1037), and the Church of the Assumption in the Monastery of the Caves (1073–78). All of these churches were built in the Byzantine tradition, though certain influences from Bulgaria, Georgia, and Armenia can be discerned. The Cathedral of St. Sophia is the only structure of this period that still stands and retains, at least in the interior, something of its original form. The central part of the cathedral was in the form of a Greek cross. The nave and four aisles terminated in semicircular apses, and it had 13 cupolas (symbolizing Christ and his Apostles). It was reconstructed and enlarged at the end of the 17th century, and it was later obscured by additional bays and stories to its lateral galleries, a new tower, and many bizarre Baroque cupolas. Only five apses and the central interior portion survive from the 11th century.

Novgorod was the centre of a unique and quite original art that lived on long after the political death of the city in the 16th century; it was there that the fundamental features of later Russian architecture were developed. The ecclesiastical architectural history of Novgorod began with the Cathedral of St. Sophia (Figure 23). It was built in 1045–52, replacing a wooden, 13-dome church of the same name. The new cathedral followed its Kievan namesake in plan, but the divergences from the Byzantine pattern are quite apparent; it has double aisles but only three apses. Externally, the church differs even more from its southern prototype; it has only five cupolas, its walls are austere, the buttresses are flat and bare, and the windows are small

and narrow. There is something unmistakably Russian in the silhouette of its helmeted cupolas and in the vigour and verticality of its solid masses.

The churches of the 12th century resemble St. Sophia, Novgorod, only in the general tendency toward simplicity and verticality; they were small, cubic in form, and modest in decoration. The severe climate and heavy snowfalls of the north necessitated various modifications of the Byzantine architectural forms. In the course of time windows were narrowed and deeply splayed; roofs became steeper; and flat-dome profiles assumed the bulbous form, which, in different varieties, eventually became the most notable feature of Russian church architecture.

The churches of Pskov in northwest Russia were relatively tiny and squat and usually had three low apses. The cupolas, roofs, and decorative elements were similar to those of Novgorod. Because these churches were too small to contain interior columns for the support of the cupola, the Pskov builders developed the structural device of recessive rows of corbel arches (*i.e.*, stepped archlike structures built out from the walls) for the support of cupola drums and cupolas. This feature—the *kokoshniki*—was to become a favourite Russian structural and decorative element. The church porches, the exterior walled-in galleries, and the arcaded bell towers were Pskov's other outstanding contributions to Russian architecture.

The region of Vladimir-Suzdal (also in northwest Russia), as another centre of early Russian culture, was a factor in a creative fusion of Byzantine, Romanesque, and Caucasian influences—the Romanesque being seen in the style that was growing up in western Europe and the Caucasian influence appearing in the churches to the south. The 12th- and early-13th-century structures were a further modification of the earlier Byzantine style, leading toward the innovations at Moscow in the 15th century.

Among the outstanding monuments of Vladimir-Suzdal are the Church of the Assumption (1158–89), which was to serve as a model for its namesake in the Moscow Kremlin; the Church of the Intercession of the Virgin on the Nerl, one of the loveliest creations of medieval Russia (1165); and the Church of St. Dmitri (1194–97). These churches as a group represent the continuation of the Kievo-Byzantine tradition in their ground plan, but the old scheme was given a new interpretation. From Byzantium the Suzdalians adopted the general features of the square plan with semicircular apses and the four columns supporting a cupola with its circular drum. Instead of brick, so characteristic of Byzantine and Kievan ecclesiastical architecture, they used cut stone, and instead of polychrome wall facings they used carved-stone embroideries. The treatment and decoration of the walls and the deeply splayed portals and windows suggest the Romanesque architecture of Western Christendom; the character of the carved ornament is analogous to the intricate decoration of the Caucasus; but the organization and arrangement of the forms and patterns is definitely Russian.

After Constantinople fell to the Turks in 1453, Russia continued for several centuries to develop a national art that had grown out of the middle Byzantine period. During the 10th–15th centuries, Russian art had begun to show marked local variation from the Byzantine model, and after the fall of Constantinople it continued along these distinctive lines of development. This period of Russian art, which lasted until the adoption of western European culture in the 18th century, is also known as the Moscow or National period.

After the hegemony in the world of Orthodox Christianity shifted to Muscovite Russia, Moscow, having become the new city of Constantine—the “third Rome”—and aspiring to rival the older centres of culture, launched a building program commensurate with its international importance. The Kremlin and two of its important churches were rebuilt by Italian architects between 1475 and 1510. These churches, the Assumption (Uspensky) Cathedral and the Cathedral of St. Michael the Archangel, were largely modeled after the churches of Vladimir. The Italians were required to incorporate the basic features of Byzantine planning and design into the new cathedrals; it was only in the exterior decoration of St. Michael the Archangel

Development of the Novgorod church type

Stylistic fusion in the Vladimir-Suzdal region

Figure 24: Church of the Ascension, Kolomenskoye, 1532.
S.C.R., London

that they succeeded in introducing Italian decorative motifs. A third church, the modest Annunciation Cathedral (1484–89), with its warm beauty, was the work of Pskov architects. There the *kokoshniki* were introduced in the treatment of the roof. This element, similar in outline to the popular Russian *bochka* roof (pointed on top, with the sides forming a continuous double curve, concave above and convex below), foreshadowed a tendency to replace the forms of the Byzantine arch by more elongated silhouettes. Ecclesiastical architecture began to lose the special features associated with the Byzantine heritage, becoming more national in character and increasingly permeated with the taste and thought of the people. The most important change in Russian church design of the 16th century was the introduction of the tiered tower and the tent-shaped roof first developed in wood by Russia's carpenters. Next was the substitution of the bulb-shaped spire for the traditional Byzantine cupola. This affected the design of masonry architecture by transforming its proportions and decoration and even its structural methods. The buildings acquired a dynamic, exteriorized articulation and specifically Russian national characteristics.

The boldest departures from Byzantine architecture were the churches of the Ascension at Kolomenskoye (1532; Figure 24) and the Decapitation of St. John the Baptist at Dyakovo (c. 1532) and, above all, the Cathedral of St. Basil (Vasily) the Blessed (the Pokrovsky Cathedral) in Red Square in Moscow (1554–60). In St. Basil the western academic architectural concepts, based on rational, manifest harmony, were ignored; the structure, with no easily readable design and a profusion of disparate colourful exterior decoration, is uniquely medieval Russian in content and form, in technique, decoration, and feeling. St. Basil, like its predecessors the churches at Kolomenskoye and Dyakovo, embodies the characteristic features of the wood churches of northern Russia, translated into masonry (Figure 25). An effective finishing touch was given to the ensemble of the Kremlin's Cathedral Square by the erection of the imposing Belfry of Ivan II the Great, begun in 1542. The colossal white stone "column of fame," with its golden cupola gleaming above the Kremlin hill, was the definite expression of an era, reflecting the tastes and grandiose political ambitions of the rising Russian state.

The basic types and structural forms of the Russian

multicolumned and tented churches were fully developed in the 16th century. It remained for the next century to concentrate its efforts on the refinement of those forms and on the embellishment of the facades. The tent spires degenerated into mere decoration; they were used as exterior ornamental features set loosely in numbers over gabled roofs and on top of roof vaulting (Church of the Nativity in Putinki in Moscow, 1649–52). This decorative use of the formerly functional element was combined with the liberal employment of the *kokoshnik*. The latter, in converging and ascending tiers and in diversified shapes and arrangements, was used as a decorative screen for the drumlike bases of the spires and sometimes as parapets over the cornices. At the same time the formerly large expanses of unbroken wall surfaces (of the Novgorod-Pskov architectural traditions) were replaced by rich decorative paneling. Polychromy asserted itself: coloured and glazed tile and carved stone ornament, used in combination with brick patterns, were employed extensively. This was especially evidenced in a large group of Yaroslavl churches.

(A.Vo.)

Refinement and embellishment in the 17th century

Western Christian

EARLY MEDIEVAL

Migratory period. The migration of European peoples, which was one of the consequences of the decline and ultimate fall of the Roman Empire, had its prelude in the transmigration of the Goths, who, about AD 200, had crossed from Sweden to the region around the mouth of the Vistula River, thence eventually reaching southern Russia. There they came into contact with an ancient artistic tradition that they largely succeeded in grafting onto decorative styles brought over from Scandinavia. When, in 375, the Huns invaded Russia, the Goths demanded and obtained permission to settle within the borders of the Roman Empire. This westward movement was the beginning of the great migration of peoples. In this way, too, new forms of art, soon to be amalgamated with influences from other tribes, also reached western and southern Europe.

When the Ostrogoths under Theodoric came into contact with the late classical and Byzantine cultures, their

Changes
in church
design

art was influenced by these civilizations. This is evident from the Mausoleum of Theodoric in Ravenna (built c. 520), which generally reflects the classical and Byzantine traditions but in its abstract ornamentation is linked with the art of the migration period. It is likely that the mausoleum also reflects influences that had lived on from prehistoric megalithic graves, which were piled up from solid blocks of stone.

Merovingian architecture

Merovingian period. *France.* Of the architecture of this period, little has survived. In the south of France there are still a few baptisteries (Fréjus, Riez, Venasque) that reveal a distinct affinity to similar structures in Italy. The Poitiers baptistery, in its present form dating from the 8th century, is on the threshold of the Carolingian epoch, but it contains much more ancient wall work. Most of the major church buildings are known only from descriptions by early medieval writers or from research work undertaken through excavation of the foundation ruins. According to Apollinaris Sidonius, the naves of the cathedral of Lyon (founded about 470) were separated from each other by a forest of columns and were covered by gilded, paneled ceilings. Gregory of Tours relates that the church of Bishop Namatus of Clermont (built c. 450) boasted 70 columns, 42 windows, and eight portals. The same author also praises the church of Saint-Martin at Tours, which was begun by Bishop Perpetuus in the latter half of the 5th century. Also 5th-century in their original form were the chapel of Saint-Maurice-d'Agaune and the church of Saint-Germain at Auxerre. Excavations have revealed the shape of such churches as those of Saint-Martin at Autun (built 590) and the church of Jouarre (c. 680). The Merovingian kings were great builders; about 510 Clovis founded a church on the tomb of Sainte-Geneviève in Paris, and Childebert built Sainte-Croix-et-Saint-Vincent (today Saint-Germain-des-Prés). Both churches were decorated with marble and mosaic and roofed with bronze tiles—as was the church of Notre-Dame-de-la-Daurade in Toulouse, which probably dates from the end of the 6th century and was demolished only as late as 1761.

Ireland. Of the earliest Irish architecture very little is known. There are some ruins of monasteries found, for example, at Skellig Michael (on the east coast of Ireland), at Nendrum (County Down), and, in England, at Tintagel (Cornwall).

England. The oldest churches in Kent and Essex (including those at Canterbury, Lyminge, Reculver, and Rochester) consist of a rectangular nave with an apse. Most of these churches were later enlarged by the addition of two smaller spaces flanking the nave and connected by narrow passageways. The outside walls are lined with pilasters, or columns projecting about one-third of their widths from the walls. In some of the churches the choir is separated from the nave by an arcade, as at St. Pancras in Canterbury and Bradwell-on-Sea in Essex.

Spain. In the second half of the 5th century, the Visigoths penetrated into Spain and, as early as 470, ruled practically the entire country. Toulouse remained their capital until 507, when Clovis I pushed them back beyond the Pyrenees. In 554 Byzantine troops invaded Spain but were driven back in the last quarter of the 6th century; nevertheless, contact with the Byzantines left an indelible impression on Visigothic art. The influence was short-lived, however, ending when the Arabs conquered almost the whole of Spain in 711. The only surviving Visigothic structure is the church of San Juan Bautista at Baños de Cerrato, consecrated in 661; it is a small structure, originally planned as a three-aisled basilica, in which the horseshoe-shaped arch is predominant.

Carolingian period. In contrast to Merovingian architecture, a comparatively large number of Carolingian buildings have survived. The most renowned edifice is the Palatine Chapel of Charlemagne at Aachen (consecrated 805), the core of the present-day cathedral (Figure 26). Built in the shape of an octagon with two superimposed galleries, this structure resembles San Vitale in Ravenna, and the ground-floor section of the interior recalls the mausoleum of Theodoric. The building was enriched with classical columns brought from Ravenna and Rome, and the bronze railings and door wings were presumably fash-

ioned by artisans from Lombardy. Above the octagonal chapel rises a dome, which is 101.5 feet high on the inside with a diameter of 46.7 feet. This desire for loftiness is neither classical nor Byzantine but Germanic, and it continued into the Romanesque and Gothic styles. Central architecture also found favour elsewhere; Bishop Theodulf of Orléans, for example, built a chapel in the vicinity of the abbey of Fleury (afterward Saint-Benoît-sur-Loire), a chapel that, unfortunately, has been greatly altered by 19th-century restoration. As in Charlemagne's chapel, the highest part is the square central section, from which four branches extend, forming a Greek cross; in the corners of the cross are four lower chapels, and at the ends are apses shaped somewhat like horseshoes. The arches are also slightly horseshoe-shaped—possibly a Visigothic influence from Spain. Unlike the cathedral at Aachen, which in the 18th century lost all mosaic decoration, this church has preserved its Carolingian apse mosaic.

In addition to central architecture, the T-shaped basilica form was frequently employed; fairly well-preserved examples of this can be found at Steinbach and at Seligenstadt in Germany. The walls of the nave at Steinbach (821–827) rest on square masonry pillars. On the east side there are two transept chapels, which are lower in height than the nave but higher than the aisles; like the nave, they end in semicircular apses. The church had a tripartite narthex no longer in existence. In the church of SS. Marcellinus and Peter at Seligenstadt (830–840) only the three-aisle nave on pillars is original. In the style of the great basilicas of Rome, this church had a hall-shaped, wide transept with a semicircular apse adjoining it. Some churches, such as Centula (Saint-Riquier, Fr.), which is known only through pictures, had a second choir on the west side (Figure 27). A fairly well-preserved west choir, forerunner of the later Romanesque westwork, is to be found in the church of Corvey, in Germany (873–885). Notable also is the gatehouse of the monastery of Lorsch (Figure 28), near Worms, Ger. (founded c. 760–764). This edifice borrowed its three arch-shaped passageways and its sectioning by means of classically influenced half-columns from ancient triumphal arches. On the other hand, Teutonic influence is evident in the upper section of the blind arcade, which

consists of baseless triangles, and in the multicoloured decoration of the masonry.

Ottonian period. Ottonian art is the official art of the realm in the epoch of the Saxon, or Ottonian, emperors and of their first successors from the Salic house (950–1050). Its centre was Saxony, birthplace of the Ottonians, but its influence extended over the whole realm, with the exception of Italy. Ottonian art was shaped by the Carolingian tradition, by early Christian art, and—because Otto III's wife, Theophano, was a Byzantine princess—by contemporary Byzantine art.

It was architecture especially that followed early Christian and specifically Roman examples, while at the same time remaining true to the Carolingian style (the west choir, for example). In Saxony, the art-loving bishop Bernward, who had seen the great basilicas in Rome and had come into contact with classical art, was the great builder; about 1001 he founded the abbey church of St. Michael in his episcopal city of Hildesheim (Figure 29). At an earlier date (961) the margrave Gero had had the Church of St. Cyriacus built at Gernrode. The two churches have wooden-roofed, three-aisle naves; but, in contrast to the Carolingian pillar basilicas, alternating pillars and columns have been used, and at Gernrode the side aisles are crowned by galleries. The two churches have both an east and a west choir and transept arms as high as the nave. At Hildesheim both choirs have a transept with a square dome over the crossing, flanked by staircase towers. Gernrode has crypts underneath both choirs whereas Hildesheim has them only beneath the west choir. The harmony and clarity that characterize both the interior and the exterior of the church at Hildesheim make it the finest example of Ottonian architecture. On the alternating pillars and columns (that is, a pair of columns between each pillar), one encounters for the first time the cubical, or cushion, capital that was later to become such a characteristic feature of the Romanesque style.

Few of the innumerable major churches built about the year 1000 have survived in a good state of preservation; others have completely disappeared. Some of the outstanding ones are, or were, the cathedrals of Magdeburg, Merseburg, Paderborn, Liège, Mainz, Worms, Strasbourg, Verdun, Basel, Metz, Eichstätt, Bamberg, Regensburg, Augsburg, Lausanne, and Dijon. The surviving ground

plans show that frequently they were wooden-roofed basilicas with east and west choirs. Of the basilicas on columns, which are rare, there is Oberzell, in the south, on the island of Reichenau, and, in the north, St. Peter's at Utrecht (The Netherlands). Churches with a nave are also rare; notable examples are the original St. Pantaleon at Cologne and St. Patroclus' Church at Soest, Germany. The Aachen chapel's octagon was fairly widely imitated; the best preserved examples are in Ottmarsheim (France) and Nijmegen (The Netherlands), both dating from the early 11th century. The west choir of the Minster at Essen is remarkable in that it imitates the forms of the chapel at Aachen on a ground plan of a semi-hexagon.

Prelude to Romanesque in the north. Northern construction of wood in pre-Romanesque times is well represented by the "long hall" or palace at Lojsta (built c. 1000) on the island of Gotland. Judging from the remains of the building, the superstructure must have consisted of tall, triangular frames stiffened by timbers that mark out a supporting square in the lower half of the triangle. There was a smoke hole above the hearth. This type of construction, originating on the Continent, spread throughout Scandinavia. It has been traced by excavation in Greenland (Gardar) and in Newfoundland (La Baie aux Meadows, near Cape Race); and actual modern examples of the traditional mode exist in Iceland (Vidhmýri). In fine medieval examples, the timbers were richly carved and painted.

By the time churches were being built, the sloping exterior bank of a longhouse, or long dwelling of wood, was often replaced by vertical timbers and plank walls. In the more ambitious buildings there might be four files of interior supports, instead of two, under the steep two-slope roof. The churches were distinguished by having the aisles carried entirely around the central space, which projected above them in order to permit small windows. The sanctuary was a small, shedlike projection with a pinnacle, and the belfry took the form of a small shed perched on the roof, with a pinnacle above it. These churches are called stave (wooden-plank) churches or, more properly, mast churches, because of the novel way in which the inner

middle part is supported by masts, or vertical posts, on its periphery; the masts themselves are supported on a stout chassis the timbers of which extend outward to sustain the aisles and porches. It is probable that this formula was achieved by the year 1000, when Christianity began to dominate in Scandinavia. The churches are extraordinarily picturesque, in contrast to the longhouses or palaces near which they were often placed as palace chapels—their special form suggested, perhaps, by reliquaries or manuscript drawings of churches. The more elaborate churches had wonderfully energetic carvings, in particular the panels of interlaced lacertine, or lizard-like, creatures (as at Urnes in Norway, c. 1100). They were replaced by simple Romanesque buildings of English and German inspiration when the congregations outgrew the mast churches, which are necessarily rather small.

When towns and cities came to be built, improved versions of the longhouses, with several stories, were placed side by side. A reminder of this persists in the many-gabled street frontages not only in Scandinavia but also in The Netherlands and along the south Baltic littoral—regions that are heavily timbered. In Russia, walls were built of horizontal timbers sometimes as much as three feet square in cross section. In Scandinavia the ancestors of the American frontier log cabin were built in this way. In the Germanic area, however, half-timber and palisade construction were preferred. A survivor of the latter type is the old part of the Saxon church (1013) at Greenstead, Essex, Eng.

ROMANESQUE

Romanesque is the name given to the architectural and artistic style current in Europe from about the mid-11th century until the advent of Gothic.

Romanesque is a less familiar term than classical, Gothic, or Renaissance because of the historical circumstances under which it entered artistic terminology. The classical and the Renaissance were clearly defined by men who consid-

ered their canons inevitable and who thought of the medieval styles as fanciful (if not objectionable) aberrations. Blinded by the fashionable canon, a critic wrote in 1750:

The Goths and Vandals, having demolished the Greek and Roman architecture, introduced in its stead a certain fantastical and incontinent manner of building, which we have since called modern or Gothic, full of fret and lamentable imagery.

Half a century later the Gothic was understood as having a noble canon of its own, but its background was still veiled—considered to be the work of untutored barbarians, whose vigour, interpreted as crudity, repelled those who cared for the arts. Romanesque did not even have a name until 1818, when the term *roman* (Romanesque, *romanico*, *romanisch*) was coined by Charles-Alexis-Adrien de Gerville. The corresponding term is Romance for the languages based on Latin; in each case the underlying elements came from Rome. Actually the name Romanesque itself is the simplest, most practical definition of the style. It is Roman, with differences—differences conditioned by a complex historical background, which brings about a marvelous richness of expression, varied from region to region, with a truly noble lucidity in the finest creations.

The Romanesque period was no less complex in its art than in its history, though it had a unifying theme in monasticism. To compensate for the loss of stable central governments, there was a strong movement to found monasteries from about 650 to 1200. Such brotherhoods, which lived the ideal Christian life as it was understood at the time, were islands of civilization in a very much disturbed world. The most effective of these institutions were in the Frankish territory between the Rhine River on the east, the Loire River on the south, and the coast on the north and west.

Records of lost buildings show how much of the later architectural development was envisaged in the time of Charlemagne. As a basis for monastic unity he chose the Rule of St. Benedict. On his estate at Aniane a later Benedict—of Aniane—with Charlemagne's encouragement, built a monastery where all the arts were brought into play (782) and later constructed a model monastery at Cornelimünster (Inden, near Aachen). Meanwhile, a monastic holy city had been built at Centula, where the monastic church of 799, with its cloister and chapels, was the centre of all. Around it, the wards and various guild quarters of the city were laid out in regular fashion; at some distance there were seven satellite villages bound to the monastery by periodical ceremonial visits in the form of processions. For better exploitation of the imperial estates everywhere, a type of villa was evolved; with the passage of time and the retreat of the gentry to their castles, many of these became ecclesiastical possessions—then priories, or even monasteries, as in the case of Cluny (910). By 820 the typical monastic layout had been fully studied (as at Inden and St. Gall). This later site, the Insula Felix in Lake Constance, was a stopping place for the imperial journeys, and it developed as a powerful monastic and missionary centre—one of the many that enlarged the boundaries of Christendom as Charlemagne's dominions expanded to the north and east.

In the Middle Ages the population of Europe had diminished by half since Roman times. Communication and transport, either by land or by sea, might be difficult or hazardous, and this tended naturally to divide the country into neighbourhoods. Under these conditions, a great monastery, like a city, could serve a considerable surrounding area as an administrative, intellectual, and spiritual centre and as a workshop, granary, and refuge. With increasing prosperity the monastic building complexes were progressively better organized, better built, and more impressive. Showing the way for cathedral and domestic architecture, the great patrons of the age were the abbots, though not to the exclusion of the bishops and magnates.

The Romans had not solved the problem of the fireproof basilican church—a problem that became pressing with the frequent conflagrations in timber-built towns and, not less, the incendiarism that was a lamentable consequence of endemic local wars and the incursions of organized marauders. By AD 1000 the monastic builders had begun

Definition
of Roman-
esque

Improvements upon Roman construction

to solve this problem by vaulting. Moreover, they had improved upon the Roman attempts at systematic plans for the monasteries themselves, which might accommodate 1,000 persons—monks, brethren, craftsmen, servants, slaves, and guests—with provision for their multiple activities and also suitable storage facilities.

The solution, well exemplified in the plan of 820 for the monastery at St. Gall, was a quadrangular court, or cloister, provided with arcaded walks, or “alleys,” and placed beside the nave of the church. Typically, the east walk had an entrance into the church near the sanctuary; and the members of the community, entering processionally, would turn into their choir enclosure in the nave, while the celebrants would occupy their posts in the sanctuary. Important rooms bordered the east walk: the chapter house, where the community met as a corporation; the parlour, where speaking was allowed for the transaction of business; and the camera, or workroom. The walk parallel to the church gave access to the calefactory (in early times often the only heated room) for fellowship, the refectory, the pantries, and the kitchens. The cellars stretched along the west walk between the kitchens and a porter’s lodge adjoining the church. The door at the porter’s lodge was the principal entrance to the cloister. The scriptorium and library were typically in the walk beside the church; the dormitory was usually located directly above the buildings of the east walk.

This plan was very flexible, for in a large monastery there would be several cloisters or courts with suitable independent arrangements for archives, administration, guests, wayfarers, servants, artisans, shops, and folds; special quarters were provided by such courts for retired or sick monks and for novices. Special chapels were provided, where necessary, in these subsidiary parts of the establishment.

The several cloisters or courts of a large monastery car-

ried on the tradition established by the greater Germanic households of the pagan time; they too were composed of “proliferating quadrangles.” The basic unit, as has been learned from excavation, was a wide, framed, compartmented longhouse with a steep, thatched roof. By Charlemagne’s time longhouses of this type were sometimes adapted as churches.

Though Rome could no longer present fresh models for universal emulation or exercise unifying control, its architectural monuments were still numerous in many regions and could not be ignored. The Roman heritage is particularly apparent in conservative southern regions, where Roman massiveness and horizontality persist and are perceptible to some degree even in the Gothic architecture of the area. In the regions where the Roman population had been large, commonplace buildings continued for a long time to be built in much the same way as before, with increasing emphasis—especially in the north—on the use of timber construction in small or utilitarian structures. In the wet northern climates steeper roofs were necessary, particularly where thatch was used. New importance accrued to the fact that the various regions had differing materials and aesthetic ideals. The artists had a wider choice among sources of inspiration than the Romans, but the choices that were made by responsible architects varied from region to region. This explains the origin of “schools” of Romanesque—families of designs inspired by successful buildings in a local context. These were usually churches, often of novel design, and situated at the centre of an important region that, in modern parlance, gives its name to the school.

The forward-looking Romanesque artists were aware of and could synthesize ideas and practices from Rome, Byzantium, the Islāmic world, Scandinavia, and the Teutonic regions. The number of options was fairly large, offering a great many possibilities of variety; moreover,

The Roman heritage

Figure 30: Saint-Sernin, Toulouse, Fr., 1077 or 1082–1118. (Top left) Chevet, east end; (top right) nave; (bottom) plan.

the importance given to certain features varied from one school to the next.

Elements of Roman origin might involve one or several important Roman types of fabric and material, plan, vaulting, decorative elements, and, in the south, the Roman canon of proportion. Early Christian works offered a choice of plans, with or without towers and porches. Elements of Eastern origin might be structural or decorative, and they might be derived from Iberian, African, or Asiatic examples. From the north came not only imaginative timber construction but also various lively decorative systems and verve in their application.

Perhaps even more important was the northern love of aspiring and intersecting forms, powerfully composed, which affected almost the entire Romanesque area, stretching from Portugal to the Holy Land, including Scandinavia and the Holy Roman Empire. The greater buildings were most often churches, which stood out boldly above the ordinary constructions but had an organic relationship to them. The resulting silhouette, so much in contrast with placid classical design, quite transformed the idea of what a city or church group should look like, either from within or from a distance as an ensemble. This dynamic mode was bequeathed to Gothic, Renaissance, and modern times.

After 950 the excellent construction, the grand scale, the assured design, the increasingly capable use of masonry vaulting, and the increasingly rich and appropriate use of foliate and figural sculpture showed that the initial period was over and that a noble, new Romanesque style had come into existence (fully, by 1050). The greatest works in the Romanesque style date from 1075 to 1125, the classic age of Romanesque, so to speak; after this, in some regions, the style entered a florid "baroque" phase that lasted a generation and then was revived as Gothic.

The coming eclipse of Romanesque may first be sensed in new structural developments that began about 1090. Sophisticated but unsatisfactory attempts to vault the great basilican naves safely, with elements of Roman, Byzantine, or Eastern origin, impelled progressive Romanesque engineers, from about 1090 onward, to invent a new type of ribbed groin-vaulted unit bay, using pointed arches to distribute thrust and improve the shape of the geometric surfaces. Fifty years of experimentation produced vaulting that was light, strong, open, versatile, and applicable everywhere—in short, Gothic vaulting. A whole new aesthetic, with a new decorative system—the Gothic—was being evolved as early as 1145. The spatial forms of the new buildings sometimes caused acoustic difficulties, which may help to account for the concomitant development of the new polyphonic music that supplemented the traditional Romanesque plainsong. Romanesque architecture became old-fashioned, but its heavy forms pleased the Cistercian monks and, likewise, other conservative patrons in Germany, Poland, Hungary, Italy, Spain, and Portugal. Thus, buildings that were essentially Romanesque in spirit continued to be built, even when such extraordinary Gothic works as the Amiens cathedral were under construction (begun 1220).

The development of proto-Romanesque in the Ottonian period culminated in the true Romanesque style represented by five magnificent churches on the international pilgrimage routes leading from central France to the reputed tomb of St. James at Santiago de Compostela in Spain: Saint-Martin at Tours (a huge once wooden-roofed basilica that was rebuilt on the new model beginning about 1050), Sainte-Foy at Conques (c. 1052–1130), Saint-Martial at Limoges (c. 1062–95), Saint-Sernin at Toulouse (1077 or 1082–1118; Figure 30), and the new cathedral at Santiago de Compostela itself (c. 1075–1211). This was a real family of buildings; each one had a splendid apse with ambulatory (a sheltered place to walk) and radiating chapels, a transept and nave with aisles and galleries, an imposing tower system, and beautiful sculptures. Each one was entirely vaulted, typically, with barrel vaults over the nave, quadrant vaults (four-part vaults, formed by two intersecting arches) over the galleries, and groin-vaulted aisles. A little later, at the Cluniac priory of Saint-Étienne (Nevers, Fr.), such a church was boldly built with

clerestory (part of the nave, choir, and transept walls above the aisle roofs) windows under the high vault.

Burgundy. Since the monasteries had done so much to create the new Europe now bursting into architectural flower, it is appropriate that there are two families of churches that express the greatness of Burgundian federative monasticism: Cluny and Cîteaux. Cluny ultimately had about 1,400 dependencies under centralized rule, of which about 200 were important establishments. The Cistercians had a ramified system that ultimately included 742 monasteries and about 900 nunneries.

It was Cluny that, after an impressive rebuilding of the monastery buildings (1077–85), undertook the Maïor Ecclesia, or Cluny III (1088–1130 and later). Until it was largely demolished in the early 19th century, it was the largest monastic church, the largest Romanesque church, and the largest French church. It had many features that prepared the way for Gothic: tall proportions, grouped piers, pointed arches, specialized wall and vault construction. It had carvings of great beauty in the apse (where one of the first medieval sculptural allegories was placed by 1095) and at the portals of the nave (where the first really grand ensemble of monumental carved and painted west portals was placed, about 1108). Cluny III inspired only a few great buildings (including, however, Paray-le-Monial, La Charité-sur-Loire, and Autun cathedral) because of its special, advanced character and the fact that the design was soon attacked in an unfortunate Cistercian polemic (1124). It may be that certain architects at Cluny itself considered the design too bold, for they built at the priory of Vézelay (1104–32) a groin-vaulted nave nearly as wide but only two-thirds as high as that of Cluny III. In the narthex at Vézelay there was one groin vault that had ribs, and buttresses resembling flying buttresses were concealed under roofs of the galleries. A pair of towers flanking a carved portal were planned for the facade.

Thus, between these features of Vézelay and the pointed arches composed in tall proportions at Cluny III, the ingredients of the Gothic style were at hand in Burgundy by 1135, awaiting the creative Gothic spark of Saint-Denis (near Paris). The rich portals of Saint-Denis show the influence of the great Burgundian carving. Account must

of archi-
ecture on
music

be taken, however, of another episode—the development of consistent ribbed vaulting in the Norman dominions. Probably the high-ranking Lombard ecclesiastics who undertook the reform and development of the Norman church brought with them some knowledge of ribbed vault construction, which then passed to England. The cathedral abbey church of Durham (1093–1133) was a very early demonstration of the dramatic potentialities of this type of construction (Figure 31). Lombard experiments may have been as early as 1080, but the dating is uncertain; in any event, the development of this structural unit into the admirable Gothic type of ribbed groin vault is due to the skill of French and Anglo-French engineers.

Cistercian
architects

Returning to another great family of Burgundian monastic builders, it should be noted that the Cistercian Order was founded as an austere reform institute in 1098 and that it spread rapidly. The Cistercian architects were commanded to build well but without bravura of any kind. They accepted the pointed arch but built ponderously within it a style that might be called half-Gothic, because it has the general appearance but not the special structural characteristics of Gothic. Cistercian constructions were for a long time massive, like the Romanesque. Fontenay Abbey (1139 and later) represented the personal preference of St. Bernard, and it is almost Roman, with its very simple and substantial scheme of pointed barrel vaulting. In general, however, the Cistercian churches came more and more to approximate Gothic designs. In the ground floors of their monastery buildings they early introduced the idea of using ribbed groin vaulting in repetitive square bays (a Gothic scheme). To the east, the south, the west, and the northwest of Europe, the first buildings resembling Gothic were erected by the Cistercians: Pontigny, 1140–1210 (Burgundy); Alcobaça, 1158–1223 (Portugal); Fossanova, 1187–1208 (Italy); Maulbronn, 1146–78 (Germany); Fountains, 1135–50 (England); Vreta, about 1100–62 (Sweden); Kercz, 1202 (Hungary); and Beirut, about 1150 (Lebanon)—all of these give an idea of the power and extension of their effort.

The Cistercian establishments were located in remote places, but the husbandry of the communities was superb and benefited the whole of Europe. Their monasteries were so uniform in conception that a monk coming from a Cistercian house anywhere would feel quite at home in one of these monasteries anywhere else. The basic plan was traditional, but the western court (where visitors were usually received) was reduced to a mere corridor. The Cistercians did not encourage visitors; they were not provided with space in guesthouses within the enclosures or even in the churches. Cistercian refectories were regularly placed at right angles opposite the church, rather than parallel, as in early plans. The monks chose well-watered sites and used waterpower. Ideally, the brotherhoods were able to supply all of their own needs.

Benedic-
tine abbey

Normandy. Another great architectural family was Norman: Rouen cathedral (c. 1037–63), followed by Westminster Abbey (1050–65) and the splendid abbeys built in Caen by Duke William and his duchess, Matilda. She built La Trinité, beginning in 1062, and was buried as queen in its sanctuary (1083). William's church, Saint-Étienne, was begun in 1067 and dedicated in 1081 (Figure 32). The Norman series was continued in England by the foundation and endowment of magnificent Benedictine abbeys after the Conquest, as royal policy—to gain the favour of the church, to improve the exploitation of the land, and to pacify the country. Many of the church buildings still exist, and they are very impressive indeed. Typically, they have, or have had, long, wooden-roofed naves with vaulted aisles and wooden-roofed galleries, embellished, stage by stage, with bold, rich interior arcading. The churches have spacious transepts and deep sanctuaries, the apses being arranged in echelon or with ambulatories. It gives one a sense of the builder's means to know that a very large part of the beautiful limestone used in facing the walls was transported across the Channel from the famous quarries of Caen. Though the walls and piers are beautiful, the mortar was not good, and only great thickness made the masonry strong. The Norman parish churches that survive are neither numerous nor striking. Among the more ambi-

Figure 32: West facade, Saint-Étienne, Caen, Fr., begun in 1067 and dedicated in 1081.

Jean Roubier

tious naves originally roofed in wood but now closed with Gothic vaults are those of the cathedrals at Winchester (1079), Gloucester (1089), and Norwich (1096). Peterborough cathedral (1118) still possesses its old ceiling, painted in lozenge-shaped panels. In many of the churches a large number of additions have been made in the Gothic style without impairing the dignity of the Norman construction. But Durham cathedral, with its Romanesque ribbed groin vault, remains by far the finest example of the Norman style.

Aquitaine, Languedoc, and Auvergne. Long united to the English crown after 1152, Aquitaine has a quite separate church architecture. To achieve free interior space, masonry domes of special construction were used, often four in line, as at Saint-Étienne-de-la-Cité, Périgueux (c. 1100–50), and the cathedral of Saint-Pierre at Angoulême (1105–28 and later), with a richly sculptured facade.

In Poitou, elaborately arcaded facades formed somewhat illogical frontispieces for spacious “three-naved” churches, with windowed aisles almost as tall as the central windowless naves. There are beautiful paintings in such churches (as at Saint-Savin-sur-Gartempe). This region has several Romanesque castles, in the usual form (as at Loches, about 1100) of a great square tower, the donjon or keep, with guard and residential rooms on several levels, and appropriate outworks.

castles

The churches of Languedoc have bold massing and beautiful sculpture, the tradition of which goes back to the formative period (Saint-Genis-des-Fontaines, 1020). Saint-Sernin at Toulouse, in the pilgrimage style, are beautiful carvings, and many churches in the region are related to it.

In Auvergne, a long tradition (Clermont cathedral, 946) developed, more or less in the manner of the pilgrimage churches. The high “lantern transepts” are characteristic (for example, Notre-Dame-du-Port at Clermont-Ferrand, 1150). The cathedral of Le Puy-en-Velay (11th and 12th centuries), with zebra work in the masonry and a file of domes, represents reflex influence from Spain; Muslim motifs were brought in via the pilgrimage road. Such influence is perceptible also in Burgundy and perhaps in the west of France.

Provence. Turning eastward to Provence, the old Provincia Romana, one finds that there Romanesque architecture is most Roman in feeling: grand, simple, spacious bulks were built, usually in fine ashlar (squared stone blocks) masonry, as at Avignon cathedral (about 1140–1200), and often with fine sculpture, as at the cathedral of Arles (Saint-Trophime, 1150 and later) and Saint-Gilles-

du-Gard (1116 and later, to about 1170). Some of the portals, especially, seem very Roman.

Germany and the Low Countries. By contrast with the fresh activity in France, the imperial lands, which had done so much to further the development of Romanesque architecture, remained conservative. The period of the mature Romanesque was prosperous in Germany; new buildings were larger and more numerous but technically less interesting. The embellishment and vaulting of the cathedrals in the Rhine country date from this time: Mainz (1036–1137), Speyer (1030–65, remade c. 1082–1137; Figure 33), and Worms (12th and 13th centuries). A prime example is the abbey church of Maria Laach (1130–56). Elsewhere, there is a spectacular church design with five towers at Tournai (c. 1110–1200), and there are ponderous but handsome palaces with fine upper rooms at Goslar (c. 1050, rebuilt after 1132) and Eisenach (the Wartburg, 12th century).

Romanesque architecture in the Low Countries is generally divided into four stylistic classifications: the style of Meuseland, the Scheldt district style, the style of the bishopric of Utrecht, and the style prevalent in the provinces of Groningen and Friesland. The Meuseland churches are characterized by their use of the Carolingian basilica plan. Among the most outstanding examples are St. Servatius at Maastricht; Saint-Denis, Saint-Barthélemy, Saint-Jean, and Sainte-Grtrude at Nivelles. At the end of the 12th century, Rhenish influences were evident in Meuseland, such as in the apse of St. Servatius at Maastricht. In the Scheldt district a pronounced Norman influence is apparent, as in the cathedral of Tournai and the Church of St. Vincent at Soignies. A blending of Ottonian, Rhenish, and Meuseland styles characterizes Romanesque churches in the bishopric of Utrecht as St. Peters at Utrecht, Grote Kerk at Deventer, and St. Martin at Emmerich. Groningen and Friesland possess a great number of Romanesque village churches that were founded by abbeys in the region. Stylistically, they are related to monastic churches in Meuseland and parts of northern France.

Iberia. The pre-Romanesque types of building in the peninsula were insufficient to satisfy the needs and ambitions of the Spaniards as the Christian states increased in population by immigration and expanded southward by the reconquest in Romanesque times. The architecture clearly testifies to the great influx of men and ideas, particularly from Burgundy, Poitou, and Languedoc (as at Santiago de Compostela cathedral). Cistercian half-Gothic

Roman-
esque
style in
Lombardy

became important (e.g., Poblet, 1180–96). Catalonia long remained faithful to the Lombard style. Everywhere there are Muslim reminiscences, sometimes obvious, sometimes very subtle.

The walls of Ávila (1090 and later) are among the finest of Romanesque military constructions, and Loarre in Aragon, with its beautiful chapel, is perhaps the finest Romanesque castle.

Italy. Lombardy was an area in which the proto-Romanesque style was transformed into the true Romanesque, particularly because of the development of ribbed groin vaulting. Decorative arcading, in enriched form, was used and brick was widely employed in later work. Romanesque forms continued in use long after the coming of Cistercian half-Gothic. The Lombard cities built tremendous cathedrals, simple in plan, during the 12th century; examples are Modena (1099–1184), Parma

(1117–32), and Cremona (1129–1342). Parma and Cremona have large freestanding baptisteries, unusual at the time. A very handsome type of belfry tower was brought to perfection by the Lombards, and impressive town halls were built with Romanesque inspiration but at Gothic dates. Turbulence in the city streets caused the construction of private fortifications in the form of taller houses: Bologna, for example, had 180, and Lucca “rose like a forest.”

Tuscany retained strong early Christian traditions, exemplified in the octagonal Baptistery of Florence (restored in 1059) and the common use of basilican church forms. In the Romanesque period, marble was used extensively, often in panels and zebra work (for example, the cathedral group at Pisa; cathedral 1063–13th century, baptistery 1152–1278, and the Camposanto 1278; Figure 34).

Central Italy was still more conservative; the early Chris-

tian style survived there with little change except degeneration. The region about Monte Cassino was more inventive; the famous abbey built the typical church of the region, basilican in form (1066–71). A school of painters developed there, under Byzantine influence, which was drawn on by the Cluniacs in their work.

Norman Italy and Sicily. Buildings basically Lombard, Tuscan, Muslim, Byzantine, or early Christian were built as the realm became prosperous. Nuances of design and a strange mingling of influences give them strong local feeling. Examples are San Nicola, Bari (1087), where St. Nicholas is buried; the cathedral of Monreale (1174), with wonderful mosaics and a poetic, half-Oriental cloister (1172–89; Figure 35); and San Cataldo at Palermo (1161), a former synagogue in the Muslim domed style. These Sicilian buildings are actually more exotic than the structures built by the crusaders in Palestine (1099–1244).

Palestine. The crusaders built extensively in the Latin Kingdom of Jerusalem. The buildings are southern French or Burgundian Romanesque or Burgundian half-Gothic in style (for example, new constructions at the Church of the Holy Sepulchre, 1099–1147, and the cathedral of Tortosa, or Tartús, late 12th century). Many remarkable castles were built before and after 1200, incorporating Byzantine and Muslim innovations in military architecture, as at the Krak des Chevaliers or at Margat, “whose bastions seemed to sustain the sky; only eagles and vultures could approach its battlements”—striking witness, in so remote a place, to Romanesque faith and power. (J.J.M.T.)

GOTHIC

Throughout this period, the central corridor of Europe running northwest from Lombardy to England, between Cologne and Paris, retains an exceptional importance. Much of the significant art—especially architecture—was produced within this geographic area, because it appears to have been an extraordinarily wealthy area, with enough

funds to attract good artists and to pay for expensive materials and buildings. Paris—for much of this period the home of a powerful and artistically enlightened court—played an especially important role in the history of Gothic art.

Early Gothic. At the technical level Gothic architecture is characterized by the ribbed vault (a vault in which stone ribs carry the vaulted surface), the pointed arch, and the flying buttress (normally a half arch carrying the thrust of a roof or vault across an aisle to an outer pier or buttress). These features were all present in a number of earlier, Romanesque buildings, and one of the major 12th- and early 13th-century achievements was to use this engineering expertise to create major buildings that became, in succession, broader and taller. How their visual appearance changed is easy to see if one compares, for instance, the early 13th-century Reims cathedral, in France, with the late 11th-century Durham cathedral, in England. A broad comparison of this sort also brings out the artistic ends to which the new engineering means were applied. Skilled use of the pointed arch and the ribbed vault made it possible to cover far more elaborate and complicated ground plans than hitherto. Skilled use of buttressing, especially of flying buttresses, made it possible both to build taller buildings and to open up the intervening wall spaces to create larger windows. In the 12th century larger windows produced novel lighting effects, not lighter churches. The stained glass of the period was heavily coloured and remained so—for example, at Chartres cathedral—well into the 13th century.

One of the earliest buildings in which these techniques were introduced in a highly sophisticated architectural plan was the abbey of Saint-Denis, Paris. The east end was rebuilt about 1135–44, and, although the upper parts of the choir and apse were later changed, the ambulatory and chapels belong to this phase. The proportions are not large, but the skill and precision with which the vaulting is

The role of Paris in Gothic art

Architecture of the crusaders

managed and the subjective effect of the undulating chain windows around the perimeter have given the abbey its traditional claim to the title "first Gothic building." The driving figure was Suger, the abbot of Saint-Denis, who wrote two accounts of his abbey that are infused with his personal aesthetic of light as a reflection of the infinite light of God. Something similar to what he intended at Saint-Denis was attempted soon after at Notre-Dame, Paris, begun in 1163 (the east end was subsequently altered; Figure 36), and Laon cathedral, begun about 1165 (the east end was rebuilt in the early 13th century; Figure 37). Perhaps because of liturgical inconvenience, it later became more common to keep firm the architectural divisions between the peripheral eastern chapels, as at Reims (rebuilt after a fire destroyed the original cathedral in 1210) and Amiens (begun 1220) cathedrals, for example. This particular feature of Saint-Denis did not, therefore, have a very long subsequent history.

It is not known what the original 12th-century interior elevation of Saint-Denis was like. Elsewhere, though, the problems that followed in the wake of the increasing ability to build gigantic buildings are easily seen. Possibly the most important one concerns the disposition of the main interior elevation. The chief elements are the arcade, the tribune (upper gallery set over the aisle and normally opening into the church) or triforium galleries (arcaded wall passages set above the main arcade) or both, and the clerestory. These may be given equivalent treatment, or one may be stressed at the expense of the others. Precedents for almost every conceivable combination existed in Romanesque architecture. In a building such as Sens cathedral (begun c. 1140), the arcade is given prominence, but in Noyon (begun c. 1150) and Laon cathedrals the four elements mentioned above are all used, with the result that the arcade is comparatively small. Subsequently, the arcade came back into prominence with Bourges cathedral (begun c. 1195). But one of the most influential buildings was Chartres cathedral (present church mainly built after 1194). There, the architect abandoned entirely the use of the tribune gallery, but, instead of increasing the size of the arcade, he managed, by a highly individual type of flying buttress, to increase the size of the clerestory. This idea was followed in a number of important buildings, such as the 13th-century Reims and Amiens cathedrals. The conception that the content of a great church should be dominated by large areas of glazing set in the upper parts was influential in the 13th century.

The decorative features of these great churches were, on the whole, simple. In the second half of the 12th century it became fashionable, as at Laon cathedral, to "bind" the interior elevation together by series of colonettes, or small columns, set vertically in clusters. Again, as at Laon, much of the elaborate figured carving of Romanesque buildings was abandoned in favour of a highly simplified version of the classical Corinthian capital—usually called a "crocket" capital. Under the influence of Chartres cathedral, window tracery (decorative ribwork subdividing the window opening) was gradually evolved.

There is one group of churches, built for houses of the Cistercian order, that requires separate consideration. They tend to be similar, but it is often a similarity of general simplicity as much as of architectural detail. The Cistercian order was bound to ideas of austerity laid down by St. Bernard of Clairvaux. During his lifetime these ideals were maintained largely through the degree of centralized control exercised from the head house at Cîteaux (Burgundy). Thus, many of the Cistercian churches built in England, Italy, or Germany seem to have had characteristics in common with French Cistercian churches. A good French example survives at Fontenay (begun 1139). These buildings probably encouraged the early dissemination of the pointed arch. That they did much more than this is doubtful.

If one examines the architecture outside north and north-eastern France, one finds, first, that buildings in what might be called a Romanesque style continued up to the end of the 12th and into the 13th century and, second, that the appreciation of the developments in France was often partial and haphazard. In England the most influen-

tial building in the new fashion was the choir of Canterbury cathedral (1175–84), which has many of the features of Laon cathedral. It is the decorative effects of Laon that are used rather than its overall architectural plan, however. There is only a rather depressed tribune gallery, and the building retains a passage at clerestory level—an Anglo-Norman feature that remained standard in English architecture well into the 13th century. Both in the shape of the piers and in the multiplicity of attached colonettes, Canterbury resembles Laon. Colonettes became extremely popular with English architects, particularly because of the large supplies of purbeck marble, which gave any elevation a special coloristic character. This is obvious at Salisbury cathedral (begun 1220), but one of the richest examples of the effect is in the nave of Lincoln cathedral (begun c. 1225).

The early stages of architectural development in the Gothic period are untidy and have a strong regional flavour. During this period in Germany, large buildings showing northern French characteristics are few. The Church of Our Lady at Trier (begun c. 1235) and the Church of St. Elizabeth at Marburg (begun 1235) both have features, such as window tracery, dependent on northern French example; but the church at Trier is highly unusual in its centralized plan, and St. Elizabeth is a "hall church" (that is, the nave is virtually the same height as the aisles), which places it outside the canon of contemporary French building.

In Spain the two most important early Gothic buildings were Burgos (begun 1222) and Toledo (begun 1221) cathedrals. Their architects probably knew Reims and Amiens; but their models were undoubtedly Bourges and Le Mans (begun 1217), since the main internal architectural feature is a giant arcade rather than an extended clerestory. By contrast, Scandinavian architects seem to have been influenced, to begin with, by English buildings. Certainly there is a strong English flavour in the 13th-century Trondheim cathedral (Norway).

High Gothic. During the period from about 1250 to

1300 European art was dominated for the first time by the art and architecture of France. The reasons for this are not clear, although it seems certain that they are connected with the influence of the court of King Louis IX (1226–70).

By about 1220–30 it must have been clear that engineering expertise had pushed building sizes to limits beyond which it was unsafe to go. The last of these gigantic buildings, Beauvais cathedral, had a disastrous history, which included the collapse of its vaults, and it was never completed. In about 1230 architects became less interested in size and more interested in decoration. The result was the birth of what is known as the Rayonnant style (from the radiating character of the rose windows, which were one of its most prominent features). The earliest moves in this direction were at Amiens cathedral, where the choir triforium and clerestory were begun after 1236 (Figure 38), and at Saint-Denis, where transepts and nave were begun after 1231. Architects opened up as much of the wall surface as possible, producing areas of glazing that ran from the top of the main arcade to the apex of the vault (Figure 39). The combination of the triforium gallery and clerestory into one large glazed area had, of course, a unifying effect on the elevations. It produced an intricate play of tracery patterns and instantly unleashed an era of intense experiment into the form that these patterns should take. Many of the achievements of the Rayonnant architects are extremely fine—for instance, the two transept facades, begun during the 1250s, of Notre-Dame, Paris. The decorative effect of this architecture depends not only on the tracery of the windows but also on the spread of tracery patterns over areas of stonework and on architectural features such as gables.

In the history of this development, one building deserves special mention, the Sainte-Chapelle, Paris (consecrated

1248). This was Louis IX's palace chapel, built to house an imposing collection of relics. It is a Rayonnant building in that it has enormous areas of glazing. Its form was extremely influential, and there were a number of subsequent "saintes-chapelles"—for instance, at Aachen and Riom—that were clearly modeled on the Parisian one. The interior of the Parisian Sainte-Chapelle is extraordinarily sumptuous (Figure 40). Although the sumptuousity itself set new standards, its characteristics belonged, curiously, to a past age. The glass is heavily coloured, the masonry heavily painted, and there is much carved detail. One of the characteristics of the second half of the 13th century is that glass became lighter, painting decreased, and the amount of carved decoration dwindled. Thus, in its chronological context, the Sainte-Chapelle is a Janus-like building—Rayonnant in its architecture but, in some ways, old-fashioned in its decoration.

Of the many smaller Rayonnant monuments that exist in France, one of the most complete is Saint-Urbain, Troyes (founded 1262). There, one can see the virtuosity practiced by the architects in playing with layers of tracery, setting off one "skin" of tracery against another.

In a sense, the Rayonnant style was technically a simple one. Depending, as it did, not primarily on engineering expertise or on sensitivity in the handling of architectural volumes and masses but on the manipulation of geometric shapes normally in two dimensions, the main prerequisites were a drawing board and an office.

Most countries produced versions of the Rayonnant style. In the Rhineland the Germans began one of the largest Rayonnant buildings, Cologne cathedral, which was not completed until the late 19th century. The German masons carried the application of tracery patterns much further than did the French. One of the most complicated essays is the west front of Strasbourg cathedral (planned originally in 1277 but subsequently altered and modified). One feature of Strasbourg and of German Rayonnant architecture in general was the application of tracery to spires—at Freiburg im Breisgau (spire begun c. 1330), for example, and the spire of Strasbourg that was begun about 1399. Few such medieval spires survive (though often they were completed in the 19th century).

Of all the European buildings of this period, the most

Application of tracery to spires

A.F. Kersting

Figure 40: Interior of Sainte-Chapelle, Paris, consecrated 1248.

Rayonnant style

important is probably the cathedral of Prague (founded in 1344). The plan was devised according to routine French principles by the first master mason, Mathieu d'Arras. When he died in 1352, his place was taken (1353–99) by Petr Parléř, the most influential mason in Prague and a member of a family of masons active in south Germany and the Rhineland. Parléř's building included the start of a south tower and spire that clearly continued the traditions of the Rhineland. His originality lay in his experiments with vault designs, from which stem much of the virtuoso achievement of German masons in the 15th century.

London, too, has Rayonnant monuments. Westminster Abbey was rebuilt after 1245 by Henry III's order, and in 1258 the remodeling of the east end of St. Paul's Cathedral began. King Henry was doubtless inspired by the work carried out by his brother-in-law, King Louis IX of France, at the Sainte-Chapelle and elsewhere. Westminster Abbey, however, lacks the clear lines of a Rayonnant church, mainly because, like the Sainte-Chapelle, it was heavily decorated with carved stonework and with colour.

In fact, English architects for a long time retained a liking for heavy surface decoration; thus, when Rayonnant tracery designs were imported, they were combined with the existing repertoire of colonettes, attached shafts, and vault ribs. The result, which could be extraordinarily dense—for instance, in the east (or Angel) choir (begun 1256) at Lincoln cathedral (Figure 41) and at Exeter cathedral (begun before 1280)—has been called the English Decorated style, a term that is in many ways an oversimplification. The interim architectural effects achieved (notably the retrochoir of Wells cathedral or the choir of St. Augustine, Bristol) were more inventive generally than those of contemporary continental buildings. The inventive virtuosity of the masons of Decorated style also produced experiments in tracery and vault design that anticipated by 50 years or more similar developments in the Continent.

English Decorated was, however, never really a court style. Already by the end of the 13th century, a style of architecture was evolving that ultimately developed into the true English equivalent of Rayonnant, generally known as Perpendicular. The first major surviving statement of the Perpendicular style is probably the choir of Gloucester cathedral (begun soon after 1330). Other major monuments were St. Stephen's Chapel, Westminster (begun 1292 but now mostly destroyed) and York Minster nave (begun 1291).

A.F. Kersting

Figure 41: Angel Choir, Lincoln cathedral, England, begun 1256.

Figure 42: Nave of Santa Croce, Florence, begun 1294.

Alinari—Art Resource/EB Inc.

Spain also produced Rayonnant buildings: León cathedral (begun c. 1255) and the nave and transepts of Toledo cathedral, both of which have, or had, characteristics similar to the French buildings. But, since the Spanish partiality for giant arcades (already seen in the earlier parts of Toledo and at Burgos) persisted, one can hardly classify as French the three major cathedrals of this period: Gerona (begun c. 1292), Barcelona (begun 1298), and Palma-de-Mallorca (begun c. 1300). They are, in fact, so individual that it is difficult to classify them at all, although peculiarities in the planning and buttressing of the outer walls gives them some similarity to the French cathedral of Albi (begun 1281).

Toward the end of the century, the influence of French ideas spread northward to Scandinavia, and in 1287 French architects were summoned to Sweden to rebuild Uppsala cathedral.

Italian Gothic (c. 1200–1400). In its development of a Gothic style, Italy stood curiously apart from the rest of Europe. For one thing, the more obvious developments of the Italian Gothic style occurred comparatively late—in the 13th century. For another, whereas in most European countries artists imitated with reasonable faithfulness architectural styles that were derived ultimately from northern France, they seldom did so in Italy. This was in part because of geographic and geologic factors. In the figurative arts the combined influences of Byzantine Constantinople and classical antiquity continued to play a far more important role in Italy than in countries north of the Alps. Furthermore, Italian architectural style was decisively affected by the fact that brick—not stone—was the most common building material and marble the most common decorative material.

The distinctiveness of Italian art emerges as soon as one studies the architecture. Twelfth-century buildings such as Laon, Chartres, or Saint-Denis, which appear to have been so important in the north, had virtually no imitators in Italy. Indeed, buildings with Romanesque characteristics, such as Orvieto cathedral (begun 1290), were still being built at the end of the 13th century. The Italians, however, were not unaware of what, by French standards, a great church ought to look like. There is a sprinkling of churches belonging to the first third of the century that have northern characteristics, such as attached (partially recessed in the wall) shafts or columns, crocket capitals, pointed arches, and ribbed vaults. Some of these were Cistercian (Fossanova, consecrated 1208), others were secular (Sant'Andrea, Vercelli; founded 1219). The chief com-

mon feature of the larger Italian 13th-century churches, such as Orvieto cathedral and Santa Croce in Florence (begun 1294), was the size of their arcades, which gives the interiors a spacious feeling (Figure 42). Yet in detail the churches vary from the French pattern in a highly individual way.

Italian
version
of French
Rayonnant
style

To the extent that Rayonnant architecture is particularly concerned with the manipulation of two-dimensional patterns, the Italian masons produced their own version of the style. In these terms, the facade of Orvieto cathedral (begun 1310), for example, is Rayonnant; the front of Siena cathedral was planned as a Rayonnant facade (Figure 43), and the Campanile, or freestanding bell tower, of Florence cathedral (founded 1334) is Rayonnant to the extent that its entire effect depends on marble patterning (which is traditionally ascribed to the painter Giotto). Finally, it is perhaps legitimate to see Filippo Brunelleschi's 15th-century architecture as a continuation of this tendency—a kind of Florentine equivalent, perhaps, to English Perpendicular. But before the 15th century, Italian architectural development never appears to have the logic or purpose of northern architecture.

Though the rebuilt Milan cathedral is, in plan and general character, Italianate, its decorative character is mainly derived from the north, probably Germany. The exterior is covered with tracery, which makes Milan cathedral more like a Rayonnant building than any other large church in Italy.

Late Gothic. During the 15th century much of the most elaborate architectural experiment took place in southern Germany and Austria. German masons specialized in vault designs; and, in order to get the largest possible expanse of ceiling space, they built mainly hall churches (a type that had been popular throughout the 14th century). Important hall churches exist at Landshut (St. Martin's and the Spitalkirche, c. 1400), and Munich (Church of Our Lady, 1468–88). The vault patterns are created out of predominantly straight lines. Toward the end of the 15th century, however, this kind of design gave way to curvilinear patterns set in two distinct layers. The new

Figure 43: Facade of the cathedral of Siena, Italy, 1285–1377.

Figure 44: The interior of Gloucester cathedral cloisters, England, begun 1337.

A.F. Kersting

style developed particularly in the eastern areas of Europe: at Annaberg (St. Anne's, begun 1499) and Kuttentberg (St. Barbara's, 1512).

Such virtuosity had no rival elsewhere in Europe. Nevertheless, other areas developed distinctive characteristics. The Perpendicular style is a phase of late Gothic unique to England. Its characteristic feature is the fan vault, which seems to have begun as an interesting extension of the Rayonnant idea in the cloisters of Gloucester cathedral (begun 1337), where tracery panels were inserted into the vault (Figure 44). Another major monument is the nave of Canterbury cathedral, which was begun in the late 1370s, but the style continued to evolve, the application of tracery panels tending to become denser. St. George's Chapel, Windsor (c. 1475–1500), is an interesting prelude to the ornateness of Henry VII's Chapel, Westminster Abbey (Figure 45). Some of the best late Gothic achievements are bell towers, such as the crossing tower of Canterbury cathedral (c. 1500).

In France the local style of late Gothic is usually called Flamboyant, from the flamelike shapes often assumed by the tracery. The style did not significantly increase the range of architectural opportunities. Late Gothic vaults, for instance, are not normally very elaborate (one of the exceptions is Saint-Pierre in Caen [1518–45], which has pendant bosses). But the development of window tracery continued and, with it, the development of elaborate facades. Most of the important examples are in northern France—for example, Saint-Maclou in Rouen (c. 1500–14; Figure 46) and Notre-Dame in Alençon (c. 1500). France also produced a number of striking 16th-century towers (Rouen and Chartres cathedrals).

Flamboyant style

The most notable feature of the great churches of Spain is the persistence of the influence of Bourges and the partiality for giant interior arcades. This is still clear in one of the last of the large Gothic churches to be built—the New Cathedral of Salamanca (begun 1510). By this time, Spanish architects were already developing their own intricate

forms of vaulting with curvilinear patterns. The Capilla del Condestable in Burgos cathedral (1482–94) provides an elaborate example of Spanish Flamboyant, as does—on a larger scale—Segovia cathedral (begun 1525).

There was a final flowering of Gothic architecture in Portugal under King Manuel the Fortunate (1495–1521). The fantastic nature of much late Gothic Iberian architecture has won for it the name *Plateresque*, meaning that it is like silversmith's work. The decorative elements used were extremely heterogeneous, and Arabic or *Mudéjar* forms emanating from the south were popular. Ultimately, during the 16th century, antique elements were added, facilitating the development of a Renaissance style. These curious hybrid effects were transplanted to the New World, where they appear in the earliest European architecture in Central America.

The end of Gothic. The change from late Gothic to Renaissance was superficially far less cataclysmic than the change from Romanesque to Gothic. In the figurative arts, it was not the great shift from symbolism to realistic representation but a change from one sort of realism to another.

Architecturally, as well, the initial changes involved decorative material. For this reason, the early stages of Renaissance art outside Italy are hard to disentangle from late Gothic. Monuments like the huge Franche-Comté chantry chapel at Brou (1513–32) may have intermittent Italian motifs, but the general effect intended was not very different from that of Henry VII's Chapel at Westminster. The Shrine of St. Sebaldus at Nürnberg (1508–19) has the general shape of a Gothic tomb with canopy, although much of the detail is Italianate. In fact, throughout Europe the "Italian Renaissance" meant, for artists between about 1500 and 1530, the *enjolivement*, or embellishment, of an already rich decorative repertoire with shapes, motifs, and figures adapted from another canon of taste. The history of the northern artistic Renaissance is in part the story of the process by which artists gradually realized that classicism represented another canon of taste and treated it accordingly.

But it is possible to suggest a more profound character to the change. Late Gothic has a peculiar aura of finality about it. From about 1470 to 1520, one gets the im-

pression that the combination of decorative richness and realistic detail was being worked virtually to death. Classical antiquity at least provided an alternative form of art. It is arguable that change would have come in the north anyway and that adoption of Renaissance forms was a matter of coincidence and convenience. They were there at hand, for experiment.

The use of Renaissance forms was certainly encouraged, however, by the general admiration for classical antiquity. They had a claim to "rightness" that led ultimately to the abandonment of all Gothic forms as being barbarous. This development belongs to the history of the Italian Renaissance, but the phenomenon emphasizes one aspect of medieval art. Through all the changes of Romanesque and Gothic, no body of critical literature appeared in which people tried to evaluate the art and distinguish old from new, good from bad. The development of such a literature was part of the Renaissance and, as such, was intimately related to the defense of classical art. This meant that Gothic art was left in an intellectually defenseless state. All the praise went to ancient art, most of the blame to the art of the more recent past. Insofar as Gothic art had no critical literature by which a part of it, at least, could be justified, it was, to that extent, inarticulate.

(A.Ma./D.J.Wa.)

The
"rightness"
of classical
antiquity

The Renaissance

The concept of the Renaissance, whose goal was the re-birth or re-creation of ancient classical culture, originated in Florence in the early 15th century and thence spread throughout most of the Italian peninsula; by the end of the 16th century the new style pervaded almost all of Europe, gradually replacing the Gothic style of the late Middle Ages. It encouraged a revival of naturalism, seen in Ital-

ian 15th-century painting and sculpture, and of classical forms and ornament in architecture, such as the column and round arch, the tunnel vault, and the dome.

Knowledge of the classical style in architecture was derived during the Renaissance from two sources: the ruins of ancient classical buildings, particularly in Italy but also in France and Spain, and the treatise *De architectura* by the Roman architect Vitruvius. For classical antiquity and, therefore, for the Renaissance, the basic element of architectural design was the order, which was a system of traditional architectural units. During the Renaissance five orders were used, the Tuscan, Doric, Ionic, Corinthian, and Composite, with various ones prevalent in different periods. For example, the ornate, decorative quality of the Corinthian order was embraced during the early Renaissance, while the masculine simplicity and strength of the Doric was preferred during the Italian High Renaissance. Following ancient Roman practice (e.g., the Colosseum or the Theatre of Marcellus), Renaissance architects often superimposed the order—that is, used a different order for each of the several stories of a building—commencing with the heavier, stronger Tuscan or Doric order below and then rising through the lighter, more decorative Ionic, Corinthian, and Composite.

Importance of proportion For the Renaissance, proportion was the most important predetermining factor of beauty. The great Italian humanist and architect Leon Battista Alberti defined beauty in architecture as

a Harmony of all the Parts in whatsoever Subject it appears, fitted together with such Proportion and Connection, that nothing could be added, diminished or altered, but for the Worse. (*Ten Books on Architecture*, trans. by J. Leoni, book vi, ch. 2, 1755.)

On the authority of Vitruvius, the Renaissance architects found a harmony between the proportions of the human body and those of their architecture. There was even a relationship between architectural proportions and the Renaissance pictorial device of perspective; the Italian painter Piero della Francesca said that perspective represented objects seen from afar “in proportion according to their respective distance.” In fact, it was an Italian Renaissance architect, Filippo Brunelleschi, who was the first to formulate perspective. The concern of these architects for proportion caused that clear, measured expression and definition of architectural space and mass that differentiates the Renaissance style from the Gothic and encourages in the spectator an immediate and full comprehension of the building.

The Renaissance was the great moment in the history of architecture for the expression of architectural theory. Inspired by the rediscovery or reevaluation of the treatise by Vitruvius, many architects recorded their theories of architecture; some were preserved in manuscript (e.g., those of the 15th-century Italian architects Francesco di Giorgio and Antonio Filarete), but most were published. Alberti's treatise *De re aedificatoria* (*Ten Books on Architecture*),

modeled on Vitruvius, was written in the middle of the 15th century and published in 1485. But it was during the last three-quarters of the 16th century that architectural theory flourished. The Italians Sebastiano Serlio, Giacomo da Vignola, and Andrea Palladio published famous books on architecture at that time. Elsewhere, works were published by the Frenchmen Jacques Androuet du Cerceau, Philibert Delorme, and Jean Bullant; the Fleming Vredeman de Vries; the German Wendel Dietterlin; and John Shute in England.

EARLY RENAISSANCE IN ITALY (1401–95)

The Renaissance began in Italy, where there was always a residue of classical feeling in architecture. A Gothic building such as the Loggia dei Lanzi in Florence continued to use the large round arch instead of the usual Gothic pointed arch and preserved the simplicity and monumentality of classical architecture. The Renaissance might have been expected to appear first in Rome, where there was the greatest quantity of ancient Roman ruins; but during the 14th and early 15th centuries, when the Italians were impelled to renew classicism, the political situation in Rome was very unfavourable for artistic endeavour. Florence, however, under the leadership of the Medici family, was economically prosperous and politically stable.

In 1401 a competition was held among sculptors and goldsmiths to design a pair of doors for the old baptistery at Florence. The sculptor Lorenzo Ghiberti won, and a losing goldsmith, Filippo Brunelleschi, resolving to be the leader in one of the arts, then turned to the study of architecture. Brunelleschi spent the period between 1402 and

Figure 47: Pazzi Chapel, in the medieval cloister of Santa Croce, Florence, by Filippo Brunelleschi, 1429–60. (Left) Exterior; (top right) plan; (bottom right) interior view.

1418 alternately in Florence and Rome. During this time he studied mathematics intensively and formulated linear perspective, which was to become a basic element of Renaissance art. At the same time, Brunelleschi investigated ancient Roman architecture and acquired the knowledge of classical architecture and ornament that he used as a foundation for Renaissance architecture. He was also influenced by the local Florentine tradition, which had flowered in the 11th and 12th centuries in the so-called Tuscan proto-Renaissance style found in churches such as San Miniato al Monte. Brunelleschi's great opportunity came in 1418 with the competition for the completion of the duomo, or cathedral, of Florence. The medieval architects had intended a great dome over the crossing of the cathedral, but it had never been created, and no one knew how to accomplish it. Winning the competition, Brunelleschi began the great dome in 1420 (the finishing touches were not applied until 1467, after his death).

The Florentine dome still belongs within the Gothic tradition, as it was built with rib construction and a pointed arch form, but the introduction of a drum, which made the dome more prominent, was to become characteristic of the Renaissance dome.

First Renaissance building

Brunelleschi also produced in Florence other notable examples of the Renaissance style. The loggia of the Ospedale degli Innocenti (1419–51) was the first building in the Renaissance manner; a very graceful arcade was designed with Composite columns, and windows with classical pediments were regularly spaced above each of the arches. This style was more fully exploited in the church of San Lorenzo (c. 1421 to c. 1460). Using the traditional basilica plan, the plan and elevations were organized on a system of proportions with the height of the nave equal to twice its width. All the ornament is classical, with Corinthian columns, pilasters, and classical moldings. Brunelleschi used almost exclusively the Corinthian order. All the moldings, door and window frames, and orders are of a soft blue-gray stone (*pietra serena*) contrasted against a light stucco wall. The ornamental features have very little projection, being rather lines on a surface. Colour was used in Florentine architecture to stress the linear

relationship rather than for overall patternistic uses (as in northern Italian architecture).

The traditional plan for medieval churches was the Latin cross plan, as at San Lorenzo; the longer arm of the cross formed the nave of the church. During the Middle Ages this plan was considered a symbolic reference to the cross of Christ. During the Renaissance the ideal church plan tended to be centralized; that is, it was symmetrical about a central point, as is a circle, a square, or a Greek cross (which has four equal arms). Many Renaissance architects came to believe that the circle was the most perfect geometric form and, therefore, most appropriate in dedication to a perfect God. Brunelleschi also worked with the central plan. In the Pazzi Chapel (1429–60), constructed in the medieval cloister of Santa Croce at Florence, the plan approaches the central type. On the inside it is actually a rectangle, slightly wider than it is deep; at its rear is a square bay for the sanctuary, and at the front is a porch. There are three domes, a large one over the centre of the chapel and small ones over the sanctuary and over the centre of the porch on the exterior. Its plan, but not its interior space, resembles a Greek cross. On the exterior the large dome is covered by a conical roof with a lantern at the top. The porch has a horizontal entablature supported by six Corinthian columns but broken in the centre by a semicircular arch that centralizes the composition, repeats the shape of the dome in the porch behind it, and gives a lift to the horizontal facade (Figure 47).

Soon after the commencement of the Pazzi Chapel, Brunelleschi began a central-plan church, that of Santa Maria degli Angeli (begun 1434) at Florence, which was never completed. It was very important because it was the first central-plan church of the Renaissance, the type of plan which dominates Renaissance thinking. The plan is an octagon on the interior and 16-sided on the exterior, with a domical vault probably intended to cover the centre.

An outstanding example of secular architecture was the Medici Palace (1444–59; now called the Palazzo Medici-Riccardi) at Florence by Michelozzo, a follower of Brunelleschi (Figure 48, left). Created for Cosimo de' Medici, a great political leader and art patron of Florence,

Early residential architecture

the palace was arranged around a central court, the traditional Florentine palace plan.

Medieval Florentine palaces were built of great rusticated blocks of stone, as if they had just been hacked out of the quarry, giving the impression of fortification. With the Renaissance, some fundamental changes appeared. Michelozzo crowned his palace with a massive horizontal cornice in the classical style and regularized the window and entrance openings. Even the rustication of the stonework was differentiated in each of the three stories. The ground floor has the usual heavy rustication; the second story is marked by drafted stonework with smooth blocks outlined by incised lines; and the third story has ashlar stonework with no indications of the blocks. Unlike medieval patternistic rustication, that of the Renaissance, which carefully distinguished between the stories, set up a logical relationship among them.

Further development of the palace facade

This Renaissance treatment of a palace facade was carried further in the Palazzo Rucellai (1452?–1470?) at Florence, following the design of the great architect Alberti (Figure 48, right). Classical orders were applied to the palace elevation by Alberti, using pilasters of the different orders superimposed on the three stories, so that there was another relationship established among the differentiated stories, from the short, strong Tuscan pilaster on the ground floor to the tall, decorative Corinthian at the top. For Alberti the beauty of architecture consisted of a harmonious relationship among the parts, with ornament, including the classical orders, being auxiliary to the proportional relationships.

The culmination of Alberti's style is seen at Mantua in the church of Sant'Andrea (begun 1472, completed in the 18th century), an early Renaissance masterpiece that was to exert much influence on later religious architecture. It is important as a brilliant application of the ancient Roman triumphal arch motif both to the facade of a church and to its interior articulation. The plan, as completed, is a Latin cross with one long arm for the nave flanked by side chapels, but the crossing at the sanctuary end was treated as a central plan with the nave added to it. It is unknown whether this plan corresponds to Alberti's intention, for only the nave portion was erected in the 15th century. The facade is of square proportion, with a wide bay at the centre twice the width of each of the side bays. The interior elevation was organized on this same alternating system, the so-called rhythmic bay that was to be popularized in the early 16th century by Bramante. As a result of this system, there is a close correspondence between the interior and exterior composition of Sant'Andrea (Figure 49).

From Florence the early Renaissance style spread gradually over Italy, becoming prevalent in the second half

of the 15th century. In the architecture of northern Italy there was a greater interest in pattern and colour. Colour was emphasized by the use of variegated marble inlays, as in the facade of the church of the Certosa di Pavia (begun 1491) or in most Venetian architecture. The favourite building material of northern Italy was brick with terracotta trim and decoration, a combination by means of which a pattern of light and dark was created over the entire building. On occasions when stone was used, as at the Palazzo Bevilacqua in Bologna (c. 1479–84), the blocks were cut with facets forming a diamond pattern on the facade. This was actually a decorative treatment of rustication. Even the classical orders were affected by this decorative approach. Classical pilasters often had panels of candelabra and arabesque decoration in delicate relief on the surfaces of their shafts; the lower third of a column was frequently carved with relief sculpture.

Florentine artists, such as Filarete with his project for the Ospedale Maggiore at Milan (begun 1457), brought classical decoration and a slight knowledge of Renaissance architecture to the region of Lombardy. The style was transferred to Venice by such Lombard architects as Pietro Lombardo and Mauro Coducci. The church of Santa Maria dei Miracoli (1481–89) at Venice, with its facade faced with coloured marble, is typical of Lombardo's work (Figure 50).

The Venetian palace, as exemplified by the Palazzo Corner-Spinelli (late 15th century) and the Palazzo Vendramin-Calergi (c. 1500–09), both of which are the work of Coducci and both with large and numerous windows, was more open than the palaces found in central Italy (Figure 51).

In Rome in the second half of the 15th century, there were several notable Renaissance palaces, principally derived from the style of Alberti, who spent extensive periods in Rome as a member of the papal court. The Palazzo Venezia (1455–1503) has a rather medieval exterior, but set within the palace is a characteristically Renaissance court (1468–71), of which only two sides forming an angle were completed. It has been suggested without definite proof that Alberti may have furnished the design for this court; it at least reveals his influence in its full understanding of the classical style. The court consists of two stories of semicircular arches supported by piers, on which are attached superimposed classical half columns, Tuscan below and Ionic above. The model for this arcade is the ancient Colosseum of Rome. The sense of mass created by the heavy piers contrasted with the lighter effect of the early Renaissance court typical of Florence, which has arches supported on columns. The Palazzo della Cancelleria (1495) shows its dependence upon Alberti's style in its facade, which resembles in part his Palazzo Rucellai in

Florence. The lower story simply has drafted or leveled and squared stonework, but the two upper stories have rather flat Corinthian pilasters as well as the drafted stone. Unlike the Rucellai palace, the bays composed by the pilasters alternate wide and narrow, but this alternation had been used by Alberti already in Sant'Andrea at Mantua. Alberti's influence is also visible in the facades of the churches of Sant'Agostino (1479–83) and Santa Maria del Popolo (rebuilt 1472–77) in Rome.

These examples of the early Renaissance in Rome were rapidly approaching the simplicity, monumentality, and

massiveness of the High Renaissance of the early 16th century. Donato Bramante, who was to create this new style, was active in Lombardy in northern Italy, but his work in Milan, as at Santa Maria presso San Satiro (about 1480–86), was still in the Lombard early Renaissance manner. He was in contact at this time, however, with the great Florentine Leonardo da Vinci, who was active at the Milanese court. Leonardo was then considering the concept of the central-plan church and filling his notebooks with sketches of such plans, which Bramante must have studied. When Bramante moved to Rome at the very end of the 15th century, his study of ancient ruins—combined with the ideas of Leonardo and the growing classicism of Roman early Renaissance architecture—resulted in the flourishing of the High Renaissance.

HIGH RENAISSANCE IN ITALY (1495–1520)

High Renaissance architecture first appeared at Rome in the work of Bramante at the beginning of the 16th century. The period was a very brief one, centred almost exclusively in the city of Rome; it ended with the political and religious tensions that shook Europe during the third decade of the century, culminating in the disastrous sack of Rome in 1527 and the siege of Florence in 1529. The High Renaissance was a period of harmony and balance in all the arts, perhaps the most classic moment in this respect since the 5th century BC in Greece.

Political and cultural leadership shifted from Florence to Rome particularly because of a succession of powerful popes who wanted to develop the papacy as a secular power. The greatest of all was Julius II (1503–13), who was likewise a fabulous patron of the arts. Almost all the leading Italian artists were attracted to Rome. With the exception of Giulio Romano, none of the important artists active in Rome at this time was Roman by birth.

Bramante, the leader of this new manner, had already acquired an architectural reputation at Milan. Almost immediately after his arrival in Rome, in 1499, there was an amazing change in Bramante's work, as he became the exemplar of the High Renaissance style and lost his Lombard early Renaissance qualities. The Tempietto (1502), or small chapel, next to San Pietro in Montorio, typifies the new style. Erected on the supposed site of the martyrdom of St. Peter, the Tempietto is circular in plan, with a colonnade of 16 columns surrounding a small cella, or enclosed interior sanctuary. The chapel was meant to stand in the centre of a circular court, which was likewise to be surrounded by a colonnade, so that the whole structure was to be self-contained and centralized. The enclosing

circular court was never erected. The ultimate inspiration of the Tempietto was a Roman circular temple, like the temples of Vesta at Rome or Tivoli, but so many notable changes were made that the Renaissance chapel was an original creation. On the exterior it was organized in two stories, the Doric colonnade forming the first story. Above is a semicircular dome raised high on a drum. The present large finial, or crowning ornament, on the dome is of a later date and destroys some of the simplicity of the massing. Niches cut into the wall of the drum help to emphasize the solidity and strength of the whole, as does the heavy Doric order that Bramante was so fond of—in contrast to Brunelleschi, who had a predilection for the ornate Corinthian. The monument is very simple, harmonious, and comprehensible.

Several churches present the same qualities as the Tempietto on a larger physical scale. The church of Santa Maria della Consolazione (1504–1617) at Todi, probably by Bramante, is likewise centralized in plan, being square with a semicircular or polygonal apse opening off each side. The mass is built up of simple geometric forms capped by the cylinder of a drum and a slightly pointed dome. On the interior the outstanding quality is a sense of quiet, harmonious spaciousness. The Florentine architect Antonio da Sangallo the Elder, influenced by Bramante, created his church of San Biagio at Montepulciano (1518–29) on a Greek cross plan. On the facade in the two recesses of the arms of the cross were to rise two towers, the right one never completed. Otherwise the massing is similar to that of Todi, with dome and drum above. All the moldings and ornamental elements were carved with strong projection, so that on the interior heavy Roman arches, with deep coffers containing rosettes, define the tunnel vaults rising over the arms of the church. The churches at Todi and Montepulciano are pilgrimage churches or shrines and thus have the centralized planning characteristic of the martyrium or church built over the tomb of a martyr or saint.

Rebuilding
of St.
Peter's

Sangallo's church at Montepulciano reflects Bramante's greatest undertaking, the rebuilding of St. Peter's in Rome. Early in 1505 Pope Julius II began to consider the question of a tomb for himself that would be appropriate to his idea of the power and nobility of his position. The sculptor Michelangelo soon presented a great project for a freestanding tomb, but such a monument required a proper setting. The Renaissance artist and biographer Giorgio Vasari claimed that the question of an appropriate location for this projected tomb brought to the Pope's mind the idea of rebuilding St. Peter's, which was in very poor condition. Bramante, therefore, prepared plans for a monumental church late in 1505, and in April 1506 the foundation stone was laid (Figure 52). Bramante's first design was a Greek cross in plan, with towers at the four corners and a tremendous dome over the crossing, inspired by that of the ancient Roman Pantheon but in this case raised on a drum. The Greek cross plan being unacceptable, Bramante finally planned to lengthen one arm

Figure 52: Plan for the Basilica of St. Peter's, Rome, 1505, by Donato Bramante.

From *Art Through the Ages* by Helen Gardner, Fifth Edition, edited by Horst de la Croix and Richard G. Tansey, © 1970 by Harcourt Brace Jovanovich, Inc. and reproduced with their permission

to form a nave with a centralized crossing. At his death in 1514 Bramante had completed only the four main piers that were to support the dome, but these piers determined the manner in which later architects attempted the completion of the church.

As important as the central-plan churches of this period were several notable secular buildings. At the papal palace of the Vatican, next to St. Peter's, Bramante added two important features. The great Belvedere court (begun 1505) was planned to bring together the two disparate elements of the older palace attached to the church and the Belvedere villa of Innocent VIII on the hill above the palace. Bramante gave the new court a neo-antique flavour recalling the imperial palaces on the hills of Rome and the *hippodromus* on the Palatine. Terraced on the hillside on three levels joined by monumental stairs, it was enclosed on the two long sides by arcaded loggias with superimposed orders. This large court was completed in the later 16th century with some minor changes, but in 1587 the whole concept was destroyed by the building of the present Vatican Library across the centre of the court. Just before his death, Bramante also began a series of superimposed loggias attached to the face of the old Vatican Palace looking out over the city and river. As completed by Raphael, there are two superimposed arcades with Tuscan and Ionic orders and a colonnade with Composite columns.

The largest palace of the High Renaissance is the Palazzo Farnese (1517–89) at Rome, designed and commenced by

The

a follower of Bramante, Antonio da Sangallo the Younger, nephew of the older Sangallo. At Sangallo's death, in 1546, Michelangelo carried the palace toward completion, making important changes in the third story. On the exterior Sangallo gave up the use of the classical orders as a means of dividing the facade into a number of equal bays; he used instead a facade more like those of the Florentines, but with quoins, or rough-cut blocks of stone at the edges of the building, to confine the composition in a High Renaissance fashion. The facade is composed in proportions as a double square. On the interior the central square court is more classical, using superimposed orders. Based on the ancient Roman Theatre of Marcellus or the Colosseum, the two first floors have an arcade supported by rectangular piers against which are half columns. On the third story Michelangelo eliminated the arcade and used pilasters flanked by half pilasters, which destroyed the High Renaissance idea of the careful separation and definition of parts (Figure 53).

One of the most charming buildings of the period is the Villa Farnesina (1509–11) at Rome by Baldassarre Peruzzi from Siena. Designed for the fabulously wealthy Siennese banker Agostino Chigi, the villa was the scene of numerous elaborate banquets for the pope and cardinals. A suburban villa, the Farnesina was planned in relation to the gardens around it with two small wings projecting from the central block to flank the entrance loggia. Originally, another loggia opened at the side upon the gardens stretching to the bank of the Tiber, but this loggia was later walled in. The elevation appears as two stories comparted into equal bays by Tuscan pilasters. The neat, reserved quality of the present building was originally lightened by painted fresco decoration over all the exterior wall surfaces. Other important buildings were designed by the painter Raphael, such as the Villa Madama (begun 1518) at Rome or the Palazzo Pandolfini (begun c. 1516) at Florence.

(D.R.C./D.J.Wa.)

ITALIAN MANNERISM OR LATE RENAISSANCE (1520–1600)

Mannerism is the term applied to certain aspects of artistic style, mainly Italian, in the period between the High Renaissance of the early 16th century and the beginnings of Baroque art in the early 17th. From the third decade of the 16th century, political and religious tensions erupted violently in Italy, particularly in Rome, which was sacked in 1527 by the imperial troops of Charles V. The school of Bramante and Raphael, which had produced the High Renaissance style, was dispersed throughout Italy as the artists fled from devastated Rome. Mannerism appeared

and prevailed in some regions until the end of the 16th century, when the Baroque style developed. Mannerism was antithetical to many of the principles of the High Renaissance. In place of harmony, clarity, and repose it was characterized by extreme sophistication, complexity, and novelty. Mannerist architects were no less interested in ancient classical architecture than were their predecessors, but they found other qualities in ancient Roman architecture to exploit. In fact, they often displayed an even greater knowledge of antiquity than did earlier artists.

For Vasari, as a practicing Mannerist architect, the same criteria of stylishness in design could be applied to a building as to a work of painting or sculpture. Vasari designed and built for an educated elite, one that would appreciate both his understanding of the rules of Roman architecture and the ingenious liberties that he took with these rules. Florentine and Roman 16th-century architecture is characterized by a secular cleverness—a building was judged on elegance, ingenuity, and variety of form.

The change in style between the High Renaissance and Mannerism can be seen in the work of Baldassarre Peruzzi, who was active in both periods. Unlike his High Renaissance Villa Farnesina, Peruzzi's design for the Palazzo Massimo alle Colonne (about 1535) in Rome shows indications of Mannerism (Figure 54). The facade of the palace was curved to fit the site on which it was erected; instead of remaining the passive form it had been in the earlier phases of Renaissance architecture, the wall surface was beginning to assert itself. The classical order is limited to the ground floor of the palace; the upper three stories have imitation drafted stonework made of brick covered with stucco, inscribed to feign stone coursing. Under these three stories in the centre of the facade is a loggia or colonnade, which seems of questionable adequacy as a support for the apparent load. The second story has rectangular windows crowned by Peruzzi's usual neat lintel supported on volutes, but the windows of the upper two stories are set horizontally with rather elaborate curvilinear moldings about them. There is, therefore, no longer a harmonious balance among the various stories. The architecture shows a greater emphasis on decorative qualities than on the expression of structural relationships.

After the resolved classical order and measured harmony of Bramante's High Renaissance buildings, two main, though interwoven, directions of Mannerist development become apparent. One of these, emanating largely from Peruzzi, relied upon a detailed study of antique decorative motifs—grotesques, classical gems, coins, and the like—which were used in a pictorial fashion to decorate the plane

The two directions of Mannerist development

Villa
architect-
ture

of the facade. This tendency was crystallized in Raphael's Palazzo Branconio dell'Aquila (destroyed) at Rome, where the regular logic of a Bramante facade was abandoned in favour of complex, out-of-step rhythms and encrusted surface decorations of medallions and swags. The detailed archaizing elements of this manner were taken up later by Pirro Ligorio, by the architects of the Palazzo Spada in Rome, and by Giovanni Antonio Dosio.

The second trend exploited the calculated breaking of rules, the taking of sophisticated liberties with classical architectural vocabulary. Two very different buildings of the 1520s were responsible for initiating this taste, Michelangelo's Laurentian Library in Florence (Figure 55) and the

came one of the hallmarks of later Mannerist architecture.

Increasingly, architecture, sculpture, and walled gardens came to be regarded as part of a complex (but not unified) whole. In the Villa Giulia (c. 1550–55), the most significant secular project of its time, Vasari appears to have been in charge of the scenic integration of the various elements; Giacomo da Vignola designed part of the actual building, while the Mannerist sculptor Bartolomeo Ammanati was largely responsible for the sculptural decoration. In spite of the continuous stepped vista, the building makes its impact through a succession of diverse effects rather than by mounting up to a unified climax. There, and in Vasari's design for the Uffizi Palace (1560), the vista seems to have been based upon the supposed style of antique stage sets, as interpreted by Peruzzi (Figure 57). It is not surprising that the Venetian architect Andrea Palladio came closest to achieving a fully Mannerist style in his Teatro Olimpico at Vicenza, where the receding vistas and rich sculptural details create an effect of extraordinary complexity. Similarly, it is not surprising that the greatest of the later Mannerist architects in Florence, Bernardo Buontalenti, should have been an acknowledged master of stage design. He was employed at the Medici court as a designer of grandly fantastic ephemera—mock river battles and stage intermezzi (interval entertainments) in which elaborate stage machinery effected miraculous transformations, figures descending from the clouds to slay dragons that spouted realistic blood, followed by music and dance *all'antica*. As a garden designer, Buontalenti enriched the traditional formal schemes with entertaining diversions, in which water often played a prominent role—either in fountains or in wetting booby traps for the strolling visitor. Buontalenti's buildings possess much of this capricious spirit in addition to his brilliantly inventive command of fluently plastic detailing.

In their treatment of detail, 16th-century Florentine architects inevitably looked toward Michelangelo as their example of innovative genius. Michelangelo's Medici Chapel in San Lorenzo (Figure 58) was executed, in Vasari's opinion, "in a style more varied and novel than that of any other master," and "thus all artists are under a great and eternal obligation to Michelangelo, seeing that he broke the fetters and chains that had earlier confined them to the creation of traditional forms." By Vasari's time the Mannerist quest for novelty had reached a thoroughly self-conscious level.

Michelangelo's later architecture in Rome was more restrained than his Florentine works. In 1546 he was commissioned to complete St. Peter's Basilica in Rome, succeeding Antonio da Sangallo the Younger. During the next 18 years he was able to complete most of his design for the church, except the facade and great dome above. In plan he returned to a central-plan church reminiscent of Bramante's first project but with fewer parts (Figure 59). Michelangelo's elevation, still visible at the rear or sides of the church, is composed of gigantic pilasters and a rather

Complexes of architecture, sculpture, and gardens

Figure 55: Staircase of the Laurentian Library, Florence, by Michelangelo, 1524–71.

Palazzo del Te by Giulio Romano in Mantua (Figure 56). Michelangelo's composition relies upon a novel reassembly of classical motifs for plastically expressive purposes, while Giulio's weird distortion of classical forms is of a more consciously bizarre and entertaining kind. The various exterior aspects of the Palazzo del Te provide a succession of changing moods, which are contrived so as to retain the surprised attention of the spectator rather than to present him with a building that can be comprehended at a glance. In the courtyard the oddly fractured cornice sections create an air of ponderous tension, whereas the loggia is lightly elegant. Similarly, the illusionistic decoration of the interior runs the full gamut from heavy (if self-parodying) tragedy to pretty delicacy. Giulio also created a series of contrived vistas, through arches and doors, much like that later projected by Michelangelo for the Palazzo Farnese in Rome. Such management of scenic effects be-

high attic story. Between the pilasters are several stories of windows or niches. Unlike the harmonious orders and openings of the High Renaissance, these are constricted by the pilasters so that a tension is created in the wall surface. Michelangelo planned a tremendous semicircular dome on a drum as the climax of the composition. Engravings of his original project suggest that this dome would have been overwhelming in relation to the rest of the design (Figure 60). The great central dome was executed toward the end of the 16th century by Michelangelo's follower, Giacomo della Porta, who gave a more vertical expression to the dome by raising it about 25 feet higher than a semicircle. In the early 17th century, the Baroque architect Carlo Maderno added a large nave and facade to the front of the church, converting it into a Latin cross plan and destroying the dominating quality of the dome, at least from the exterior front.

Early Mannerism in northern Italy developed out of the dissolution of the school of Bramante after 1527. Giulio Romano, the chief assistant of Raphael, became court

artist and architect in the city of Mantua. With the works of Galeazzo Alessi of Genoa, Leone Leoni of Milan, and Sebastiano Serlio of Bologna, Mannerist architecture gained a firm hold. In 1537 Serlio began to publish his series of books on architecture, in which antiquity was examined through Mannerist eyes and a series of pattern-book Mannerist designs was provided. Three years later, Serlio joined the Italian Mannerist painter Francesco Primaticcio at Fontainebleau, where he helped to consolidate the early acceptance of Mannerist ideals in France. In the work of Alessandro Vittoria, the influence of central Italy was pronounced. His heavy ceiling moldings are composed of classical motifs and bold strapwork. The north's taste for bizarre fancies—such as Vittoria's fireplace for the Palazzo Thiene—was often in advance of that in Rome and Florence.

Even Venice proved to be quickly susceptible to the clever tricks of Mannerist license. Michele Sanmicheli, a pupil of Bramante and Antonio da Sangallo the Younger, returned after the sack of Rome to his native town of

Verona and later went to Venice, where his architecture shows a clear awareness of Giulio Romano's Mantuan experiments. Another prominent architect in Venice was the Florentine sculptor Jacopo Sansovino, who also had fled to the north from Rome after the sack. Sansovino's architecture, as represented by the Loggetta (1537–40) at the foot of St. Mark's campanile or by the Old Library of St. Mark's (Libreria Vecchia [1536–88]), is rich in surface decorative qualities. The library has two stories of arcades; it has no basement but merely three low steps, so as to match the Gothic Palazzo Ducale opposite it. The upper entablature is extremely heavy, equaling half the height of the Ionic columns on which it rests. The rich application of relief sculpture with no unadorned wall surfaces creates this decorative quality, which has only superficial affinities with Florentine Mannerism.

This period of free and decorative Mannerism was followed by a more restrained classical architecture seen to

perfection in the work of one of the greatest architects of the Renaissance, Andrea Palladio. The city of Vicenza, not far from Venice, was almost completely rebuilt with edifices after his design, including the basilica or town hall (1549) and the Loggia del Capitaniato (1571), as well as many private palaces. In the varied design of these buildings and in numerous villas in the Venetian mainland around Vicenza, Palladio brilliantly demonstrated the versatility of a range of neo-antique formulas. The Villa Capra or Rotonda (1550–51; with later changes) is magnificent in its simplicity and massing. In the centre of a cubelike block (typical of most Palladian villas) is a circular hall, and on all four sides are projecting classical temple fronts as porticoes, resulting in an absolute classical symmetry in the plan. In Venice, Palladio built several churches, all with the Latin-cross plan and rather similar facades (Figure 61). San Giorgio Maggiore (1566–1610) has a Roman temple front, on four giant half columns, applied to the centre of the facade; abutting the sides are two half temple fronts with smaller coupled pilasters. The resulting composition suggests the interpenetration of two complete temple fronts in a Mannerist way, since the elements of the composition are less independent than they would be in High Renaissance architecture (Figure 62). Also typical of Mannerism is the way in which the interior space, instead of being classically confined, is permitted to escape through a colonnaded screen behind the sanctuary into a large choir at the rear. Palladio's greatest fame rests on his treatise *I quattro libri dell'architettura* (1570; *Four Books on Architecture*).

The most important architect of this period in Rome is Giacomo da Vignola, who wrote a treatise, *Regola delle cinque ordini d'architettura* (1562; "Rule of the Five Orders of Architecture"), devoted solely to a consideration of the architectural orders and their proportions. Like Palladio's book, Vignola's *Regola* became a textbook for later classical architecture.

Of his many buildings the project for the church of Il Gesù (1568) at Rome, the central church of the Jesuit Order, was very influential on the later history of architecture (Figure 63). The plan is a Latin cross with side chapels flanking the nave, but the eastern end is a central plan, capped by a dome. Il Gesù's plan was imitated throughout Europe, but especially in Italy, during the early Baroque period of the 17th century. Vignola built the church except for its facade, which was executed by Giacomo della Porta. Della Porta, inspired by Vignola's original design,

THE RENAISSANCE OUTSIDE ITALY

France. The Renaissance style of architecture appeared in France at the very end of the 15th century and flourished until the end of the 16th century. As in other northern European countries and in the Iberian Peninsula, the new Renaissance manner did not completely supplant the older Gothic style, which survived in many parts of France throughout the 16th century. French Renaissance architecture is divided into two periods: the early Renaissance, from the end of the 15th century until about 1530, and Mannerism, dating from about 1530 to the end of the 16th century.

Early Renaissance. The many invasions of Italy from 1494 until 1525 by French armies acquainted the French kings and nobles with the charms of Renaissance art. During the reigns of Louis XII and Francis I, the French possessed the city of Milan for the first 25 years of the 16th century. It was in Lombardy, therefore, that contact was made between French art and the Renaissance, and it was the Lombard Renaissance style that appeared in France during its early Renaissance.

The new style had a certain prestige since it was imported by the nobility and aristocracy, while the middle-class burghers continued to support their native Gothic style.

This social difference also applied to the artists themselves. The French aristocracy imported Italian architects and artists who had been influenced by the Italian Renaissance, in which artists were considered to have a higher social standing than artisans. The French builders and craftsmen who executed the designs of the Italians still belonged to the social level of medieval artisans. This created a friction between the two groups, which was furthered by French resentment of imported foreign artists.

With the exception of a few brief outcroppings of classicism in such centres as Marseille and Gaillon, French early Renaissance architecture was centred in the Loire Valley since the capital of France was at nearby Tours during the reign of Louis XII and the early part of the reign of Francis I. Most of the new architecture was secular, such as the château, which was an offshoot of the medieval feudal castle combined with the idea of an Italian villa. A characteristic example is the château at Blois, where two wings in the early Renaissance manner replaced parts of the 13th-century château. The first wing, erected (1498–1503) for Louis XII, is almost completely in the late Gothic Flamboyant style, with high roofs, an asymmetrical elevation, and pointed, depressed, and ogee arches. The only hint of the Renaissance is the occasional use of a bit of classical decoration, such as egg and dart molding, mingled with the Gothic. The second wing, built (1515–24) by Francis I, is more nearly in the Renaissance style. The structure remained Gothic with a high roof and dormers and the irregular spacing of the vertical windows, but all the ornament was in the classical mode, although its handling was often non-classical. Classical pilasters were used to divide the elevation into bays, but there is no consistency in the proportions of the pilasters. The most notable feature of the interior elevation of the wing of Francis I is a great octagonal open staircase, five sides of which project into the court. Within is a spiral staircase set on a continuous tunnel vault that is supported by radiating piers. On the surface of the piers are panels in low relief of arabesque decoration, of a type that is found often in Lombard Renaissance architecture. The richness of the Lombard style blends very well with Flamboyant Gothic, which had always been characterized by intricate and rich decoration. The exterior elevation of the wing of Francis I consists of a series of open loggias—the two lower ones arched, the upper one with a straight entablature—reminiscent of the famous series of loggias just completed by Bramante and Raphael at the Vatican Palace in Rome. Yet the Italian High Renaissance concept was expressed in France in early Renaissance terms with squat pilasters, irregularly spaced bays, and somewhat depressed arches.

Chambord

The finest example of the early Renaissance style is the château, or hunting lodge, erected between 1519 and 1547 for Francis I at Chambord (Figure 64). The Italian architect Bernabei Domenico da Cortona presumably made the basic model for the château, but the designs of Italian architects were usually executed by French builders (in this case Pierre Nepveu), often with many changes. Chambord is a tremendous structure, about 500 feet wide, with a plan showing the gradual breakdown of the old castle plan. There is a rectangular court surrounded by walls with round towers at the corners, but on three sides of the court there are only low walls serving as screens. The old donjon, or massive chief tower of medieval castles, developed into the château proper as a blocklike building with round towers at each corner. The flat passageways over the screen walls and on top of the central block were intended to form galleries from which the ladies of the court could observe the hunt. The plan of the main block of the château reveals Italian influence in its symmetrical organization on cross axes with a double spiral staircase at the centre. In the four corners left by the cross axes are four identical apartments, each of which consists of three basic rooms (chamber, antechamber, and cabinet); this

form of apartment was from then on the favourite unit of French domestic planning.

Typically for this period, the silhouette and structure remained Gothic in elevation with strip windows, a multiplicity of elements, and a general vertical expression. Ornament, however, is in the classical vocabulary of pilasters, round arches, and at times a geometric decoration consisting of slate panels set in the cream-coloured stone.

Mannerism. From about 1530, Francis I imported numerous Italian artists, such as Rosso Fiorentino (Giovanni Battista di Jacopo Rosso), Primaticcio, Serlio, Vignola, and Benvenuto Cellini. Most of these artists were followers of Michelangelo or Raphael, so that the new period of French architecture partook of Italian Mannerism. The style that resulted lasted until about 1590 and is sometimes known as the style of Henry II, although it actually was produced under five different kings, beginning late in the reign of Francis I.

The full influence of the new Italian style can best be seen in the château at Fontainebleau. In 1528 Francis I began to make revisions and additions to this medieval château, the exterior architecture being carried out by French builders under Gilles Le Breton. The Italian

Archives Photographiques, Paris

painter Rosso Fiorentino was placed in charge of the interior decoration of the Gallery of Francis I (c. 1533–45). The gallery is a long, narrow room covered by a wooden ceiling. On each side of the room is a high dado (*i.e.*, the lower section of a wall) of carved walnut with rich decoration above of stucco relief sculpture and painting. As Rosso was a Mannerist painter, France went directly from the early Renaissance style of the Loire châteaux to Mannerism. Rosso, who died in 1540, was succeeded by another Italian, Primaticcio, who decorated the ballroom, or gallery (1548–56), of Henry II and added the wing called the Aile de la Belle Cheminée (1568).

The most important Italian architect to build in France was Serlio, who arrived in 1541 to take Rosso's place as court architect. Serlio prepared plans for the rebuilding of the royal palace of the Louvre at Paris, but his ideas seem to have been too grandiose for Francis I. He did manage to build two châteaux, the casino of the Cardinal of Ferrara at Fontainebleau (1544–46), now destroyed, and the château of Ancy-le-Franc (begun 1546) in Burgundy. Serlio devoted most of his time to an architectural treatise that he had begun in Italy. Various books of the treatise were published during his lifetime from 1537 on, but the collected work was published after his death with the title *Tutte l'opere d'architettura, et prospetiva* (1619; "Complete Works of Architecture and Perspective"). It was influential in spreading the Renaissance style in France, England, and the Low Countries.

The influx of Italian artists soon compelled the French architects to adopt Renaissance principles of design as well as Renaissance ornamental details. Many French architects began to study the theory of design and often went to Italy as the source of the Renaissance style.

Rebuilding
of the
Louvre

After Serlio's failure with the palace of the Louvre in Paris, a French gentleman of the court, Pierre Lescot, was ordered to design and build a Renaissance palace to replace the medieval castle. Lescot, in collaboration with the sculptor Jean Goujon, designed a palace set around a square court about 175 feet wide. Only two sides, the west and south, of Lescot's court were built (1546–51). The execution and amplification of this design extended to the middle of the 19th century. The small section carried out under Lescot, the Gallery of Francis I, reveals a thorough understanding of the principles of Italian design but is expressed in French terms. The classical elements are used as low-relief surface decoration with little emphasis on mass (Figure 65).

The two leading architects of the second half of the 16th century, Philibert Delorme and Jean Bullant, studied in

Rome. Delorme was trained as a builder before going to Rome and, therefore, was always interested in the constructive side of architecture as well as in the theory of design. About 1547 Delorme was commissioned by the mistress of Henry II, Diane de Poitiers, to design her château at Anet. The original château (about 1547–52) formed three sides of a court closed at the front by a screen wall and entrance gateway. Much of the château has been destroyed; only the left wing of the house, the screen wall, and the chapel that formed part of the right wing survive. The entrance gateway, which originally contained Cellini's bronze relief of Diana (now in the Louvre), is very Mannerist with a complicated superstructure, a semicircular arch with raised bands cutting across the moldings, and, at the top, a bronze group of a stag that strikes the hour with its hoof as the accompanying hounds bay mechanically. The chapel at Anet has a centralized Greek-cross plan with a large circle capped by a dome at the crossing. The exterior of the chapel is Mannerist, with the windows cutting through the entablature and half pediments abutting the main block. Delorme commenced in 1564 a large palace called the Tuileries, since it was situated on the site of tileworks in front of the Louvre. Again, elements of Mannerism were visible. On the first story Delorme used his own so-called French order, consisting of Ionic half columns and pilasters with decorative bands across the shafts, but this order was actually an Italian Mannerist treatment of the classical order.

Delorme's
French
order

Bullant's architecture was rather like that of Vignola in that it was very classical in details but often Mannerist in relationships. His early and best-preserved works were for Anne, duc de Montmorency and constable of France: part of the Château d'Ecouen (about 1555) and the chatelet (about 1560) at the Château de Chantilly. The architect Jacques Androuet du Cerceau the Elder prepared a two-volume set of engravings, *Les plus excellents bastiments de France* (1576–79), which depict the new Renaissance 16th-century buildings of France, many of which have been destroyed or drastically altered. The Mannerist style died out in the early 17th century as slight hints of the Baroque style blended with a renewed classicism to form gradually the Academic style prevalent in the 17th century.

Spain and Spanish America. Italian Renaissance decorative elements first appeared in Spanish architecture at about the time of the unification of Spain and the expulsion of the Moors in 1492. There were three phases of Spanish Renaissance architecture: (1) the early Renaissance, or Plateresque, from the late 15th century until about 1560; (2) a brief classical period, coexistent with the

Tradition
of
elaborate
ornamenta-
tion

Plateresque from about 1525 to 1560; and (3) the Herreran style from 1560 until the end of the 16th century.

Plateresque. The earliest phase of Renaissance architecture in Spain is usually called the Plateresque (from *platero*, "silversmith") because its rich ornament resembles silversmith's work. There has always been a long tradition in Spain of elaborate decoration, explained in part as an influence from Moorish art. The Moors possessed almost all of Spain during the Middle Ages and left this decorative heritage to the Spaniards. During the early 16th century, minor northern Italian sculptors and artisans, particularly from Lombardy and Genoa, were imported into Spain to execute tombs and altars for the Spanish nobles and ecclesiastics. These artisans introduced the northern Italian Renaissance vocabulary of classical decoration, such as the pilaster paneled with arabesques or the candelabrum shaft. Spanish architects picked up these elements and applied them to their buildings.

The Renaissance Plateresque style is purely one of architectural ornament. There was no change in structure; heavy walls were used with either Gothic ribbed vaults or intricately carved wooden ceilings (*artesanado*) that indicated Moorish influence. Many of the elements of decoration also preserved the influence of Gothic and Moorish art, such as the Flamboyant Gothic pinnacle and pierced balustrade or coats of arms and bits of heraldry used as ornamental motifs. Richly coloured tiles created decorative patterns on the walls as in Moorish art. The richness of the classical decoration imported from northern Italy blended effectively with the elements of the Moorish and Flamboyant Gothic styles to form the new Plateresque style. The luxuriance of its ornament was a fitting expression of the splendour-loving culture that Spain developed as the wealth of the Americas began to pour in during the early 16th century.

In most cases the new Plateresque decoration was confined to rich spots or panels of ornament around the portals and windows of the buildings. These ornamental areas were relieved by large expanses of bare wall, as in the facade of the Royal Hospital at Santiago de Compostela (1501-11) by Enrique de Egas or his Santa Cruz Hospital at Toledo (1504-14).

The greatest centre of the Plateresque style was the town of Salamanca, with buildings such as the university (about 1516-29) and the Monterey Palace (1539). Perhaps the most outstanding example of the style is the Ayuntamiento, or town hall, of Seville (begun 1527) by Diego de Riaño, with Lombard paneled pilasters on the ground floor and half columns completely covered with relief sculpture on the second floor. Also in the Lombard manner are the numerous medallions spotted over the wall under the windows or between the pilasters.

Classical. Although the exuberant Plateresque style lingered in some regions until about 1560, it was soon superseded by a much more classical style, which appeared in 1526 in the Palace of Charles V within the Alhambra at Granada. The Palace of Charles V was the first Italian classical building in Spain, in contrast to Plateresque buildings whose classicism was limited to a few elements of Italian Renaissance decoration. Charles V, as king of Spain and Holy Roman emperor, was the most powerful political figure in Europe, dominating Italy, as well as Spain, the Low Countries, and Austria. His palace in the Alhambra reflected the increasing contact with Italy. Designed by the Spaniard Pedro Machuca, who had studied in Italy, the Palace of Charles V has never been completed, although work on it continued throughout most of the 16th century. The palace is square in plan with a huge central circular court (100 feet in diameter), which was intended for bullfights and tournaments. The plan is, therefore, fully Renaissance, being centralized and symmetrical; it is organized on cross-axes formed by the four entrances, one in the centre of each side. The facade shows a full understanding of the principles of Italian Renaissance design in its superimposition of orders and in the alternating rhythm of the triangular and segmental pediments above the windows of the second story. The interior court is surrounded by a colonnade with a similar superimposition of Doric and Ionic.

The
Palace of
Charles V

Herreran. The classicism of the Palace of Charles V was succeeded by an extremely austere and cold style named after the greatest Spanish architect of the 16th century, Juan de Herrera. Perhaps more important than the architect was the social and cultural atmosphere in which the Herreran style developed, from about 1560 to the end of the 16th century. Charles V had been a true Renaissance prince; his only son, Philip II, who came to the throne in 1556, was one of the most typical representatives of the age of Mannerism as it was manifested in Spain. Philip II was morbid and melancholic, a religious fanatic against whose strict rule the Low Countries soon rose in revolt, beginning the difficulties that gradually dispelled Spanish political and cultural power in Europe.

The finest example of the Herreran style illustrates clearly the change in cultural atmosphere under Philip II. This is the palace-monastery of El Escorial (1563-84), which Philip II had built as a retreat outside Madrid. It is a great contrast to the worldly Palace of Charles V with its tournament court set in the luxurious, sensuous Alhambra. El Escorial was more than a royal palace, as it also contained provisions for a monastery and college. A city in itself, El Escorial was planned as a tremendous rectangle (675 by 525 feet), with a large church at the centre.

El Escorial

El Escorial was begun by the architect Juan Bautista de Toledo, who may be responsible for the planning, but the execution and architectural style were that of his assistant and successor, Herrera. Philip II himself reviewed the drawings for the palace, removing anything ornamental or ostentatious. On the exterior the architecture is very simple, a plain wall with a monotonous series of unadorned windows expressing the general monastic character of the whole. The only segment of the classical Renaissance style on the exterior is at the central portal with two stories of giant Doric half columns supporting a triangular pediment. The church, at the centre of the complex, has two bell towers and a great dome set on a drum, which surmount the whole. The austerity is enhanced by the cold, gray granite of which El Escorial was built (Figure 66, left). On the interior a similar severity of manner is indicated by the lack of decoration. Except for the classical Doric order, which is the least ornamental of the orders, there is no architectural decoration. Plain arches of stone were used under the vaults without any coffering. Occasional raised panels on the wall surface suggest where Plateresque ornament would normally be located, but instead of relief sculpture, there are only starkly smooth panels (Figure 66, right). Even the Doric order was handled severely; the pilasters on the interior show no entasis (*i.e.*, an upward taper of the width of the pilaster to give a sense of lightness and to relieve the strict verticals). El Escorial is impressive in its size and mass and in the consistency of its austerity, but it has a forbidding quality that no other building can match. Other examples of Herrera's design are the cathedral of Valladolid (begun 1585, completed in the 18th century) and the court of the Lonja, or Exchange (1582-99), of Seville. (D.R.C./D.J.Wa.)

Spanish America. In Spanish America the high quality as well as the great quantity of colonial architecture establish it as a major contribution of the New World to civilization. The zeal and power of the Spanish church were abetted by the wealth of the colonies in the construction of sumptuous ecclesiastical buildings. Skilled Indian labour also contributed to the early development of large-scale programs in both religious and domestic architecture. Types of buildings and styles were Spanish in origin, although local conditions produced modifications. In centres of European culture, such as Santo Domingo, Mexico City, Quito, Lima, and Cuzco, architectural styles were contemporary with those in Spain. Medieval traditions survived, however, especially in monastic structures; even in the 17th century, late Gothic ribs persisted in the vaults of churches. Spanish-Moorish elements (*Mudéjar*), such as wooden ceilings in geometric patterns, coloured tiles, the rectangular frame of an arch (*alfiz*), and the trefoil arch, were popular throughout Spanish-American architecture.

In Santo Domingo, Dom. Rep., site of the first Spanish settlement, is preserved the earliest cathedral (1523-37), which has a superb Renaissance facade and a Gothic

Figure 66: El Escorial, near Madrid, by Juan de Herrera, 1563–84. (Left) Exterior; (right) interior.

Archivo Mas, Barcelona

interior. In Mexico large building campaigns (c. 1550–1600) were carried out by Franciscan, Augustinian, and Dominican friars. Their monasteries generally have a huge vaulted church, cloister, and monastic buildings, all based upon Spanish prototypes. The large atrium yard and the open chapel (*capilla abierta*) for outdoor religious services are special features developed in America to accommodate crowds of Indians, as at Acolman, Cuernavaca, and Huejotzingo. Portals display a wide variety of styles, including medieval and Renaissance elements and occasional Indian influences. The largest Mexican cathedrals, those of Mexico City (begun 1563) and Puebla (1575–1690), have the rectangular basilican plan and other features of the Andalusian Renaissance.

Important early monuments of Peru were destroyed by earthquakes; the surviving structures, of modest character, are found in Ayacucho, on the shores of Lake Titicaca, and in Sucre, Bol. Vaulted churches were virtually unknown in South America until the 17th century. In Quito, Ecuador, the Franciscan and Dominican monasteries are notable for their cloisters and Mudéjar ceilings, and the cathedral (1562–72) is an example of Andalusian Gothic-Mudéjar construction. (H.E.W.)

Portugal. The architecture of Portugal tends to parallel the development of Spanish architecture. The Manueline style of the late 15th and early 16th centuries, like the Plateresque of Spain, is a very decorative mode in which small motifs of classical ornament are introduced into a local late Gothic style. After the middle of the 16th century, a fully Italianate classical style is visible in the architecture of Diogo de Torralva. His cloister in the Cristo Monastery (1557–62) at Tomar is composed of the rhythmic bay of alternating arches and coupled Classical orders made popular by Bramante in Italy. The full projection of the superimposed Doric and Ionic columns suggests the stolidity of the Italian High Renaissance. During the last two decades of the century the work of the Bolognese architect Filippo Terzi presents that austere planarity, seen in the church of São Vicente de Flora, Lisbon (1582–1605), reminiscent of Herrera.

Germany. The burgeoning of Italian Renaissance architectural forms in Germany was even slower than in

other northern European countries. Only by the middle of the 16th century was the Renaissance style manifestly important, generally in those regions in closest contact with Italy, such as southern Germany or the trade route along the Rhine River leading from the south to the Low Countries. The style lingered in Germany until about the middle of the 17th century. The few hints of classicism in Germany prior to the mid-16th century can be considered the early Renaissance phase. They were limited to minor architectural monuments, such as the Fugger Chapel in St. Anne's Church at Augsburg (1509–18), which was the first Renaissance building in Germany, or they consisted of bits of Renaissance decoration attached to Gothic structures. An example of the latter is Hartenfels Castle (c. 1532–44) at Torgau by Konrad Krebs, which is completely medieval in design but has occasional fragments of classical ornament applied to the surface. The rear portion of the Residence (c. 1537–43) at Landshut is exceptional in that its architecture and decoration are fully Italianate, but this is explained by the visit in 1536 of Duke Ludwig X of Munich to Mantua, where Giulio Romano had just completed the Palazzo del Te.

After 1550 Renaissance style architecture in Germany often had Mannerist details derived from Italian ornamental engravings. German architecture of this period was abundant with medallions, herms (*i.e.*, architectural elements topped by human busts), and caryatids and atlantes (*i.e.*, human figures used as columns or pilasters). The German treatise on the five orders by Wendel Dietterlin, entitled *Architectura* (1598), is filled with such Mannerist ornament. An architectural example is the Otto-Heinrichsbau added to the Gothic castle at Heidelberg (burned by the French in 1689). The three tall stories presented the usual verticality of northern architecture, but there was an understanding of the classical superimposition of the orders with Corinthian above Ionic. Nevertheless, there was a certain freedom in the treatment of the orders, for a Doric frieze was supported by the Ionic pilasters. From Italian Mannerism came the rustication of the lower order, the use of herms as window mullions, and the caryatids flanking the portal. Other examples of the German Renaissance are the porch of the Rathaus, or Town Hall (1569–73),

Use of
Italian
Mannerist
ornamenta-
tion

at Cologne by the Dutchman Wilhelm Verniuken (Figure 67) and the Friedrichsbau (1601–07), which was added to the castle at Heidelberg by Johannes Schoch.

Flanders and Holland. In the Low Countries, Flanders, because of trade and finance, was in close communication with Italy from the 15th century. As a result, there are slight hints of the Renaissance style in the Flemish architecture of the early 16th century, as in the palace of Margaret of Austria, now the Palais de Justice (1507–25), at Mechelen (Malines), completed by Rombout Keldermans.

The most important building of the Flemish Renaissance style was the Stadhuis, or Town Hall (1561–65), at Antwerp, designed by Loys du Foys and Nicolo Scarini and executed by Cornelis II Floris (originally de Vriendt [1514–75]). It was decided to replace Antwerp's small medieval town hall with a large structure, 300 feet long, in the new style, as a reflection of Antwerp's prosperity as the leading northern port of the 16th century. As with many northern buildings, there is a lack of monumentality, for its physical hugeness is not expressed in the details. There is a low basement with a rusticated arcade, which was originally used by traders during fairs. Above are two principal stories with superimposition of Doric and Ionic pilasters, between which large windows almost completely open each bay (Figure 68).

The advent of the Baroque style early in the 17th century replaced the Renaissance in Flanders much sooner than it did in Germany. Among the few examples of the 16th-century Renaissance style in Holland were the town hall (1597) at Leiden and the town hall (c. 1564) at The Hague.

England. The Renaissance style of architecture made a very timid appearance in England during the first half of the 16th century, and it was only from about 1550 that it became a positive style with local qualities. In fact, the Gothic style continued in many parts of England throughout most of the 16th century, and English Renaissance architecture was a very original fusion of the Tudor Gothic and classical styles. This style flourished until the early 17th century when Inigo Jones created a much more Italianate style that gradually replaced the English Renaissance style.

During the reign of Henry VIII (1509–47), some elements of Italian Renaissance decoration were imported by England through a few minor Italian artists, such as Pietro Torrigiani, who executed the tomb (1512–18) of Henry VII in Westminster Abbey. At the great palace of Hampton Court, begun by Cardinal Wolsey in 1515 and continued by Henry VIII until 1540, a few bits of Italian Renaissance decoration have been added, although the structure is completely in the Tudor manner. On the gateways are several terra-cotta medallions by the Italian Giovanni da

Maiano, and there is a symmetry and regularity in the plan of the palace that hints of the Renaissance.

The Renaissance style really begins in England in the middle of the 16th century in architecture built for the circle of the Lord Protector Somerset, who served as regent after Henry VIII's death. During the 16th century the patron played a much greater role in the development of English Renaissance architecture than did the architect; there were almost no professional architects who were trained as the Italians were in the theory of design and building. Most of the building was executed by mason or carpenter designers. A typical example of the role of the patron in introducing the Renaissance style of England is to be found in the quadrangle that John Caius added to Gonville Hall (now Gonville and Caius) at Cambridge. Caius had spent a long time in Italy as well as elsewhere in Europe. The architecture of the new court was basically Tudor Gothic, but Caius planned three gateways in connection with the court, two of which were in the Italian style. The three gates were to mark the progress of the student through the university. At the entrance was the Gate of Humility (1565), a modest doorway, now in the Master's garden. The Gate of Virtue (after 1565), opening into the new quadrangle, is a fine classical portal with Ionic pilasters, but with a Tudor Gothic many-centred arch for the opening. Finally, the Gate of Honour (1573) is a separate tiny triumphal arch leading out toward the schools for the final disputation and degree. Caius probably designed these gates with the aid of the Flemish 16th-century architect Theodore de Have.

There was little religious architecture created in England during the 16th century, in part because of the break of Henry VIII with Rome. It is in the great country houses of the nobility that the Renaissance style is visible. Sir John Thynne, steward to the Lord Protector Somerset, designed several notable examples. The finest of these was his own house, Longleat (1568–c. 1580), on which he had the assistance of the mason Robert Smythson, who was to be the leading architect of the late 16th century. Except for the symmetry of the plan, arranged around two courts, there was little new in planning at Longleat, for the Tudor house was usually organized about a court. The typical English great hall at Longleat was an element derived from the hall of the medieval castle and retained in English architecture through the 16th century. The main entrance of the house opens directly into one end of the great hall, but a low screen at the end of the hall, topped by a musicians' gallery, forms a passageway. In elevation Longleat is a long, horizontal building with a wealth of windows; it is one of the most open secular buildings in Europe of the 16th century. There is a rectangular quality about the

whole exterior that is characteristic of English architecture; it is augmented by the repeated use of the bay window unit. There are now three stories on the exterior, with the correct classical superimposition of the Doric order on the ground floor and Ionic and Corinthian orders above, but the third story was probably added after Thynne's death, replacing a pitched roof and dormers (Figure 69, right).

Wollaton Hall

Robert Smythson, who aided Thynne at Longleat, later designed and built several notable houses, the finest being Wollaton Hall (1580–88) near Nottingham. Wollaton has a magnificent site on a small hill overlooking a large park. The plan of the house is a square with four square corner towers, resembling a plan in the treatise on architecture by Serlio, whose book was influential in English Renaissance architecture. The great hall is in the centre of the square; it rises an extra story above the whole building. The house has a low basement story that contained the kitchens and service rooms; it is one of the first buildings to use this arrangement, which became common in the history of later English and American architecture. On the exterior the massing is that of a rectangular block the rectilinear quality of which is further emphasized by the numerous many-mullioned rectangular windows (Figure 69, left). The decoration is completely classical, with superimposed pilasters, round-arched niches, and classical balustrades, but it shows touches of Italian Mannerism, which came into England primarily from Flanders. The pilasters and half columns have raised bands across their middles, and the gables crowning the corner towers are decorated with

Flemish strapwork (*i.e.*, bands raised in relief assuming curvilinear forms suggestive of leather straps). Other examples of this style are Hardwick Hall (1590–97) in Derbyshire, probably by Smythson; Kirby Hall (about 1570–78) in Northamptonshire, perhaps by the mason Thomas Thorpe; and Montacute House (1588–1601) in Somerset.

Eastern Europe. Because of the unstable political situation in eastern Europe, the appearance there of the Renaissance style of architecture is very sporadic and usually closely dependent upon the ruling personalities. The election in 1458 of Matthias Corvinus as king of Hungary marks the first serious interest in this region in the new architectural style. Matthias had translations prepared of the contemporary Italian architectural treatises of Filarete and Alberti and in 1467 invited to Hungary briefly the Bolognese architect and engineer Aristotele Fioravanti. The buildings designed for Matthias, such as his hunting lodge of Nyek, have been destroyed. The Bakócz Chapel (1507) erected by Cardinal Tamás Bakócz as his sepulchral chapel at the Cathedral of Esztergom is completely Italianate. Built on a Greek-cross plan surmounted by a dome, the chapel resembles late 15th-century Florentine chapels. Turkish occupation, however, soon delayed the adoption of the classical architectural style until the 18th century.

The patronage of Matthias Corvinus

In Russia during the reign of Ivan III the Great (1462–1505), as Tatar pressure lessened and Moscow gradually assumed importance, there was a brief interest in Western cultural developments. Thus, in 1475 Fioravanti, who had

been in Hungary earlier, was brought to Moscow. Soon Tsar Ivan resolved to rebuild the Kremlin, most of which was still of wood. From 1485 to 1516 the Italian architects Antonio Solario and Marco Ruffo enclosed the Kremlin with brick walls and erected within them the Granovitaya Palace (1487–91). This was a two-story blocklike palace with a rusticated exterior, as its name (*granovitaya*, “faceted”) indicates, in the manner of early Renaissance palaces of Bologna and Ferrara. Cultural contacts with the West then diminished under the impact of rising nationalism until the reign of Peter the Great in the early 18th century.

The Renaissance architectural style appears in Poland under the late Jagiellon dynasty, and especially in the reign of Sigismund I (1506–48), whose wife came from the Sforza family of Lombardy. The rebuilding of his Wawel Castle (1507–36) in Kraków was begun by the Italian Francesco della Lore and continued by Bartolommeo Berecci of Florence. It presents a blend of local Gothic and 15th-century Italian architecture. The great courtyard has three stories of loggias; the two lower ones, with semicircular arches on squat Ionic columns, suggest the new style, but the much taller upper story, with the steep roof supported by excessively slender posts, betrays a medieval wooden tradition. The mortuary chapel (1517–33) for Sigismund attached to the Wawel Cathedral in Kraków, also after the design of Berecci, represents one of the richest examples of the Italian Renaissance style in central Europe. Square in plan, each wall is divided by elaborately carved pilasters into a wide central bay for the tombs or altar, flanked by narrower bays with statue niches. Above, a coffered, semicircular dome rests on a drum with great circular windows. Unlike the other central European countries, in Poland Renaissance architecture continued to flourish throughout the remainder of the 16th century. In 1578 Jan Zamoyski, chancellor of Poland, commissioned the Venetian architect Bernardo Morando to design the fortified town of Zamość following the latest Italian ideas. The resultant town with street arcades resembles those of northern Italy.

The shift from the Gothic style to the Renaissance in Bohemia is visible in the architecture of the leading late 15th-century architect in Prague, Benedikt Ried. The interior of his Vladislav Hall, Prague (1493–1510), with its intertwining ribbon vaults, represents the climax of the late Gothic; but as the work on the exterior continued, the ornamental features of windows and portals are classical. Religious architecture continued in the Gothic mode, and most secular architecture was local in style with only a slight influence from the Italianate Renaissance. A few

minor royal commissions were more classical, such as the Letohrádek (1538–63), or garden belvedere (summerhouse), at Prague for Queen Anne, wife of Ferdinand I, with its delicate exterior arcade (Figure 70). The nearby tennis court (1565–68), designed by Bonifaz Wolmut, is in a heavier classicism expressed by the alternation of engaged Ionic half columns with deeply recessed arched openings. Several castles or large houses like that at Opočno (1560–67) or of Bučovice (1566–87), designed by the Italian Pietro Ferrabosco, had spacious courtyards with arcades on classical columns. (D.R.C./D.J.Wa.)

Baroque and Rococo

Baroque and late Baroque, or Rococo, are loosely defined terms, applied by common consent to European art of the period from the early 17th century to the mid-18th century.

Baroque was at first an undisguised term of abuse, probably derived from the Italian word *barocco*, which was a term used by philosophers during the Middle Ages to describe an obstacle in schematic logic. Subsequently, this became a description for any contorted idea or involuted process of thought. Another possible source is the Portuguese word *barroco*, with its Spanish form *barrueco*, used to describe an irregular or imperfectly shaped pearl; this usage still survives in the jeweler's term baroque pearl.

The derivation of the word Rococo is equally uncertain, though its source is most probably to be found in the French word *rocaille*, used to describe shell and pebble decorations in the 16th century. In the 18th century, however, the scope of the word was increased when it came to be used to describe the mainstream of French art of the first half of the century; Neoclassical artists used it as a derogatory term. Fundamentally a style of decoration, Rococo is much more a facet of late Baroque art than an autonomous style, and the relationship between the two presents interesting parallels to that between High Renaissance and Mannerist art. (P.C.-B./D.J.Wa.)

During the Baroque period (c. 1600–1750), architecture, painting, and sculpture were integrated into decorative ensembles. Architecture and sculpture became pictorial, and painting became illusionistic. Baroque art was essentially concerned with the dramatic and the illusory, with vivid colours, hidden light sources, luxurious materials, and elaborate, contrasting surface textures, used to heighten immediacy and sensual delight. Ceilings of Baroque churches, dissolved in painted scenes, presented vivid views of the infinite to the worshiper and directed him through his senses toward heavenly concerns. Sev-

The Renaissance style in Bohemia

Origin of the terms Baroque and Rococo

The aesthetic of Baroque art

enteenth-century Baroque architects made architecture a means of propagating faith in the church and in the state. Baroque palaces expanded to command the infinite and to display the power and order of the state. Baroque space, with directionality, movement, and positive molding, contrasted markedly with the static, stable, and defined space of the High Renaissance and with the frustrating conflict of unbalanced spaces of the preceding Mannerist period. Baroque space invited participation and provided multiple changing views. Renaissance space was passive and invited contemplation of its precise symmetry. While a Renaissance statue was meant to be seen in the round, a Baroque statue either had a principal view with a preferred angle or was definitely enclosed by a niche or frame. A Renaissance building was to be seen equally from all sides, while a Baroque building had a main axis or viewpoint as well as subsidiary viewpoints. Attention was focused on the entrance axis or on the central pavilion, and its symmetry was emphasized by the central culmination. A Baroque building expanded in its effect to include the square facing it, and often the ensemble included all the buildings on the square as well as the approaching streets and the surrounding landscape. Baroque buildings dominated their environment; Renaissance buildings separated themselves from it.

The Baroque rapidly developed into two separate forms: the strongly Roman Catholic countries (Italy, Spain, Portugal, Flanders, Bohemia, southern Germany, Austria, and Poland) tended toward freer and more active architectural forms and surfaces; in Protestant regions (England, the Netherlands, and the remainder of northern Europe) architecture was more restrained and developed a sober, quiet monumentality impressive in its refinement. In the Protestant countries and France, which sought the spirit through the mind, architecture was more geometric, formal, and precise—an appeal to the intellect. In the Roman Catholic south, buildings were more complex, freer, and done with greater artistic license—an appeal to the spirit made through the senses.

Treatises on the orders and on civil and military architecture provided a theoretical basis for Baroque architects. While many 16th-century architects published treatises on architecture or prepared them for publication, major 17th-century architects published very little. Two fragmentary volumes by Francesco Borromini appeared years after his death, and Guarino Guarini's major contribution (though he brought out two volumes on architecture before he died) did not appear until well into the 18th century. Other Italian publications tended to be repetitions of earlier ideas with the exception of a tardily published manuscript of Teofilo Gallaccini, whose treatise on the errors of Mannerist and early Baroque architects became a point of departure for later theoreticians.

In France, François Blondel and Augustin d'Aviler published notes for lectures given at the Academy of Architecture, but the most important publications were those of Fréart de Chambray and Claude Perrault. Perrault attacked established Italian theory. Other notable French works included writings by René Ouvard, André Félibien, Pierre Le Muet, and Julien Mauclerc. In England, Sir Henry Wotton's book was an adaptation of Vitruvius, and Balthazar Gerbier's was a compendium of advice for builders. Among the notable 17th-century German publications were books by Georg Boeckler, Josef Furtenbach, and Joachim von Sandrart.

During the period of the Enlightenment (about 1700 to 1780), various currents of post-Baroque art and architecture evolved. A principal current, generally known as Rococo, refined the robust architecture of the 17th century to suit elegant 18th-century tastes. Vivid colours were replaced by pastel shades; diffuse light flooded the building volume; and violent surface relief was replaced by smooth flowing masses with emphasis only at isolated points. Churches and palaces still exhibited an integration of the three arts, but the building structure was lightened to render interiors graceful and ethereal. Interior and exterior space retained none of the bravado and dominance of the Baroque but entertained and captured the imagination by intricacy and subtlety.

In Rococo architecture, decorative sculpture and painting are inseparable from the structure. Simple dramatic spatial sequences or the complex interweaving of spaces of 17th-century churches gave way to a new spatial concept. By progressively modifying the Renaissance-Baroque horizontal separation into discrete parts, Rococo architects obtained unified spaces, emphasized structural elements, created continuous decorative schemes, and reduced column sizes to a minimum. In churches, the ceilings of side aisles were raised to the height of the nave ceiling to unify the space from wall to wall (Church of the Carmine, Turin, Italy, 1732, by Filippo Juvarra; Pilgrimage Church, Steinhäusen, near Biberach, Ger., 1728, by Dominikus Zimmermann; Saint-Jacques, Lunéville, Fr., 1730, by Germain Boffrand). To obtain a vertical unification of structure and space, the vertical line of a supporting column might be carried up from the floor to the dome (e.g., church of San Luis, Seville, Spain, begun 1699, by Leonardo de Figueroa). The entire building was often lighted by numerous windows placed to give dramatic effect (Schloss Brühl, near Cologne, Balthasar Neumann, 1740) or to flood the space with a cool diffuse light (Pilgrimage Church, Wies, Ger., Zimmermann, 1745).

Concept of Rococo space

ORIGINS AND DEVELOPMENT IN ROME

The work of Carlo Maderno in Rome represented the first pure statement of the principles that became the basis of most of the architecture of the Western world in the 17th century. A northern Italian, Maderno worked most of his life in Rome where, about 1597, he designed the revolutionary facade of the church of Santa Susanna (Figure 71). Roman church facades in the late 16th century tended to be either precise, elegant, and papery thin or disjointed, equivocal, and awkwardly massive. Maderno's Santa Susanna facade is an integrated design in which each element contributes to the central culminating feature. Precision and elegance were relinquished to gain vitality and movement. Disjointed and ambiguous features were suppressed to achieve unity and harmony. A towering massiveness obtained by an increased surface relief

Architectural treatises

Definition of the Rococo style

and quickened rhythm of architectural members toward the centre replaced the papery-thin walls and hesitant massiveness of the 16th century. Vertical unification was achieved by breaking the entablature at similar places on both stories and by repeating pilasters and columns at both levels. Maderno also conceived the facade as part of an integrated unit, including the two-story church and one-story associated areas to either side, and thereby gave form to the Baroque desire to associate buildings, street facades, and squares in a continuous whole.

Aesthetic
principles
of early
Baroque
archi-
tecture

The basic premises of the early Baroque as reaffirmed by Maderno in the facade and nave of St. Peter's, Rome (1607), were: (1) subordination of the parts to the whole to achieve unity and directionality; (2) progressive alteration of pilaster rhythm and wall relief to emphasize massiveness, movement, axiality, and activity; and (3) directional emphasis in interiors through diagonal views and culminating light and spatial sequences (Figure 72).

The three great masters of the Baroque in Rome were Gian Lorenzo Bernini, Francesco Borromini, and Pietro da Cortona. Bernini, also a brilliant sculptor, designed both the baldachin (an ornamental canopy-like structure) with bronze spiral columns over the grave of St. Peter (1624–33) and the vast enclosing colonnade (begun 1656) that forms the piazza of St. Peter's. He was responsible also for the facade of the Palazzo Chigi-Odescalchi (1664), a model for later urban palaces, and the exquisite oval church of Sant'Andrea al Quirinale (1658–70), the epitome of richly coloured marble-encrusted church interiors.

In contrast to Bernini, Borromini preferred monochromatic interiors. The buildings of Borromini, who came from northern Italy, are characterized by their inventive transformations of the established vocabulary of space,

light, and architectural elements in order to increase the content of their work. Borromini's works, composed of fluid and active concave and convex masses and surfaces (San Carlo alle Quattro Fontane, 1634–41; Figure 73), contain spaces that are intricate, geometrically derived irregular ovals, octagons, or hexagons (Sant'Ivo della Sapienza, 1642–60). His late palace facade for the College of the Propagation of the Faith (1646–67) was a bold and vigorous essay that became a major source for Rococo architects in the early years of the 18th century.

Pietro da Cortona's early design for the Villa del Pigneto, near Rome (before 1630), was derived from the ancient Roman temple complex at Palestrina, Italy, and decisively altered villa design; his San Luca e Santa Martina, Rome (1635), was the first church to exhibit fully developed high Baroque characteristics in which the movement toward plasticity, continuity, and dramatic emphasis, begun by Maderno, achieved fruition. Pietro's reworking of a small square in Rome to include his facade of Santa Maria della Pace (1656–59) as an almost theatrical element is a cogent example of the Baroque insistence on the participation of a work in its environment.

In the early years of the 18th century in Rome, parallel to the development of Rococo in France, renewed interest in the work of Borromini was shown by Alessandro Specchi in his Ripetta Gate (1704), and by Filippo Juvarra, a gifted, if unorthodox, pupil of Carlo Fontana, in his early architectural projects and scene designs. Italian Rococo developed out of this new interest in Borromini. In Rome the Rococo developed further with the so-called Spanish Steps (1723) by Francesco de Sanctis; the facade of Santa Maria della Quercia (begun 1727) and Piazza Sant'Ignazio (1727) by Filippo Raguzzini; and, in Piedmont, Santa Caterina, Casale Monferrato (1718) by Giovanni Battista Scapitta.

NATIONAL AND REGIONAL VARIATIONS

Italy. Architects in northern Italy, notably Guarino Guarini, Filippo Juvarra, and Bernardo Vittone, developed a Baroque style of great structural audacity. Guarini's San Lorenzo (1668–80) and Palazzo Carignano (1679), both

in Turin, have swelling curvilinear forms, terra-cotta construction, exposed structural members, and intricate spatial compositions that show his relation to Borromini and also represent significant developments in the relationship between structure and light. Juvarra's Palazzo Madama, Turin (1718–21), has one of the most spectacular of all Baroque staircases, but the true heir to Guarini was Vittone. To increase the vertical effect and the unification of space in churches such as Santa Chiara, Brà (1742), Vittone raised the main arches, eliminated the drum, and designed a double dome in which one could look through spherical openings puncturing the inner dome and see the outer shell painted with images of saints and angels: a glimpse of heaven.

Emphasis
on surface
and
decoration

Spain. Spanish Baroque was similar to Italian Baroque but with a greater emphasis on surface decorations. Alonso Cano, in his facade of the Granada cathedral (1667), and Eufasio López de Rojas, with the facade of the cathedral of Jaén (1667), show Spain's absorption of the concepts of the Baroque at the same time that it maintained a local tradition. The greatest of the Spanish masters was José Benito Churriguera, whose work shows most fully the Spanish Baroque interest in surface texture and decorative detail (Figure 74). His lush ornamentation attracted many followers, and Spanish architecture of the late 17th century and early 18th century has been labeled Churrigueresque. Narciso and Diego Tomé, in the University of Valladolid (1715), and Pedro de Ribera, in the facade of the San Fernando Hospital (now the Municipal Museum) in Madrid (1722), proved themselves to be the chief inheritors of Churriguera.

The outstanding figure of 18th-century Spanish architecture was Ventura Rodríguez, who, in his designs for the Chapel of Our Lady of Pilar in the cathedral of Saragossa (1750), showed himself to be a master of the developed Rococo in its altered Spanish form; but it was a Fleming, Jaime Borty Miliá, who brought Rococo to Spain when he built the west front of the cathedral of Murcia in 1733.

Robert Ferreck/Odyssey Productions

Figure 74: Facade of the church of San Esteban, Salamanca, by José Benito Churriguera, 1693.

Flanders. Roman Catholicism, political opposition to Spain, and the painter Peter Paul Rubens were all responsible for the astonishing full-bodied character of Flemish Baroque. Rubens' friends Jacques Francart and Pieter Huyssens created an influential northern centre for vigorous expansive Baroque architecture to which France, England, and Germany turned. Francart's Béguinage Church (1629) at Mechelen (Malines) and Huyssens' St. Charles Borromeo (1615) at Antwerp set the stage for the more fully developed Baroque at St. Michel (1650) at Louvain, by Willem Hesius, as well as at the Abbey of Averbode (1664), by Jan van den Eynde.

Holland. Seventeenth-century architecture in Holland, in contrast, is marked by sobriety and restraint. Pieter Post, noted for the Huis ten Bosch (1645) at The Hague and the Town Hall of Maastricht (c. 1658), and Jacob van Campen, who built the Amsterdam Old Town Hall (1648; now the Royal Palace), were the principal Dutch architects of the 17th century. After the middle of the century, Dutch architecture exerted influence on architecture in France and England. Dutch colonial architecture was especially evident in the 17th and 18th centuries in the Hudson River Valley of North America and the Dutch West Indies (notably Willemstad on the island of Curaçao).

France. Salomon de Brosse's Luxembourg Palace (1615) in Paris and Château de Blérancourt (1614), northeast of Paris between Coucy and Noyon, were the bases from which François Mansart and Louis Le Vau developed their succession of superb country houses.

Mansart was the more accomplished of the two architects, and his Orléans wing of the Château de Blois (1635) in the Loire Valley and Maisons-Laffitte, near Paris (1642), are renowned for their high degree of refinement, subtlety, and elegance. Mansart's church of Val-de-Grâce (1645) in Paris and his designs for the Bourbon mausoleum (1665) established the full Baroque in France; it was a rich, subtle Baroque that was quiet in its strength and restrained in its vigour.

Le Vau was Mansart's only serious competitor, and in 1657, with his Château de Vaux-le-Vicomte, near Paris, he fired the imagination of Louis XIV and of his finance minister Jean-Baptiste Colbert. Vaux, though exhibiting certain Dutch influences, is noted for its integration of Le Vau's architecture with the decorative ensembles of the painter and designer Charles Le Brun and the garden designs of landscape architect André Le Nôtre. By serving as a model for Louis XIV's Palace of Versailles, the complex at Vaux was perhaps the most important mid-century European palace. Le Vau showed a sensitivity to Italian Baroque architecture that was unusual in a French architect, and his College of Four Nations (1662; now the Institute of France) in Paris owes much to the Roman churches of Santa Maria della Pace by Pietro da Cortona and Sant'Agnese in Agone (1652–55) in the Piazza Navona by Borromini and Carlo Rainaldi. Le Vau, Le Nôtre, and Le Brun began working at Versailles within a few years of their success at Vaux, but the major expansion of the palace did not occur until after the end of the Queen's War (1668). At Versailles, Le Vau showed his ability to deal with a building of imposing size. The simplicity of his forms and the rich, yet restrained, articulation of the garden facade mark Versailles as his most accomplished building. Le Nôtre's inventive disposition of ground, plant, and water forms created a wide range of vistas, terraces, gardens, and wooded areas that integrated palace and landscape into an environment emphasizing the delights of continuity and separation, of the infinite and the intimate. Upon Le Vau's death, Jules Hardouin-Mansart, grandnephew of François, succeeded him and proved himself equal to Louis XIV's desires by more than trebling the size of the palace (1678–1708). Versailles became the palatial ideal and model throughout Europe and the Americas until the end of the 18th century. A succession of grand palaces was built, including the following: Castle Howard and Blenheim Palace by Sir John Vanbrugh in England; the Residenz of Würzburg, Ger. (1719), by Neumann; the Zwinger in Dresden, Ger. (1711), by Matthäus Daniel Pöppelmann; the Belvedere, Vienna (1714), by Johann Lukas von Hildebrandt; the

Royal Palace at Caserta, Italy (1752), by Luigi Vanvitelli; and the Royal Palace (National Palace) at Madrid (1736), by Giovanni Battista Sacchetti.

Hardouin-Mansart's Dôme des Invalides, Paris (c. 1675), is generally agreed to be the finest church of the last half of the 17th century in France (Figure 75). The correctness and precision of its form, the harmony and balance of its spaces, and the soaring vigour of its dome make it a landmark not only of the Paris skyline but also of European Baroque architecture.

After Nicolas Pineau returned to France from Russia, he, with Gilles-Marie Oppenordt and Juste-Aurèle Meissonier, with their increasing concern for asymmetry, created the full Rococo. Meissonier and Oppenordt should be noted too for their exquisite, imaginative architectural designs, unfortunately never built (e.g., facade of Saint-Sulpice, Paris, 1726, by Meissonier).

The early years of the 18th century saw the artistic centre of Europe shift from Rome to Paris. Pierre Lepautre, working under Hardouin-Mansart on the interiors of the Château de Marly (1679), invented new decorative ideas that became the Rococo. Lepautre changed the typical late 17th-century flat arabesque, which filled a geometrically constructed panel, to a linear pattern in relief, which was enclosed by a frame that determined its own shape. White and gold-painted 17th-century interiors (the central salon of the palace at Versailles) were replaced by varnished natural-wood surfaces (Château de Meudon, Cabinet à la Capucine) or by painted pale greens, blues, and creams (Cabinet Vert, Versailles, 1735). The resulting delicate asymmetry in relief and elegant freedom revolutionized interior decoration and within a generation exerted a profound effect on architecture. Architects rejected the massive heavy relief of the Baroque in favour of a light and delicate, but still active, surface. Strong, active, and robust interior spaces gave way to intricate, elegant but restrained spatial sequences.

Origins of
the Rococo
style

England. The late designs of Inigo Jones for Whitehall Palace (1638) and Queen's Chapel (1623) in London introduced English patrons to the prevailing architectural ideas of northern Italy in the late 16th century. Although he was influenced heavily by 16th-century architects such as Palladio, Serlio, and Vincenzo Scamozzi, Jones approached the Baroque spirit in his late works by unifying them with a refined compositional vigour. Sir Christopher Wren presented English Baroque in its characteristic restrained but intricate form in St. Stephen's, Walbrook, London (1672), with its multiple changing views and spatial and structural complexity. Wren's greatest achievement, St. Paul's Cathedral, London (1675–1711), owes much to French and Italian examples of the Baroque period; but the plan shows a remarkable adaptation of the traditional English cathedral plan to Baroque spatial uses (Figure 76). Wren is notable for his large building complexes (Hampton Court Palace, 1689, and Greenwich Hospital, 1696), which, in continuing the tradition of Inigo Jones, paved the way for the future successes of Sir John Vanbrugh. Vanbrugh's Castle Howard in Yorkshire (1699) and Blenheim Palace in Oxfordshire (1705) mark the culmination of the Baroque style in England.

Wren as a
Baroque
architect

Even in England, reflections of an interest in continuous curvilinear form inspired by Borromini and Bernini may be seen in isolated examples such as St. Philip, Birmingham (1710), by Thomas Archer.

Central Europe. A stable political situation in central Europe and the vision of Rudolf II in Prague in the late 16th and early 17th centuries created an intellectual climate that encouraged the adoption of new Baroque ideas. The Thirty Years' War and the defense against the encroachments of the expanding French and Ottoman

Angelo Hornak

empires, however, absorbed all of the energies of central Europe. The fully developed Baroque style appeared in Germany, Austria, Bohemia, and Poland after 1680 but flourished only after the end of the debilitating War of the Spanish Succession (1714). In the late 17th and early 18th centuries, Germany and Austria turned for their models principally to Italy, where Guarini and Borromini exerted an influence on Johann Bernhard Fischer von Erlach and Johann Lucas von Hildebrandt. The third Austrian master, Jakob Prandtauer, on the other hand, came from a local stonemason tradition and worked primarily for monastic orders. Fischer von Erlach's University Church in Salzburg (1696) is particularly noteworthy and shows direct Italian inspiration, while the Karlskirche, Vienna (1715), demonstrates his original, mature phase. Hildebrandt's Belvedere

palace in Vienna and Prandtauer's superbly sited Abbey of Melk overlooking the Danube (1702) are among their most notable works.

In Bohemia the developed, or high, Baroque was heralded by the work of a French architect, Jean-Baptiste Mathey, who carried both Roman and French ideas to Prague from Rome in 1675. The Bavarian Christoph Dientzenhofer, however, transformed architecture in Prague and Bohemia with his boldly conceived buildings in the high Baroque style (Prague, nave of St. Nicholas, 1703, and Břevnov, Benedictine church, 1708).

The spectacular Rococo of central Europe, Germany, and Austria, which by 1720 had begun to influence Italian architecture, grew out of a fusion of Italian Baroque and French Rococo. Its chief monuments are to be found in the Roman Catholic regions. Johann Michael Fischer, Balthasar Neumann, the brothers Cosmas Damian and Egid Quirin Asam, and Dominikus Zimmermann were the most accomplished of the native architects, while the Frenchmen François de Cuvilliers, Philippe de La Guêpière, and Nicolas de Pigage made the most important foreign contributions to mid-century architecture in Germany.

Fischer's austere, dignified facade of the church at Diessen (1732) and his masterpiece of integrated painting, decorative stucco, sculpture, and architecture, the Benedictine abbey of Ottobeuren (1744), are landmarks of the Bavarian Rococo (Figure 77). Neumann's joyous, airy Rococo Pilgrimage Church atierzehnheiligen (1743) and his later, more restrained Benedictine abbey at Neresheim (1745) characterize the increasing influence of classicism in Germany. In the north, in Berlin, Georg Wenzeslaus von Knobelsdorff alternated between Rococo (Potsdam, Sanssouci, 1745) and neo-Palladian classicism (Berlin, Opera House, 1741). Two influential country houses, La Guêpière's Solitude, near Stuttgart (1763), and Cuvilliers's Amalienburg, Munich (1734), exquisitely graceful and refined, are examples of French influence in Württemberg and Bavaria.

Russia. The Baroque appeared in Russia toward the end of the 17th century. The Russians imaginatively transformed its modes into a clearly expressed national style that became known as the Naryshkin Baroque, a delightful example of which is the Church of the Intercession of the Virgin at Fili (1693) on the estate of Boyarin Naryshkin, whose name had become identified with this phase of the Russian Baroque.

Western Europeans brought the prevailing Baroque styles characteristic of their own countries, but the very different artistic and physical setting of St. Petersburg produced a new expression, embodying Russia's peculiar sense of form, scale, colour, and choice of materials. The transformed Baroque eventually spread all over Russia and,

with its vast register of variations, developed many regional idioms.

A French architect, Nicolas Pineau, went to Russia in 1716 and introduced the Rococo style to the newly founded city of St. Petersburg (e.g., Peter's study in Peterhof, before 1721). The Rococo in Russia flourished in St. Petersburg under the protection of Peter I and Elizabeth. Peter's principal architect, Gaetano Chiaveri, who drew heavily on northern Italian models, is most noted for the library of the Academy of Sciences (1725) and the royal churches of Warsaw and Dresden. Bartolomeo Rastrelli was responsible for all large building projects under the reign of Elizabeth, and among his most accomplished designs in St. Petersburg (now Leningrad) are the Smolny Cathedral (Figure 78) and the turquoise and white Winter Palace. Colonial architecture in the Americas. *North America.* The colonial architecture of the United States and Canada was as diverse as the peoples who settled there: English, Dutch, French, Swedish, Spanish, German, Scots-Irish. Each group carried with it the style and building customs of the mother country, adapting them as best it could to the materials and conditions of a new land. Thus, there were several colonial styles. The earliest buildings of all but the Spanish colonists were medieval in style: not the elaborate Gothic of the great European cathedrals and manor houses but the simple late Gothic of village houses and barns. These practical structures were well adapted to the pioneer conditions that prevailed in the colonies until about 1700, and few changes were needed to adapt them to the more severe climate. The styles were frank expressions of functional and structural requirements, with only an occasional bit of ornament. So far as is known, no single new structural technique or architectural form was invented in the North American colonies.

There were seven reasonably distinct regional colonial styles: (1) the New England colonial, visible in almost 100 surviving 17th-century houses, was predominantly of wood construction with hand-hewn oak frames and clapboard siding; its prototypes are to be found chiefly in the southeastern counties of England. (2) The Dutch colonial, centring in the Hudson River Valley, western Long Island, and in northern New Jersey, made more use of stone and brick or a combination of these with wood; its prototypes were in Holland and Flanders. The style persisted in this region until after the American Revolution. (3) The Swedish colonial settlement, established in 1638 along the lower Delaware River, was of short duration but contributed the log cabin (in the sense of a structure with round logs, notched at the corners and with protruding ends) to American architecture. (4) The Pennsylvania

colonial style was late in origin (the colony was not founded until 1681) and rapidly developed into a sophisticated Georgian mode, based on English precedents. A local variant, often called Pennsylvania Dutch, evolved in the southeastern counties where Germans settled in large numbers after 1710. (5) The Southern colonial flourished in Maryland, Virginia, and the Carolinas. Story-and-a-half brick houses, sometimes with large projecting end chimneys and decorative brick masonry, prevailed. (6) The French colonial, stemming from medieval French sources, evolved in Canada in the Maritime Provinces and the St. Lawrence Valley. The earliest impressive structure was the Habitation of the French explorer Samuel de Champlain, built at Port Royal, N.S., in 1604. Most of the surviving early houses of New France are to be found in the province of Quebec. The French settled the Great Lakes and Mississippi regions by the late 17th century and introduced the Quebec style. Far to the south, Louisiana was established as a colony in 1699, and New Orleans became the capital in 1718. There grew up a distinctive regional style in the close-packed streets of the Vieux Carré of New Orleans and in the quiet plantations of the bayou country. (7) The Spanish colonial style in the United States extended geographically and chronologically from St. Augustine in 1565 to San Francisco in 1848. The five great mission fields were in Florida, New Mexico (from 1598), Texas, Arizona (both from 1690), and California (from 1769). Unlike other colonial styles, which were essentially medieval, the Spanish colonial followed the Renaissance and Baroque styles of Spain and Mexico.

The architectural style of the 18th century in England and in the English colonies in America was called Georgian. There are slight differences in usages of the term in the two countries. In England, Georgian refers to the mode in architecture and the allied arts of the reigns of George I, II, and III, extending from 1714 to 1820. In America, Georgian refers to the architectural style of the English colonies from about 1700 to the American Revolution in the late 1770s. Formal and aristocratic in spirit, it was at first based on the Baroque work of Sir Christopher Wren and his English followers; but after 1750 it became more severely Palladian. Typically, houses were of red brick with white-painted wood trim. Interiors had central halls, elaborately turned stair balustrades, paneled walls painted in warm colours and white plaster ceilings. All of these features were new to the colonies in 1700. Some of the earliest Georgian buildings were at Williamsburg, capital of Virginia from 1699 to 1780 (Figure 79); other notable examples are Independence Hall, Philadelphia (1745), and King's Chapel, Boston (1750). The style was followed by the Federal style, 1780–1820. (Hu.M.)

Spanish South America. The architecture of the first half of the 17th century in Spanish America preserves the late classical style of Juan de Herrera, the 16th-century Spanish architect of El Escorial. Herreran austerity, for example, also characterizes San Agustín and Santo Domingo in Puebla, Mex., as well as the facade of the cathedral.

Most impressive is the cathedral (1598–1654) of Cuzco, Peru, rectangular in plan and Herreran in its sobriety except for the early Baroque portal. The Jesuit church in Cuzco, whose handsome facade was designed in 1664 by Diego Martínez de Oviedo, constituted the first late Baroque architecture in the Americas. The city abounds in handsome churches and palaces, built of Andean stone in the second half of the 17th century, and it is in many respects unrivaled in America. At Lima, the rebuilding of the monastery of San Francisco (1657–c. 1673) brought a new wave of Mudéjar influence in the geometric designs of the plasterwork. The main portal (1674) of the church inaugurated in that city the late Baroque type of facade, closely resembling a carved altarpiece.

Mudéjar
influence

In Bolivia the chief architectural centre was Sucre, where Gothic vaults persisted; but otherwise both religious and domestic buildings adhered to simple classical designs. The Jesuit church of St. Ignatius (c. 1625–50) in Bogotá, Colom., owes its Italianate classicism to an Italian architect, the Jesuit priest Father Coluccini. The greatest masterpiece of Jesuit architecture in North and South America is, however, the church La Compañía, in Quito. There the Mudéjar patterns, which stand out in gold against a red background, make the interior (1605–89) of the church unforgettably sumptuous. More provincial though extremely colourful Mudéjar interiors are characteristic of the monastic churches of Tunja, Colom. Due to the splendid designs of its monastic buildings, Quito stands with Cuzco as one of the major schools of architecture in South America.

The first stage of Baroque architecture in Spanish America is generally distinguished by richly sculptured facades, whereas the interiors often remain sober settings for resplendently carved and gilded altarpieces. The late Baroque altar of spiral columns (Salomonica) was imported from Spain about 1650–60. Its translation into stone on the facade of a church first occurred (1697–1704) in South America in Our Lady of La Merced at Lima, to be followed by San Agustín there and by three churches in Cajamarca, Peru.

In this period there appeared in southern Peru and Bolivia a school of architectural decoration characterized by native Indian contributions in the primitive manner of carving and in the introduction of non-European ornament. The crossbred style is known as mestizo because

it, like the people, is compounded of European and native Indian stock. Evidences of Indian contribution are also found in Mexico throughout the colonial period, and there exist parallel phenomena in Central America. The first examples of the independent Peruvian-Bolivian style are preserved in Arequipa, Peru, where the facade (1698) of the Jesuit church La Compañía is carved like a stone tapestry. Other examples of mestizo style are the church of Santiago at Pomata, Peru (c. 1690–1722), San Lorenzo (1728–44), and the Jesuit church La Compañía (1700–07) at Potosí, Bol., and San Francisco (1753–72) at La Paz, Bol.

Mestizo
style

Argentina lay in the outer periphery of the Spanish colonies, and its early architecture consisted of provincial chapels of rubble and adobe, with the exception of the Jesuit monastery La Compañía (1654–71) at Córdoba. In the 18th century, two Italian Jesuit architects, Blanco and Primoli, established the spacious style of the Italian Baroque in the Jesuit estates of Alta Gracia and Santa Catalina near Córdoba and in the church of Our Lady of Pilar at Buenos Aires.

Baroque architecture reached its climax in Mexico with lavishly carved facades in which the tapering pilaster (*es-típite*) was a distinguishing feature. Introduced in Mexico City in the Metropolitan Sacristy facade (1749–68) under the architect Lorenzo Rodríguez (Figure 80), it spread rapidly and appeared in La Santísima, in the Jesuit seminary at Tepotzotlán, in the churches of Guanajuato, and elsewhere. The school of Puebla maintained independence in producing an extraordinary array of brilliantly coloured exteriors of glazed tiles, both in churches and in countless palaces. The varied geometric contours of doorways, windows, and roof levels created picturesque effects in Mexican buildings of this period.

Throughout Spanish America, cities were designed and built on a gridiron plan, with a rectangular plaza in the centre and the covered sidewalks (*portales*) of Mediterranean tradition. Houses, large or small, were arranged about a central patio. Handsome domestic buildings exist throughout the region; notable were those in Mexico City and Puebla; in South America at Tunja, Potosí, Lima, and Cuzco. Many remarkable civil edifices, such as the customhouse and viceregal palace, survive in Mexico City, whereas elsewhere only the royal mint at Potosí, Bol. (1753–73), and the government palace (1764) in Antigua, Guat., are comparable in architectural importance. Spanish colonial architecture came to an abrupt end with the triumph of Neoclassicism (1800).

Brazil. The architecture, language, and culture of Portugal were transplanted to Brazil, which was the only major area of non-Spanish origin throughout Latin Amer-

Archivo Mas, Barcelona

The Jesuit
style

ica. Unlike the unified Spanish settlements, the first cities were built upon hills in medieval style. Little of importance survives from the 16th century, when buildings were mostly of wattle and palm thatch.

The Jesuits carried to Brazil the first significant ecclesiastical style, a severe and undecorated architecture (Olinda, 1592). With variations, it persisted in Brazil until 1750. Plans are rectangular with square sanctuary and sacristy directly behind, and basilican structures are few. Long lateral chapels parallel with the nave are an unusual feature, derived from Portugal. Vaults and domes are rare, and decoration is limited to the occasional use of imported blue glazed tiles.

Salvador, the viceregal capital until 1763, had the closest ties with Lisbon; and its architecture reflected contemporary Portuguese models. A former Jesuit church, now the cathedral of São Salvador (1657–72), has a late Mannerist facade of stone in two principal stories, decorated with Doric pilasters and topped by a large attic story. The prominent windows in the second story are typical of Portuguese and Brazilian ecclesiastical and domestic design.

The more exotic Brazilian church facades began to make their appearance in the 18th century; great volutes over the centres between square towers created extraordinarily ingenious effects. This development can be traced in the facades at São Salvador, Deodoro, Penedo, Olinda, João Pessoa, and elsewhere, in a series of Franciscan churches that feature arched open porticos, three windows in the second story, and fantastic volutes crowning the top.

In the last period of Brazilian colonial architecture (1750–1822) the court style of Lisbon took hold in Belém and the new viceregal capital (1763) at Rio de Janeiro. The neo-Palladian church of the Candelaria (1775) there is the most important monument in the early Neoclassical style. The Rococo was, however, still well entrenched, and in the mining country of Minas Gerais it found its most original expression after 1750. There the great sanctuary of the Bom Jesus de Matozinhos at Congonhas do Campo is approached by terraces, a provincial version of the shrines at Braga and Lamego in Portugal (Figure 81). The oval and octagonal plans, which earlier had been introduced at Rio and Recife, reached a new development in São Pedro dos Clérigos at Mariana and in the double oval plan of the Rosario at Ouro Preto (1785), where they are combined with round towers and curving facades. Curving exteriors in various forms in the Franciscan churches at Ouro Preto (1766) and São João del Rei, designed by Aleijadinho (Antônio Francisco Lisboa), and in other monuments established the keynote of this late period.

Extreme decorative luxuriance characterized the altars and church furnishings in the 18th century, and often the

walls of chapels and churches were overlaid with carved ornament. Rio, Salvador, and Minas Gerais became the chief centres of interiors in which gilding, spiral columns, late Baroque ornament, and illusionistic painting combined to create extraordinary decorative ensembles. An equal flowering of late Rococo ornament distinguished portals, windows, and profiles of both ecclesiastical and domestic buildings. (H.E.W.)

URBAN DESIGN

17th century. The basic rational principles of Renaissance urban design—geometric order, gridiron or single focus radial plans, primary and dispersed activity centres, and restricted and unlimited vistas—as stated early in the Renaissance by the 15th-century Italian architects Filarete, Alberti, and Francesco di Giorgio, remained basic to 17th-century thought. Only in the New World—in the Utopian religious settlements that were founded by dissident sects in the American colonies—were there new cities planned as agrarian communities composed of closely spaced but freestanding houses that seemed to reject both medieval and Renaissance urban-design theories.

By the middle of the 17th century, new organizational principles, developed in France by Le Nôtre in garden design (Vaux-le-Vicomte and Versailles), replaced the diffuseness of Renaissance urban design with a more highly integrated radial axial scheme, with multiple subordinate radial focuses at locations of significant activities that gave overall coherent form to an entire city. A city form that disclosed the hierarchical interrelationship of functions and portions of a city reinforced prevailing concepts of hierarchical social and political order. The fusion of form and content had the effect of transforming the concept of a city and continues to be felt to the present day.

In the late 16th century in Rome the major street pattern was largely the creation of Domenico Fontana, who, under Pope Sixtus V in the years just before 1600, imposed an avenue plan that linked all the major pilgrimage churches. The avenues were laid out over the most direct routes, regardless of the terrain; and at the focal points (*i.e.*, piazzas in front of the major monuments) obelisks were erected. Fontana's emphasis on communication routes and gathering spaces became the model for most later large-scale urban designs or renovations, such as Wren's plan for London, submitted after the Great Fire of 1666. This unexecuted proposal showed a series of avenues linking the major religious and commercial centres superimposed on a rational gridiron plan.

The regularized residential city square received its greatest development in France with the planning of the royal squares. The Parisian Place des Vosges (1605), with its

The

square

From *Brazil Builds* by Goodwin and Kidder Smith

Figure 81: Statues of the 12 prophets, soapstone sculpture by Aleijadinho, 1800–05, on the terraces of the sanctuary of Bom Jesus de Matozinhos (attributed to Aleijadinho, 1780), Congonhas do Campo, Braz.

well-proportioned facades, shadowed arcades, and balanced colour scheme, was the beginning of a series that culminated with the circular Place des Victoires (1685) and the Place Vendôme (1698), both in Paris. Italian city squares tended to be either open, grand, and monumental (St. Peter's Square, Rome) or intimate, formally provocative, and spatially exciting (Santa Maria della Pace, Rome).

18th century. Urban design in the 18th century placed greater emphasis on unity and direction through the subordination of lesser parts to the whole. Entire cities were laid out on regularized multiaxial schemes (e.g., Washington, D.C., 1792, by Pierre L'Enfant); the spaces between the radiating avenues were subdivided either geometrically or on a gridiron pattern. New principles calling for a sequence of different spatial experiences were also introduced, as in the plan for Nancy, Fr. (1752–55), by Emmanuel Héré de Corny. In Italy outstanding examples of the new style are the splendid oval Piazza Sant'Ignazio, Rome (1727), by Filippo Raguzzini; and the grand military quarter of Turin (1716), by Juvarra. Notable among the many English examples of planned urban development in this period are St. James's Square, London (1726), and the Circus (1754) and the Royal Crescent (begun 1767), Bath, by John Wood the Elder and the Younger. In Reims, Fr., the solemn Place Royale (1756) by the engineer J.G. Legendre is notable, but the finest example of an 18th-century large, urban pedestrian square may be the Place Louis XV (now the Place de la Concorde), Paris (1755), by Jacques-Ange Gabriel. On the banks of the Seine, in its original design, it served as a focal point for the gardens of the Louvre, for the street which led to the Church of the Madeleine, and for three radiating streets of the Champs-Élysées.

(H.A.M.)

Classicism, 1750–1830

ORIGINS AND DEVELOPMENT

The classicism that flourished in the period 1750–1830 is often known as Neoclassicism, in order to distinguish it, perhaps unnecessarily, from the classical architecture of ancient Rome or of the Renaissance. In the 18th century, modern classicism was described as the “true style,” the word Neoclassical being then unknown. The search for intellectual and architectural truth characterized the period. Stylistically this began with an onslaught on Baroque architecture, which—with its emphasis on illusion and applied ornament—was felt to be manifestly untruthful. As early as the 1680s the French architect Claude Perrault had undermined the Renaissance concept of the absolute right of the orders. According to Perrault, the proportions of the orders had no basis in absolute truth but were the result of fancy and association. The consequent attempt to discover a new basis for architectural reality took many forms, from archaeology to theory.

Essentially representing a new taste for classical serenity and archaeologically correct forms, 18th-century classicism manifested itself in all the arts. It corresponded to a new attitude toward the past that began to be perceptible about 1750. In Europe it represented a reaction against the last phase of the Baroque and was symptomatic of a new philosophical outlook. As the Baroque was the style of absolutism, so Neoclassicism corresponded loosely with the Enlightenment and the Age of Reason. Coincidental with the rise of Neoclassicism and exerting a formative and profound influence on the movement at all stages was a new and more scientific interest in classical antiquity. The discovery, exploration, and archaeological investigation of classical sites in Italy, Greece, and Asia Minor were crucial to the emergence of Neoclassicism.

Neoclassicism, in its nostalgia for past civilizations and its attempt to re-create order and reason through the adoption of classical forms, was, paradoxically, also a Romantic movement. Prompted by feeling as well as by reason, architects interested themselves as much in the picturesque aspects of nature and objects in nature (such as ruins) as in rational procedures. While superficially opposite, Neoclassicism and Romanticism share the same roots. Two movements as different as the Greek Revival and the Gothic Revival were essentially alike, sharing, at

least in their earlier phases, similar motivations and even compositional expressions and equally reflecting the mood of the age that created them.

The term Romantic Classicism has been used by some 20th-century art historians to describe certain aspects of Neoclassical architecture. This widening of the term admits non-Greco-Roman forms and the many attempts to imitate Chinese, Moorish, Indian, Egyptian, and, of course, Gothic buildings.

The emergence of the science of archaeology was indicative of a new attitude to the past in which separate and distinct chronological periods could be distinguished. This sense of a plurality of valid styles replaced the older conception of classical Rome as the unique object of veneration. An important architectural corollary of this idea, which was to spring into prominence in the 19th century, was the notion of a modern style of building. Just as the past could now be interpreted and re-created by the study of a diverse range of monuments, each now seeming to be uniquely characteristic of its own particular moment in time, so it was thought possible that a mode of building reflecting the present, a mode recognizable by future archaeologists as uniquely representative of their own time, might be created.

Numerous events beginning in the second decade of the 18th century, when English tourists began to visit Italy to experience, explore, and collect fragments of its antique past, herald this new and increasing interest in archaeology. As early as 1719, Bernard de Montfaucon, a French antiquarian, began to publish his 10-volume *Antiquité expliquée*. It was an immediate success. Excavations at the newly discovered ancient cities of Pompeii and Herculaneum (discovered in 1719) began in 1748 and 1738, respectively. The publication of the Comte de Caylus's *Recueil d'antiquités*, which began to appear in 1752, was another landmark. Influential plates of Roman antiquities drawn by Giovanni Battista Piranesi first appeared in 1743, the year of publication of the *Prima parte di architettura*. A steady stream of similar works followed from Piranesi's workshop, among them the *Antichità romane* (1748), the *Carceri* (c. 1745), *Della magnificenza ed architettura de' Romani* (1761), and the *Parere su l'architettura* (1764). The first of a long and significant list of publications of measured drawings and picturesque views of Roman and Greek antiquities was Robert Wood's *Ruins of Palmyra* (1753), which was followed in 1757 by the same author's *Ruins of Balbec* and by the *Ruins of the Palace of the Emperor Diocletian at Spalatro in Dalmatia*, written in 1764 by the English Neoclassical architect and designer Robert Adam.

At the same time a significant interest in Greek antiquities was emerging along with a growing belief in the superiority of Greek over Roman that was to result in a Greek Revival in architecture. At about this time the 6th-century Greek ruins at Paestum in southern Italy and in Sicily began to attract the attention of visitors. The Paestum sites were first described by the Italian artist Domenico Antonini in 1745. In 1750 the French architect Jacques-Gabriel Soufflot visited Paestum. The following year Giuseppe Maria Pancrazi's *Antichità siciliane* appeared, and in 1769 the architect Gabriel-Pierre-Martin Dumont's *Ruines de Paestum* was published. The picturesque qualities of these Greek temples, with their heavy baseless columns broken and overgrown with romantic vegetation, prompted those interested in architecture to venture farther afield and to explore the Greek mainland and Asia Minor. The first book with detailed illustrations of Greek monuments to be published was the Frenchman Julien-David LeRoy's *Ruines des plus beaux monuments de la Grèce* (1758). This was followed by *The Antiquities of Athens* by two English architects, James Stuart and Nicholas Revett, which appeared in three parts in 1762, 1789, and 1795.

The pursuit of Greek architecture had as one incentive the pursuit of primitive truth and thus of an inherent rationalism. This line of thought had been developed early in the 18th century and was popularized by a French Jesuit, Marc-Antoine Laugier, whose *Essai sur l'architecture* appeared in French in 1753 and in English in 1755. Ad-

The role of classical archaeology

Characteristics of the Neoclassical movement

Rationalism in architecture

vocating a return to rationalism and simplicity in building and taking the primitive hut as his example of the fundamental expression of human needs, Laugier was both reacting against the excesses of the Rococo period and laying the theoretical groundwork for Neoclassicism. He did not advocate copying Greek forms, with which he was probably unacquainted, but argued that all forms not having a structural or functional purpose should be eliminated. The actual imitation of Greek architecture developed slowly, though the idea of the superiority of Greek over Roman architecture was established by Johann Joachim Winckelmann's *Gedanken über die Nachahmung der griechischen Werke in der Malerei und Bildhauerkunst* (1755; *Reflections on the Painting and Sculpture of the Greeks*).

The centre of international Neoclassicism was Rome, a gathering place, from the 1740s on, for talented young artists from all over Europe. Virtually every figure who was to play a significant role in the movement passed through that city. Piranesi arrived in 1740, Anton Raphael Mengs in 1741, Robert Adam in 1754, Winckelmann in 1755, the French painter Jacques-Louis David in 1755, and the Italian sculptor Antonio Canova in 1779. Although it was Rome, the cradle of Italian antiquities, that provided the stage, the leading actors in the Neoclassical drama were French, German, or English; very little was contributed by Italians to this new movement. The centre of activity was the French Academy, where winners of the academy's coveted Prix de Rome went to study the monuments firsthand and to be exposed to the artistic life of the Italian capital. The projects produced by French Prix de Rome winners are characterized by their grandeur of scale; strict geometric organization; simplicity of geometric forms; Greek or Roman detail; dramatic use of columns, particularly to articulate interior spaces and create urban landscapes; and a preference for blank walls and the contrast of formal volumes and textures. The same qualities describe Neoclassical architecture as it was to emerge throughout Europe and in America.

NATIONAL AND REGIONAL VARIATIONS

Great Britain. In England the Palladianism of architects such as Lord Burlington, Colen Campbell, and their followers, beginning in the 1720s, had already marked a turning away from the Baroque style of Wren's successors Vanbrugh and Nicholas Hawksmoor and the adoption of a simpler and more restrained style. As early as 1715 the new spirit was discernible in Campbell's introduction to the first volume of his *Vitruvius Britannicus*. Advocating the judgment "truly of the Merit of Things by the Strength of Reason," his heroes were Vitruvius, Palladio, and Inigo Jones; his villains, the architects of the Italian Baroque: "The Italians can no more now relish the Antique Simplicity." The works of Bernini and Carlo Fontana are "affected and licentious"; for Borromini, "who has endeavoured to debauch Mankind with his odd and chimerical beauties," he feels only disgust. By 1731 Burlington's Assembly Rooms at York, based on Palladio's reconstruction of an Egyptian hall, was fully Neoclassical. Similarly, William Kent's entrance hall at Holkham Hall, Norfolk, begun in 1734 and reminiscent of a Roman basilica, would not in a European context seem out of date 50 years later. Despite these early essays by Burlington and his circle, the next generation of English designers remained conservatively in the Palladian mold and showed little interest in the architecture of Greece and Rome.

By mid-century the atmosphere was beginning to change, and two events of 1758 marked the birth of English Neoclassical architecture: the erection of a Greek Doric garden temple in the grounds of Hagley Park, Worcestershire, by James ("Athenian") Stuart and the return to England of the 30-year-old Robert Adam.

Adam, the son of a leading Scottish Baroque architect, William Adam, arrived in London fresh from four years in Italy, his head full of Roman ruins and Renaissance arabesques, his style of drawing and composition bearing the telling marks of his friendship with Piranesi and the French draftsman Charles-Louis Clérissseau. Essential to the Adam style, that mode of decoration and planning that was to effect a revolution in English taste, was the

notion of freedom. Absorbing a variety of influences ranging from the Palladianism of the Burlington-Campbell school and the decorative elements and spirit of France to the archaeology of Italy, Greece, and Asia Minor, Adam re-created and recombined the elements of architecture in a way that was wholly new—and wholly Neoclassical. His executed works consisted mainly of the remodeling of existing houses, the most important of which were Osterley Park, Middlesex (1761–80); Syon House, Middlesex (1762–69); and Kenwood House, Hampstead, London (1767–69). At Kedleston Hall, Derbyshire (c. 1765–70), he completed James Paine's plan and added a garden front in which the central portion (centrepiece) is clearly derived from an ancient Roman triumphal arch, the first use of this form in domestic architecture. This use of antique forms in a new context is a recurring characteristic of Neoclassical architecture. Adam's planning, to which he devoted considerable attention, was based on a variety of contrasting room shapes, each geometric in itself and contained within an overall geometric plan yet creating a sense of movement, variety, and surprise. Such play with shapes and spaces was to characterize Neoclassical planning, particularly in France.

But the Adam revolution was over by 1780, and a new mood, one closer to that exemplified by Stuart's small Doric temple at Hagley, was taking its place. Now it was "noble simplicity" and "antique grandeur" that were sought after, and Horace Walpole, that weather vane of fashion, was writing how sick he was of "gingerbread" and "snippets of embroidery."

Of the next generation the leading architects were George Dance the Younger, Henry Holland, and James Wyatt. Dance's Newgate Prison, London (1769; demolished 1902), was among the most original English buildings of the century, a grim, rusticated complex combining the romantic drama of Piranesi with the discipline of Palladio and the Mannerist details of Giulio Romano in an imaginative paradigm of Neoclassicism. Holland was architect to the Prince of Wales and his most important work in this capacity was the extensive remodeling of Carlton House begun in 1783, a refined and elegant whole with a joint debt to Adam and to France and a simplicity that pleased Walpole. Wyatt, tremendously successful and busy, was equally at home in his own classical idiom, a stripped derivative of the Adam style, as in Gothic. There was no contradiction, for Wyatt's Gothic, like that of Adam before him, was classical in all but its details with cloisters substituted for arcades and battlements for balustrades.

By 1800 nearly all English architecture reflected the Neoclassical spirit. Sir John Soane, pupil of the younger Dance and architect to the Bank of England, developed a highly personal style characterized by a stripping down and linear abstraction of the classical elements, use of archaeological detailing such as the Greek key pattern, and the creation of dramatic interior space by toplighting. Totally original, his work invites comparison with the projects of Boullée and Ledoux in France.

After 1800 the interest in revival of Greek forms intensified and the stream of buildings based either wholly or in part on Greek models continued well into the 19th century. One of the earliest was William Wilkins' Downing College, Cambridge (1806–11), with details closely copied from the Erechtheum on the Acropolis at Athens. Following this were Sir Robert Smirke's Covent Garden Theatre (1809), London's first Greek Doric building; Wilkins' Grange Park, Hampshire (1809), a monumental attempt to cram an English country house into the form of a Greek temple; Smirke's vast Ionic British Museum (1824–47); and St. Pancras Church (1819–22) by William and Henry William Inwood, with a portico and two caryatid porches based on the Erechtheum and an octagonal tower based on the ancient Athenian Tower of the Winds. The design of Regent Street and Regent's Park (with its palatial terraces) by John Nash in the second decade of the 19th century exemplifies the kind of town planning associated with the mood of Neoclassicism, a combination of formal elements with the picturesque (Figure 82).

Both Ireland and Scotland produced significant Neoclassical buildings. In Dublin, James Gandon's Four Courts

A.F. Kersting

(1786–96), with its shallow saucer dome raised on a high columnar drum with echoes of Wren's St. Paul's Cathedral, and his Custom House (1781–91) owe joint allegiance to the Palladianism of Sir William Chambers and contemporary French Neoclassicism. Edinburgh, the "Athens of the North," experienced a particularly tenacious Greek Revival. Among its monuments are the Royal High School (begun 1825) by Thomas Hamilton and the Royal Institution (now the Royal Scottish Academy) by William Henry Playfair. David Hamilton built the Royal Exchange (now Stirling's Library), Glasgow (1829–30), in a style showing the Greek influence, and the revival in that city remained strong well into the 19th century, culminating in the work of Alexander ("Greek") Thomson, whose Caledonia Road Free Church (1856–57) is among the finest monuments of Neoclassical architecture in Scotland.

France. In France a reaction against the Rococo style began in the 1740s. Never very satisfactory for exterior architecture, the Rococo nevertheless had considerable appeal as a decorative program, reaching its height in the work of Meisssonier and Oppenordt. A dogmatic classicism in architecture had been a serious consideration in France as early as 1671 when Louis XIV's Royal Academy of Architecture was formed. The style, produced for Louis XIV, adopted the richness and grandeur of the Roman Baroque while modifying its more dramatic excesses by a rational application of *le bon goût* ("good taste"). A cornerstone of rationalism already had been laid in 1714 with the publication of the French theorist the Abbé de Cordemoy's *Nouveau traité de toute l'architecture* (1714; "New Treatise on All Architecture"). Reaction against the Rococo crystallized in the writings of Charles-Nicolas Cochin and in the lectures of the Comte de Caylus at the Royal Academy of Painting and Sculpture in 1747. Along with the return to nature and reason, the twisting curvilinear forms of the Rococo were seen to work against nature. The same desire for truth to nature accounted for the growing preference in France for the informal landscape gardens of the English.

The *Essai sur l'architecture* of Laugier provided a rational alternative to the Rococo and formed the theoretical basis for Neoclassicism in France and in the rest of Europe. Already by mid-century a new interest in archaeology, Rome, and antiquity had been established.

A significant architectural event marking a reaction against the Baroque was the design of a new facade for the important Paris church of Saint-Sulpice in 1733 by Giovanni Nicolò Servandoni, who manifested a new taste

for sobriety. His project for Saint-Sulpice represented a break with the Roman Baroque tradition of church facades deriving from Giacomo da Vignola's Gesù church, Rome (1568), and still being used in Paris at Saint-Roch (by Robert de Cotte) in 1735. Servandoni's design derived inspiration from Roman basilicas, from Perrault's Louvre colonnade, and from Wren's St. Paul's. In execution the design lost its central pediment and arches. Superimposed open colonnades were substituted and the two lateral towers were built to different designs, the north one being completed only in 1777 by Jean-François-Thérèse Chalgrin. Nevertheless, the new restraint and classicism that pervades Servandoni's facade was a portent of what was to come.

The work of Jacques-Angé Gabriel, director of the Academy of Architecture from 1735, is a successful compromise between the new rationalism of the 18th century and the French classical tradition of the 17th century. In 1757 he began the Place de la Concorde in Paris, with its twin palaces (Hôtel de Crillon and the Admiralty) that boast columnar facades inspired by Perrault's great east front of the Louvre (begun 1667). Despite his many major public works, Gabriel is probably best known for his enchanting Petit Trianon, built at Versailles in 1761–64 for Louis XV and Madame de Pompadour (Figure 83). Classically restrained and elegant, this subtle cubic composition achieves a timeless gravity that seems beyond the compass of stylistic terms such as Baroque or Neoclassical.

The leading Neoclassical architect was Jacques-Germain Soufflot, who was in Italy in the 1750s and was the first French architect to study the Greek ruins at Paestum. Soufflot's great building was the church of Sainte-Geneviève (now the Panthéon), Paris (1757–90), a domed cruciform edifice combining the new taste for antique grandeur and simplicity with a structural rationalism, the offspring of the marriage of a Roman temple and a Gothic cathedral. A crucial Neoclassical building that owes nothing to the Baroque, Soufflot's church nevertheless is not purely antique in character, as its dome is derived from Wren's St. Paul's and it has a Roman rather than a Greek temple front.

A second Parisian church already fully Neoclassical in feeling is Chalgrin's Saint-Philippe-du-Roule of 1768–84. Saint-Philippe, inspired by early Christian basilicas, is remarkably pure, with an Ionic colonnade separating nave from aisles. The nave terminates in a semicircular apse and is covered with a coffered Roman barrel vault. The exterior is a model of simplicity in the antique taste with

a Roman Doric portico framed against the cubic mass of the wall. Similar and of about the same date (1764–70) is Louis-François Trouard's church of Saint-Symphorien at Versailles, again basilical with a Roman Doric portico.

Boullée's
originality
of design

A most remarkable and original architect of the Revolutionary period was Étienne-Louis Boullée, whose work before 1780 was in the style of his contemporaries but who after that date produced a number of curious and revolutionary projects. Of his several Paris townhouses, or *hôtels*, the Hôtel de Monville of about 1770 and the Hôtel de Brunoy of 1772 deserve mention. The former has a central facade featuring giant Ionic pilasters divided by sculptured panels and the latter a giant Ionic colonnade flanked by arcaded wings forming the three-sided court (*cour d'honneur*). Boullée's project for a cenotaph to Sir Isaac Newton based on a pure spherical form (c. 1780) is an example of that formalistic aspect of Neoclassicism that sought pure geometry and simplicity.

Other Neoclassical architects of the pre-Revolutionary period were Marie-Joseph Peyre, whose *Livre d'architecture* of 1765 was influential in publicizing the type of work being produced by French students in Rome; Charles de Wailly, who was an important teacher and, with Peyre, was the architect of the Paris Odéon; Jacques Gondoin, architect of the School of Medicine (1769–76), which, with its Corinthian temple portico and Roman-inspired amphitheatre covered by a coffered half dome and lit from

a half oculus (a round opening in the top of a dome), was one of the most advanced interiors of its date anywhere; Jacques-Denis Antoine, winner of the competition for the new Mint (*Hôtel des Monnaies*); and Victor Louis, whose theatre at Bordeaux (1772–80) with its Roman colonnade and vaults set the model for Neoclassical theatres. All had studied in Rome.

The boldest innovator in the world of French Neoclassical architecture was Claude-Nicolas Ledoux. Like Boullée he designed a number of buildings between 1765 and 1780 in which he attempted to reconcile the traditional elements of French classicism with the new spirit of the antique. Among these were the Château de Benouville, Calvados (1768–75), and the Hôtel de Montmorency, Paris (c. 1770–72), both of which feature Ionic colonnades with straight entablatures and are somewhat English in feeling. More original were the Pavilion at Louveciennes of 1771 for Madame du Barry, which again invited comparison with contemporary English villas and with the Petit Trianon, and the Hôtel Guimard of 1772. The theatre at Besançon, with its cubic exterior and interior range of baseless columns stylistically derived from those at Paestum, dates from 1775–84.

But it is for later projects, such as the royal saltworks at Arc-et-Senans (1775–79), with their simplified forms, and the highly original series of *barrières* (tollgates) for Paris (1784–89), that ensure to Ledoux his central role in the evolution of Neoclassical and, indeed, of modern architecture. The Barrière de la Villette, consisting of a tall cylinder rising out of a low square block with porticoes of the style: megalomania, geometry, simplicity, antique detail, formalism, and stylophily (use of many columns). Even more influential were the unexecuted projects by Ledoux published in his *Architecture considérée sous le rapport de l'art, des mœurs et de la législation* ("Architecture Considered with Respect to Art, Customs, and Legislation") in 1804, which contains his ideal city of Chaux, a plan for a whole city with buildings in which symbolism and abstraction are carried to new heights (Figure 84).

The revolutionary Neoclassicism of Ledoux resulted in few monuments. It was the Paris of Napoleon that saw the erection of the most conspicuous examples of the style, intended to symbolize in stone the grandeur of the Emperor. The two architects associated with this transformation of Paris were Charles Percier and Pierre-François Fontaine, who were responsible for the extensive planning scheme at the beginning of the 19th century that included the rue de Castiglione, the rue and Place des Pyramides, and the rue de Rivoli. The Arc du Carrousel was built to their designs in 1806–08 and the grander Arc de Triomphe by Chalgrin and Jean-Armand Raymond in 1806–35 (Figure 85). Conspicuous in Napoleonic Paris was an imposing

Corinthian temple, the Church of the Madeleine, begun in 1806 by Pierre-Alexandre Vignon and completed in 1842 (Figure 86). Similar in scale and effect were the Paris Bourse (1808–15) by Alexandre-Théodore Brongniart and the Chamber of Deputies of 1806–51 by Bernard Poyet (now the National Assembly).

Italy. Italy was the centre from which Neoclassicism emanated in the sense that Neoclassicism would be unimaginable without Rome. The remains of antiquity on Italian soil, many of which were by the 18th century romantically overgrown and half buried, inspired all artists and architects. Yet Italian architects were followers rather than initiators of international Neoclassicism. One of the most important formative influences on the movement was Piranesi, whose etchings of Roman ruins transformed those antique fragments into sublime romantic compositions. Piranesi was in the forefront of Roman activity, and through his acquaintance with the foreign architects and patrons who visited the Italian capital he helped to crystallize the growing taste for Neoclassicism. Juvvarra's designs for a tomb for the King of France (1715?) served as a source for Piranesi in his design for the Piazza of the Knights of Malta in Rome (c. 1765). In the church of Santa Maria del Priorato, Piranesi incorporated classical references that were to greatly influence the succeeding generation of architects.

Lodoli's theories of functionalism

In the field of pure theory a Venetian, Carlo Lodoli, was an important early advocate of functionalism whose ideas are known through the writings of Francesco Algarotti, the *Saggio sopra l'architettura* (1753) and *Lettere sopra l'architettura* (beginning 1742). Lodoli's theories were similar to those of Laugier, requiring that every part of a building derive from necessity and that architecture be true to the nature of materials, and tolerating no useless ornament. The theories of Francesco Milizia contained in his *Principi d'architettura civile* of 1785 were similar.

The tradition of the Baroque was of course strong in Italy and lingered on throughout the 18th century in many parts of what was still an agglomeration of independent states. Early tendencies toward Neoclassicism appear in the late work of Luigi Vanvitelli; for example, the Castelluccio Reale (1774) in the park at Caserta, an octagonal structure with a round superstructure. Other barometers of the new taste were the Villa Albani, Rome (completed c. 1760), built by Carlo Marchionni to house a collection of ancient marbles formed by Cardinal Alessandro Albani; and the new Pio-Clementino Museum at the Vatican (1776–81), the work of Michelangelo Simonetti.

Palladian revival

Early in the 18th century Italy had experienced a fertile Palladian revival, and a number of buildings based on

the Pantheon model were built, among them Tommaso Temanza's church of Santa Maria Maddalena in Venice in 1748. Palladianism was a significant element in much Italian Neoclassical architecture.

Giacomo Quarenghi, who was to work in Russia for Catherine II, built the monastery of Santa Scolastica, Subiaco (1774–77), with a barrel-vaulted nave characteristic of the new taste. In 1787 the first baseless Greek Doric columns in Italy appeared in the Chiesetta di Piazza di Siena in the gardens of the Villa Borghese, Rome, designed by Mario Asprucci, 20 years after Stuart's temple at Hagley. Also Greek was the Gymnasium, in the Botanic Garden, Palermo (1789–92), built by Léon Dufourny, who had been a pupil of LeRoy and Peyre.

Neoclassical buildings after 1800 were more numerous, and a few examples illustrate the character and range of the movement. Peter von Nobile's Sant'Antonio, Trieste (1826–49); Luigi Cagnola's Rotunda, Ghisalba (1834); and Giovanni Antonio Selva's Canova Temple, Possagno (1819–33), all took the Pantheon as their starting point. Cagnola also built the Ionic Ticinese Gate, Milan (1801–14), and the Arch of Sempione, Milan (1806–38), a Roman triumphal arch similar to the contemporary Parisian Arc du Carrousel. Luigi Canina's Greek propylea, or gateway, at the entrance to the Villa Borghese (1827–29); Carlo Barabino's Doric Teatro Carlo Felice, Genoa (1826–28); and Giuseppe Japelli's meat market at Padua (1821) using the unfluted Paestum order, all exemplify the continuing taste for Greek forms. Japelli was also the architect of the Pedrocchi Café, Padua (1816–42), which, with its Doric and Gothic exteriors and equally eclectic interiors is a remarkable extravaganza.

The greatest achievement in urban planning of the period was the design of the Piazza del Popolo in Rome (1813–31) by Giuseppe Valadier, a great open space with three diagonal avenues leading off it.

Spain and Portugal. In Spain the leading Neoclassical architect was Juan de Villanueva, who studied in Rome and returned to Spain in 1705 with a style similar to that evolved by the leading contemporary French and English architects. His buildings include three villas; the Casita de Arriba (1773) and the Casita de Abajo (1773), both at El Escorial, and the Casita del Principe at El Prado (1784). His major building was the Prado, Madrid (1785–87). In Portugal the destruction of Lisbon by earthquake in 1755 necessitated rebuilding, most of which was carried out by military engineers. The Ajuda Palace (begun 1802) by the Italian Manuel Fabris is Neoclassical; and in Oporto, the Hospital of Santo Antonio with a vast Doric portico was designed by the English architect John Carr.

Germany. The Louis XVI style of mid-18th century France was taken to Germany by the many French architects who worked there, such as Philippe de La Guépière (Mon Repos, near Ludwigsburg, 1760–64, and La Solitude, Stuttgart, 1763–67). Many German patrons were also Anglophiles, including Prince Franz of Anhalt-Dessau, for whom the talented architect Friedrich Wilhelm von Erdmannsdorff created the schloss and park at Wörlitz, near Dessau (1766–90). Schloss Wörlitz was directly inspired by English Palladian country houses such as Claremont, Surrey; and Erdmannsdorff laid out the park with a range of exotic garden buildings around a lake, recalling contemporary English gardens such as Stourhead and Stowe. The association of such naturalistic gardens with ideals of political liberty is underlined by the presence at Wörlitz of the remarkable Rousseau Island, which was planted with poplars in 1782 in imitation of the island on which Rousseau was buried in the celebrated landscaped garden at Ermenonville in France.

King Frederick William II of Prussia (reigned 1786–97) decided to make Berlin a cultural centre dominated by German artists. Among the architects he called to Berlin were Carl Gotthard Langhans and David Gilly, who, with Heinrich Gentz, created a severe but inventive style in the 1790s that was indebted to Ledoux as well as to Winckelmann's call for a return to the spirit of ancient Greek architecture. The great early monument of the Berlin school was the Brandenburg Gate (1789–93) by Langhans. Distantly inspired by the propylaea on the Acropolis in Athens, it was the first of the ceremonial Doric gateways to rise in modern Europe. The Greek Revival in Germany was linked with the growth of Prussian nationalism and imbued with the supposed moral virtues of the Doric order. Key buildings in this stern geometric style include the Berlin Mint (1798), by Gentz, and the Vieweg House, Brunswick (1800–07), by David Gilly. Gilly also founded a school of architecture in Berlin, where both Karl Friedrich Schinkel and Leo von Klenze received formative training. The apogee of German Neoclassical architecture can be traced in the work of three brilliant designers: David Gilly's son, Friedrich, and the latter's disciples, Schinkel and Klenze.

Friedrich Gilly built little, dying in 1800, but left some remarkable designs that justify his central place in German Neoclassicism. His project for a monument to Frederick the Great (1797) consisted of a raised Greek Doric temple on a geometric substructure surrounded by obelisks and set in a vast open space (Figure 87). This caught the imagination of German architects as a symbol of Prussian nationhood during the humiliating occupation of Berlin by Napoleon in 1806–13. It was in those years that Gilly's pupil Schinkel was active as a designer of theatre sets and as a Romantic painter. Schinkel, who was named state

architect in 1815 by Frederick William III, transformed Berlin with a series of monuments in a rationalist Greek style, beginning with the New Royal Guardhouse (1816–18). His Schauspielhaus (theatre and concert hall) of 1818–26 is essentially a grid of trabeated elements framing glazed openings. The modern flavour of this construction, which, according to Schinkel, derived from the Choragic Monument of Thrasyllos in Athens, has contributed to Schinkel's popularity as an architect in the 20th century.

Schinkel's next major work in Berlin, the Old (Altes) Museum (1823–33), is important as an early example of a national museum built in order to educate the public. With its long but undemonstrative Ionic colonnade, it is comparable to Smirke's contemporary British Museum. Indeed, in 1826 Schinkel made an important tour of France and, more particularly, of Britain to collect information on the display of paintings. The detailed diary he kept on his tour shows that what interested him most was the architecture and technology of the Industrial Revolution in Britain. On his return to Berlin he designed a number of buildings in which he incorporated the new methods of fireproof construction he had seen in England. The most important of these was the School of Architecture (1831), with walls of red brick ornamented with glazed violet tiles, windows of unpainted terra-cotta, and internal construction of iron beams and brick cap vaults. For Schinkel, who was not a pure functionalist, the poetry of architecture was as important as it was for Soane in England. Thus the facades of the School of Architecture were ornamented with carved terra-cotta panels depicting the history and symbolism of architecture.

As part of his concern for poetry in architecture, Schinkel was also keenly aware of the need to relate buildings to their settings. He gave beautiful expression to this in the 1820s in a number of asymmetrical but classical villas—for example, Schloss Charlottenhof at Sanssouci, for Crown Prince Frederick William, and Schloss Glienicke, near Potsdam, for his younger brother, Prince Charles. Schinkel developed this theme on a more extravagant scale in two unexecuted palaces of the 1830s, one on the Acropolis in Athens for the King of Greece and one at Orianda on the Black Sea for the Empress of Russia. The coloured lithographs that he subsequently published of these gorgeous polychromatic dream-palaces are among the greatest products of the 19th-century Romantic imagination.

Klenze, who had studied in Paris with Durand and Percier and had visited Italy, developed Munich into a monumental souvenir of the Grand Tour for his patron, Ludwig I of Bavaria. The result was an extraordinarily successful transformation of a minor court city into a great cultural capital that was intended to be the Florence of the 19th century. Klenze laid out a wide new street, the Ludwigstrasse, which he lined with palaces and public

Figure 87: Project for a monument to Frederick the Great by Friedrich Gilly, 1797.

Dr. Franz Stödtner

buildings. The program was widely adopted in the expansion of European capitals, notably Vienna, later in the 19th century.

More eclectic than Schinkel, Klenze created a living museum of styles in Munich, including his noble Sculpture Gallery (Glyptothek, 1816–30), with its Greek Ionic portico; his Leuchtenberg Palace (1816), modeled on the Palazzo Farnese in Rome; and his Königsbau (1826–35) at the Residenz, which was an echo of the Pitti Palace in Florence. Klenze's Sculpture Gallery, commissioned by the future Ludwig I, has some claim to be regarded as the first public museum ever erected solely for the display of sculpture. With no examples to follow, Klenze produced a novel plan with galleries around the four sides of a square courtyard. In accordance with the desire of both patron and architect to make the building a total work of art, its interiors were decorated with (now destroyed) stuccowork and frescoes that were stylistically related to the exhibits they contained. This decoration mounted in richness from the first rooms, which contained Egyptian sculpture, to the final gallery, which exhibited Roman sculpture.

Scandinavia and Finland. Neoclassical taste was introduced into Denmark and Sweden between 1750 and 1790 by French designers such as Louis Le Lorrain, Nicolas-Henri Jardin, and Louis-Jean Desprez. In Denmark, Jardin's pupil Caspar Frederik Harsdorff built the austere royal mortuary chapel of Frederick V in Roskilde cathedral (1774–79), while in Sweden Desprez was responsible for the Botanical Institute, Uppsala (1791–1807), with a Greek Doric portico. The Danish architect Christian Frederik Hansen, a pupil of Harsdorff, turned the medieval and Baroque city of Copenhagen into a Neoclassical capital. He built the town hall, court house, and prison (1803–16) and the Church of Our Lady (1810–29), with its Boullée-inspired interior. Schinkel's example in Berlin was followed by Hansen's pupil Heinrich Grosch, who provided Christiania (Oslo), the new capital of Norway, with a series of Greek Revival public buildings. Perhaps the finest example of this classical urban planning is in Helsinki, established as capital of Finland in 1812. Beginning in 1818, Johan Ehrenström and Carl Engel created a monumental group of the Lutheran Cathedral flanked by the Senate, University, and University Library.

Poland. Stanisław II August Poniatowski, king of Poland from 1764 to 1795, brought the Louis XVI style of contemporary France to the Royal Castle in Warsaw in a series of interiors designed by Dominik Merlini and Jan Chrystian Kamsetzer in 1776–85. Merlini also designed the Łazienki Palace at Ujazdów near Warsaw (1775–93) for the King, while Szymon Bogumił Zug brought Neoclassicism to ecclesiastical architecture in his Lutheran Church, Warsaw (1777–81), modeled on the Pantheon. Zug also designed Arkadia (1777–98), one of the many Picturesque gardens in Poland. Laid out on the Radziwiłł family estate of Nieborów, the garden contains numerous romantic buildings. After 1815, Warsaw was rebuilt as a model Neoclassical city with major public buildings by Merlini's pupil Jakub Kubicki and the Italian architect Antonio Corazzi.

Russia. The leading role played by Russia in the production of early Neoclassical architecture was almost entirely due to Catherine II. Under her aegis St. Petersburg

was transformed into an unparalleled museum of Neoclassical buildings as advanced as contemporary French and English work. As in other countries, the new taste for antique simplicity represented a reaction against the excesses of the Rococo, which in Russia had its apotheosis in the work of Bartolomeo Francesco Rastrelli.

Two foreign architects played important roles: a Scotsman, Charles Cameron, whose most extensive work was at Tsarskoye Selo in the style invented by Robert Adam and who was responsible for introducing the first correct Greek Doric column and entablature in Russia in the circular Temple of Friendship at Pavlovsk (1780); and an Italian, Giacomo Quarenghi, who arrived in Russia in 1780 and built for Catherine the Palladian English Palace at Peterhof (1781–89).

The two leading Russian architects were Vasily Ivanovich

J. Allan Cash

Figure 88: Main gate to the Admiralty, St. Petersburg (now Leningrad), by Andreyan Dmitriyevich Zakharov, 1806–15.

Bazhenov and Ivan Yegorovich Starov, both of whom studied in Paris under de Wailly in the 1760s, bringing back to Russia the most advanced Neoclassical ideas. Bazhenov designed the new Arsenal in St. Petersburg (1765) and prepared unexecuted designs for the Kamenni Ostrov Palace (1765–75) and for a new Kremlin. Starov designed a country house for Prince Gagarin at Nikolskoye (1774–76), the new cathedral of the Trinity, St. Petersburg (1776), and the influential prototype of Russian country houses, the Tauride Palace (1783–88), for Grigory Potemkin, Catherine's lover. The Tauride Palace consisted of a central-domed and porticoed central block connected by narrow galleries to large wings.

Under Catherine's grandson, Alexander I (reigned 1801–25), the Russian version of the Empire style flourished. The great monument of this later period was the St. Petersburg Bourse (1804–16) by Thomas de Thomon, a vast peripteral (surrounded by a row of columns) edifice. Andrey Nikiforovich Voronikhin, also a pupil of de Wailly, was architect of the Kazan Cathedral, St. Petersburg (1801–11), and Andreyan Dmitriyevich Zakharov built the Admiralty (1806–15) in the same city (Figure 88).

United States. Neoclassical architecture thrived in the United States throughout the 19th century, and examples of it exist in nearly every major city. The analogy with imperial Rome and later (after the War of Greek Independence, 1821–32, in particular) with the grandeur and political ideals of Periclean Athens strengthened the case for the adoption of Roman and Greek architectural models in the United States. In 1785 Thomas Jefferson planned the Virginia State Capitol with the Frenchman Charles-Louis Clérissseau, taking as his model the ancient Roman Maison-Carrée at Nîmes. It was to be the first public building in the modern world directly based on an antique temple. Jefferson's own house at Monticello, in Virginia, featured a central-domed space and was indebted to ancient Roman villas as well as to Palladianism and to modern French and English domestic design (Figure 89). If Monticello echoed the private agrarian retreat of classical statesmen, as described in the writings of Cicero and the younger Pliny, the University of Virginia at Charlottesville (1817–26) was an example of Jefferson's effort to educate the public of the new United States. He conceived the campus as an academic village of extraordinary charm and novelty in which a central Pantheon-like rotunda, containing a library, stands at the head of a grassy open space flanked by two lines of small templelike pavilions, which are linked by colonnades.

In Boston, the Massachusetts State House, designed 1787–88 and built 1795–98 by Charles Bulfinch, derived from English Neoclassical models. By far the most gifted architect working in the United States in these years was

Benjamin Latrobe. Latrobe was born in England, where he was trained by the innovative architect Samuel Pepys Cockerell. He evidently became familiar with the radical work of Dance, Soane, and Ledoux and of engineers such as John Smeaton. In 1796 he went to the United States, where he worked as the first fully professional architect and eventually became known as the father of the American architectural profession. A characteristic early building is his Bank of Pennsylvania (1798–1800), in Philadelphia, which was then the largest American city and was, indeed, the U.S. capital from 1790 to 1800. The bank is a novel reinterpretation of ancient temple architecture, with a Greek Ionic portico at each end but no classical order on its long side walls. It was also fireproof, being the first American building to be vaulted in masonry throughout. The shallow top-lit saucer dome in the central banking hall recalls the work of Soane, as does Latrobe's Roman Catholic Cathedral at Baltimore (1805–18). Drawing on the Pantheon and on Soufflot's Sainte-Geneviève, the cathedral contains a dome resting on segmental arches perhaps inspired by Soane's interiors at the Bank of England. Latrobe's most poetic and inventive work is a series of interiors at the Capitol in Washington, D.C., which he executed in his capacity as surveyor of public works, a position to which Jefferson appointed him in 1803. The Supreme Court Chamber (1815–17), with its strange lobed vault resting on stunted Doric columns, suggests a search for a new architecture, as do the capitals of corn (maize) and tobacco leaves that he invented for use in other parts of the building. Jefferson responded warmly to Latrobe's attempt to symbolize in architecture the values of the newly founded republic. (S.Mi./D.J.Wa.)

Spanish America and Brazil. In the Caribbean, Neoclassical influences are evident in the Post Office of 1770–92 and the Government House of 1776–92 in Havana, Cuba, both attributed to the architects Pedro de Medina of Cadiz and Fernández Trevejos of Havana.

From about 1780 Neoclassicism began to replace the ornamental Churrigueresque style in Mexico. The leading Neoclassical architects were the Spaniard Manuel Tolsá and two Creoles, Eduardo Tresguerras and José Damián Ortiz de Castro. Among the most distinguished Mexican examples of Neoclassicism are the School of Mines (1797–1813) in Mexico City by Tolsá and the church of El Carmen at Celaya (1803–07) by Tresguerras. Many of the Mexican missions in California were designed with Neoclassical features.

Neoclassical architecture was built throughout South America, but especially in Brazil, Argentina, Uruguay, and Chile, where initially many of the most important Neoclassicists were French: Prosper Catelin in Buenos Aires, Auguste-Henri-Victor Grandjean de Montigny in Rio de

Janeiro, and François Brunet de Baines in Santiago. The Palace of the Mint (1788–99) in Santiago, one of the finest Neoclassical buildings in South America, was conceived, not by an architect designing in the French tradition, but by an Italian, Joaquín Toesca, who had worked in Madrid with Francisco Sabatini, an Italian whose architecture was stylistically transitional between the Baroque and Neoclassicism. (Ed.)

Gothic revival, c. 1730–c. 1930

ORIGINS AND DEVELOPMENT

The architectural movement most commonly associated with Romanticism is the Gothic Revival, a term first used in England in the mid-19th century to describe buildings being erected in the style of the Middle Ages and later expanded to embrace the entire Neo-Gothic movement. The date of its beginning is not easy to pinpoint, for, even when there was no particular liking for Gothic, conservatism and local building practices had conditioned its use as the style for churches and collegiate buildings. In its earliest phase, therefore, Gothic Revival is not easily distinguished from Gothic survival.

The first clearly self-conscious imitation of Gothic architecture for reasons of nostalgia appeared in England in the early 18th century. Buildings erected at that time in the Gothic manner were for the most part frivolous and decorative garden ornaments, actually more Rococo than Gothic in spirit. But, with the rebuilding beginning in 1747 of the country house Strawberry Hill by the English writer Horace Walpole, a new and significant aspect of the revived style was given convincing form; and, by the beginning of the 19th century, picturesque planning and grouping provided the basis for experimentation in architecture. Gothic was especially suited to this aim. Scores of houses with battlements and turrets in the style of a castle were built in England during the last years of the 18th century.

Archaeological
revivalism

With developing archaeological interest, a new and more earnest turn was given to the movement—a turn that coincided with the religious revivals of the early 19th century and that manifested itself in a spate of church building in the Gothic style. Only toward the middle of the century were the seriousness and moral purpose that underlay this movement formulated as a doctrine and presented to architects as a challenge to the intellect. Augustus Charles Pugin, in England, was the first to codify the principles of the Gothic Revival. Far more persuasive and influential exponents, however, were Eugène-Emmanuel Viollet-le-Duc in France and John Ruskin in England, who gave to the movement a moral and intellectual purpose. The second half of the 19th century saw the active and highly productive period of the Gothic Revival. By then, the mere imitation of Gothic forms and details was its least important aspect; architects were intent on creating original works based on the principles underlying Gothic architecture and deeply infused with its spirit.

Another contribution that the Gothic Revival made to

architecture was the encouragement of freedom and honesty of structural arrangement. Structural elements could be provided as and where they were needed. There was no need for dissimulation. French architects, in particular Viollet-le-Duc, who restored a range of buildings from the Sainte-Chapelle and Notre-Dame in Paris to the whole town of Carcassonne, were the first to appreciate the applicability of the Gothic skeleton structure, with its light infilling, to a modern age, and the analogy was not lost on subsequent architects at a time when the steel frame was emerging as an important element of structural engineering. Functionalism and structural honesty as ideals in the Modern movement were a legacy of the Gothic Revival.

Not surprisingly, the Gothic Revival was felt with most force in those countries in which Gothic architecture itself was most in evidence—England, France, and Germany. Each conceived it as a national style, and each gave to it a strong and characteristic twist of its own.

NATIONAL AND REGIONAL VARIATIONS

Great Britain. A Gothic Revival was in a sense initiated early in England during the late 16th century under the influence of Elizabethan and Jacobean notions of chivalry and again between 1620 and 1630 under the impetus of William Laud's Anglicanism; but it is in the Gothic experimentalism of the late 17th century, particularly that of Wren's circle, in which seeds of a Gothic Revival can be discerned. Although buildings erected at these times imitated Gothic forms, none of them were revivalist in spirit. The Gothic Revival was largely conditioned by literary theory and practice. Although it had antecedents, the so-called "revolution of taste" in the mid-18th century was most clearly marked by publication of Richard Hurd's *Letters on Chivalry and Romance* (1762) and Thomas Percy's *Reliques of Ancient English Poetry* (1765). Thomas Gray, especially in his poems of the 1750s and, later, in his letters, was the first major poet to seek inspiration in a "Gothic" past—not only medieval but Celtic and Icelandic. Thomas Warton, poet and critic, acquired his interest in the Middle Ages from architecture and, in his work on medieval English cathedrals and churches, connected the literary aspect of the Gothic Revival with the work that was begun by a group of antiquaries in the late 17th century and that was continued into the 18th.

The transition from a survival to a revival phase of Gothic architecture took place almost imperceptibly. Curiously enough, it was Vanbrugh, England's great exponent of the Baroque spirit, who made the first successful attempt to evoke sensations of the medieval past. In 1717 he built a house for himself at Greenwich, near London, that was intended to conjure up a "castle air." It is a simple, robust, brick building that relies for its effect on slender proportion rather than detail. But it is an isolated work of its kind.

Only toward the end of the 18th century did "picturesque" take on a precise meaning, affecting the planning and the forms of English architecture, but, from the late 17th century onward, isolated gardens and estates were

laid out to take advantage of the irregularity of landscape, resulting in compositions that approximated those in the paintings of such 17th- and 18th-century artists as Claude Lorrain, Salvator Rosa, and Gaspard Poussin—hence, the denomination of the style as Picturesque. It was William Kent, in response to the literary ideal of “naturalness” of such writers as Sir William Temple, Joseph Addison, and Alexander Pope, who was first acclaimed for fashioning the Picturesque landscape that was to be made famous in the 18th century by Lancelot (“Capability”) Brown and who introduced occasional buildings into it, often in a Gothic style, to serve as a focus of interest. There were, however, other precursors, notably Vanbrugh and Charles Bridgeman.

Kent first used the fanciful Rococo Gothick that was to become characteristic of the 18th century in 1732, on a gateway in the Clock Tower at Hampton Court. He also reconstructed the Tudor buildings of Esher Lodge between 1729 and 1733, introducing ogee arches and quatrefoil openings. These he used again in the late 1730s in the Temple of the Mill at Rousham, Oxfordshire, where he laid out one of the first irregular gardens. The ornamental character of the Gothic Revival was thus established from the start, and it was popularized as such within a few years by Batty Langley, author of *Gothic Architecture Improved by Rules and Proportions* (1742). Pretensions to archaeological accuracy appear in two churches built in 1753 by Henry Keene—that at Shobdon, Herefordshire, and a charming, though now derelict, octagonal church at Hartwell, Buckinghamshire. An ardent admirer of Gothic, Keene had begun Gothicizing Arbury Hall, Warwickshire, as early as 1748. It was to the amateurs Sanderson Miller and Horace Walpole, however, that the credit for a full-scale domestic Gothic Revival was due.

Miller, a Warwickshire squire, began about 1744 by inserting pointed arches in the south front of his Tudor house at Radway, Warwickshire. Later, he put up a garden ornament in the form of a mock Gothic castle at nearby Edgehill, the idea of which became fashionable and made a reputation for him as a designer of Gothic extravaganzas. His most significant work was Lacock Abbey, Wiltshire, the symmetrical, flattened facade of which is thinly decorated with Gothic motifs. Walpole's Gothic, though apparently as lighthearted, was more serious in intent. When, in 1747, he decided to rebuild his house, Strawberry Hill, Twickenham, Middlesex (Figure 90), he proposed to reflect faithfully in its architecture his tastes for topography, history, and heraldry. He formed a “committee on taste” to advise him on the design. Among the members were the amateur archaeologists Richard Bentley and John Chute, both of whom provided designs. The architect responsible for the execution of most of the work was William Robinson. During the early phase of building, alterations and interior decorations were made in a pretty, decorative style, with a freedom unhampered by any serious archaeological study. Nor was there any real feeling for medieval composition in the massing of the elements. But in 1761, when a vast circular tower was added to the southwest corner of the house, Walpole gave evidence of a deliberate attempt to achieve an asymmetrical, picturesque composition. The west of the house was more freely grouped. Finally, in 1776, James Essex, probably the most earnest Gothickist of the period, inserted the Beauclerc Tower between the west end and the round tower, making the whole the first and most determined example of a large-scale Picturesque composition.

The fortuitous appearance and the deliberate irregularity of Strawberry Hill were exploited in many late 18th-century buildings. The most extravagant and sensational of all Gothic Revival buildings was Fonthill Abbey (1796–1806), Wiltshire, designed by James Wyatt primarily as a landscape feature for the arch-Romantic William Beckford (Figure 91). The great central tower collapsed in 1807, and most of the building has today disappeared; but, in John Rutter's *Delineations of Fonthill* (1823), it is still possible to perceive something of the grotesquely spectacular quality that made this building, for a short time, notorious.

Although many classical architects, including Sir William Chambers and Robert Adam, applied Gothic details to

J.R. Freeman & Co. Ltd.

the exterior of their country houses (and Adam was even employed at Strawberry Hill), they displayed no great interest in the style and always retained strict symmetry of composition. George Dance used it more thoughtfully and originally in his occasional Gothic buildings—the facade of the Guildhall (1789), London; Cole Orton Hall (1804–08), Leicestershire; Ashburnham Place (1813–17), Sussex; and the churches of St. Bartholomew-the-Less (1789), London, and Micheldever (1808), Hampshire.

Walpole's innovation assumed real significance only toward the end of the century, after the theory of the Picturesque was evolved and publicized by Richard Payne Knight and Uvedale Price. Already Knight had given architectural form to his ideas of rugged, irregular, and apparently “natural” composition in Downton Castle, Herefordshire, near Ludlow (1774–78). This was the first irregularly planned castellated (castle-style) building with a classical interior. It inspired a vast range of such buildings. John Nash is the best known and most proficient exponent of the style. Starting with his own house, East Cowes Castle, on the Isle of Wight, in about 1798, he exploited the deliberate irregularity of plan and silhouette afforded by the castellated style; from Caerhays (1808), Cornwall, in the south, to Ravensworth Castle (1808), Durham, in the north, Nash dotted England (and also Ireland) with Picturesque castles, houses, and ornamental cottages all of vaguely Gothic or Italianate inspiration.

Sir John Soane attempted the Gothic style on at least three occasions—at Port Eliot (1804–06), Cornwall, at Ramsey Abbey (1804–06), Huntingdonshire, and for the library at Stowe (1805–07), Buckinghamshire—but, like his master Dance, strongly influenced by the French Neoclassical theorists Cerdemoy and Laugier, he attempted to distill the effects of Gothic rather than to imitate the style. His suspended arches and his clustered ribs rising sheer from the floor and continuing around the vault are, ultimately, of Gothic inspiration.

The great change that occurred at the beginning of the 19th century, when the Gothic Revival moved from a phase of sentimental and picturesque attraction to one of greater archaeological exactitude, was determined largely by the research and publications of antiquarians. In the *Itinerarium Curiosum* of 1725 William Stukeley first introduced plans, in addition to topographical views, of Gothic buildings; but it was not until 1753, with the publication of Francis Price's *Salisbury*, that sectional drawings were included. Knowledge was but slowly accumulated, and active, enterprising scholars appeared only toward the end of the 18th century. Foremost of these was John Carter, author of *The Ancient Architecture of England* (1795 and 1807), in which Gothic details were more faithfully and ac-

curately recorded than in any earlier publication. Thomas Rickman designated the various styles of medieval architecture in *An Attempt to Discriminate the Styles of English Architecture* (1817), and the French refugee Augustus Charles Pugin, who was first employed by Nash, produced a series of meticulously measured details in *Specimens of Gothic Architecture* (1821–23). The great popularizer of Gothic archaeology was John Britton, who diffused a knowledge of the medieval buildings of Great Britain with two series of books, *The Architectural Antiquities of Great Britain* (1807–26) and *The History and Antiquities of the Cathedral (Churches of England)* (1814–35).

For many years architecture, however, lagged far behind scholarship. Buildings continued to be put up in an effete, decorative, and unconvincing Gothic style. Dozens of castellated houses were built during the first decades of the century. The first successes of Smirke—Lowther Castle (1806–11), Westmorland, and Eastnor Castle (c. 1810–15), Herefordshire—were in this style. The most spectacular was Windsor Castle, by James Wyatt's nephew, Sir Jeffry Wyattville, who began the remodeling in 1824. Gothic was also employed in collegiate work. William Wilkins built the screen and hall at King's College, Cambridge, between 1824 and 1827, and Rickman and Henry Hutchinson added New Court to St. John's College, Cambridge, between 1827 and 1831. But Gothic was to be most widely used—and even exploited—for church architecture, not because it was thought more appropriate than classical architecture but because it was cheaper.

The Church Building Act of 1818, providing for the expenditure of £1,000,000 on churches, emphasized once more Gothic as the ecclesiastical style. It was the discovery by the commissioners responsible for the spending of this money (together with an additional £500,000 voted in 1824) that a Gothic church cost less to build than a Neoclassical one with its requisite stone portico that determined the widespread utilization of the Gothic style. The first significant church to which the commissioners contributed, St. Luke's (1820–24), Chelsea, London, by James Savage, was splendidly vaulted in Bath stone, but meanness as well as meagreness progressively controlled the design of their churches. Of the 612 churches built for the commissioners, more than 550 were Gothic or some related style.

Gothic was established as a national style when, in 1836, the commissioners for the rebuilding of the Palace of Westminster (Houses of Parliament) accepted a Gothic design by Sir Charles Barry. This was to be the first public building of any consequence in the style. Barry had already experimented with Gothic in no less than nine churches—the best known being St. Peter's (1824–26), Brighton—and had built King Edward's Grammar School (1833–37) in Birmingham in the Gothic style. His great and elaborate Palace of Westminster, however, is not a convincing essay in Gothic composition. The plan is formal, the facade to the river altogether symmetrical, and the detail repetitive. But it derives a Picturesque effect from the placing and proportioning of its two towers, St. Stephen's (Big Ben), halfway along the north face, and the squatter Victoria tower, in the west facade. In England the Palace of Westminster was not imitated—though in Budapest it was formally commemorated in Imre Steindl's Parliament House (1883–1902). Work at Westminster was completed slowly and was finished only after Barry's death. By then the Gothic Revival had been put on an altogether different footing, paradoxically, by the man who was responsible for all the Gothic details of both the King Edward's Grammar School and the Palace of Westminster, Augustus Welby Northmore Pugin, son of the author of *Specimens of Gothic Architecture*.

A Roman Catholic convert, the younger Pugin was intent to show that Gothic was an expression of the Catholic spirit and thus the only form of architecture properly suited to its ritual. In his book *Contrasts* (1836) he also sought to show that architecture reflects the state of the society by which it is built: The society of the Middle Ages was good; therefore, Gothic architecture was good. In *The True Principles of Pointed or Christian Architecture* (1841) he first laid down firm principles for the Victorian Gothic

Revival. Architecture, he held, should be honest in its expression. Every feature of a building should be essential to its proper functioning and construction, and every feature of this construction should be frankly expressed. Architecture was to be judged by the highest standards of morality. Such concepts are a part of Pugin's French heritage; they were commonplace in 18th-century France, but Pugin's ideals came as a revelation to British architects and gave to the Gothic Revival a wholly new seriousness of purpose.

Most of the buildings in which Pugin attempted to give form to his ideas were built between 1837 and 1844. His first church of any consequence was St. Mary's (1837–39), Derby; his most influential were St. Wilfrid's (1839–42), Hulme, Manchester, and St. Oswald's (1840–42), Old Swan, Liverpool. But all three—like most of his other buildings and even his own favourite, St. Augustine's (1845–51), built near his house at Ramsgate, Kent—though solid and broadly proportioned and far more convincingly imbued with the Gothic spirit than earlier buildings, are not successful as works of architecture. Pugin was too much concerned with the minutiae of medieval detail. When incomplete in their detail and furnishing, his churches are grim; fully and expensively finished, as at St. Giles's (1841–46), Cheadle, Cheshire, they appear overexquisite.

Pugin's doctrines were taken up by the Anglican reformers, the Tractarians of Oxford and the Camdenians of Cambridge. The Ecclesiological Society, into which the Camden Society was transformed in 1845, so successfully aroused the liturgical enthusiasm of the clergy that most architects employed by the established Church of England in the years that followed were subject to the most doctrinaire of disciplines. Numerous architects were castigated by the critics of the *Ecclesiologist*, though Richard Cromwell Carpenter—who in 1838 had applied Neo-Tudor details to Lonsdale Square in Islington, London—was consistently upheld for the “correctness” of his work, as were those far more original and competent architects William Butterfield and John Loughborough Pearson. Pearson's masterpiece was St. Augustine's (1870–80), Kilburn Park Road, London.

Butterfield is remembered today chiefly for the polychromy of his collegiate work at Keble College (1866–86), Oxford, and Rugby School (1868–86), but he was responsible for a range of simple, though no less rigorous and emphatic, country parsonages and churches in Yorkshire, culminating in the group at Baldersby St. James (1855–61), and those bold, ruthless, and highly idiosyncratic churches, St. Matthias' (1849–58), Stoke Newington, London; St. Alban's (1859–63), off Holborn, also in London; St. Augustine's (1864–66), Penarth, near Cardiff, and All Saints' (1865–74), Babbacombe, Devon. Butterfield brought a new vigour to the Gothic Revival. The building that first gave evidence of his power and originality was All Saints', Margaret Street, London, designed in 1849 and largely completed by 1852 (Figure 92). This church was sponsored by the Ecclesiological Society. But it is not its liturgical correctness that makes it so important in the history of the Gothic Revival. From the pavement to the top of the tower, the church was built in bands of black and red brickwork, setting a fashion for "structural polychromy." Internally, marbles and tiles were used to cover all surfaces, giving them a rich coloration. Butterfield became famous for his polychromy.

This taste for polychromatic decoration was initiated, encouraged, and sustained by the greatest apologist of the Gothic Revival, the critic John Ruskin. In 1849 he published *The Seven Lamps of Architecture* in time to influence Butterfield at All Saints', Margaret Street. Ruskin's *Stones of Venice* appeared between 1851 and 1853; and within a few years architects throughout England were adapting the details and colour combinations of Italian, especially Venetian Gothic, architecture for myriad clients who had been enraptured by Ruskin's mellifluous descriptions and high-sounding sanctions for a Gothic Revival. Like Pugin and the Camdenians, he judged Gothic to be a style with a firm moral basis.

By the middle of the 1850s, Gothic had become the established mode for church architecture in Great Britain, but it was also considered appropriate to many other types

of architecture. In the prodigiously productive decades that followed, the style was applied by a host of industrious and competent architects to many buildings that had no medieval precedents. The most active practitioners of Gothic were Sir George Gilbert Scott and George Edmund Street. Both were busy restorers of medieval cathedrals and churches, but they found time to build a great number of new buildings in the Gothic style. Scott designed no less than 800. His first success was the Martyrs' Memorial (1841) in Oxford; others included the Albert Memorial (1862–72), Hyde Park, London; Glasgow University (1866–71); and the vast and picturesque Midland Hotel (1867–74) at St. Pancras Station, London (Figure 93, left). He firmly established the supremacy of England as arbiter in the Gothic Revival by winning a competition in 1844 for the Church of St. Nicholas (1844–63), Hamburg. Street, who was trained by Scott, designed about 260 original buildings, starting with a number of small churches and schools in Cornwall, an outcrop of churches in Oxfordshire, Buckinghamshire, and Berkshire, and another in Yorkshire. His churches vary in style, from the elaborate, decorative polychromy of St. James-the-Less (1858–61), Thorndike Street, London, through the more forcefully detailed style of St. Philip and St. James's (1860–62), Oxford, to the bare barn of St. George's (1861), Oakengates, Shropshire. His most famous and probably his noblest work was a secular building, the Law Courts, London, competed for in 1866 but not begun until 1874 and completed only after his death in 1882 (Figure 93, right). His influence was exerted through both his architecture and his famous publication *Brick and Marble in the Middle Ages* (1855).

The other great secular work of the Gothic Revival, Manchester Town Hall, was won in competition in the same year as the Law Courts, 1866, and begun in 1869. The designer was Alfred Waterhouse, an architect almost as active as Street but one who was responsible for very few churches. Waterhouse demonstrated conclusively that, because of its flexibility, Gothic was not only suit-

able but was virtually the only revival style applicable to the design of the large and complex buildings required by Victorian administration and institutions. A master planner, he first achieved fame as a result of a competition for the Manchester Assize Court (1859–64); then followed the ingenious Town Hall (1869–77) and later Owens College (1870–98), also in Manchester. For Oxford he designed Balliol College (1867–69); for Cambridge, the Union (1865–67), Gonville and Caius Colleges, started in 1870, and buildings at Pembroke College (1871–72). His vast London buildings include the Natural History Museum (1873–81), the Prudential Assurance building (1879, 1899–1903), and University College Hospital (1897–1906).

Though Scott, Street, and Waterhouse dominated the mature phase of the Gothic Revival, they were not always responsible for the most interesting and experimental work of the period. William Burges (1827–81) designed St. Finbar's Church of Ireland Cathedral in Cork (1863–76) in a curious 12th-century French style. In 1865, at Cardiff Castle in Wales, he began to interpret medieval architecture with merry and decorative freedom. The interiors of this building and of Castell Coch, built 10 years later, are a riot of decoration. His friend Edward William Godwin, on the other hand, was more restrained; he built two small, neat town halls in the Gothic style, one at Northampton (1861–64), the other at Congleton (1864–67), Cheshire. Other notable Gothicists were George F. Bodley, who often employed the artist William Morris and his associates, including the painters Ford Madox Brown and Sir Edward Burne-Jones, to decorate his churches; and Philip Webb, who had himself been a pupil with Morris in the office of Street and was to build for Morris the Red House (1859–60) at Bexleyheath near London. Little in this building is overtly Gothic—rather, it is intended to evoke the solidity and sound craftsmanship of medieval architecture, an ideal he had adopted from a greatly neglected architect, William White, and one that was to be taken up later by Richard Norman Shaw.

20th-century British Gothic

The Gothic Revival survived into the 20th century, though largely for ecclesiastical architecture. Truro Cathedral, Cornwall, was built in 1880–1910 from designs by J.L. Pearson. After his death in 1897, it was completed by his son, Frank Loughborough Pearson, as was his last work, Brisbane Cathedral, Australia, the construction of which did not begin until 1901. Similarly, Sir Giles Gilbert Scott, the grandson of Sir George Gilbert Scott, maintained the family tradition by designing a cathedral for Liverpool in 1903 in a Gothic style; this magnificent building was completed in 1978. Stephen Dykes-Bower made extensive additions in a late Gothic style to Bury St. Edmunds cathedral (1960–70).

Scott, Butterfield, and Carpenter all supplied designs for churches in the British Commonwealth, but their designs were often modified and slowly executed: Butterfield's Anglican cathedral, St. Paul's, in Melbourne, Australia, although designed in 1847 and begun in 1850, was not finished until 1934. The direct influence of the English leaders on colonial Gothic was thus small, and numerous churches built in the British dominions during the second half of the 19th century were mostly in a meagre, uninspired Gothic mode.

France. In France a taste for medieval legend survived into the 16th century in aristocratic circles and was nurtured not only by the literary works of the Italian Renaissance poets Ludovico Ariosto and Torquato Tasso but also by books on heraldry and blazonry by humanist scholars. More remarkable as evidence of conscious, widespread, and continuing popular interest in the Middle Ages—and especially in Gothic building—were topographical studies and guidebooks published from the middle of the 16th century onward. The Gothic tradition of building continued, especially in ecclesiastical circles, far into the 18th century. But it was largely survival rather than revival. French admirers of Gothic architecture regarded it primarily as a challenge to the intellect. The architects Delorme in the 16th century and Derand in the 17th analyzed the construction of the Gothic vault. They were quick to appreciate it as a highly efficient and economical framework of columns and ribs, supporting the webs of the vaults

(which they regarded as no more than infilling panels carrying no thrust) and counterbalanced by buttresses and flying buttresses—as something, indeed, of a structural scaffold. It was this structural elegance that early 18th-century enthusiasts of Gothic, such as Cordemoy, sought to infuse into contemporary architecture. In the *Nouveau Traité de toute l'architecture* (1706) Cordemoy proposed that a new, honest, and economical architecture might be arrived at by abstracting the principles of Gothic construction and applying them in a perfectly regular classical way. There was no question of reviving the Gothic style; interest in Gothic was to be altogether transmuted into classical terms. The building of the church of Sainte-Geneviève (now known as the Panthéon) in Paris, designed in a style confirming the Neoclassical ideal but on principles derived from Gothic architecture, gave a new impetus to the study of Gothic construction. French architects were imbued with a rational appreciation of Gothic that was without parallel.

Although there was a native French vogue in the 18th century for the medieval literature of the troubadours, it was the intrusion of English ideas that prompted more authentic representations of the medieval world in stage settings and history paintings after 1772. Certainly, the Gothic taste in architecture was conditioned by the introduction of the informal landscape garden. By 1781 there were a number of English gardens in France with mock-Gothic pavilions, and, during the last two decades of the century, many more were built. But the frivolous, light-hearted “Gothick” of 18th-century England never took hold in France; the French made virtually no attempt to imitate, let alone rival, the splendours of Strawberry Hill and Fonthill Abbey.

To the Revolutionaries at the end of the 18th century, Gothic architecture seemed a symbol of the vested power of the aristocracy and the church, and many buildings were wantonly destroyed. Yet, popular interest in the picturesque charms of Gothic architecture was sustained and even intensified by such men as Alexandre Lenoir, who in 1795 turned the largest of the Paris depots for plundered works of art, the Petits-Augustins (now the École des Beaux-Arts), into the Museum of French Monuments. Here, by clever juxtaposition and subtle lighting, the Middle Ages seemed to be endowed with an aura of magic. By suggesting a relationship between a chivalric past and the actual forms of Gothic sculpture and architecture, Lenoir coloured the imagination of a whole generation of Romantics. The great Romantic writer François-René, vicomte de Chateaubriand, was fascinated by Lenoir's collection. Indeed, a celebrated chapter on Gothic architecture in Chateaubriand's *Le Génie du christianisme* (1802; “The Genius of Christianity”), in which Gothic is not only taken as the symbol for the old French Catholic spirit but also is traced beyond, through the forests of Gaul, to nature itself, was directly inspired by Lenoir's work. Inevitably, a Romantic Gothic image was popularized in the years that followed; Romantic playwrights, novelists, and painters were seduced by the charms of Gothic. Even antiquarians succumbed to the Romantic myth, and from 1810 onward a spate of popular guidebooks and studies of Gothic architecture was published.

In spite of a few Gothic-inspired fantasies and an archaeological interest in medieval architecture that found expression in the Neo-Romanesque church of Saint-Paul (1835) at Nîmes by Charles-Auguste Questel, architecture remained a virtually impregnable stronghold until after 1840, when a hard core of Gothic Revivalists began to emerge. This was composed of consistent medievalists who were stirred primarily by archaeological pretensions. Stimulated by the activity of English scholars in Normandy, they patiently studied the medieval remains of that region and slowly forged the science of French Gothic archaeology. An equally important aspect of the Gothic Revival was inaugurated by the great Romantic author Victor Hugo, when he published in 1831 *Notre-Dame de Paris*, the explicit purpose of which was the glorification of Gothic as a national and Catholic style of architecture. But it was the Protestant statesman François Guizot who first gave real impetus to those ideas promoted by Hugo.

Gothic as a symbol of the old French Catholic spirit

In 1830 he inaugurated the organization that seven years later became the Commission on Historical Monuments.

All the serious, acceptable architects of the Gothic Revival were amateur archaeologists, and they acknowledged an archaeological standard of taste. They designed from the first in the 13th-century style, and nearly all had restored at least one Gothic building before they undertook to build anything new. The patronage of the Commission on Historical Monuments and later of the Diocesan Buildings Service (formed in 1848), for which thousands of medieval buildings were restored and enlarged, was thus of enormous importance in furthering the aims and the technical skill of the Gothic Revivalists. The men who sustained the Gothic Revival were almost all taught by the commission's leading architects, Jean-Baptiste Lassus and Viollet-le-Duc. Lassus trained Viollet-le-Duc first on the restorations in Paris of Saint-Germain-l'Auxerrois (1838) and the Sainte-Chapelle (1842). In 1844 they were both appointed to restore Notre-Dame de Paris and to build a new sacristy in the Gothic style; this was regarded as an official sanction for the Gothic Revival. But, although a picturesque revival of Gothic had already been initiated in the provinces, official sanction for a full-scale revival was not easily accorded. The members of the French Academy, faithful to Neoclassical ideals, were firmly against it.

In 1844 the north tower of the abbey church of Saint-Denis, begun under Suger in 1135, was found to be in danger of collapse. All Gothic Revivalists were aghast. Adolphe-Napoléon Didron, editor of the *Annales archéologiques* and propagandist for the Gothic Revival, tactlessly accused the Council of Civil Buildings, which was charged with the approval of all building plans in France, of irresponsibility. Its members, mainly academicians, retaliated by arbitrarily stopping the construction of three churches in the Gothic style that Didron had acclaimed in his journal. Didron then launched a counteroffensive; he demanded a public inquiry into the restoration of Saint-Denis. Under threat of this inquiry, which was powerfully supported by the prefect of the Seine district, Barthélot Rambuteau, the council was forced to approve the plans for Sainte-Clotilde in Paris by Franz Christian Gau, plans that they had held up for more than four years. It became a cause célèbre. A furious pamphlet war followed, from which the Gothic Revivalists emerged triumphant, and in 1852 Didron estimated that 200 neo-Gothic churches had been built or were in the process of construction. But the victory was short-lived. Sainte-Clotilde, as completed by Gau and his successor Théodore Ballu in 1857, was an anomalous expression of revivalist ideals. Didron disliked it intensely, and the dispute caused many admirers of Gothic architecture to reflect seriously on the merits of a Gothic Revival.

Lassus went on to build Saint-Nicolas (1848) at Moulins, Saint-Pierre at Dijon (1852), and Saint-Jean-Baptiste-de-Belleville (1854) in Paris. Viollet-le-Duc constructed Saint-Gimer (1853–57) at Carcassonne, the church of Nouvelle Aude (1855) and Saint-Denys-de l'Estrée (1860–67) at Saint-Denis; he restored the Château de Pierrefonds (1858–70) to a state of colourful medieval splendour for Louis-Napoleon; and, in his *Dictionnaire raisonné de l'architecture française* (1854–68; "Analytical Dictionary of French Architecture") and the *Dictionnaire raisonné du mobilier française* (1858–75; "Analytical Dictionary of French Furniture"), together running into 16 volumes, he provided the vital visual and intellectual inspiration required to sustain the Gothic movement. But he was by no means a convinced revivalist. All but one of his secular works are in an uneasy Renaissance mode. He determined to think his way beyond the Romantic attractions of the Gothic style. Pursuing the inquiries of 18th-century theorists, he envisaged an architecture of the 19th century that would be based on the rational system of construction and composition that he recognized to be embodied in Gothic but would in no way imitate its forms and details. Architecture, he thought, should be the clear expression in 19th-century materials of 19th-century structural and functional needs. He was unable to accept the challenge of his own ideas. Both he and his disciples—Paul Abadie, Émile Boeswillwald, Eugène-Louis Millet, Maurice Ouradou, Anatole

de Baudot, Édouard Corroyer, Félix Narjoux, and Édmond Duthoit—continued to design buildings (primarily churches) in a weak Gothic style. There were many less thoughtful and determined men who put up imitations of Gothic architecture in the late 19th century, but the Gothic Revival was never a full-blooded affair. Some of the finest buildings designed after the medieval manner—Saint-Pierre-de-Montrouge (1864–72) in Paris, by Joseph-Auguste-Émile Vaudremer, is one—were isolated works by architects who worked outside the orbit of the Gothic Revivalists and who had no qualms about the intellectual honesty of their chosen mode of expression.

Germany and central Europe. As in France, German interest in medieval legend, history, art, and architecture was sustained throughout the Renaissance both by the general public and by scholars and antiquarians. Interest was focused, in particular, on the cathedrals of Strasbourg and Cologne, buildings that were to assume an almost symbolic significance in the history of the Gothic Revival on the Continent. In his *Rerum Germanicarum Epitome* (1505; "Epitome of Things German") the humanist Jakob Wimpfeling extolled Strasbourg cathedral as the rarest and most excellent of buildings, and Oseas Schadaeus' guide to the cathedral, *Summum Argentoratensium Templum* (1617; "Strasbourg's Finest Church") was the first illustrated guidebook ever devoted to a single medieval building and, in spite of its Latin title, was written in German. Other 17th- and early 18th-century histories and guides—and there were many—give ample evidence of a respectful appreciation of Gothic, despite the jibes of fashionable leaders. Appreciation of Gothic was a traditional and emotional affair, far removed from the studied and analytical interest of the French. Not surprisingly, English Gothic sentiments permeated Germany with the mid-18th-century taste for things English. *Conjectures on Original Composition* (1759) by the English poet Edward Young enjoyed a vogue in Germany that it never aspired to in England. English attitudes and ideas provided the German Gothic Revival with its peculiarly impassioned character.

The Sturm und Drang ("Storm and Stress") conception of the late 18th century invested Gothic with extraordinary and unparalleled qualities; it seemed to such philosophers as Johann Gottfried von Herder (and, under his inspiration, to the genius and writer Goethe) to be of the most sublime and exalted inspiration—an expression at once of all nature, all things divine and infinite. Goethe's paean to the cathedral at Strasbourg—and to its builder Erwin von Steinbach—was a 16-page pamphlet, *Von deutscher Baukunst* (1772; "On German Architecture"), that was an inspiration to all future revivalists. Goethe epitomized Gothic as the expression of the German spirit. Gothic became a German architecture, and it was to remain such in the estimate of all Germans, even German scholars, for 50 years and more. Goethe's passion for Gothic was not long sustained, but his enthusiasm was shared by other contemporaries, notably, the author and statesman Friedrich von Schlegel, who saw Gothic not only as an expression of the German spirit but specifically of a German Catholic spirit. This belief he shared with the brothers Sulpiz and Melchior Boisserée, by whom he was largely inspired.

Sulpiz Boisserée was the most active and enthusiastic of early Gothic Revivalists. His great preoccupation was the cathedral of Cologne, which he measured minutely, starting in 1808 but continuing up to the publication of *Ansichten, Risse und einzelne Theile des Doms von Köln* ("Elevations, Sections, and Details of the Cathedral of Cologne"), issued between 1823 and 1831, and an accompanying text, *Geschichte und Beschreibung des Doms von Köln* ("History and Description of the Cathedral of Cologne"), of 1823. The purpose of this study was the restoration and completion of the unfinished cathedral. He enlisted the moral support even of Goethe and the financial support of King Frederick William III, who in 1824 ordered the preservation of the building. This work of conservation was carried out by Friedrich Ahlert, under the guidance of Schinkel, and after his death by the most gifted of Schinkel's pupils, Ernst Friedrich Zwirner. The task of completion was started in 1842, at the command of King Frederick William IV, and was carried through

after Zwirner's death by Richard Voigtel, who finished the work only in 1880. The building of the Cologne cathedral was an expression of German nationalism and marked the beginning of the Gothic Revival proper in Germany.

Earlier expressions of the Gothic Revival in architecture were of a Rococo or Picturesque nature and were much influenced by contemporary fashions in England. Between 1725 and 1728, Joseph Effner, gardener to the elector Maximilian II Emanuel of Bavaria, built the Gothic-inspired Magdalene Chapel on the grounds of the Nymphenburg Palace in Munich. In 1755 Frederick II the Great of Prussia himself designed the Nauener Gate in Potsdam, and in 1768 Prince Franz of Anhalt-Dessau laid out his park in the Picturesque manner and scattered it, in the years that followed, with Gothic hermitages and ruins. Other 18th-century German gardens were similarly embellished: the New Garden in Potsdam, laid out in the 1780s for Frederick William II by Langhans, or the more spectacular ruined Ritterburg (1793–98), in the park of the landgrave William IX of Hesse at Wilhelmshöhe. There were even odd or idiosyncratic interpretations of Gothic—the tower of Mainz cathedral (1767–74) by Franz Ignaz Neumann or the Laugier-inspired remodeling of the St. Nikolai Church in Leipzig (1784–97) by Johann Friedrich Carl Dauthe. In the latter church, the Gothic ribs of the vault were transformed into palm fronds.

The first architect of any distinction to take an active interest in Gothic was Karl Friedrich Schinkel. He was inspired by Friedrich Gilly's engravings of the castle of Marienburg in East Prussia (1799) to paint, between 1810 and 1815, a number of visionary studies of Gothic buildings in the manner of the German Romantic painter Caspar David Friedrich. He also designed several stage sets in the Gothic style. Schinkel's first serious architectural composition was a Gothic mausoleum designed in 1810 for Queen Louisa of Prussia. He did other equally Romantic designs in Gothic, the most spectacular being that for a cathedral in the Leipzig Square, Berlin. But none of his ambitious Gothic projects was executed; those that were built are of little consequence.

Other prominent Neoclassicists who experimented with Gothic were Friedrich von Gärtner, designer of the Ludwigskirche (1829–44) in Munich, and Gottfried Semper, who provided the plans for the Cholera Fountain in Dresden (1843). But their handling of Gothic forms was stiff and awkward, as was that of most German architects of the period, whose works were adulterated and unconvincing essays into the style.

Gothic
Revival
architecture
in
Vienna

The first significant church of the Gothic Revival was the Votive Church (1856–79) in Vienna by Heinrich von Ferstel (Figure 94). Indeed, Vienna was the centre of the most active and intriguing adaptations of Gothic. Friedrich Schmidt, who had worked under Zwirner at Cologne, was the leading revivalist. He built no less than eight churches in Vienna, ranging in date from the Church of the Lazarists (1860–62) to St. Severinus Church (1877–78). The most ambitious is the Fünfhaus parish church (1868–75) outside Vienna. He was the architect also of the Akademische Gymnasium on Beethoven Square (1863–66) and the town hall (1872–83).

Along the Rhine, several great castles were restored and dramatized with spiky Gothic trimmings. In Dresden there was a minor outburst of revivalism, but these works cannot be said to have contributed much to the course of architectural history. The Gothic Revival in Germany was not a concerted movement, and there is no specific term in German to describe it. One of the rare buildings that may be considered as characteristic of a specifically German revival and exuberantly Gothic is the Munich Town Hall (1867–74, enlarged 1899–1909), by Georg Joseph von Hauberisser.

The Low Countries. The Gothic style continued strong in the Low Countries throughout the 16th, 17th, and 18th centuries, inflecting the revived classical architecture to so great an extent that it retained a peculiar, hybrid quality. But no significant contribution was made to the Gothic movement until the Dutch architect Petrus Josephus Hubertus Cuypers, an ardent and painstaking interpreter of the ideas of Viollet-le-Duc, began work. The career of

Cuypers was, indeed, parallel to that of Viollet-le-Duc; he restored numerous Gothic churches and built many new ones in that style, mainly of brick, the Vondel Church of 1870 and the Church of Mary Magdalene of 1887, both in Amsterdam, being the most impressive. For his great secular buildings in that city, the Rijksmuseum (1876–85) and the Central Station (1881–89), he chose a Gothic that passes rather into the Renaissance style.

In Belgium the work of Cuypers finds its counterpart in that of Jozef Schadde, architect of the Antwerp stock exchange (1858–80) and the station in Brugge.

Scandinavia. The emergence of National Romanticism in the 1880s gave rise to buildings such as Martin Nyrop's Copenhagen Town Hall (1892–1902), which combined Northern Renaissance features with a crenellated Gothic skyline. Its fine craftsmanship and delicate eclecticism were echoed in the celebrated Town Hall at Stockholm, designed in 1908 by Ragnar Östberg and executed in 1911–23. In Finland, Lars Sonck worked in a powerful Arts and Crafts Gothic style reminiscent of the work of H.H. Richardson in the United States: for example, his Tampere Cathedral (1902–07) and Telephone Exchange, Helsinki (1905).

Italy. The Gothic Revival never really took hold in Italy. The Pedrocchi Café (1837), with its Venetian Gothic wing erected in Padua by Giuseppe Japelli, and Pelagio Palagi's pavilion La Margheria (1834–39), at Racconigi, are isolated examples. The revival was confined in the main to the completion of church facades, starting with that of the cathedral in Milan (1806–13) by Carlo Amati and Giuseppe Zanoia. It included Giorgio Morandi's fanciful addition to the front of the cathedral at Biella (c. 1825) and the facades of Santa Croce (1857–63) in Florence, by Niccolò Matas; the cathedral of Florence (1867–87) by Emilio de Fabris; and the cathedral of Naples (1876–1907) by Enrico Alvino, Niccolò Breglia, and Giuseppe Pisanti.

Spain and Portugal. There was virtually nothing in the way of revived Gothic architecture in Spain before the

middle of the 19th century, when Juan Martorell and a group of his disciples in Catalonia took up the idea of evolving a national style based on medieval precedent. The source of their inspiration was the work of Viollet-le-Duc. But it was not until Antoni Gaudí i Cornet, the most idiosyncratic of all Catalan architects, started designing in the 1870s that anything of more than marginal interest was built. His first independent work, the house of Don Manuel Vicens in Barcelona (1878–80), was, however, Mudéjar rather than Gothic in style, as were such later works as the Episcopal Palace at Astorga (1887–93) and the College of Santa Teresa de Jesús (1889–94) in Barcelona. His Gothic sympathies were evident in the crypt of the church of the Holy Family in Barcelona, which he completed from 1884 to 1887, to the design of his master Francesc de Paula del Villar i Carmona. Gaudí also restored the Gothic cathedral of Palma, on the island of Mallorca, between 1901 and 1914. The Gothic element is implicit rather than overt, however, in most of his intensely personal mature works.

United States. The Gothic Revival in the United States was inevitably a stylistic import; it was not the outcome of deeply felt original sentiments of either a Romantic or moral nature. At first, it was regarded only as a facet of architectural historicism. Architects later adopted the aspirations and ideals of Pugin, the Camdenians, and even of Viollet-le-Duc and attempted to use the Gothic style in conformity with the principles that they had laid down; but few were consistent (the Episcopalians alone adhered to the doctrines of the Ecclesiologists), and fewer still had sufficient first-hand knowledge of the style to interpret it with any conviction.

Early
examples
of Gothic
design in
the United
States

Drawings exist for Gothic garden pavilions for Monticello, Thomas Jefferson's plantation near Charlottesville, Va.; but the first recorded building in the Gothic style was Sedgeley, a mansion erected outside Philadelphia in 1798 to the design of Benjamin Latrobe. The thin, etiolated Gothic of this house was repeated in other of his designs—an unexecuted project for Baltimore cathedral (1805); the Bank of Philadelphia (1807–08); Christ Church (1808), Washington, D.C.; and St. Paul's at Alexandria, Va. (1817)—but he was essentially a Neoclassical architect. The same could be said of other early practitioners of Gothic—William Strickland, who built the Masonic Hall (1809–11) and St. Stephen's (1822–23), both in Philadelphia, and Charles Bulfinch, architect of the Federal Street Church, Boston (1809).

The first Gothic Revival church of any consequence, St. Mary's Seminary in Baltimore (1807), was designed by a Frenchman, Maximilien Godefroy. Others were built in the early decades of the 19th century—e.g., St. Luke's at Rochester, N.Y. (1824–26)—but not before the 1830s was a series of churches put up in and around Boston that gives evidence of a consistent Gothic Revival movement—Solomon Willard's Bowdoin Street Church (1830) and the First Methodist Episcopal Church in Temple Street, both in Boston, and St. Peter's (1833) and the First Unitarian Church (1936–37) in Salem, Mass., are examples. Most of these churches are constructed of granite and consequently are plain and simple in detail. In sharp contrast are the light timber churches with intricate and fanciful Gothic details put up at the same period, in particular St. Peter's at Waterford, Pa. (1831), by Bishop John Hopkins, author of an *Essay on Gothic Architecture* (1836).

The second
phase of
the U.S.
Gothic
Revival

The active, enterprising architect of the next phase of the Gothic Revival was Richard Upjohn. In 1835 he built a somewhat thin and vitiated Gothic mansion, Oaklands, at Gardiner, Maine. He achieved fame, however, as a builder of churches. St. John's (1836), Bangor, Maine, was his first Gothic church; but it was Trinity Church (1839–46) at New York City, in a flat, harsh Gothic style, that established his reputation (Figure 95). This was built for the Episcopalians and was rigidly "correct" in the ecclesiological sense. During the next 30 years he designed no fewer than 40 Gothic churches, mostly for the Episcopalians. Externally, they appear as brittle, uninspired adaptations of English models, but in his internal work and especially in such buildings as the First Parish Church (1845–46), Brunswick, Maine, he showed himself to be an extraordi-

Wayne Andrews

nary and unparalleled manipulator of timber arcing and trussing. Equally important as exemplars of intrinsically American interpretations of the Gothic Revival theme are his churches built entirely of timber—wooden framed and sheathed with vertical boarding and battening—such as St. Paul's at Brunswick, Maine, of 1845, or St. Thomas', Hamilton, N.Y., of 1847.

The timber tradition (or "carpenter's Gothic") was in no way limited to ecclesiastical work. Upjohn's *Rural Architecture* (1852) applied the same method of design to the construction of timber houses and cottages. Decorated with details deriving from Gothic sources, this domestic architecture was, in sheer quantity, the chief expression of the Gothic Revival during the middle years of the century. Powerful support for the movement came also from Andrew Jackson Downing, landscape gardener and architectural critic, who was a close friend of the architect Alexander Jackson Davis. In 1845 Davis designed the first plantation mansion in the Gothic style (Belmead, Powhatan County, Va.) and, more significantly, Ericstan (1855), the John J. Herrick house in Tarrytown, N.Y., which introduced castellated Gothic into the Hudson River Valley, and did Gothic cottage designs like the home of William H. Drake at Hartford, Conn. (Figure 96). Downing leaned heavily on the theorists of the English Picturesque style—his major work, *A Treatise on the Theory and Practice of Landscape Gardening Adapted to North America* (1841), is, indeed, a paraphrase of their arguments—but, in his pattern books *Cottage Residences* (1842) and *The Architecture of Country Houses* (1850), he provided an inherently American variant on the "stick style," with its use of board-and-batten finish to imitate half-timbering, that was soon diffused widely as the "bracketed cottage style."

About 1860 the Gothic movement entered a new and de-

Influence
of Ruskin
in the
United
States

terminedly serious phase. James Renwick (1818–95), who in 1848 had designed the Smithsonian Institution in Washington, D.C., in a Neo-Norman style, used continental models again in 1859 when building St. Patrick's Roman Catholic Cathedral in New York City. Most architects of the period, however, sought inspiration from England and acclaimed the writings of Ruskin. The first building to give expression to his teachings was perhaps the Alumni Hall, Union College, Schenectady, N.Y., designed in 1858 and completed in 1875, by Edward T. Potter, a pupil of Upjohn. The banded and pointed arches of this building at once suggest the influence of Ruskin. More successful—and controversial—as an exponent of the Ruskinian aesthetic was Peter B. Wight, architect of the National Academy of Design, New York City (1863–65). There the Venetian Gothic mode came into its own. Wight and Potter—and, later, Potter's brother William Appleton—were responsible for a number of collegiate and public buildings in this harsh, polychrome Gothic style, but it was William Robert Ware and his partner Henry Van Brunt who were to become its most fashionable exponents. In 1859 Ware built St. John's Chapel at the Episcopal Theological Seminary on Brattle Street in Cambridge, Mass.; six years later he and his partner started the First Church (Unitarian) in Boston, and in 1870 they began Memorial Hall at Harvard, a conspicuous, if not altogether polished, exemplar of the style. Other purveyors of "collegiate Gothic" were Richard Morris Hunt, architect of the Yale Divinity School (1869), and Russell Sturgis, a partner of Wight, who designed several of the halls at Yale University between 1869 and 1885.

John H. Sturgis and Charles Brigham, architects of the Museum of Fine Arts on Copley Square (1876) and the Church of the Advent (1878), both in Boston, attempted to give to this tough, uneasy Gothic style something of monumental grandeur in their competition design of 1872 for the Connecticut State Capitol Building in Hartford. Their design was reminiscent of that submitted by William

Burges in 1866 for the Royal Courts of Justice in London. The competition, however, was won by Richard M. Upjohn, son of the church builder, who provided a Gothic project that was equally grandiose if more equivocal in expression. Within a few years Hartford was to possess an authentic Burges building, Trinity College. Only a small part of Burges' magnificent design of 1873 was, however, executed.

The most original architects to emerge from the late Gothic Revival movement were Frank Furness, known for his vigorous handling of Gothic motifs on the Pennsylvania Academy of Fine Arts (1872–76) and a series of banks in Philadelphia—the most extraordinary of which was the Provident Institution on Chestnut Street (1879)—and Henry Hobson Richardson, who used characteristics of the Gothic and Romanesque as a point of departure for the creation of a distinctive and altogether personal style. Richardson started his Gothic career with the Unity Church (1866–69), Springfield, Mass. During the following years he developed a robust, broadly proportioned style in a series of churches—Grace Episcopal Church, West Medford, Mass. (1867–68); Brattle Square Church, Boston (1870–72); and the North Congregational Church, Springfield, Mass. (1872–73)—culminating in Trinity Church on Copley Square, Boston (c. 1872–77). Overt Gothic influence is evident in most of Richardson's early works, but later the Gothic style was to be superseded by the introduction of Romanesque paradigms, to which he gave so strong an imprint of his own distinct sense of style that they are rarely disquieting.

In the 20th century the most ardent exponents of Gothic were Ralph Adams Cram and his partners, Bertram G. Goodhue and Frank W. Ferguson, who regarded it as particularly suitable for educational establishments. The Graduate College (1913) and University Chapel (1929) at Princeton University are among their finest achievements. Other powerful Gothic buildings include their Cadet Chapel, United States Military Academy, West

Point, N.Y. (1910), and James Gamble Rogers' Memorial Quadrangle and Harkness Tower, Yale University, New Haven, Conn. (1916–33). Goodhue's most arresting building is his State Capitol, Lincoln, Neb. (1921–32), with a soaring tower that has a Gothic flavour though its design is fundamentally abstract. Gothic elements are also responsible for the medieval-tower aspect of many of the early skyscrapers, the most notable example being Cass Gilbert's Woolworth Building, New York City (1910–13), which has a steel frame clad in fireproof, lightweight terracotta, richly carved with Gothic detail and dramatically illuminated at night. (R.D.Mi./D.J.Wa.)

Classicism, 1830–1930

CONTINUING DEVELOPMENT

Until recently conventional histories of architecture treated the 19th century as an unfortunate period in which historicist architects needlessly obstructed the path to a new functionalist architecture based on technology and engineering. The importance of the 20th century, according to this view, consisted in the establishment of the Modern movement as the final victory of functionalism—in which buildings are designed so as to avoid all historical reference and are even constructed of “new” materials.

Today, however, a new interpretation has arisen, for two reasons: first, the growth of serious study of the historical architecture of the 19th century led to its reappraisal as an independent architectural movement of high quality; second, the arrival of postmodernism in the 1970s led to a realization that the Modern movement was not a permanent plateau to which the whole of the 19th and 20th centuries had been leading but was simply another historical period. With the withdrawal of the privileged status that had been for so long granted to the Modern movement, it became possible to take a broader look at the period from 1830 to 1930. From the conventional histories, for example, one would scarcely be aware that most buildings erected up to the 1930s were designed in a range of classical and traditional styles.

NATIONAL AND REGIONAL VARIATIONS

École des
Beaux-Arts

France. The École des Beaux-Arts (School of Fine Arts) in Paris was the most important centre of architectural education in the Western world in the 19th century. Founded in 1819 as the successor to the Royal Academy of Architecture, the École drew students not only from France but also from throughout Europe and, after 1850, from North America. At the École, architecture was seen as a public service involving the representation in stone of national and civic dignity, and teaching thus centred on the problems of designing monumental public buildings in the classical style. Jacques-Ignace Hittorff was typical of those architects who combined the practice of modern classicism with archaeological investigation into Greek and Roman architecture. His Gare du Nord, Paris (1861–65), showed brilliantly how a language ultimately inspired by the triumphal arches of ancient Rome could lend an appropriate monumental emphasis to a major metropolitan railway terminus. In Saint-Vincent-de-Paul, Paris (1830–46), a church with a giant portico leading to an aisled basilican interior, Hittorff incorporated polychromatic decoration inspired by his discoveries that Greek temples had been systematically painted in strong colours. His publications on this subject between 1827 and 1851 were important because the gaudy and essentially ephemeral character of polychromatic decoration was incompatible with the image of timeless purity with which Greek art had been invested by Winckelmann.

Henri Labrousse, a more inventive architect than Hittorff, pursued similar research into Greek architecture with the ambition of making it seem human rather than divine or unapproachable; for example, he argued that what is now known as the Temple of Hera I at Paestum was not a temple but a civil assembly hall. His drawings showing the building in use, with transitory adornments such as trophies, inscriptions, paintings, and even graffiti, shocked the members of the Academy of Fine Arts to whom he submitted them in 1828. Ten years later he

had the opportunity of designing a great public building in which he could express his ideals of modernized classicism. This was the Library of Sainte-Geneviève, Paris, designed in 1838–39 and built from 1843 to 1850; it is one of the masterpieces of 19th-century architecture. The austere arcuated (arched) facade, owing something to Alberti's Malatesta Temple at Rimini, is adorned with the carved names of more than 800 of the most important authors whose books are housed within: an extraordinary modern parallel to the graffiti with which he had boldly adorned the walls of the basilica at Paestum. The columns and arches supporting the huge barrel-vaulted ceiling of the main reading room are constructed of cast iron, elegantly ornamented—an early use of this material in a major public building.

Louis Duc's Palace of Justice, Paris (1857–68), articulated with a powerful Doric order, is a major expression of Beaux-Arts ideals, but it is Charles Garnier's Paris Opera House (1862–75) that is widely regarded as the climax of 19th-century French classicism. The ingenious planning and spatial complexity of the Opera owe much to Beaux-Arts methods of organization, but the scale is new, as is the lavish provision of circulation space, including the grand staircase and numerous richly decorated galleries, foyers, and corridors (Figure 97). Garnier planned this spectacular setting so that visitors would begin their theatrical experience the moment they entered the building. The Opera fits into the web of new streets or boulevards built for Emperor Napoleon III by Baron Haussmann in 1854–70. These broad avenues of apartment blocks and shops, frequently contrived in Baroque fashion to create vistas converging on major public buildings, set a pattern that was widely followed in the expansion and modernization of European capital cities.

Haussmann's
boulevards

The classical language of Hittorff and Duc was echoed throughout the 19th century by French architects such as Jean-Louis Pascal (Faculty of Medicine and Pharmacy, Bordeaux; 1880–88) and Henri-Paul Nénot (New Sorbonne, Paris; 1885–1901), both of whom were influential teachers at the École des Beaux-Arts. A high point was reached with the Paris Exposition of 1889, for which Henri Deglane and Victor Laloux erected, respectively, the Grand Palais and the Gare d'Orsay (renovated as the Orsay Museum, 1979–86). These monumental buildings are in a frothy Baroque style, though they incorporate much glass and iron. Reaction to this exuberance was expressed in the work of Auguste Perret, who attempted to apply the newly developed technique of reinforced-concrete construction to buildings designed in a trabeated (post-and-lintel) style that was ultimately classical: for example, his Theatre of the Champs-Élysées, Paris (1911–12), and the much drier Museum of Public Works, Paris (1936), now the headquarters of the Economic and Social Council. At the International Exposition of 1937, or Paris World's Fair, pavilions in a range of styles were dominated by the Chaillot Palace, built from designs by Jacques Carlu, Louis-Hippolyte Boileau, and Léon Azéma. This is a striking example of the austere trabeated classicism that was the most popular style for public buildings in the 1930s in many parts of the United States and Europe, including the Soviet Union. It is often known as stripped classicism because features such as columns and pilasters were reduced to a grid and deprived of their customary mouldings.

Great Britain. Britain in 1830 was still in the middle of a building boom that had begun at the end of the Napoleonic Wars in 1815. Towns were expanded with buildings in the international Greek Revival manner such as William Wilkins' Yorkshire Museum, York (1827–30). The architect Charles Robert Cockerell, despite being a distinguished classical archaeologist, regarded this rigid Greek formula as stylistically restricting. He felt that he belonged to a continuing classical tradition that linked Ictinus with Borromini. In his masterpiece, the Ashmolean Museum and Taylorian Institution, Oxford (1841–45), he produced a type of Grecian mannerism in which elements from Greek, Roman, Renaissance, and Baroque architecture were united in a rich sculptural weave of powerful originality. He was also important for bringing the same high quality of design and materials to the field of com-

English
domestic
architec-
ture

mercial architecture, as in his Bank of England, Liverpool (1844–47).

Despite the high regard in which the allusive classical buildings of this learned and sensitive architect were held, the immediate future for British architecture did not lie with Cockerell. The Gothic Revival attracted the most thoughtful minds and the most gifted architects between about 1840 and 1870. From the 1870s, however, Richard Norman Shaw and William Eden Nesfield led a move away from the Gothic Revival, with its strongly ecclesiastical flavour, to the more domestic charms of the so-called Queen Anne Revival. In prominent buildings such as his red-brick mansion for Frederick White at No. 170, Queen's Gate, London (1888–90), and Parr's (now National Westminster) Bank, Liverpool (1898–1901), Shaw demonstrated the virtues of the simple astylar (columnless) classical tradition of English 17th- and 18th-century architecture.

Among the many who were profoundly influenced by the brilliance and diversity of Shaw in the field of domestic and commercial architecture, none was more important than Sir Edwin Lutyens. In early houses such as Deanery Garden, Sonning, Berkshire (1901), he adopted local vernacular styles but was nonetheless able to display his characteristic geometric massing on the exteriors and his love of complex spatial flow in the interiors. These qualities make such houses an interesting parallel to the domestic work of Lutyens' contemporary Frank Lloyd Wright. The same play with volume and space governs the design of Lutyens' masterpieces such as Viceroy's House (now the Presidential Palace), New Delhi (1912–30), and the Memorial to the Missing of the Somme, Thiepval, Fr. (1928–30), in which he reduced the language of the classical orders to an almost abstract synthesis.

Italy. The Neoclassical town planning of the years around 1815 was succeeded in Italy, as elsewhere in Europe, by a Renaissance Revival of which an ambitious example is the Palace of Justice, Rome (1888–1910), by Guglielmo Calderini. This revival was appropriate in a country that was home to the Renaissance. It thus blended well with the growth of Italian nationalism, of which the most conspicuous architectural expression is Giuseppe Sacconi's Monument to Victor Emmanuel II, Rome (1885–1911). This amazingly confident, if generally unloved, recreation of imperial Roman grandeur commemorates the king under whom Italian unity had been achieved in 1861.

Italy's ancient Roman past was recalled once more in the 1920s and '30s as a consequence of Mussolini's attempt to legitimate his political regime. In Rome during the 1930s Marcello Piacentini and Vittorio Ballio Mopurgo created, respectively, the Via della Conciliazione and the Piazza Augusto Imperiale. Though monumental in scale, these were in a dull and simplified classical style and involved the destruction of substantial parts of the historic centre of the city. More attractive were the new towns, such as Littoria (now Latina) and Aprilia, created south of Rome in 1932–39, whose architects drew on the recent archaeological discoveries at the ancient Roman town of Ostia.

Germany and Austria. Schinkel set the pattern for the transformation of 18th-century royal cities into modern urban centres with numerous Neoclassical public buildings built in Berlin between 1815 and 1835. His many successors in Berlin included Friedrich Stüler and Johann Strack, who designed the National Gallery (1865–69), but architects such as Paul Wallot adopted an increasingly turgid neo-Renaissance manner, as in the Reichstag Building (1884–94). In the mid-19th century Munich was transformed for King Ludwig I of Bavaria by Leo von Klenze and Friedrich von Gärtner into a major cultural capital. Their twin models were Periclean Athens and Renaissance Florence, the former providing the inspiration for Klenze's Greek Doric Ruhmeshalle (1843–54) and Propylaeon (1846–60) and the latter for Gärtner's Bavarian State Library (1832–43). The most poetic product of a Winckelmannesque identification of the spirit of modern Germany with that of ancient Greece was the Walhalla above the Danube River near Regensburg. This great Greek temple was built in 1830–42 for Ludwig I from designs by Klenze as a monument to pan-German unity.

Vienna was also transformed from 1858 by the construction of the Ringstrasse, a great boulevard on the site of the old city walls. In the 1870s and '80s it was lined with monumental public buildings in a variety of styles thought historically appropriate for their functions: the Danish architect Theophilus Hansen's neo-Greek Parliament House, Gottfried Semper's and Karl von Hasenauer's neo-Baroque Burgtheater, and Friedrich von Schmidt's neo-Gothic Town Hall.

About 1900 the search for a more indigenous German classicism encouraged Alfred Messel in Berlin to study the austere Neoclassicism of Gentz and Gilly of a century earlier, hence the Greek Revival flavour of Messel's offices for the AEG (formerly the Allgemeine Elektrizitäts-Gesellschaft) and his National Bank, both built in Berlin in 1905–07. Messel was succeeded as architect to the AEG by Peter Behrens, who worked in many styles, of which the most influential was the neo-Schinklesque stripped classicism of his German Embassy in St. Petersburg (1911–12). This style was popular between the world wars when it was regarded as so essentially Germanic that it was adopted for the design of key monuments of the Third Reich, such as Paul Ludwig Troost's House of German Art, Munich (1933–37), and Albert Speer's New Chancellery, Berlin (1938–39).

Scandinavia and Greece. The key building in the development of Scandinavian classicism in the period 1830–1930 is the Thorvaldsen Museum in Copenhagen, erected in 1839–48 from designs by Michael Gottlieb Bindesbøll. It was built to house the collection of sculpture that the celebrated Danish Neoclassical sculptor Bertel Thorvaldsen presented to his native country in 1837. The opportunity was taken of providing a major cultural monument to strengthen national consciousness at a time of political crisis and to symbolize the new constitutional democracy that was established in 1849. The exterior walls of Bindesbøll's grave Schinklesque courtyard were enlivened with polychromatic decoration and painted with appropriate narrative scenes. This system of ornament was inspired by his knowledge of the recent archaeological discoveries in Greece and Sicily. He had visited Athens in 1835–36, and it was in this city, appropriately, that the Greek Revival was given perhaps its most fitting civic expression: Hans Christian Hansen, a friend of Bindesbøll, excavated and restored the ancient Greek monuments on the Acropolis and built the University (1839–50). This crisp Ionic building eventually formed a group with the National Library and the Academy of Science, which were added from designs by Hans Christian and his brother Theophilus between 1859 and 1892.

The buildings of Bindesbøll and the Hansen brothers were a potent influence on the Scandinavian classicists of the early 20th century such as Carl Petersen (Fåborg Museum, Denmark, 1912–15) and Hack Kampmann (Police Headquarters, Copenhagen, 1919–24). Other notable expressions of this cool and austere language in Stockholm are Ivar Tengbom's Concert House (1920–26) and two masterpieces by Gunnar Asplund, the City Library (1920–28) and Woodland Crematorium (1935–40). (D.J.Wa.)

United States. The followers of Latrobe lacked his inventive genius but adapted the more conventional aspects of his Greek Revival work to create a public style that symbolized the dignity of the new democracy. The Greek Revival in the United States had as its leading exponents William Strickland, Robert Mills, Thomas Walter, and Ithiel Town. Strickland was the architect of the Merchants' Exchange, Philadelphia (1832–34), which featured a soaring lantern reminiscent of the Choragic Monument of Lysicrates in Athens. Mills built many government buildings in Washington, D.C., including the Treasury (1836–42) and the Patent Office (begun 1836). He also designed the Washington Monument in Baltimore (1815–29), a giant Doric column, the first such monument in the United States. Walter worked on the U.S. Capitol building and in Philadelphia, where he designed Girard College (1833–47) in the form of an elegant Corinthian temple. Countless state houses and public buildings throughout the United States continued to be built from Greco-Roman models into the 20th century. Alexander Jackson Davis was one

Ancient
Greek in-
fluences in
Germany

of the leading architects of the Greek-temple house, of which the Bowers House, Northampton, Mass. (1825–26), is an example. Such Greek houses were particularly numerous in the South, fine examples being Berry Hill, Halifax County, Va. (1835–40), and Belle Meade, near Nashville, Tenn. (1853). (S.Mi./D.J.Wa.)

Hunt and
Richardson

These Neoclassical buildings were ultimately of English derivation, but the pattern of architecture in the United States shifted in 1846 when Richard Morris Hunt became the first American to enroll as an architectural student at the École des Beaux-Arts in Paris. Hunt specialized in mansions for the new commercial aristocracy of America: for example, The Breakers, Newport, R.I., built in 1892–95 in an opulent neo-Renaissance style for Cornelius Vanderbilt II (Figure 98). In 1859–62 Henry Hobson Richardson trained at the École, and on his return to the United States he specialized in a rock-faced Romanesque style probably inspired by the work of Viollet-le-Duc's rationalist follower, Vaudremer. Richardson's most celebrated buildings in this vein are the Allegheny County Court House and Jail, Pittsburgh (1883–88), and the Marshall Field and Company Wholesale Store, Chicago (1885–87; demolished in 1930; Figure 99).

Richardson's pupil Charles Follen McKim, who had been trained at the École in 1867–70, set up a partnership with William Rutherford Mead and Stanford White that was to change the course of American architecture. Following their early domestic masterpieces in the vernacular, or Shingle, style, such as the Low House, Bristol, R.I. (1887; demolished in 1962; Figure 100), McKim, Mead, and White produced a chain of classical buildings that were more consistently monumental than anything seen since the days of the Roman Empire. These include the Boston Public Library (1887–95), the Rhode Island State Capitol (1891–93), Columbia University, New York City (1894–98), and Pennsylvania Station, New York City (1902–11; demolished in 1963); the last is a mighty adaptation of the Baths of Caracalla and a reminder that the Roman baths exercised a powerful influence on the imagination of architects from at least the time of Bramante.

The World's Columbian Exposition at Chicago in 1893, which included buildings by McKim, Mead, and White, commemorated the 400th anniversary of the discovery of the New World and also helped modern Americans rediscover the value of classical planning in civic design. The dazzling spectacle of monumental classical architecture on the fair's Midway caught the fancy of Americans who saw in its great axes, lagoons, sculpture, white buildings, and large plazas an answer to the dreary urban environments of their hometowns. Similar schemes were supported in other cities; some of these were designed by the fair's principal planner, Daniel Burnham, who brought the "great white city" to Cleveland, Washington, D.C., New York

City, and San Francisco. The best parts of many American cities are spacious because of the planners of the City Beautiful movement.

Three of the many architects who continued this classical tradition after World War I were John Russell Pope (Jefferson Memorial, 1934–43, and National Gallery of Art, 1937–41, both in Washington, D.C.), Paul Philippe Cret (Hartford County Building, Connecticut, 1926), and Philip Trammell Shutze (Temple of the Hebrew Benevolent Congregation, Atlanta, Ga., 1931–32). Despite this classical strain, the keynote of 1930s architecture was stylistic pluralism. The Gothic Revival continued, especially in university buildings, whereas domestic architecture in the suburbs could be neo-Tudor or neo-Georgian. With the aid of technology, buildings in the style of Spanish estates were built in Florida, French farmhouses in Philadelphia, Georgian and colonial houses in New England, and pueblos in the Southwest. Georgia revived its antebellum architecture, and Santa Barbara, Calif., which was destroyed by an earthquake in 1925, was quickly rebuilt in the style of a Spanish mission. (D.J.Wa.)

Late 19th-century developments

19TH-CENTURY CONSTRUCTION IN IRON AND GLASS

The Industrial Revolution in Britain introduced new building types and new methods of construction. Marshall, Benyou, and Bage's flour mill (now Allied Breweries) at Ditherington, Shropshire (1796–97), is one of the first iron-frame buildings, though brick walls still carry part of the load and there are no longitudinal beams. The cloth mill at King's Stanley, Gloucestershire (1812–13), is more convincing as an iron-frame building. Fully fireproof and avoiding the use of timber, it is clad in an attractive red-brick skin with Venetian windows and angle quoins. Leading Regency architects even used cast-iron construction members in major public buildings in the classical style: Smirke incorporated concealed cast-iron beams in the British Museum (1823–46), while Nash openly displayed cast-iron Doric columns at Buckingham Palace (1825–30).

Iron was frequently combined with glass in the construction of conservatories; early surviving examples include the conservatory (1827–30) at Syon House, Middlesex, by Charles Fowler and the Palm House (1845–47) at Kew Gardens, Surrey, by Decimus Burton. These led naturally to the Crystal Palace, the climax of early Victorian technology. In the design of the Crystal Palace, built for the Great Exhibition held at London in 1851, Sir Joseph Paxton, a botanist, employed timber, cast iron, wrought iron, and glass in a ridge-and-furrow system he had developed for greenhouses at Chatsworth in 1837. Paxton was partly inspired by the organic structure of the Amazonian lily *Victoria regia*, which he successfully cultivated. The

The importance of the Crystal Palace

Crystal Palace contained important innovations in mass production of standardized materials and rapid assembly of parts, but its chief architectural merit lay in its cadence of colossal spaces. French designers recognized its magic, and a series of buildings for universal exhibitions held at Paris in 1855, 1867, and 1878 showed its influence.

The emancipation of markets and stores was no less impressive. Designers erected iron and glass umbrellas, such as Victor Baltard's Halles Centrales, Paris (1853-70; demolished 1971). An especially beautiful example of iron-and-glass construction is Labrousse's nine-domed reading room at the Bibliothèque Nationale, Paris (1859-67; Figure 101).

Closer to the English tradition are the billowing Laeken glass houses, Brussels (1868-76), by Alphonse Balat. Visitors were admitted to the Coal Exchange in London (1846-49, J.B. Bunning) through a round towered classical porch at the corner of two Renaissance palaces to a magnificent rotunda hall, which was surrounded by three tiers of ornamental iron balconies and roofed by a lace-like dome of iron and glass. In Paris, Alexandre-Gustave Eiffel, together with the architect Louis-Auguste Boileau, gave the retail shop a new and exciting setting in the Bon Marché (1876), where merchandise was displayed around the perimeters of skylighted, interior courts. The United States saw nothing comparable, but cast-iron columns and arches appeared during the 1850s in commercial buildings such as the Harper Brothers Building at New York City (1849) by John B. Corlies and James Bogardus. Stores were given cast-iron faces, as in the pioneering Stewart's

Department Store (later Wanamaker's) by John Kellum in New York City (1859-62). Iron was frequently intended to simulate stone, and it was admired for its economy of maintenance as well as such neglected qualities as precision, standardization, and efficient strength. British parallels to these American examples include Gardner's Warehouse, Glasgow (1855-56), by John Baird and Oriell Chambers, Liverpool (1864), by Peter Ellis.

The Eiffel Tower (1887-89), the most important emblem of the Paris exhibition of 1889, was designed by Alexandre-Gustave Eiffel, an engineer who had done outstanding work in the Paris Exposition of 1878 and in steel structures such as the trussed parabolic arches in the viaduct at Garabit, Fr. (1880-84). In the Palais des Machines (at the 1889 exhibition) by Ferdinand Dutert and Victor Contamin, a series of three-hinged trussed arches sprang from small points across a huge space, 385 feet long and 150 feet high. Similar spaces had already been created in railway stations in England such as St. Pancras, London (1864-68, by William H. Barlow), where the wrought-iron arches have a span of 243 feet and rise to a height of 100 feet.

In the United States a major effort took place in one of the most important new building types, the large office building. This building type was made necessary by the concentration of markets, banks, railroad terminals, and warehouses in small sections of growing cities, and it pushed skyward as a result of the attempt to get maximum income from expensive urban properties, the desire for the commercial prestige of tall emblems, and the need of businesses for mutual proximity in the days before rapid electronic communication. The safe, fast elevator removed the major prejudice against height. Designed by traditionalist architects, the tall buildings stretched masonry construction to its limits; they frequently resembled towers composed of smaller buildings stacked one on another, as in Hunt's Tribune Building at New York City (1874). The structural problem was solved at Chicago in 1884-85, when an engineer, William Le Baron Jenney, developed in the Home Insurance Company Building a metal skeleton of cast-iron columns—sheathed in masonry—and wrought-iron beams, carrying the masonry walls and windows at each floor level. Technically innovative, the building retained masonry sidewalls, and its elevations were disunified and inept.

Inspired by the architectural rationalism of Viollet-le-Duc, Chicago architects sought a better aesthetic expression of the metal frame, but even the talented John Wellborn Root, working with Daniel Burnham, failed to achieve it in the Ashland Block (completed 1892). Lesser designers, such as William Holabird and Martin Roche in the Tacoma Building (1887-89), also missed their chance. Even the great Louis Sullivan was not successful in his early buildings, such as the Ryerson (1884). Covering them with gross, somewhat Art Nouveau ornament, he accentuated first the vertical columns and then the horizontal beams in a covert admission of failure. At his best, as in

W. Rawlings/Robert Harding Picture Library

his Auditorium Building, Sullivan trod Richardson's path toward unified Romanesque forms. The Marshall Field Wholesale Store showed Sullivan the way toward a theme for the skyscraper, which he first stated with assurance in the Wainwright Building at St. Louis (1890–91). Brick piers mark each steel column and half module to create a rhythm of tall, narrow bays punctuated by recessed spandrels (the spaces above and below each window), terminating at the roofline. Jenney's Leiter Building II (1891; later Sears, Roebuck and Company's main retail store) and Burnham and Root's Monadnock Building (1891), both in Chicago, went beyond the Wainwright Building and were the first modern commercial buildings to demonstrate in their designs formal simplicity and ornamental abstinence, resulting from a new form of harmony between the demands of artistic expression, function, and technology.

The ferment in Chicago was neither halted nor marred by classicism's transcontinental popularity. Burnham's firm went on to produce Chicago's Reliance Building (1890–95), an excellent office building with logically ordered spaces enclosed by faceted walls of glass and a steel skeleton covered by terra-cotta panels (Figure 102). Sullivan found his best expression of the skyscraper in the Prudential Building, Buffalo (1894–95), and developed the theory for it in an essay published in *Lippincott's Magazine* (1896). That theory received even more dramatic expression in the Schlesinger-Mayer Department Store (later Carson Pirie Scott) in Chicago (1899–1904), in which the towered corner marked the climax of the logic of the steel frame and the entrance was made inviting with rich, naturalistic ornament (Figure 103). At the very end of the 19th century, the important emblem of modern commerce thus received an appropriate form: its structure was made of steel, its spaces were planned efficiently, its elevations were expressive of the skeleton, and its scale was marked by the fenestration and ornament. (A.B.-B./D.J.Wa.)

ART NOUVEAU

Although known as Jugendstil in Germany, Sezessionstil in Austria, Modernista in Spain, and Stile Liberty or Stile Floreale in Italy, Art Nouveau has become the general term applied to a highly varied movement that was European-centred but internationally current at the end of the century. Art Nouveau architects gave idiosyncratic expression to many of the themes that had preoccupied the 19th century, ranging from Viollet-le-Duc's call for structural honesty to Sullivan's call for an organic architecture. The extensive use of iron and glass in Art Nouveau buildings was also rooted in 19th-century practice. In France bizarre forms appeared in iron, masonry, and concrete, such as the structures of Hector Guimard for the Paris Métro (c.

1900), the Montmartre church of Saint-Jean L'Évangéliste (1894–1904) by Anatole de Baudot, Xavier Schollkopf's house for the actress Yvette Guilbert at Paris (1900), and the Samaritaine Department Store (1905) near the Pont Neuf in Paris, by Frantz Jourdain (1847–1935). The Art Nouveau architect's preference for the curvilinear is es-

pecially evident in the Brussels buildings of the Belgian Victor Horta. In the Hôtel Tassel (1892–93) he used floral, tendrilous ornaments (Figure 104), while his Maison du Peuple (1896–99) exhibits undulating enclosures of space. Decorative exploitation of the architectural surface with flexible, S-shaped linear ornament, commonly called whiplash or eel styles, was indulged in by the Jugendstil and Sezessionstil architects. The Studio Elvira at Munich (1897–98) by August Endell and Otto Wagner's Majolika Haus at Vienna (c. 1898) are two of the more significant examples of this German and Austrian use of line.

Wagner continued to combine academic geometry with classical modified Art Nouveau decoration in his Karlsplatz Stadtbahn Station (1899–1901) and in the Postal Savings Bank (1904–06), both in Vienna. Wagner's pupils broke free of his classicism and formed the Secessionists. Joseph Olbrich joined the art colony at Darmstadt, Germany, where his houses and exhibition gallery of about 1905 were boxlike, severe buildings. Josef Hoffmann left Wagner to found the Wiener Werksätze, an Austrian equivalent of the English Arts and Crafts Movement; his best work, the Stoclet House at Brussels (1905), was an asymmetrical composition in which white planes were defined at the edges by gilt lines and decorated by formalized Art Nouveau motifs reminiscent of Wagner's ornament. Josef Pečnik, a talented pupil of Wagner, began his career in 1903–05 with the office and residence of Johannes Zacherl in Vienna. This was in a Wagner-inspired style that Pečnik developed in the 1930s in a fascinating series of buildings, especially in his native city of Ljubljana, Yugos.

In Finland Eliel Saarinen brought an Art Nouveau flavour to the National Romanticism current in the years around 1900. His Helsinki Railway Station (1906–14) is close to the work of Olbrich and the Viennese Secessionists. Close links existed between Art Nouveau designers in Vienna and in Glasgow, where Charles Rennie Mackintosh's School of Art (1896–1909), with its rationalist yet poetic aesthetic, is one of the most inventive and personal of all Art Nouveau buildings. In The Netherlands, Hendrik Petrus Berlage also created a sternly fundamentalist language of marked individuality that is best appreciated in

his masterpiece, the Amsterdam Exchange (1897–1903). The exterior is in a rugged and deliberately unpicturesque vernacular, while the even more ruthless interior deploys brick, iron, and glass in a manner that owes much to the rationalist aesthetic of Viollet-le-Duc.

In the United States the Art Nouveau movement arrived with Louis Comfort Tiffany and was especially influential on ornamental rather than spatial design, particularly upon Sullivan's decorative schemes and, for a time, those of Frank Lloyd Wright. Decorative exuberance and the formally picturesque were elements of Stile Floreale buildings by the Italian Raimondo D'Aronco, such as the main building for the Applied Art Exhibition held at Turin, Italy, in 1902. These qualities, along with dynamic spatial innovations, were manifested in the works of perhaps the most singular Art Nouveau architect, the Spaniard Antonio Gaudí. His highly imaginative and dramatic experiments with space, form, structure, and ornament fascinate the visitor to Barcelona. With their peculiar organicism, the Casa Milá apartment house (1905–10; Figure 105), the residence of the Batlló family (1904–06), Gaudí's unfinished lifetime projects of the surrealistic Güell Park and the enigmatic Church of the Holy Family were amazingly personal statements. Their effect, like that of most Art Nouveau architecture, was gained through bizarre form and ornament.

20th-century architecture

THE MODERN MOVEMENT

Before World War II. The Modern movement was an attempt to create a nonhistorical architecture of functionalism in which a new sense of space would be created with the help of modern materials. A reaction against the stylistic pluralism of the 19th century, the Modern movement was also coloured by the belief that the 20th century had given birth to "modern man," who would need a radically new kind of architecture.

The Viennese architect Adolf Loos opposed the use of any ornament at all and designed purist compositions of bald, functional blocks such as the Steiner House at Vienna (1910), one of the first private houses of reinforced concrete. Peter Behrens, having had contact with Olbrich at Darmstadt and with Hoffmann at Vienna, was in 1907

appointed artistic adviser in charge of the AEG (Allgemeine Elektrizitäts Gesellschaft), for which he designed a turbine factory (1909) at Berlin. Behrens strongly affected three great architects who worked in his office: Walter Gropius, Le Corbusier, and Ludwig Mies van der Rohe.

In Germany, Gropius followed a mechanistic direction. His Fagus Works factory at Alfeld-an-der-Leine in Germany (1911) and the Werkbund exposition building at the Cologne exhibition (1914) had been models of industrial architecture in which vigorous forms were enclosed by masonry and glass; the effect of these buildings was gained by the use of steel frames, strong silhouette, and the logic of their plans (Figure 106). There were no historical influences or expressions of local landscape, traditions, or materials. The beauty of the buildings derived from adapting form to a technological culture.

Gropius succeeded van de Velde as director of the ducal

Arts and Crafts School at Weimar in 1919. Later called the Bauhaus, it became the most important centre of modern design until the Nazis closed it in 1933. While he was at Weimar, Gropius developed a firm philosophy about architecture and education, which he announced in 1923. The aim of the visual arts, he said, is to create a complete, homogeneous physical environment in which all the arts have their place. Architects, sculptors, furniture makers, and painters must learn practical crafts and obtain knowledge of tools, materials, and forms; they must become acquainted with the machine and attempt to use it in solving the social problems of an industrial society. At the Bauhaus, aesthetic investigations into space, colour, construction, and elementary forms were flavoured by Cubism and Constructivism. Moving the school to Dessau in 1925, Gropius designed the pioneering new Bauhaus (1925–26) in which steel frames and glass walls provided workshops within severely Cubistic buildings. Gropius assembled a staff of modern teachers, including the artists László Moholy-Nagy, Wassily Kandinsky, Paul Klee, Marcel Breuer, and Adolf Meyer, whose projects, such as the 116 experimental standardized housing units of the Törten Estate at Dessau, Ger. (1926–28), bore a highly machined, depersonalized appearance.

In France, Tony Garnier caught the modern currents in materials, structure, and composition when he evolved his masterful plan for a *Cité industrielle* (1901–04), published in 1917, in which reinforced concrete was to be used to create a modern city of modern buildings. With insight, Garnier developed a comprehensive scheme for residential neighbourhoods, transportation terminals, schools, and industrial centres, and his plan became a major influential scheme for 20th-century urban design. Garnier received no mandate to build such a city, but his town hall at Boulogne-Billancourt (1931–34) recalled the promise he had shown, though it was not so innovative and masterful as might have been expected.

The Futurist movement counted among its members another early 20th-century urban planner, the Italian architect Antonio Sant'Elia. Influenced by American industrial cities and the Viennese architects Wagner and Loos, he designed a grandiose futuristic city, entitled "Città nuova" ("New City"), the drawings for which were exhibited at Milan in 1914. He conceived of the city as a symbol of the new technological age. It was an affirmative environment for the future, however, in opposition to the negating inhuman Expressionistic city of the future conceived by Fritz Lang in the 1926 film classic *Metropolis*.

Centred in Germany between 1910 and 1925, Expressionist architects, like the painters who were part of the

Dyckerhoff & Widmann

Expressionism in Germany

Brücke and Blaue Reiter groups, sought peculiarly personal and often bizarre visual forms and effects. Among the earliest manifestations of an Expressionistic building style were the highly individual early works of Hans Poelzig, such as the Luban Chemical Factory (1911–12) and the municipal water tower (1911) of Posen, Ger. (now Poznań, Pol.), which led to his monumental, visionary “space caves,” such as the project for the Salzburg Festival Theatre (1920–21) and the Grosses Schauspielhaus, built in Berlin (1919) for Max Reinhardt’s Expressionistic theatre. These later works by Poelzig show the influence of the structural audacity of Max Berg’s Centenary Hall at Breslau, Ger. (now Wrocław, Pol.; 1912–13), with its gigantic reinforced concrete dome measuring 213 feet in diameter (Figure 107). The second generation of Expressionists centred their activities in postwar Germany and The Netherlands. Distinctly personal architectural statements were given form in such dynamically sculptured structures as the Einstein Observatory in Potsdam (1920), by Erich Mendelsohn (Figure 108); the anthroposophically based design by Rudolf Steiner for the Goetheanum in Dornach, Switz. (1925–28); the Eigen Haard Estates (housing development) at Amsterdam (1921), by Michel de Klerk; and Fritz Höger’s (1877–1949) Chilehaus office building in Hamburg (1922–23), with its imperative thrust of mass and acute angularity.

As Germany was the centre of Expressionism, Paris was the stronghold of the advocates of a new vision of space, Cubism, which Georges Braque and Pablo Picasso developed in 1906. Forms were dismembered into their faceted components; angular forms, interpenetrated planes, transparencies, and diverse impressions were recorded as though seen simultaneously. Soon architectural reflections of the Cubist aesthetic appeared internationally. Interior spaces were defined by thin, discontinuous planes and glass walls; supports were reduced to slender metal columns, machine finished and without ornamentation; and Cubistic voids and masses were arranged programmatically in asymmetric compositions.

The Dutch de Stijl movement was influenced by Cubism, although it sought a greater abstract purity in its geomet-

ric formalism. Organized in Leiden in 1917, the painters Piet Mondrian and Theo van Doesburg and the architects Jacobus Johannes Oud and Gerrit Thomas Rietveld were counted among its members. Their Neoplastic aesthetic advocated severe precision of line and shape, austere pristine surfaces, a Spartan economy of form, and purity of colour. Rietveld’s Schroeder House, built in 1924 at Utrecht, was a three-dimensional parallel to Mondrian’s paintings of the period (Figure 109). Van Doesburg’s work for the Bauhaus art school at Weimar brought the influence of Dutch Neoplasticism to bear upon Gropius and Mies, whose plans for houses at times markedly resembled van Doesburg’s paintings. Meanwhile Oud collaborated with van Doesburg for a time and vigorously proclaimed the new style in housing developments he built at Rotterdam (after 1918), Hook of Holland (1924–27), and Stuttgart, Ger. (1927).

Cubism and the related movements of Futurism, Constructivism, Suprematism, and Neoplasticism, like any artistic styles, might have faltered and fallen into a merely decorative cliché, as at the Paris Exposition of 1925, but for Gropius, Mies van der Rohe, and Le Corbusier.

Gropius was succeeded at the Bauhaus in 1930 by Mies van der Rohe, whose training as a mason was supplemented by the engineering experience he had gained from 1908 to 1911 in the office of Behrens; both of these elements of his education were synthesized in his project for the Kröller House in The Hague (1912). Influenced by van Doesburg’s *de Stijl*, Mies’s natural elegance and precise orderliness soon revealed themselves in unrealized projects for a brick country house, a steel and glass skyscraper, and a glazed, cantilevered concrete-slab office building (1920–22). He directed the Weissenhof estate project of the Werkbund Exposition at Stuttgart (1927), contributing the design for an apartment house. Such practical problems failed to show his talent, which was not fully known until he designed the German pavilion for the International Exposition at Barcelona in 1929. The continuous spaces partitioned with thin marble planes and the chromed steel columns drew international applause. His Tugendhat House at Brno, Czech. (1930), along with Le Corbusier’s Savoye House, epitomized the Modern domestic setting at its best.

The Swiss-French architect Charles-Édouard Jeanneret, known as Le Corbusier, gave the new architecture, sometimes referred to as the International Style, a firm foundation by writing the strong theoretical statement, *Vers une*

Le Corbusier's support of the international style

architecture (*Towards a New Architecture*), published in 1923. It revealed a world of new forms—not classical capitals and Gothic arches but ships, turbines, grain elevators, airplanes, and machine products, which Le Corbusier said were indexes to 20th-century imagination. His love of machines was combined with a belief in communal authority as the best means of accomplishing social reforms, and Le Corbusier directed his attention toward the problems of housing and urban patterns. An architectural attack, using standardized building components and mass production, was required. His sociological and formal ideas appeared in a Cubist project for Domino housing (1916), and his aesthetic preferences led him, after World War I, to develop an extreme version of Cubist painting that he and the painter Amedée Ozenfant called Purism. Returning to architecture in 1921, he designed a villa at Vaucresson, Fr. (1922), the abstract planes and strip windows of which revealed his desire to “arrive at the house machine,” that is, standardized houses with standardized furniture. In 1922 he also brought forth his project for a skyscraper city of 3,000,000 people, in which tall office and apartment buildings would stand in broad open plazas and parks with the Cubist spaces between them defined by low row housing.

Much of his work thereafter—his Voisin city plan, his Pavilion of the New Spirit at the Paris Exposition of 1925, his exhibit of workers' apartments at the Werkbund Exposition at Stuttgart (1927), and his influential but unexecuted submission to the League of Nations competition—was a footnote to that dream of a new city. The villa, Les Terrasses, at Garches, Fr. (1927), was a lively play of spatial parallelepipeds (six-sided solid geometric forms the faces of which are parallelograms) ruled by horizontal planes, but his style seemed to culminate in the most famous of his houses, the Savoye House at Poissy, Fr. (1929–30). The building's principal block was raised one story above the ground on pilotis (heavy reinforced-concrete columns); floors were cantilevered to permit long strip windows; and space was molded plastically and made to flow horizontally, vertically, and diagonally until, on the topmost terrace, the whole composition ended in a cadenza of rounded, terminating spaces. Gaining greater facility in manipulating flowing spaces, Le Corbusier designed the dormitory for Swiss students at the Cité Universitaire (1931–32) in Paris.

Early Soviet architecture

In the period after the Revolution the Soviet Union at first encouraged modern art, and several architects, notably the German Bruno Taut, looked to the new government for a sociological program. The Constructivist project for a monument to the Third International (1920) by Vladimir Tatlin was a machine in which the various sections (comprising legislative houses and offices) would rotate within an exposed steel armature. A workers' club

in Moscow (1929) had a plan resembling half a gear, and the Ministry of Central Economic Planning (1928–32), designed by Le Corbusier, was intended to be a glass-filled slab but, because of Stalin's dislike of modern architecture, was never completed. Its foundation later was used for an outdoor swimming pool.

Modern European styles of architecture were subjected to official disfavour in the Soviet Union in the 1930s, as Stalin's government adopted classical monuments—such as Boris Mikhaylovich Iofan's winning design for the Palace of the Soviets (1931), which was intended to pile classical colonnades to a height of 1,365 feet and have a colossal statue of Lenin at its summit. With its gigantic Corinthian columns, the building for the Central Committee of the Communist Party at Kiev (1937) showed an overbearing scale.

After 1930 the Modern movement spread through Europe. In Switzerland Robert Maillart's experiments with reinforced concrete attained great grace in his Salginatobel Bridge (1930). Finland's Alvar Aalto won a competition for the Municipal Library at Viipuri (now Vyborg, U.S.S.R.) in 1927 with a building of glass walls, flat roof, and round skylights (completed 1935; destroyed 1943); but he retained the traditional Scandinavian sympathy for wood and picturesque planning that were evident in his Villa Mairea at Noormarkku (1938–39), the factory and housing at Sunila (1936–39, completed 1951–54), and his later civic centre at Säynätsalo (1950–52). Aalto and other Scandinavians gained a following among those repelled by severe German modernism. Sweden's Erik Gunnar Asplund and Denmark's Kay Fisker, Christian Frederick Møller, and Arne Jacobsen also brought regional character into their modern work. In The Netherlands, Johannes Andreas Brinkman and Lodewijk Cornelis van der Vlugt, at the Van Nelle Tobacco Factory in Rotterdam (1929–30), aimed at more mechanistic, universal form. In England, refugees from Germany and other countries, alone or with English designers, inaugurated a radical modernism—for example, the apartment block known as Highpoint I, Highgate, London (by Berthold Lubetkin and the Tecton group, 1935).

The locus for creative architecture in the United States remained the Middle West, although Californians such as the brothers Charles Sumner Greene and Henry Mather Greene struck occasional regional and modern notes, as in the Gamble House at Pasadena, Calif. (1908–09). The second generation of architects of the Chicago school, such as William G. Purcell, G.G. Elmslie, and William Drummond, disseminated Middle Western modern architecture throughout the United States.

The greatest of all these new Chicago architects was Frank Lloyd Wright. His “prairie architecture” expressed its site,

The

Lloyd
Wright

region, structure, and materials and avoided all historical reminiscences; beginning with its plan and a distinctive spatial theme, each building burgeoned to its exterior sculptural form. Starting from Richardson’s rustic, shingle houses and making free use of Beaux-Arts composition during the 1880s and 1890s, Wright hinted at his prairie house idiom with the Winslow House at River Forest, Ill. (1893), elaborated it in the Coonley House at Riverside, Ill. (1908), and, ultimately, realized it in 1909 in the flowing volumes of space defined by sculptural masses and horizontal planes of his Robie House at Chicago (Figure 110). Meanwhile, he scored a triumph with his administration building for the Larkin Company at Buffalo in 1904 (destroyed 1950), which grouped offices around a central skylighted court, sealed them hermetically against their smoky environs, and offered amenities in circulation, air conditioning, fire protection, and plumbing. In its blocky fire towers, sequences of piers and recessed spandrels were coupled together in a powerful composition. Wright was, however, ignored by all except a select following. The buildings of the single figure who gave international distinction to early 20th-century American architecture remained the cherished property of personal clients, such as Aline Barnsdall, for whom Wright designed the Hollyhock House at Los Angeles (1918–20).

Organic
architecte-
ture in the
United
States

Wright’s *Autobiography* (1943) recorded his frustrations in gaining acceptance for organic architecture. The first edition summarized the chief features of that architecture: the reduction to a minimum in the number of rooms and the definition of them by point supports; the close association of buildings to their sites by means of extended and emphasized planes parallel to the ground; the free flow of space, unencumbered by boxlike enclosures; harmony of all openings with each other and with human scale; the exploitation of the nature of a material, in both its surface manifestations and its structure; the incorporation of mechanical equipment and furniture as organic parts of structure; and the elimination of applied decoration. There were also four new properties: transparency, which was obtained through the use of glass; tenuity, or plasticity of mass achieved through the use of steel in tension, as in reinforced concrete; naturalism, or the expression of materials; and integration, in which all ornamental features were natural by-products of manufacture and assembly.

The Millard House at Pasadena, Calif. (1923), exemplified many of these principles; its concrete-block walls were cast with decorative patterns. Taliesin East, Wright’s house near Spring Green, Wisc., went through a series of major rebuildings (1911, 1914, 1915, and 1925), and each fitted the site beautifully; local stone, gabled roofs, and outdoor gardens reflected the themes of the countryside. A period of withdrawal at Taliesin afforded Wright several years of intensive reflection, from which he emerged with fabulous drawings for the Doheny ranch in California (1921), a skyscraper for the National Life Insurance Company at Chicago (1920–25), and St. Mark’s Tower, New York City (1929). The last was to have been an 18-story apartment house comprising a concrete stem from which four arms

branched outward to form the sidewalls of apartments cantilevered from the stem to an exterior glass wall. Unexecuted like most of Wright’s most exciting projects, St. Mark’s Tower testified to his revolutionary thinking about skyscraper architecture. His ideas gained a wide hearing in 1931 when he published the Kahn lectures he had delivered at Princeton in 1930. In keeping with the needs of the United States during the Depression, Wright turned his attention to the low-cost house, designing a “Usonian house” for Herbert Jacobs near Madison, Wisc. (1937), and a quadruple house, “the Sun houses,” at Ardmore, Pa. (1939). These exemplified the residences he intended for his ideal communities, such as rural, decentralized Broadacre City (1936), which was Wright’s answer to European schemes for skyscraper cities.

At about the same time, Wright produced four masterpieces: Fallingwater, Bear Run, Pa. (1936), the daringly cantilevered weekend house of Edgar Kaufmann; the administration building of S.C. Johnson & Son, in which brick cylinders and planes develop a series of echoing spaces, culminating in the forest of graceful “mushroom” columns in the main hall, and the Johnson House (1937), aptly called Wingspread, both at Racine, Wisc.; and Taliesin West at Paradise Valley, near Phoenix, Ariz. (begun 1938), where rough, angular walls and roofs echo the desert valley and surrounding mountains. With increasing sensitivity to local terrain and native forms and materials, Wright stated more complex spatial and structural themes than European modernists, who seldom attempted either extreme programmatic plans or organic adaptation of form to a particular environment. Eventually, Wright himself developed a more universal geometry, as he revealed in the sculptural Solomon R. Guggenheim Museum at New York City (1956–59).

The emblem of business, the office building, continued to suffer from demands for unique, distinctive towers. Harvey Wiley Corbett, a New York architect, admitted that publicity was the ruling motivation. Sometimes a business with nationwide suboffices developed a corporate iconography; Sears, Roebuck and Company, Bell Telephone, Howard Johnson, A & P, and the various gasoline companies were recognizable instantly. The Gothic skyscraper, popularized by Gilbert’s Woolworth Building, was the style used by Raymond Hood for his winning entry in the *Chicago Tribune* competition (1922). Some buildings gained attention through their classical ornament; others were Renaissance palaces. About 1920 some architects developed simple cubical forms, and the stepped zigurat was popularized by renderers, notably Hugh Ferriss, and such painters as Georgia O’Keeffe, John Marin, and Charles Sheeler. This soaring and jagged form received legal support from the New York City zoning law of 1916 and economic justification from the fact that, in order to obtain rentable, peripheral office space in the upper floors, where the banks of elevators diminished, whole increments of office space had to be omitted. These cubical envelopes were not without ornament at their crests, as in Hood’s American Radiator Building in New York City

(1924–25), suitably described as “one huge cinder incandescent at the top.” Such decoration might be chic, as in New York City’s Barclay–Vesey (telephone company) Building, where Ralph Walker re-created the Art Deco interiors of the Paris Exposition of 1925. In San Francisco, Miller, Pflueger, & Cantin used Chinese ornament to enliven their telephone building (1926). Paradoxically, one archaeological find led to simpler buildings when, about 1930, Mayan pyramids inspired Timothy Pflueger in his work on the 450 Sutter building in San Francisco. Clifflike blocks arose in Chicago, the Daily News and Palmolive buildings (1929) being the best examples; New York City acquired a straightforward expression of tall vertical piers and setback cubical masses in the Daily News Building (1930), by the versatile Hood, who had run the course from Gothic to modern form (Figure 111). The bank and office building of the Philadelphia Savings Fund Society (1931–32) by George Howe and William Lescaze, a Swiss architect, gave the skyscraper its first thoroughly 20th-century form, and Hood, again, produced a counterpart in New York City, the McGraw-Hill Building (1931). Few of these, including the Empire State Building (1931), did anything to solve urban density and transportation problems; indeed, they intensified them. Rockefeller Center, however, begun in 1929, was, with its space for pedestrians within a complex of slablike skyscrapers, outstanding and too seldom copied.

American industry showed some inclination to respect function, materials, and engineering between the world wars, as was evident in Joseph Leland’s glazed, skeletal buildings for the Pressed Steel Company at Worcester, Mass. (1930). Occasionally, a traditional architect had produced an innovation, such as Willis Polk’s (1867–1924) Hallidie Building at San Francisco (1918). With the aid of Ernest Wilby, the engineering firm of Albert Kahn cre-

Figure 111: The Daily News Building, New York City, by Raymond Hood, 1930.

ated a work of architectural merit in Detroit’s Continental Motors Factory (about 1918). The National Cash Register, United States Shoe Company, National Biscuit, Sears, Roebuck and Company and various automobile companies, such as Ford, sponsored Functional architecture.

Rockefeller Center indicated that by 1930 there was a move toward simple form, which was presaged by the architecture of the TVA (Tennessee Valley Authority). European modernism gained a firm following in the United States as some of its best practitioners emigrated there. Eliel Saarinen, who won second prize in the *Chicago Tribune* competition, gained the acclaim of Sullivan and other architects. He settled in Bloomfield Hills, Mich., a Detroit suburb, where he established a school of architecture at the Cranbrook Academy. Saarinen designed its new buildings, gradually freeing himself from historical reminiscences of his native Scandinavia. He remained sensitive to the role of art in architecture, best revealed by his use of the sculpture of the Swede Carl Milles. The Austrian architect Richard Neutra established a practice in California, notable products of which were the Lovell House at Los Angeles (1927–28) and the Kaufmann Desert House at Palm Springs (1946–47).

A modern architecture exhibit in the Museum of Modern Art, New York City, in 1932, recorded by the architectural historian Henry-Russell Hitchcock and the architect Philip Johnson in the book *International Style; Architecture Since 1922*, familiarized Americans with the International Style. After 1933, as modernists fled the Soviet Union, Germany, and Italy, the United States received Gropius, Breuer, and Mies. Gropius joined the architectural school of Harvard University and established an educational focus recalling the Bauhaus.

After World War II. Initially, the leading interwar architects of modernism, Gropius, Mies van der Rohe, Le Corbusier, Wright, and Aalto, continued to dominate the scene. In the United States, Gropius, with Breuer, introduced modern houses to Lincoln, Mass., a Boston suburb, and formed a group, The Architects Collaborative, the members of which designed the thoroughly modern Harvard Graduate Center (1949–50). Mies became dean of the department of architecture at the Illinois Institute of Technology at Chicago in 1938 and designed its new campus. Crown Hall (1952–56) marked the apogee of this quarter-century project (Figure 112).

Not all the immigrants remained in the United States. Aalto, whose work first appeared on the American scene in the Finnish pavilion at the New York World’s Fair and again in the Massachusetts Institute of Technology’s Baker Dormitory (1947–49), returned to Finland. The European who might have contributed most was Le Corbusier. The United Nations buildings at New York City, for which he was a member of a 10-man commission headed by New York architect Wallace Harrison, is a token of the new forms he might have suggested for American cities. His plan for rebuilding Saint-Dié, Fr. (1945), was the inspiration for many city-planning proposals made after mid-century.

Beginning with private houses by Hood, Lescaze, Edward Stone, Neutra, Gropius, and Breuer during the 1930s, American Modernism gradually supplanted the historical styles in a range of building types, including schools and churches; for example, Eliel Saarinen’s simple, brick Christ Lutheran Church (1949–50) at Minneapolis, Minn.

After World War II, big industry turned to Modern architects for distinctive emblems of prestige. The Connecticut General Life Insurance Company hired one of the largest modern firms, Skidmore, Owings, and Merrill, to design their new decentralized headquarters outside Hartford, Conn. (1955–57). Lever Brothers turned to the same firm for New York City’s Lever House (1952), in which the parklike plaza, glass-curtain walls, and thin aluminum mullions realized the dreams of Mies and others in the 1920s of freestanding crystalline shafts (Figure 113). Designed by Eliel Saarinen’s son Eero, the General Motors Technical Center (1948–56) at Warren, Mich., was compared with Versailles in its extent, grandeur, and rigorous conformity to an austere, geometric aesthetic of Miesian forms. The Harrison and Abramovitz’s tower for

Hedrich-Blessing photo

the Aluminum Company of America at Pittsburgh (1954) advertised its own product, as did Skidmore, Owings, and Merrill's Inland Steel Building at Chicago (1955-57). Perhaps the most chaste of all was the Seagram Building (1954-58) at New York City, designed by Mies and Philip Johnson. Wright alone avoided the rectilinear geometry of these office buildings. In 1955 he saw his Price Tower rise at Bartlesville, Okla., a richly faceted, concrete and copper fulfillment of the St. Mark's Tower he had designed more than 25 years earlier.

Advent of Formalism

About 1952 there was a significant shift within Modernism from what had come to be called Functionalism, or the International Style, toward a monumental Formalism. There was increasing interest in highly sculptural masses and spaces, as well as in the decorative qualities of diverse building materials and exposed structural systems. Wright's Guggenheim Museum is a manifestation of this aesthetic. Those who had focused their attention on the rectilinear portions of Le Corbusier's Savoye House and Unité d'Habitation apartments at Marseille (1946-52), tended to ignore the plastic sculpture on the roofs of those buildings; to such people, Le Corbusier's highly individual buildings at Chandigarh, India (begun 1950), and the cavernous space in the lyrical church of Notre-Dame-du-Haut at Ronchamp, Fr., seemed to be examples of personal whimsy (Figure 114). Pier Luigi Nervi in Italy gave structural integrity to the complex curves and geometry of reinforced-concrete structures, such as the Orbetello aircraft hangar (begun 1938) and Turin's exposition hall (1948-50). The Spaniard Eduardo Torroja, his pupil Felix Candela, and the American Frederick Severud followed his lead. Essentially, each attempted to create an umbrella roof the interior space of which could be subdivided as required, such as Torroja's grandstand for the Zarzuela racetrack in Madrid (1935). Mies constructed rectilinear versions of such a space in Crown Hall and in his Farnsworth House at Plano, Ill. (1946-50), while Philip Johnson allowed a single functional unit, the brick-cylinder utility stack, to protrude from his precise glass house at New Canaan, Conn. (1949). Other designers used curvilinear structural geometry, best indicated by Matthew Nowicki's (1910-49) sports arena at Raleigh, N.C. (1952-53), in which two tilted parabolic arches, supported by columns, and a stretched-skin roof enclose a colossal space devoid of interior supports. In 1949 Nowicki had challenged Louis Sullivan's precept, form follows function, with another, form follows form, a dictum that freed architecture from programmatic expression. Hugh Stubbins' congress hall, at Berlin (1957), and Eero Saarinen's Trans World Airlines terminal at John F. Kennedy International Airport, New York City (1956-62), were outstanding examples of these dynamically monumental, single-form buildings the geometric shapes and silhouettes of which were derived from mathematical computation and technological innovation. International competitions for the opera house at Sydney

(1957) and a government centre at Toronto (1958) were won by the Dane Jørn Utzon and the Finn Viljo Revell, respectively. Both architects were exponents of the new monumentalism.

These designs posed problems in structural engineering and in scale, but many architects, such as the American Minoru Yamasaki in the McGregor Building for Wayne State University at Detroit (1958), attempted to make structure become decorative, while the decorative screen, as used by Edward Durell Stone at the U.S. embassy in New Delhi (1957-59), offered a device for wrapping

programmatic interiors within a rich pattern of sculptured walls.

Mexico and South America broke their bonds to French, Spanish, and Portuguese academic design during the 1930s. Le Corbusier's influence became partially strong in Brazil, where the Brazilian Oscar Niemeyer and other architects designed the Corbusier-inspired Ministry of Education and Public Health at Rio de Janeiro (1937–42). Brazil's Lúcio Costa, Affonso Reidy, and Niemeyer; Mexico's Felix Candela, Juan O'Gorman, José Villagran Garcia, and Luis Barragán; and Venezuela's Carlos Raúl Villanueva were the vanguard of Latin-American architectural modernism. Whole communities such as Caracas and São Paulo essentially were rebuilt during the 1950s, and new cities, such as Brasília, the capital of Brazil, and "university cities," such as those of Mexico and Venezuela, were conceived and erected. In Mexico there was avid support for modern design in buildings such as the Presidente Juárez housing at Mexico City (1950) by Mario Pani and Salvador Ortega. In Colombia, after World War II, enormous strides were made in thin-shelled reinforced-concrete construction. In Brazil, dramatic complexes were erected from concrete by Reidy, such as the school and gymnasium at Pedregulho housing at Rio de Janeiro (1953) and Rio's Museum of Modern Art (1960–67).

After 1959, office buildings for administrative headquarters of large corporations followed the 1955–57 suburban-campus model of Skidmore, Owings, and Merrill's Connecticut General Life Insurance Company or, if urban, the towerlike form, often with strong structural expression (Torre Velasca, Milan, by Belgiojoso, Peressutti, and Rogers, 1959) or the slab form, usually emphasizing glazed walls (Mannesmann Building, Düsseldorf, by Paul Schneider-Esleben, 1959), but they rarely achieved an urban composition such as the 1962 Place Ville-Marie, built at Montreal by the Chinese-born American architect I.M. Pei.

Air transportation, trade exhibitions, and spectator sports summoned the often awesome spatial resources of modern technology. The stadiums for the 1964 Olympics at Tokyo by Tange Kenzō, Rome's Pallazzi dello Sport done by Nervi (1960), Eero Saarinen's Dulles International Airport at Chantilly, Va. (1958–62), and Chicago's exposition hall, McCormick Place, by C.F. Murphy and Associates (1971) are examples of the colossal spaces achieved in reinforced concrete or steel and glass. International exhibitions seldom offered comparable architecture. At the New York World's Fair (1964) the Spanish pavilion by Javier Carvajal and the Japanese pavilion by Maekawa Kunio were buildings of merit. There were also several notable examples at Montreal's Expo 67: the West German pavilion by Frei Otto, the U.S. pavilion by R. Buckminster Fuller,

and the startling Constructivist apartment house, Habitat 67, by the Israeli Moshe Safdie, in association with David, Barott, and Boulva, whose 158 precast-concrete apartment units were hoisted into place and post-tensioned to permit dramatic cantilevers and terraces.

World's fairs continued to provide a setting for occasionally distinguished examples of modern structures that demonstrated innovations in building technology.

The architecture of South and Southeast Asia as well as of Japan has been decisively influenced by Western architects, particularly Le Corbusier. The leading figure in Japan was Tange Kenzō, whose many powerful buildings of rough concrete include the Peace Centre, Hiroshima (1949–55), and St. Mary's Roman Catholic Cathedral at Tokyo (1965). His disciples included the so-called Metabolism Group, led by Kikutake Kiyonori, Maki Fumihiko, and Otaka Masato. Their work, characterized by a dynamic science-fiction quality expressive of fluidity and change, culminated in the Osaka Expo 1970, with constructions such as Tange's giant space frame, known as the Theme Pavilion, and Kikutake's Landmark Tower.

Much significant architecture in the postwar period was sponsored by cultural centres and educational institutions, such as Berlin's philharmonic hall (1963) by Hans Scharoun. Louis I. Kahn, in his design for the Richards Medical Research Building (1960), gave the University of Pennsylvania in Philadelphia a linear programmatic composition of laboratories, each served by vertical systems for circulating gases, liquids, and electricity. Paul Rudolph's art and architecture building (1963) at Yale University in New Haven, Conn., gathered its studios, galleries, classrooms, and light wells on 36 interpenetrating levels distributed over six stories. The Morse and Stiles colleges (1962), also at Yale, were designed by Eero Saarinen and set a new standard for multiple-entry urban dormitories. Even the traditionalist campuses of New England preparatory schools gained modern architecture, such as the art building and science building at Phillips Academy in Andover, Mass., by Benjamin A. Thomson (1963) and the dormitories at St. Paul's School in Concord, N.H., by Edward Larrabee Barnes (1965).

The innovations in educational architecture were international. In England, distinctive educational architecture arrived at Hunstanton Secondary School, Norfolk (1949–54), by Peter and Alison Smithson. An example of what became known as the New Brutalism, this building was influenced by Mies van der Rohe. Most New Brutalist buildings, however, owed more to Le Corbusier's late work—for example, the gray concrete masses of Denys Lasdun's University of East Anglia, Norfolk (1962–68)—while James Stirling's History Faculty, Cambridge (1964–67), brought a neo-Constructivist element to the Brutalist

tional
archi-
tecture

World's
fair archi-
tecture

tradition. Canada gained the Central Technical School Arts Center by Robert Fairfield Associates (1964) and Scarborough College by John Andrews, with Page and Steele (1966), both at Toronto. Italian innovative educational architecture is exemplified in Milan's Instituto Marchiondi (1959) by Vittoriano Viganò. Led by disciples of Le Corbusier, the Japanese built Waseda University (1964), which was designed by Katsuo Ardo, and Maekawa Kunio's Gakushuin University (1964), both in Tokyo.

Some of the new educational settings proposed solutions to what was undoubtedly the mid-20th century's greatest problem, its urban environment. The high-rise, dense campus at Boston University by José Luis Sert and the skyscraper towers of MIT's earth-sciences building (1964) by I.M. Pei, as well as Harvard's behavioral sciences building (1964) by Minoru Yamasaki, were imaginative single buildings responding to urban circumstances. The Air Force Academy at Colorado Springs, Colo., and the Chicago Circle Campus of the University of Illinois (1965), both by the firm of Skidmore, Owings, and Merrill with Walter A. Netsch as the principal designer (1956), and the Salk Institute for Biological Studies at La Jolla, Calif., by Louis I. Kahn (1966), all offered intimations of a new city built around a cultural, educational centre.

New cities

No comparable concentration of intensive, harmonious urban architecture was achieved for cities, even though, after 1955, the building of new cities produced some remarkable examples such as Vällingby, Swed.; Brasília, the new capital of Brazil; Cumbernauld, in Scotland; and Chandigarh, in India; and some remarkable renovations of old cities, as in Eastwicks in Philadelphia (Reynolds Metals Co.; plans by Constantinos Doxiadis, 1960) and Constitution Plaza in Hartford, Conn. (Charles DuBose, with Sasaki, Walker & Associates 1964), and New York's Lincoln Center for the Performing Arts (1962). By this time, however, it was beginning to be felt that the application of Modern movement principles had caused visual damage to historic cities and had also failed to create a humane environment in new cities. It was at this moment that the postmodernist era began. (A.B.-B./D.J.Wa.)

POSTMODERNISM

The 1960s saw the rise of dissatisfaction with consequences of the Modern movement, especially in North America, where its failings were exposed in two influential books, Jane Jacobs' *The Death and Life of Great American Cities* (1961) and Robert Venturi's *Complexity and Contradiction in Architecture* (1966). Jacobs highlighted the destruction of urban coherence wrought by the utopian iconoclasm of the Modern movement, whereas Venturi implied that Modern buildings were without meaning because they were designed in a simplistic and puritan way that lacked the irony and complexity which enrich historical architecture. This dissatisfaction was translated into direct action in 1972 with the demolition of several 14-story slab blocks that had been built only 20 years earlier from designs by Yamasaki as part of the award-winning Pruitt-Igoe housing development in St. Louis, Mo. Similar apartment blocks in Europe and North America were demolished in the following decades, but it was at St. Louis that the postmodernist era was begun.

Venturi's *Learning from Las Vegas* (with Denise Scott Brown and Steven Izenour) was also published in 1972. In seeking to rehumanize architecture by ridding it of the restricting purism of the Modern movement, the authors pointed for guidance to the playful commercial architecture and billboards of the Las Vegas highways. Venturi and his partner John Rauch reintroduced to architectural design elements of wit, humanity, and historical reference in buildings such as the Tucker House, Katonah, N.Y. (1975), and the Brant-Johnson House, Vail, Colo. (1976). These owed something to Lutyens, who, as a master of paradox and complexity, exercised a deep appeal for Venturi and for his followers, such as Charles Moore and Michael Graves. Graves's Portland Public Service Building, Portland, Ore. (1980–82; Figure 115), and Humana Tower, Louisville, Ky. (1986), have the bulk of the modern skyscraper yet incorporate historical souvenirs such as the colonnade, belvedere, keystone, and swag. Like Moore's

Wit and historical reference in buildings

Figure 115: Portland Public Service Building, Oregon, by Michael Graves, 1980–82.
Peter Aaron/ESTO

Piazza d'Italia, New Orleans (1975–80), and Alumni Center, University of California at Irvine (1983–85), these confident and colourful buildings are intended to reassure the public that it need no longer feel that its cultural identity is threatened by modern architecture. That mood was encapsulated in Venice in 1980 when a varied group of American and European architects, including Venturi, Moore, Paolo Portoghesi, Aldo Rossi, Hans Hollein, Ricardo Bofill, and Léon Krier, provided designs for an exhibition organized by the Venice Biennale under the title, "The Presence of the Past." These key architects of postmodernism represented several different outlooks but shared the ambition of banishing the fear of memory from modern architectural design.

The many American architects in the 1970s and '80s who adopted a populist language scattered with classical souvenirs included Philip Johnson and his partner John Burgee and the prolific Robert Stern. Johnson and Burgee designed the AT&T Building, New York City (1978–84), a skyscraper with a Chippendale skyline. Their School of Architecture Building, University of Houston (1982–85), is inspired by Ledoux's project for a House of Education at Chaux (1773–79). Stern's Observatory Hill Dining Hall, University of Virginia, Charlottesville (1982–84), is in a cheerful Jeffersonian classicism, while his Prospect Point Office Building, La Jolla, Calif. (1983–85), incorporates Spanish Colonial references. Many postmodernist architects were either trained by or began their careers as modernists, and many elements of Modernism carried over into postmodernism, especially in the work of architects such as Graves, Venturi, and Richard Meier.

Rejecting the playful elements in such buildings as kitsch, some architects, notably Allan Greenberg and John Blatteau, chose a more historically faithful classical style, as in their official reception rooms of the U.S. Department of State in Washington, D.C. (1984–85). The most complete instance of historical accuracy is probably the J. Paul Getty Museum, Malibu, Calif. (1970–75), an essay in Neoclassicism designed by the Los Angeles partnership of Langdon and Wilson, who relied on archaeological advice to achieve the authentic character of a Roman villa at Herculaneum.

A similar duality existed in this period in Britain, where the populist style of Graves was paralleled in the work of

Figure 116: Interior of the Clore Gallery at the Tate Gallery, London, by James Stirling, 1980–87.

Angelo Hornak

Terry Farrell (TV-am Studios, Camden Town, London, 1983), and of James Stirling (Clore Gallery at the Tate Gallery, London, 1980–87; Figure 116), while undeviating classicism was pursued by Quinlan Terry (Riverside Development, Richmond, Surrey, 1986–88), Julian Bicknell (Henbury Rotunda, Cheshire, 1984–86), and John Simpson (Ashfold House, Sussex, 1985–87). The spirit of classical urban renewal was represented in France by Christian Langlois's Senate Building, rue de Vaugirard, Paris (1975), and the Regional Council Building in Orléans (1979–81). Urban preoccupations have been more

dramatically expressed in France by Ricardo Bofill's vast housing developments, such as Les Espaces d'Abraxas, Marne-la-Vallée, near Paris (1978–83; Figure 117). The gargantuan scale of this columnar architecture of prefabricated concrete pushes the language of classicism to its limits and beyond.

A third branch of postmodernism was represented by a neorationalist or elemental approach that echoes the stripped classicism of the 19th and early 20th century. This movement was again in part a reaction to changes in the urban environment by the combination of commercial pressure and Modern movement ideology. Neorationalism originated in Italy where the architect Aldo Rossi published an influential book, *L'architettura della città* (1966; *The Architecture of the City*), Rossi's Modena Cemetery (1971–77) exhibits both his austere fundamental classicism and his concern for contextualism, since it echoes features of the local farms and factories of Lombardy.

Neorationalist ideals have also been realized in the Italian-speaking Swiss canton of Ticino: for example, in the work of Mario Campi (Casa Maggi, Arosio, 1980); Mario Botta; and Bruno Reichlin and Fabio Reinhardt, whose Casa Tonino, Torricella (1972–74), is a pristine stripped Palladian essay in white concrete. Close to this work is a group of buildings in the Basque region, including the School at Ikastola (1974–78) by Miguel Garay and José-Ignacio Linazasoro; Casa Mendiola at Andoian (1977–78) by Garay; and the Rural Centre at Cordobilla (1981) by Manuel Iniguez and Alberto Ustarroz. The projects of the German architect Oswald Matthias Ungers—for example, his Stadtloggia in the Hildesheim marketplace (1980)—promoted the same kind of rationalist contextualism in Germany. They have been influential on the design of infill buildings in other historic towns in West Germany, Italy, and France. The Viennese architect Hans Hollein also contributed to this vein of radical eclecticism, as in his sophisticated interiors in the Austrian Travel Bureau, Vienna (1978), which distantly recall the city of Otto Wagner and Josef Hoffmann. The urban work of the Belgian architect Rob Krier has been related to this movement, as can be seen in his housing in the Ritterbergstrasse, West Berlin (1978–80). His brother, Léon Krier, has been influential in both the United States and Britain for his iconlike drawings of city planning schemes in a ruthlessly simple classical style and for his polemical attacks on what he sees as the destruction by modern technology of civic order and human dignity.

The 1920s revivalist element in the neorationalist move-

architec-
ture

ment is demonstrated in the United States in the work of Richard Meier, for example in his Smith House, Darien, Conn. (1965–67), inspired by Le Corbusier's Citrohan and Domino houses, and his more complex High Museum, Atlanta (1980–83). Helmut Jahn's Bank of the South West, Houston (1982), recalls the Art Deco glass skyscraper, while the prolific Kevin Roche, originally a minimalist trained in the 1950s by Eero Saarinen, returned to the heroic formalism of the early skyscrapers for his Morgan Bank headquarters, New York City (1983–87), a 48-story skyscraper resting on a 70-foot-high entrance loggia of coupled granite columns.

In Japan, Isozaki Arata and Yamashita Kazumasa led the move away from Brutalism and Metabolism toward a postmodernism inspired by Charles Moore—for example, Isozaki's Tsukuba Centre building, Tsukuba Science City, Ibaraki (1983), and Yamashita's Japan Folk Arts Museum, Tokyo (1982). In India, Charles Correa led a parallel shift away from high-rise mass-housing of the Le Corbusier type. In the 1950s he worked in the International style, as in his hotel of white concrete at Ahmadabad, but in later low-rise housing and in his book, *The New Landscape* (1985), he demonstrated the virtues of a return to the more indigenous building types of the Third World.

The spirit of technology is, by contrast, celebrated in the Centre Pompidou, Paris (1971–77), by Renzo Piano and Richard Rogers. With its services and structure exposed externally and painted in primary colours, this exhibition centre can be seen as an outrageous joke in the historic centre of Paris. Though defiantly "modern," it has a post-modernist flavour as a playful statement of the modernist belief, going back at least to Viollet-le-Duc, in the truthful exposure of the structural bones of a building. Rogers repeated the theme in his Lloyd's Building, London (1984–86), but Stirling's addition to the Staatsgalerie, Stuttgart, W.Ger. (1977–82), is a key postmodernist building in the Venturi sense: that is, it makes ironic references to the language of Schinkel without accepting the fundamental principles of classicism. (D.J.Wa.)

BIBLIOGRAPHY

General works: Sir Banister Fletcher's *A History of Architecture*, 19th ed., edited by JOHN MUSGROVE (1987), provides a comprehensive standard survey of Western architecture; as do DAVID WATKIN, *A History of Western Architecture* (1986); SPIRO KOSTOF, *A History of Architecture: Settings and Rituals* (1985); and NIKOLAUS PEVSNER, *An Outline of European Architecture*, 7th ed. (1963, reprinted 1974). Standard reference works include ULRICH THIEME and FELIX BECKER (eds.), *Allgemeines Lexikon der bildenden Künstler von der Antike bis zur Gegenwart*, 37 vol. (1907–50, reprinted 1978); continued by HANS VOLLMEIER (ed.), *Allgemeines Lexikon der bildenden Künstler des XX. Jahrhunderts*, 6 vol. (1953–62); *Encyclopedia of World Art*, 16 vol. (1959–83); and ADOLF K. PLACZEK (ed.), *Macmillan Encyclopedia of Architects*, 4 vol. (1982). See also ALEXANDER TZONIS and LIANE LEFAIVRE, *Classical Architecture: The Poetics of Order* (1986; originally published in Dutch, 1983); and ROGER SCRUTON, *The Aesthetics of Architecture* (1979).

Bronze Age: Introductions to the architecture of the period are found in EMILY VERMEULE, *Greece in the Bronze Age* (1972); and JOHN BOARDMAN, *Pre-Classical: From Crete to Archaic Greece* (1967, reprinted 1978). SIR ARTHUR EVANS, *The Palace of Minos: A Comparative Account of the Successive Stages of the Early Cretan Civilization as Illustrated by the Discoveries at Knossos*, 4 vol. in 6 (1921–35, reissued 1964), is a classic on Minoan architecture; it is in part superseded by RICHARD W. HUTCHINSON, *Prehistoric Crete* (1962); and SINCLAIR HOOD, *The Minoans: The Story of Bronze Age Crete* (1971). For Hellenic art, see GEORGE E. MYLONAS, *Mycenae and the Mycenaean Age* (1966); and LORD WILLIAM TAYLOR, *The Mycenaean Age*, rev. ed. (1983). For Cyprus, see VASSOS KARAGEORGHIS, *Cyprus, from the Stone Age to the Romans*, new ed. (1982), with a useful bibliography; and for the western Mediterranean, ANTONIO ARRIBAS, *The Iberians* (1964); DAVID TRUMP, *Central and Southern Italy Before Rome* (1966); and MARIO MORETTI and GUGLIELMO MAETZKE, *The Art of the Etruscans* (1970; originally published in Italian, 1969).

Classical Greek and Hellenistic: Major surveys are offered in WILLIAM B. DINSMOOR, *The Architecture of Ancient Greece: An Account of Its Historic Development*, 3rd rev. ed. (1950, reprinted 1975); D.S. ROBERTSON, *Greek and Roman Architecture*, 2nd ed. (1943, reprinted 1969); A.W. LAWRENCE, *Greek Architecture*, 4th ed., rev. by R.A. TOMLINSON (1983); J.J. COULTON,

Greek Architects at Work: Problems of Structure and Design (1977, reprinted 1982); RHYS CARPENTER, *The Architects of the Parthenon* (1970); BERNARD ASHMOLE, *Architect and Sculptor in Classical Greece* (1972); JOHN TRAVLOS, *Pictorial Dictionary of Ancient Athens*, trans. from Greek (1971); and J.J. POLLITT, *The Art of Greece, 1400–31 B.C.: Sources and Documents* (1965), and *Art in the Hellenistic Age* (1986).

Roman: The basic source is VITRUVIUS, *The Ten Books on Architecture*, trans. from Latin by MORRIS HICKY MORGAN (1914, reprinted 1960), the only complete treatise to survive from antiquity. Authoritative surveys with informative bibliographies are AXEL BOETHIUS, *Etruscan and Early Roman Architecture*, 2nd rev. ed. by ROGER LING and TOM RASMUSSEN (1978); and J.B. WARD-PERKINS, *Roman Imperial Architecture* (1981). See also WILLIAM L. MACDONALD, *The Architecture of the Roman Empire*, rev. ed., 2 vol. (1982–86); and MARGARET LYTTTELTON, *Baroque Architecture in Classical Antiquity* (1974); MARION E. BLAKE, *Ancient Roman Construction in Italy from the Prehistoric Period to Augustus* (1947, reprinted 1968) and *Roman Construction in Italy from Tiberius Through the Flavians* (1959, reprinted 1968); MARION E. BLAKE and DORIS TAYLOR BISHOP, *Roman Construction in Italy from Nerva Through the Antonines* (1973); J.J. POLLITT, *The Art of Rome, c. 733 B.C.–337 A.D.: Sources and Documents* (1966, reprinted 1983); and ERNEST NASH, *Pictorial Dictionary of Ancient Rome*, 2nd rev. ed., 2 vol. (1968, reissued 1981).

Early Christian and Byzantine: RICHARD KRAUTHEIMER, *Early Christian and Byzantine Architecture*, 4th ed., rev. by RICHARD KRAUTHEIMER and SLOBODAN ĆURČIĆ (1986), and Rome, *Profile of a City, 312–1308* (1980), are major studies. See also E. BALDWIN SMITH, *Architectural Symbolism of Imperial Rome and the Middle Ages* (1956, reprinted 1978); WILLIAM L. MACDONALD, *Early Christian & Byzantine Architecture* (1962); and STEVEN RUNCIMAN, *Byzantine Style and Civilization* (1975). On Constantinople (Istanbul), see THOMAS F. MATHEWS, *The Byzantine Churches of Istanbul: A Photographic Survey* (1976); and DAVID TALBOT RICE (ed.), *The Great Palace of the Byzantine Emperors* (1958). HUBERT FAENSEN and VLADIMIR IVANOV, *Early Russian Architecture* (1975; originally published in German, 1972), is a useful introduction.

Early Medieval and Romanesque: The fundamental study is KENNETH JOHN CONANT, *Carolingian and Romanesque Architecture, 800 to 1200*, 3rd ed. (1973). HARALD BUSCH and BERND LOHSE (eds.), *Romanesque Europe* (1960; originally published in German, 1959), is a good photographic survey. See also A.W. CLAPHAM, *Romanesque Architecture in Western Europe* (1936, reprinted 1967); JOAN EVANS, *The Romanesque Architecture of the Order of Cluny* (1938, reprinted 1972); and WALTER HORN and ERNEST BORN, *The Plan of St. Gall: A Study of Architecture & Economy of Life in a Paradigmatic Carolingian Monastery*, 3 vol. (1979). On England, see H.M. TAYLOR and JOAN TAYLOR, *Anglo-Saxon Architecture*, 3 vol. (1965–78); A.W. CLAPHAM, *English Romanesque Architecture Before the Conquest* (1930), and *English Romanesque Architecture After the Conquest* (1934), reprinted as *English Romanesque Architecture*, 2 vol. (1969); and ERIC FERNIE, *The Architecture of the Anglo-Saxons* (1983).

Gothic: PAUL FRANKL, *Gothic Architecture*, trans. from German (1962), provides a full scholarly survey; while LOUIS GRODECKI, *Gothic Architecture*, trans. from French (1977, reissued 1985), offers a well-illustrated summary. Earlier classics include JOHN FITCHEN, *The Construction of Gothic Cathedrals: A Study of Medieval Vault Erection* (1961, reissued 1981); OTTO VON SIMSON, *The Gothic Cathedral: Origins of Gothic Architecture and the Medieval Concept of Order*, 3rd expanded ed. (1988); and ERWIN PANOFSKY, *Gothic Architecture and Scholasticism* (1951, reissued 1976); while later scholarship is represented in JEAN BONY, *The English Decorated Style: Gothic Architecture Transformed, 1250–1350* (1979), and *French Gothic Architecture of the 12th and 13th Centuries* (1983). See also TERESA G. FRISCH, *Gothic Art 1140–c. 1450: Sources and Documents* (1971, reissued 1987).

Renaissance: The best general survey of Italian Renaissance architecture is LUDWIG H. HEYDENREICH and WOLFGANG LOTZ, *Architecture in Italy, 1400 to 1600*, trans. from German (1974). PETER MURRAY, *The Architecture of the Italian Renaissance*, new ed. (1969, reprinted 1986), is a useful account. RUDOLF WITTKOWER, *Architectural Principles in the Age of Humanism*, 4th ed. (1973), a scholarly study, may be read in conjunction with historical treatises, especially LEON BATTISTA ALBERTI, *The Ten Books of Architecture*, trans. from Latin (1755, reprinted 1986); and ANDREA PALLADIO, *The Four Books of Architecture* (1738, reprinted 1977; originally published in Italian, 1570). On Rome, see PAOLO PORTOGHESI, *Rome of the Renaissance* (1972; originally published in Italian, 1971); and DAVID R. COFFIN, *The Villa in the Life of Renaissance Rome* (1979).

For Renaissance architecture outside of Italy see ANTHONY BLUNT, *Art and Architecture in France, 1500 to 1700*, 4th ed.

(1980); GEORGE KUBLER and MARTIN SORIA, *Art and Architecture in Spain and Portugal and Their American Dominions, 1500 to 1800* (1959); JOHN SUMMERSON, *Architecture in Britain, 1530–1830*, 7th rev. ed. (1983); HOWARD COLVIN, *A Biographical Dictionary of British Architects, 1600–1840* (1980); HENRY-RUSSELL HITCHCOCK, *German Renaissance Architecture* (1981); BRIAN KNOX, *Bohemia and Moravia, an Architectural Companion* (1962); HELENA KOZAKIEWICZOWA and STEFAN KOZAKIEWICZ, *The Renaissance in Poland* (1976; originally published in Polish, 1976); and GEORGE HEARD HAMILTON, *The Art and Architecture of Russia*, 3rd ed. (1983).

Baroque and Rococo: Important general studies include ANTHONY BLUNT (ed.), *Baroque & Rococo: Architecture and Decoration* (1978); VICTOR L. TAPIÉ, *The Age of Grandeur: Baroque Art and Architecture*, 2nd ed. (1966; originally published in French, 1957); and FISKE KIMBALL, *The Creation of the Rococo* (1943; reprinted as *The Creation of the Rococo Decorative Style*, 1980). The classic study on Italian Baroque is RUDOLF WITTKOWER, *Art and Architecture in Italy, 1600 to 1750*, 3rd rev. ed. (1973, reprinted with corrections, 1980). On Rome, see ANTHONY BLUNT, *Guide to Baroque Rome* (1982); and RICHARD KRAUTHMEIER, *The Rome of Alexander VII, 1655–1667* (1985); and for other parts of Italy, see ANTHONY BLUNT, *Sicilian Baroque* (1968), and *Neapolitan Baroque & Rococo Architecture* (1975); and RICHARD POMMER, *Eighteenth-Century Architecture in Piedmont: The Open Structures of Juvavara, Alfieri & Vittone* (1967). See also EBERHARD HEMPEL, *Baroque Art and Architecture in Central Europe: Germany, Austria, Switzerland, Hungary, Czechoslovakia, Poland*, trans. from German (1965); JOHN BOURKE, *Baroque Churches of Central Europe*, 2nd rev. ed. (1962, reprinted 1978); HENRY-RUSSELL HITCHCOCK, *Rococo Architecture in Southern Germany* (1968); NICHOLAS POWELL, *From Baroque to Rococo: An Introduction to Austrian and German Architecture from 1580 to 1790* (1959); KARSTEN HARRIES, *The Bavarian Rococo Church: Between Faith and Aestheticism* (1983); HAROLD E. WETNEY, *Colonial Architecture and Sculpture in Peru* (1949, reprinted 1971); PÁL KELEMEN, *Baroque and Rococo in Latin America*, 2 vol., 2nd ed. (1967; reprinted in 1 vol., 1977); ANTHONY BLUNT, *Art and Architecture in France, 1500 to 1700*, 4th ed. (1980); JACOB ROSENBERG, SEYMOUR SLIVE, and E.H. TER KUILE, *Dutch Art and Architecture: 1600–1800*, 3rd ed. (1977); W. KUYPER, *Dutch Classicist Architecture: A Survey of Dutch Architecture, Gardens, and Anglo-Dutch Architectural Relations from 1625 to 1700* (1980); PETER THORNTON, *Seventeenth-Century Interior Decoration in England, France, and Holland* (1978); KERRY DOWNES, *English Baroque Architecture* (1966); and JUDITH HOOK, *The Baroque Age in England* (1976).

Classicism, 1750–1830: Stimulating general studies include JOSEPH RYKWERT, *The First Moderns: The Architects of the Eighteenth Century* (1980), and *On Adam's House in Paradise: The Idea of the Primitive Hut in Architectural History*, 2nd ed. (1981); EMIL KAUFMANN, *Architecture in the Age of Reason: Baroque and Postbaroque in England, Italy, and France* (1955, reprinted 1968); and ROBIN MIDDLETON and DAVID WATKIN, *Neoclassical and 19th Century Architecture* (1980, reissued in 2 vol., 1987). Special subjects are covered in ALLAN BRAHAM, *The Architecture of the French Enlightenment* (1980); WEND GRAF KALNEIN and MICHAEL LEVEY, *Art and Architecture of the Eighteenth Century in France* (1972); SVEND ERIKSEN, *Early Neo-Classicism in France: The Creation of the Louis Seize Style in Architectural Decoration, Furniture and Ormolu, Gold and Silver, and Sevres Porcelain in the Mid-Eighteenth Century*, trans. from Danish (1974); WOLFGANG HERRMANN, *Laugier and Eighteenth Century French Theory* (1962, reprinted 1985); DORA WIEBENSON, *The Picturesque Garden in France* (1978); J. MORDAUNT CROOK, *The Greek Revival: Neo-Classical Attitudes in British Architecture, 1760–1870* (1972); DAVID WATKIN and TILMAN MELLINGHOFF, *German Architecture and the Classical Ideal* (1987), a well-illustrated survey with a full bibliography; HERMANN G. PUNDT, *Schinkel's Berlin: A Study in Environmental Planning* (1972); BRIAN KNOX, *The Architecture of Poland* (1971); GEORGE HEARD HAMILTON, *op.cit.*; and MIKHAIL A. IL'IN, *Moscow Monuments of Architecture, 18th–the First Third of the Nineteenth Century*, parallel Russian and English texts, 2 vol. (1975); WILLIAM H. PIERSON, JR., *American Buildings and Their Architects: The Colonial and Neo-Classical Styles* (1970, reprinted 1986), which largely supersedes the pioneering study by TALBOT HAMLIN, *Greek Revival Architecture in America* (1944, reprinted 1964). See also HUGH MORRISON, *Early American Architecture: From the First Colonial Settlements to the National Period* (1952, reissued 1987), a well-illustrated account; CARL W. CONDIT, *American Buildings: Materials and Techniques from the First Colonial Settlements to the Present*,

2nd ed. (1982); and MARCUS WHIFFEN and FREDERICK KOEPER, *American Architecture, 1607–1976* (1981).

Gothic Revival: PAUL FRANKL, *The Gothic: Literary Sources and Interpretations Through Eight Centuries* (1960), is a fundamental study. GEORG GERMANN, *Gothic Revival in Europe and Britain: Sources, Influences, and Ideas*, trans. from German (1972), has an unusually broad perspective. For Britain, see CHARLES L. EASTLAKE, *A History of the Gothic Revival*, 2nd ed., edited by J. MORDAUNT CROOK (1978), a basic text first published in 1872; later analyses include KENNETH CLARK, *The Gothic Revival: An Essay in the History of Taste*, 3rd ed. (1962, reprinted 1974); STEFAN MUTHESIUS, *The High Victorian Movement in Architecture, 1850–1870* (1972); and GEORGE L. HERSEY, *High Victorian Gothic: A Study in Associationism* (1972). Comprehensive information for Germany is found in W.D. ROBSON-SCOTT, *The Literary Background of the Gothic Revival in Germany: A Chapter in the History of Taste* (1965); and for the United States, PHOEBE B. STANTON, *The Gothic Revival & American Church Architecture: An Episode in Taste, 1840–1856* (1968); and WILLIAM H. PIERSON, JR., *Technology and the Picturesque: The Corporate and the Early Gothic Styles* (1978).

Classicism, 1830–1930: The standard general study is HENRY-RUSSELL HITCHCOCK, *Architecture, Nineteenth and Twentieth Centuries*, 4th ed. (1977). PETER COLLINS, *Changing Ideals in Modern Architecture, 1750–1950* (1965, reissued 1975), offers a challenging interpretative approach. See also ARTHUR DREXLER (ed.), *The Architecture of the École des Beaux-Arts* (1977, reprinted 1984); ROBIN MIDDLETON (ed.), *The Beaux-Arts and Nineteenth-Century French Architecture* (1982); NORMA EVENSON, *Paris: A Century of Change, 1878–1978* (1979); HENRY-RUSSELL HITCHCOCK, *Early Victorian Architecture in Britain*, 2 vol. (1954, reissued 1972); ALBERT E. RICHARDSON, *Monumental Classic Architecture in Great Britain and Ireland*, new ed. (1982); CARROLL L.V. MEEKS, *Italian Architecture, 1750–1914* (1966); SPIRO KOSTOF, *The Third Rome, 1870–1950: Traffic and Glory* (1973); TILMANN BUDDENSIEG, *Industriekultur: Peter Behrens and the AEG, 1907–1914* (1984; originally published in German, 1981); BARBARA MILLER LANE, *Architecture and Politics in Germany, 1918–1945* (1968, reprinted 1985); SIMO PAAVILAINEN (ed.), *Nordic Classicism, 1910–1930* (1982); E. KIRICHENKO, *Moscow Architectural Monuments of the 1830–1910s*, parallel English and Russian text (1977); JOHN W. REPS, *Monumental Washington: The Planning and Development of the Capital Center* (1967); DAVID F. BURG, *Chicago's White City of 1893* (1976); and WILLIAM H. JORDY, *American Buildings and Their Architects: Progressive and Academic Ideals at the Turn of the Twentieth Century* (1972).

20th century: (Iron and glass): FRANÇOIS LOYER, *Architecture of the Industrial Age, 1789–1914* (1983; originally published in French, 1983); SIGFRIED GIEDION, *Mechanization Takes Command: A Contribution to Anonymous History* (1948, reprinted 1969); CARROLL L.V. MEEKS, *The Railroad Station: An Architectural History* (1956, reissued 1978); and CARL W. CONDIT, *American Building Art: The Twentieth Century* (1961). (*Art Nouveau*): A comprehensive survey is provided in FRANK RUSSELL (ed.), *Art Nouveau Architecture* (1979, reprinted 1986); ROBERT SCHMUTZLER, *Art Nouveau*, trans. from German (1962, reissued 1978); and S. TSCHUDI MADSEN, *Art Nouveau*, trans. from Norwegian (1967, reprinted 1976).

(Modern movement): Early classic studies include HENRY-RUSSELL HITCHCOCK and PHILIP JOHNSON, *The International Style: Architecture Since 1922* (1932, reprinted 1966); NIKOLAUS PEVSNER, *Pioneers of Modern Design: From William Morris to Walter Gropius*, rev. ed. (1975, reprinted 1986); SIGFRIED GIEDION, *Space, Time, and Architecture: The Growth of a New Tradition*, 5th rev. ed. (1967, reprinted 1982); and REYNER BANHAM, *Theory and Design in the First Machine Age*, 2nd ed. (1967). For broader explorations, see KENNETH FRAMPTON, *Modern Architecture: A Critical History*, rev. ed. (1985); and ARTHUR DREXLER, *Transformations in Modern Architecture* (1979). Modern American architecture is discussed in WILLIAM H. JORDY, *American Buildings and Their Architects: The Impact of European Modernism in the Mid-Twentieth Century* (1972, reissued 1986); JANE JACOBS, *The Death and Life of Great American Cities* (1961, reissued 1984); and CARL W. CONDIT, *American Building Art: The Twentieth Century* (1961). (*Postmodernism*): Postmodernism has been surveyed in PAOLO PORTOGHESI, *Postmodern: The Architecture of the Post-Industrial Society* (1983; originally published in Italian, 1982); and CHARLES A. JENCKS, *The Language of Post-Modern Architecture*, 4th rev. ed. (1984), and *Post-Modernism: The New Classicism in Art and Architecture* (1987).
