Accounting

The purpose of accounting is to provide information about the economic affairs of an organization. This information may be used in a number of ways: by the organization's managers to help them plan and control the organization's operations; by owners and legislative or regulatory bodies to help them appraise the organization's performance and make decisions as to its future; by owners, lenders, suppliers, employees, and others to help them decide how much time or money to devote to the organization; and by governmental bodies to determine how much tax the organization must pay.

Accounting provides information for all these purposes

through the maintenance of files of data and the preparation of various kinds of reports. Most accounting information is historical—that is, the accountant observes the things that the organization does, records their effects, and prepares reports summarizing what has been recorded.

Accounting information can be developed for any kind of organization, not just for privately owned, profit-seeking businesses. One branch of accounting deals with the economic operations of entire nations. The remainder of this article, however, will be devoted primarily to business accounting.

The article is divided into the following sections:

Company financial statements	1	Net income	4
The balance sheet	1	Problems of measurement	4
The income statement	1	Managerial accounting	5
The statement of changes in retained earnings	2	Cost finding	5

Asset cost	3		

COMPANY FINANCIAL STATEMENTS

Some accounting reports are issued only to the company's management or to tax agencies (see below *Managerial accounting* and *Other purposes of accounting systems*); others are sent to investors and others outside the management group. The reports most likely to go to investors are called the company's financial statements, and their preparation is the province of the branch of accounting known as financial accounting. Four kinds of financial statements will be discussed: the balance sheet, the income statement, the statement of changes in retained earnings, and the statement of changes in financial position.

The balance sheet. A balance sheet describes the resources that are under the company's control on a specified date and indicates where these resources have come from. It consists of three major sections: (1) the assets: valuable rights owned by the company; (2) the liabilities: the funds that have been provided by outside lenders and other creditors in exchange for the company's promise to make payments or to provide services in the future; and (3) the owners' equity: the funds that have been provided by the company's owners or on their behalf (as retained earnings, for example).

The list of assets shows the forms in which the company's resources are lodged; the lists of liabilities and the owners' equity indicate where these same resources have come from. The balance sheet, in other words, shows the company's resources from two points of view, and the following relationship must always exist: total assets equals total liabilities plus total owners' equity.

This same identity is also expressed in another way: total assets minus total liabilities equals total owners' equity. In this form, the equation emphasizes that the owners' equity in the company is always equal to the net assets (assets minus liabilities). Any increase in one will inevitably be accompanied by an increase in the other, and the only way to increase the owners' equity is to increase the net assets.

Assets and liabilities

Assets are ordinarily subdivided into current assets and noncurrent assets. The former include cash, amounts receivable from customers, inventories, and other assets that are expected to be consumed or can be readily converted into cash during the next operating cycle (production, sale, and collection). Noncurrent assets may include noncurrent receivables, fixed assets (such as land and buildings), and long-term investments.

The liabilities are similarly divided into current liabilities and noncurrent liabilities. Most amounts payable to the company's suppliers (accounts payable), to employees (wages payable), or to governments (taxes payable) are included among the current liabilities. Noncurrent liabilities consist mainly of amounts payable to holders of the company's long-term bonds and such items as obligations to employees under company pension plans.

The difference between the total of the current assets and the total of the current liabilities is known as net current assets, or working capital.

The owners' equity of a U.S. company is divided between paid-in capital and retained earnings. Paid-in capital represents the amounts paid to the corporation in exchange for shares of the company's preferred and common stock. The major part of this, the capital paid in by the common shareholders, is usually divided into two parts, one representing the par value, or stated value, of the shares, the other representing the excess over this amount. The amount of retained earnings is the difference between the amounts earned by the company in the past and the dividends that have been distributed to the owners.

Owners' equity

A slightly different breakdown of the owners' equity is used in most of continental Europe and in other parts of the world. The classification distinguishes between those amounts that cannot be distributed except as part of a formal liquidation of all or part of the company (capital and legal reserves) and those amounts that are not restricted in this way (free reserves and undistributed profits).

A simple balance sheet is shown in Table 1. Because the two sides of this balance sheet represent two different aspects of the same entity—the corporation's capital—the totals must always be identical. Thus, a change in the amount for one item must always be accompanied by an equal change in some other item. For example, if the company pays \$40 to one of its trade creditors, the cash balance will go down by \$40, and the balance in accounts payable will go down by the same amount.

The income statement. The company uses its assets to produce goods and services. Its success depends on whether it is wise or lucky in the assets it chooses to hold and in the ways it uses these assets to produce goods and services.

The company's success is measured by the amount of profit it earns—that is, the growth or decline in its stock of assets from all sources other than contributions or

Net income

Table 1: Any Company, Inc.: Balance Sheet as of Dec. 31, 19__

assets		liabilities and owners' equity	
Current assets		Current liabilities	
Cash	\$100	Wages payable	\$ 20
Marketable securities	50	Accounts payable	160
Accounts receivable	150	Total current liabilities	\$180
Inventories	180	Long-term bonds payable	80
Total current assets	\$480	Total liabilities	\$260
Long-term investments		Owners' equity	
Plant and equipment	70	Common stock	\$100
Original cost	\$300	Additional paid-in capital	150
Less: accumulated depreciation	110	Retained earnings	230
	190	Total owners' equity	480
Total assets	\$740	Total liabilities and owners' equity	\$740

withdrawals of funds by owners and creditors. Net income is the accountant's term for the amount of profit that is reported for a particular time period.

The company's income statement for a period of time shows how the net income for that period was derived. For example, the first line in Table 2 shows the company's sales revenues for the period: the assets obtained from customers in exchange for the goods and services that constitute the company's stock-in-trade. The second line summarizes the company's revenues from other sources.

The income statement next shows the expenses of the period: the assets that were consumed while the revenues were being created. The expenses are usually broken down into several categories indicating what the assets were used for. In Table 2, six expense items are distinguished, starting with the cost of the merchandise that was sold during the period and continuing down through the provision for income taxes.

Table 2: Any Company, Inc.: Income Statement for the Year Ended Dec. 31, 19__

Net sales revenues	\$800
Interest and other revenues	14
Total revenues	\$814
Expenses	
Cost of merchandise sold	\$492
Salaries of employees	116
Depreciation	30
Interest expense	4
Other expenses	78
Provision for taxes on ordinary income	47
Operating income	\$ 47
Gain on sale of investment	
(less applicable income taxes)	5
Net income	\$ 52

The bottom portion of the income statement in this case shows the result of the company's sale of some of its long-term investments for more than their original purchase price. Because this was not part of the company's normal operations, the sale price, costs, and taxes on the sale were kept separate from the operating revenue and expense totals; the income statement shows only a single number, the net gain on the sale.

Net income summarizes all of the gains and losses recognized during the period, including both the results of the company's normal, day-by-day activities and any other events. If net income is negative, it is referred to as a net loss.

The statement of changes in retained earnings. Like the income statement, the statement of changes in retained earnings refers to a period of time rather than to a single date. It explains the change from one balance sheet date to the next in the amount shown as retained earnings.

The retained earnings statement is the link between the income statement and the balance sheet. This relationship can be demonstrated by rewriting the accounting equation in the following way: assets minus liabilities equals paid-in capital plus retained earnings. When the company reports net income, this means that more assets came in as revenues than went out as expenses; more precisely, it means that the net asset total (assets minus liabilities) increased. Therefore, if the accounting equation is to remain balanced, an amount equal to net income must be added to retained earnings.

The distribution of cash dividends reduces net assets, and this change is balanced by a reduction in the retained earnings. Thus the typical statement of changes in retained earnings consists of the items shown in Table 3.

Table 3: Any Company, Inc.: Statement of Changes in Retained Earnings for the Year Ended Dec. 31, 19__

Retained earnings, Jan. 1, 19__	\$213
Net income earned during 19__	52
	\$265
Less: dividends distributed to shareholders during 19__	35
Retained earnings, Dec. 31, 19__	\$230

Starting with retained earnings of \$213 at the beginning of the year, the company added \$52 in net income during the year (from Table 2). Dividends amounting to \$35 were distributed to shareholders during the year, leaving a year-end balance of \$230. This is the amount on the year-end balance sheet (Table 1).

The statement of changes in financial position. The statement of changes in financial position, or funds statement, identifies the major flows of funds during the period. In many corporate reports, "funds" means working capital. The idea is easier to understand, however, if the flow of funds means simply the flow of cash. For example, if a salesman receives \$48,000 in salary and commission, from which he pays \$15,000 for airline tickets, hotel rooms, meals, and other travel expenses, his operations have provided him with funds amounting to \$33,000. Further investigation reveals that he borrowed \$5,000 from the bank during this same year, bought a car for \$11,000, purchased stock for \$4,000, and spent \$24,000 on ordinary living expenses. At the end of the year, he had \$1,000 less in his bank account than he had had at the beginning. A funds statement for the year would show the following:

The flow of funds

sources of funds		uses of funds	
from operations	\$33,000	to purchase car	\$11,000
from bank borrowing	5,000	to buy stock	4,000
from past savings	1,000	to pay living expenses	24,000
total sources	\$39,000	total uses	\$39,000

This is very different from an income statement. The sources of funds include amounts borrowed from the bank and taken from past personal savings. These are not current revenues. Similarly, the purchases of stock and of the car are not current expenses: the purchases are made in the expectation of future benefits, not mainly to produce current revenues.

The amount referred to as funds from operations (\$33,000) comes from the income statement, but it is not the same as net income. For example, the salesman may say that his expenses should include some recognition of depreciation on the automobile that he used in his business. If depreciation is estimated to be \$1,500 for the year, his net income would be \$31,500, not \$33,000.

The purpose of the funds statement is to permit an examination of the company's financial activities during the period. For example, Table 4 shows that \$77 flowed in from ordinary operations, \$20 came from the issuance of

the company's own bonds, and \$13 came from the sale of securities that the company had held as a long-term investment. Almost half of these funds were used to buy a new plant and equipment. Another \$35 went to stockholders in the form of dividends, and the remaining \$25 was invested in working capital.

Table 4: Any Company, Inc.: Statement of Changes in Financial Position for the Year Ended Dec. 31, 19__

Sources of funds	
From ordinary operations	\$ 77
From sale of investments	13
From sale of bonds	20
Total sources of funds	\$110
Uses of funds	
To pay dividends	\$ 35
To acquire plant and equipment	50
To increase working capital	25
Total uses of funds	\$110

The statement itself serves merely to identify existing relationships. It reveals, for instance, that operations did not generate enough funds to cover the company's dividend and capital investment requirements. An observer may reasonably ask whether this seems to be the result of an aggressive and imaginative expansion program or the product of competitive weaknesses that limit the company's fund-generating capacity. Similarly, the amount of funds going into working capital is a statement of fact; whether it is good or bad depends on the reasons for it.

Consolidated statements. Most large corporations in the United States and other industrialized countries own other corporations. Their primary financial statements are consolidated statements, reflecting the total assets, liabilities, owners' equity, net income, and funds flows of all the corporations in the group. Thus, for example, the consolidated balance sheet of the parent corporation (the corporation that owns the others) does not list its investments in its subsidiaries (the companies it owns) as assets; instead, it includes their assets and liabilities with its own.

Some subsidiary corporations are not wholly owned by the parent; that is, some shares of their common stock are owned by others. The equity of these minority shareholders in the subsidiary companies is shown separately on the balance sheet. For example, if Any Company, Inc., had minority shareholders in one or more subsidiaries, the owners' equity section of its December 31, 19__ balance sheet might appear as follows:

Minority interests in subsidiaries	\$ 30	
Shareholders' equity:		
Common stock	\$100	
Additional paid-in capital	150	
Retained earnings	200	450

The consolidated income statement also must show the minority owners' equity in the earnings of a subsidiary as a deduction in the determination of net income. For example:

Income before minority interest	\$52
Minority interest in earnings	3
Net income	\$49

Disclosure and auditing requirements. A corporation's obligations to issue financial statements are prescribed in the company's own statutes or bylaws and in public laws and regulations. The financial statements of most large and medium-sized companies in the United States fall primarily within the jurisdiction of the federal Securities and Exchange Commission (SEC). The SEC has a good deal of authority to prescribe the content and structure of the financial statements that are submitted to it.

A company's financial statements are ordinarily prepared initially by its own accountants. Outsiders review, or audit, the statements and the systems the company used to accumulate the data from which the statements were prepared. In most countries, including the United States, these outside auditors are selected by the company's shareholders. The audit of a company's statements is ordinarily performed by professionally qualified, independent

accountants who bear the title of Certified Public Accountants (CPA) in the United States. In the United Kingdom and many other countries with British-based accounting traditions, they are members of government-chartered organizations. Their primary task is to investigate the company's accounting figures and methods carefully enough to permit them to give their opinion that the financial statements are complete and that the figures have been arrived at through the use of acceptable measurement principles.

MEASUREMENT PRINCIPLES

In preparing financial statements, the accountant has several measurement systems to choose from. Assets, for example, might be measured at what they cost in the past or what they could be sold for now, to mention only two possibilities. To enable users to interpret statements with confidence, companies in similar industries should use the same measurement concepts or principles.

In some countries these concepts or principles are prescribed by government bodies; in the United States they are embodied in "generally accepted accounting principles" (GAAP), which represent partly the consensus of experts and partly the work of the Financial Accounting Standards Board (FASB), a private body. The principles or standards issued by the FASB can be overridden by the SEC. In practice, however, the SEC generally requires corporations within its jurisdiction to conform to the standards of the FASB.

Asset value. One principle that accountants might adopt would be to measure assets at their value to their owners. Under this principle, the economic value of an asset is the maximum amount that the company would be willing to pay for it. This amount depends on what the company expects to be able to do with it. For business assets, these expectations are usually expressed in terms of forecasts of the inflows of cash the company will receive in the future. If, for example, the company believes that by spending \$1 on advertising and other forms of sales promotion it can sell a certain product for \$5, then this product is worth \$4 to the company.

Economic
value

When cash inflows are expected to be delayed, value is less than the anticipated cash flow. For example, if the company has to pay interest at the rate of 10 percent a year, an investment of \$100 in a one-year asset today will not be worthwhile unless it will return at least \$110 a year from now (\$100 plus 10 percent interest for one year). In this example, \$100 is the present value of the right to receive \$110 one year later. Present value is the maximum amount the company would be willing to pay for a future inflow of cash after deducting interest on the investment at a specified rate for the time the company has to wait before it receives its cash.

Value, in other words, depends on three factors: (1) the amount of the anticipated future cash flows, (2) their timing, and (3) the interest rate. The lower the expectation, the more distant the timing, or the higher the interest rate, the less valuable the asset will be.

Value may also be represented by the amount the company could obtain by selling its assets. This sale price is seldom a good measure of the assets' value to the company, however, because few companies are likely to keep many assets that are worth no more to the company than their market value. Continued ownership of an asset implies that its present value to the owner exceeds its market value, which is its apparent value to outsiders.

Asset cost. Accountants are traditionally reluctant to accept value as the basis of asset measurement in the going concern. Although monetary assets such as cash or accounts receivable are usually measured by their value, most assets are measured at cost. The reason is that the accountant finds it difficult to verify the forecasts upon which a generalized value measurement system would have to be based. As a result, the balance sheet does not pretend to show how much the company's assets are worth; it shows how much the company has invested in them.

The historical cost of an asset is the sum of all the expenditures the company made to acquire it. This amount is not always easily measurable. If, for example, a company has built a special-purpose machine in one of its own

Historical
cost

Government
regulation

factories for use in manufacturing other products, and the project required logistical support from all parts of the factory organization, from purchasing to quality control, then a good deal of judgment must be reflected in any estimate of how much of the costs of these logistical activities should be “capitalized” (*i.e.*, placed on the balance sheet) as part of the cost of the machine.

Net income. From an economic point of view, income is defined as the change in the company’s wealth during a period of time, from all sources other than the injection or withdrawal of investment funds. Income is the amount the company could consume during the period and still have as much real wealth at the end of the period as it had at the beginning. For example, if the value of the net assets (assets minus liabilities) has gone from \$1,000 to \$1,200 during a period and dividends of \$100 have been distributed, income measured on a value basis would be \$300 (\$1,200 minus \$1,000, plus \$100).

Accountants generally have rejected this approach for the same reason that they have found value an unacceptable basis for asset measurement: such a measure would rely too much on estimates of what will happen in the future, estimates that would not be readily susceptible to independent verification. Instead, accountants have adopted what might be called a transactions approach to income measurement. They recognize as income only those increases in wealth that can be substantiated from data pertaining to actual transactions that have taken place with persons outside the company. In such systems, income is measured when work is performed for an outside customer, when goods are delivered, or when the customer is billed.

Transac-
tions
approach

Recognition of income at this time requires two sets of estimates: (1) revenue estimates, representing the value of the cash that the company expects to receive from the customer; and (2) expense estimates, representing the resources that have been consumed in the creation of the revenues. Revenue estimation is the easier of the two, but it still requires judgment. The main problem is to estimate the percentage of gross sales for which payment will never be received, either because some customers will not pay their bills or because they will demand and receive credit for returned merchandise or defective work.

Expense estimates are generally based on the historical cost of the resources consumed. Net income, in other words, is the difference between the value received from the use of resources and the cost of the resources that were consumed in the process. As with asset measurement, the main problem is to estimate what portion of the cost of an asset has been consumed during the period in question.

Some assets give up their services gradually rather than all at once. The cost of the portion of these assets the company uses to produce revenues in any period is that period’s depreciation expense, and the amount shown for these assets on the balance sheet is their historical cost less an allowance for depreciation, representing the cost of the portion of the asset’s anticipated lifetime services that has already been used. To estimate depreciation, the accountant must predict both how long the asset will continue to provide useful services and how much of its potential to provide these services will be used up in each period.

Depreciation is usually computed by some simple formula. The two most popular formulas in the United States are straight-line depreciation, in which the same amount of depreciation is recognized each year, and declining-charge depreciation, in which more depreciation is recognized during the early years of life than during the later years, on the assumption that the value of the asset’s service declines as it gets older.

The role of the independent accountant (the auditor) is to see whether the company’s estimates are based on formulas that seem reasonable in the light of whatever evidence is available and that these formulas are applied consistently from year to year. Again, what is “reasonable” is clearly a matter of judgment.

Depreciation is not the only expense for which more than one measurement principle is available. Another is the cost of goods sold. The cost of goods available for sale in any period is the sum of the cost of the beginning inventory and the cost of goods purchased in that period.

This sum then must be divided between the cost of goods sold and the cost of the ending inventory:

Beginning inventory
+
Purchases

=

Cost of goods sold
+
Ending inventory

Accountants can make this division by any of three main inventory costing methods: (1) first in, first out (FIFO), (2) last in, first out (LIFO), or (3) average cost. The LIFO method is widely used in the United States, where it is also an acceptable costing method for income tax purposes; companies in most other countries measure inventory cost and the cost of goods sold by some variant of the FIFO or average cost methods. Average cost is very similar in its results to FIFO; so only FIFO and LIFO need be described.

FIFO and
LIFO

Each purchase of goods constitutes a single batch, acquired at a specific price. Under FIFO, the cost of goods sold is determined by adding the costs of the various batches of the goods available, starting with the oldest batch in the beginning inventory, continuing with the next oldest batch, and so on until the total number of units equals the number of units sold. The ending inventory, therefore, is assigned the costs of the most recently acquired batches. For example, suppose the beginning inventory and purchases were as follows:

Inventory, January 1	1,000 units × \$5.00	\$ 5,000
Purchases, March 19	800 units × \$5.25	4,200
Purchases, September 12	1,200 units × \$5.50	6,600
Total goods available	3,000 units	\$15,800

The company sold 1,900 units during the year and had 1,100 units remaining in inventory at the end of the year. The FIFO cost of goods sold is:

Oldest batch,	1,000 units × \$5.00	\$5,000
Next oldest batch,	800 units × \$5.25	4,200
Next oldest batch,	100 units × \$5.50	550
Total cost of goods sold	1,900 units	\$9,750

The ending inventory consists of 1,100 units at a FIFO cost of \$5.50 each (the price of the last 1,100 units purchased), or \$6,050.

Under LIFO, the cost of goods sold is the sum of the most recent purchase, the next most recent, and so on, until the total number of units equals the number sold during the period. In the example, the LIFO cost of goods sold is:

Most recent purchase,	1,200 units × \$5.50	\$ 6,600
Next most recent purchase,	700 units × \$5.25	3,675
Total cost of goods sold	1,900 units	\$10,275

The LIFO cost of the ending inventory is the cost of the oldest units in the cost of goods available. In this simple example, assuming the company adopted LIFO at the beginning of the year, the ending inventory cost is the 1,000 units in the beginning inventory at \$5 each (\$5,000), plus 100 units from the first purchase during the year at \$5.25 each (\$525), a total of \$5,525.

Problems of measurement. Accounting income does not include all of the company’s holding gains or losses (increases or decreases in the market values of its assets). For example, construction of a superhighway may increase the value of a company’s land, but neither the income statement nor the balance sheet will report this holding gain. Similarly, introduction of a successful new product increases the company’s anticipated future cash flows, and this increase makes the company more valuable. Those additional future sales show up neither in the conventional income statement nor in the balance sheet.

Holding
gains and
losses

Accounting reports have also been criticized on the grounds that they confuse monetary measures with the underlying realities when the prices of many goods and services have been changing rapidly. For example, if the wholesale price of an item has risen from \$100 to \$150 between the time the company bought it and the time it is sold, many accountants and businessmen claim that \$150 is the better measure of the amount of resources consumed by the sale. The \$50 is simply a holding gain that should not be classified as ordinary income.

Price
changes

When inventory purchase prices are rising, LIFO inventory costing keeps many gains from the holding of inven-

stories out of net income. If purchases equal the quantity sold, the entire cost of goods sold will be measured at the higher current prices; the ending inventory will be measured at the lower prices shown for the beginning-of-year inventory. The difference between the LIFO inventory cost and the replacement cost at the end of the year is an unrealized (and unreported) holding gain.

In the inventory example cited earlier, the LIFO cost of goods sold (\$10,275) exceeded the FIFO cost of goods sold (\$9,750) by \$525. In other words, LIFO kept \$525 more of the inventory holding gain out of the income statement than FIFO did. Furthermore, the replacement cost of the inventory at the end of the year was \$6,050 ($1,100 \times \5.50), which was just equal to the inventory's FIFO cost; under LIFO, in contrast, there was an unrealized holding gain of \$525 (\$6,050 minus the \$5,525 LIFO inventory cost).

The amount of inventory holding gain that is included in net income is usually called the "inventory profit." The implication is that this is a component of net income that is less "real" than other components because it results from the holding of inventories rather than from trading with customers.

Purchasing
power

When most of the changes in the prices of the company's resources are in the same direction, the purchasing power of money is said to change. Conventional accounting statements are stated in nominal currency units (dollars, francs, lire, etc.), not in units of constant purchasing power. Changes in purchasing power—that is, changes in the average level of prices of goods and services—have two effects. First, net monetary assets (essentially cash and receivables minus liabilities calling for fixed monetary payments) lose purchasing power as the general price level rises. These losses do not appear in conventional accounting statements. Second, holding gains measured in nominal currency units may merely result from changes in the general price level. If so, they represent no increase in the company's purchasing power.

In 1980 the FASB began requiring major corporations in the United States to report the effects of some changes in specific and general price levels, but these measurements are not incorporated in the primary financial statements. In other countries that have experienced severe and prolonged inflation, companies have been allowed or even required to restate their assets to reflect the more recent and higher levels of purchase prices. The increment in the asset balances in such cases has not been reported as income, but depreciation thereafter has been based on these higher figures.

MANAGERIAL ACCOUNTING

Although published financial statements are the most widely visible products of business accounting systems and the ones with which the public is most concerned, they are only the tip of the iceberg. Most accounting data and most accounting reports are generated solely or mainly for the company's managers. Reports to management may be either summaries of past events, forecasts of the future, or a combination of the two. Preparation of these data and reports is the focus of managerial accounting, which consists mainly of three broad functions: (1) cost finding, (2) budgetary planning and performance reporting, and (3) cost and profit analysis.

Cost finding. Cost finding is the process by which the company obtains estimates of the costs of producing a product, providing a service, performing a function, or operating a department. Some of these estimates are historical—how much did it cost?—while others are predictive—what will it cost?

Process
costing

The most fully developed methods of cost finding are used to estimate the costs that have been incurred in a factory to manufacture specific products. The simplest of these methods is known as process costing. In this method, the accountant first accumulates the costs of each separate production operation or process for a specified period of time. The total of these costs is then restated as an average by dividing it by the total output of the process during the same period.

Process costing can be used whenever the output of individual processes is reasonably uniform or homogeneous,

as in cement manufacturing, flour milling, and other relatively continuous production processes.

A second method, job order costing, is used when individual production centres or departments work on a variety of products rather than just one during a typical time period. Two categories of factory cost are recognized under this method: prime costs and factory overhead costs. Prime costs are those that can be traced directly to a specific batch, or job lot, of products. These are the direct labour and direct materials costs of production. Overhead costs, on the other hand, are those that can be traced only to departmental operations or to the factory as a whole and not to individual job orders. The salary of a departmental supervisor is an example of an overhead cost.

Job order
costing

Direct materials and direct labour costs are recorded directly on the job order cost sheets, one for each job. Although not traceable to individual jobs, overhead costs are generally assigned to them by means of overhead rates—i.e., the ratio of total overhead cost to total production volume for a given time period. A separate overhead rate is usually calculated for each production department, and, if the operations of a department are varied, it is often subdivided into a set of more homogeneous cost centres, each with its own overhead rate. Separate overhead rates are sometimes used even for individual processing machines within a department if the machines differ widely in such factors as power consumption, maintenance cost, and depreciation.

Because output within a cost centre is not homogeneous, production volume must be measured by something other than the number of units of product, such as the number of machine hours or direct labour hours. Once the overhead rate has been determined, a provision for overhead cost can be entered on each job order cost sheet on the basis of the number of direct labour hours or machine hours used on that job. For example, if the overhead rate is \$3 a machine hour and Job No. 7128 used 600 machine hours, then \$1,800 would be shown as the overhead cost of this job.

Most overhead rates are predetermined—that is, they represent the average planned overhead cost at some production volume. The main reason for this is that actual overhead cost averages depend on the total volume and efficiency of operations and not on any one job alone. The relevance of job order cost information will be impaired if these external fluctuations are allowed to change the amount of overhead cost assigned to a particular job.

The methods of cost finding described in the preceding paragraphs are known as full, or absorption, costing methods, in that the overhead rates are intended to include provisions for all manufacturing costs. Both process and job order costing methods can also be adapted to variable, or direct, costing in which only variable manufacturing costs are included in product cost. Variable costs are those that will be greater in total in the upper portions of the company's normal range of volumes than in the lower portion. Total fixed costs, in contrast, are the same at all volume levels within the normal range.

Variable
costing

Unit cost under variable costing represents the average variable cost of making the product. The main argument for the variable costing approach is that average variable cost is more relevant to many managerial decisions than average full cost. In deciding whether to manufacture goods in large lots, for example, management needs to estimate the cost of carrying larger amounts of finished goods in inventory. More variable costs will have to be incurred to build the inventory to a higher level; fixed manufacturing costs presumably will be unaffected.

Furthermore, when a management decision changes the company's fixed costs, the change is unlikely to be proportional to the change in volume; therefore, average fixed cost is seldom a valid basis for estimating the cost effects of such decisions. Variable costing eliminates the temptation to assume without question that average fixed cost can be used to estimate changes in total fixed cost.

Estimates of product costs can be built up in exactly the same way as historical averages. Once the route that the product will take through the factory is known, estimates of the amounts of materials, labour, and overhead required

at each stage can be written down, totalled, and averaged. Many systems go even further than this. Estimates of the average costs of each type of material, each operation, and each product are prepared routinely and identified as standard costs. These standard cost figures are then readily available whenever estimates are needed and also serve as an important element in the company's performance reporting system, as described below.

Distribution cost analysis. Similar methods of cost finding can be used to determine or estimate the cost of providing services rather than physical goods. Most advertising agencies and consulting firms, for example, maintain some form of job cost records, either as a basis for billing their clients or as a means of estimating the profitability of individual jobs or accounts.

The unit cost of distributing the company's products or of providing administrative and supporting services is more difficult to estimate. Any such estimates are likely to be prepared on the basis of special studies, mostly centring on observations of how employees spend their time during selected test periods. Providing these estimates is the task of distribution cost analysis.

Budgetary planning and performance reporting. The second major component of internal accounting systems for management's use is the company's budgetary planning and performance reporting system. This consists of two highly interrelated elements: (1) establishing budgetary plans and setting performance standards and (2) measuring actual results and reporting differences between actual performance and the plans.

The simplified diagram in Figure 1 illustrates the interrelationships between these elements. Planning leads to plans, which then are translated into action. The results of these actions are compared with the plans and reported in comparative form. Management can then respond to substantial deviations from plan, either by taking corrective action or, if outside conditions differ from those predicted or assumed in the plans, by preparing revised plans.

Figure 1: Budget planning and performance reporting.

Although plans can be either broad, strategic outlines of the company's future or schedules of the inputs and outputs associated with specific independent programs, most business plans are periodic plans—that is, they refer to company operations for a specified period of time. These periodic plans are summarized in a series of projected financial statements, or budgets.

The two principal budget statements are the profit plan and the cash forecast. The profit plan is an estimated income statement for the budget period. It summarizes the planned level of selling effort, shown as selling expense, and the results of that effort, shown as sales revenue and the accompanying cost of goods sold. Separate profit plans are ordinarily prepared for each major segment of the company's operations.

The details underlying the profit plan are contained in departmental sales and cost budgets, each part identified with the executive or group responsible for carrying out that part. Figure 2 shows the essence of this relationship: the company's profit plan is really the integrated product of the plans of its two major product divisions. The arrows connecting the two divisional plans represent the coordinative communications that tie them together on matters of mutual concern.

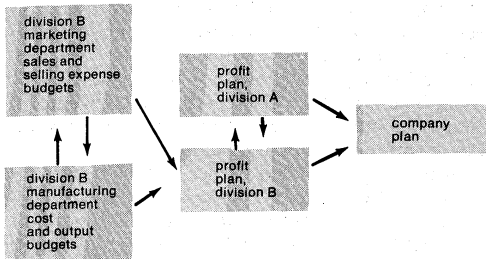

Figure 2: Relationship of company profit plan to responsibility structure.

The exhibit also goes one level farther down, showing that division B's profit plan is really a coordinated synthesis of the plans of the division's marketing department and manufacturing department. Arrows again emphasize the necessary coordination between the two. Each of these departmental plans, in turn, is a summary of the plans of the major offices, plants, or other units within the division. A complete representation of the company's profit plan would require an extension of the diagram through several layers to encompass every single responsibility centre in the entire company.

If standard costs have been established, they are shown in the factory cost budgets and in the standard cost of goods sold on the summary profit plans, with anticipated deviations, or variances, from standard cost budgeted separately. Many companies also prepare alternative budgets for operating volumes other than the volume anticipated for the period. A set of such alternative budgets is known as the flexible budget. The practice of flexible budgeting has been adopted widely by factory management to facilitate evaluation of cost performance at different volume levels and has also been extended to other elements of the profit plan.

The second major component of the annual budgetary plan, the cash forecast or cash budget, summarizes the anticipated effects on cash of all of the company's activities. It lists the anticipated cash payments, cash receipts, and the amount of cash on hand, month by month throughout the year. In most companies, responsibility for cash management rests mainly in the head office rather than at the divisional level. For this reason, divisional cash forecasts tend to be less important than divisional profit plans.

Company-wide cash forecasts, on the other hand, are just as important as company profit plans. Preliminary cash forecasts are used in deciding how much money will be made available for the payment of dividends, for the purchase or construction of buildings and equipment, and for other programs that do not pay for themselves immediately. The amount of short-term borrowing or short-term investment of temporarily idle funds is then generally geared to the requirements summarized in the final, adjusted forecast.

Other elements of the budgetary plan, in addition to the profit plan and the cash forecast, include capital expenditure budgets, manpower budgets, production budgets, and budgeted balance sheets. They all serve the same purpose: to help management decide upon a course of action and to serve as a point of reference against which to measure subsequent performance.

Planning is a management responsibility, not an accounting function. To plan is to decide, and only the manager has the authority to choose the direction the company is to take. Accounting personnel are nevertheless deeply involved in the planning process. First, they administer the budgetary planning system, establishing deadlines for the completion of each part of the process and seeing that these deadlines are met. Second, they analyze data and help management at various levels compare the estimated effects of different courses of action. Third, they are responsible for collating the tentative plans and proposals coming from the individual departments and divisions and then reviewing them for consistency and feasibility and sometimes for desirability as well. Finally, they must draw up the final plans and see that these plans are understood by the operating executives.

Performance
measurement

Once the budgetary plan has been adopted, accounting's next task is to prepare information on the results of company activities and make it available to management. The manager's main interest in this information centres on three questions: Have his or her own actions had the results expected, and, if not, why not? How successful have subordinates been in managing the activities entrusted to them? What problems and opportunities seem to have arisen since the budgetary plan was prepared? For these purposes, the information must be comparative, relating actual results to the level of results that management regards as satisfactory. In each case, the standard for comparison is provided by the budgetary plan.

Much of this information is contained in periodic financial reports. At the top management and divisional levels, the most important of these is the comparative income statement, one of which is illustrated in Table 5. This shows the profit that was planned for this period, the actual results received for this period, and the differences, or variances, between the two. It also gives an explanation of some of the reasons for the difference between a planned and an actual income.

Table 5: Any Company, Inc.: Comparative Income Statement for the Month of October 19__
(in \$000,000)

	actual	planned	difference
Divisional profit contribution			
Division A	\$100	\$120	\$(20)
Division B	70	65	5
Division C	140	150	(10)
Total profit contribution	\$310	\$335	\$(25)
Head office expenses	110	105	(5)
Income before taxes	\$200	\$230	\$(30)
Comments			
(1) An industry-wide strike in customer factories caused a slowdown in division A deliveries, reducing profit by \$24,000,000.			
(2) Demand continued strong in division B, reflected in increased volume and a stronger price structure.			
(3) Division C's unfavourable results were the result of production losses due to the model change and heavy introductory costs for the new line. These losses should be recovered by the end of the year.			
(4) Salary increases account for most of the variance in head office expense. The methods department is seeking ways to offset this.			

The report in this exhibit employs the widely used profit contribution format, in which divisional results reflect sales and expenses traceable to the individual divisions, with no deduction for head office expenses. Company net income is then obtained by deducting head office expenses as a lump sum from the total of the divisional profit contributions.

Measuring
variances

A similar format can be used within the division, reporting the profit contribution of each of the division's product lines, with divisional headquarters expenses deducted at the bottom. By far the greatest number of reports, however, are cost or sales reports, mostly on a departmental basis. Departmental sales reports usually represent comparisons of actual sales with the volumes planned for the period. Departmental cost performance reports, in contrast, typically compare actual costs incurred with standards or budgets that have been adjusted to correspond to the actual volume of work done during the period. This practice reflects a recognition that volume fluctuations generally originate outside the department and that the department head's responsibility is ordinarily limited to minimizing cost while meeting the delivery schedules imposed by higher management.

For example, a factory department's output consists entirely of a single product, with a standard materials cost of \$3 a unit and standard labour cost of \$16. Materials cost represents three pounds of raw materials at \$1 a pound; standard labour cost is two hours of labour at \$8 an hour. Overhead costs in the department are budgeted at \$10,000 a month plus \$2 a unit. Under normal conditions, volume is 7,000 units a month, but during October only 6,000

units were produced. The cost standards for the month would be as follows:

materials 6,000 units \times 3 lb \times \$1.00 per lb = \$18,000
labour 6,000 units \times 2 hr \times \$8.00 per hr = \$96,000
overhead 6,000 units \times \$2.00 + \$10,000 = \$22,000

The actual cost this month was \$17,850 for materials (17,000 pounds at \$1.05), \$101,250 for labour (12,500 hours at \$8.10 an hour), and \$23,000 for overhead. A summary report would show the following:

	actual	standard	variance
materials	\$17,850	\$18,000	\$150
labour	101,250	96,000	(5,250)
overhead	23,000	22,000	(1,000)
total	\$142,100	\$136,000	\$(6,100)

These variances are usually analyzed even further in order to identify the underlying causes. The labour variance, for example, can be seen to be the result of both high wage rates (\$8.10 instead of \$8.00) and high labour usage (12,500 hours instead of 12,000). The factory accountant ordinarily would measure the effect of the rate change in the following way:

actual labour cost = 12,500 \times \$8.10 = \$101,250
(actual hours \times actual wage rate)
actual labour hours at standard
wage rate = 12,500 \times \$8.00 = 100,000
labour rate variance = \$(1,250)

The labour usage variance would then be obtained as follows:

actual labour hours \times standard wage rate
= 12,500 \times \$8 = \$100,000
standard labour cost (standard labour hours
 \times standard wage rate) = 6,000 \times 2 \times \$8 = 96,000
labour usage variance = \$(4,000)

In most cases, the labour rate variance would not be reported to the department head, because it is not subject to his or her control.

Cost and profit analysis. Accountants share with many other people the task of analyzing cost and profit data in order to provide guidance in managerial decision making. Even if the analytical work is done largely by others, they have an interest in analytical methods because the systems they design must collect data in forms suitable for analysis.

Managerial decisions are based on comparisons of the estimated future results of the alternative courses of action that the decision maker is choosing among. Recorded historical accounting data, in contrast, reflect conditions and experience of the past. Furthermore, they are absolute, not comparative, in that they show the effects of one course of action but not whether these were better or worse than those that would have resulted from some other course.

For decision making, therefore, historical accounting data must be examined, modified, and placed on a comparative basis. Even estimated data, such as budgets and standard costs, must be examined to see whether the estimates are still valid and relevant to managerial comparisons. To a large extent, this job of review and restatement is an accounting responsibility. Accordingly, a major part of the accountant's preparation for the profession is devoted to the study of methods and principles of analysis for managerial decision making.

OTHER PURPOSES OF ACCOUNTING SYSTEMS

Accounting systems are designed mainly to provide information that managers and outsiders can use in decision making. They also serve other purposes: to produce operating documents, to protect the company's assets, and to provide data for company tax returns.

The accounting organization is responsible for preparing documents that contain instructions for a variety of tasks, such as payment of customer bills or preparing employee payrolls. It also must prepare documents that serve what might be called private information purposes, such as the employees' own records of their salaries and wages. Many of these documents also serve as sources of data for other accounting purposes, but they would have to be prepared even if no information reports were necessary. Measured

Document
preparation

by the number of people involved and the amount of time required, document preparation is one of accounting's biggest jobs.

Accounting systems must provide means of reducing the chance of losses of assets due to carelessness or dishonesty on the part of employees, suppliers, and customers. Asset protection devices are often very simple; for example, many restaurants use numbered meal checks so that waiters will not be able to submit one check to the customer and another, with a lower total, to the cashier. Other devices entail a partial duplication of effort or a division of tasks between two individuals to reduce the opportunity for unobserved thefts.

These are all part of the company's system of internal controls. Another important element in the internal control system is internal auditing. The task of internal auditors is to see whether prescribed data handling and asset protection procedures are being followed. To accomplish this, they usually observe some of the work as it is being performed and examine a sample of past transactions for accuracy and fidelity to the system. They may insert a set of fictitious data into the system to see whether the resulting output meets a predetermined standard. This technique is particularly useful in testing the validity of the programs that are used to process data through electronic computers.

Finally, the accounting system must provide data for use in the completion of the company's tax returns. This function is the concern of tax accounting. In some countries financial accounting must obey rules laid down for tax accounting by national tax laws and regulations, but no such requirement is imposed in the United States, and figures prepared for tax purposes often diverge from those submitted to shareholders and others. "Taxable income" is a legal concept rather than an accounting concept. Tax laws include incentives to encourage companies to do certain things and discourage them from doing others. Accordingly, what is "income" or "capital" to a tax agency may be far different from the accountant's measures of these same concepts.

BIBLIOGRAPHY

Classics: R. GENE BROWN and KENNETH S. JOHNSTON, *Paciolo on Accounting* (1963, reprinted 1984), an annotated translation of the treatise, published in 1494, that is widely accepted as the foundation stone of modern accounting and bookkeeping systems, with biographical notes and a reproduction of the original manuscript; A.C. LITTLETON, *Accounting Evolution to 1900* (1933, reprinted 1981), a scholarly, well-written analysis of the development of accounting from the Renaissance to modern times; JOHN B. CANNING, *Economics of Accountancy* (1929, reprinted 1978), an early landmark in the development of 20th-century accounting thought and one of the first systematic attempts to build a structure of accounting on the basis of economic theory; E. SCHMALENBACH, *Dynamic Accounting* (1959, reprinted 1980), a translation of the 12th ed. of the most influential accounting book published in Germany in the first half of the 20th century, which had a measurable impact on the accounting systems in use in most continental European countries and shaped many of the uniform accounting schemes that have been proposed or adopted in individual European countries. EDGAR O. EDWARDS and PHILIP W. BELL, *The Theory and Measurement of Business Income* (1961), a critical review of conventional accounting measurements, with a detailed examination of possible alternative measurement systems.

Aesthetics

Aesthetics (or esthetics) may be vaguely defined as the philosophical study of beauty and taste. To define its subject matter more precisely is, however, immensely difficult. Indeed, it could be said that self-definition has been the major task of modern aesthetics. We are acquainted with an interesting and puzzling realm of experience: the realm of the beautiful, the ugly, the sublime, and the elegant; of taste, criticism, and fine art; and of contemplation, sensuous enjoyment, and charm. In all these phenomena we believe that similar principles are operative and that similar interests are engaged. If we

are mistaken in this impression, we will have to dismiss such ideas as beauty and taste as having only peripheral philosophical interest. Alternatively, if our impression is correct and philosophy corroborates it, we will have discovered the basis for a philosophical aesthetics.

This article seeks to clarify the nature of modern aesthetics and to delineate its underlying principles and concerns. Although the article focusses on Western aesthetic thought and its development, it surveys some of the seminal features of Marxist and Eastern aesthetics.

The article is divided into the following sections:

The nature and scope of aesthetics	9
Three approaches to aesthetics	9
The aesthetic recipient	10
The aesthetic object	10
The aesthetic experience	11

THE NATURE AND SCOPE OF AESTHETICS

Aesthetics is broader in scope than the philosophy of art, which comprises one of its branches. It deals not only with the nature and value of the arts but also with those responses to natural objects that find expression in the language of the beautiful and the ugly. A problem is encountered at the outset, however, for terms such as beautiful and ugly seem too vague in their application and too subjective in their meaning to divide the world successfully into those things that do, and those that do not, exemplify them. Almost anything might be seen as beautiful by someone or from some point of view; and different people apply the word to quite disparate objects for reasons that often seem to have little or nothing in common. It may be that there is some single underlying belief that motivates all of their judgments. It may also be, however, that the term beautiful has no sense except as the expression of an attitude, which is in turn attached by different people to quite different states of affairs.

Moreover, in spite of the emphasis laid by philosophers on the terms beautiful and ugly, it is far from evident that they are the most important or most useful either in the discussion and criticism of art or in the description of that which appeals to us in nature. To convey what is significant in a poem we might use such terms as ironical, moving, expressive, balanced, and harmonious. Likewise, in describing a favourite stretch of countryside, we may find more use for peaceful, soft, atmospheric, harsh, and evocative, than for beautiful. The least that should be said is that beautiful belongs to a class of terms from which it has been chosen as much for convenience' sake as for any sense that it captures what is distinctive of the class.

At the same time, there seems to be no clear way of delimiting the class in question—not at least in advance of theory. Aesthetics must therefore cast its net more widely than the study either of beauty or of other aesthetic concepts if it is to discover the principles whereby it is to be defined. We are at once returned, therefore, to the vexing question of our subject matter: What should a philosopher study in order to understand such ideas as beauty and taste?

Three approaches to aesthetics. Three broad approaches have been proposed in answer to that question, each intuitively reasonable:

1. The study of the aesthetic concepts, or, more specifically, the analysis of the "language of criticism," in which particular judgments are singled out and their logic and justification displayed. In his famous treatise *On the Sublime and Beautiful* (1757), Edmund Burke attempted to draw a distinction between two aesthetic concepts, and, by studying the qualities that they denoted, to analyze the separate human attitudes that are directed toward them. Burke's distinction between the sublime and the beautiful was extremely influential, reflecting as it did the prevailing style of contemporary criticism. In more recent times, philosophers have tended to concentrate on the concepts of modern literary theory—namely, those such as representation, expression, form, style, and sentimentality. The study invariably has a dual purpose: to show how (if at all) these descriptions might be justified, and to show what is distinctive in the human experiences that are expressed in them.

2. A philosophical study of certain states of mind—responses, attitudes, emotions—that are held to be involved in aesthetic experience. Thus, in the seminal work of modern aesthetics *Kritik der Urteilsskraft* (1790; *The Critique of Judgment*), Immanuel Kant located the distinctive features of the aesthetic in the faculty of "judgment," whereby we take up a certain stance toward objects, separating them from our scientific interests and our practical concerns. The key to the aesthetic realm lies therefore in a certain "disinterested" attitude, which we may assume toward any object and which can be expressed in many contrasting ways.

More recently, philosophers—distrustful of Kant's theory of the faculties—have tried to express the notions of an "aesthetic attitude" and "aesthetic experience" in other ways, relying upon developments in philosophical psychology that owe much to G.W.F. Hegel, the Phenomenologists, and Ludwig Wittgenstein (more precisely, the Wittgenstein of the *Philosophical Investigations* [1953]). In considering these theories (some of which are discussed below) a crucial distinction must be borne in mind: that between philosophy of mind and empirical psychology. Philosophy is not a science, because it does not investigate the causes of phenomena. It is an a priori or conceptual investigation, the underlying concern of which is to identify rather than to explain. In effect, the aim of the

philosopher is to give the broadest possible description of the things themselves, so as to show how we must understand them and how we ought to value them. The two most prominent current philosophical methods—Phenomenology and conceptual analysis—tend to regard this aim as distinct from, and (at least in part) prior to, the aim of science. For how can we begin to explain what we have yet to identify? While there have been empirical studies of aesthetic experience (exercises in the psychology of beauty), these form no part of aesthetics as considered in this article. Indeed, the remarkable paucity of their conclusions may reasonably be attributed to their attempt to provide a theory of phenomena that have yet to be properly defined.

3. The philosophical study of the aesthetic object. This approach reflects the view that the problems of aesthetics exist primarily because the world contains a special class of objects toward which we react selectively and which we describe in aesthetic terms. In effect, the existence of such objects constitutes the prime phenomenon; aesthetic experience should thus be described according to them and the meaning of aesthetic concepts be determined by them. The usual class singled out as prime aesthetic objects is that comprising works of art. All other aesthetic objects (landscapes, faces, *objets trouvés*, and the like) tend to be included in this class only because, and to the extent that, they can be seen as art (or so it is claimed).

If we adopt such an approach, then there ceases to be a real distinction between aesthetics and the philosophy of art; and aesthetic concepts and aesthetic experience deserve their names through being, respectively, the concepts required in understanding works of art and the experience provoked by confronting them. Thus Hegel, perhaps the major philosophical influence on modern aesthetics, considered the main task of aesthetics to reside in the study of the various forms of art and of the spiritual content peculiar to each. Much of recent aesthetics has been similarly focussed on artistic problems, and it could be said that it is now orthodox to consider aesthetics entirely through the study of art.

The third approach to aesthetics does not require this concentration upon art. Even someone who considered art to be no more than one manifestation of aesthetic value—perhaps even a comparatively insignificant manifestation—may believe that the first concern of aesthetics is to study the objects of aesthetic experience and description and to find in them the true distinguishing features of the aesthetic realm. Unless we restrict the domain of aesthetic objects, however, it becomes extremely difficult to maintain that they have anything significant in common beyond the fact of inspiring a similar interest. This means that we should be compelled to adopt the second approach to aesthetics after all. And there seems no more plausible way of restricting the domain of aesthetic objects than through the concept of art.

The three approaches may lead to incompatible results. Alternatively, they may be in harmony. Once again, it can only be at the end point of our philosophy that we shall be able to decide. Initially, it must be assumed that the three approaches may differ substantially, or merely in emphasis, and thus that each question in aesthetics has a tripartite form.

The aesthetic recipient. Whichever approach we take, however, there is an all-important question upon the answer to which the course of aesthetics depends: the question of the recipient. Only beings of a certain kind have aesthetic interests and aesthetic experience, produce and appreciate art, employ such concepts as those of beauty, expression, and form. What is it that gives these beings access to this realm? The question is at least as old as Plato but received its most important modern exposition in the philosophy of Kant, who argued, first, that it is only rational beings who can exercise judgment—the faculty of aesthetic interest—and, second, that until exercised in aesthetic judgment rationality is incomplete. It is worth pausing to examine these two claims.

Rational beings are those, like us, whose thought and conduct are guided by reason; who deliberate about what to believe and what to do; and who affect each other's be-

liefs and actions through argument and persuasion. Kant argued that reason has both a theoretical and a practical employment, and that a rational being finds both his conduct and his thought inspired and limited by reason. The guiding law of rational conduct is that of morality, enshrined in the categorical imperative, which enjoins us to act only on that maxim which we can at the same time will as a universal law.

By virtue of practical reason, the rational being sees himself and others of his kind as subject to an order that is not that of nature: he lives responsive to the law of reason and sees himself as a potential member of a "kingdom of ends" wherein the demands of reason are satisfied. Moreover, he looks on every rational being—himself included—as made sacrosanct by reason and by the morality that stems from it. The rational being, he recognizes, must be treated always as an end in himself, as something of intrinsic value, and never as a mere object to be disposed of according to purposes that are not its own.

The capacity to see things as intrinsically valuable, irreplaceable, or ends in themselves is one of the important gifts of reason. But it is not exercised only practically or only in our dealings with other reasoning beings. It may also be exercised contemplatively toward nature as a whole. In this case, practical considerations are held in abeyance, and we stand back from nature and look on it with a disinterested concern. Such an attitude is not only peculiar to rational beings but also necessary to them. Without it, they have only an impoverished grasp of their own significance and of their relation to the world in which they are situated through their thoughts and actions. This disinterested contemplation and the experiences that arise from it acquaint us, according to Kant, with the ultimate harmony that exists between the world and our faculties. They therefore provide the ultimate guarantee, both of practical reasoning and of the understanding, by intimating to us directly that the world answers to our purposes and corresponds to our beliefs.

Disinterested contemplation forms, for Kant, the core of aesthetic experience and the ultimate ground of the judgment of beauty. He thus concludes (1) that only rational beings have aesthetic experience; (2) that every rational being needs aesthetic experience and is significantly incomplete without it; and (3) that aesthetic experience stands in fundamental proximity to moral judgment and is integral to our nature as moral beings.

Modern philosophers have sometimes followed Kant, sometimes ignored him. Rarely, however, have they set out to show that aesthetic experience is more widely distributed than the human race. For what could it mean to say of a cow, for example, that in staring at a landscape it is moved by the sentiment of beauty? What in a cow's behaviour or mental composition could manifest such a feeling? While a cow may be uninterested, it cannot surely be disinterested, in the manner of a rational being for whom disinterest is the most passionate form of interest. It is in pondering such considerations that one comes to realize just how deeply embedded in human nature is the aesthetic impulse, and how impossible it is to separate this impulse from the complex mental life that distinguishes human beings from beasts. This condition must be borne in mind by any philosopher seeking to confront the all-important question of the relation between the aesthetic and the moral.

The aesthetic object. The third approach to aesthetics begins with a class of aesthetic objects and attempts thereafter to show the significance of that class to those who selectively respond to it. The term aesthetic object, however, is ambiguous, and, depending on its interpretation, may suggest two separate programs of philosophical aesthetics. The expression may denote either the "intentional" or the "material" object of aesthetic experience. This distinction, a legacy of the Scholastic philosophers of the Middle Ages, has played a major role in recent Phenomenology. It may be briefly characterized as follows: When someone responds to object *O*, his response depends upon a conception of *O* that may, in fact, be erroneous. *O* is then the material object of his response, while his conception defines the intentional object. (The term intentional

Kant's conception of aesthetic experience

Two types of objects

Kant's notion of judgment

comes from the Latin *intendere*, “to aim.”) To cite an example: A person is frightened by a white cloth flapping in a darkened hall, taking it for a ghost. Here, the material object of the fear is the cloth, while the intentional object is a ghost. A philosophical discussion of fear may be presented as a discussion of things feared, but if so, the phrase denotes the class of intentional objects of fear and not the (infinitely varied and infinitely disordered) class of material objects. In an important sense, the intentional object is part of a state of mind, whereas the material object always has independent (and objective) existence. If the expression “aesthetic object” is, therefore, taken in its intentional construction, the study of the aesthetic object becomes the study, not of an independently existing class of things, but of the aesthetic experience itself. It is in this sense that the term occurs in the writings of Phenomenologists (e.g., Mikel Dufrenne, *La Phénoménologie de l'expérience esthétique* [1953; *The Phenomenology of Aesthetic Experience*] and Roman Ingarden, *Das literarische Kunstwerk* [1931; *The Literary Work of Art*]), whose studies of the aesthetic object exemplify not the third, but the second, of the approaches considered above.

Which of those two approaches should be adopted? We can already see one reason for adopting the approach that puts the aesthetic experience first and examines the aesthetic object primarily as the intentional object of that experience. It is, after all, to experience that we must turn if we are to understand the value of the aesthetic realm—our reason for engaging with it, studying it, and adding to it. Until we understand that value, we will not know why we ought to construct such a concept as the aesthetic, still less why we should erect a whole branch of philosophy devoted to its analysis.

A further reason also suggests itself for rejecting the approach to aesthetics that sees it merely as the philosophy of art, because art, and the institutions that sustain it, are mutable and perhaps inessential features of the human condition. While we classify together such separate art forms as poetry, the novel, music, drama, painting, sculpture, and architecture, our disposition to do so is as much the consequence of philosophical theory as its premise. Would other people at other times and in other conditions have countenanced such a classification or seen its point? And if so, would they have been motivated by similar purposes, similar observations, and similar beliefs? We might reasonably be skeptical, for while there have been many attempts to find something in common—if only a “family resemblance”—between the various currently accepted art forms, they have all been both contentious in themselves and of little aesthetic interest. Considered materially (i.e., without reference to the experiences that we direct to them), the arts seem to have little in common except for those properties that are either too uninteresting to deserve philosophical scrutiny (the property, for example, of being artifacts) or else too vast and vague to be independently intelligible.

Consider the theory of Clive Bell (*Art*, 1914) that art is distinguished by its character as “significant form.” Initially attractive, the suggestion crumbles at once before the skeptic. When is form “significant”? The only answer to be extracted from Bell is this: “when it is art.” In effect, the theory reduces to a tautology. In any normal understanding of the words, a traffic warden is a significant form, at least to the motorist who sees himself about to receive a ticket. Thus, to explain Bell’s meaning, it is necessary to restrict the term significant to the significance (whatever that is) of art.

Moreover, it is of the greatest philosophical importance to attend not only to the resemblances between the art forms but also to their differences. It is true that almost anything can be seen from some point of view as beautiful. At the same time, however, our experience of beauty crucially depends upon a knowledge of the object in which beauty is seen. It is absurd to suppose that I could present you with an object that might be a stone, a sculpture, a box, a fruit, or an animal, and expect you to tell me whether it is beautiful before knowing what it is. In general we may say—in opposition to a certain tradition in aesthetics that finds expression in Kant’s theory—that our

sense of beauty is always dependent upon a conception of the object in the way that our sense of the beauty of the human figure is dependent upon a conception of that figure. Features that we should regard as beautiful in a horse—developed haunches, curved back, and so on—we should regard as ugly in a man, and those aesthetic judgments would be determined by our conception of what men and horses generally are, how they move, and what they achieve through their movements. In a similar way, features that are beautiful in a sculpture may not be beautiful in a work of architecture, where an idea of function seems to govern our perceptions. In every case, our perception of the beauty of a work of art requires us to be aware of the distinctive character of each art form and to put out of mind, as largely irrelevant to our concerns, the overarching category of art to which all supposedly belong. But if that is so, it is difficult to see how we could cast light upon the realm of aesthetic interest by studying the concept of art.

Whether or not that concept is a recent invention, it is certainly a recent obsession. Medieval and Renaissance philosophers who approached the problems of beauty and taste—e.g., St. Thomas Aquinas, Peter Abelard, and even Leon Battista Alberti—often wrote of beauty without reference to art, taking as their principal example the human face and body. The distinctively modern approach to aesthetics began to take shape during the 18th century, with the writings on art of Jean-Jacques Rousseau, Charles Batteux, and Johann Winckelmann and the theories of taste proposed by the 3rd Earl of Shaftesbury, Francis Hutcheson, Lord Kames (Henry Home), and Archibald Alison. This approach materialized not only because of a growing interest in fine art as a uniquely human phenomenon but also because of the awakening of feelings toward nature, which marked the dawn of the Romantic movement. In Kant’s aesthetics, indeed, nature has pride of place as offering the only examples of what he calls “free beauty”—i.e., beauty that can be appreciated without the intermediary of any polluting concept. Art, for Kant, was not merely one among many objects of aesthetic interest; it was also fatally flawed in its dependence upon intellectual understanding.

Even without taking that extreme position, it is difficult to accept that the fragile and historically determined concept of art can bear the weight of a full aesthetic theory. Leaving aside the case of natural beauty, we must still recognize the existence of a host of human activities (dress, decoration, manners, ornament) in which taste is of the essence and yet which seems totally removed from the world of fine art. It has been common, following the lead of Batteux, to make a distinction between the fine and the useful arts, and to accommodate the activities just referred to under the latter description; but it is clear that this is no more than a gesture and that the points of similarity between the art of the dressmaker and that of the composer are of significance only because of a similarity in the interests that these arts are meant to satisfy.

The aesthetic experience. Such considerations point toward the aforementioned approach that begins with the aesthetic experience as the most likely to capture the full range of aesthetic phenomena without begging the important philosophical questions about their nature. Can we then single out a faculty, an attitude, a mode of judgment, or a form of experience that is distinctively aesthetic? And if so, can we attribute to it the significance that would make this philosophical enterprise both important in itself and relevant to the many questions posed by beauty, criticism, and art?

Taking their cue from Kant, many philosophers have defended the idea of an aesthetic attitude as one divorced from practical concerns, a kind of “distancing,” or standing back, as it were, from ordinary involvement. The classic statement of this position is Edward Bullough’s “‘Psychical Distance’ as a Factor in Art and an Aesthetic Principle,” an essay published in the *British Journal of Psychology* in 1912. While there is certainly something of interest to be said along those lines, it cannot be the whole story. Just what kind of distance is envisaged? Is the lover distanced from his beloved? If not, by what right

Factors involved in the perception of beauty

The notion of distance

does he call her beautiful? Does distance imply a lack of practical involvement? If such is the case, how can we ever take up an aesthetic attitude to those things that have a purpose for us—things such as a dress, building, or decoration? But if these are not aesthetic, have we not paid a rather high price for our definition of this word—the price of detaching it from the phenomena that it was designed to identify?

Kant's own formulation was more satisfactory. He described the recipient of aesthetic experience not as distanced but as disinterested, meaning that the recipient does not treat the object of enjoyment either as a vehicle for curiosity or as a means to an end. He contemplates the object as it is in itself and "apart from all interest." In a similar spirit, Arthur Schopenhauer argued that a person could regard anything aesthetically so long as he regarded it in independence of his will—that is, irrespective of any use to which he might put it. Regarding it thus, a person could come to see the Idea that the object expressed, and in this knowledge consists aesthetic appreciation (*Die Welt als Wille und Vorstellung* [1819; *The World as Will and Idea*]).

Of a piece with such a view is the popular theory of art as a kind of "play" activity, in which creation and appreciation are divorced from the normal urgencies of existence and surrendered to leisure. "With the agreeable, the good, the perfect," wrote Friedrich Schiller, "man is merely in earnest, but with beauty he plays" (*Briefe über die ästhetische Erziehung des Menschen* [1794–95; *Letters on the Aesthetic Education of Man*]).

Such thoughts have already been encountered. The problem is to give them philosophical precision. They have recurred in modern philosophy in a variety of forms—for example, in the theory that the aesthetic object is always considered for its own sake, or as a unique individual rather than a member of a class. Those particular formulations have caused some philosophers to treat aesthetic objects as though they were endowed with a peculiar metaphysical status (see below *The work of art*). Alternatively, it is sometimes argued that the aesthetic experience has an intuitive character, as opposed to the conceptual character of scientific thought or the instrumental character of practical understanding.

The simplest way of summarizing this approach to aesthetics is in terms of two fundamental propositions:

1. The aesthetic object is an object of sensory experience and enjoyed as such: it is heard, seen, or (in the limiting case) imagined in sensory form.

2. The aesthetic object is at the same time contemplated: its appearance is a matter of intrinsic interest and studied not merely as an object of sensory pleasure but also as the repository of significance and value.

The first of these propositions explains the word aesthetic, which was initially used in this connection by the Leibnizian philosopher Alexander Baumgarten in *Meditationes Philosophicae de Nonnullis ad Poema Pertinentibus* (1735; *Reflections on Poetry*). Baumgarten borrowed the Greek term for sensory perception (*aisthēsis*) in order to denote a realm of concrete knowledge (the realm, as he saw it, of poetry), in which a content is communicated in sensory form. The second proposition is, in essence, the foundation of taste. It describes the motive of our attempt to discriminate rationally between those objects that are worthy of contemplative attention and those that are not.

Almost all of the aesthetic theories of post-Kantian Idealism depend upon those two propositions and try to explain the peculiarities of aesthetic experience and aesthetic judgment in terms of the synthesis of the sensory and the intellectual that they imply—the synthesis summarized in Hegel's theory of art as "the sensuous embodiment of the Idea." Neither proposition is particularly clear. Throughout the discussions of Kant and his immediate following, the "sensory" is assimilated to the "concrete," the "individual," the "particular," and the "determinate," while the "intellectual" is assimilated to the "abstract," the "universal," the "general," and the "indeterminate"—assimilations that would nowadays be regarded with extreme suspicion. Nevertheless, subsequent theories have repeatedly returned to the idea that aesthetic experience

involves a special synthesis of intellectual and sensory components, and that both its peculiarities and its value are to be derived from such a synthesis.

The idea at once gives rise to paradoxes. The most important was noticed by Kant, who called it the antinomy of taste. As an exercise of reason, he argued, aesthetic experience must inevitably tend toward a reasoned choice and therefore must formulate itself as a judgment. Aesthetic judgment, however, seems to be in conflict with itself. It cannot be at the same time aesthetic (an expression of sensory enjoyment) and also a judgment (claiming universal assent). Yet all rational beings, by virtue of their rationality, seem disposed to make these judgments. On the one hand, they feel pleasure in some object, and this pleasure is immediate, not based, according to Kant, in any conceptualization or in any inquiry into cause, purpose, or constitution. On the other hand, they express their pleasure in the form of a judgment, speaking "as if beauty were a quality of the object," and so representing their pleasure as objectively valid. But how can this be so? The pleasure is immediate, based in no reasoning or analysis. So what permits this demand for universal agreement?

However we approach the idea of beauty, we find this paradox emerging. Our ideas, feelings, and judgments are called aesthetic precisely because of their direct relation to sensory enjoyment. Hence, no one can judge the beauty of an object that he has never encountered. Scientific judgments, like practical principles, can be received "second hand." I can, for example, take you as my authority for the truths of physics or for the utility of railways. But I cannot take you as my authority for the merits of Leonardo or Mozart if I have not seen or heard works by either artist. It would seem to follow from this that there can be no rules or principles of aesthetic judgment, since I must feel the pleasure immediately in the perception of the object and cannot be talked into it by any grounds of proof. It is always experience, and never conceptual thought, that gives the right to aesthetic judgment, so that anything that alters the experience of an object alters its aesthetic significance as well. As Kant put it, aesthetic judgment is "free from concepts," and beauty itself is not a concept.

Such a conclusion, however, seems to be inconsistent with the fact that aesthetic judgment is a form of judgment. When I describe something as beautiful, I do not mean merely that it pleases me: I am speaking about it, not about myself, and, if challenged, I try to find reasons for my view. I do not explain my feeling but give grounds for it by pointing to features of its object. Any search for reasons has the "universalizing" character of rationality: I am in effect saying that others, insofar as they are rational, ought to feel exactly the same delight as I feel. Being disinterested, I have put aside my interests, and with them everything that makes my judgment relative to me. But, if that is so, then "the judgment of taste is based on concepts, for otherwise there could be no room even for contention in the matter, or for the claim to the necessary agreement of others."

In short, the expression aesthetic judgment seems to be a contradiction in terms, denying in the first term precisely that reference to rational considerations that it affirms in the second. This paradox, which we have expressed in Kant's language, is not peculiar to the philosophy of Kant. On the contrary, it is encountered in one form or another by every philosopher or critic who takes aesthetic experience seriously, and who therefore recognizes the tension between the sensory and the intellectual constraints upon it. On the one hand, aesthetic experience is rooted in the immediate sensory enjoyment of its object through an act of perception. On the other, it seems to reach beyond enjoyment toward a meaning that is addressed to our reasoning powers and that seeks judgment from them. Thus criticism, the reasoned justification of aesthetic judgment, is an inevitable upshot of aesthetic experience. Yet, critical reasons can never be merely intellectual; they always contain a reference to the way in which an object is perceived.

Two related paradoxes also emerge from the same basic conception of the aesthetic experience. The first was given extended consideration by Hegel, who argued, in his *Vorlesungen über die Aesthetik* (1832; "Lectures on

Antinomy
of taste

Art as
play

Hegel's
conception
of form

Aesthetics"; Eng. trans., *Philosophy of Fine Art*), roughly as follows: Our sensuous appreciation of art concentrates upon the given "appearance"—the "form." It is this that holds our attention and that gives to the work of art its peculiar individuality. Because it addresses itself to our sensory appreciation, the work of art is essentially concrete, to be understood by an act of perception rather than by a process of discursive thought. At the same time, our understanding of the work of art is in part intellectual; we seek in it a conceptual content, which it presents to us in the form of an idea. One purpose of critical interpretation is to expound this idea in discursive form—to give the equivalent of the content of the work of art in another, nonsensuous idiom. But criticism can never succeed in this task, for, by separating the content from the particular form, it abolishes its individuality. The content presented then ceases to be the exact content of that work of art. In losing its individuality, the content loses its aesthetic reality; it thus ceases to be a reason for attending to the particular work of art that first attracted our critical attention. It cannot be this that we saw in the original work and that explained its power over us. For this content, displayed in the discursive idiom of the critical intellect, is no more than a husk, a discarded relic of a meaning that eluded us in the act of seizing it. If the content is to be the true object of aesthetic interest, it must remain wedded to its individuality: it cannot be detached from its "sensuous embodiment" without being detached from itself. Content is, therefore, inseparable from form and form in turn inseparable from content. (It is the form that it is only by virtue of the content that it embodies.)

Relation-
ship
between
form and
content

Hegel's argument is the archetype of many, all aimed at showing that it is both necessary to distinguish form from content and also impossible to do so. This paradox may be resolved by rejecting either of its premises, but, as with Kant's antinomy, neither premise seems dispensable. To suppose that content and form are inseparable is, in effect, to dismiss both ideas as illusory, since no two works of art can then share either a content or a form—the form being definitive of each work's individuality. In this case, no one could ever justify his interest in a work of art by reference to its meaning. The intensity of aesthetic interest becomes a puzzling, and ultimately inexplicable, feature of our mental life. If, on the other hand, we insist that content and form are separable, we shall never be able to find, through a study of content, the reason for attending to the particular work of art that intrigues us. Every work of art stands proxy for its paraphrase. An impassable gap then opens between aesthetic experience and its ground, and the claim that aesthetic experience is intrinsically valuable is thrown in doubt.

The
"heresy of
para-
phrase"

A related paradox is sometimes referred to as the "heresy of paraphrase," the words being those of the U.S. literary critic Cleanth Brooks (*The Well Wrought Urn*, 1949). The heresy is that of assuming that the meaning of a work of art (particularly of poetry) can be paraphrased. According to Brooks, who here followed an argument of Benedetto Croce, the meaning of a poem consists precisely in what is not translatable. Poetic meaning is bound up with the particular disposition of the words—their sound, rhythm, and arrangement—in short, with the "sensory embodiment" provided by the poem itself. To alter that embodiment is to produce either another poem (and therefore another meaning) or something that is not a work of art at all, and which therefore lacks completely the kind of meaning for which works of art are valued. Hence no poetry is translatable, and no critic can do better than to point to the objective features of the poem that most seem to him to be worthy of attention. Yet, that result too is paradoxical. For what does the critic see in those objective features and how is his recommendation to be supported? Why should we attend to poetry at all if nothing can be said about its virtues save only "look!"? Why look at a poem rather than an advertisement, a mirror, or a blade of grass? Everything becomes equally worthy of attention, since nothing can be said that will justify attention to anything.

The role of imagination. Such paradoxes suggest the need for a more extensive theory of the mind than has been so far assumed. We have referred somewhat loosely

to the sensory and intellectual components of human experience but have said little about the possible relations and dependencies that exist between them. Perhaps, therefore, the paradoxes result only from our impoverished description of the human mind and are not intrinsic to the subject matter of aesthetic interest.

Many modern philosophers have at this point felt the need to invoke imagination, either as a distinct mental "faculty" (Kant) or as a distinctive mental operation by virtue of which thought and experience may be united. For Empiricist philosophers (such as David Hume, Joseph Addison, Archibald Alison, and Lord Kames), imagination involves a kind of "associative" process, whereby experiences evoke ideas, and so become united with them. For Kant and Hegel, imagination is not associative but constitutive—part of the nature of the experience that expresses it.

Once again it is useful to begin from Kant, who distinguished two uses of the imagination: the first in ordinary thought and perception, the second in aesthetic experience. When I look before me and see a book, my experience, according to Kant, embodies a "synthesis." It contains two elements: the "intuition" presented to the senses and the "concept" ("book"), contributed by the understanding. The two elements are synthesized by an act of the imagination that constitutes them as a single experience—the experience of seeing a book. Here imagination remains bound by the concepts of the understanding, which is to say that how I see the world depends upon my disposition to form determinate beliefs about it—in this case, the belief that there is a book before me. In aesthetic experience, however, imagination is free from concepts and engages in a kind of free play. This free play of the imagination enables me to bring concepts to bear on an experience that is, in itself, free from concepts. Thus there are two separate ways in which the content of experience is provided: one in ordinary perception, the other in aesthetic experience. In both cases the operative factor, in holding thought and sensation together, is the imagination.

Whether such theories can cast light on the mysterious unity between the intellectual and the sensory that we observe in aesthetic experience remains doubtful. The argument for saying that there is a single process of imagination involved in all perception, imagery, and remembering seems to consist only in the premise (undoubtedly true) that in these mental processes thought and experience are often inseparable. But to suppose therefore that there is some one "faculty" involved in forging the connection between them is to fail to take seriously the fact that they are inseparable.

Nevertheless, even if we find this general invocation of imagination, as the "synthesizing force" within perception, vacuous or unilluminating, we may yet feel that the imagination has some special role to play in aesthetic experience and that the reference to imagination has some special value in explaining the precise way in which a content and an experience become "fused" (to use George Santayana's term). Whether or not Kant was right to refer to a free play of imagination in aesthetic experience, there certainly seems to be a peculiarly creative imagination that human beings may exercise and upon which aesthetic experience calls. It is an exercise of creative imagination to see a face in a picture, since that involves seeing in defiance of judgment—seeing what one knows not to be there. It is not in the same sense an imaginative act to see a face in something that one also judges to be a face. This creative capacity is what Jean-Paul Sartre is referring to in *L'Imaginaire: Psychologie phénoménologique de l'imagination* (1940; "The Imaginary: The Phenomenological Psychology of the Imagination"; Eng. trans., *The Psychology of Imagination*) when he describes imagining as "the positing of an object as a nothingness"—as not being. In memory and perception we take our experience "for real." In imagination we contribute a content that has no reality beyond our disposition to "see" it, and it is clear that this added content is frequently summoned by art when, for example, we see the face in a picture or hear the emotion in a piece of music.

Recent work in aesthetics, to some extent inspired by the

Creative
imagina-
tion

seminal writings of Sartre and Wittgenstein, has devoted considerable attention to the study of creative imagination. The hope has been to provide the extra ingredient in aesthetic experience that bridges the gap between the sensory and the intellectual and at the same time shows the relation between aesthetic experience and the experience of everyday life—an enterprise that is in turn of the first importance for any study that seeks to describe the moral significance of beauty.

Consider, for example, the spectator at Shakespeare's *King Lear*. He sees before him an actor who, by speaking certain lines and making certain gestures, earns his bread. But that is not all that he sees. He also sees a hoary king, cast down by age, pride, and weakness, who rages against the depravity of man. Yet the spectator knows that, in a crucial sense, there is no such king before him. It is intellectual understanding, not psychical distance, that prevents him from stepping onto the stage to offer his assistance. He knows that the scene he enjoys is one that he contributes, albeit under the overwhelming compulsion induced by the actor and his lines. The spectator is being shown something that is outside the normal commerce of theoretical and practical understanding, and he is responding to a scene that bears no spatial, temporal, or causal relation to his own experience. His response is quintessentially aesthetic. For what interest could he have in this scene other than an interest in it for its own sake, for what it is in itself? At the same time, what it is in itself involves what it shows in general. In imaginatively conjuring this scene the spectator draws upon a wealth of experience, which is brought to mind and, as it were, condensed for him into the imaginative perception of the play. (Hence, Aristotle believed poetry is more general than history, since its concreteness is not that of real events, but rather of imaginary episodes constructed so as to typify human destiny in exemplary representations.)

Such an exercise of the imagination clearly has much to tell us about the nature of aesthetic experience. Whether or not it could found a theory of the "missing link" between sensory enjoyment and intellectual understanding, it at least provides a paradigm of the relation between aesthetic experience and the experience of everyday life. The former is an imaginative reconstruction of the latter, which becomes interesting for its own sake precisely because—however realistic—it is not real.

Emotion, response, and enjoyment. It is natural to suppose that a spectator's response to *King Lear* is at least in part emotional, and that emotion plays a crucial role both in the enjoyment of art and in establishing the value of art. Moreover, it is not only art that stirs our emotions in the act of aesthetic attention: the same is or may be true of natural beauty whether that of a face or of a landscape. These things hold our attention partly because they address themselves to our feelings and call forth a response which we value both for itself and for the consolation that we may attain through it. Thus we find an important philosophical tradition according to which the distinctive character of aesthetic experience is to be found in distinctively "aesthetic" emotions.

This tradition has ancient origins. Plato banished the poets from his ideal republic partly because of their capacity to arouse futile and destructive emotions, and in his answer to Plato, Aristotle argued that poetry, in particular tragic poetry, was valuable precisely because of its emotional effect. This idea enabled Aristotle to pose one of the most puzzling problems in aesthetics—the problem of tragedy—and to offer a solution. How can I willingly offer myself to witness scenes of terror and destruction? And how can I be said to enjoy the result, set store by it, or accord to it a positive value? Aristotle's answer is brief. He explains that by evoking pity and fear a tragedy also "purges" those emotions, and that is what we enjoy and value:

Tragedy, then, is an imitation of an action that is serious, complete, and of a certain magnitude; in language embellished with each kind of artistic ornament, the several kinds being found in separate parts of the play; in the form of action, not of narrative; through pity and fear effecting the proper purgation of these emotions.

Aristotle implies that this purgation (*katharsis*) is not unpleasant to us precisely because the fictional and formalized nature of the action sets it at a distance from us. We can allow ourselves to feel what we normally shun to feel precisely because no one is really threatened (or at least no one real is threatened).

Attractive though that explanation may seem, it immediately encounters a serious philosophical problem. It is a plausible tenet of philosophical psychology that emotions are founded on beliefs: fear on the belief that one is threatened, pity on the belief that someone is miserable, jealousy on the belief that one has a rival, and so forth. In the nature of things, however, these beliefs do not exist in the theatre. Confronted by fiction, I am relieved precisely of the pressure of belief, and it is this condition that permits the Aristotelian *katharsis*. How, then, can I be said to experience pity and fear when the beliefs requisite to those very emotions are not present? More generally, how can my responses to the fictions presented by works of art share the structure of my everyday emotions, and how can they impart to those emotions a new meaning, force, or resolution?

Various answers have been proposed to that question. Samuel Taylor Coleridge, for example, argued that our response to drama is characterized by a "willing suspension of disbelief," and thus involves the very same ingredient of belief that is essential to everyday emotion (*Biographia Literaria*, 1817). Coleridge's phrase, however, is consciously paradoxical. Belief is characterized precisely by the fact that it lies outside the will: I can command you to imagine something but not to believe it. For this reason, a suspension of disbelief that is achieved "willingly" is at best a highly dubious example of belief. In fact, the description seems to imply, not belief, but rather imagination, thus returning us to our problem of the relation between emotions directed to reality and those directed to merely imaginary scenes.

This is part of a much larger problem—namely, that of the relation between aesthetic and everyday experience. Two extreme positions serve to illustrate this problem. According to one, art and nature appeal primarily to our emotions: they awaken within us feelings of sympathy, or emotional associations, which are both pleasant in themselves and also instructive. We are made familiar with emotional possibilities, and, through this imaginative exercise, our responses to the world become illuminated and refined. This view, which provides an immediate and satisfying theory of the value of aesthetic experience, has been espoused in some form or other by many of the classical British Empiricists (Shaftesbury, Hume, Addison, Lord Kames, Alison, and Burke, to cite only a few). It is also related to the critical theories of writers such as Coleridge, Matthew Arnold, and F.R. Leavis, whose criticism would make little or no sense without the supposition that works of art have the power to correct and corrupt our emotions.

According to the opposite view, aesthetic interest, because it focusses on an object for its own sake, can involve no interest in "affect." To be interested in a work of art for the sake of emotion is to be interested in it as a means and, therefore, not aesthetically. In other words, true aesthetic interest is autonomous, standing outside the current of ordinary human feeling—an attitude of pure contemplation or pure "intuition" that isolates its object from the stream of common events and perceives it in its uniqueness, detached, unexplained, and inexplicable. This position has been taken in modern times by Benedetto Croce and, following him, by R.G. Collingwood, whose resolute defense of the autonomy of aesthetic experience was also associated with a theory of the autonomy of art. Art is not only seen as an end in itself but it is an end in itself, in a profound and significant sense that distinguishes art from all its false substitutes (and, in particular, from craft, which for Collingwood is not an end but merely a means).

Between those two poles, a variety of intermediate positions might be adopted. It is clear, in any case, that many questions have been begged by both sides. The aesthetic of sympathy, as Croce called it, has enormous difficulties

The relation between aesthetic and everyday experience

Collingwood's defense of the autonomy of aesthetic experience

Aristotle's interpretation of tragedy

in describing the emotions that are awakened in aesthetic experience, particularly the emotions that we are supposed to feel in response to such abstract arts as music. With what am I sympathizing when I listen to a string quartet or a symphony? What emotion do I feel? Moreover, the position encounters all the difficulties already noted in forging a link between the imaginary and the real.

The aesthetic of autonomy, as we may call it, encounters complementary difficulties and, in particular, the difficulty of showing why we should value either aesthetic experience itself or the art that is its characteristic object. Moreover, it assumes that whenever I take an emotional interest in something, I am interested in it for the sake of emotion, a false inference that would imply equally that the lover is interested only in his love or the angry man only in his anger. Collingwood thus dismisses "amusement art," on the spurious ground that to be interested in a work of art for the sake of amusement is to be interested not in the work but only in the amusement that it inspires. That is to say, it is to treat the work as a means to feeling rather than as an end in itself. Such a conclusion is entirely unwarranted. Amusement is, in fact, a species of interest in something for its own sake: I laugh not for the sake of laughter, but for the sake of the joke. While I may be interested in an object for the sake of the emotion that it arouses, the case is peculiar—the case, in fact, of sentimentality, often dismissed by moralists as a spiritual corruption and equally by critics as a corruption of the aims of art.

The difficulties for both views are brought out by a fundamental aesthetic category: that of enjoyment. Whatever the ultimate value of aesthetic experience, we pursue it in the first instance for enjoyment's sake. Aesthetic experience includes, as its central instance, a certain kind of pleasure. But what kind of pleasure? While our emotions and sympathies are sometimes pleasurable, this is by no means their essential feature; they may equally be painful or neutral. How then does the aesthetic of sympathy explain the pleasure that we take, and must take, in the object of aesthetic experience? And how does the aesthetic of autonomy avoid the conclusion that all such pleasure is a violation of its strict requirement that we should be interested in the aesthetic object for its own sake alone? Neither theory seems to be equipped, as it stands, either to describe this pleasure or to show its place in the appreciation of art.

THE WORK OF ART

As the above discussion illustrates, it is impossible to advance far into the theory of aesthetic experience without encountering the specific problems posed by the experience of art. Whether or not we think of art as the central or defining example of the aesthetic object, there is no doubt that it provides the most distinctive illustration both of the elusive nature and the importance of aesthetic interest. With the increasing attention paid to art in a corrupted world where little else is commonly held to be spiritually significant, it is not surprising that the philosophy of art has increasingly begun to displace the philosophy of natural beauty from the central position accorded to the latter by the philosophers and critics of the 18th century. Nor is this shift in emphasis to be regretted; for the existence of art as a major human institution reminds us of the need for a theory that will attribute more to aesthetic experience than enjoyment and that will explain the profundity of the impressions that we receive from beauty—impressions that may provide both meaning and solace to those who experience them. It is thus worth reviewing some of the special problems in the philosophy of art that have most influenced contemporary aesthetics.

Understanding art. The use of the concept of understanding in describing the appreciation of art marks out an interesting distinction between art and natural beauty. A person may understand or fail to understand T.S. Eliot's *Four Quartets*, Michelangelo's "David," or Beethoven's *Ninth Symphony*, but he cannot understand or fail to understand the Highlands of Scotland, even when he finds them beautiful or ugly. Understanding seems to be a prerequisite to the full experience of art, and this has

suggested to many critics and philosophers that art is not so much an object of sensory experience as an instrument of knowledge. In particular, art seems to have the power both to represent reality and to express emotion, and some argue that it is through appreciating the properties of representation and expression that we recognize the meaning of art. At least, it might be supposed that, if we speak of understanding art, it is because we think of art as having content, something that must be understood by the appropriate audience.

The most popular approach to this concept of understanding is through a theory of art as a form of symbolism. But what is meant by this? Is such symbolism one thing or many? Is it a matter of evocation or convention, of personal response or linguistic rule? And what does art symbolize—ideas, feelings, objects, or states of affairs?

Representation, expression, and symbolism. Various theories have been proposed in answer to these questions, the most popular being that the forms of art are similar to language and are to be understood as language is understood, in terms of conventions and semantic rules. A few examples of contemporary theories that have described art in this way include Ernst Cassirer's philosophy of symbolic forms, Susanne K. Langer's theory of presentational symbols, and the works on semiology and semiotics, largely inspired by the writings of Roland Barthes, that have been fashionable in continental Europe. It seems important to review some of the arguments that have been employed both for and against the overall conception of art that such theories share.

In favour of the view, it is undeniable that many works of art are about the world in somewhat the way that language may be about the world. This is evident in the case of literature (which is itself an instance of natural language). It is no less evident in the case of painting. A portrait stands to its sitter in a relation that is not unlike that which obtains between a description and the thing described. Even if the majority of pictures are of, or about, entirely imaginary people, scenes, and episodes, this is no different from the case of literature, in which language is used to describe purely imaginary subjects. This relation between a work of art and its subject, captured in the word "about," is sometimes called representation—a term that owes its currency in aesthetics to Croce and Collingwood, who used it to draw the familiar contrast between representation and expression.

The concept of expression is variously analyzed. Its principal function in modern aesthetics, however, is to describe those aspects and dimensions of artistic meaning that seem not to fall within the bounds of representation, either because they involve no clear reference to an independent subject matter or because the connection between the subject and the artistic form is too close and inextricable to admit description in the terms appropriate to representation. Therefore, it is widely recognized that abstract art forms—music, abstract painting, architecture—may yet contain meaningful utterances, and most frequently philosophers and critics use terms such as expression in order to describe these elusive meanings. Music, in particular, is often said to be an expression of emotion and to gain much of its significance from that. Expression in such a case is unlike representation, according to many philosophers, in that it involves no descriptive component. An expression of grief does not describe grief but rather presents it, as it might be presented by a face or a gesture.

Expression must be distinguished from evocation. To say that a piece of music expresses melancholy is not to say that it evokes (arouses) melancholy. To describe a piece of music as expressive of melancholy is to give a reason for listening to it; to describe it as arousing melancholy is to give a reason for avoiding it. (Music that is utterly blank expresses nothing, but it may arouse melancholy.) Expression, where it exists, is integral to the aesthetic character and merit of whatever possesses it. For similar reasons, expression must not be confused with association, in spite of the reliance on the confusion by many 18th-century Empiricists.

The distinction between representation and expression is one of the most important conceptual devices in contem-

Expression
in art

Emphasis
on the
philosophy
of art

Distinction
between
representa-
tion and
expression

porary philosophy of art. Croce, who introduced it, sought to dismiss representation as aesthetically irrelevant and to elevate expression into the single, true aesthetic function. The first, he argued, is descriptive, or conceptual, concerned with classifying objects according to their common properties, and so done to satisfy our curiosity. The second, by contrast, is intuitive, concerned with presenting its subject matter (an "intuition") in its immediate concrete reality, so that we see it as it is in itself. In understanding expression, our attitude passes from mere curiosity to that immediate awareness of the concrete particular that is the core of aesthetic experience.

Later philosophers have been content merely to distinguish representation and expression as different modes of artistic meaning, characterized perhaps by different formal or semantic properties. Nelson Goodman of the United States is one such philosopher. His *Languages of Art* (1968) was the first work of analytical philosophy to produce a distinct and systematic theory of art. Goodman's theory has attracted considerable attention, the more so in that it is an extension of a general philosophical perspective, expounded in works of great rigour and finesse, that embraces the entire realm of logic, metaphysics, and the philosophy of science.

Goodman's
theory of
symbolism

Goodman, like many others, seeks the nature of art in symbolism and the nature of symbolism in a general theory of signs. (This second part of Goodman's aim is what Ferdinand de Saussure called semiology, the general science of signs [*Cours de linguistique générale*, 1916; *Course of General Linguistics*]). The theory derives from the uncompromising Nominalism expounded in Goodman's earlier works, a Nominalism developed under the influence of two other U.S. philosophers, Rudolf Carnap and W.V. Quine, but also showing certain affinities with the later philosophy of Wittgenstein. According to Goodman's general theory of signs, the relation between signs and the world can be described, like any relation, in terms of its formal structure, the objects related, and its genealogy. But, apart from that formal and factual analysis, there is nothing to be said. Words are labels that we attach to things, but the attempt to justify that practice merely repeats it: in using words, it presupposes precisely the justification that it aims to provide.

A corollary of this view is that relations of identical logical structure and identical genealogy between relevantly similar terms are really one and the same relation. Thus, if we assume that paintings, like words, are signs, then portraits stand to their subjects in the same relation as proper names to the objects denoted by them. (This is the substance of Goodman's proof that representation is a species of denotation.) We should not worry if that leads us to no new understanding of the relation (e.g., if it leads to no procedure for decoding the painted sign), for Goodman believes the search for such procedure is incoherent. The meaning of a sign is simply given, along with the artistic practice that creates it.

Goodman proceeds to generalize his theory of symbolism, using the word reference to express the relation between word and thing. (We might well characterize this relation as labelling.) Denotation is the special case of reference exemplified by proper names and portraits—a case in which a symbol labels one individual. When a single label picks out many things, then we have not a name but a predicate.

Sometimes the process of labelling goes both ways. A colour sample is a sign for the colour it possesses—say, the colour red. It therefore refers to the label red, which in turn refers back to the sample. In this case, the predicate red and the sample mutually label each other. Goodman calls this relation exemplification, and analyzes expression as a special case of it—namely, the case where the exemplification of a predicate proceeds by metaphor. For example, a piece of music may refer to sadness; it may also be metaphorically sad. In this case, Goodman argues, we may speak of the music as expressing sadness.

The economy and elegance of Goodman's theory are matched by its extreme inscrutability. On the surface it seems to provide direct and intelligible answers to all the major problems of art. What is art? A system of symbols.

What is representation? Denotation. What is expression? A kind of reference. What is the value of art? It symbolizes (displays) reality. What is the distinction between art and science? A distinction between symbol systems but not between the matters they display. Yet, at each point we feel at a loss to know what we are learning about art in being told that it is essentially symbolic.

In this respect, Goodman's theory is similar to many semantic theories of art: it proves that expression, for example, describes a symbolic relation only by giving a theory of symbolism that is so general as to include almost every human artifact. It becomes impossible to extract from the result a procedure of interpretation—a way of understanding a work of art in terms of its alleged symbolic function. In particular, we cannot extend to the discussion of art those theories that show how we understand language in terms of its peculiar syntactic and semantic structure, for such theories always seem to rely precisely on what is peculiar to language and what distinguishes language from, say, music, painting, and architecture.

A similar result can be found in an earlier theory upon which Goodman's is to some extent modelled—the one proposed by Langer in her *Philosophy in a New Key* (1942) and *Feeling and Form* (1953). She argues that works of art symbolize states of mind ("feelings"), but that the relation is not to be explained in terms of any rule of reference such as operates in language. Works of art are, Langer says, "presentational symbols" whose relation to their objects is purely morphological. The symbol and its object are related by virtue of the fact that they possess the same "logical form." It follows that what the symbol expresses cannot be restated in words; words do not present the "logical form" of individuals but rather that of the properties and relations that characterize them. (Here again is the familiar view that art presents the individuality of its subject matter and is therefore not conceptual or descriptive.) With such a view we can no longer explain why we say that a work of art expresses a feeling and not that the feeling expresses the work; for the relation of expression, explained in these morphological terms, is clearly symmetrical. Moreover, like other semantic theories, Langer's analysis provides no procedure for interpretation, nothing that would give application to the claim that in understanding a work of art we understand it as a symbol.

Notwithstanding these difficulties for semantic theories of art, most philosophers remain convinced that the three categories of representation, expression, and understanding are all-important in making sense of our experience of art. They have become increasingly persuaded, however, with Croce and Collingwood, that the differences between representation and expression are more important than the similarities. In particular, while representation may be secured by semantic rules (as in language itself), there cannot be rules for the production of artistic expression. To think otherwise is to imagine that the difference between a Mozart and a Salieri is merely a difference of skill. Expression occurs in art only where there is expressiveness, and expressiveness is a kind of success to be measured by the response of the audience rather than by the grammar of the work. This response crucially involves understanding, and no theory of expression that is not also a theory of how expression is understood can be persuasive.

Form. Expression and representation form part of the content of a work of art. Nonetheless, it is not only content that is understood (or misunderstood) by the attentive recipient. There is also form, by which term we may denote all those features of a work of art that compose its unity and individuality as an object of sensory experience. Consider music. In most cases when a listener complains that he does not understand a work of music, he means, not that he has failed to grasp its expressive content, but that the work has failed to cohere for him as a single and satisfying object of experience. He may put the point (somewhat misleadingly) by saying that he has failed to grasp the language or logic of the composition he hears. What matters, however, is that the appreciation of music (as of the other arts) depends upon the perception of certain "unities" and upon feeling the inherent order and reasonableness in a sequence (in this case, a sequence of

Langer's
semantic
theory
of art

Art as
form

tones). It is this perception of order that is fundamental to understanding art, whether abstract or representational, and that to many philosophers and critics has seemed more basic than the understanding of content. When Clive Bell wrote of art as "significant form," he really meant to defend the view, first, that form is the essence of art and, second, that form must be understood and therefore understandable (*i.e.*, significant). Other philosophers have espoused one or another version of formalism, according to which the distinguishing feature of art—the one that determines our interest in it—is form. Part answers part, and each feature aims to bear some cogent relation to the whole. It is such facts as these that compel our aesthetic attention.

Impact of
Gestalt
psychology
on
formalism

The study of form must involve the study of our perception of form. A considerable amount of work on this subject has been inspired by the theories of the Gestalt psychologists Max Wertheimer, Wolfgang Köhler, and Kurt Koffka, whose semiempirical, semiphilosophical researches into the perception of form and pattern seem to make direct contact with many of the more puzzling features of our experience of art. The influence of the Gestalt psychologists is also apparent in works of visual aesthetics; *e.g.*, Rudolf Arnheim's *Art and Visual Perception* (1954), which explores the significance of such well-known Gestalt phenomena as the figure-ground relationship and the perception of completed wholes for our understanding of pictures.

Fruitful though this emphasis on the "good Gestalt" has been, it cannot claim to have covered in its entirety the immensely complex subject of artistic form. For one thing, the theories and observations of the Gestalt psychologists, while evidently illuminating when applied to music and painting, can be applied to our experience of literature only artificially and inconclusively. Furthermore, it is impossible either to subsume all formal features of music and literature under the idea of a Gestalt or to demonstrate why, when so subsumed, the emotional effect and aesthetic value of form is made intelligible. Too much of aesthetic importance is left unconsidered by the study of the Gestalt, so that formalist critics and philosophers have begun to look elsewhere for an answer to the questions that concern them.

Signifi-
cance of
structure

One recurring idea is that the operative feature determining our perception of form is "structure," the underlying, concealed formula according to which a work of art is constructed. This idea has had considerable influence in two areas, music theory and literary criticism, the former through the Austrian music theorist Heinrich Schenker and the latter through the Russian formalists and the structuralist linguists of Prague and Paris. Schenker argued in *Harmonielehre* (1906–35; *Harmony*) that musical form can be understood as generated out of musical "cells," units that are expanded, repeated, and built upon in ways that create a web of significant relationships, including a background and a foreground of musical movement. Certain structuralist critics, notably Tzvetan Todorov and Roland Barthes, have tried to perceive the unity of works of literature in terms of a similar development of literary units, often described tendentiously as "codes," but perhaps better understood as themes. These units are successively varied and transposed in ways that make the whole work into a logical derivation from its parts.

Against this approach it has been argued that in neither case does structural analysis succeed in making contact with the real source of artistic unity. This unity lies within the aesthetic experience itself and so cannot be understood as a structural feature of the work of art. Once again the temptation has been to enshrine in a body of rules what lies essentially beyond the reach of rules: a unity of experience that cannot be predicted but only achieved. Structuralist aesthetics has therefore come under increasing criticism, not only for its pedantry but also for its failure to make genuine contact with the works of art to which it is applied.

In general, the study of artistic form remains highly controversial and fraught with obstacles that have yet to be overcome. This area of the theory of art remains difficult and inaccessible equally to the critic and the philosopher,

both of whom have therefore tended to turn their attention to less intractable problems.

The ontology of art. One such problem is that of the ontological status of the work of art. Suppose that A has on the desk before him *David Copperfield*. Is *David Copperfield* therefore identical with this book that A can touch and see? Certainly not, for another copy lies on B's desk, and a single work of art cannot be identical with two distinct physical things. The obvious conclusion is that *David Copperfield*, the novel, is identical with no physical thing. It is not a physical object, any more than is a piece of music, which is clearly distinct from all its performances. Perhaps the same is true of paintings. For could not paintings be, in principle at least, exactly reproduced? And does not that possibility show the painting to be distinct from any particular embodiment in this or that area of painted canvas? With a little stretching, the same thought experiment might be extended to architecture, though the conclusion inevitably becomes increasingly controversial.

The problem of the nature of the work of art is by no means new. Such an argument, however, gives it a pronounced contemporary flavour, so that both Phenomenologists and Analytical philosophers have been much exercised by it, often taking as their starting point the clearly untenable theory of Croce. According to Croce, the work of art does not consist in a physical event or object but rather in a mental "intuition," which is grasped by the audience in the act of aesthetic understanding. The unsatisfactory nature of this theory, sometimes called the "ideal" theory of art, becomes apparent as soon as we ask how we would identify the intuition with which any given work of art is supposedly identical. Clearly, we can identify it only in and through a performance, a book, a score, or a canvas. These objects give us the intuition that cannot exist independently of them. (Otherwise we should have to say that the world contains an uncountable number of great works of art whose only defect is that they have never been transcribed.)

Clearly then, the physical embodiment of the work—in sounds, language, scores, or other inscriptions—is more fundamentally a part of it (of its "essence") than the ideal theory represents it to be. What then is the work of art, and what is its relation to the objects in which it is embodied? These questions have been discussed by Richard Wollheim in *Art and Its Objects* (1968), and again by Goodman in *Languages of Art* (see above). Wollheim argues that works of art are "types" and their embodiments "tokens." The distinction here derives from the U.S. philosopher and logician C.S. Peirce, who argued that the letter *a*, for example, is neither identical with any particular token of it (such as the one just written) nor distinct from the class of such tokens. Peirce therefore calls *a* a type (*i.e.*, a formula for producing tokens).

Wollheim's theory is open to various objections. For example, works of architecture are not, as things stand, tokens of types but physical objects, and to make them into types by endlessly reproducing them would be to destroy their aesthetic character. To identify an object in terms of a process that destroys its character is not in any evident sense to identify it. The theory, moreover, seems to be unable to distinguish a musical performance containing a wrong note from a performance of a new work of music containing precisely that note as part of its type.

Goodman's theory is more technical and displaces the question of the nature of art in favour of that of the nature of an inscription: Just what is it for a particular set of marks to identify a work of art? Other philosophers have concentrated on the question of identity: What makes this work of art the same as that one? Some argue, for example, that works of art have a distinct criterion of identity, one that reflects the peculiar nature and demands of aesthetic interest. Others dismiss the search for a criterion of identity as both aesthetically insignificant and illusory in itself. Still others, notably the Phenomenologist Roman Ingarden, argue that the work of art exists on several levels, being identical not with physical appearance but with totality of interpretations that secure the various formal and semantic levels that are contained in it.

Questions that so obviously lend themselves to the pro-

Question
of
identity

cedures of modern philosophy have naturally commanded considerable attention. But whether they are aesthetically significant is disputed, and some philosophers go so far as to dismiss all questions of ontology and identity of art as peripheral to the subject matter of aesthetics. The same could not be said, however, of the question of the value of art, which, while less discussed, is evidently of the first importance.

The value of art. Theories of the value of art are of two kinds, which we may call extrinsic and intrinsic. The first regards art and the appreciation of art as means to some recognized moral good, while the second regards them as valuable not instrumentally but as objects unto themselves. It is characteristic of extrinsic theories to locate the value of art in its effects on the person who appreciates it. Art is held to be a form of education, perhaps an education of the emotions. In this case, it becomes an open question whether there might not be some more effective means to the same result. Alternatively, one may attribute a negative value to art, as Plato did in his *Republic*, arguing that art has a corrupting or diseducative effect on those exposed to it.

The extrinsic approach, adopted in modern times by Leo Tolstoy in *Chto takoye iskusstvo?* (1896; *What Is Art?*), has seldom seemed wholly satisfactory. Philosophers have constantly sought for a value in aesthetic experience that is unique to it and that, therefore, could not be obtained from any other source. The extreme version of this intrinsic approach is that associated with Walter Pater, Oscar Wilde, and the French Symbolists, and summarized in the slogan "art for art's sake." Such thinkers and writers believe that art is not only an end in itself but also a sufficient justification of itself. They also hold that in order to understand art as it should be understood, it is necessary to put aside all interests other than an interest in the work itself.

Between those two extreme views there lies, once again, a host of intermediate positions. We believe, for example, that works of art must be appreciated for their own sake, but that, in the act of appreciation, we gain from them something that is of independent value. Thus a joke is laughed at for its own sake, even though there is an independent value in laughter, which lightens our lives by taking us momentarily outside ourselves. Why should not something similar be said of works of art, many of which aspire to be amusing in just the way that good jokes are?

The analogy with laughter—which, in some views, is itself a species of aesthetic interest—introduces a concept without which there can be no serious discussion of the value of art: the concept of taste. If I am amused it is for a reason, and this reason lies in the object of my amusement. We thus begin to think in terms of a distinction between good and bad reasons for laughter. Amusement at the wrong things may seem to us to show corruption of mind, cruelty, or bad taste; and when it does so, we speak of the object as not truly amusing, and feel that we have reason on our side.

Similarly, we regard some works of art as worthy of our attention and others as not. In articulating this judgment, we use all of the diverse and confusing vocabulary of moral appraisal; works of art, like people, are condemned for their sentimentality, coarseness, vulgarity, cruelty, or self-indulgence, and equally praised for their warmth, compassion, nobility, sensitivity, and truthfulness. (The same may apply to the object of natural beauty.) Clearly, if aesthetic interest has a positive value, it is only when motivated by good taste; it is only interest in appropriate objects that can be said to be good for us. All discussion of the value of art tends, therefore, to turn from the outset in the direction of criticism: Can there be genuine critical evaluation of art, a genuine distinction between that which deserves our attention and that which does not? (And, once again, the question may be extended to objects of natural beauty.)

TASTE, CRITICISM, AND JUDGMENT

All aesthetic experience, whether of art or nature, seems to be informed by and dependent upon an exercise of taste. We choose the object of aesthetic experience, and

often do so carefully and deliberately. Moreover, we are judged by our choices, not only of works of art but also of colour schemes, dresses, and garden ornaments, just as we are judged by our manners and our sense of humour. By his taste an individual betrays himself: not merely a small part of himself but the whole. Yet, the relation between taste and morality is by no means straightforward. There seems, in fact, to be a puzzling question as to the precise nature of the relation between aesthetic and moral values, and between the good taste that discerns the first and the good conduct that responds to the second. If there is no relation, the enormous amount of human energy that is invested in art and criticism may begin to seem rather pointless. If the relation is too close, however, the result is an intolerable moral elitism that makes refinement the sole standard of acceptable conduct, as for example, the elitism depicted by Villiers de L'Isle-Adam in *Axel*, by J.K. Huysmans in *À Rebours*, and by Oscar Wilde in *The Picture of Dorian Gray*. The aesthete is one who puts aesthetic values above all others and who seeks for a morality that conforms to them. But like his opposite, the philistine, he fails to see that the relation between the aesthetic and the moral is not one of priority; each informs and is informed by the other, without taking precedence and without dictating the choice that belongs within the other's sphere.

Contemporary aesthetics has been less disposed to discuss the idea of taste than that of criticism. But clearly, the two ideas are so closely related that anything said about the one has a direct bearing on the other. In both cases, the approach has been the first of those outlined at the beginning of this article: the approach that starts with a study of the concepts and modes of argument employed in discussing beauty and tries to grasp the distinctive problems of aesthetics through a study of the logical and ideological puzzles that these concepts and arguments arouse.

Philosophers often distinguish between two kinds of critical discussion—the interpretative and the evaluative—and two classes of concepts corresponding to them. In describing an object of natural beauty or a work of art, we may use a host of so-called aesthetic terms, terms that seem to have a particular role when used in this context and that articulate the aesthetic impression which it is the first task of criticism to convey. Among such terms we may notice affective terms—moving, frightening, disturbing; terms denoting emotional qualities—sad, lively, mournful, wistful; terms denoting the expressive or representational content of a work of art, its formal features, and its overall artistic genre—comic, tragic, ironic. Some of these terms can be applied meaningfully only to works of art; others may be applied to the whole of nature in order to articulate an aesthetic experience. The examination of their logic has had an increasingly important role in analytical aesthetics. Frank N. Sibley, for example, has argued that such terms are used in aesthetic judgment in a peculiar way, without conditions (*i.e.*, without a reasoned basis), and in order to describe aesthetic properties that are discernible only by the exercise of taste. This sophisticated reminder of Kant's theory that aesthetic judgment is free from concepts has been criticized as creating too great a gap between the language of criticism and the language of everyday life. But it is of considerable interest in itself in attempting to revive a conception of taste that was highly influential in 18th-century aesthetics. As noted above, taste is, according to this conception, a faculty not of evaluation but of perception.

In aesthetics, however, evaluative judgments are inescapable. Theories avoiding the implication that taste is a form of discrimination, which naturally ranks its objects according to their merit, are peculiarly unsatisfying, not the least because they have so little bearing on the practice of criticism or the reasons that lead us to assign such overwhelming importance to art.

What then of the concepts employed in aesthetic evaluation? Burke introduced a famous distinction between two kinds of aesthetic judgment corresponding to two orders of aesthetic experience: the judgment of the beautiful and that of the sublime. The judgment of beauty has its origin in our social feelings, particularly in our feelings toward

Inter-
pretative
and
evaluative
criticism

the other sex, and in our hope for a consolation through love and desire. The judgment of the sublime has its origin in our feelings toward nature, and in our intimation of our ultimate solitude and fragility in a world that is not of our own devising and that remains resistant to our demands. In Burke's words,

Whatever is fitted in any sort to excite the ideas of pain, and danger, that is to say, whatever is in any sort terrible, or is conversant about terrible objects, or operates in a manner analogous to terror, is a source of the sublime; that is, it is productive of the strongest emotion which the mind is capable of feeling.

Burke's distinction emerges as part of a natural philosophy of beauty: an attempt to give the origins of our sentiments rather than to explain the logic of the judgments that convey them. In Kant, the distinction is recast as a distinction between two categories of aesthetic experience and two separate values that attach to it. Sometimes when we sense the harmony between nature and our faculties, we are impressed by the purposiveness and intelligibility of everything that surrounds us. This is the sentiment of beauty. At other times, overcome by the infinite greatness of the world, we renounce the attempt to understand and control it. This is the sentiment of the sublime. In confronting the sublime, the mind is "incited to abandon sensibility"—to reach over to that transcendental view of things that shows to us the immanence of a supersensible realm and our destiny as subjects of a divine order. Thus, from the presentiment of the sublime, Kant extracts the ultimate ground of his faith in a Supreme Being, and this is for him the most important value that aesthetic experience can convey.

The distinction between the sublime and the beautiful is now less frequently made than at the time of Burke and Kant. Nevertheless, it is undeniable that aesthetic judgment exists in many contrasting forms, of both praise and condemnation. A philosopher who sought to account for the idea of beauty without attending to those of the elegant, the refined, the great, the delicate, the intelligent, the profound, and the lovely would be unlikely to provide us with much understanding of the nature and function of criticism. There may be, however, something that these judgments have in common which might be used in order to cast light on all of them. Kant certainly would have thought so, since he argued that all such judgments share the distinctive features of taste revealed in his antinomy. In other words, they are all grounded in an immediate ("subjective") experience, while at the same time being "universal"—*i.e.*, held forth as valid for all rational beings irrespective of their particular interests and desires. Thus, the critic tries to justify his aesthetic judgments, seeking reasons that will persuade others to see what he sees as elegant or beautiful in a similar light.

Could there be a genuine critical procedure devoted to that enterprise of providing objective grounds for subjective preferences? This question is integrally connected to another that we have already discussed: the question of the value of aesthetic experience. If aesthetic experience is valueless, or if it has no more value than attaches to idle enjoyment, then it becomes far less plausible to insist on the existence of objective evaluation than if aesthetic experience has the kind of importance attributed to it by Kant.

Modern considerations of this exceedingly difficult question tend to concentrate on the criticism of art and on the role of the critic of art. What is a critic doing when he discusses a work of art, what does he look for, and with what purpose? It might be said that a critic should first of all study the artist's intention, since this will show the real meaning of his work, the real content that he is trying to communicate. The U.S. critics W.K. Wimsatt and Monroe C. Beardsley, however, argue that there is a fallacy (the so-called intentional fallacy) involved in this approach. What is to be interpreted is the work of art itself, not the intentions of the artist, which are hidden from us and no subject for our concern. If judgment is to be aesthetic, it must concern itself with the given object, and the meanings that we attribute to the object are those that we see in it, whatever the artist intended.

The existence of an intentional fallacy has been doubted.

Some argue, for example, that Wimsatt and Beardsley make too sharp a distinction between an intention and the act that expresses it, assuming the intention to be a kind of private mental episode forever hidden from an observer rather than a revealed order in the work itself. But when a critic refers to the artistic intention, it is not clear whether he means anything more than the general purposiveness of the work of art, which can be interpreted by a critic without supposing there to be some intention beyond that of producing the precise work before him. (Indeed, in Kant's view, there can be purposiveness without purpose, and this phenomenon provides the central object of aesthetic interest whether in art or in nature.) The dispute here is tortuous and obscure. Nevertheless, the move away from intentionalism, as it is called, has been regarded as imperative by most modern critics, who tend to see the role of criticism in either one of two ways: (1) criticism is devoted to the study and interpretation of the aesthetic object rather than of the artist or the recipient; and (2) criticism is devoted to the articulation of a response to the work of art and to the justification of a particular way of seeing it.

Underlying both these conceptions is the fashionable preoccupation with art as the principal object of critical judgment. Nevertheless, in suggesting that the choice which lies before the critic is between the aesthetic object and the experience that it arouses, the two views ensure that the artist is kept hidden. As a consequence, it is not difficult to adapt them to a wider view of aesthetic judgment and aesthetic experience—to a view that makes room for natural beauty and for the aesthetics of everyday life, as it is manifested in dress, manners, decoration, and the other useful arts.

It might be thought that only the first of the two conceptions can give rise to an objective critical procedure, since it alone requires that criticism focus on an object whose existence and nature is independent of the critic. The most important contemporary defense of an objective criticism, that of the British literary critic F.R. Leavis, has relied heavily on the second idea, however. In a celebrated controversy with his U.S. counterpart, René Wellek, Leavis argued that it is precisely because criticism is devoted to the individual response that it may achieve objectivity. Although there may be objectivity in the scientific explanation of the aesthetic object—*i.e.*, in the classification and description of its typology, structure, and semiotic status—this is not, according to Leavis, the kind of objectivity that matters, for it will never lead to a value judgment and will therefore never amount to an objective criticism. Value judgments arise out of, and are validated by, the direct confrontation in experience between the critical intelligence and the aesthetic object, the first being informed by a moral awareness that provides the only possible ground for objective evaluation.

If criticism were confined to the study of nature, it would look very peculiar. It is only because of the development of artistic and decorative traditions that the habit of aesthetic judgment becomes established. Accordingly, contemporary attempts to provide a defense of aesthetic judgment concentrate almost exclusively on the criticism of art, and endeavour to find principles whereby the separate works of art may be ordered according to their merit, or at least characterized in evaluative terms. Leavis' "objective" criticism is expressly confined to the evaluation of literary works taken from a single tradition. The reason for this narrowness can be put paradoxically as follows: Criticism can be objective only when it is based in subjectivity. Criticism is the justification of a response, and such justification requires a frame of reference that both the critic and his reader can readily recognize. The successful communication and justification of a response are possible only by reference to the canon of works accepted within a common culture. The canonical works—what Matthew Arnold called the touchstones of criticism—provide the context of relevant comparisons, without which no amount of detailed analysis could convey the quality of the individual work. Critical reasoning is an attempt to place works of art in relation to one another, so that the perceived greatness of the one will provide the standard of

The role of modern criticism

Taste as a common denominator of aesthetic judgments

The intentional fallacy

Leavis' method of literary criticism

measurement for the other. At the same time, the individual quality of feeling in each work must be elicited and discussed exactly as we might discuss the quality of feeling in everyday life, praising it for its intensity, exactness, and generosity, and criticizing it for its sentimentality, obscurity, or lack of seriousness. All of the moral categories that we apply to human feeling and character we may therefore apply equally to art, and the basis of an objective criticism will be no different from the basis (whatever it might be) for an objective morality. The value of art, on this account, resides partly in the fact that it gives exemplary expression to human feeling and character, and so enables us to measure our own lives and aspirations against their imaginary counterparts.

These ideas are vague and have been frequently criticized for their moralistic overtones as well as for the seeming narrowness of their application. Even if they apply to the criticism of literature, what do we say about the criticism of music, of architecture, of dress and decor, of natural beauty? In the nonliterary arts much criticism is directed first to form, style, and workmanship, and only secondly to the moral content of the works under consideration. There are exceptions to this rule, and once again the principal exception is English—namely, John Ruskin's profoundly moralized criticism of architecture. Nevertheless, the extreme difficulty experienced in extending the Leavisite procedures of practical criticism (in which the reader's response becomes the principal focus of critical attention) to the nonliterary arts has given sustenance to the view that this "moralized" criticism is really only one kind of criticism and not necessarily the most widely applicable or the most important. If such is the case, it cannot really claim to have discovered a basis for the objective exercise of taste.

THE DEVELOPMENT OF WESTERN AESTHETICS

The contributions of the ancient Greeks. The two greatest Greek philosophers, Plato and Aristotle, shared a sense of the importance of aesthetics, and both regarded music, poetry, architecture, and drama as fundamental institutions within the body politic. Plato notoriously recommends the banning of poets and painters from his ideal republic and in the course of his argument provides an extended theory of imitation (*mimesis*), along with spurious reasons for thinking that imitation derogates both from the laws of morality and from the rational cognition of the world. Much of Aristotle's extended and diverse reply to Plato is concerned with rehabilitating imitation as the foundation of moral education (*Ethica Nicomachea*), as the origin of a necessary *katharsis* (*Poetica*), and as the instrument—through music, dance, and poetry—of character formation (*Politica*).

Plato's more mystical writings, notably the *Timaeus*, contain hints of another approach to aesthetics, one based on the Pythagorean theory of the cosmos that exerted a decisive influence on the Neoplatonists. Through the writings of St. Augustine, Boethius, and Macrobius, the Pythagorean cosmology and its associated aesthetic of harmony were passed on to the thinkers of the Middle Ages. The Aristotelian theory of imitation and the concern with the expressive and emotionally educative aspect of aesthetic experience were not truly influential until the 17th century. At that time much attention was also paid to another classical work, the Hellenistic treatise on the sublime ascribed to Longinus, which is perhaps the most interesting and extended piece of antique literary criticism to have been passed on to the modern world.

Medieval aesthetics. St. Thomas Aquinas devoted certain passages of his *Summa Theologiae* (c. 1266–73) to the study of beauty. To his thinking, man's interest in beauty is of sensuous origin, but it is the prerogative of those senses that are capable of "contemplation"—namely, the eye and the ear. Aquinas defines beauty in Aristotelian terms as that which pleases solely in the contemplation of it and recognizes three prerequisites of beauty: perfection, appropriate proportion, and clarity. Aquinas' position typifies the approach to aesthetics adopted by the Scholastics. More widely diffused among medieval thinkers was the Neoplatonist theory, in which beauty is seen as a kind of

divine order conforming to mathematical laws: the laws of number, which are also the laws of harmony. Music, poetry, and architecture all exhibit the same conformity to a cosmic order, and, in experiencing their beauty, we are really experiencing the same order in ourselves and resonating to it as one string to another. This theory, expounded in treatises on music by St. Augustine and Boethius, is consciously invoked by Dante in his *Convivio* (c. 1304–07; *The Banquet*). In this piece, generally considered one of the first sustained works of literary criticism in the modern manner, the poet analyzes the four levels of meaning contained in his own poems.

The Neoplatonist emphasis on number and harmony dominated aesthetics during the early Renaissance as well and was reaffirmed by Leon Alberti in his great treatise on architecture, *De Re Aedificatoria* (1452; *Ten Books on Architecture*). Alberti also advanced a definition of beauty, which he called *concinntas*, taking his terminology from Cicero. Beauty is for Alberti such an order and arrangement of the parts of an object that nothing can be altered except for the worse. This kind of definition can hardly stand alone as a basis for aesthetics, for what does the word worse mean? The obvious answer, "less beautiful," at once reduces the definition to circularity.

The origins of modern aesthetics. Francis Bacon wrote essays on beauty and deformity, but he confined his remarks to the human figure. René Descartes produced a treatise on music, although it contains little that would be recognized as aesthetics in the modern sense. During the first decades of modern philosophy, aesthetics flourished, not in the works of the great philosophers, but in the writings of such minor figures as Baltasar Gracián, Jean de La Bruyère (who began the study of taste that was to dominate aesthetics for a century), and Georges-Louis Leclerc, comte de Buffon.

It was not until the end of the 17th century that the distinctive concerns of modern aesthetics were established. At that time, taste, imagination, natural beauty, and imitation came to be recognized as the central topics in aesthetics. In Britain the principal influences were the 3rd Earl of Shaftesbury and his disciples Francis Hutcheson and Joseph Addison. Shaftesbury, a follower of the political and educational philosopher John Locke, did more than any of his contemporaries to establish ethics and aesthetics as central areas of philosophical inquiry. As a naturalist, he believed that the fundamental principles of morals and taste could be established by due attention to human nature, our sentiments being so ordered that certain things naturally please us and are naturally conducive to our good (*Characteristiks of Men, Manners, Opinions, Times*, 1711). Taste is a kind of balanced discernment, whereby a person recognizes that which is congenial to his sentiments and therefore an object of pleasurable contemplation. Following Locke, Shaftesbury laid much emphasis on the association of ideas as a fundamental component in aesthetic experience and the crucial bridge from the sphere of contemplation to the sphere of action. Addison adopted this position in a series of influential essays, "The Pleasures of the Imagination" in *The Spectator* (1712). He defended the theory that imaginative association is the fundamental component in our experience of art, architecture, and nature, and is the true explanation of their value to us.

Francis Hutcheson was perhaps the first to place the problem of aesthetic judgment among the central questions of epistemology: How can we know that something is beautiful? What guides our judgment and what validates it? His answer was decidedly Empiricist in tone: aesthetic judgments are perceptual and take their authority from a sense that is common to all who make them. In *An Inquiry into the Original of our Ideas of Beauty and Virtue* (1725), Hutcheson explained: "The origin of our perceptions of beauty and harmony is justly called a 'sense' because it involves no intellectual element, no reflection on principles and causes."

The significance of Baumgarten's work. Such a statement would have been vigorously repudiated by Hutcheson's contemporary Alexander Baumgarten, who, in his aforementioned *Reflections on Poetry*, introduced the term

Neoplatonist conception of beauty

Plato
and
Aristotle

Imaginative association in aesthetic experience

Baumgarten's
theory of
the value
of art

aesthetic in its distinctively modern sense. Baumgarten was a pupil of Christian Wolff, the Rationalist philosopher who had created the orthodox philosophy of the German Enlightenment by building the metaphysical ideas of Gottfried Wilhelm Leibniz into a system. He was thus heir to a tradition that dismissed the senses and the imagination as incapable of providing a genuine cognition of their objects and standing always to be corrected (and replaced) by rational reflection. Baumgarten, however, argued that poetry is surely cognitive: it provides insight into the world of a kind that could be conveyed in no other way. At the same time, poetic insights are perceptual ("aesthetic") and hence imbued with the distinctive character of sensory and imaginative experience. According to Baumgarten, the ideas conveyed by poetry are "clear and confused," as opposed to the "clear and distinct" ideas of reason in the sense that they had been described by Descartes and the 17th-century Rationalists. Baumgarten held that the aesthetic value of a poem resides in the relative preponderance of clarity over confusion. Accordingly, his theory of the value of art was ultimately cognitive.

It was some decades before Baumgarten's coinage became philosophical currency. But there is no doubt that his treatise, for all its pedantry and outmoded philosophical method, deserves its reputation as the founding work of modern aesthetics.

Major concerns of 18th-century aesthetics. The development of aesthetics between the work of Baumgarten and that of Immanuel Kant, who had been influenced by Baumgarten's writings, was complex and diverse, drawing inspiration from virtually every realm of human inquiry. Yet, throughout this period certain topics repeatedly received focal attention in discussions pertaining to aesthetic questions.

Analysis
of taste

One such topic was the faculty of taste, the analysis of which remained the common point among German, French, and English writers. Taste was seen either as a sense (Hutcheson), as a peculiar kind of emotionally inspired discrimination (Hume), or as a part of refined good manners (Voltaire). In an important essay entitled "Of the Standard of Taste" (in *Four Dissertations*, 1757), Hume, following Voltaire in the *Encyclopédie*, raised the question of the basis of aesthetic judgment and argued that "it is natural for us to seek a standard of taste; a rule by which the various sentiments of men may be reconciled; at least, a decision afforded, confirming one sentiment, and condemning another." But where is this standard of taste to be found? Hume recommends an ideal of the man of taste, whose discriminations are unclouded by an emotional distemper and informed by a "delicacy of imagination . . . requisite to convey a sensibility of . . . finer emotions." For, Hume argues, there is a great resemblance between "mental" and "bodily" taste—between the taste exercised in aesthetic discrimination and that exercised in the appreciation of food and drink, which can equally be deformed by some abnormal condition of the subject. Hume proceeded to lay down various procedures for the education of taste and for the proper conduct of critical judgment. His discussion, notwithstanding its skeptical undercurrent, has proved lastingly influential on the English schools of criticism, as well as on the preferred Anglo-Saxon approach to the questions of aesthetics.

A second major concern of 18th-century writers was the role of imagination. Addison's essays were seminal, but discussion of imagination remained largely confined to the associative theories of Locke and his followers until Hume gave to the imagination a fundamental role in the generation of commonsense beliefs. Kant attempted to describe the imagination as a distinctive faculty, active in the generation of scientific judgment as well as aesthetic pleasure. Between them, Hume and Kant laid the ground for the Romantic writers on art: Johann Gottfried von Herder, Friedrich Schiller, Friedrich Schelling, and Novalis (pseudonym of Friedrich Leopold, Freiherr von Hardenberg) in Germany, and Samuel Taylor Coleridge and William Wordsworth in England. For such writers, imagination was to be the distinctive feature both of aesthetic activity and of all true insight into the human condition. Meanwhile, Lord Kames and Archibald Alison

had each provided full accounts of the role of association in the formation and justification of critical judgment. Alison, in particular, recognized the inadequacies of the traditional Empiricist approach to imaginative association and provided a theory as to how the feelings aroused by a work of art or a scene of natural beauty may become part of its appearance—qualities of the object as much as of the subject (*Essays on the Nature and Principles of Taste* [1790]).

The concept of imitation, introduced into the discussion of art by Plato and Aristotle, was fundamental to the 18th-century philosophy of art. Imitation is a vague term, frequently used to cover both representation and expression in the modern sense. The thesis that imitation is the common and distinguishing feature of the arts was put forward by James Harris in *Three Treatises* (1744) and subsequently made famous by Charles Batteux in a book entitled *Les Beaux Arts réduits à un même principe* (1746; "The Fine Arts Reduced to a Single Principle"). This diffuse and ill-argued work contains the first modern attempt to give a systematic theory of art and aesthetic judgment that will show the unity of the phenomena and their common importance. "The laws of taste," Batteux argued, "have nothing but the imitation of beautiful nature as their object"; from which it follows that the arts, which are addressed to taste, must imitate nature. The distinction between the fine and useful arts (recast by Collingwood as the distinction between art and craft) stems from Batteux.

Still another characteristic of 18th-century aesthetics was the concern with the distinction between the sublime and the beautiful. Burke's famous work, *On the Sublime and Beautiful*, has already been discussed. Its influence was felt throughout late 18th-century aesthetics. For example, it inspired one of Kant's first publications, an essay on the sublime. Treatises on beauty were common, one of the most famous being *The Analysis of Beauty* (1753) by the painter William Hogarth, which introduces the theory that beauty is achieved through the "serpentine line."

The view that art is expression emerged during the 1700s. Rousseau put forth the theory of the arts as forms of emotional expression in an essay dealing with the origin of languages. This theory, regarded as providing the best possible explanation of the power of music, was widely adopted. Treatises on musical expression proliferated during the late 18th century. One illustrative example of such writings is James Beattie's *Essay on Poetry and Music as They Affect the Mind* (1776), in which the author rejects the view of music as a representational (imitative) art form and argues that expression is the true source of musical excellence. Another example is provided by Denis Diderot in his didactic novel *Le Neveu de Rameau* (1761–74; *Rameau's Nephew and Other Works*). The theory of expression was inherited by the German Romantics, especially by Schelling, Schiller, and Herder. It was, furthermore, developed in a novel direction by the Italian philosopher Giambattista Vico in his *Scienza nuova* (1725–44; *New Science*). Vico integrated art into a comprehensive theory of the development and decline of civilization. According to him, the cyclical movement of culture is achieved partly by a process of successive expression, through language and art, of the "myths" that give insight into surrounding social conditions.

Kant, Schiller, and Hegel. As previously noted, Kant's *Kritik der Urteilskraft* introduced the first full account of aesthetic experience as a distinct exercise of rational mentality. The principal ingredients of Kant's work are the following: the antinomy of taste, the emphasis on the free play of the imagination, the theory of aesthetic experience as both free from concepts and disinterested, the view that the central object of aesthetic interest is not art but nature, and the description of the moral and spiritual significance of aesthetic experience, which opens to us a transcendental point of view of the world of nature and enables us to see the world as purposive, but without purpose. In that perception, observes Kant, lies the deepest intimation of our nature and of our ultimate relation to a "supersensible" realm.

Schiller's *Briefe über die ästhetische Erziehung des Menschen*, inspired by Kant, develops further the theory of

Concept of
imitation

Art as
expression

Aesthetic
experience
is a
vehicle
of moral
and
political
education

the disinterested character of the aesthetic. Schiller argues that through this disinterested quality aesthetic experience becomes the true vehicle of moral and political education, providing man both with the self-identity that is his fulfillment and with the institutions that enable him to flourish: "What is man before beauty cajoles from him a delight in things for their own sake, or the serenity of form tempers the savagery of life? A monotonous round of ends, a constant vacillation of judgment; self-seeking, and yet without a self; lawless, yet without freedom; a slave, and yet to no rule."

Schiller's *Briefe* exerted a profound influence on Hegel's philosophy in general and on his *Vorlesungen über die Aesthetik* in particular. In discussions of remarkable range and imaginative power, Hegel introduces the distinctively modern conception of art as a request for self-realization, an evolving discovery of forms that give sensuous embodiment to the spirit by articulating in concrete form its inner tensions and resolutions. For Hegel, the arts are arranged in both historical and intellectual sequence, from architecture (in which *Geist* ["spirit"] is only half articulate and given purely symbolic expression), through sculpture and painting, to music and thence to poetry, which is the true art of the Romantics. Finally, all art is destined to be superseded by philosophy, in which the spirit achieves final articulation as *Idea*. The stages of art were identified by Hegel with various stages of historical development. In each art form a particular *Zeitgeist* (i.e., spirit of the time) finds expression, and the necessary transition from one art form to its successor is part of a larger historical transformation in which all civilization is engaged.

The incidental discussions of Hegel's *Vorlesungen* introduce most of the themes of contemporary philosophy of art, though in the peculiar language of Hegelian Idealism. Nineteenth-century Idealist aesthetics can reasonably be described as a series of footnotes to Hegel, who was, however, less original than he pretended. Many of the individual thoughts and theories in his lectures on aesthetics were taken from the contemporary literature of German Romanticism (in particular, the writings of Herder, Jean Paul [pseudonym of Johann Paul Friedrich Richter] and Novalis) and from the works of German critics and art historians (notably G.E. Lessing and Johann Winckelmann) who had forged the link between modern conceptions of art and the art of antiquity. The influence of Hegel was, therefore, the influence of German Romanticism as a whole, and it is not surprising that the few who escaped it lost their audience in doing so.

Post-Hegelian aesthetics. Little of 19th-century aesthetics after Hegel has proved of lasting interest. Perhaps the most important exception is the controversial literature surrounding Richard Wagner, particularly the attack on the expressive theory of music launched by Wagner's critic Eduard Hanslick in his *Vom musikalisch-Schönen* (1854; *On the Beautiful in Music*). With this work modern musical aesthetics was born, and all the assumptions made by Batteux and Hegel concerning the unity (or unity in diversity) of the arts were thrown in doubt.

The most impressive work on aesthetics of the late 1800s was George Santayana's *The Sense of Beauty* (1896), which shows a welcome move away from the 19th-century obsession with art toward more fundamental issues in the philosophy of mind. Santayana argues against Kant's theory of the disinterested and universal quality of aesthetic interest, and defends the view that pleasure is the central aesthetic category, beauty being "pleasure regarded as the quality of a thing." All human functions and experiences may contribute to the sense of beauty, which has two broad categories of object: form and expression. In his theory of expression Santayana again takes up the problem raised by the theory of the association of ideas, and argues that in aesthetic pleasure the associative process achieves a kind of fusion between the response aroused and the object which arouses it, and that this is the fundamental experience of expression.

Expressionism. After Kant and Hegel, the most important influence on modern aesthetics has been Croce. His oft-cited *Estetica come scienza dell'espressione e linguistica generale* (1902; *Aesthetic as Science of Expression*

and *General Linguistics*, or *Aesthetic*) presents, in a rather novel idiom, some of the important insights underlying the theories of his predecessors. In this work, Croce distinguishes concept from intuition: the latter is a kind of acquaintance with the individuality of an object, while the former is an instrument of classification. Art is to be understood first as expression and second as intuition. The distinction between representation and expression is ultimately identical with that between concept and intuition. The peculiarities of aesthetic interest are really peculiarities of intuition: this is what explains the problem of form and content, and what gives the meaning of the idea that the object of aesthetic interest is interesting for its own sake and not as a means to an end.

Croce conceived his expressionism as providing the philosophical justification for the artistic revolutions of the 19th century and, in particular, for the Impressionist style of painting, in which representation gives way to the attempt to convey experience directly onto the canvas. His extreme view of the autonomy of art led him to dismiss all attempts to describe art as a form of representation or to establish direct connections between the content of art and the content of scientific theories. Croce's disciple R.G. Collingwood (*Principles of Art*, 1938) was similarly dismissive of representation and similarly concerned with presenting a theory of art that would justify the revolutionary practice of his contemporaries (in this case, the post-Symbolist poetry of T.S. Eliot's *The Waste Land*). As pointed out earlier, Collingwood distinguishes craft, which is a means to an end, from art, which is an end in itself. But since art is also, for Collingwood, expression, expression too must be an end in itself. It cannot be construed as the giving of form to independently identifiable states of mind. The feeling must reside in the form itself and be obtainable exclusively in that form. If it were otherwise, art would be simply another kind of craft—the craft of giving expression to preexisting and independently identifiable states of mind. Therefore, like Croce, Collingwood opposes expression in art to description: expression gives us the particularity and not the generality of states of mind.

Collingwood sets his aesthetics within the context of a theory of the imagination, in which he shows the influence of the British Empiricists as well as of the Idealist metaphysicians who had influenced Croce. A similar attempt to unite the theory of art with a philosophy of the imagination had been made by the French philosopher Alain in his *Système des beaux-arts* (1920, revised 1926; "System of the Fine Arts"), a work that is distinguished by its detailed attention to dress, fashion, manners, and the useful arts, and by its idea of the artist as *artisan d'abord*. Along with John Dewey's *Art As Experience* (1934), in which aesthetic experience is presented as integral to the organic completion of human nature, these works provide the culminating expression of a now defunct view of the subject as central to the understanding not of art alone but of the human condition as well.

MARXIST AESTHETICS

Many attempts have been made to develop a specifically Marxist aesthetics, one that would incorporate the Marxian theory of history and class consciousness and the critique of bourgeois ideology, so as to generate principles of analysis and evaluation and show the place of art in the theory and practice of revolution. William Morris in England and Georgy V. Plekhanov in Russia both attempted to unite Marx's social criticism with a conception of the nature of artistic labour. Plekhanov's *Iskusstvo i obshchestvennaya zhizn* (1912; *Art and Social Life*) is a kind of synthesis of early Marxist thought and attempts to recast the practices of art and criticism in a revolutionary mold. The ideology of "art for art's sake," Plekhanov argues, develops only in conditions of social decline when artist and recipient are in "hopeless disaccord with the social environment in which they live." Drawing on Kant and Schiller, Plekhanov presents a theory of the origins of art in play; play, however, must not be understood in isolation. It is indissolubly linked to labour, of which it is the complementary opposite. An art of play will be the

Plekha-
nov's
theory
of the
origins
of art
in play

Croce's
conception
of art

"free" art of the revolution, of mankind returned to social harmony, but only because play and labour will then be reunited and transcended. In place of their opposition will be a harmonious whole in which art is continuous with labour.

The aesthetic theories of the Russian Revolution owe something to Plekhanov; something to the school of Formalist criticism, typified by the proto-Structuralist M. Bakhtin; and something to the anti-aesthetic propaganda of the Russian Constructivists, who believed in an art expressive of man's dominion over raw materials—an art that would be destructive of all existing patterns of subordination. The official approach to art in the Soviet Union, however, has been typified, first, by the persecution of all those who have expressed adherence to those theories, and, second, by the adoption under Stalin of Socialist Realism (the view that art is dedicated to the "realistic" representation of proletarian values and proletarian life) as the sole legitimate basis for artistic practice.

Benjamin
and
Lukács

Subsequent Marxist thinking about art has been largely influenced by two major central European thinkers: Walter Benjamin and György Lukács. Both are exponents of Marxian theory to aesthetics in the analysis of the condition of labour and in the critique of the alienated and "reified" consciousness of man under capitalism. Benjamin's collection of essays *Das Kunstwerk im Zeitalter seiner technischen Reproduzierbarkeit* (1936; *The Work of Art in the Age of Mechanical Reproduction*) attempts to describe the changed experience of art in the modern world, and sees the rise of Fascism and mass society as the culmination of a process of debasement, whereby art ceases to be a means of instruction and becomes instead a mere gratification, a matter of taste alone. "Communism responds by politicizing art"—that is, by making art into the instrument by which the false consciousness of the mass man is to be overthrown.

Lukács developed a multifaceted approach to literary criticism, in which the historical condition of society and the reality of class consciousness are singled out as the ideological agenda of works of literature and the major source of their appeal. This position is set forth in such works as *Die Theorie des Romans* (1920; *The Theory of the Novel*). Neither Lukács nor Benjamin produced a coherent aesthetics as defined in this article, although each has been immensely influential on the practice of modern literary criticism whether Marxist or not in its ultimate inspiration. (Ro.Sc.)

EASTERN AESTHETICS

India. The disparagement of the sensory realm as mere illusion ("the veil of Maya"), characteristic of much Indian religion, went hand in hand with a philosophy of embodiment (karma), which gave a distinctive role to art both as an instrument of worship and as an earthly delight. The legends of the great god Krishna abound in exaggerated fantasies of erotic and physical power; the art of the temples testifies to a sensuality that belies the mystical gestures of renunciation which form the commonplaces of Hindu morality. In providing theories of such art, and of the natural beauty that it celebrates, Indian philosophers have relied heavily on the concept of aesthetic flavour, or *rasa*, a kind of contemplative abstraction in which the inwardness of human feelings irradiates the surrounding world of embodied forms.

Theory
of
rasa

The theory of *rasa* is attributed to Bharata, a sage-priest who may have lived about AD 500. It was developed by the rhetorician and philosopher Abhinavagupta (c. AD 1000), who applied it to all varieties of theatre and poetry. The principal human feelings, according to Bharata, are delight, laughter, sorrow, anger, fear, disgust, heroism, and astonishment, all of which may be recast in contemplative form as the various *rasas*: erotic, comic, pathetic, furious, terrible, odious, marvellous, and quietistic. These *rasas* comprise the components of aesthetic experience. The power to taste *rasa* is a reward for merit in some previous existence.

Confucian
aesthetics

China. Confucius (551–479 BC) emphasized the role of aesthetic enjoyment in moral and political education, and,

like his near contemporary Plato, was suspicious of the power of art to awaken frenzied and distracted feelings. Music must be stately and dignified, contributing to the inner harmony that is the foundation of good behaviour, and all art is at its noblest when incorporated into the rituals and traditions that enforce the stability and order of social life.

Lao-tzu, the legendary founder of Taoism, was even more puritanical. He condemned all art as a blinding of the eye, a deafening of the ear, and a cloying of the palate. Later Taoists were more lenient, however, encouraging a freer, more intuitive approach both to works of art and to nature. The philosophy of beauty presented in their works, and in the writings of the Ch'an (Zen) Buddhists who succeeded them, is seldom articulate, being confined to epigrams and short commentaries that remain opaque to the uninitiated.

The same epigrammatic style and the same fervent puritanism can be discerned in the writings of Mao Tse-tung, who initiated in the Cultural Revolution the most successful war against beauty that has been waged in modern history.

Japan. The practice of literary commentary and aesthetic discussion was extensively developed in Japan and is exemplified at its most engaging in the great novel *Genji monogatari* (c. 1000; *Tale of Genji*), written by Murasaki Shikibu, lady-in-waiting to the Empress. Centuries of commentary on this novel, as well as on the court literature that it inspired, on the Nō and puppet plays, and on the lyrical verses of the haiku poets, led to the establishment of an aesthetics of supreme refinement. Many of the concepts of this form of aesthetics were drawn from the writings of Zeami Motokiyo (1363–1443), a playwright and actor-manager. Zeami argued that the value of art is to be found in *yūgen* ("mystery and depth"), and that the artist must follow the rule of *sōdō* ("consonance"), according to which every object, gesture, and expression has to be appropriate to its context.

The
concepts
of
yūgen
and
sōdō

The domination of aesthetic scruples over Japanese life has, as its culminating instance, the tea ceremony—a marvel of constrained social ballet—to the study of which whole lives have been devoted. Associated with this triumph of manners is an art of mood and evocation, in which significance is found in the small, concentrated gesture, the sudden revelation of transcendent meaning in what is most ordinary and unassuming. In the late 18th century, Motoori Norinaga, a leading literary scholar, summed up the essence of Japanese art and literature as the expression of a touching intimation of transience, which he captured in the famous phrase *mono no aware*, meaning roughly "the sensitivity to the sadness of things." Other aesthetic qualities emphasized by classical scholars and critics are *en* ("charming"), *okashi* ("amusing"), and *sabi* (having the beauty of old, faded, worn, or lovely things). In all such aesthetic categories, we can sense the resonance of the Taoist and Buddhist ideas of renunciation. (Th.M./Ro.Sc.)

BIBLIOGRAPHY. Two of the most useful anthologies of contemporary aesthetics are ELISEO VIVAS and MURRAY KRIEGER (eds.), *The Problems of Aesthetics* (1953); and JOSEPH MARGOLIS (ed.), *Philosophy Looks at the Arts*, rev. ed. (1978). See also JOHN HOSPERS, *Introductory Readings in Aesthetics* (1969); and HAROLD OSBORNE, *Aesthetics* (1972), the latter of which contains a particularly useful bibliography. MONROE C. BEARDSLEY, *Aesthetics: Problems in the Philosophy of Criticism*, 2nd ed. (1981), provides a broad, scholarly overview of the subject; RICHARD WOLLHEIM, *Art and Its Objects* (1968; 2nd ed., 1980), is more narrow. For the definition of aesthetics, the above texts are relevant, as is ROGER SCRUTON, *The Aesthetics of Architecture* (1979; 2nd printing with corrections, 1980). See also PAUL ZIFF, "The Task of Defining a Work of Art," *Philosophical Review*, 62:58–78 (1953); and GEORGE DICKIE, *Aesthetics: An Introduction* (1971).

The first approach to the subject (see article) is exemplified in JOHN CASEY, *The Language of Criticism* (1966); the second in ROGER SCRUTON, *Art and Imagination* (1974, reissued 1982); and the third in RICHARD WOLLHEIM (see above). The classical study of the aesthetic recipient remains that of IMMANUEL KANT, *Kritik der Urteilskraft* (1790); to which one may add BERNARD BOSANQUET, *Three Lectures on Aesthetic* (1915, reprinted 1968). The aesthetic object is dealt with in considerable detail by

ROMAN INGARDEN, *The Literary Work of Art* (1973; originally published in German, 1931); and MIKEL DUFRENNE, *The Phenomenology of Aesthetic Experience* (1973; originally published in French, 1953). For the differences between the various art forms, see JOHN DEWEY, *Art As Experience* (1934, reissued 1980); and SUSANNE K. LANGER, *Feeling and Form* (1953). In addition to the works already cited, the following are particularly important discussions of paradoxes: LUDWIG WITTGENSTEIN, *Lectures and Conversations on Aesthetics, Psychology and Religious Belief*, ed. by CYRIL BARRETT (1966); F.N. SIBLEY and MICHAEL TANNER, "Objectivity and Aesthetics," *The Aristotelian Society: Supplementary Volume 42* (1968), proceedings. Some philosophical approaches to imagination are summarized in MARY WARNOCK, *Imagination* (1976). The most important 20th-century texts are JEAN-PAUL SARTRE, *The Psychology of the Imagination* (1948, reprinted 1978; originally published in French, 1940); and LUDWIG WITTGENSTEIN, *Philosophical Investigations* (1953), pt. 2. For a later attempt to describe the place of imagination in aesthetic experience as a whole, see SCRUTON, *Art and Imagination* (above). The matters of emotion, response, and enjoyment are considered in some depth by BERNARD BOSANQUET, "On the Nature of Aesthetic Emotion," in *Science and Philosophy and Other Essays* (1927, reprinted 1967); and CASEY (above). For a detailed bibliography on the understanding of art, see the section *Philosophy of art* in the article PHILOSOPHIES OF THE BRANCHES OF KNOWLEDGE.

Many of the individual problems are discussed in WOLLHEIM (above); and in ROGER SCRUTON, *The Aesthetic Understanding* (1983). See also SUSANNE K. LANGER, *Philosophy in a New Key* (1972, reissued 1979); ROLAND BARTHES, *Elements of Semiology* (1967; originally published in French, 1965); BENEDETTO CROCE, *Aesthetic* (1909; originally published in Italian, 1902); R.G. COLLINGWOOD, *Principles of Art* (1938); NELSON GOODMAN, *Languages of Art*, 2nd ed. (1976); P.F. STRAWSON, "Aesthetic

Appraisal and Works of Art," in his *Freedom and Resentment* (1974); and OSCAR WILDE, *The Critic As Artist* (1925). For discussions of the logic of music, see RUDOLF ARNHEIM, *Art and Visual Perception*, new, rev. ed. (1974); HEINRICH SCHENKER, *Harmony* (1954, reissued 1973; originally published in German, 1906); ROLAND BARTHES, *S/Z* (1974; originally published in French, 1970); and ROGER SCRUTON, "Understanding Music," in his *The Aesthetic Understanding* (above).

Criticism and aesthetic judgment are dealt with in F.N. SIBLEY, "Aesthetic Concepts," *Philosophical Review*, 68:421-450 (1959), and "Aesthetic and Non Aesthetic," *Philosophical Review*, 74:135-159 (1965); W.K. WIMSATT and MONROE C. BEARDSLEY, "The Intentional Fallacy," in W.K. WIMSATT, *The Verbal Icon* (1954); and F.R. LEAVIS, "Literary Criticism and Philosophy," in his *The Common Pursuit* (1952). For a discussion of some contemporary problems, see ANTHONY SAVILE, *The Test of Time* (1982).

An idiosyncratic but useful historical summary is provided in MONROE C. BEARDSLEY, *Aesthetics from Classical Greece to the Present* (1966, reprinted 1975). A full summary, in an outmoded idiom, is given by W. TATARKIEWICZ, *History of Aesthetics*, 3 vol. (1970-74; originally published in Polish, 1960). For additional information pertaining to ancient aesthetics, see the *Macropædia* entries PLATONISM and ARISTOTELIANISM. For Marxist aesthetics, see also MAYNARD SOLOMON (ed.), *Marxism and Art* (1974, reprinted 1979).

For Eastern aesthetics, see THOMAS MUNRO, *Oriental Aesthetics* (1965), which includes a comparison of Eastern and Western attitudes and beliefs (with many bibliographic notes). Other informative studies are NIHAR-RANJAN RAY, *Indian Aesthetics and Art Activity* (1968); MAI-MAI SZE, *The Tao of Painting*, 2 vol. (1956); and MAKOTO UEDA, *Literary and Art Theories of Japan* (1967).

(Ro.Sc.)

Afghanistan

Afghanistan is located in the heart of south central Asia. The country is officially named the Republic of Afghanistan (Dari Persian: Jomhūri-ye Afghānestān; Pashto: Da Afghānestān Jamhawriyat). It has an area of some 251,825 square miles (652,225 square kilometres) and is completely landlocked, the nearest coast lying along the Arabian Sea, about 300 miles to the south. Its longest border, of 1,125 miles (1,810 kilometres), is with Pakistan, to the east and south. Slightly shorter is the 1,050-mile border with the Soviet Union—the Turkmen, Uzbek, and Tadzhik Soviet Socialist republics—in the north. The 510-mile border in the west separates Afghanistan from Iran, and there is a 200-mile border with the part of Jammu and Kashmir claimed by Pakistan. The shortest border—of 50 miles—is with the Uighur Autonomous Region of

Sinkiang of the People's Republic of China, at the end of a long, narrow corridor, the Vākhān (Wakhan Corridor), in the extreme northeast. The capital of Afghanistan is its largest city, Kabul, which is located in a triangular-shaped valley in the east-central part of the country at an altitude of about 5,900 feet (1,800 metres). The city is connected by road to most Afghan provinces, the Soviet Union, and Pakistan.

The boundaries of Afghanistan were established in the late 19th century, mainly as a result of the rivalry between Britain and Russia. In the 20th century Afghanistan became a pawn in a struggle of political ideologies and a search for commercial influence. Part of that struggle was the invasion of Afghanistan by the Soviet Union in 1979.

Physical and human geography

THE LAND

Relief. Afghanistan's shape has been compared to a leaf, of which the Vākhān strip forms the stem. The outstanding geographic feature of Afghanistan is its mountain range, the Hindu Kush (in Afghanistan, Hendū Kosh). This formidable range is a barrier between the comparatively fertile northern provinces and the rest of the country, and it creates the major pitch of Afghanistan from northeast to southwest. The Hindu Kush, when it reaches a point some 100 miles north of Kabul, spreads out and continues westward under the names of Bābā, Bāyan, Safid Kūh (Paropamisus), and others, each section in turn sending spurs in different directions. One of these spurs is the Torkestan Mountains, which extend northward. Other important ranges include the Kasa Murgh, south of the Harī River; the Heṣār Mountains, which extend northward; and two formidable ranges, the Mazar and the Khurd, extending in a southwestern direction. On the eastern frontier with Pakistan, several mountain ranges effectively isolate the interior of the country from the rain-laden winds that blow from the Indian Ocean, accounting for the dryness of the climate.

The Hindu Kush and subsidiary ranges divide Afghanistan into three distinct geographic regions, which roughly can be designated as the Central Highlands, the Northern Plains, and the Southwestern Plateau. The Central Highlands, actually a part of the Himalayan chain, include the main Hindu Kush range. Its area of about

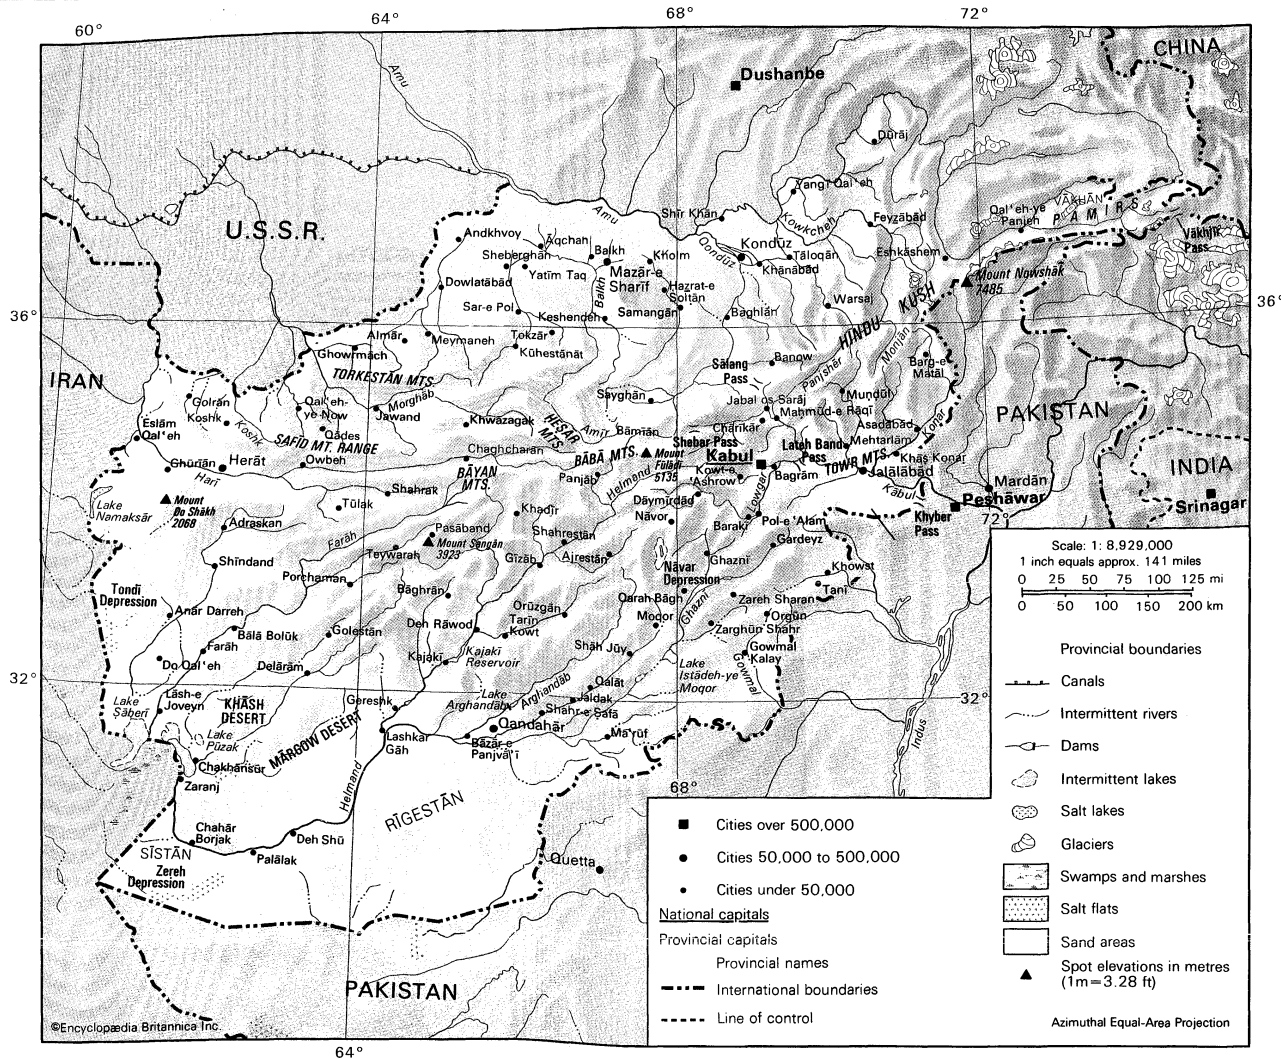

160,000 square miles is a region of deep, narrow valleys and lofty mountains, some peaks of which rise above 21,000 feet. High mountain passes, generally between 12,000 and 15,000 feet above sea level, are of great strategic importance and include the Shebar Pass, located northwest of Kabul where the Bābā Mountains meet the Hindu Kush, and the Khyber Pass, which leads to the Indian subcontinent, on the Pakistan border southeast of Kabul. The Badakhshān area in the northeastern part of the Central Highlands is the location of the epicentres for many of the 50 or so earthquakes that occur in the country each year.

The Northern Plains region, north of the Central Highlands, extends eastward from the Iranian border to the foothills of the Pamirs, near the border with the Tadzhik Soviet Socialist Republic. It comprises 40,000 square miles of plains and fertile foothills sloping gently toward the Amu River (the ancient Oxus River). This area is a part of the much larger Central Asian steppe, from which it is separated by the Amu River. The average elevation is about 2,000 feet. The Northern Plains region is intensively cultivated and densely populated. In addition to fertile soils, the region possesses rich mineral resources, particularly deposits of natural gas.

The Southwestern Plateau, south of the Central Highlands, is a region of high plateaus, sandy deserts, and semideserts. The average altitude is about 3,000 feet. The Southwestern Plateau covers about 50,000 square miles, one-fourth of which forms the sandy Rigestān Desert. The smaller Mārgow Desert of salt flats and desolate steppe lies west of the Rigestān Desert. Several large rivers cross

the Southwestern Plateau; among them are the Helmand River and its major tributary, the Arghandāb.

Most of Afghanistan lies between 2,000 and 10,000 feet in elevation. Along the Amu River in the north and the delta of the Helmand River in the southwest, the altitude is about 2,000 feet. The Sīstān depression of the Southwestern Plateau, 1,500 to 1,700 feet in elevation, was the seat of a flourishing ancient civilization that was ended in the 14th century by Timur (Tamerlane).

Drainage. Practically the entire drainage system of Afghanistan is enclosed within the country. Only the rivers in the east, which drain an area of 32,000 square miles, reach the sea. The Kābul River, the major eastern stream, flows into the Indus River in Pakistan, which empties into the Arabian Sea of the Indian Ocean. Almost all the other important rivers of the country originate in the Central Highlands region and empty into inland lakes or dry up in sandy deserts. The major drainage systems are those of the Amu, Helmand, Kābul, and Hari.

The Amu, a 1,578-mile-long river originating in the glaciers of the Pamirs, drains an area of approximately 93,000 square miles in the northeastern (Badakhshān) and northern (Khānābād and Mazār-e Sharīf) parts of the country. It forms the frontier between the Soviet Union and Afghanistan for 600 miles of its upper course. Two of its major Afghan tributaries, the Kowkchēh and the Qondūz, rise in the mountains of Badakhshān and Kondūz provinces. The Amu becomes navigable from its confluence with the Kowkchēh, 60 miles west of the city of Feyzābād. It empties into the Aral Sea in the Soviet Union.

The northwestern drainage system is dominated by the Hari River, originating on the western slopes of the Bābā Mountains, at an altitude of 9,000 feet. The river flows westward, just south of Herāt and across the broad Herāt Valley. After irrigating the fertile lands of the valley, the Hari River turns north about 80 miles west of Herāt and forms the border between Afghanistan and Iran for a distance of 65 miles. It then crosses into Soviet Central Asia and disappears in the Kara-Kum Desert.

The principal river in the southwest is the 715-mile-long Helmand, which rises in the Bābā Mountains, about 50 miles west of Kabul. With its many tributaries, mainly the Arghandāb, it drains more than 100,000 square miles. The river empties into the Šāberī, an inland lake. In its course through the southern region of the country, the Helmand flows north of the Rīgestān Desert and then crosses the Mārgow Desert until it reaches a region of seasonal lakes in the Sīstān depression.

The largest drainage system in the southeastern region is that of the Kābul River, which flows eastward from the slopes of the Mazar Range to join the Indus River at Attock, Pak. Its major tributary in the south is the Lowgar.

Afghanistan has few lakes of any considerable size. The two most important are Lake Šāberī in the southwest and the saline Lake Īstādeh-ye Moqor, situated 60 miles south of Ghaznī in the southeast. There are five small lakes in the Bābā Mountains known as the Amīr lakes; they are noted for their unusual shades of colour, from milky white to dark green, caused by the underlying bedrock.

Soils. The country possesses extremes in the quality of its soils. The Central Highlands have desert-steppe or meadow-steppe types of soil. The Northern Plains have extremely rich, fertile, loesslike soils, while the Southwestern Plateau has infertile desert soils except along the rivers in the southwest, where alluvial deposits can be found. Erosion is very much in evidence in the Central Highlands, especially in the regions affected by seasonal monsoons and heavy precipitation.

Climate. In general, Afghanistan has extremely cold winters and hot summers, typical of a semiarid steppe climate. There are many regional variations, however. While the mountain regions of the northeast have a subarctic climate with dry, cold winters, the mountainous areas on the border of Pakistan are influenced by the Indian monsoons, usually coming between July and September and bringing maritime tropical air masses with humidity and rains. In addition, strong winds blow almost daily in the southwest during the summer.

Local variation is also produced by differences in altitude. The weather in winter and early spring is strongly influenced by cold air masses from the north and the Atlantic low depression from the northwest; these two air masses bring snowfall and severe cold in the highlands and rain in the lower altitudes.

Afghanistan has a wide range of temperatures. High temperatures over 95° F (35° C) have been recorded in the drought-ridden Southwestern Plateau region. In Jalālābād, one of the hottest localities in the country, the highest temperature of 120° F (49° C) has been recorded in July. January temperatures may drop to 5° F (−15° C) and below in the high mountain areas, while at the city of Kabul, located at an altitude of 5,900 feet, the lowest temperature has been recorded at −24° F (−31° C).

In the mountains the annual mean precipitation increases from west to east; there, as in the southeastern monsoon region, it averages about 16 inches (400 millimetres). The

The Sīstān depression

Helmand River

The Amīr lakes in the Bābā Mountains.

Daniele Pellegrini—Photo Researchers

extremes of precipitation have been recorded in the Sālang Pass of the Hindu Kush, with the highest annual precipitation of 53 inches, and in the arid region of Farāh in the west, with only three inches a year. Most of the country's precipitation occurs from December to April; in the highlands snow falls from December to March, while in the lowlands, it rains intermittently from December to April or May. The summer months are hot, dry, and cloudless everywhere but in the monsoon region.

Plant and animal life. Vegetation is sparse in the southern part of the country, particularly toward the west, where dry regions and sandy deserts predominate. Trees are rare, and only in the rainy season of early spring is the soil covered with flowering grasses and herbs. The plant cover becomes more dense toward the north, where precipitation is more abundant; and at higher altitudes the plants are almost luxuriant, particularly in the mountainous region north of Jalālābād, where the climate is influenced by the monsoons. The high mountains abound in large forest trees, among which conifers, such as pine and fir, predominate. Some of these trees are 180 feet high. The average altitude for the fir line is over 10,000 feet. At lower altitudes, somewhere between 5,500 and 7,200 feet, cedar is abundant; below the fir and cedar lines, oak, walnut, alder, ash, and juniper trees can be found. There are also shrubs, several varieties of roses, honeysuckle, hawthorn, and currant and gooseberry bushes.

Most of the wild animals of the subtropical temperate zone inhabit Afghanistan. Large mammals, formerly abundant, are now greatly reduced in numbers. The Siberian tiger, which inhabited the banks of the Amu River, has all but disappeared, as have the tigers that inhabited the southeastern region. There is still a great variety of wild animals roaming the mountains and foothills, including wolves, foxes, striped hyenas, and jackals. Gazelles, wild dogs, and wild cats, such as snow leopards, are widespread. Wild goats, including the markhor (prized for its long, twisted horns) and the ibex (with long, backward-curving horns), can be found in the Pamirs, and wild sheep, including the urial and argali (or Marco Polo sheep), in the Pamirs and the Hindu Kush. Brown bears are found in the mountains and forests. Smaller animals, such as mongooses, moles, shrews, hedgehogs, bats, and several species of kangaroo rat (jerboas), may be found in the many isolated, sparsely populated areas.

Birds of prey include vultures, which occur in great numbers, and eagles. Migratory birds abound during the spring and fall seasons. There are also many pheasant, quail, cranes, pelicans, snipe, partridge, and crows.

There are many varieties of freshwater fish in the rivers, streams, and lakes, but their numbers are not great except on the northern slopes of the Hindu Kush, where the rivers are well stocked with brown trout.

Settlement patterns. The Hindu Kush divides the country into northern and southern regions, which can be further subdivided on the basis of topography, national and ethnolinguistic settlement patterns, or historical tradition. Northern Afghanistan, for example, may be subdivided into the Badakhshān–Vākhān region in the east and the Balkh–Meymaneh region in the west. The east, which is

mainly a conglomeration of mountains and high plateaus, is inhabited chiefly by Tadjiks (Tajiks), while the west, which is mostly plains of comparatively low altitude, contains a mixture of peoples in which Uzbeks and Turkmens of Turkic origin predominate.

Southern Afghanistan can be subdivided into four subregions—those of Kabul, Qandahār, Herāt, and Hazārajāt. The Kabul region combines the area drained by the Kābul River and the high plateau of eastern Afghanistan, bounded in the south by the Gowmal (Gumal) River. This region is inhabited by Pashtuns (formerly called Pathans, a term now considered to be derogatory), Tadjiks, and Nūristānis. This region is the main corridor connecting the other regions and their peoples.

The Qandahār region consists of the sparsely populated southern part of Afghanistan. The people inhabiting this region belong principally to the Durrānī branch of the Pashtuns. In addition, there is a small number of Baluch and Brahui peoples. The city of Qandahār is located in a fertile oasis near the Arghandāb River.

The region of Herāt, or western Afghanistan, is inhabited by a mixture of Tadjiks, Pashtuns, and Chahar Aimaks. The life of the region revolves around the city of Herāt.

The mountainous region of Hazārajāt occupies the central part of the country and is inhabited principally by the Hazāras. Although Hazārajāt is located in the heart of the country, its high mountains and poor communication facilities make it the most isolated part of Afghanistan.

Urban settlement. Most urban settlements have grown along the road that runs from Kabul southwestward to Qandahār, then northwest to Herāt, northeast to Mazār-e Sharif, and southeast back to Kabul. The rural population of farmers and nomads is distributed unevenly over the rest of the country, mainly concentrated along the rivers. The most heavily populated part of the country is between the cities of Kabul and Chārikār. Other concentrations of people can be found east of the city of Kabul near Jalālābād, in the Herāt oasis and the valley of the Hari River in the northwest, and in the valley of the Qondūz River in the northeast. The high mountains of the central part of the country and the deserts in the south and southwest are sparsely populated or uninhabited.

The major cities of Afghanistan are Kabul, Qandahār, Herāt, Baghlān, Jalālābād, Kondūz, Chārikār, and Mazār-e Sharif. Kabul is the administrative capital of the country, located south of the Hindu Kush at the crossroads of the trade routes between the Indian subcontinent and Central Asia and between the Middle and Far East. It is built on both sides of the Kābul River and is the main centre of economic and cultural activity. Qandahār, second to Kabul in population, is located on the Asian Highway in the south-central part of the country, between Kabul and Herāt. Qandahār became the first capital of modern Afghanistan in 1747 under Aḥmad Shāh Durrānī.

Rural settlement. Sedentary farmers usually live in small villages, most of them scattered near irrigated land in the valleys of major rivers. These villages, as a rule, are built in the form of small forts. Each fort-village contains several mud houses, inhabited by closely connected families who form a defensive community.

Southern
Afghan-
istan

Major
cities

The semisedentary farmers, who breed livestock and raise a few crops, live in the high alpine valleys. Since cultivable land there is scarce, they live in scattered isolated hamlets. Each household owns a few head of livestock, which are moved in summer to the highland pastures. The people usually divide themselves into two groups in summer: one group remains in the hamlet to tend the crops, while the other accompanies the livestock to the highlands.

The nomads are mainly Pashtun herdsman; there are also several thousand Baluch and Kirgiz nomads. They move in groups (tribes or clans) from summer to winter pasturages, living in tents and, while on the move, packing their belongings on the backs of camels, donkeys, and cattle. Between one-sixth and one-fifth of the total population may be classified as nomadic. Since 1977, however, some nomads have been settled in the plains north of the Hindu Kush or in the area of the Helmand Valley (irrigation) Project.

THE PEOPLE

Ethnolinguistic groups. The people of Afghanistan form a mosaic of ethnic and linguistic groups. Pashto (Pushtu) and Dari, a dialect of Persian (Fārsī), are Indo-European languages; they are the official languages of the country. About half of the population speaks Pashto, the language of the Pashtuns, while about a third of the population speaks Dari, the language of the Tadjik (Tajik), Hazāra, Chahar Aimak, and Kizilbash peoples. Other Indo-European languages, spoken by smaller groups, include Western Dardic (Nūristāni or Kafiri), Baluchi, and a number of Indic and Pamiri languages spoken principally in isolated valleys in the northeast. Turkic languages, a subfamily of the Altaic languages, are spoken by the Uzbek and Turkmen peoples, the most recent settlers, who are related to peoples from the steppes of Central Asia. The Turkic languages are closely related; within Afghanistan they include Uzbek, Turkmen, and Kirgiz, the last spoken by a small group in the extreme northeast.

The present population of Afghanistan contains a number of elements, which, in the course of history and as a result of large-scale migration and conquests, have been superimposed upon each other. Dravidians, Indo-Aryans, Greeks, Scythians, Arabs, Turks, and Mongols have, at different times, inhabited the country and have influenced its culture and ethnography. Intermixture of the two principal linguistic groups is evident in such peoples as the Hazāras and Chahar Aimaks, who speak Indo-European languages but have pronounced Mongoloid physical characteristics and cultural traits usually associated with Central Asia.

Pashtuns The Pashtuns of Afghanistan principally inhabit the southern and eastern parts of the country but are also well represented in the west and north. They are divided into a number of tribes, some sedentary and others nomadic. The traditional homeland of the Pashtuns lies in an area east, south, and southwest of Kabul; many live in contiguous territory of Pakistan. The two most important groups of the Pashtun tribal confederation are the Durrānis, who live in the area around the city of Qandahār, and the Ghilzays, who inhabit the region between Kabul and Qandahār. The Durrānis formed the traditional nucleus of Afghanistan's social and political elite.

The Tadjiks, mostly farmers and artisans, live in the Kābol and Badakhshān provinces of the northeast and the Herāt region in the west; there are also pockets of Tadjiks in other areas. They are sedentary in the plains and semisedentary in the higher valleys. The Tadjiks are not divided into clear-cut tribal groups.

The Nūristānis, who speak Western Dardic, inhabit an area of some 5,000 square miles in Laghmān, Nangarhār, and Konarhā provinces, north and east of Kabul. The Hazāras traditionally occupy the central mountainous region of Hazārajāt. Because of the scarcity of land, however, many have migrated to other parts of the country. The Hazāras speak a Dari dialect that contains a number of Turkish and Mongolian words.

Uzbeks and Turkmen The Chahar Aimaks are probably of Turkic or Turco-Mongolian origin, judging by their Mongoloid physical appearance and their housing of Mongolian-style yurts. They are located mostly in the western part of the central

mountain region. The Uzbeks and Turkmens inhabit a region north of the Hindu Kush, and there are small numbers of Kirgiz in the Vākhān in the extreme northeast. The Uzbeks are usually farmers, while the Turkmens and Kirgiz are mainly seminomadic herdsman. The Uzbeks are the largest Turkic-speaking group in Afghanistan. There are also other smaller Turco-Mongolian groups.

Afghanistan has very small ethnic groups of Dravidian and Semitic speakers. Dravidian languages are spoken by the Brahuis, residing in the extreme south. There is also a small number of Jews, most of whom speak Dari in their daily lives but use Hebrew for religious ceremonies.

Religion. About 99 percent of the people of Afghanistan are Muslims, of whom some three-fourths are members of the Sunnī sect (Hanafi branch). The others, particularly the Hazāras, Kizilbash, and a few Ismā'īlis, follow Shī'ite Islām. The Nūristānis are descendants of a large ethnic group, the Kafirs, who were forcibly converted to Islām in 1895; the name of their region was then changed from Kafiristan ("Land of the Infidels") to Nūristān ("Land of Light"). There are also a few thousand Hindus and Sikhs.

Demographic trends. The establishment of the Democratic Republic of Afghanistan in 1978 and the Soviet invasion of the country the following year disrupted the country's population patterns. Civil war and the destruction of towns and villages caused mass movements of people in two major directions—emigration, mainly to Pakistan and Iran, or escape to the relative safety of the capital city, Kabul. By some estimates, almost 3,000,000 people escaped to Pakistan and some 1,850,000 to Iran; the population of Kabul is estimated to have doubled in size. Kabul has grown to encompass almost half of the urban population of the country. Afghanistan's population is mainly rural; almost half of the population is under 15 years of age. Life expectancy is less than 40 years.

THE ECONOMY

When Afghanistan began to plan the development of its economy in the mid-1950s, it lacked not only the necessary social organization and institutions for modern economic activities but also managerial and technical skills. The country was at a much lower stage of economic development than most of its neighbours. Between 1956 and 1979, however, the country's economic growth was guided by several five-year and seven-year plans and was aided by extensive foreign assistance, primarily from the Soviet Union and the United States. Roads, dams, power plants, and factories were constructed, irrigation projects carried out, and education broadened.

The Soviet invasion in 1979 and the subsequent civil war severely disrupted Afghanistan's economic development. Agricultural production declined and food shortages were reported, and, with the exception of natural gas production and some other industries considered essential by the Soviet Union, industrial output stagnated. Thus, Afghanistan remains economically one of the world's poorest countries.

Management of the economy. The Socialist government is committed to developing a mixed, guided economy by means of a series of five-year plans. In practice, the effectiveness of such a policy has been limited by the paucity of government resources, by a cumbersome bureaucracy, and by a shortage in technical personnel.

Before the Soviet invasion, the government budget was divided into two parts, ordinary and development. The former covered administrative activities and the latter investment expenditures, incorporated into the national plans of development. Total domestic revenue was usually exceeded by expenditures; the difference was covered through deficit financing and foreign loans and grants. Following the Soviet invasion, a balanced budget was achieved with revenue derived principally from the sale of natural gas and from foreign loans and grants. Expenditures were mainly for governmental ministries, the developmental budget, and foreign debt service.

The private sector engages primarily in agriculture and livestock breeding. There formerly was a mixed pattern of small, medium, and large landholdings, but this system underwent drastic change, particularly after 1978. The bulk of the trade and transport and most manufacturing

were in the hands of private entrepreneurs until the late 1970s when these sectors of the economy were nationalized. Public enterprise formerly was confined to a section of the foreign trade, to mining, and to some industries.

Because most of the population is engaged in agriculture, the industrial labour force is insignificant, and labour unions have failed to develop. Traditional loyalties to families and tribes are stronger than those to workers' organizations.

Natural gas

Resources. *Mineral resources.* Extensive surveys have revealed the existence of a number of minerals of economic importance. The most important discovery has been that of natural gas, with large reserves near Sheberghān in Jowzjān province, near the Soviet border, about 75 miles west of Mazār-e Sharif. The Khvājeh Gügerdak and Yatim Taq fields are major producers, with storage and refining facilities. Pipelines deliver natural gas to the Soviet Union and to a thermal power plant and chemical fertilizer plant in Mazār-e Sharif.

Petroleum resources have proved to be insignificant. Many coal deposits have been found in the northern slopes of the Hindu Kush. Major coal fields are at Karkar and Eshposhteh, in Baghlān province, and Fort Sarkārī, in Balkh province.

High-grade iron ore, with an iron content of 62–63 percent, has been discovered at Hājigak, 60 miles northwest of Kabul. Copper is mined at 'Aynak, near Kabul, and uranium is extracted in the mountains near Khvājeh Rawāsh, east of Kabul. There are also deposits of copper, lead, and zinc near Kondūz; beryllium in Khās Konar; chrome ore in the Lowgar valley near Herāt; and the semi-precious stone lapis lazuli in Badakhshān. Afghanistan also has deposits of rock salt, beryl, barite, fluor spar, bauxite, lithium, tantalum, gold, silver, asbestos, mica, and sulfur.

Biologic resources. Afghanistan is essentially a pastoral country. Only 12 percent of the total land area is arable, and only about half of the arable acreage is cultivated annually. Much of the arable area consists of fallow cultivable land or steppes and mountains that serve as pastureland. In addition, a large area is desert.

Forests cover about 3 percent of the total land area; they are found mainly in the eastern part of the country and on the southern slopes of the Hindu Kush. Those in the east consist mainly of conifers, providing timber for the building industry as well as some wild nuts for export. Other trees, especially oaks, are used as fuel. North of the Hindu Kush are pistachio trees, the nuts of which are exported.

Power resources. Afghanistan is potentially rich in hydroelectric resources. The seasonal flow of the country's many streams and waterfalls, however—torrential in spring, when the snow melts in the mountains, but negligible in summer—necessitates the costly construction of dams and reservoirs in remote areas. The nation's negligible demand for electricity renders such projects unprofitable except near large cities or industrial centres. The potential of hydroelectricity has been tapped substantially only in the Kabul–Jalālābād region.

Irrigation

Agriculture. Agriculture and animal husbandry, much of which consists of subsistence farming and pastoral nomadism, are by far the most important items of the gross national product, accounting for more than half of its total value. Since much of the land is arid or semiarid, about half of the cultivated land is irrigated.

Most of the cultivated land is planted with cereals. Of these, wheat is the chief crop and the staple food of the population. The other food grains are corn (maize), rice, and barley. Cotton is important, both for the domestic textile industry and for export. Fruits and nuts are also important items of export. Opium poppy and cannabis are grown for the illegal international drug trade.

Animal husbandry produces meat and dairy products for local consumption; skins, especially the famous karakul, and wool (both for export and for domestic carpet weaving) are also important products. Livestock includes sheep, cattle, goats, donkeys, horses, camels, buffalo, and mules. About two-thirds of the annual milk production is from cows, the rest from sheep and goats.

Industry. Industry is based mainly on agricultural and pastoral raw materials. Most important is the cotton tex-

tile industry. The country also produces rayon and acetate fibres. Other industrial products are cement, sugar, vegetable oil, furniture, soap, shoes, and woolen textiles. A nitrogenous fertilizer plant, based on natural gas, has been constructed in Mazār-e Sharif, and phosphate fertilizers are also produced. In addition, Afghanistan has a number of traditional handicrafts, which account for a fair proportion of the country's export earnings.

Finance. In 1975 the government nationalized all banks. The largest bank in the country, the Bank of Afghanistan, is the centre of the formal banking system. It is the sole bank of issue, and it plays an important role in determining and implementing the government's financial policies. There are private money traders who provide nearly all the services of a commercial bank.

Trade. Total annual imports usually exceed exports. Roughly two-thirds of Afghanistan's exports go to the Soviet Union and one-seventh to the United Kingdom and West Germany. The Soviet Union is also the leading source of imports, followed by Japan, West Germany, Hong Kong, and the United Kingdom. The principal export is natural gas, which goes mainly to the Soviet Union. In addition, dried fruit, nuts, carpets, wool, and karakul pelts are exported. Imports include vehicles, petroleum products, sugar, textiles, processed animal and vegetable oils, and tea.

Transportation. Being a landlocked country, Afghanistan is primarily dependent on transit facilities from its neighbours for its international trade. Lacking railways and with few navigable rivers, it relies on roads as the mainstay of its transport system. These factors produce high transport costs and also add to the difficulty of integrating the transport system of the country with those of its neighbours. Nevertheless, in the 1960s major efforts were directed toward upgrading the highway system and to connecting the main trading centres of the country with one another, as well as with the railheads or road networks of neighbouring countries.

The road network of Afghanistan now connects Soviet railheads in Kushka and Termez with those at Chaman and Peshāwar, Pak., respectively, and provides for direct overland transit between the Soviet Union and the Indo-Pakistani subcontinent. The most important Afghan highways are those connecting Kabul with Shir Khān, on the Soviet border in the north, and with Peshāwar. Other paved roads link Qandahār, Herāt, and Mazār-e Sharif with Kabul and with frontier towns of Pakistan, Iran, and the Soviet Union.

Despite the rapid development of motor transport, camels and donkeys are still commonly used as draft animals. In the countryside many people have not abandoned their cherished horses, which are important for prestige.

Civil aviation has increased in importance. Almost all provincial centres have at least a seasonally operable airport, while there are international airports at Kabul and Qandahār. (V.P.P.)

Major highways

ADMINISTRATION AND SOCIAL CONDITIONS

Government. Until the middle of the 20th century, Afghanistan was ruled by the absolute power of the king. Two constitutions were promulgated, in 1923 and 1931, both affirming the power of the monarchy. The constitution of 1964, however, provided for a constitutional monarchy, based on the separation of executive, legislative, and judicial authorities. A military coup in 1973 overthrew the monarchy, abolished the constitution of 1964, and established the Republic of Afghanistan. The Grand National Assembly (*Loya Jirgah*) adopted a new constitution in February 1977, but it was abrogated in 1978 when another coup established the Democratic Republic of Afghanistan, governed by the Afghan Revolutionary Council. Political turmoil continued, marked by a third coup in September 1979, a massive invasion of troops from the Soviet Union, and the installation of a socialist government in December 1979. A new constitution promulgated in 1987 changed the name of the country back to the Republic of Afghanistan and reaffirmed its nonaligned status, strengthened the post of president, and permitted other parties to participate in government.

Political instability

The highest government authority is vested in the Grand National Assembly, a body defined as "the highest manifestation of the will of the people of Afghanistan" and made up of members of the executive, legislative, and judicial branches. The Grand National Assembly has the power to elect the president, amend and interpret the constitution, declare war, and adopt decisions on "the most important questions concerning the country's national destiny." The head of state and commander in chief of the armed forces is the president, who is elected for a seven-year term. The Council of Ministers is the highest executive body and is responsible for domestic and foreign policy. The National Assembly is the highest legislative body and comprises a 192-member council of elders and a 234-member council of representatives.

Afghanistan has a centralized system of local government. For administrative purposes the country is divided into provinces, each administered by a centrally appointed governor. The provinces are further subdivided into districts and subdistricts, headed by appointed commissioners.

Armed forces. Regular army officers are trained in a military school in Kabul. There is a small air force, equipped with modern Soviet aircraft and with bases at Bagrām and Shindand. A secret police force was organized in the late 1970s. (V.P.P./Ed.)

Education. Education is free at all levels, and elementary education is officially compulsory wherever it is provided by the state. Nonetheless, fewer than one-fourth of all Afghan children attend school. There are primary schools throughout the country but secondary schools only in the provincial and in some district centres. Less than one-fourth of the population is literate. Kabul University was founded in 1946 by the incorporation of a number of faculties, the oldest of which is the faculty of medicine, established in 1932. The University of Nangarhār was formed in Jalālābād in 1963.

Health and welfare. Health care and the availability of hospitals, doctors, and nurses in Afghanistan are greatly deficient. Medical training is almost nonexistent, and the medical aid that is available is provided mainly by foreign countries. The major proportion of medical services is concentrated in Kabul, and many rural areas do not have hospitals or doctors. The lack of health care accounts for a high mortality rate among young children. Welfare measures offered by the government are minimal.

Social divisions. The bulk of the population in the rural areas consists of small farmers exploiting their tiny plots of land. The majority of the city and town dwellers are artisans, small traders, or government employees. The industrial labour force, though small, has grown. There is also a business community of merchants and industrialists. Since the 1960s the wearing of a veil by women has been voluntary, and women have found employment in offices and shops. Some Afghan women have received a university education.

CULTURAL LIFE

Afghanistan has a rich cultural heritage, covering more than 5,000 years. Because of almost complete isolation from the outside world, however, little in art, literature, or architecture was produced between the 16th and early 20th centuries. Because most Afghans live outside the cities, their mode of living can be described as that of a peasant tribal society. Kinship is the basis of social life and determines the patriarchal character of the community. Religion plays a very important role.

Archaeological research carried out since 1922 has uncovered many fine works of art of the pre-Islāmic and Islāmic periods. A revival of the traditional arts and an interest in new forms of expression have given a new dynamism to artistic creation. Of the new painters, some draw direct inspiration from the Herāt school of the 15th-century Timurid period; others are influenced by Western styles. Through government initiative, some of the old monuments of architectural value are being restored and redecorated. The School of Fine Arts was established in Kabul in the 1930s. In architecture, the traditional Timurid techniques are preserved, particularly in the design of the exterior walls of mosques or tombs. Handicrafts include

the world-renowned Afghan carpets and copper utensils.

Theatre as known in the West has flourished only since about 1960. Adaptations of European classics were introduced at first, but the present trend favours the didactic treatment of themes from everyday Afghan life. In addition to city theatres such as those in Kabul, Herāt, or Qandahār, there are traveling companies that take plays to provincial centres or country fairs.

In music and dance, a revival of traditional folksinging has gone hand in hand with the imitation of modern Western and Indian music. Afghan music is different from Western music in many ways, particularly in its scales, note intervals, pitch, and rhythm, but it is closer to Western than to Asian music. Afghans celebrate their religious or national feast days, and particularly weddings, by public dancing. The performance of the *attan* dance in the open air has long been a feature of Afghan life. It is the national dance of the Pashtuns and now of the nation.

The *attan* dance

The Afghan Historical Society is devoted to disseminating information on Afghan history. It publishes *Aryana*, a monthly, in Pashto and Dari. The society also arranges for the publication of research works on Afghan history, manuscripts, and historical sites and monuments. The Pashto Society works for the development of Pashto literature and for its promotion among the non-Pashto-speaking population. It publishes the monthly *Kābul* and arranges for the publication of old Pashto manuscripts as well as of works on Pashto linguistics and literature.

For statistical data on the land and people of Afghanistan, see the *Britannica World Data* section in the BRITANNICA WORLD DATA ANNUAL. (V.P.P.)

History

Variations on the word "Afghan" may go back as early as a 3rd-century-AD Sāsānian reference to "Abgan." The earliest Muslim reference to the Afghans probably dates to AD 982, but tribes related to the modern Afghans have lived in the region for many generations. For millennia, the land now called Afghanistan has been the meeting place of four cultural and ecological areas: the Middle East, Central Asia, South Asia, and the Far East.

PREHISTORY

Paleolithic peoples probably roamed Afghanistan as early as 100,000 BC. The earliest definite evidence of human occupation was found in the cave of Darra-i-Kur in Badakhshān, where a transitional Neanderthal skull fragment in association with Mousterian-type tools was discovered; the remains are of the Middle Paleolithic, dating about 30,000 years ago. Caves near Aq Koprūk yielded evidence of an early Neolithic culture (c. 9000–6000 BC) based on domesticated animals. Archaeological research since World War II has revealed Bronze Age sites, dating both before and after the Indus Valley (or Harappān) civilization of the 3rd to the 2nd millennium BC. There was trade with Bronze Age Mesopotamia and Egypt, the main export from the Afghan area being lapis lazuli from the mines of Badakhshān. In addition, a site with definite links to the Harappān civilization has been excavated at Shortugai near the Amu River, northeast of Kondūz.

HISTORICAL BEGINNINGS (TO THE 7TH CENTURY AD)

The Achaemenians and the Greeks. In the 6th century BC the Achaemenian ruler Cyrus II the Great established his authority over the area. Darius I the Great consolidated Achaemenian rule of the region through the provinces, or satrapies, of Aria (in the region of modern Herāt), Bactria (Balkh), Sattagydia (Ghazni to the Indus River), Arachosia (Qandahār), and Drangiana (Seistan).

Alexander the Great overthrew the Achaemenians and conquered most of the Afghan satrapies before he left for India in 327 BC. Ruins of an outpost Greek city founded about 325 BC were discovered at Ay Khānom, at the confluence of the Amu and Kowkchek rivers. Excavations there produced inscriptions and transcriptions of Delphic precepts written in a script influenced by cursive Greek. Greek decorative elements dominate the architecture, including an immense administrative centre, a theatre, and

Alexander the Great

a gymnasium. A nomadic raid about 130 BC ended the Greek era at Ay Khānom.

After Alexander's death in 323 BC, the eastern satrapies passed to the Seleucid dynasty, which ruled from Babylon. In about 304 BC the territory south of the Hindu Kush was ceded to the Maurya dynasty of northern India. Bilingual rock inscriptions in Greek and Aramaic (the official language of the Achaemenians) found at Qandahār and Laghmān (in eastern Afghanistan) date from the reign of Aśoka (c. 265–238 BC, or c. 273–232 BC), the Maurya dynasty's most renowned emperor. Diodotus, a local Greco-Bactrian governor, declared the Afghan plain of the Amu River independent about 250 BC; Greco-Bactrian conquerors moved south about 180 BC and established their rule at Kabul and in the Punjab. The Parthians of eastern Iran also broke away from the Seleucids, establishing control over Seistan and Qandahār in the south.

The Kushāns. About 135 BC a loose confederation of five Central Asian nomadic tribes known as the Yüeh-chih wrested Bactria from the Bactrian Greeks. These tribes united under the banner of the Kushān (Kuṣāṇa), one of the five tribes, and conquered the Afghan area. The zenith of Kushān power was reached in the 2nd century AD under King Kanīška (c. AD 78–144), whose empire stretched from Mathurā in north-central India beyond Bactria as far as the frontiers of China in Central Asia.

Kushān
art

The Kushāns were patrons of the arts and of religion. A major branch of the Silk Road carrying luxury goods and ideas between Rome, India, and China passed through Afghanistan, where a transshipment centre existed at Balkh. Indian pilgrims traveling the Silk Road introduced Buddhism to China during the early centuries AD, and Buddhist Gandhāra art flourished during this period. The world's largest Buddha figures (175 feet and 120 feet tall) were carved into a cliff at Bāmiān in the central mountains of Afghanistan during the 3rd and 4th centuries AD. Further evidence of the trade and cultural achievement of the period has been recovered at the Kushān summer capital of Bagrām, north of Kabul; it includes painted glass from Alexandria; plaster matrices, bronzes, porphyries, and alabasters from Rome; carved ivories from India; and lacquers from China. A massive Kushān city at Delbarjīn, north of Balkh, and a major gold hoard of superb artistry near Sheberghān, west of Balkh, also have been excavated.

The Sāsānians and Hephthalites. The Kushān Empire did not long survive Kanīška, though for centuries Kushān princes continued to rule in various provinces. Persian Sāsānians established control over parts of Afghanistan, including Bagrām, in AD 241. In AD 400 a new wave of Central Asian nomads under the Hephthalites took control, only to be defeated in AD 565 by a coalition of Sāsānians and Western Turks. From the 5th through the 7th century many Chinese Buddhist pilgrims continued to travel through Afghanistan. The pilgrim Hsüan-tsang (Xüanzang) wrote an important account of his travels, and several of the religious centres he visited, including Hadda, Ghazna, Kondūz, Bāmiān, Shotorak, and Bagrām, have been excavated.

MEDIEVAL PERIOD (7TH–18TH CENTURY)

Under the Hephthalites and Sāsānians, many of the Afghan princedoms were influenced by Hinduism. The Hindu kings (Shāhi) were concentrated in the Kabul and Ghaznī areas. Excavated sites of the period include a major Hindu Shāhi temple north of Kabul and a chapel in Ghaznī that contains both Buddhist and Hindu statuary, indicating that there was a mingling of these two religions.

The first Muslim dynasties. Islāmic armies defeated the Sāsānians in AD 642 at Nahāvand (near modern Hamadān, Iran) and moved on to the Afghan area, but they were unable to hold the territory; cities submitted, only to rise in revolt, and the hastily converted returned to their old beliefs once the armies had passed. The 9th and 10th centuries witnessed the rise of numerous local Islāmic dynasties. One of the earliest was the Tāhirids of Khorāsān, whose kingdom included Balkh and Herāt; they established virtual independence from the 'Abbāsīd caliphate in AD 820. The Tāhirids were succeeded in 867–869 by a native dynasty from Seistan, the Šaffārids. Lo-

cal princes in the north soon became feudatories of the powerful Sāmānids, who ruled from Bukhara. From 872 to 999 Bukhara, Samarkand, and Balkh enjoyed a golden age under Sāmānid rule. (L.Du./N.H.D.)

The Ghaznavids. In the middle of the 10th century a former Turkish slave named Alptegin seized Ghazna (Ghaznī). He was succeeded by another former slave, Subūktigin, who extended the conquests to Kabul and the Indus. His son was the great Maḥmūd of Ghazna, who came to the throne in 998. Maḥmūd conquered the Punjab and Multan and carried his raids into the heart of India. The hitherto obscure town of Ghazna became a splendid city, as did the second capital at Bust (Lashkar Gāh).

Maḥmūd
of Ghazna

The Ghūrids. Maḥmūd's descendants continued to rule over a gradually diminishing empire until 1150, when 'Alā'-ud-Dīn Husayn of Ghūr, a mountain-locked region in central Afghanistan, sacked Ghazna and drove the last Ghaznavid out to India. 'Alā'-ud-Dīn's nephew, Mu'izz-ud-Dīn Muḥammad, known as Muḥammad of Ghūr, first invaded India in 1175. After his death in 1206, his general, Quṭb-ud-Dīn Aybak, became the sultan of Delhi.

The Khwārezm-Shāhs. Shortly after Muḥammad of Ghūr's death, the Ghurid Empire fell apart, and Afghanistan was occupied by Sultan 'Alā' ad-Dīn Muḥammad, the Khwārezm-Shāh. The territories of the Khwārezm-Shāh dynasty extended from Chinese Turkistan in the east to the borders of Iraq in the west. (F.R.A.I.)

The Mongol invasion. Genghis Khan invaded the eastern part of 'Alā' ad-Dīn's empire in 1219. Avoiding a battle, 'Alā' ad-Dīn retreated to a small island in the Caspian Sea, where he died in 1220. Soon after 'Alā' ad-Dīn's death, his energetic son Jalāl ad-Dīn Mingburnu rallied the Afghan highlanders at Parwan (modern Jabal os Sarāj), near Kabul, and inflicted a crushing defeat on the Mongols under Kutikorian. Genghis Khan, who was then at Herāt, hastened to avenge the defeat and laid siege to Bāmiān. There Mutugen, the Khān's grandson, was killed, an event so infuriating to Genghis Khan that when he captured the citadel he ordered that no living being be spared. Bāmiān was utterly destroyed. Advancing on Ghazna, Genghis won a great victory over Jalāl ad-Dīn, who then fell back toward the Indus (1221), where he made a final but unsuccessful stand.

Later medieval dynasties. After his death in 1227, Genghis Khan's vast empire fell to pieces. In Afghanistan some local chiefs succeeded in establishing independent principalities, and others acknowledged Mongol princes as suzerains. This state of affairs continued until the end of the 14th century, when Timur (Tamerlane) conquered a large part of the country.

Timur's successors, the Timurids, were great patrons of learning and the arts who enriched their capital city of Herāt with fine buildings. Under their rule (1404–1507) Afghanistan enjoyed peace and prosperity.

Early in the 16th century the Turkic Uzbeks rose to power in Central Asia under Muḥammad Shaybānī, who took Herāt in 1507. In late 1510 the Šafavid shāh Esmā'il besieged Shaybānī in Merv and killed him. Bābur, a descendant of Genghis Khan and Timur, had made Kabul the capital of an independent principality in 1504. He captured Qandahār in 1522, and in 1526 he marched on Delhi. He defeated Ibrāhīm, the last of the Lodi Afghan kings of India, and established the Mughal Empire, which lasted until the middle of the 19th century and included all of eastern Afghanistan south of the Hindu Kush. The capital was at Agra. Nine years after his death in 1530, the body of Bābur was taken to Kabul for burial.

The
Mughals

During the next 200 years Afghanistan was parceled between the Mughals of India and the Šafavids of Persia—the former holding Kabul north to the southern foothills of the Hindu Kush and the latter Herāt and Farāh. Qandahār was for many years in dispute.

LAST AFGHAN EMPIRE

Overthrow of foreign rule. Periodic attempts were made to gain independence. In 1709 Mir Veys Khān, a leader of the Hotaki Ghilzay tribe, led a successful rising against Gorgin Khān, the Persian governor of Qandahār.

The Hotakis. Mir Veys Khān governed Qandahār until his death in 1715. In 1716 the Abdālīs of Herāt, encouraged by his example, took up arms against the Persians and under their leader, Asadullāh Khān, succeeded in liberating their province. Mahmūd, Mir Veys's young son and successor, was not content with holding Qandahār, and in 1722 he led some 20,000 men against Isfahan; the Ṣafavid government surrendered after a six-month siege.

Maḥmūd died in 1725 and was succeeded by Ashraf, who had to contend with Russian pressure from the north and Ottoman Turk advances from the west. Shāh Ashraf halted both the Russian and Turkish onslaughts, but a brigand chief, Nāder Qolī Beg, defeated the Afghans at Dāmghān in October 1729 and drove them from Persia. During the retreat Ashraf was murdered, probably on orders from his cousin, who was then holding Qandahār.

Nāder Shāh. Nāder Qolī Beg took Herāt in 1732 after a desperate siege. Impressed by their courage, Nāder recruited many Herātīs to serve in his army. He was elected *shāh* of Persia, with the name Nāder Shāh, in 1736.

In 1738, after a year's siege, the city of Qandahār fell to Nāder Shāh's army of 80,000 men. Nāder Shāh seized Ghazna and Kabul and occupied the Mughal capital at Delhi in 1739. His booty included the Koh-i-noor diamond and the Peacock Throne. He was assassinated at Khabushan in 1747, which led to the disintegration of his empire and the rise of the last great Afghan empire.

The Durrānī dynasty. The commander of the Shāh's 4,000-man Afghan bodyguard was Aḥmad Khān Abdālī, who returned to Qandahār where he was elected king (*shāh*) by a tribal council. He adopted the title Durr-i Durrān ("Pearl of Pearls"). Supported by most tribal leaders, Aḥmad Shāh Durrānī extended Afghan control from Meshed to Kashmir and Delhi, from the Amu River to the Arabian Sea. The Durrānī was the second greatest Muslim empire in the second half of the 18th century, surpassed in size only by the Ottoman.

Aḥmad Shāh died in 1772 and was succeeded by his son, Timūr Shāh, who received but nominal homage from the tribal chieftains. Much of his reign was spent in quelling their rebellions. Because of this opposition, Timūr shifted his capital from Qandahār to Kabul in 1776.

Zamān Shāh (1793–1800). After the death of Timūr in 1793, his fifth son, Zamān, seized the throne with the help of Sardār Pāyenda Khān, a chief of the Bārakzay. Zamān then turned to India with the object of repeating the exploits of Aḥmad Shāh. This alarmed the British, who induced Faṭḥ 'Alī Shāh of Persia to bring pressure upon the Afghan king and divert his attention from India. The *shāh* went a step further, helping Maḥmūd, governor of Herāt and a brother of Zamān, with men and money and encouraging him to advance on Qandahār. Maḥmūd, assisted by his vizier, Faṭḥ Khān Bārakzay, eldest son of Sardār Pāyenda Khān, and by Faṭḥ 'Alī Shāh, took Qandahār and advanced on Kabul. Zamān, in India, hurried back to Afghanistan. There he was handed over to Maḥmūd, blinded, and imprisoned (1800). The Durrānī Empire had begun to disintegrate after 1798, when Zamān Shāh appointed a Sikh, Ranjit Singh, as governor of Lahore.

Shāh Maḥmūd (1800–03; 1809–18). Shāh Maḥmūd left affairs of state to Faṭḥ Khān. Some of the chiefs who had grievances against the King or his ministers joined forces and invited Zamān's brother Shāh Shojā' to Kabul. The intrigue was successful. Shāh Shojā' occupied the capital, and Maḥmūd sued for peace.

Shāh Shojā' (1803–09; 1839–42). The new king, Shāh Shojā', ascended the throne in 1803. The chiefs had become powerful and unruly, and the outlying provinces were asserting their independence. The Sikhs of the Punjab were encroaching upon Afghan territories from the east, while the Persians were threatening from the west.

Napoleon, then at the zenith of his power in Europe, proposed to Alexander I of Russia a combined invasion of India. A British mission, headed by Mountstuart Elphinstone, met Shāh Shojā' at Peshāwar to discuss mutual defense against this threat, which never developed. A treaty of friendship was concluded (June 7, 1809), the *shāh* promising to oppose the passage of foreign troops through his dominions. Shortly after the mission left Pe-

shāwar news was received that Kabul had been occupied by the forces of Maḥmūd and Faṭḥ Khān. Shāh Shojā's troops were routed, and he withdrew from Afghanistan and found asylum with the British at Ludhiāna in 1815.

The rise of the Bārakzay. The Bārakzay were now dominant. This situation incited the jealousy of Kāmran, Maḥmūd's eldest son, who seized and blinded Faṭḥ Khān. Later, Shāh Maḥmūd had him cut to pieces.

Dōst Moḥammad (1826–39; 1843–63). Advancing from Kashmir in 1818, Dōst Moḥammad, younger brother of Faṭḥ Khān, took Peshāwar and Kabul and drove Shāh Maḥmūd and Kāmran from all their possessions except Herāt, where they maintained a precarious footing for a few years. Balkh was seized by the ruler of Bukhara; the trans-Indus Afghan districts were occupied by the Sikhs; and the outlying provinces of Sind and Baluchistan assumed independence. Ghazna, Kabul, and Jalālābād fell to Dōst Moḥammad.

Dōst Moḥammad established the Bārakzay (or Moḥammadzai) dynasty. His position secure after he assumed the title of *amir* in 1826 at Kabul, he decided to recover Peshāwar from the Sikhs. Declaring a jihād, or Islāmic holy war, in 1836, he advanced on Peshāwar. The Sikh leader Ranjit Singh, however, sowed dissension in Dōst Moḥammad's camp, the invading army melted away, and Peshāwar was permanently lost to the Afghans.

In November 1837 Moḥammad Shāh of Persia laid siege to Herāt, which the British saw as the key to India. The Russians supported the Persians. The British, fearful that Persia was falling completely under Russian influence, entered into alliances with the rulers of Herāt, Kabul, and Qandahār. A British mission to Kabul under Captain (later Sir) Alexander Burnes in 1837 was welcomed by Dōst Moḥammad, who hoped the British would help him recover Peshāwar. Burnes could not give him the required assurances; and when a Russian agent appeared in Kabul, the British left for India.

With the failure of Burnes's mission, the governor general of India, Lord Auckland, ordered an invasion of Afghanistan, with the object of restoring Shāh Shojā' to the throne. In April 1839, after suffering great privations, the British Army entered Qandahār; Shāh Shojā' was then crowned *shāh*. Ghazna was captured in the following July, and in August Shāh Shojā' was installed at Kabul. Dōst Moḥammad escaped first to Balkh, then to Bukhara, where he was arrested. The Afghans, however, would tolerate neither a foreign occupation nor a king imposed on them by a foreign power, and insurrections broke out. Dōst Moḥammad escaped from prison and returned to Afghanistan to lead his partisans against the British. In a battle at Parwan on Nov. 2, 1840, Dōst Moḥammad had the upper hand, but the next day he surrendered to the British in Kabul. He was deported to India with the greater part of his family.

Outbreaks continued throughout the country, and the British eventually found their position untenable. Terms for their withdrawal were discussed with Akbar Khān, Dōst Moḥammad's son, but Sir William Hay Macnaghten, the British political agent, was killed during a parlay with the Afghans. On Jan. 6, 1842, some 4,500 British and Indian troops, with 12,000 camp followers, marched out of Kabul. Bands of Afghans swarmed around them, and the retreat ended in a blood bath. Shāh Shojā' was killed after the British left Kabul.

Though in the summer of the same year British forces reoccupied Kabul, the new governor general, Lord Ellenborough, decided on the evacuation of Afghanistan. In 1843 Dōst Moḥammad returned to Kabul. During the next 20 years Dōst Moḥammad consolidated his rule by occupying Qandahār (1855), Balkh and the northern Khanates (1859), and Herāt (1863), the last less than a month before his death in June 1863.

Shir 'Alī (1863–66; 1868–79). Shir 'Alī Khān, Dōst Moḥammad's third son, then became *amir*, but his two elder brothers took the throne from him in May 1866. Shir 'Alī regained his throne in September 1868. Shir 'Alī's reception of a Russian mission at Kabul and his refusal to receive a British one, on British terms, led directly to the war of 1878–80. Shir 'Alī, leaving his son, Ya'qūb Khān,

as his regent in Kabul, sought help from the Russians, but they advised him to make peace. Shīr 'Alī died in Mazār-e Sharīf on Feb. 21, 1879.

Yāqūb Khān (1879). The Treaty of Gandamak (Gandomak; May 26, 1879) recognized Yāqūb Khān as *amīr*, and he subsequently agreed to receive a permanent British embassy at Kabul. In addition, he agreed to conduct his foreign relations with other states in accordance "with the wishes and advice" of the British government. This British triumph, however, was short-lived. On Sept. 3, 1879, the British envoy and his escort were murdered in Kabul. British forces were again dispatched, and before the end of October they occupied Kabul. Yāqūb abdicated and was given exile in India, where he died in 1923.

(M.A.I./L.Du./N.H.D.)

'Abdor Raḥmān Khān (1880–1901). The British finally withdrew from Qandahār in April 1881. In 1880 'Abdor Raḥmān Khān, a cousin of Shīr 'Alī, had returned from exile in Central Asia and proclaimed himself *amīr* of Kabul. During the reign of 'Abdor Raḥmān, the boundaries of modern Afghanistan were drawn by the British and the Russians. The Durand Line of 1893 divided zones of responsibility for the maintenance of law and order between British India and the kingdom of Afghanistan; it was never intended as a *de jure* international boundary. Afghanistan, therefore, although never dominated by a European imperial government, became a buffer between Tsarist Russia and British India.

'Abdor Raḥmān exerted his influence, if not actual control, over the various ethnolinguistic groups inside Afghanistan, fighting some 20 small wars to convince them that a strong central government existed in Kabul. 'Abdor Raḥmān was so successful that, at his death, his designated successor and eldest son, Ḥabībollāh Khān, succeeded to the throne as Ḥabībollāh I without the usual fratricidal fighting. 'Abdor Raḥmān can be considered the founder of modern Afghanistan.

Ḥabībollāh Khān (1901–19). The introduction of modern European technology begun by 'Abdor Raḥmān was furthered by Ḥabībollāh. Western ideals and styles penetrated the Afghan royal court and upper classes. An Afghan nationalist, Maḥmūd Beg Tarzī, published (1911–18) the periodical *Serāj ol-Akbār* ("Torch of the News"), which had political influence far beyond the boundaries of Afghanistan.

Ḥabībollāh Khān visited British India in 1907 as guest of the viceroy of India, Gilbert Elliot, 4th earl of Minto. Impressed with British power, Ḥabībollāh resisted pressures from Tarzī, Amānollāh (Ḥabībollāh's third son, who had married Soraya, a daughter of Tarzī), and others to enter World War I on the side of the Central Powers (Germany, Austria-Hungary, the Ottoman Empire, and Bulgaria). The peace ending World War I brought death to Ḥabībollāh; he was murdered on Feb. 20, 1919, by persons associated with the anti-British movement, and Amānollāh seized power.

Amānollāh (1919–29). Amānollāh launched the inconclusive Third Anglo-Afghan War in May 1919. The month-long war gained the Afghans the conduct of their own foreign affairs. The Treaty of Rāwālpindi was signed on Aug. 8, 1919, and amended in 1921. Before signing the final document with the British, the Afghans concluded a treaty of friendship with the new Bolshevik regime in the Soviet Union; Afghanistan thereby became one of the first nations to recognize the Soviet government, and a "special relationship" evolved between the two governments and lasted until December 1979, when the Soviet Union invaded Afghanistan.

Amānollāh changed his title from *amīr* to *padshah* ("king") in 1923 and inaugurated a decade of reforms—including constitutional and administrative changes, removal of the veil from women, and coeducational schools—that offended conservative religious and tribal leaders.

Civil war broke out in November 1928, and a Tadzhik folk hero called Baccheh Saqow (Bacha Saqqao; "Son of a Water Carrier") occupied Kabul. Amānollāh abdicated on Jan. 14, 1929, in favour of his elder brother, Inayatollāh, but Baccheh Saqow proclaimed himself Ḥabībollāh Ghāzī (or Ḥabībollāh II), *amīr* of Afghanistan. Amānollāh failed

to retrieve his throne and went into exile in Italy. He died in 1960 in Zürich.

Moḥammad Nāder Shāh (1929–33). Ḥabībollāh II was driven from the throne by Moḥammad Nāder Khān and his brothers, distant cousins of Amānollāh. On Oct. 10, 1929, Ḥabībollāh II was executed along with 17 of his followers. A tribal assembly elected Nāder Khān as *shāh*, and the opposition was bloodily persecuted.

Nāder Shāh produced a new constitution in 1931 that was modeled on Amānollāh's constitution of 1923 but was more conservatively oriented to appease Islāmic religious leaders. The national economy developed in the 1930s under the leadership of several entrepreneurs who began small-scale industrial projects. Nāder Shāh was assassinated on Nov. 8, 1933, and the 19-year-old crown prince, Zahir, succeeded his father.

Moḥammad Zahir Shah (1933–73). The first 20 years of Zahir Shah's reign were characterized by cautious policies of national consolidation, an expansion of foreign relations, and internal development using Afghan funds alone. World War II brought about a slowdown in development processes, but Afghanistan maintained its traditional neutrality. The "Pashtunistan" problem regarding the political status of those Pashtun living on the British (Pakistani) side of the Durand Line developed after the independence of Pakistan in 1947.

Shah Mahmud, prime minister from 1946 to 1953, sanctioned free elections and a relatively free press, and the so-called Liberal Parliament functioned from 1949 to 1952. Conservatives in government, however, encouraged by religious leaders, supported the seizure of power in 1953 by Lieutenant General Mohammad Daud Khan.

Prime Minister Daud Khan (1953–63) took a stronger line on Pashtunistan, and, to the surprise of many, turned to the Soviet Union for economic and military assistance. The Soviets ultimately became Afghanistan's major aid-and-trade partner. The Afghans refused to take sides in the Cold War, and Afghanistan became an "economic Korea," testing the Western (particularly U.S.) will and capability to compete with the Soviet bloc in a nonaligned country. Daud Khan successfully introduced several far-reaching educational and social reforms, such as the voluntary removal of the veil from women and the abolition of purdah (the practice of secluding women from public view), which theoretically increased the labour force by about 50 percent. The regime remained politically repressive, however, and tolerated no direct opposition.

The Pashtunistan issue precipitated Daud Khan's downfall. In retaliation for Afghan agitation, Pakistan closed the border with Afghanistan in August 1961. A prolongation of the closure led to Afghan dependence on the Soviet Union for trade and in-transit facilities. To reverse the trend, Daud Khan resigned in March 1963, and the border was reopened in May. The Pashtunistan problem still existed, however.

Zahir Shah and his advisers instituted an experiment in constitutional monarchy. In 1964 the National Assembly approved a new constitution, under which the House of the People was to have 216 elected members, and the House of the Elders was to have 84 members, one-third elected by the people, one-third appointed by the king, and one-third elected indirectly by new provincial assemblies.

Elections for both houses of the legislature were held in 1965 and 1969. Several unofficial parties ran candidates with beliefs ranging from fundamentalist Islām to the extreme left. National politics became increasingly polarized, a situation reflected in the appointment by the King of five successive prime ministers between September 1965 and December 1972. The King refused to promulgate the Political Parties Act, the Provincial Councils Act, and the Municipal Councils Act, thereby effectively blocking the institutionalization of the political processes guaranteed in the constitution. Struggles for power developed between the legislative and the executive branches, and an independent Supreme Court, as called for in the 1964 constitution, was never appointed.

Mohammad Daud Khan, the former prime minister and a brother-in-law and first cousin of Zahir Shah, sensed the stagnation of the constitutional processes and seized

power on July 17, 1973, in a virtually bloodless coup. Leftist military officers and civil servants of the Banner (Parcham) Party assisted in the overthrow. Daud Khan abolished the constitution of 1964 and established the Republic of Afghanistan, with himself as chairman of the Central Committee of the Republic and prime minister.

AFGHANISTAN SINCE 1973

The Republic of Afghanistan (1973–78). During Daud Khan's second tenure as prime minister, he attempted to introduce socioeconomic reforms, to write a new constitution, and to effect a gradual movement away from the socialist ideals his regime initially espoused. Afghanistan broadened and intensified its relationships with other Muslim countries, trying to move away from its dependency on the Soviet Union and the United States. In addition, Daud Khan and Zulfikar Ali Bhutto, the prime minister of Pakistan, reached tentative agreement on a solution to the Pashtunistan problem.

Daud Khan received approval in 1977 of his new constitution from the National Assembly, which wrote in several new articles and amended others. In March 1977 Daud Khan, then president of Afghanistan, appointed a new Cabinet composed of sycophants, friends, sons of friends, and even collateral members of the royal family. The two major leftist organizations, the People's (Khalq) and Banner parties, then reunited against Daud Khan after a 10-year separation. There followed a series of political assassinations, massive antigovernment demonstrations, and arrests of major leftist leaders. Before his arrest Hafizullah Amin, a U.S.-educated People's Party leader, contacted party members in the armed forces and devised a makeshift but successful coup. Daud Khan and most of his family were killed, and the Democratic Republic of Afghanistan was born on April 27, 1978.

The Afghan Civil War. Nur Mohammad Taraki was elected president of the Revolutionary Council, prime minister of the country, and secretary general of the combined People's Democratic Party of Afghanistan (PDPA). Babrak Karmal, a Banner leader, and Hafizullah Amin were elected deputy prime ministers. The leaders of the new government insisted that they were not controlled by the Soviet Union and proclaimed their policies to be based on Afghan nationalism, Islāmic principles, socioeconomic justice, nonalignment in foreign affairs, and respect for all agreements and treaties signed by previous Afghan governments.

Unity between the People's and Banner factions rapidly faded as the People's Party emerged dominant, particularly because their major base of power was in the military. Karmal and other selected Banner leaders were sent abroad as ambassadors, and there were systematic purges of any Banner members or others who might oppose the regime.

The Taraki regime announced its reform programs, including the elimination of usury, equal rights for women, land reforms, and administrative decrees in classic Marxist-Leninist rhetoric. The people in the countryside, familiar with Marxist broadcasts from Soviet Central Asia, assumed that the People's Party was Communist and pro-Soviet. The reform program—which threatened to undermine basic Afghan cultural patterns—and political repression antagonized large segments of the population, but major violent responses did not occur until the uprising in Nūrestān late in the summer of 1978. Other revolts, largely uncoordinated, spread throughout all of Afghanistan's provinces, and periodic explosions rocked Kabul and other major cities. On Feb. 14, 1979, U.S. Ambassador Adolph Dubs was killed, and the elimination of U.S. assistance to Afghanistan was guaranteed.

Hafizullah Amin became prime minister on March 28, 1979, although Taraki retained his posts as president of the Revolutionary Council and secretary general of the PDPA. The expanding revolts in the countryside, however, continued, and the Afghan Army collapsed. The Amin regime asked for and received more Soviet military aid.

Taraki was killed in a confrontation between Taraki and Amin supporters on Sept. 14, 1979. Amin then tried to broaden his internal base of support and to again interest Pakistan and the United States in Afghan security. Despite

his efforts, on the night of Dec. 24, 1979, the Soviets began their invasion of Afghanistan, and Amin and many of his followers were killed on December 27.

(L.Du./N.H.D.)

Babrak Karmal returned to Afghanistan from the Soviet Union and became prime minister, president of the Revolutionary Council, and secretary general of the PDPA. Opposition to the Soviets and Karmal spread rapidly, urban demonstrations and violence increased, and resistance escalated in all regions. By early 1980, several regional groups, collectively known as mujahideen (from the Persian word meaning "warriors"), had united inside Afghanistan, or across the border in Peshāwar, to resist the Soviet invaders and the Soviet-backed Afghan Army. Friction among the Banner and People's members heightened in 1980 when Karmal removed Assadullah Sarwari, a member of the People's Party, from his position as first deputy prime minister and replaced him with a Banner leader, Sultan Ali Keshtmand. Banner Party dominance was broadened again in June 1981 when Karmal, retaining his other offices, resigned as prime minister and was succeeded by Keshtmand.

On May 4, 1986, Mohammad Najibullah, former head of the secret police, replaced Karmal as secretary general of the PDPA, and in November 1986 Karmal was relieved of all his government and party posts. Friction among the Banner and People's parties continued. A national reconciliation campaign approved by the Politburo in September 1986, which included a unilateral six-month cease-fire to begin on Jan. 15, 1987, met with little response inside Afghanistan and was rejected by resistance leaders in Pakistan.

In November 1987 a new constitution changed the name of the country back to the Republic of Afghanistan and allowed other political parties to participate in the government. Najibullah was elected to the newly strengthened post of president. Despite renewals of the official cease-fire, Afghan resistance to the Soviet presence continued, and the effects of the war were felt in neighbouring countries: Afghan refugees in Pakistan and Iran numbered in the millions. Morale in the Afghan military was low. Men were drafted only to desert at the earliest opportunity, and the Afghan military dropped from its 1978 strength of 105,000 to about 20,000–30,000 by 1987. The Soviets attempted new tactics, but the resistance always devised countertactics. For example, the use of the Spetsnaz (special forces) was met by counter-ambushes.

The only weapons systems that solidly continued to bedevil the resistance were combat helicopter gunships and jet bombers. Toward the end of 1986, however, the resistance fighters began to receive more and better weapons from the outside world—particularly from the United States, the United Kingdom, and China—via Pakistan, the most important of these being shoulder-fired ground-to-air missiles. The Soviet and Afghan air forces then began to suffer considerable casualties.

Pressure from the Pakistanis, from outside supporters, and from the guerrilla commanders had forced the seven major resistance groups based in Peshāwar to form an alliance in May 1985. Inside Afghanistan, neighbouring ethnolinguistically oriented resistance groups united for military and political purposes within their various regions. Internal struggles for leadership also occurred in certain areas where the Soviets had little influence, such as Hazārajāt and Nūrestān. Although no national liberation front existed, the resistance groups began to feel that they were part of an overall effort to liberate Afghanistan.

During the 1980s talks between the foreign ministers of Afghanistan and Pakistan were held in Geneva under the auspices of the United Nations, the primary stumbling blocks being the timetable for the withdrawal of Soviet troops and the cessation of arms supplies to the mujahideen. Peace accords were finally signed in April 1988. General Secretary Mikhail Gorbachev subsequently carried out an earlier promise to begin withdrawing Soviet troops in May of that year; troops began pulling out as scheduled, and the last Soviet soldier left Afghanistan on Feb. 15, 1989. The civil war continued, however, despite predictions of an early collapse of the Najibullah govern-

The 1987 constitution

Nur
Moham-
mad
Taraki

ment upon the withdrawal of the Soviets. The mujahideen formed an interim government in Pakistan and steadfastly resisted efforts of reconciliation by Najibullah. Outside forces continued to supply arms to both sides.

For later developments in the history of Afghanistan, see the *Britannica Book of the Year* section in the BRITANNICA WORLD DATA ANNUAL. (L.Du./N.H.D./Ed.)

(V.P.P./L.Du./N.H.D.)

Africa

Africa is the second largest continent, being smaller only than Asia and covering about one-fifth of the total land surface of the world. The continent is bounded on the west by the Atlantic Ocean, on the north by the Mediterranean Sea, on the east by the Red Sea and the Indian Ocean, and on the south by the mingling waters of the Atlantic and Indian oceans.

Africa's total land area is approximately 11,667,000 square miles (30,217,000 square kilometres), and the continent measures about 5,000 miles (8,000 kilometres) from north to south and about 4,600 miles from east to west. Its northern extremity is Al-Ghīrān Point, near Al-Abyaḍ Point (Cape Blanc), Tun.; its southern extremity is Cape Agulhas, S.Af.; its farthest point east is Xaafuun (Hafun) Point, near Cape Gwardafuy (Guardafui), Somalia; and its western extremity is Almadi Point (Pointe des Almadies), on Cape Verde (Cap Vert), Senegal. In the northeast, Africa was joined to Asia by the Sinai Peninsula until the construction of the Suez Canal. Paradoxically, the coastline of Africa—18,950 miles in length—is shorter than that of Europe, because there are few inlets and few large bays or gulfs.

Off the coasts of Africa a number of islands are associated with the continent, of which Madagascar, one of the largest islands in the world, is the most significant. Other smaller islands include the Seychelles, Socotra, and other islands to the east; the Comoros, Mauritius, Réunion, and other islands to the southeast; Ascension, St. Helena, and Tristan da Cunha to the southwest; Cape Verde, the Bi-jagós Islands, Bioko, and São Tomé and Príncipe to the west; and the Azores and the Madeira and Canary islands to the northwest.

The continent is cut almost equally in two by the equator, so that most of Africa lies within the tropical region, bounded on the north by the tropic of Cancer and on the south by the tropic of Capricorn. Because of the bulge formed by western Africa, the greater part of Africa's territory lies north of the equator. Africa is crossed from north to south by the prime meridian (0° longitude), which passes a short distance to the east of Accra, Ghana.

In antiquity, the Greeks are said to have called the continent Libya and the Romans to have called it Africa, perhaps from the Latin *aprica* ("sunny"), or the Greek *aphrike* ("without cold"). The name Africa, however, was chiefly applied to the northern coast of the continent, which was, in effect, regarded as a southern extension of Europe. The Romans, who for a time ruled the North African coast, are also said to have called the area south of their settlements *Afriga*, or the Land of the *Afrigs*—the name of a Berber community south of Carthage.

The whole of Africa can be considered as a vast plateau rising steeply from narrow coastal strips and consisting of ancient crystalline rocks. The plateau's surface is higher in the southeast and tilts downward toward the northeast. In general, the plateau may be divided into a southeastern portion and a northwestern portion. The northwestern part, which includes the Sahara (desert) and that part of North Africa known as the Maghrib, has two mountain-

ous regions—the Atlas Mountains in northwestern Africa, which are believed to be part of a system that extends into southern Europe, and the Ahaggar (Hoggar) Mountains in the Sahara. The southeastern part of the plateau includes the Ethiopian Plateau, the East African Plateau, and—in eastern South Africa, where the plateau edge falls downward in a scarp—the Drakensberg range. One of the most remarkable features in the geologic structure of Africa is the East African Rift System, which lies between 30° and 40° E. The rift itself begins northeast of the continent's limits and extends southward from the Ethiopian Red Sea coast to the Zambezi River basin.

Africa contains an enormous wealth of mineral resources, including some of the world's largest reserves of fossil fuels, metallic ores, and gems and precious metals. This richness is matched by a great diversity of biological resources that includes the intensely lush equatorial rain forests of central Africa and the world-famous populations of wildlife of the eastern and southern portions of the continent. Although agriculture (primarily subsistence) still dominates the economies of most African countries, the exploitation of these resources has become the most significant economic activity in Africa in the 20th century.

Climatic and other factors have exerted considerable influence on the patterns of human settlement in Africa. While some areas appear to have been inhabited more or less continuously since the dawn of humanity, enormous regions—notably the desert areas of northern and southwestern Africa—have been largely unoccupied for prolonged periods of time. Thus, although Africa is the second largest continent, it contains only about 10 percent of the world's population and can be said to be underpopulated. The greater part of the continent has long been inhabited by black peoples, but in historic times there have also occurred major immigrations from both Asia and Europe. Of all foreign settlements in Africa, that of the Arabs has made the greatest impact. The Islāmic religion, which the Arabs carried with them, spread from North Africa into many areas south of the Sahara, so that many western African peoples are now largely Islāmized.

(D.S.H.W.N./Ed.)

This article treats the physical and human geography of Africa, followed by discussion of geographic features of special interest. For discussion of individual countries of the continent, see the articles EGYPT; SOUTH AFRICA; and SUDAN, THE. Other African countries are treated in articles on regions under the titles CENTRAL AFRICA, EASTERN AFRICA, INDIAN OCEAN ISLANDS, NORTH AFRICA, SOUTHERN AFRICA, and WESTERN AFRICA; these articles also contain the principal treatment of African historical and cultural development. For discussion of major cities of the continent, see the articles ALEXANDRIA, CAIRO, CAPE TOWN, JOHANNESBURG, and KINSHASA. Related topics are discussed in the articles AFRICAN ARTS; EGYPTIAN ARTS AND ARCHITECTURE, ANCIENT; ISLĀM, MUḤAMMAD AND THE RELIGION OF; ISLĀMIC ARTS; and ISLĀMIC WORLD, THE. PHYSICAL AND HUMAN GEOGRAPHY

Geologic history

The Precambrian shield

The African continent consists of an ancient Precambrian shield (formed between 3.8 billion and 570 million years ago) that has since been folded, metamorphosed (altered in composition or structure by heat and pressure), and granitized. As a result of later erosion, Precambrian rock outcrops appear on about three-fifths of the surface.

An examination of the shield leads to three preliminary observations. First, geologically the continent of Africa includes the Arabian Peninsula, which was closely linked to it until the appearance of the Red Sea Trough. Second, northwestern North Africa belongs to the Mediterranean and Alpine area; it emerged and became joined to Africa only quite recently in geologic time. Third, the Precambrian shield shows numerous traces of life. These are found, for example, in the microorganisms of the Fig Tree System of rocks in South Africa, which are 3.2 billion years old; in the Bulawayo series, which are 2.7 billion years old; in the Ivory Coast series, which are 2.5 billion years old; in the Gabon series, which are 1.7 billion years old; and in all of Africa in formations that are between 600 million and 1 billion years old.

Geologic analysis is simpler after the end of the Precambrian because of the existence of this shield. There are no traces of geosynclines (large linear troughs, in which sediments accumulated over geologic time cause the trough itself to sag deeper) or of orogenic (mountain-building) processes comparable to those of other continents. On the western rim of the continent, however, there are eroded traces of ancient mountains that have been called the Mauritanides; these thrust from the west toward the east. If, however, they were associated with a geosynclinal trough, this was situated farther west in the Atlantic Ocean.

The relative geologic stability that characterized the continent did not, however, hold true in the north. The Tethys Sea, a sea ancestral to the Mediterranean, ran along the northern edge of the Sahara, and a geosynclinal depression covered the region; from this depression the Alpine chain of the Tell Atlas and Saharan Atlas mountains later arose during the Tertiary Period (66.4 to 1.6 million years ago).

Seas of the Paleozoic Era (from 570 to 245 million years ago) covered northwestern Africa, extending first from the Mediterranean to the Gulf of Guinea and then to southern Africa. At the end of the era, during the Permian Period (286 to 245 million years ago), the Permian Sea advanced as far as the Mozambique Channel.

The Mesozoic Era (245 to 66.4 million years ago) is represented by marine deposits of the Jurassic Period (208 to 144 million years ago) in the Western Sahara and Senegal and on the Indian Ocean coast. Marine deposits of the Early Cretaceous Epoch (144 to 97.5 million years ago) occur on all African coasts, while deposits of the Late Cretaceous Epoch (97.5 to 66.4 million years ago) are located in the Sahara and on the coasts of the Atlantic and Indian oceans. During the Tertiary Period, North Africa emerged, and the rift valley of the Red Sea subsided, isolating Arabia from the continent.

A quick glance at any geologic map of Africa reveals first the distinctive effects of the great rifts, running northwest to southeast and northeast to southwest, and second the volcanic activity that took place both in the Tertiary and in the Quaternary Period (up to 1.6 million years ago).

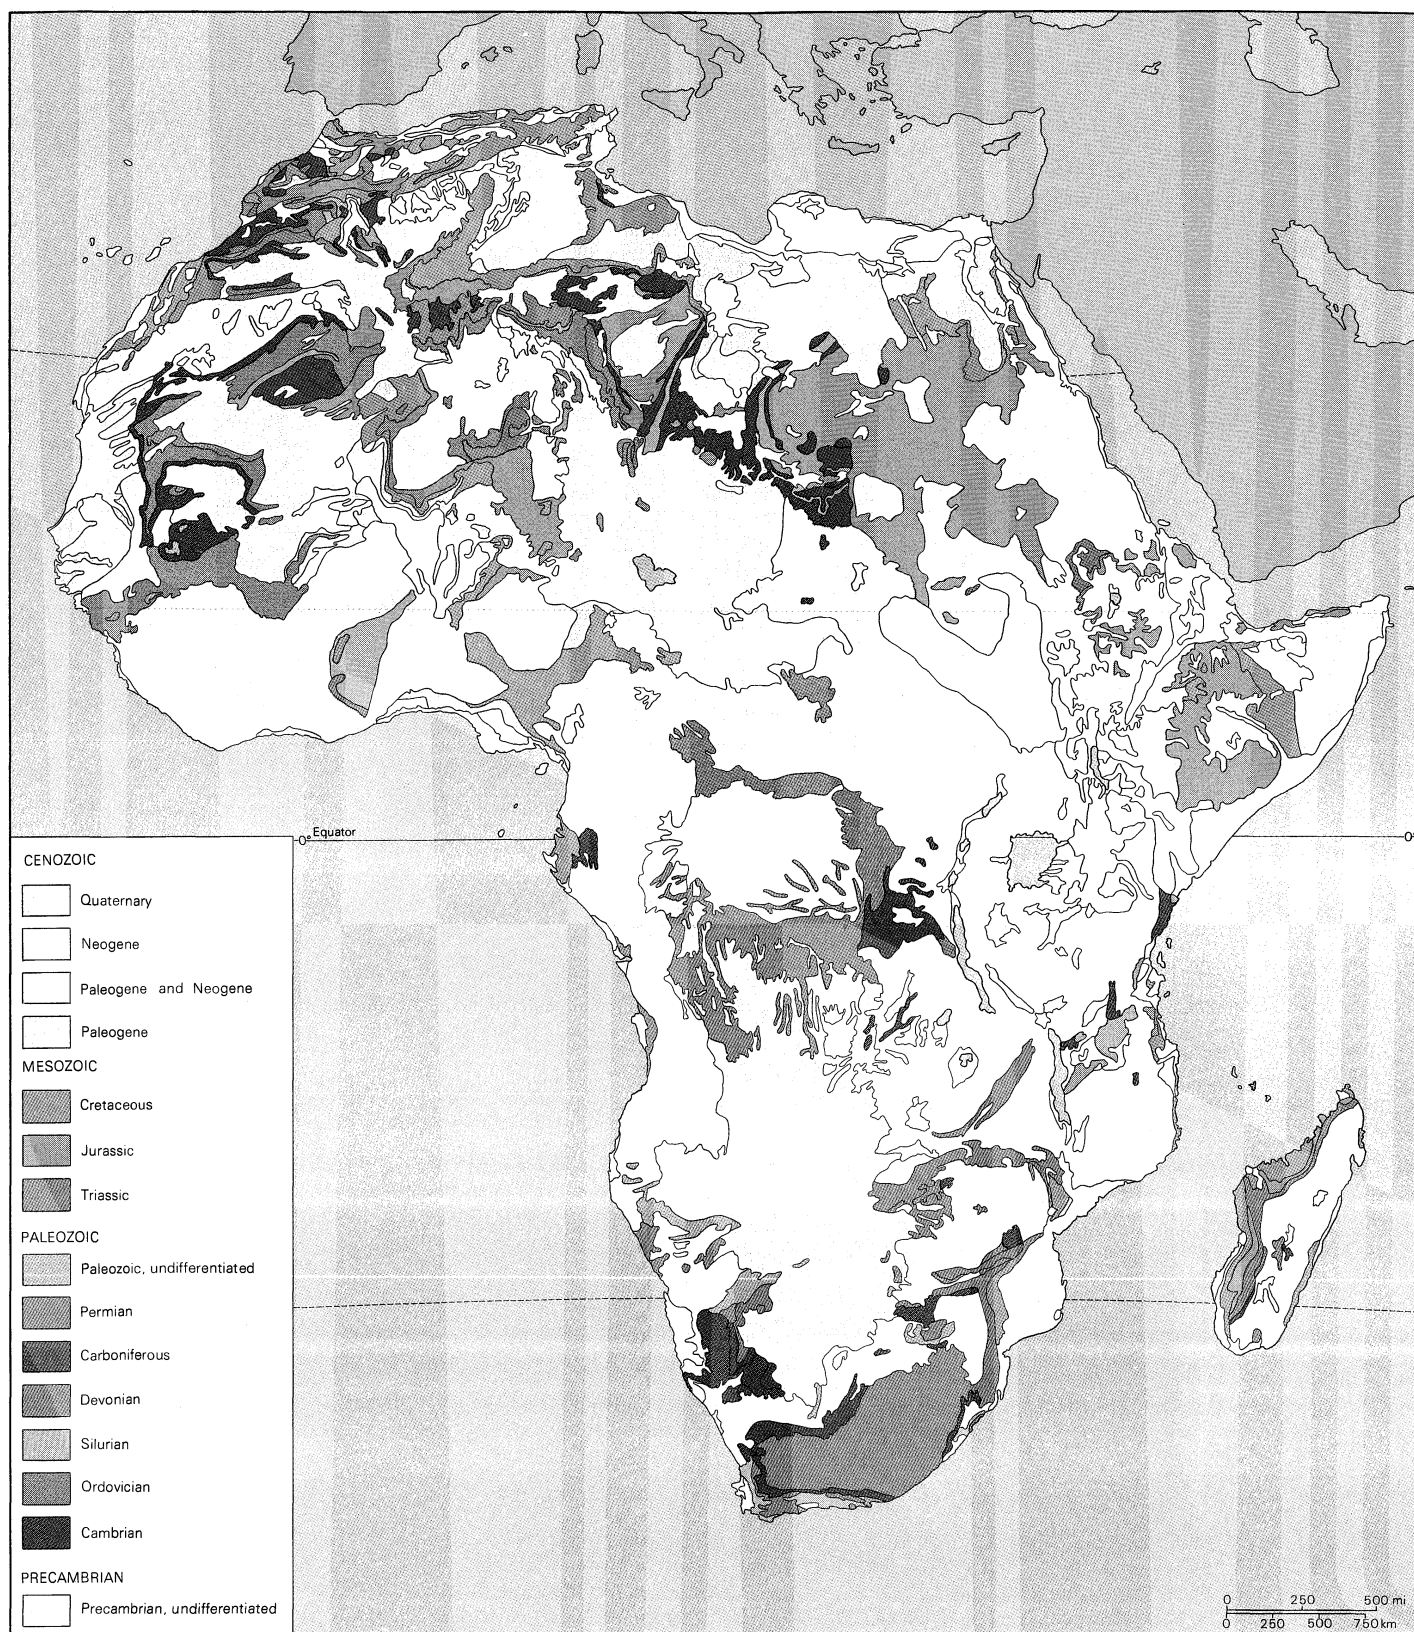

STRATIGRAPHY AND STRUCTURE

The Precambrian. The Precambrian landmass in Africa consists of four groups of interconnected cratons (immobile parts of the Earth, usually of large size). These are the West African Craton, which became stable about two billion years ago and which today comprises the states of Mauritania, Mali, Guinea, Liberia, Côte d'Ivoire (Ivory Coast), Ghana, and the western Ahaggar Mountains of southern Algeria; the Arabo-Nubian Shield, which includes the eastern Ahaggar Mountains of Algeria, the Tibesti Mountains (extending into Chad, Niger, and Libya), Egypt, and the Arabian Peninsula; the Congolese and Kalahari cratons; and Madagascar, the eastward extension of which is unknown, as it subsided into the Indian Ocean during the Late Cretaceous.

The final period of the Archean (early) Eon (which came to an end approximately 2.5 billion years ago) was marked by important orogenic processes, traces of which are clearly defined in the West Nile System on the borders of Zaire and The Sudan, and in the Swaziland System of southern Africa. Still later mountain building at the end of this era is visible in West Africa (in Liberia), in East Africa (in the Bulawayan, Dodomanian, and Sebakwian systems, found in Tanzania, Kenya, and Uganda respectively), and in Madagascar (in the Androyan System). It was during this period that the first discoverable traces of life are to be found in the fossilized unicellular algae of the Fig Tree Series in Swaziland and in the Orange Free State, S.A.F.

The Early Proterozoic Era (about 2.5 to 1.6 billion years ago) was characterized by orogenic activity that was man-

The African cratons

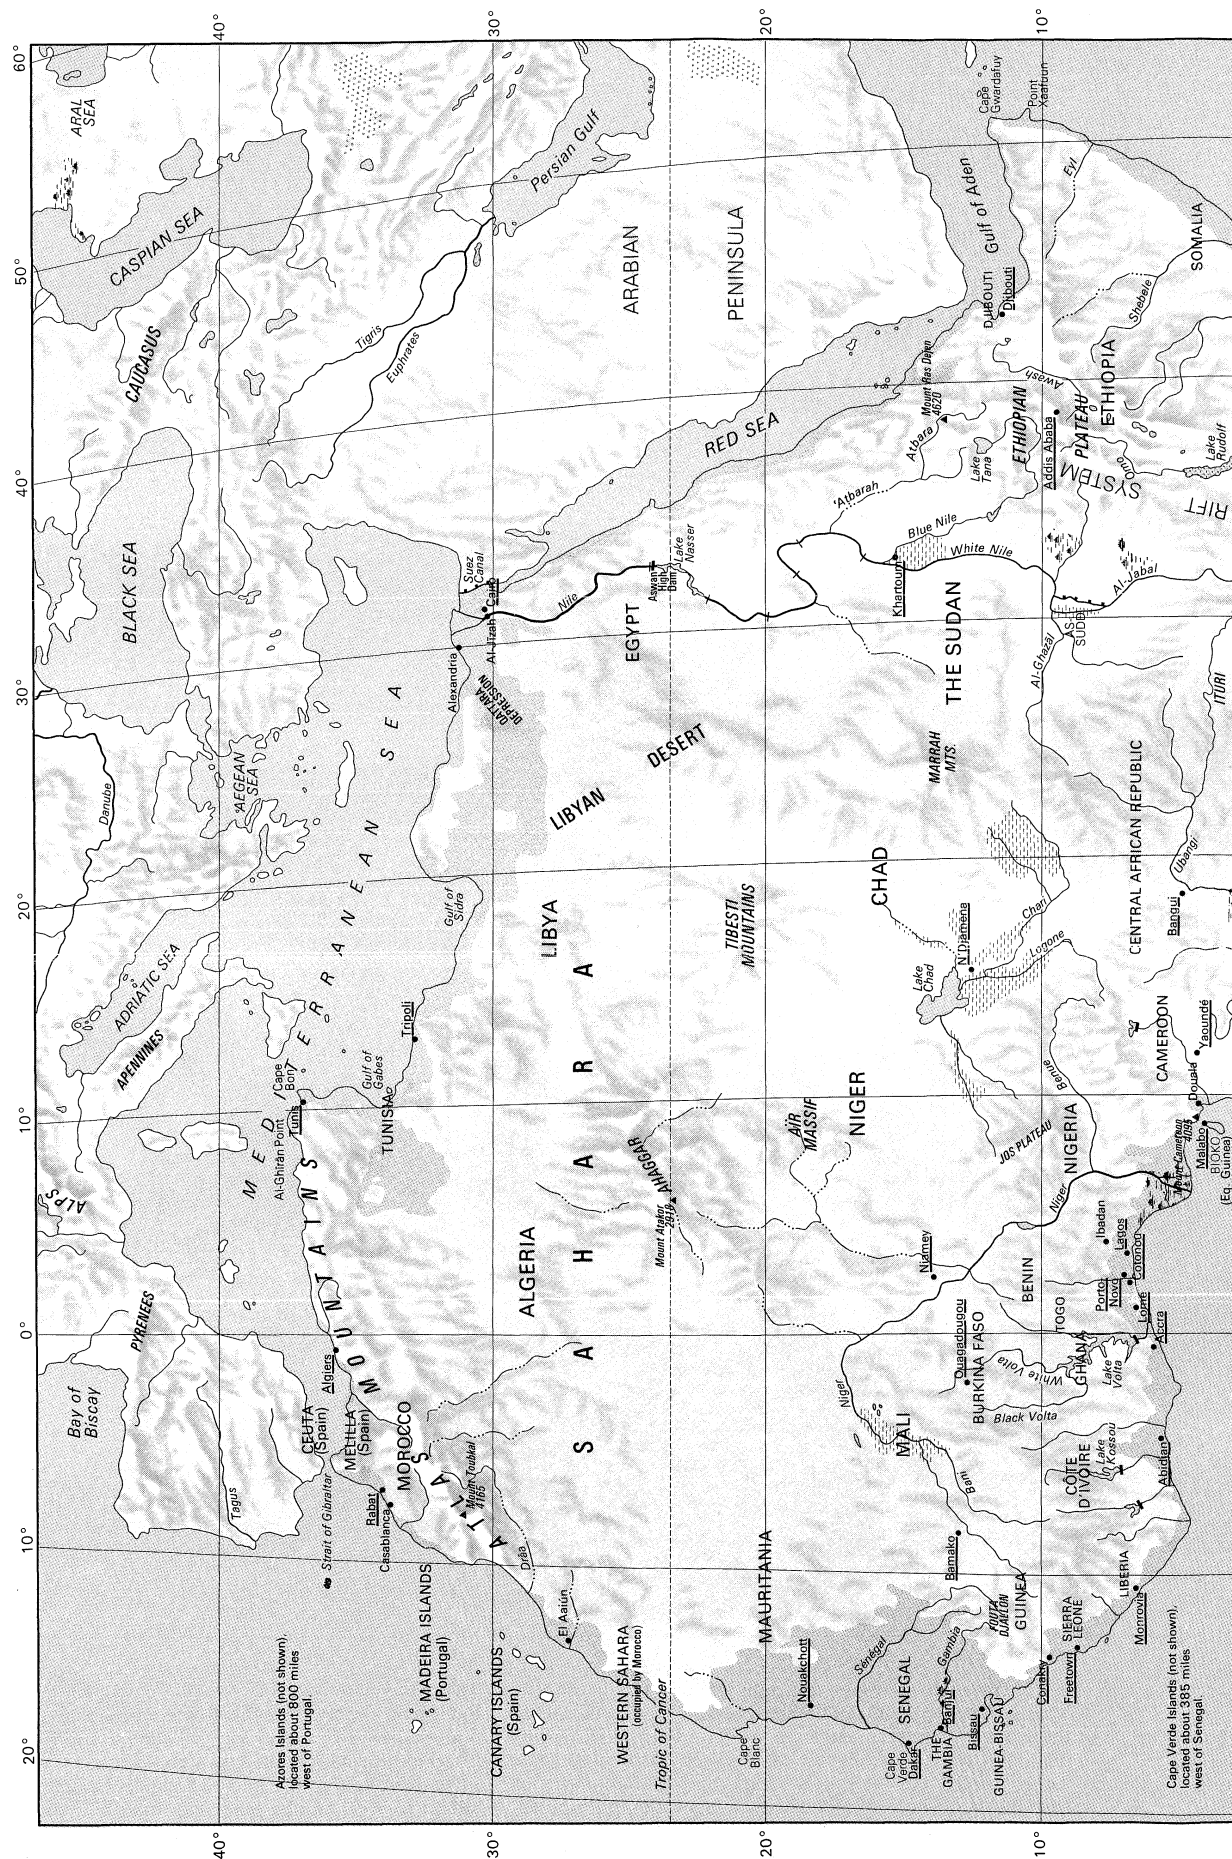

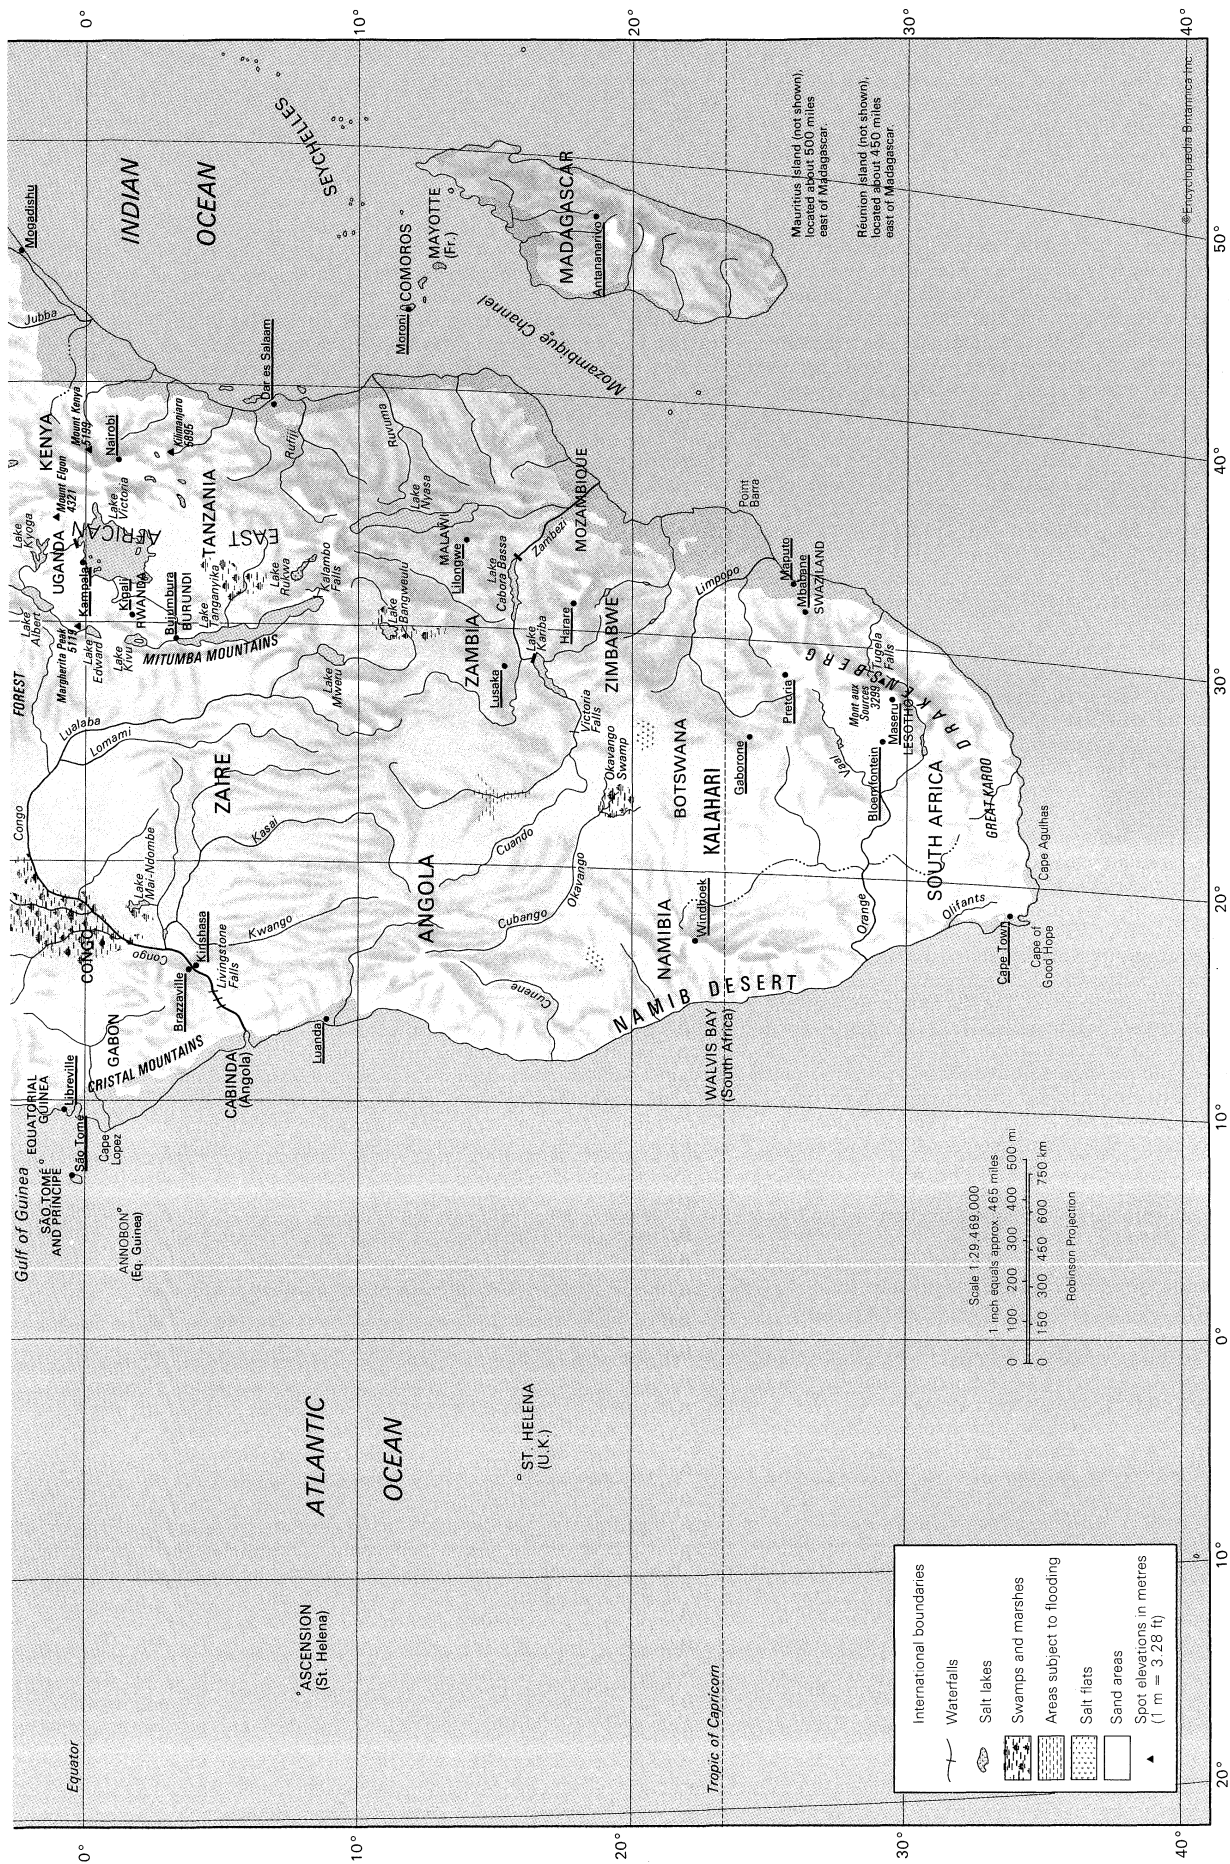

Geologic structure of Africa.

ifested in such series as the Amsaga and Ghallaman of Mauritania, the Kambui of Sierra Leone, the Zadinian of the Congo basin, the Dibayan of Namibia, the Kaviron-dian of East Africa, the Great Dyke of Zimbabwe, the Transvaal System of South Africa, and the Vohibory of Madagascar. The era ended with a new mountain-building episode, the widespread continental effects of which may be seen in such formations as the Berberids of the

Anti-Atlas Mountains in North Africa, the West African Birrimian Formation, the Buganda-Kibali-Toro Formation of East Africa, and the Witwatersrand, Bushveld, and Limpopo formations in southern Africa.

The Middle Proterozoic, which lasted from about 1.6 billion to 900 million years ago, may be divided into two orogenic cycles. The first of these cycles is marked by the uplifting of the Anti-Atlas Mountains of Morocco and

of such formations as the Tarkwaian (Ghana), Francevillian (Gabon), and Mayumbian (Congo). The second cycle consisted of the rise of the western Kibarian mountain chain (Zaire), the Irumian chain in central Africa, and the Waterberg and Matsap chains of South Africa.

The Late Proterozoic, which lasted from about 900 to 570 million years ago, is represented throughout the continent by several thousand feet of sandstone, schist (medium- or coarse-grained metamorphic rock containing micaceous materials), and dolomite limestone (limestone rich in magnesium carbonate) with stromatolites (fossilized calcareous algae). Among these are such formations as the Adoundounian Series of Morocco, the Adrar Series of Mauritania and Mali, the Western Congo System, the Katangan Series of Zaire and Zambia, and the Damara-Otavi System of South Africa. The end of the Precambrian, at which time the Lufilian and Katangan orogenies occurred in central Africa, is separated from the start of the Cambrian Period by a glacial period.

The Paleozoic Era. The Paleozoic Era, which comprises the Cambrian, Ordovician, Silurian, Devonian, Carboniferous, and the Permian periods, includes two principal mountain-building episodes—the Caledonian and the Hercynian. During this era the continent of Africa may be said to have taken shape—the cratons fused and the landmass emerged. A glacial period during this era was marked by deposition tillites (consolidated sedimentary rock formed by lithification of glacial till), which may be seen in southern Morocco and throughout western Africa and subequatorial Africa as far as Namibia. The tillite is considered as marking the break between the end of the Precambrian and the beginning of the Cambrian Period (which lasted from 570 to 505 million years ago).

Marine fossils of the Cambrian are found in southern Morocco, Western Sahara, Mauritania, and Namibia. In Egypt and Arabia their presence has been revealed by drilling. Elsewhere they remain unknown.

During the Ordovician Period (505 to 438 million years ago) fossiliferous marine sandstone completely covered North and West Africa. The table sandstones of southern Africa constitute its only other trace. This period is, in addition, remarkable for the tectonics (forces or conditions causing movements of the Earth's crust) of the Caledonian mountain-building episode. Although no great folds resembling those of Europe and North America formed, the episode was marked by at least two important epeirogenic (continent-forming) movements, which raised the continental table of the central and western Sahara by approximately 5,000 feet (1,500 metres). Each emergence resulted in the creation of valleys that became flooded when the continent subsided. It is known that toward the end of the period the Sahara became glaciated, and tillites and sandstones filled the valleys.

Although no major folding took place, except in local instances, granites were rejuvenated. Many authentic Precambrian granites show ages that are between 45 and 550 million years. These are not new granites, for nowhere do they pierce the covering of Cambrian or Ordovician sediments. They constitute a phenomenon that is found from the central Sahara to southern Africa.

A complete change of sedimentation characterized the Silurian Period (438 to 408 million years ago); this is indicated by the deposits of graptolitic shales (containing fossils of colonies of extinct animals of uncertain zoological affinity) in Arabia and in northwestern Africa.

Marine fossils of the Devonian (408 to 360 million years ago) are found in North Africa and in the Sahara. Traces also remain in parts of Guinea, Ghana, and Arabia, as well as in Gabon; they also occur in the Bokkeveld Series of South Africa. Fossils of vegetation that includes *Archaeosigillaria* (ancient club mosses) may be traced in formations of the earlier Devonian in the Sahara and in southern Africa (Witteberg Series).

The Carboniferous Period lasted from about 360 to 286 million years ago. Evidence of marine life that existed in the earlier part of this period comes from fossils found in North Africa, in the central and western Sahara, and in Egypt. During the middle and later parts of this period, the Hercynian mountain-building episodes occurred.

The Mauritanide mountain chain appeared, running from north to south along the edge of northwestern Africa from Morocco to Guinea. Ancient sediments were metamorphosed and pushed from west to east, locally covering the tabular Paleozoic formations. Elsewhere, great swellings or subsidences took place, continuing until the Late Triassic Epoch (230 to 208 million years ago). These structures were synclinal (folded with the strata dipping inward toward a central axis) in form in the Tindouf area of western Algeria, dorsal (forming a mountainous spine) at Reguibat in eastern Western Sahara, basinal (forming a basin) at Taoudeni in Mali, dorsal at Kinshasa in Zaire, and synclinal in Ghana.

The Late Carboniferous Epoch (320 to 286 million years ago) is represented throughout the Sahara by layer upon layer of fossilized vegetation, and sometimes—as in Morocco and Algeria—by seams of coal. Different phenomena may be observed, however, in the region of subequatorial Africa, including the important Dwyka Tillite, which covers South Africa, Madagascar, an extensive portion of the Congo basin, and Gabon. At several places in South Africa, these Dwyka strata are covered by thin marine layers that serve to demarcate the transition from the Carboniferous to the Permian periods and that form the beginning of the great Karoo System.

Marine fossils of the Permian Period are visible in southern Tunisia (in the Mount at-Tabaqah region), in Egypt (at the Abū Daraj Reef), in the Arabian Peninsula (southwest of Riyadh), on the coasts of Tanzania, and in the Mozambique Channel.

Everywhere else, the traces of the Permian are of continental rather than marine origin and are included in the Karoo System in South Africa. There, the Early Permian strata are known as the Eccia Series and are divided into three groups—the Lower Eccia, containing almost 1,000 feet of clay-bearing schists; the Middle Eccia, containing 1,650 feet of sandstone, seams of coal, and fossilized vegetation; and the Upper Eccia, containing 660 feet of clay-bearing schists.

The Late Permian is represented by the lower part of the Beaufort Series (which was also formed during the Early Triassic Period), which is almost 10,000 feet thick and which is famous for its amphibian and reptile fossils, a similar series of which are also found in the southern Soviet Union. Other Permian formations, not as rich in coal, are found in Zaire, Tanzania, Kenya, Uganda, Zambia, Zimbabwe, Mozambique, and Madagascar.

The absence of primary marine formations throughout southern Africa should be emphasized; it is not known whether this absence is due to a hiatus in deposition or to erosion.

The Mesozoic Era. Consisting of three periods—the Triassic, Jurassic, and Cretaceous—the Mesozoic Era is remarkable for the overflowing of ancient seas and for the emergence of massive land formations containing interesting fossil remains.

Marine formations. During the Triassic Period ancient seas left deposits in North Africa, the southern Sahara, Egypt, Arabia, and parts of Tanzania and northern Madagascar. Jurassic deposits extended to the Atlantic basins of Río de Oro and Senegal. In the middle of the Jurassic Period a great transgression of the Indian Ocean extended over Somalia and Ethiopia as far as Eritrea. In the Cretaceous Period this was followed by a series of transgressions, including one on the coast of equatorial Africa at the time the present Atlantic and Indian Ocean coasts took shape; one that totally invaded the Sahara and Egypt as far as The Sudan; and one that covered the same places once more, as well as western Arabia and the east coast of Madagascar.

Continental formations. In northern equatorial Africa, including Arabia, the continental formations took the shape of an interlocked landmass. During the Triassic Period the Saharan Zarzaitine Series, containing dinosaur and reptilian fossil remains, was laid down. During the Jurassic Period the Saharan Taouratine Series, containing fossils of vegetation and great reptilian fossils, was formed. In the Upper Karoo System of subequatorial Africa, formed during the Early Triassic, the Beaufort

iferous
Period

The
Triassic
Period

Series contains fossils of fish, amphibians, and reptiles. The final stages of the Triassic and Early Jurassic periods were characterized by the folding of the Cape mountain chain, by the rise of the Karoo basin, by fracturing, and by widespread upwelling of basaltic lavas through fissures, creating formations from 3,000 to 6,000 feet thick, such as the Drakensberg range in South Africa.

During the Jurassic and the Cretaceous periods layers similar to those of the interlocked landmasses of the north were formed; they contained fossil vegetation, dinosaurs, and reptiles. During the Cretaceous certain eruptions of a particular type occurred, resulting in the creation of the Kimberlite diamond pipes (such a pipe being a cylindrical rock body, usually approximately vertical).

The Tertiary Period. The Tertiary Period of the Cenozoic Era (the Cenozoic has lasted from 66.4 million years ago to the present) was remarkable for its great tectonic movements; these resulted in the Alpine mountain-building episode, during which the North African mountains were uplifted. It was also remarkable for the creation of the Red Sea Rift Valley and for the volcanism and rifting that took place during its later stages.

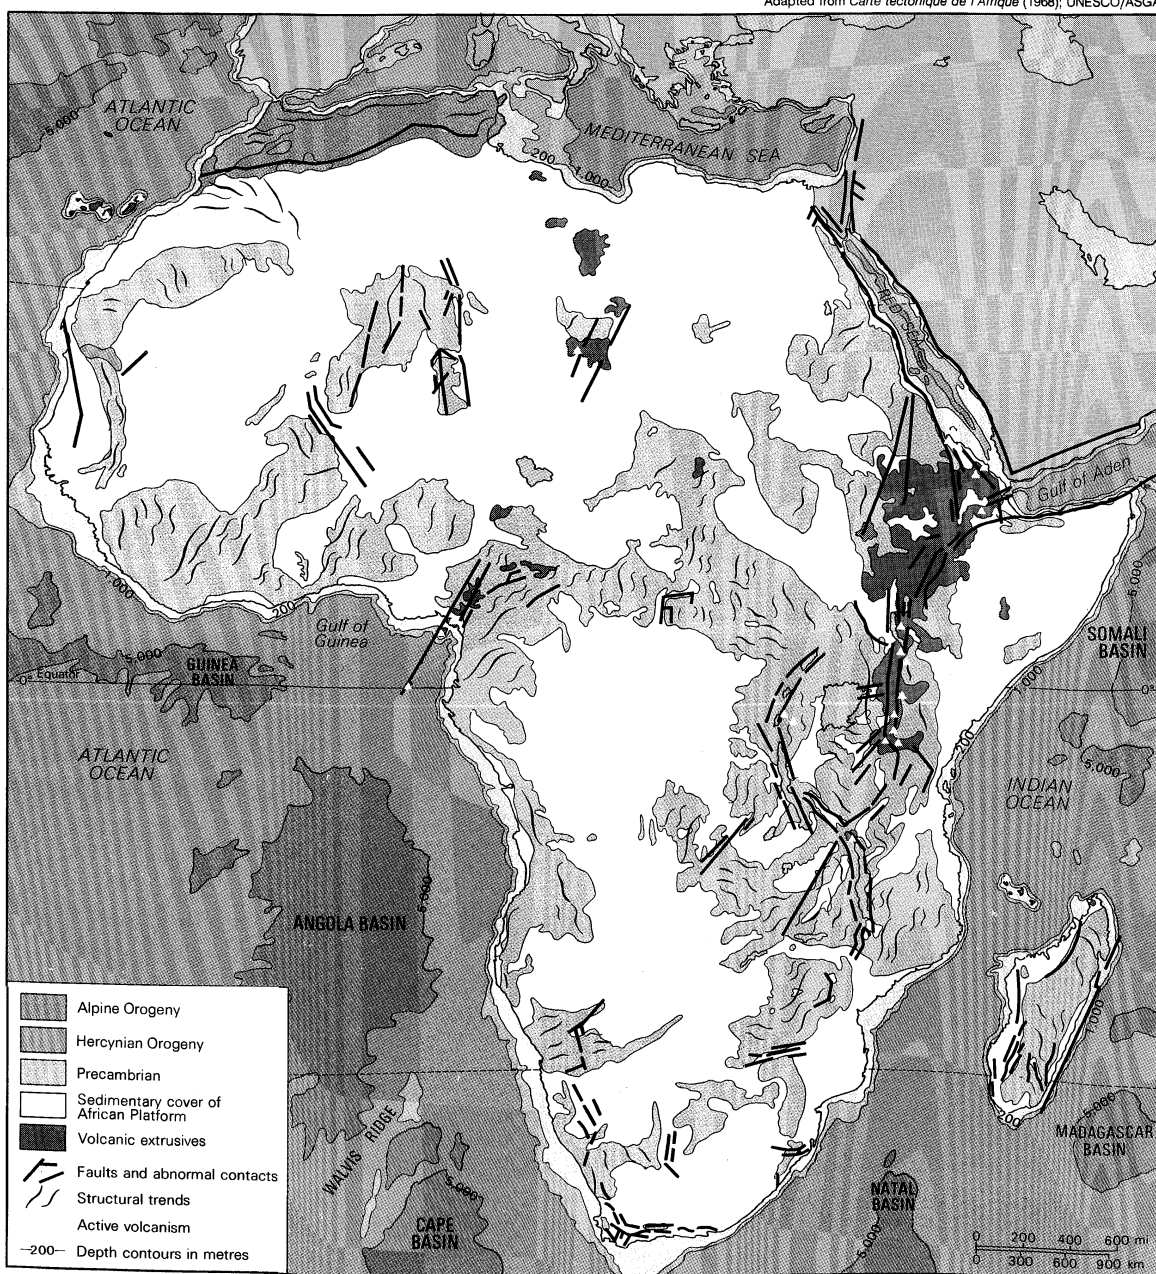

Marine formations. The Paleocene Epoch (66.4 to 57.8

million years ago) is important for its animal fossils, which include nummulites (a large kind of foraminifera, which are unicellular animals of macroscopic size), nautiloids (shelled cephalopods, which are mollusks with tentacles attached to their heads), and echinoids (sea urchins); all of these are found in North and West Africa and in the Sahara. With the exception of the Sahara, nummulites of the Eocene Epoch (57.8 to 36.6 million years ago) are found in the same places, as well as on the African coasts of the Indian Ocean, as also are lepidocyclines (foraminifera) of the Oligocene Epoch (36.6 to 23.7 million years ago) and the Miocene Epoch (23.7 to 5.3 million years ago).

Continental formations. Several levels may sometimes be distinguished in the continental formations of the Tertiary Period. They include lower Eocene levels containing *Pseudoceratodes* (gastropod genus) and *Dyrosaurus* (type of reptile), as well as Late Eocene and Oligocene levels containing silicified woods and fossilized fish, turtles, crocodiles, snakes, and mammals. In Egypt the Oligocene deposits found in the al-Fayyūm area contain mammals, birds, turtles, and crocodiles. The levels of the Early Miocene, which are found on the banks of Lakes Rudolf (Turkana) and Victoria in East Africa, contain mastodon

Structural features of Africa.

(a large, elephant-like mammal) and *Proconsul africanus* (a large, extinct ape of the superfamily Hominoidea). Central Asian hipparions (three-toed ancestors of the horse), which simultaneously entered Africa and Europe during the Late Miocene Epoch, also left their fossilized remains in this region, as did the *Kenyapithecus* of Kenya (another hominoid primate) at about the same time.

Tectonic movements. The first great foldings of the Tell Atlas took place in the Oligocene Epoch. In the Miocene, North African flyschs (thick and extensive deposits, largely of sandstone) formed layers that, from the Er-Rif to northern Tunisia, pushed from the north toward the south. The movements of the Tellian layers continued into the Late Miocene Epoch and the Pliocene Epoch (5.3 to 1.6 million years ago).

The High Plains area, farther south, which as a whole underwent few tectonic movements, was bounded on the south by the northern Atlas, which intervened between it and the Saharan Atlas. Continental movements lifted the Aurès Massif (mountain mass) to a height of about 3,300 feet during the middle of the Miocene; the Aurès is bounded on the south by the northern Sahara structural line, which extends from Agadir in Morocco in the west to the Gulf of Gabes in Tunisia in the east, dividing the African Shield from the folded Mediterranean or Alpine zone.

Formation of the Red Sea. Tectonic movements in the region of the Arabo-Nubian Shield that took place at the end of the Oligocene and the beginning of the Miocene epochs almost separated Arabia from Africa. A trough sank down, and the Mediterranean Sea swept into the rift valley, forming a gulf that extended to Yemen. The gulf was only prevented from joining the Indian Ocean by an isthmus stretching from Djibouti to Aden.

At the end of the Miocene Epoch the Isthmus of Suez was formed, and the gulf became a saline lake at the bottom of which thick evaporites (sediments formed as a result of evaporation) were laid down. The isthmus permitted Asian animal life to pass into Africa during part of the Pliocene Epoch. The sinking of the Djibouti-Aden isthmus, also during the Pliocene, allowed the Indian Ocean to flow into the Red Sea as far as the Isthmus of Suez.

Volcanism and rifting. Tectonic movements in the Miocene and Pliocene scored the continent with a net-

work of northeast to southwest and northwest to southeast faults. Volcanic eruptions and basaltic upwellings accompanied fracturing in the Ahaggar Mountains of southern Algeria, in the Tibesti area of Libya and Chad, in Ethiopia, throughout East Africa, and in Cameroon, as well as in the islands of Bioko (formerly Fernando Po) and São Tomé and Príncipe in the Gulf of Guinea.

The Quaternary Period. The Quaternary Period is divided into the Pleistocene Epoch (1,600,000 to 10,000 years ago) and the Holocene, or Recent, Epoch (from 10,000 years ago to the present). It represented a phase of continuing volcanic activity that caused the basement rocks of the Ahaggar and Tibesti mountains of the central Sahara to rise. The activity manifested itself in eruptions and in the deepening of the Saharan valleys—sometimes to a depth of about 660 feet—as well as in the welling up of basalt. Although the marine deposits of the Quaternary Period as a whole are of no particular interest, continental deposits of this period in Africa bear witness to a human chronology and to human activities that parallel those developments in Europe during the same period.

During the cold humid periods called pluvials, which correspond to the glacial phases of the Northern Hemisphere, the glaciers that covered the high mountains of East Africa were from 3,000 to 5,000 feet thicker than those remaining in the summit zones today. Elsewhere, the desert zones of the Sahara and the Kalahari were alternately subjected first to humid and then to dry and arid phases that expanded the desert surface at the expense of adjacent forested zones.

The oldest levels at which hominids (humanlike primates) are to be found, known as the Villafranchian-Kagerian Series and recognized in Ethiopia and Kenya, date to about four million years ago and are characterized by ancient forms of animal life, including in particular some ancient hominids. These hominids, called Australopithecines, may be classified roughly into two groups, termed "gracile" and "robust." Both groups left traces of stone and bone implements.

Primitive
hominids

The Kagerian-Kamasian Interpluvial levels, which date to about 500,000 years ago, contain the fossils of *Homo erectus* (thought to be the ancestor of modern humans) that are found at such sites as Olduvai Gorge (Tanzania) and Ternifine (Algeria). The Kamasian, or Second, Plu-

Photo Almasy

Simen Mountains, rising above the Ethiopian Plateau in northwestern Ethiopia.

vial of the Middle Pleistocene (900,000 to 130,000 years ago) corresponds to the Mindel in Europe and contains the remains of *Dinotherium* (which has been described as a large mammal with tusks on its lower jaw). A dry but not a desert climate is implied by the Kamasian-Kanjeran Interpluvial levels at Olduvai Gorge. The Kanjeran, or Third, Pluvial, which occurred during the Middle Pleistocene and corresponds to the Riss Pluvial in Europe, bears traces of such animals as the elephant, giraffe, and hippopotamus.

An arid phase, which greatly reduced the area of forest, is revealed in the Kanjeran-Gamblian Interpluvial levels, which were laid down between about 60,000 and 55,000 years ago. This period corresponds to an important tectonic phase marked by undulations in North Africa and activity along all the faults, in particular those in East Africa; it was at this time that East Africa assumed its present topographical aspect.

During the Gamblian, or Fourth, Pluvial, which occurred from approximately 30,000 to 15,000 years ago, three distinct humid phases were separated by drier intervals. During these phases the dimensions of Lake Chad and of the glaciers of Mounts Kenya and Kilimanjaro diminished rapidly. The postpluvial phase that followed this period, equivalent to the postglacial phase of the Northern Hemisphere, was marked by a succession of alternately dry and humid stages, in which traces of Mesolithic (a transitional period of the Stone Age) and Neolithic (New Stone Age) civilizations are apparent, and by the desertization of both the Sahara and the Kalahari, a process which began about 3000 BC.

PRESENT GEOLOGIC STRUCTURES AND RELIEF

The continent of Africa represents a magnificent example of the relation of geologic structure to relief. In the north the chains of the Atlas Mountains, extending from southwest to northeast, evoke the orogenesis of the Alpine episode and are separated from the Sahara basement rock by the great interrupted line of the southern Atlas ranges. The physiography of Egypt, by contrast, exposes the magnitude of the Cretaceous and Tertiary marine transgressions. Between the southern Atlas and the Ahaggar mountains the lower Sahara basin contains a wide, water-bearing fossiliferous substratum and is partly covered by the great sand dunes of the Eastern and Western Ergs. Encircling the Ahaggar Mountains, the Tassili-n-Ajjer plateaus are edged by cliffs that bound accumulations of Paleozoic deposits.

The West African landmass includes the Taoudeni syncline, the average diameter of which is more than 620 miles. The syncline is situated between the Ahaggar Mountains in the east and the Mauritania-Sénégal basin in the west and between western Algeria in the north and Kinshasa in the south. The east-to-west crystalline dorsal formations running from Cameroon through the Ubangi (Oubangui) River basin to The Sudan completely separate northern from subequatorial Africa. Karoo and continental deposits fill the Congo basin, which is surrounded by Precambrian rock formations dating from all periods of that era.

In southern Africa the Kalahari basin and the plateaus of the Karoo System have been formed upon 23,000 feet of undifferentiated Carboniferous, Permian, and Triassic continental deposits.

East Africa is isolated from the rest of the continent by huge tectonic rift valleys that have been volcanized (subjected to volcanic heat) and that extended from Syria southward through the Red Sea and the East African Rift Valley lakes to Mozambique. The Mozambique Channel, which dates from the Permian Period, bounds Madagascar on the west, while on Madagascar's eastern periphery a great fault dates from the Early Cretaceous.

Along the coasts of Africa a number of basins disappear beneath the sea—in the west off Western Sahara; Senegal; Côte d'Ivoire and Ghana; Benin, Nigeria, and Cameroon; Gabon; the Congo; and Angola; and in the east off Mozambique; Tanzania; and Somalia.

Africa's geologic structure as a whole may thus be said to express its geomorphology. (R.L.C.F.)

The land

RELIEF

The physiography of Africa is essentially a reflection of the geologic history and geology that is described in the previous section. The continent, largely composed of a vast rigid block of ancient rocks, has geologically young mountains at its extremities in the highlands of the Atlas Mountains in the northwest and the Cape ranges in the south. Between these mountainous areas is a series of plateau surfaces, with huge areas that are level or slightly undulating, above which stand occasional harder and more resistant rock masses. Surrounding these surfaces is a zone of plateau slopes below which are narrow coastal belts widening along the Mediterranean coast, the coastlands of Tanzania and Mozambique, a narrow belt between the Niger and Kunene rivers, and an area northward of the Gambia and Sénégal rivers.

Kilimanjaro (19,340 feet [5,895 metres]) is the highest point on the continent; the lowest is Lake Assal (502 feet [153 metres] below sea level) in Djibouti. In proportion to its size, Africa has fewer high mountains and fewer lowland plains than any other continent. The limited areas above 8,000 feet are either volcanic peaks or resistant massifs. All the land below 500 feet occurs within 500 miles of the coast, except for two small basins in the Sahara.

The higher areas of the south and east are in marked contrast to the considerably lower elevation of the western and northern parts of the continent. South of a line drawn from near the mouth of the Congo (Zaire) River to the Gulf of Aden, most of the land lies 1,000 feet or more above sea level, and much of it exceeds 3,000 and even 4,000 feet. North of the line there is relatively little land above 3,000 feet, most of the area being between 500 and 1,000 feet above sea level; there are also broad coastal lowlands, except in the region of the Atlas Mountains and, in the east, beyond the Nile.

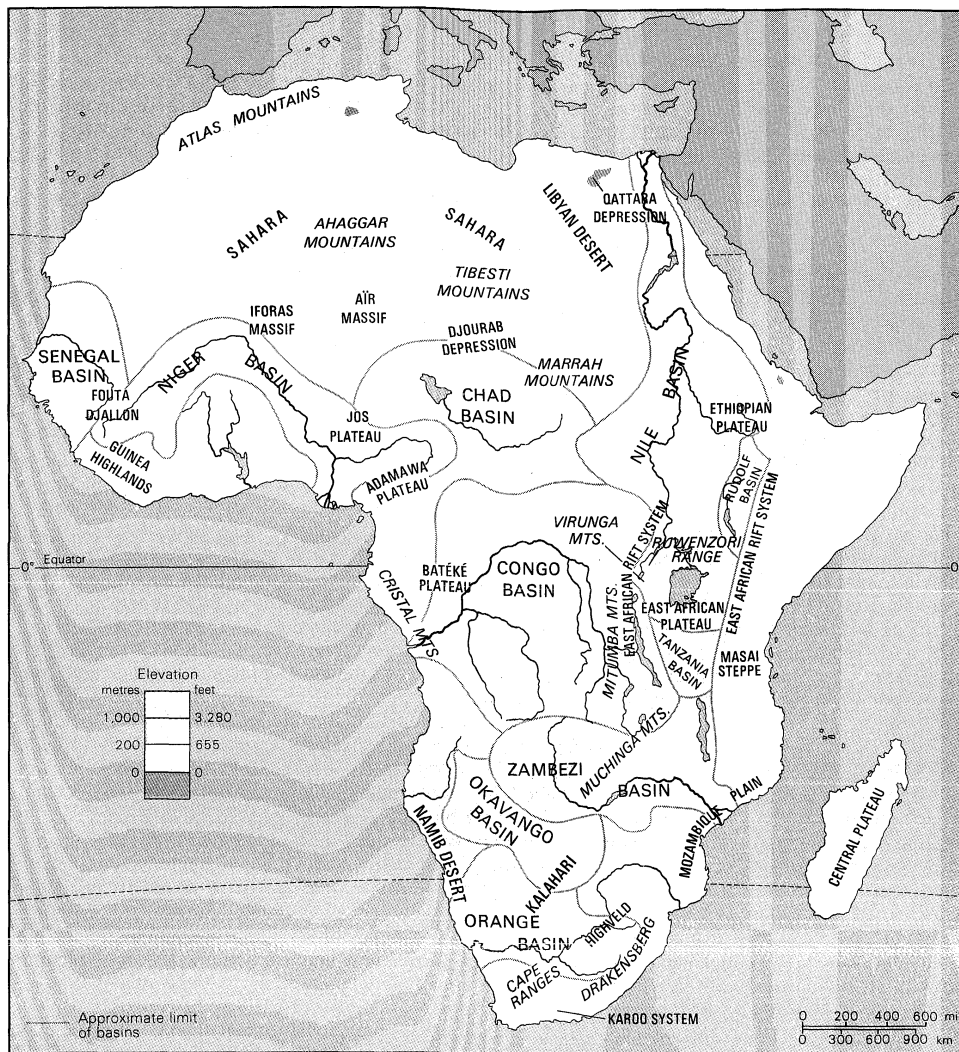

The highest extensive areas are to be found in Ethiopia, parts of which exceed 15,000 feet. Southward the East African Plateau is highest in Kenya, where it is often 8,000 feet or more above sea level; there are occasional volcanic peaks that are much higher, such as Kilimanjaro, Mount Kenya (17,058 feet), Meru (14,978 feet), and Elgon (14,178 feet). The Ruwenzori (Rwenzori) Range—sometimes called the Mountains of the Moon—which reaches its highest elevation at Margherita Peak (16,763 feet) on the borders of Zaire and Uganda, is not volcanic in origin. From East Africa the plateau extends southward, often with a well-defined, though not continuous, escarpment particularly noticeable in the Drakensberg of southern Africa, where Ntlenyana, or Ntshonyana, is 11,425 feet and Mont aux Sources is 10,822 feet. There, the plateau edges are especially marked, because the rock formations are hard and horizontal, whereas in Ethiopia they are conspicuous because of faulting. Where the rocks are softer and less resistant, the escarpment is not so pronounced and so forms less of a barrier to climatic influences and to human movement.

To the north and west of the plateau area of the southern parts of the continent there is a general descent to the lower areas of the basins of the Congo, Niger, and Nile rivers. The only large areas that extend above 3,000 feet are in the folded ranges of the Atlas Mountains and in the central Sahara, where resistant granites form the massifs of Ahaggar and Tibesti. The interior uplands of West Africa and of Cameroon consist of ancient crystalline rocks, reaching considerable heights only in the Fouta Djallon plateau in Guinea, in the Guinea Highlands, which also extend over the borders of Sierra Leone and Liberia, in the Jos Plateau in Nigeria, in the Adamawa region of Nigeria and Cameroon, and in the Cameroon Highlands. There are extensive low-lying areas near the coast and in the basins of the Sénégal, Gambia, Volta, and Niger-Benue rivers. The high areas of Darfur in The Sudan (more than 10,000 feet) and of Mount Cameroon (13,435 feet) are volcanic in origin and are evidence of the same tensions that have resulted in rifting and volcanism in East Africa.

Physiographic regions of Africa.

Volcanic activity

and distinctive relief feature of the continent. Associated with its formation was the volcanic activity responsible for most of the higher peaks of East Africa, including Kilimanjaro, which is always snowcapped despite its nearness to the equator. Seismic and volcanic disturbances are still recorded in the western portions of the rift valley system. In the Virunga Mountains, northeast of Lake Kivu, there are periodic outbursts (about every 10 or 12 years) that have created a series of lava flows. One of these volcanoes dammed the rift valley and converted a large area, formerly drained by a tributary of the Nile, into Lake Kivu.

The rift valley extends for about 4,000 miles, its course being clearly marked out by many of the lakes of East Africa as well as by the adjacent volcanic peaks. From the Gulf of Aqaba it can be traced southward along the Red Sea and into the Ethiopian Plateau to Lakes Rudolf, Naivasha, and Magadi in Kenya. Farther south, through Tanzania, the line of the rift is not quite so obvious. The walls that constitute the eastern rim have been more easily eroded, while the lakes of this area are generally smaller and not in line, and some of them are only waterless salt beds. The largest of these lakes are Natron and Manyara, with Eyasi in a side branch of the main rift. The edges are obvious enough to the south in Malawi, where a huge crusted block collapsed along the parallel faults that constitute the steeply rising slopes of Lake Nyasa (Malawi). The lake is 360 miles long but never more than 50 miles wide; it has a maximum depth of 2,310 feet. The rift then follows the line of the Shire Valley to reach the Indian Ocean near Beira, Mozambique.

The western branch, or Western Rift Valley, extends from the northern end of Lake Nyasa in a great arc, taking

in Lakes Rukwa, Tanganyika (after Lake Baikal in Siberia the deepest lake in the world), Kivu, Edward, and Albert. Subsidiary branches of this valley include the basins in which lie Lakes Mweru and Upemba.

Most of the lakes that occur along the course of the rift valley lie well below the general level of the plateau, ranging from about 1,300 to 3,000 feet above sea level. They are generally very deep and bear a striking resemblance to fjords; some have floors that are below sea level, even though their surfaces are hundreds of feet above sea level.

In complete contrast is Lake Victoria, the largest of all African lakes, which occupies a shallow depression on a plateau 3,720 feet above sea level between the major branches of the rift valley. Its greatest depth is only 270 feet, but, with an area of 26,828 square miles, it is the third largest of the world's lakes, after the Caspian Sea and Lake Superior.

Detailed discussion of the Atlas Mountains, East African mountains, Ituri Forest, Kalahari, Namib, Sahara, and Veld can be found in *African geographic features of special interest* at the end of this article. (Ro.W.St.)

DRAINAGE

The uplifting and warping of the surface of the African continent that occurred during the Pliocene and Pleistocene epochs produced a number of structural basins; these are now either individually occupied by, or are linked up with, drainage systems. With the exception of the Chad basin, all the major drainage basins have outlets to the sea. In addition, minor drainage basins, similar to that of Lake Chad, are situated in the East African Rift Valley. Some, again like Lake Chad, constitute the focus

of centripetal drainage (drainage directed toward the centre), while others are linked to river systems. Although the East African lakes are climatically and economically important, relatively little is known of their hydrological characteristics.

Climate, geology, and the history of tectonic activity have imparted certain common characteristics to African rivers. Spatial variations in the incidence and amount of rainfall are reflected in their hydrological regimes. In areas that have one rainfall season, for example, and have pronounced drought throughout the rest of the year, the rivers flood in the rainy season and shrink in the dry season.

Whatever their hydrological regimes, all the important African rivers are interrupted by rapids, cataracts, and waterfalls. This is explained by several factors, the most important of which is the past tectonic activity, or regional land movements, that caused ridges to be formed across the courses of the major rivers. Waterfalls are often found where the rivers are still engaged in cutting downward as they flow across these ridges; Cabora-Bassa (falls) on the Zambezi and the Augrabies Falls on the Orange River are examples. Another factor that contributes to the creation of rapids or falls is the incidence of rock strata that have proved resistant to the erosive effect of the rivers' flow. (Tropical rivers do not generally carry large quantities of stone or rock; instead, they have a tendency to carry loads of fine silt, produced by chemical weathering.)

Although the Nile, the Zambezi, and the Niger rivers have large deltas, their size does not compare with, for example, the enormous delta region of the Ganges and Brahmaputra rivers. In Africa the generally poor development of deltas is mainly because of the restricted extent of the coastal plain, together with the relatively narrow continental shelf, which provides neither sufficient room nor shallow enough water for the deposition of delta-forming material. The great speed with which most of the rivers flow into the sea is another factor inhibiting delta formation.

Major
drainage
basins

The major drainage basins of Africa are those of the Nile, the Niger, the Congo, the Zambezi, and the Orange rivers and of Lake Chad.

The Nile basin. There are two theories concerning the development of the Nile, which, it appears, originally consisted of two sections. The first theory is that the lower Nile had its source at about latitude 20° N, whence it flowed directly into the sea, while the upper Nile, issuing from Lake Victoria, flowed into an inland lake that covered the As-Sudd region in what is now The Sudan. The lake became filled with water, which then spilled over at its northern end and flowed into what is now the upper Nile. According to the second theory, the upper section originally flowed into a vast lake between Mount as Silsilah (near Luxor, Egypt) and what is now Aswān; this was tapped by the lower section of the Nile after the so-called Sebile erosion (which takes its name from the fact that the breakthrough by the lower Nile was identified at Sebile).

The Nile, which is about 4,132 miles long, is the longest river in the world. From Lake Victoria it flows, as the Victoria Nile, into Lake Albert, from which it emerges as the Albert Nile. Further north it is known as the Al-Jabal River. Thereafter, having received several tributaries, it becomes the White Nile, and finally the Nile, emptying at last into the Mediterranean Sea. Its major left-bank tributary is the Al-Ghazāl, and the largest right-bank tributaries are the Sobat, Blue Nile, and Atbara. Because of the numerous rapids and waterfalls, the Nile descends fairly rapidly from source to mouth, as do its major right-bank tributaries. This is especially true of the Blue Nile, which, after issuing from Lake Tana on the Ethiopian Plateau at a height of approximately 6,000 feet, flows for most of its length through a steep gorge. Swamps also interrupt the river's course. Of these, the largest is the As-Sudd, a vast area of floating swamp reeds, mostly papyrus.

The river's regime is now controlled by a series of dams situated on the Nile itself or on one of its various tributaries; of these, the largest is the Aswan High Dam on the main Nile.

The Niger basin. The Niger basin is the largest river basin of western Africa. The Niger River, which rises in

the mountains of Guinea, enters the sea through its delta in southern Nigeria; it is about 2,600 miles in length. Rapids interrupt its course at several points, although some of these (such as below Bamako, Mali) have been submerged in waters impounded by dams.

The Niger receives its largest tributary, the Benue, which flows in from its left bank, in Nigeria. The valleys of both the Niger downstream from Taoussa and of the Benue appear to be faulted troughs dating from the Early Cretaceous Period. Originally, the middle Niger was separate from the upper Niger, which flowed into an inland lake, the remnants of which now form the inland Niger delta. The middle Niger flowed southeastward to the sea; its valley eroded toward its headwaters, eventually tapping the inland lake and linking the middle with the upper Niger.

The Congo basin. With a total area of about 1,335,000 square miles, the Congo basin consists of a vast shallow depression that rises by a series of giant steps to an almost circular rim of highlands through which the river has cut a narrow exit into the Atlantic Ocean. The present exit is geologically relatively recent, the previous exit being to the north of the present one.

The Congo River is some 2,900 miles in length. Its many waterfalls and rapids cause its valley, like that of the Nile, to lose elevation quickly. The river's course is often constricted by gorges. The best-known are the Boyoma (Stanley) Falls at Kisangani, where the river swings through an arc to flow westward; in fact, the Boyoma Falls are no more than a series of unevenly spaced rapids at no great height, extending along a 60-mile stretch of the river. Downstream from Kisangani, the Congo is joined first by the Ubangi from the right and then by the Kasai—which rivals the Ubangi in the size of its drainage basin—from the left. Below its confluence with the Kasai, the main river cuts through the Cristal Mountains in a deep gorge, which at one point expands into Malebo (Stanley) Pool, a shallow lake measuring 22 miles in length and 14 miles in width. The Congo enters the sea through a swampy estuary that is about 6 miles wide at its mouth.

Boyoma
(Stanley)
Falls

The Zambezi basin. The Zambezi River is about 2,200 miles in length; it occupies a basin with an approximate area of 463,000 square miles. Originally, there were two rivers, corresponding to the upper and lower courses of the present river; the valley of the lower section eroded toward the headwaters until it captured the waters of the upper section. Although there are stretches of the river where the gradient is very gentle—a drop of only about three inches to the mile—the valley as a whole has a fairly steep gradient. There are numerous waterfalls, the most spectacular of which is the Victoria Falls. After these falls, the river winds through a number of deep gorges cut out of basalt and, after flowing through a broad valley, enters Kariba Gorge, which is more than 16 miles in length and is cut through paragneiss (a gneiss, or coarse-grained rock, in which bands rich in granular minerals alternate with bands containing schistose minerals, formed out of sedimentary rock). The Kafue and the Luangwa, the two main tributaries, which both flow through gorges, join the Zambezi on its left bank downstream from Kariba. At the mouth of the main river is a delta about 37 miles wide.

The Orange basin. The Orange River is the longest in South Africa. Flowing across almost the entire width of the country, it makes its way from the highlands in the east through the Kalahari depression in the west to empty into the South Atlantic Ocean. Its major tributary, the Vaal River, is one of its northern headwaters; the two rivers together have a combined length of about 1,300 miles. Together with other major rivers on the continent, the Orange-Vaal river system shares the characteristic of flowing over steep gradients for numerous stretches of its course. The largest drop (about 400 feet) occurs at the Augrabies Falls.

The Chad basin. The Chad basin constitutes the largest inland drainage area in Africa. Lake Chad, a large sheet of fresh water with a mean depth between 3.5 and 4 feet, lies at the centre of the basin but not in its lowest part. Lake Chad is fed by three major streams, the Komadugu Yobe, Logone, and Chari, but these are in danger of having their waters captured by the drainage systems of rivers

that flow in opposite directions. Lake Chad itself, with an area of only some 5,000 square miles, was formerly much more extensive.

Detailed discussion of Lake Chad, the Congo River, the East African lakes, the Niger River, the Nile River, the Orange River, the Sénégal River, the Suez Canal, and the Zambezi River can be found in *African geographic features of special interest* at the end of this article.

SOILS

Soil types. In general, soil types on the African continent may be divided into five or six broad categories. There are desert soils; chestnut-brown soils, which border the deserts; and chernozem-like soils (dark black soils rich in humus and carbonates), which are found immediately south of the chestnut soils from The Sudan westward to just beyond the Niger Bend (the bend in the middle course of the Niger River), and pockets of which are also found in East Africa, Zambia, Zimbabwe, and South Africa. In addition, there are black soils (often grouped with chernozems and found on the Accra Plains of Ghana); red tropical soils and laterites (leached red iron-bearing soils), which occur in the tropical wet-and-dry and equatorial climatic zones; and Mediterranean soils, found in the Atlas Mountains of North Africa and the Cape region of South Africa.

The most important factors that affect soil formation are climate, parent material, relief, drainage, vegetation cover, and the passage of time. Where the land has been generally stable and fairly flat for prolonged periods, as in Africa, the climate becomes the major determinant of the soil groups. The different rocks are deeply weathered and

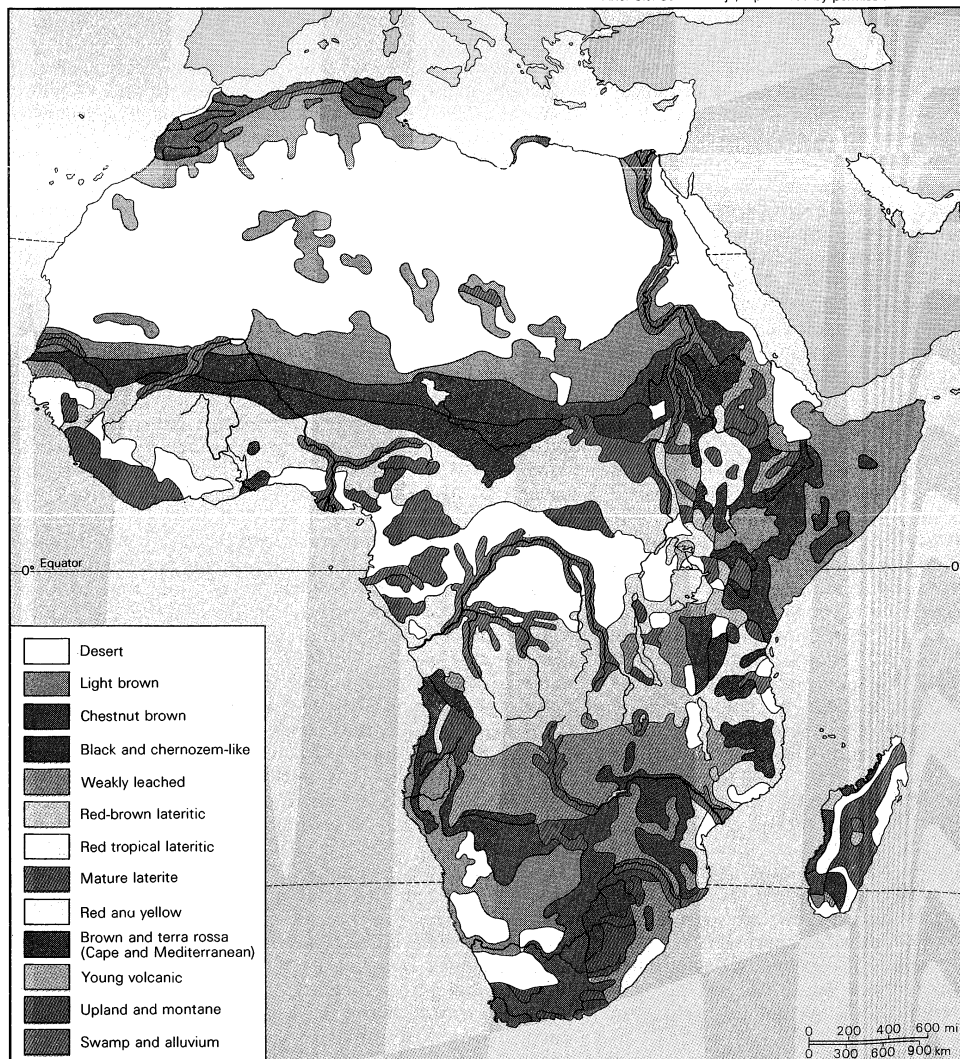

are broken down into their common component elements to produce broadly similar soils under the same climatic conditions. Given sufficient time under a tropical climate, the differences in humus content of the great soil groups, which are introduced by vegetation types, are minimized. But within these groups there will naturally be differences in soil types as a function of local differences in physical factors.

Desert soils. These soils are characterized by the general lack of organic content; by the types of rock reflected in them, the chemical weathering of which has been inhibited by the lack of water; and by the crusts or concretions of soluble salts on or just below their surface. While these crusts are in general thought to have been formed as a result of evaporation, it is nevertheless possible that they may have been formed under a wetter climate during the Pleistocene Epoch.

Chestnut-brown soils. In the semiarid areas bordering the desert, increased rainfall makes grass vegetation more plentiful, results in rocks becoming more weathered than in the desert, and produces better developed soils with a higher humus content. It is the humus content that, according to the amount present, gives the chestnut soils their characteristic light or dark brown colour. Chestnut soils also differ from desert soils because they receive enough water to wash out some of the salt accumulations either on the surface or immediately below it.

Chernozem-like and black soils. An unfailing characteristic of the chernozem is the presence of a subsurface zone of calcium carbonate, sometimes accompanied by calcium sulfate, which is left behind after all the soluble salts have been washed out. Grouped with them are the

After S.J. Schokalskaja, reproduced by permission of UNESCO

black soils, which should, perhaps, be differently classified, for their black colour is not necessarily due to high humus content but rather to the presence of certain minerals, as in the black soils of the Accra Plains, in Ghana.

Red tropical soils and laterites. The majority of tropical soils have shades of colour varying from yellow and brown to red. The reddish colour reflects the presence of iron oxides that form as a result of chemical weathering. At one time all tropical red earths or soils were indiscriminately referred to as laterites, but it is now clear that the term laterite should be confined to those tropical soils with large concentrations of iron and aluminum sesquioxides (insoluble compounds) that have formed a hard pan at or just below the surface. At the most advanced state of laterization, bauxite, from which aluminum is extracted, is formed. Most tropical soils are in varying stages of laterization, which is to say they are at various stages of accumulating insoluble compounds as the soluble elements are leached out. The compounds accumulate more readily in areas with a pronounced dry season and where the water table is not too far below the surface. If the top horizons (layers) of the soils should erode, the subsurface concentrations of sesquioxides are then exposed to the atmosphere, whereupon they crystallize irreversibly to form true laterite concretions.

Mediterranean soils. Mediterranean soils are generally deficient in humus, not so much because of sparse vegetation cover as because of the slowness of the chemical processes that convert the vegetable matter to humus. Low rainfall, occurring when temperatures are lowest, retards chemical weathering. The uneven surface relief of the regions where these soils occur also makes it difficult for mature soils to develop, since the land, except in the valley bottoms, is not sufficiently flat over wide enough areas to allow the soil-forming (parent) materials to remain in place and thus to be thoroughly weathered.

Soil problems. Soil is the foundation of Africa's economic life, and as such its detailed study is most important. Failure to appreciate the physical and chemical properties of the soils has led to disastrous results for several projects for agricultural improvement.

In studying the soils of Africa, it is essential not to lose sight of the importance of such social factors as the ability or inability of mostly uneducated farmers to judge the quality of the soil. Thus, schemes for transforming traditional systems of farming that are based on soil classification but that do not take into account local perception may have little chance of success.

For desert soils to be productive they must be irrigated, as they are on the desert margins of North Africa; their excessive salinity or alkalinity must also be reduced. Compared to desert soils, the chestnut-brown soils are easier to work and are more productive under irrigation. Black soils tend to have a markedly crumbly structure and are sometimes difficult to plow. In the wet season, the black soils of the Accra Plains swell and become slippery, while in the dry season they shrink once more and crack to such an extent that they are said to plow themselves. Red tropical soils need careful handling. Despite their luxuriant vegetation cover, high temperatures coupled with humidity promote the rapid decay of organic matter and keep the humus content low. Erosion is a constant threat if the soils are exposed to the elements for any length of time; the soils remain cultivable only if the sesquioxides remain below the surface.

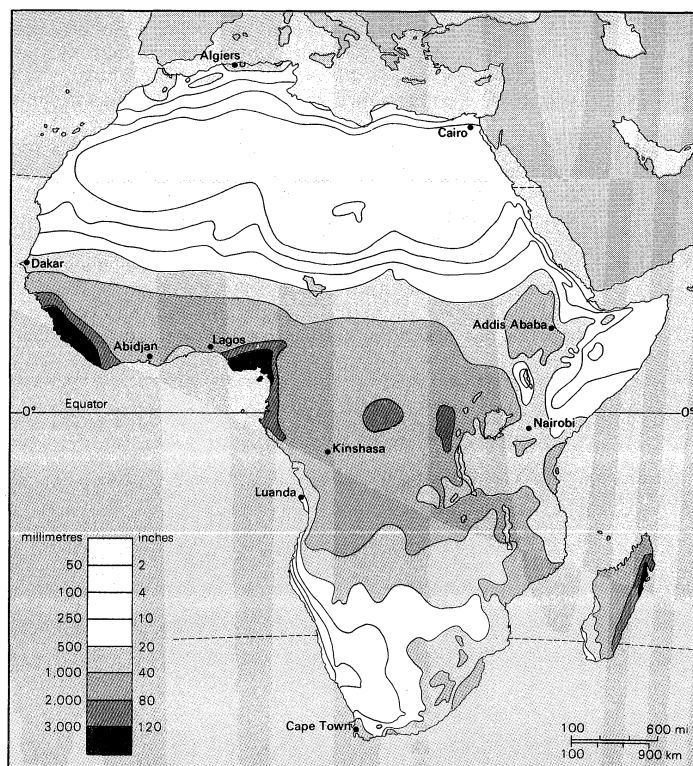

In the Atlas and Cape regions, there is a clearer relationship between soil characteristics and parent material than in the humid tropical areas. Over expanses of limestone, for example, the soils contain large amounts of calcium compounds, some of which must be washed away or neutralized before the soils can become fully productive.

CLIMATE

Factors influencing the African climate. A number of factors influence the climate of the African continent. First, most of the continent—which extends from latitude 35° S to about latitude 37° N—lies within the tropics. Second, the near bisection of the continent by the equator results in a largely symmetrical arrange-

ment of climatic zones on either side. This symmetry is, however, imperfect because of a third factor—the great east–west extent of the continent north of the equator, in contrast to its narrow width to the south. In consequence, the influence of the sea extends farther inland in southern Africa. Moreover, a quasi-permanent subtropical high-pressure cell (the Saharan anticyclone) develops in the heart of northern Africa, while in southern Africa the belt of high pressure on land weakens during the time of high sun (the season when the Sun is overhead—in December and January in the south). A fourth factor consists of the cool ocean currents, which chill the winds that blow over them and thereby influence the climate of the neighbouring shores. Fifth, because of the extensive plateau surfaces of the continent and the absence of high and long mountain ranges comparable to, for example, the Andes in South America or the Himalayas in Asia, climatic zones in Africa tend to shade into one another, rather than to change abruptly from place to place. Finally, the high mountains have climatic zones of their own that vary with altitude.

While these factors help to account for the broad climatic patterns of the African continent, there are, nevertheless, numerous local variations to be found from place to place within the same climatic zone. Urban areas, for example, have climates that often differ in many respects from those of the surrounding countryside. Typically experiencing higher average temperatures, urban areas also frequently have less wind and lower relative humidity; there is too little relevant data from Africa, however, to permit a detailed study of urban climates.

Average annual precipitation for Africa.

The most important differentiating climatic element is rainfall; this, together with several other climatic elements, depends upon the characteristics of the dominating air mass. The air masses of relevance to the African climate may be broadly classified as maritime tropical, maritime equatorial, continental tropical, maritime polar, and continental polar. Of these, the least important are the continental polar air masses, which may occasionally bring intense cold to northern Egypt in December and January, and the maritime polar air masses, which are associated with rain-bearing depressions over the northern and southern extremities of the continent during the winter. With the exception of these, the continent is affected both by a

The air masses

Lateriza-
tion of
soils

continental tropical air mass to the north and by maritime tropical and maritime equatorial air masses to the south.

These northern and southern air masses meet at the intertropical convergence zone (ITCZ). The hot, dry continental tropical air mass, which is present in the upper levels of the atmosphere, descends to the ground only at the convergence zone. Less hot than the continental tropical are the maritime tropical and maritime equatorial air masses, which originate from the Indian and South Atlantic oceans, respectively; they differ only in that the maritime equatorial air mass is unstable and brings rain, while the maritime tropical air mass, when fully developed, is stable and does not normally bring rain unless it is forced to rise by a high mountain.

In July the ITCZ—following the sun—moves northward toward the area of low pressure over the Sahara; there, the maritime and continental tropical air masses converge, with the maritime air masses swinging inland from the sea. There is no rainfall on the northern side of the convergence zone, since the region is completely under the dry continental tropical air mass originating over the Sahara. At the ITCZ itself, however, precipitation is prolonged and intense as air converges between the maritime and continental air masses and is forced aloft. Immediately south of the convergence zone, rainfall is heavy because of the unstable nature of maritime tropical air over a heated land surface. South of the equator, at yet greater distance from the convergence zone, the maritime air masses are less heated, thick, and stable, and they bring hardly any rainfall, except over some of the East African highlands. Only the southern tip of South Africa receives rainfall at this time, from winter cyclones.

During the period of low sun in the Northern Hemisphere (from December to January, when the sun has moved to its southern limit), the situation described above is reversed. The convergence zone moves southward, dipping into southern Africa. At this season the whole of northern Africa (except the Atlas Mountains) is under the dry continental tropical air mass, while southern Africa receives rainfall except in the Cape region and on the southwest coast, where the maritime air mass remains stable offshore over the cool Benguela Current.

Climatic regions. When considered in detail, the movement of air masses and their effects provide the basis for a division of the continent into eight climatic regions. These are the hot desert, semiarid, tropical wet-and-dry, equa-

torial (tropical wet), Mediterranean, humid subtropical marine, warm temperate upland, and mountain regions.

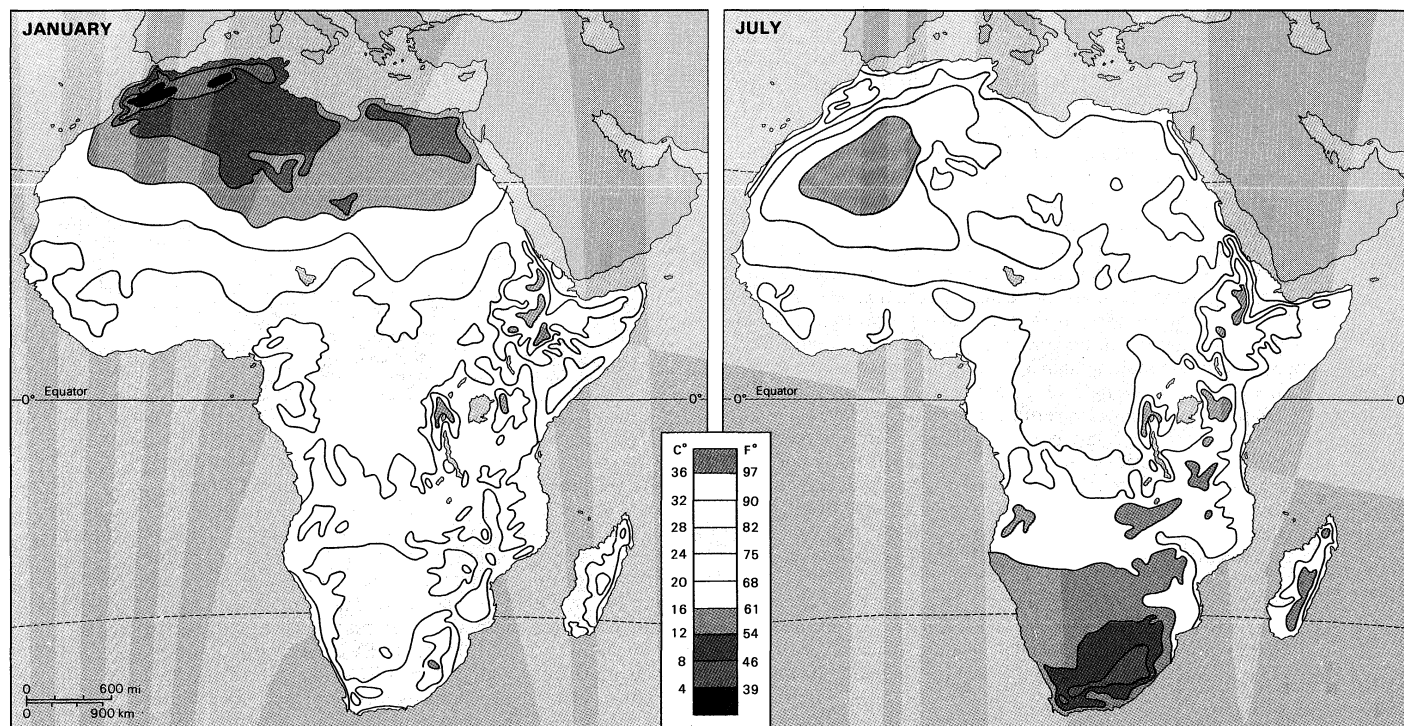

The hot desert region consists of the Sahara and Kalahari deserts, which are always under the influence of dry continental tropical air masses, and the northern Kenya-Somali desert, the aridity of which is principally caused by the stable nature of the maritime air masses that pass over it throughout the year. The stability of these maritime air masses is induced by their passing over the cool body of water offshore. In addition to aridity, the desert climate is characterized by high mean monthly temperatures; the diurnal (daily) temperature range is, however, greater than the annual range of the mean monthly temperature.

Semiarid climatic regions fringe the desert areas and include the greater part of the land south of the Zambezi River. They differ from true desert regions in being just within reach of the ITCZ in the course of its seasonal movement and therefore receiving more rainfall. Temperatures are about the same as those in the desert regions.

The tropical wet-and-dry region is often called the savanna climatic region; this implies, incorrectly, that all areas with savanna vegetation have this type of climate. This region covers a little less than half of the total surface area of the continent, extending toward the equator from the semiarid areas. The great distinguishing feature of this climatic region is the seasonal character of its rainfall. During the period of high sun the maritime air masses produce up to six months of rainfall—the length of the rainy season depending on nearness to the equator. The rest of the year is dry. In a few places—for example, on the coast of Mauritania and Senegal—there is also a little rainfall in the period of low sun. As in the desert and semiarid climatic zones, mean monthly temperatures show less variation than daily temperatures. In western Africa the period of low sun corresponds to the harmattan season. The harmattan is a warm, dry northeasterly or easterly wind that blows out of the southern Sahara and is frequently laden with large quantities of sand and dust.

Regions with the equatorial, or tropical wet, type of climate, or variants thereof, are the wettest in Africa. There are two peak periods of rainfall corresponding to the double passage of the ITCZ. Because areas with an equatorial climate are constantly covered by warm maritime air masses, variations in their monthly and daily temperatures are less pronounced than in the tropical wet-and-dry regions.

The eight climatic regions

Average temperatures for January (left) and July (right) in °C for Africa.

Marked variations in the rhythm of equatorial climate sometimes occur; for example, the rainfall may be monsoonal and the second rainy season may be all but nonexistent. But the most notable anomaly can be observed on the West African coast from around Cape Three Points, Ghana, eastward to Benin, where, although the bimodal rainfall regime prevails, the total annual precipitation is less than 40 inches (1,000 millimetres). Among the many explanations that have been suggested are that the presence of a cold body of water offshore chills the lower layers of the maritime air mass and makes it stable; that the body of cold air that forms offshore diverts the incoming airstreams to the west and east of the anomalously dry area; that there is a strong tendency for the winds to blow parallel to the shore during the rainy seasons; that the absence of highlands deprives the region of orographic (mountain) rainfall; that fluctuations in the offshore, moisture-bearing winds occur during the rainy season and reduce rainfall; and that local meteorological peculiarities of thunderstorms contribute to the reduction in rainfall.

In the northern and southern extremities of the continent there is a dry summer subtropical, or Mediterranean, type of climate. Rain falls only in winter (December–January in North Africa, June–July in southern Africa), although in some localities it may fall in autumn (September in North Africa, April in southern Africa). Mean monthly temperatures are lower than in tropical climates, dropping to about 50° F (10° C) in winter, while summer (June–July in North Africa, and December–January in southern

Africa) temperatures may sometimes exceed those of tropical climates. Clear blue skies are characteristic.

The humid subtropical marine climate is restricted to the southeast coast of Africa. This region is characterized by rainfall throughout the year, but it is heaviest in summer. In South Africa, south of Natal, the winter rainfall is more pronounced, and the temperatures are a little lower than in the north. Thus, at Port Elizabeth there are six months when temperatures are below 62° F (17° C), while at Durban mean monthly temperatures do not fall below 64° F (18° C).

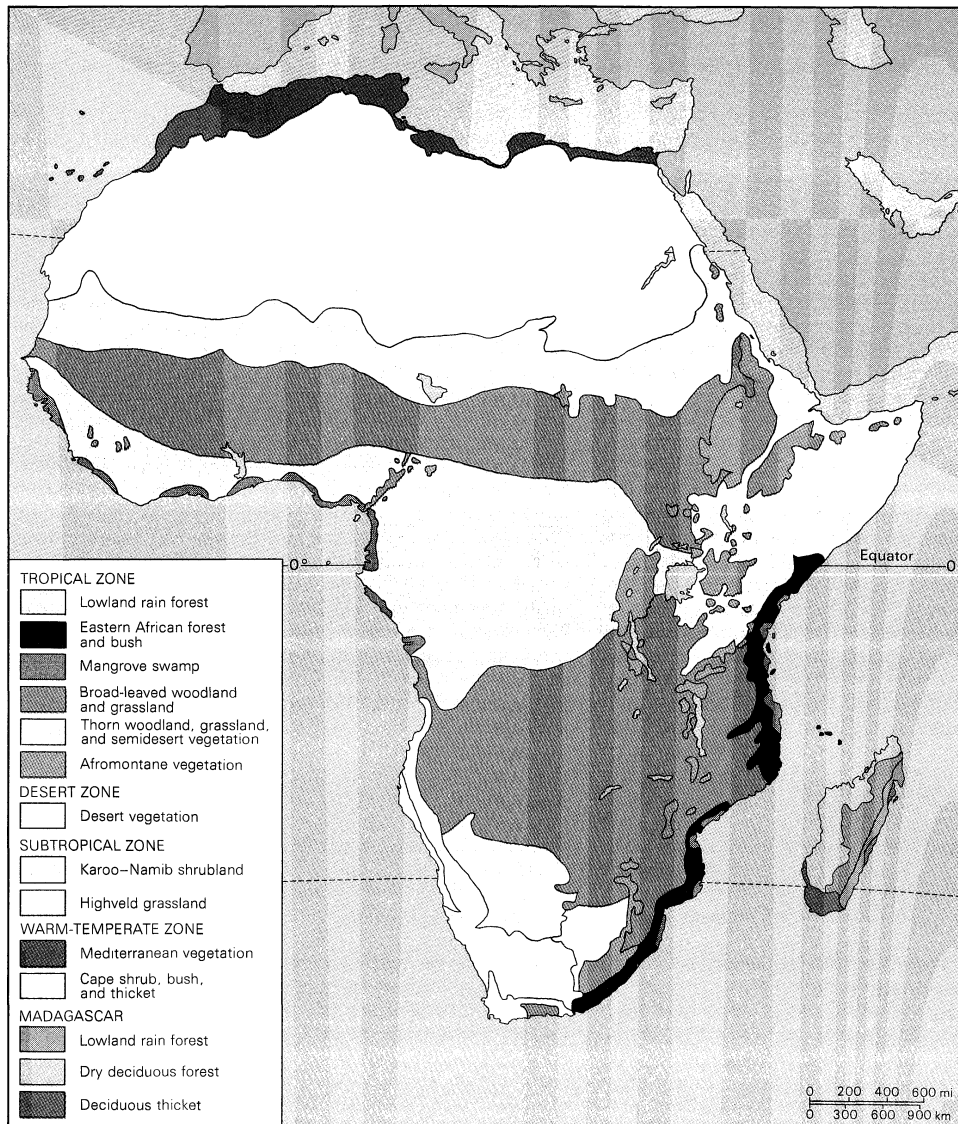

The warm temperate upland climatic region is found on the Highveld of southern Africa. Its rainfall regime is similar to that of the tropical wet-and-dry climate, but temperatures are greatly modified by the altitude; frost, for example, occasionally occurs in Lesotho. Toward the coast the climate shows maritime characteristics, and there is a tendency toward winter rainfall.

The mountain climatic region includes the high mountain areas of Ethiopia and the lake region of East Africa. In some respects the climate is similar to the warm, temperate upland climate, except that temperatures are even lower and snow occurs on the tops of the highest peaks, such as Kilimanjaro. The rainfall regime is similar to that of the adjacent lowland areas. (K.B.D.)

PLANT LIFE

African vegetation develops in direct response to the interacting effects of rainfall, temperature, topography, and

The
Mediterranean
climatic
zone

Vegetation zones of Africa.

type of soil; it is further modified by the incidence of fire, human agriculture, and grazing and browsing by livestock. Of the total land area of the continent, forests cover about one-fifth; woodlands, bushlands, grasslands, and thickets about two-fifths; and deserts and their extended margins the remaining two-fifths.

Ecological relationships. Until about two million years ago Africa's vegetation had always been controlled by the interactions of climate; geology, soil, and groundwater conditions (edaphic factors); and the activities of animals (biological factors). The addition of humans to the latter group, however, has increasingly rendered unreal the concept of a fully developed "natural" vegetation—i.e., one approximating the ideal of a vegetational climax. Nevertheless, in broad terms, climate remains the dominant control over vegetation. Zonal belts of precipitation, reflecting latitude and contrasting exposure to the Atlantic and Indian oceans and their currents, give some reality to related belts of vegetation. Early attempts at mapping and classifying Africa's vegetation stressed this relationship: sometimes the names of plant zones were derived directly from climates. In this discussion the idea of zones is retained only in a broad descriptive sense.

As more has become known of the many thousands of African plant species and their complex ecology, naming, classification, and mapping have also become more particular, stressing what was actually present rather than postulating about climatic potential. In addition, over time more floral regions of varying shape and size have been recognized. Many schemes have arisen successively, all of which have had to take views on two important aspects: the general scale of treatment to be adopted, and the degree to which human modification is to be comprehended or discounted.

Once, as with the scientific treatment of African soils, a much greater uniformity was attributed to the vegetation than would have been generally acceptable in the same period for treatments of the lands of western Europe or the United States. Quite the opposite assumption is now frequently advanced. An intimate mosaic of many species—in complex associations and related to localized soils, slopes, and drainage—has been detailed in many studies of the African tropics. In a few square miles there may be a visible succession from swamp with papyrus, through swampy grassland and broad-leaved woodland and grass to a patch of forest on richer hillside soil, and finally to succulents on a nearly naked rock summit.

The span of human occupation in Africa is believed to exceed that of any other continent. All the resultant activities have tended, on balance, to reduce tree cover and increase grassland; but there has been considerable dispute among scholars concerning the natural versus human-caused development of most African grasslands at the regional level. Correspondingly, classifications have differed greatly in their principles for naming, grouping, and describing formations: some have chosen terms such as forest, woodland, thornbush, thicket, and shrub for much of the same broad tracts that others have grouped as wooded savanna, savanna, and steppe. This is best seen in the nomenclature adopted by two of the most comprehensive and authoritative maps of Africa's vegetation that have been published: R.W.J. Keay's annotated *Vegetation Map of Africa South of the Tropic of Cancer* (1959) and its more widely based successor, *The Vegetation Map of Africa* (1983), compiled by Frank White. In the Keay map the terms "savanna" and "steppe" were adopted as precise definitions of formations, based on the herb layer and the coverage of woody vegetation; the White map, however, discarded these two categories as specific classifications. Yet any rapid demise of savanna in its popular and more general sense (i.e., as dry tropical grassland or mixed woods and grassland) is doubtful.

The vegetational map of Africa and general vegetation groupings used in this article mainly follow the White map and its extensive annotations, although some 100 specific types of vegetation identified on the source map have been compressed into 14 broader classifications.

Vegetational zones. *Lowland rain forest.* African lowland rain forests occur along the Guinea Coast of West

Africa and in the Congo basin. The full development of this tropical formation requires continuously warm conditions and an annual rainfall exceeding 50 to 60 inches (1,270 to 1,520 millimetres) distributed fairly evenly over the year. The vertical limit is about 3,500 to 4,000 feet. This multistoried, highly diverse, extensive, and potentially self-perpetuating assemblage has been described by some as the source of virtually all tropical floristic diversity. No other part of the world sustains a greater biomass (total weight of organic matter in a given surface area) than lowland tropical rain forests. Even though the speciation (proliferation of distinct types of plant) within the African rain forests is notably poorer than that of its counterparts in Southeast Asia and the Amazon basin of South America, these forests sustain a huge multiplicity of life forms, occupying different strata (generalized levels of plant height) and niches (separate, small-scale habitats). Characteristically, tropical rain forest is composed of a ground story, from 6 to 10 feet tall, of shrubs, ferns, and mosses; a middle story of trees and palms 20 to 60 feet in height; and a dominant top canopy consisting of trees up to 150 feet high with straight unbranched trunks, buttressed roots, and spreading crowns of perennial leafage. The large branches of these crowns provide niches for epiphytes, including orchids, ferns, and mosses. Lianas tie trees to one another, parasitic species cling to trunks and branches, and strangler figs (*Ficus pretoriae*) put down aerial taproots. Nevertheless, these are not "impenetrable" jungles. It has been suggested that some early European travelers and pioneer botanists may have exaggerated the difficulties of human penetration because they journeyed along atypical waterways and along tracks where disturbance of the original vegetation had thickened the regenerating ground layer.

In true rain forests, grasses are adventitious (occurring in consequence of fortuitous intrusions). Elephant grass (*Pennisetum purpureum*) can grow abundantly in areas where the vegetation has been disturbed, providing good fodder for grazing animals when young but quickly becoming rank, coarse, and a refuge for insects. Cogon grass (*Imperata cylindrica*) is a troublesome grass on depleted and fire-seared ground.

Eastern African forest and bush. Lowland forests and evergreen bushland form a long belt of land some 125 miles broad along the Indian Ocean. From various causes—notably the monsoonal climate, freely draining soils, and long historical impact of humans—these forests are much more limited in their structure (physical form), speciation, and robustness. On more favoured terrain—such as estuarine fringes, the seaward flanks of the islands of Zanzibar and Pemba, and hill masses athwart the rain-bearing southeast monsoon—forest and a close broad-leaved woodland are still dominant. Where land is in a rain shadow, in areas of unfavourable geology (e.g., raised coral reefs), and near cities and small ports, thorny bush, succulent shrubs, and scrawny grassland prevail. Nevertheless, the region now sustains a number of economically important domesticated trees—both indigenous and exotic—such as the coconut palm, cashew, mango, and (especially on Zanzibar and Pemba) clove.

Mangrove swamp. Mangroves include a variety of species of broad-leaved, shrubby trees (10–40 feet high) that fringe muddy creeks and tidal estuaries. They require warm, saline water—hence their distribution along tropical coastlines. Often they form nearly impenetrable stands, for which the easiest access is by sea. The trunks and roots are termite-resistant, and they have long been favoured as a building material and for making charcoal.

Broad-leaved woodland and grassland. This classification constitutes one of the most extensive composite categories now recognized and includes much of the land formerly labeled as savanna. Two broad bands extend across the continent, one from about 7° to 12° N latitude and the other from about 8° to 22° S latitude. Structure and floristic composition vary greatly with the increase of latitude, both in the north and the south. Annual rainfall averages 35 to 45 inches, with marked seasonality of occurrence and considerable fluctuations from year to year, both in total rainfall and in the onset of rainy periods.

Typical
tree species

The woodlands of western Africa strikingly resemble those south of the equator. In both areas, undulating wooded interfluvies on light soils successively alternate with swampy, clay-based valley grasslands (called *fadamas* in Nigeria and *dambos* in Zambia and Malaŵi) in a topographically linked sequence of soils called a catena.

Trees, 30 to 50 feet high, are typically deciduous and often fire-resistant, since much of this land is burned annually. Common West African species include types of *Isobertinia* (a spreading leguminous tree of the pea family), *Daniellia* (a leguminous tree with white bark), and *Lophira* (a tree with strap-shaped leaves that is said to yield the most durable timber in the region). Other hardwoods, forming distinct communities, are *Combretum* and *Terminalia*, which are better suited to the drier areas. Prevalent southern equivalents include *Brachystegia* (a leguminous hardwood, the bark of which formerly was used to make cloth) and *Julbernardia* (another plant of the pea family resembling *Isobertinia*). Over much of the interior of Tanzania, in areas of reduced rainfall and poorer soils, a light-canopied, sustained woodland called Miombo forest rises above a rather scrawny ground layer. This is an excellent habitat for bees, and honey has long been gathered there.

Because of periodic burning, tall grasses have become dominant over large expanses of plateau land, which sometimes contains few, if any, of its original trees. The tall, coarse red grass *Hyparrhenia* can form prominent stands, but it makes poor grazing land and often harbours insects that spread disease. Much better for the pastoralists are induced swards of *Themeda*.

For centuries humans have selectively retained certain economically important tree species in areas cleared for farming; the effect has been to create what is called "farmed parkland," in which a few favoured trees rise above the fields. Examples include the shea butter nut tree (*Butyrospermum*), common in Ghana and Côte d'Ivoire; *Acacia albida*, found in Senegal and Zambia; and the truly domesticated baobab (*Adansonia digitata*), which is perhaps the most widely distributed.

Thorn woodland, grassland, and semidesert vegetation. Toward the margins of the tropics the vegetation cover becomes lower and thinner as the fluctuating transition to desert vegetation ensues. In the same progression the concept of an annual rainfall (nominally 5 to 20 inches) yields to the reality of extreme unreliability in both incidence and expectation. Under such restraints a definitive "boundary" with the desert becomes meaningless. Moreover, there appears to have been a trend toward declining precipitation in the last half of the 20th century, and human impact certainly has enhanced the natural deprivation of plant life in the marginal regions. The southern margin of the Sahara—roughly between the latitudes of

15° and 20°—is called the Sahel (Arabic: *Sāhil*; "shore," or "edge"), the word being extended by implication to comprehend the fluctuating margins of the great sand seas of the Sahara to the north. The southern equivalent covers much of the Kalahari, which is often called a desert but is more properly a thirstland.

Thorn woodland displays a predominance of xerophytic, sometimes succulent or semisucculent trees, such as acacia, *Commiphora* (the myrrh tree), or *Boscia* (an evergreen hard-leaved tree). The occurrence of the bunched and thorny desert date (*Balanites*) seems to accompany land impoverishment. A relatively luxuriant shrub layer, often forming dense thickets, is found in conjunction with succulents, such as aloes, *Sansevieria* (a fibrous species), and *Adenium*, or desert rose (a succulent shrub with smooth grey bark, a huge water-storing base, and beautiful red or pink flowers), and smaller euphorbias.

Farther toward the desert, tree growth and perennial grass—surviving in narrow strips along watercourses—separate much larger areas of sparse annual grasses (*Cenchrus* in western Africa, *Eragrostis* south of the equator, and *Chrysopogon* on the margins) and scattered low shrubs, often mainly acacias. Shrubs may often be salt-tolerant. While shrubs may die from inadequate moisture, they are little affected by the rare fires that occur.

Afromontane vegetation. All high mountains exhibit azonality; i.e., their vegetation differs from that found in the climatic zones from which they rise. The differences manifest themselves as progressive modifications, which are usually well stratified and reflect altitude-dependent climatic changes. Generally, as elevation increases temperature decreases (to the point where frost and even glaciation can occur) and precipitation increases (although above a certain level precipitation decreases markedly). Mountainous terrain can retain ancient climatic conditions—making possible, for example, the survival of relict species—and the relative inaccessibility of the higher elevations to humans has helped preserve more of the vegetal patterns of the past.

Vegetation strata typically are skewed with regard to slope orientation (aspect). This is mainly due to a contrast between exposure to rain-bearing winds and shadowing from them but may also reflect long-term history. If lower slopes rise abruptly from the base (as they often do in Africa), then a distinct boundary between vegetation formations may be clearly distinguished; if the rise is gentle, vegetations merge (as in the western Kenyan highlands). (All the circumstances mentioned above are represented in the African mountain systems, but for purposes of illustration the vegetational map identifies only areas of altitudinal modification. Thus, some areas that are included are not tropical, such as parts of the Red Sea Hills and the mountains of South Africa and Lesotho.)

Azonality
of high
mountains

Caroline Weaver—Ardea London

Altitudinal modifications of vegetation are clearly discernible on the high East African peaks near the equator (e.g., Kilimanjaro and Mounts Kenya and Elgon), and a rich forest belt—much reduced upslope by human activities, except where the land has been reserved—clothes the zone that receives the maximum rainfall and is free of frosts (up to about 5,000 to 6,000 feet). Such mountains have great human importance as watersheds and as repositories of native plants.

Desert vegetation. The Sahara has one of the lowest species densities in the world, and a sustained vegetation cover (which can include trees and bushes) occurs only in the massifs and oases. Elsewhere, the vegetation is discontinuous and consists of two main types: perennials with huge root systems and sparse aerial parts, often protected by waxy cuticles, thorns, and hairs; and ephemerals with slight root systems and little foliage but with the ability to flower profusely immediately after occasional storms and then to seed quickly and abundantly. The stony and rocky expanses give more hold for plants than do the vast areas of shifting sands. In some areas with slightly more rainfall, grass tufts may grow 50 yards apart. *Aristida* is the dominant grass, and for brief periods it can yield a nutritious forage called *ashab*.

The Namib is one of the world's driest deserts. The area along the coast, however, is almost always foggy, and succulent shrubs (such as aloes) manage to survive on this moisture. The Namib also contains the strange tumboa, or welwitschia (*Welwitschia mirabilis*), which may live 100 years or more.

Karoo-Namib shrubland. In this drought-prone land, soils are often shallow, even saline. The low shrubs that grow there can be divided into two groups: woody plants, such as species of *Acacia* and *Pentzia* and the saltbush (*Atriplex*); and succulents, including aloes, euphorbias, and *Mesembryanthemum*. *Aristida* and *Themeda* are characteristic grasses. Every year the blossoms of bulbous plants lay short-lived carpets of colour. Being both drought-resistant

and high in minerals, many of the shrubs can provide useful grazing for goats and sheep.

Highveld grassland. The grassland classification is restricted to regions with 10 percent or less woody plant cover. The Highveld meets this definition and probably owes much to unaided nature for its creation and perpetuation, since fires caused by lightning strikes are relatively frequent. Its extent has always been fairly precisely defined: areas with more than 15 inches of rainfall during the summer. Highveld vegetation, though modified considerably by human activity, traditionally has been differentiated into sweet veld (dominated by *Themeda*) or sour veld (*Andropogon* and *Eragrostis*), the latter making poorer pasturage.

Mediterranean vegetation. This zone is determined chiefly by its climate, which is characterized by very dry summers and mild, rainy winters, but it has long been much differentiated by its inhabitants; large tracts have been degraded into maquis (macchie), garigue, or dry semidesert (steppe) vegetation. Maquis consists of dense scrub growths of xerophytic (drought-resistant) and sclerophyllous (leathery) shrubs and small trees, which are often fire-resistant. Garigue characteristically is found on limestone soils and has more woody growth, including evergreen and cork oaks (*Quercus suber*). The higher slopes of the Atlas Mountains once carried large stands of pine and cedar, but they have been much depleted. Typical grasses, progressing from the coast to the desert, are *Ampelodesmos*, *Phalaris*, and *Stipa*.

Cape shrub, bush, and thicket. This region constitutes the southern counterpart of the Mediterranean zone, although (with the exception of the Atlas Mountains) it is richer in its vegetation potential. There were once considerable enclaves of true evergreen bushland, which have reverted to shrubland (*fynbos*). Sclerophyllous foliage and proteas abound. Although grassy tracts occur on the mountains, they are characteristically unusual lower down. Beyond the Cape Ranges, *fynbos* grades into karoo.

Madagascar. Physically and biologically, Madagascar has long formed a separate entity. White has identified eastern and western regions of endemic (unique) vegetation. In the eastern centre, about one-sixth of the plant genera and more than three-fourths of the thousands of

species are regarded as endemic. The Madagascar rain forest has shorter trees and a somewhat drier climate than its equatorial counterpart and contains its own dwarf palms (*Dypsis*) and bamboos (*Ochlandra*). The western deciduous forest stands in the rain shadow; some of its trees resemble Mediterranean oaks. The southern thickets have prominent euphorbias and species of the Didiereaceae family. The island has much degraded secondary forest (locally called *savoka*) along the eastern and northern coasts.

Sudd. In addition to the major types of vegetation described above, a special vegetation called sudd (literally meaning "barrier") occurs in the great Nile, Niger, and Zambezi drainage systems of the African interior plateau. Characteristic is the sudd along the White Nile River in The Sudan and Uganda. Sedges (especially papyrus), reeds, and other water plants—including the floating Nile cabbage (*Pistia stratiotes*)—form masses of waterlogged plant material that are largely unproductive and are a nuisance to fishing and navigation. *Pistia* has become an unwelcome invader of Lake Kariba, the body of water formed by the impounding (1959) of the Zambezi River in the Kariba Gorge.

Long-term changes in vegetation. Africa's basic vegetational zones are believed to have existed in approximately

the same climatically controlled series and with the same characteristically developed species for a long period of time; and, indeed, some ancient African plant families—such as the cycads, which evolved some 200 million years ago—still have living representatives. Nonetheless, the continent's vegetation has been altered continuously by geologic and climatic changes and by the movement of the caloric (heat) equator. The past million years have been a time of unusually rapid changes, with major consequences for Africa's vegetation.

The vegetational history of Africa is of great scientific relevance. Studying the lichens growing in the high East African mountains, for example, may yield a better understanding of the continent's climatic trends, and a knowledge of past conditions in the Sahel might help explain what influence natural phenomena have had on the disastrous droughts of the region since the late 1960s.

Geologic influences. The two most important geologic modifications of vegetation have been the very ancient separation of Madagascar from the mainland, which gave rise to the distinct speciation of the island's flora, and the long-continuing faulting and vulcanism along East Africa's huge rift system that has thrown up high ranges (e.g., the Ruwenzori between Uganda and Zaire) and great vol-

canoes (Kilimanjaro) and has thus created and reshaped Afromontane flora.

Climatic influences. The repercussions of the great Pleistocene Ice Ages of Europe have constituted the most notable climatic influence on African flora in relatively recent geologic history. These consisted of a succession of colder periods marked by glacial advances, interrupted by warmer, drier interglacials; the last series of these ended between about 5,000 and 10,000 years ago. Tropical Africa experienced contemporaneous fluctuations in its climate, although it is misleading to infer any simple equivalences between these fluctuations and the European periods of glacial advances and retreats.

During the wetter times (pluvials) in Africa equatorial forests spread, separating northern woodlands from their southern counterparts (with consequent species differentiation); mountain vegetation descended onto the plateaus; and there is evidence that the Saharan climate was greatly ameliorated, much to the advantage of humans. During the warmer, drier interpluvials the existing vegetation was degraded in many zones. Dunes spread from the Sahara and over the Kalahari, for example, and their fossilized alignments—now vegetated—can be traced across the thorny woodlands and grasslands of Niger, Nigeria, Namibia, and Botswana.

Human influences. The greater part of the reduction of Africa's natural vegetation has happened in the last 2,000 years—probably since the late 19th century for the tropical portions—the time during which humans have been most numerous and active. Pastoralism, agriculture, the rapid growth of human and livestock populations, the expansion of cities and towns, and the external demands for primary resources have made ever-greater demands upon the land for sustenance and perceived economic betterment. Much is known of the detailed processes of vegetation modification along the Mediterranean, since they have been observed and studied since classical times, and a good deal is also known from the more than three centuries of study of the Cape area of South Africa; but until the late 19th century very little was understood about these processes in tropical Africa. Indeed, the time scale of actual human impact on African vegetation may be causally linked to the awareness of it by Europeans.

Within the tropical forests and woodlands, fire undoubtedly has been the great human agent of clearance and degradation, of far greater efficacy than felling, bark-ringing, or uprooting—at least until the introduction of

modern plantation agriculture and logging. Hunters, pastoralists, and cultivators have all fired the land for centuries and have gathered wild foodstuffs, thatch timber for construction, and fuelwood from the volunteer (*i.e.*, uncultivated or self-generating) vegetation. The long-term effects of such activity bear directly upon the debated question of the origin of the savannas.

In earlier times, African cultivators found the fabric of the tropical rain forest comparatively difficult to modify substantially. In the 20th century, however, it has been greatly reduced in extent (such as in Sierra Leone), patched and frayed (Nigeria), and exploited for timber exports (Gabon). Moreover, many of tropical Africa's largest cities and busy seaports are in this zone. The most diverse and seemingly inexhaustible floral realm in Africa has therefore become a cause for widespread concern.

Conserving the vegetation. Perceptions of the need for environmental conservation in Africa held by those outside the continent are sometimes expressed in terms that seem opposed to the legitimate priorities and aspirations of African peoples (in meeting which agriculture and livestock management must remain crucial). It is not surprising that projections based upon the assumptions from these external sources frequently end in pessimism. A more constructive approach is to identify ways in which to more fully integrate wild plant life, crops, and animals, which can be expressed in the concept of productive countryside. The capacity and precision of resource surveys have been greatly enhanced by remote sensing, and this has been coupled with the worldwide transmissibility of information. Research and interest in agroforestry have expanded and become institutionalized. Above all, however, confidence must be put in the capacities of many millions of African farmers to expand agriculture while working toward the reintegration with wild plant life.

ANIMAL LIFE

Africa includes parts of two of the Earth's six main zoogeographic regions: the Ethiopian region, which comprises the continent south of the Sahara and the southwestern part of Arabia, as well as Madagascar; and a southern part of the Palaearctic (Old World) subregion of the Holarctic region (*i.e.*, the lands of the Northern Hemisphere), consisting of North and northwestern Africa south to roughly the tropic of Cancer.

Genera and distribution. Africa is best known for the enormous diversity and richness of its wildlife. It has a

Zoo-
geographic
regions

Typical southern African herbivores at a watering hole in the Transvaal, S.Af.

John Rushmer—Ostman Agency

greater variety of large ungulates, or hoofed mammals (some 90 species), and freshwater fish (2,000 species) than any other continent.

Mammals. The main group of herbivores are the African antelope, which belong to four subfamilies of the ox family (Bovidae). The first subfamily is the oxlike Bovinae, which is further subdivided into the African buffalo and the twist-horned antelope, including the eland (the largest of all antelope), kudu, nyala, and bushbuck. The second subfamily is the duiker, a small, primitive bovid that lives in the thickets, bush, and forests. Third is the "horse antelope," further divided into sable-horned sable, roan, and oryx antelope; the "deer antelope," kongois, hartebeest, topi, gnu (wildebeest), and blesbok, all mostly inhabitants of the open plains; and the "marsh antelope," waterbuck, lechwe, kob, puku, and reedbuck. The fourth subfamily is the antelope proper, divided into two distinct tribes, the first of which includes royal, dikdik, klipspringer, oribi, steenbok, and grysbok and the second, gazelle, impala, springbok, and reneek. Other well-known large African herbivores include the zebra, giraffe, hippopotamus, rhinoceros, and African elephant.

Probably no group of animals is more identified with Africa than its Carnivora (the order of flesh-eating mammals), of which there are more than 60 species. In addition to the better-known big (or roaring) cats—the lion, leopard, and cheetah—are the wild dog, hyena, serval (a long-limbed cat), wildcat, jackal, fox, weasel, civet, and mongoose. These predators and scavengers are vital in maintaining the ecological equilibrium of the areas that they inhabit.

The primates include some 45 species of Old World monkeys, as well as two of the world's great apes: the chimpanzee and the world's largest ape, the gorilla. Presimian primates—such as pottos (African lemurs) and galagos (bush babies, or small arboreal lemurs), as well as Lorisidae (a family of arboreal lemurs, moving with a slow, delicate crawl)—are mainly small and nocturnal, but in Madagascar, where there are no true monkeys, the world's most diverse assemblage of large and small diurnal and nocturnal presimian lemurs survives.

Marine mammals include one Mediterranean and one South African seal (the Cape fur seal) and two Sirenia (an order of aquatic herbivores)—the dugong and the manatee. In addition, whales, porpoises, and dolphins frequent Africa's coastal waters.

Endemic
mammals

Africa's large number of endemic mammal species is second only to that of South America. These include several families of the ungulate order Artiodactyla (composed of mammals with an even number of toes), such as giraffes and hippopotamuses. Some families of Carnivora—such as civets (of the Viverridae family), their smaller relations the genetids, and hyenas—are chiefly African. The rodent family of jumping hares (Pedetidae) is endemic, and one order, the aardvark (Tubulidentata)—a large nocturnal burrowing mammal, with one species—is exclusively African. Madagascar also has a remarkable insect-eating family, the tenrecs (animals with long pointed snouts, some of which are spiny and tailless).

Birds. South of the Sahara the birdlife includes nearly 1,500 resident species, to which must be added another 275 species that are either resident in northwestern Africa or else are Palaearctic winter migrants; the migrants once totaled perhaps two billion individuals, but their numbers have been reduced considerably by severe droughts and by human land use and predation. Birds are mainly of Old World families, but of those that are endemic the most noteworthy are perhaps the ostrich, shoebill, hammerkop (a brown heronlike bird), and secretary bird (a large long-legged predatory bird) and the touracos (brightly coloured birds, some with helmetlike crests). Other families, such as bustards, sand grouse, honey guides (small dull-coloured birds, several species of which are noted for leading people to the nests of honeybees, in order to feed on them after the nests have been broken), and larks are predominantly African. There are many avian predators of land mammals, including eagles, hawks, and owls; more of fish, such as storks, waders, and a few species of kingfishers; and even more of insects, this latter group usually being

of benefit to humans. Scavengers include vultures and the large marabou stork.

Reptiles and amphibians. Reptiles, of which there are few endemic families, have mainly Old World affinities. Those most likely to be seen include lizards of the agamid family, skinks (a family of lizards characterized by smooth overlapping scales), crocodiles, and tortoises. Endemic reptiles include girdle-tailed and plated lizards. Within the African realm lizards of the iguana family and boa constrictors occur only in Madagascar. Large vipers are abundant and varied; certain species have extremely toxic venom, but they are seldom encountered. A wealth of both colubrine snakes (with fangs at the posterior end of the upper jaw) and elapine snakes (with fixed poison fangs at the front of the upper jaw) include such highly venomous elapine species as mambas.

Amphibians also belong mainly to Old World groups. Salamanders and hyliid tree frogs (having teeth in the upper jaw) are confined to the Palaearctic northwest. Abundant commoner frogs and toads include such oddities as the so-called hairy frog of Cameroon, whose hairs are auxiliary respiratory organs. The frog subfamily Phrynomerinae is exclusively African.

Arthropods. Africa possesses an abundant and varied population of arthropods (which include insects and other segmented invertebrates). Among them are found large butterflies of the *Charaxes* (brush-footed) and *Papilio* (swallow-tailed) genera, stick insects, and mantises, grasshoppers, driver, or safari, ants (tropical ants that travel in vast, serried ranks), termites, and dung beetles. Spiders abound throughout the continent, and scorpions and locusts can also be plentiful locally. Periodically huge swarms of locusts spread over wide areas, causing enormous destruction to vegetation. Other serious pests are mosquitoes, which act as vectors in the spread of such human diseases as malaria, and tsetse flies, which transmit the parasite that causes African trypanosomiasis (sleeping sickness) in humans and nagana in livestock.

Aquatic life. Freshwater fish include both remarkable archaic forms and examples of rapid recent evolution. Among the ancient forms are lungfish (*Protopterus*), bichirs, or lobefins (*Polypterus*), and reedfish (*Clamioichthys*), all of which can breathe air—a property also possessed by certain catfish (Clariidae), which are able to travel overland for some distance in wet weather. Characteristic of more recent evolutionary trends are the approximately 200 species of fish found in Lake Nyasa, four-fifths of which occur only there.

Archaic
fish species

The coelacanth, an archaic marine form believed extinct for more than 60 million years, was discovered to be alive off the east coast of South Africa in 1938, and since then many others have been found. A rich and varied invertebrate animal life on the east and west coasts includes marine organisms typical of the Indo-Pacific and Atlantic oceans. Coral reefs and associated organisms are mainly found in the warm waters of Africa's east coast, while the southwest and west coasts—washed, respectively, by the cold Benguela and Canary currents—abound in fish.

Origin and adaption of African fauna. At one time most African fauna was thought to derive from elsewhere. There is no doubt, however, that as little as 15,000 years ago an amelioration of the present Saharan climate enabled such typical Ethiopian forms as clariid catfish to reach the river systems of North Africa. Likewise, Palaearctic animal life and vegetation appear to have extended far south into the Sahara, and the white rhinoceros apparently lived beside elklike, typically Palaearctic deer.

Within the Ethiopian region, repeated climatically controlled expansion and contraction of vegetational zones resulted first in organisms establishing themselves in numerous specialized ecological communities (niches) of plants and animals and second in the proliferation of those species that successfully adapted themselves to the prevailing conditions. The spread of forests during the pluvials, separating northern and southern wooded grasslands, led to the evolution of such closely related northern and southern species of antelope as the kob and puku, the Nile and common lechwe, and the northern and southern forms of white rhinoceros.

Some subfamilies of Bovidae, like the spiral-horned antelope (Tragelaphinae), have adapted to almost every ecological environment—forest, woodland, grassland, Afro-Alpine zones, and even to sudd vegetation. Others, like the hartebeests (Alcelaphinae), which inhabit savannas and grasslands, are less adaptable.

Freshwater fishes demonstrate the existence of the relation to one another of former river systems and lakes. Large rivers containing Ethiopian fish evidently existed quite recently in the northern Sahara. The fish life of the now-isolated Lake Rudolf (Lake Turkana), in East Africa, demonstrates that the lake was once connected to the Nile, though Lake Victoria, the present source of the White Nile, was not. Lake Kivu, too, was formerly connected with the Nile, but as a result of volcanic activity it is now part of the Congo drainage system.

In earlier periods the animal life was even more remarkable than today. Fossil deposits have revealed sheep as big as present-day buffalo, huge hippopotamuses, giant baboons, and other types similar to existing species. These huge types probably lived in pluvial periods, dying out as aridity increased. Smaller types survived.

The effects of humans. Until they acquired firearms, humans made relatively little impact on animal numbers or—with some exceptions—their range. From the last half of the 19th century, however, and particularly since 1940, direct or indirect human wastage of Africa's animal life has been intense and has reduced stocks considerably. The antelope known as the Zambian black lechwe, for example, believed to have numbered 1,000,000 in 1900, had been reduced to less than 8,000 by the late 20th century, and the population of African elephants declined from 2,000,000 in the early 1970s to some 600,000 by 1990, largely because of poaching for the ivory trade. The African white rhinoceros reached the verge of extinction in 1980.

Though European hunters and colonists were rightly blamed for much of the decline at its onset, hunting and destruction and the disturbance of habitats by Africans have become more important. Rinderpest, an acute, and usually fatal, infectious disease of livestock, entered Africa with domestic stock in the 1890s and ravaged herds of indigenous ungulates. The accelerated spread of agriculture and stock raising involving the destruction of forests, as well as heavy grazing and burning of vegetation, eliminated large animals from wide tracts. In the southern Sudan, for example, political strife and warfare in the 1960s entirely eliminated wildlife from some areas. The demand for fancy leather and fur has also endangered the Nile crocodile and the leopard.

Humans, however, have been of benefit to many smaller species. Dams and irrigation schemes, for example, have provided habitats for waterfowl, frogs, and fish, and the spread of grain crops has encouraged certain pests. Even the patchy cultivation of forests has resulted in the development of a mosaic of habitats that can provide new, if small, niches for some species.

Ecology. There are still sufficiently large tracts of relatively unspoiled country in which animal life may be studied in its environment. The complementary roles of wild ungulates, for example, show that in any area inhabited by a wide variety of species, the grass is grazed in regular succession and at different stages of growth—for example, by zebra, gnu, hartebeest, and gazelle—while specific adaptations enable a still greater variety to survive. A much smaller variety of domestic stock cannot duplicate such effects. Overpopulation by domestic or wild species may upset the delicate natural balance, as may be seen by the example of elephant overpopulation in Murchison Falls (Kabalega) National Park, Uganda, and in Tsavo National Park, Kenya; whether the elephants survive or not, they have ineradicably altered the environment to the detriment of many other typical species.

Animal life of particular interest. Animal life of particular interest to humans includes four main groups that are not mutually exclusive. They are: (1) species potentially or actually useful to humans as food (large ungulates), (2) dangerous or pest species that may have to be controlled or eliminated (locusts, tsetse flies, *Quelea* finches or black-faced diochs—which do immense damage to grain crops—

and some ungulates or carnivores), (3) species that provide a spectacle and bring economic benefit (elephants, the larger plain ungulates, primates, or carnivores), and (4) endangered, rare, or unique species.

Much of the study of African wildlife has been addressed to the first two groups described above. For example, after it was learned that the feeding habits of domesticated livestock and wild ungulates are complementary, it became possible to incorporate the ungulates into pastoral and mixed-farming systems. This has happened on limited scales with the oryx (which was domesticated by the ancient Egyptians), the springbok (which has been run with cattle for decades in southern Africa), and the African buffalo and eland. Similarly, much attention has been given to controlling pests. In the 1950s and '60s considerable progress was made in the control of mosquitoes and locust swarms, although these achievements have been partially lost by governmental instability and mismanagement and by warfare between states. Infestation by the tsetse fly remains as one of tropical Africa's most critical problems, not only because the tsetse spreads disease but also because—by effectively restricting livestock farming—it denies relief of the chronic protein shortage of many African peoples. Control of the tsetse is possible, but it is complex and requires a coordinated effort within and between countries.

Much research has also been carried out on animals in the third and fourth groups. Studies of predators, such as the lion, for example, have shown that they do not generally control the numbers of ungulates to the same degree as do disease or starvation. It has also been established that the hyena is as much a potent predator as a scavenger. Intensive studies have been made of such primates as baboons, Ethiopian geladas (to which baboons are related), and especially chimpanzees and gorillas; of great interest has been learning what associations there are between human and other primate behaviour and psychology.

Conservation. Many countries have now set aside large tracts as national parks, game reserves, or forest reserves. Of these parks, only some are large enough to be self-contained ecosystems, and most have been set aside to accommodate large mammals. In East Africa there are also sanctuaries for birds and marine organisms. The conservation of vegetation is undertaken mainly in forest reserves but also in national parks. In addition, a number of countries are attempting to conserve wildlife by refusing export licenses for certain kinds of skins, especially those of the leopard, cheetah, and zebra.

The oldest and best-known national park is the Kruger National Park in South Africa, where representative populations of most savanna species are maintained. The Kalahari Gemsbok National Park, which South Africa shares with Botswana, conserves a tract of arid country with such associated types of antelope as springbok and gemsbok; smaller reserves and parks conserve particular species. Only one large mammal species, the blaubok (or blaauwbok), has become extinct, though several subspecies have nearly disappeared; one such subspecies—the quagga, a race of zebra—has vanished. East and central African countries have large national parks, which have been expanded in size or have increased in number as a result of the economic benefits of tourism. Kenya's parks include Tsavo, one of the largest, with an area of more than 8,000 square miles, Lake Nakuru National Park for flamingos, several montane parks, and a marine park. Uganda has three large national parks. Tanzania has the famous Serengeti National Park, with its unrivalled populations of plains ungulates, and the parks of Ngorongoro, Lake Manyara, Arusha, and others. Other countries with notable national parks and game reserves are Botswana, Malaŵi, Namibia, Zambia, and Zimbabwe. All parks in these countries preserve representative woodland, thornbush, grassland, and succulent-desert habitats and species.

Elsewhere the situation is less satisfactory. In Zaire, national parks were all seriously depleted after independence. Zaire now has seven major national parks, including the Virunga National Park (3,100 square miles). Though The Sudan is one of the countries with the largest numbers

Attempts to control pests

Depletion of wildlife

Parks of East and central Africa

of remaining ungulates, their status is little known, and the country is not served by an adequate park network. Ethiopia has nine parks developed largely during the 1970s, while Somalia has only a rudimentary system consisting mostly of game reserves and one area (Luc Badana) nominally a national park but failing to meet UN criteria for such parks. The "W" park is shared between Burkina Faso (formerly Upper Volta), Niger, and Benin, but most West African countries have only small national parks if any at all.

Animals not protected in parks are not necessarily threatened. Many large species are still plentiful in forest or game reserves or in controlled-hunting areas. Well-managed forest reserves in particular provide secure habitats for many smaller unprotected forms.

Animals affecting land usage. Historically, the abundance of elephants and other large ungulates may have stimulated some individuals—notably West African hunters in the forests and Europeans in southern Africa—to occupy certain areas. Trade routes were established and early hunter-explorers were influenced by the availability of elephants, whose ivory tusks slaves could carry.

Large or small animals now affect humans by competing with them or with their livestock. They may prey on people or on livestock or carry diseases affecting either. The bilharzia snail and the *Simulium* fly (host to an organism causing blindness), the tsetse fly, and the mosquito collectively affect human beings and their livestock far more than do such individually large or formidable species as lions or elephants.

The larger ungulates may compete with domestic livestock for forage, but they are more keenly resented and hunted by those agriculturists whose crops they eat. Pastoralists are much more concerned about lions that occasionally kill cattle than they are about locusts or rats, which, by depleting forage, indirectly cause the death of much livestock; such perceptions may hinder eradication or better control of these pests.

Danger to humans from large animals—carnivorous or otherwise—has been greatly exaggerated, but disease carried by living organisms has remained a serious problem. Diseases have reduced crop productivity, spoiled harvests, and acted as a curb on the better integration of land use and on the extension of pastoralism and mixed farming into underused areas. (D.N.McM.)

Diseases

The people

Africa is now widely recognized as the birthplace of Hominidae (the family to which modern humans belong). Archaeological evidence indicates that the continent has been inhabited by humans and their hominid forebears for some four million years or more. Anatomically modern African peoples are believed to have appeared about 100,000 years ago in sub-Saharan Africa and somewhat later in northern Africa. Exactly how and when the modern races emerged is not known, though the northern and southern groups are believed to have been distinct for some time; nonetheless, Africa is now overwhelmingly populated by the European geographic race in the north and the African geographic race in the south, the great majority being sub-Saharan peoples. Some rough generalizations about these geographic races can be made based on physical appearances (e.g., people in northern Africa tend to have less skin pigmentation than those in sub-Saharan Africa), but the real distinctions between them are largely biochemical (e.g., differences in blood types).

In all African countries the majority of the population is indigenous. In South Africa there are large numbers of Europeans (about 20 percent of the population). Other countries with significant European populations are Zimbabwe, Zambia, Namibia, Mozambique, Kenya, and Senegal. Other substantial minority groups are Asian peoples (chiefly in southern and East Africa), Arabs (in West and East Africa), and people of mixed origin.

CULTURAL AREAS

The basic units of African society have been—and in much of sub-Saharan Africa still are—the ethnic groups,

tribes, or peoples. They number almost 3,000. Most are not politically or economically independent social units but rather groups that have a common sense of culture and identity, especially in terms of a distinct language and religion. Boundaries between them are usually not clearly defined, and frequently it is difficult to know whether a collection of very similar communities should be regarded as one tribal group or as many tribal groups. It is convenient to classify these peoples by languages and by the main outlines of their cultures.

There have been many attempts at cultural classifications of African peoples based on the concept of a culture area consisting of a number of societies with certain common features. Although to some extent useful, the generally accepted culture areas for Africa are too large to be very meaningful because each includes widely differing forms of social and political organization. The best-known of many older classifications is that by the American anthropologist Melville J. Herskovits (1924), which is still referred to despite its inadequacies. A later classification (1959), by another American, G.P. Murdock, takes as units relatively small clusters of peoples, who are grouped largely on linguistic and ethnohistorical grounds. Murdock divided the continent into 55 clusters of tribes, forming 11 main groupings, some of which are defined by livelihood (such as hunting or pastoralism) rather than by ethnic or linguistic affiliation. If one chooses to ignore these rather numerous divisions, then the principal cultural regions are northern, western, west-central, eastern, and central and southern Africa; Madagascar should also be included on this list.

Northern Africa. Africa north of the Sahara is inhabited primarily by peoples who speak languages that belong to the Hamito-Semitic, or Afro-Asian, group. These peoples include, for example, the Berbers of Morocco, Algeria, and Tunisia. The Berbers are most numerous in Morocco and least in Tunisia, where, as a result of culture contact and intermarriage, they have become largely assimilated into the Semitic-speaking Arabs who migrated into North Africa from Arabia in a number of waves; the first of these waves occurred in the 7th century AD. The distinctive nature of Maghrebian, or western Arab, culture resulted from this admixture. In the Sahara, such Arab peoples as the Shuwa live side by side with such Berber peoples as the Tuareg.

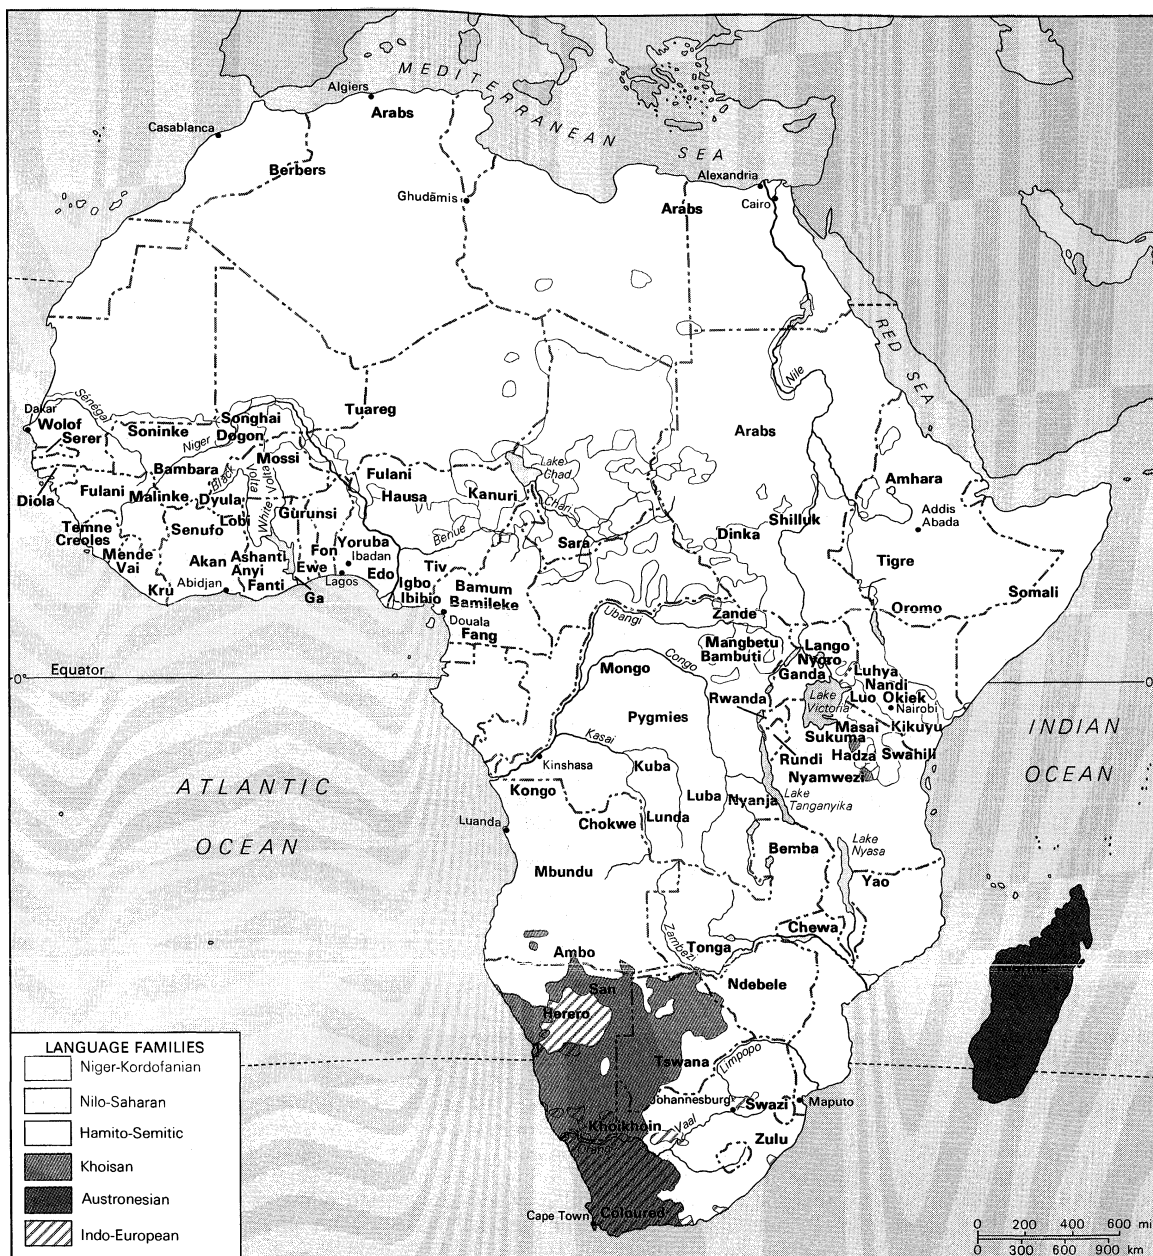

Western Africa. Western Africa contains a remarkable diversity of ethnic and cultural groups in the two east-west-trending zones of the savanna along the southern Saharan borderland and the rain forest along the Atlantic coastline. Most of the larger and more powerful of the traditional societies are kingdoms, each surrounded by lesser and politically weaker communities.

Among the more important of the savanna peoples are the three main clusters known as Mande (in Senegal and Mali and including the Bambara, Malinke, and Soninke); the Voltaic group in the savanna zone to the east (including the Senufo, Lobi, Gurunsi, Dogon, and Mossi); and in northern Nigeria, Niger, and Cameroon the many small, mainly non-Muslim tribes of the plateau and highland areas. Throughout this region live the many groups of the Fulani (known also as Fulbe and Peul), a cattle-keeping Muslim people who have either conquered indigenous peoples (such as the numerous Hausa) or live in a symbiotic relationship with agricultural peoples. In the Sahara fringe are the many Berber-speaking groups collectively known as the Tuareg, the Kanuri of Lake Chad, and the many Semitic-speaking Bedouin Arab peoples. Many of the kingdoms are successor states to those of the Middle Ages.

The larger societies in the coastal zone are also mostly kingdoms. In Nigeria are the Igbo (Ibo) and Ibibio, organized into many autonomous polities; the Tiv; the Edo; and the several powerful kingdoms of the Yoruba. Westward are the Fon of Benin; the various peoples of the Akan confederacy, mostly in Ghana, the largest group being the Ashanti (Asante); the Ewe, Ga, Fanti (Fante), and Anyi (Agni) of the coast; the Mende and Temne of Sierra Leone; the Kru of Liberia; the Wolof, Serer, Dyula, and others of Senegal; and the Creoles of Sierra Leone and

Classifications of culture areas

Societies of western Africa

Major language families and peoples of Africa.

Liberia, descendants of freed slaves from the New World or of those who were on their way there.

West-central Africa. Geographically, west-central Africa may be considered as an eastern extension of western Africa: in the north are the savannas of Chad, the Central African Republic, and The Sudan, stretching to the Nile River, and in the south is the largely forested area of the Congo basin. It is ethnically very mixed, with Arabs in the north, Pygmies in the Congo and Gabon, and Sudanic- and Bantu-speaking peoples in the more southern areas. Agriculture is the basic economy of virtually the entire region. The savanna includes many peoples of the Cameroon area, divided into many small kingdoms, of which the Bamileke tribes are the most numerous. Between Cameroon and the Nile are many large Sudanic-speaking peoples, such as the Sara, Mangbetu, and Azande. Southward are Bantu peoples, of which the more important include the Fang of Gabon and the Kongo, Mongo, Kuba, Luba, Lunda, and Chokwe of Zaire and Angola.

Eastern Africa. Eastern Africa contains several ecological and cultural areas. In the north and east are the arid Sudan and Somalia separated by the Ethiopian Plateau; in the centre are the fertile areas of the East African lakes—Victoria, Albert (Mobutu Sese Seko), Tanganyika, Nyasa

(Malaŵi)—and the highlands around Mounts Kenya and Kilimanjaro. The remainder consists of savanna, with the depression of the East African Rift Valley running from north to south. The areas of densest population are the more fertile highlands.

This ethnically complex region includes the Eastern Sudanic-speaking pastoralists of the Nile valley (Shilluk, Dinka, Luo, Lango, and others, formerly called Nilotes), those of the central plains (Masai, Nandi, and others, formerly known as Nilo-Hamites), and the Cushitic-speaking Somali and Oromo (Galla) of the Horn of Africa. In Ethiopia also are the Semitic-speaking Amhara, Tigre, and others. Most of the remaining peoples of the region are Bantu speakers who, although they vary widely in other ways, are all peasant farmers. Near the East African lakes are several formerly powerful Bantu kingdoms (Ganda, Nyoro, Rwanda, Rundi, and others). In the Kenya highlands are the Kikuyu, Luhya, and others. On the coast are the various Swahili-speaking tribes, while in Tanzania are the Bantu-speaking Chaga (Chagga), Nyamwezi, Sukuma, and many more. There are also remnants of other groups: the hunting Okiek (Dorobo), Hadza, and some Pygmies. And on the coast are the remnants of the once politically powerful Arabs, formerly based on Zanzibar.

Ethnic complexity of East Africa

Central and southern Africa. Central and southern Africa may be considered as forming a single large culture area. Most of it consists of open and dry savanna grasslands: to the northwest are the edges of the Congo forests; the southwest is very arid; and the coastline of South Africa and Mozambique is more fertile, most of it with subtropical or Mediterranean climate.

The region was once populated by San (Bushmen) and Khoikhoi (Hottentots), both Khoisan-speaking peoples, the former being hunters and the latter pastoralists. The San are today restricted to the arid areas of southwestern Africa and Botswana, and most of the Khoikhoi are merged into the racially mixed Coloured people of the Cape Province of the Republic of South Africa, with European and Asian admixtures. The other indigenous groups are all Bantu-speaking peoples, originally from the area of Cameroon, who dispersed across this region some 2,000 years ago. The vanguard, known linguistically as the Southern Bantu, drove the Khoisan before them and adopted some of their click gutturals into their own languages. After contact with Europeans in the 18th and 19th centuries, the Bantu speakers turned upon one another, establishing the conquest states of the Zulu, Swazi, Tswana, Ndebele (Matabele), Sotho, and others. To the north are the Central Bantu speakers of Zaire, Zimbabwe, Malawi, and Tanzania, as well as farmers with many kinds of political systems but who differ markedly from the Southern Bantu speakers in their kinship systems; they include the Bemba, Tonga, Chewa (Cewa), Nyanja, and Yao. In southwestern Africa are the Southwestern Bantu, including the Ovambo and Herero.

Madagascar. Finally, the island of Madagascar forms a distinct culture area. The various Malagasy ethnic groups, of which the politically most important is the Merina, are mainly of Indonesian origin, following migrations across the Indian Ocean probably during the 5th and 6th centuries AD.

(R.K.A.G./J.F.M./J.I.C.)

CULTURAL PATTERNS

Languages. Many attempts to classify the languages of Africa have been inadequate because of the great complexity of the languages and because of a confusion between language, race, and economy; for example, there was once a spurious view of pastoralism as related to cultures whose members spoke Hamitic languages and were descendants of ancient Egyptians. The knowledge of most of the individual languages of the continent is still very inadequate, but there are known to be at least 1,000 distinct languages.

One of the most recent and accurate attempts to classify African languages, prepared by the American linguist Joseph Greenberg, is based on the principles of linguistic analysis used for Indo-European languages rather than on geographic, racial, or other nonlinguistic criteria. The four main language families, or phyla, of the continent according to this classification (not totally accepted by all specialists) are the following: Niger-Kordofanian, Nilo-Saharan, Hamito-Semitic (Afro-Asiatic), and Khoisan.

The Niger-Kordofanian is the most widespread family and consists of two subfamilies, Niger-Congo and Kordofanian. These languages are found from Senegal to the Cape of Good Hope, with a geographically widespread extension due to relatively recent migrations over eastern and southern Africa. Niger-Congo covers most of central and southern Africa and includes the West Atlantic, Mande, Voltaic, Kwa, Benue-Congo, and Adamawa-Eastern subgroups; Kordofanian includes subgroups all spoken within a very small area of western Sudan. The most original point in this classification is the group called Benue-Congo, which linguistically subsumes all the Bantu languages found dispersed over most of eastern, central, and southern Africa. This dispersal is attributable to the rapid expansion of people from the area of the Bight of Benin from the beginning of the second millennium AD onward: the vanguard, the Southern Bantu speakers, had not reached the Cape of Good Hope when the Dutch arrived there in the 17th century. The close linguistic similarity among the Bantu languages points to the speed of this vast migration. Swahili, grammatically Bantu but with much Arabic in its vocabulary, is widely used as a lingua

franca in eastern Africa; as the language of the people of Zanzibar and the east coast, it was spread by 19th-century Arab slavers in the hinterland as far as the Congo.

The Nilo-Saharan family classification is perhaps the most controversial—because of inadequate research—and the family is the most scattered. It comprises languages spoken along the savanna zone south of the Sahara from the middle Niger to the Nile, with outlying groups among the Para-Nilotic pastoralists of eastern Africa. Its subgroups are Songhai, Saharan, Maban, Fur, Chari-Nile (including the large clusters of Eastern and Central Sudanic), and Koman.

The Hamito-Semitic family includes languages both from Africa and the Middle East: Semitic (including Arabic, Amharic, and Tigrinya), Ancient Egyptian (extinct), Berber, Cushitic, and Chadic (*e.g.*, Hausa). It is found over much of northern Africa and eastward to the Horn of Africa. Arabic is both the official and unofficial language in states north of the Sahara, as well as in The Sudan. In many other countries it is the language of Islam. Amharic is the official language of Ethiopia. Hausa and Fulani are also widely spoken as lingua francas along the northern fringe of sub-Saharan West Africa, a wide area that encompasses many ethnic and political boundaries.

The Khoisan, or Click, family comprises the languages of the San and Khoikhoi, who are now limited to the arid parts of southwestern Africa, and perhaps of the outlying Hadza and Sandawe peoples of northern Tanzania.

The Austronesian (Malayo-Polynesian) family is represented by the various dialects of Malagasy in Madagascar.

There are also many widespread trade languages and lingua francas in addition to those mentioned above. Some were imported and used by administrators, missionaries, and traders during the colonial period. They include English, French, and other languages of the former colonial powers; some of them are today the national languages of independent nation-states, and, with the spread of formal education, they are gaining greater acceptance. Between the Sahara and the Zambezi River, either English or French is widely understood. French is the official language in the states that formerly made up French West Africa and French Equatorial Africa, as well as in Madagascar (Malagasy is also an official language) and Zaire. Similarly, English is the official language, or is widely spoken, in the states of West, central, and East Africa formerly under British administration and is also the official language in Liberia. Portuguese is the language, officially and otherwise, in the countries formerly under Portugal. In South Africa, Afrikaans (which developed out of a colloquial version of 17th-century Dutch) and English are both official. Hindi, Gujarati, Urdu, and other languages of the Indian subcontinent are spoken among the Asian communities. In West Africa forms of Creole (Krio) and Pidgin are widespread in the coast towns of very heterogeneous ethnic composition. In southern Africa, Fanagalo, a mixture of English and local Bantu tongues, is spoken in mining areas.

The great majority of African languages have no indigenous forms of writing, although today governments and missions have been reducing them to writing. Many African languages (such as Swahili) have for centuries been written in Arabic script. There are exceptions, however. The best known are those of the Vai of Sierra Leone, the Mum of Cameroon, and the Tuareg and other Berber groups of the southern Sahara, all of whom invented their own scripts.

Religions. In general, northern Africa is predominantly Islāmic and southern Africa largely Christian, although their distributions are not discrete. For example, the Coptic church is found in Egypt and Ethiopia, and Islām is common along the coast of eastern Africa and is expanding southward in western Africa. Many of the Sudanic peoples—such as the Malinke, Hausa, Songhai, and Bornu—are Islāmized, and the religion has also achieved substantial gains among such Guinea Coast people as the Yoruba of Nigeria and the Temne of Sierra Leone. Much conversion to Christianity also has occurred, most notably to Roman Catholicism and in the coastal regions of sub-Saharan Africa.

Traditional
religions

In most of the rest of sub-Saharan Africa the people practice a variety of traditional religions, which have certain common features. All of those known include the notion of a high or creator God, remote from humans and beyond their comprehension or control. This God is typically not attributed a sex but in some cases is male or female; often God is given an immanent and visible aspect as well. The most important "spiritual" powers are usually associated with things or beings with which people have day-to-day contact or that they know from the past. Thus, there may be many kinds and levels of spirits of the air, of the earth, of rivers, and so on. There may be ancestors and ghosts of the dead who have achieved a partial divinity. There may be mythical heroes who led the people to their present land and founded their society as it is known today.

The ritual functionaries found in most African societies include priests, lineage and clan elders, rainmakers, diviners, prophets, and others. Very few of these are specialists; typically they hold ritual authority by virtue of age, genealogy, or political office and are primarily responsible for the ritual well-being only of the members of the social groupings that they head; their congregations consist of their joint families, lineages, clans, local village communities, chieftaincies, or the like. Their ritual authority is thus a sanction for their secular and domestic authority.

A central element of every indigenous African religion is its cosmology—which tells of tribal origins and early migrations and explains the basic ideological problems of any culture, such as the origin of death, the nature of society, the relationship of men and women and of living and dead, and so on. Social values are typically expressed in myths, legends, folktales, and riddles; the overt meanings of these various oral statements frequently conceal sociological and historical meanings not easily apparent to outsiders.

In the past, witchcraft and sorcery were given widespread credence and served to explain or control the misfortunes of people who were aware of their lack of mastery and understanding of nature and society. Travelers' tales of African people living in fear of witchcraft, however, were of course grossly exaggerated; the colonial powers usually assumed (incorrectly) that witch doctors were socially harmful and prohibited them. Although belief in witchcraft is receding, it is still important in both rural and urban areas, often serving as a means of explaining the misfortunes that beset urban dwellers and labour migrants who find themselves in new and confusing social milieus. There have been many cases in modern times of "epidemics" of beliefs in witches, and there have arisen a number of evanescent cults led by various kinds of prophets and evangelists. Such manias arise in periods of radical change and its resultant uncertainty and stress.

Social and religious changes in Africa have often been accompanied by the appearance of prophets who advocate the expulsion of the Europeans or the eradication of epidemic diseases threatening the traditional ways of life. More recently, also, the spread of Christianity and, to a lesser extent, Islām has given rise to Christian prophets and to leaders of separatist movements repudiating European-controlled mission churches for nationalistic, tribalistic, or racial reasons. Such prophets lead their own cults and establish their own churches, typically gaining new political power sanctioned by their presumed direct links with God. These new churches have been reported in almost all parts of the continent.

Domestic groupings. The forms of the family found in Africa are consistent with the forms of economic production. Throughout most of the rural areas the typical domestic group is the joint or extended family consisting of several generations of kin and their spouses, the whole being under the authority of the senior male. The size of the group varies, but it typically consists of three to five generations of kin. It provides a stable and long-lasting domestic unit able to work as a single cooperative group, to defend itself against others, and to care for all of its members throughout their lifetimes. Polygyny is traditionally widespread as an ideal, its extent depending on the status and wealth of the husband: chiefs and rulers need

many wives to give them a mark of high position and to enable them to offer hospitality to their subjects.

In most of Africa these residential groups are based upon descent groups known as clans and lineages, the latter being segments of the former. The significance given to descent groups varies, but they are important in providing for heirs, successors, and marital partners.

In the second half of the 20th century this pattern has been changing, rapidly in the urban and poverty-stricken areas, more slowly in those areas less affected by economic and political development. In cities and in major labour-supplying areas, such as most of southern Africa, the joint or extended family is giving way to the independent nuclear family of husband, wife, and children. There is also a tendency toward the breakdown of family structure because of labour migration—the younger men moving to the cities, leaving women, older men, and children in the impoverished homelands. (J.F.M./J.I.C.)

DEMOGRAPHIC PATTERNS

Africa has the most rapidly expanding population of any region in the world, even though the continent's birth and death rates are also the world's highest. There has been some decline in overall death rates in the latter half of the 20th century; but infant and child mortality rates have remained high, and gains in life expectancy have been smaller than in other developing regions of the world. On average, Africa's population is increasing at about 3 percent per annum, and this growth rate is associated with an increasingly youthful population: in nearly every African country more than 40 percent of the population is less than 15 years of age.

The great majority of the working population is still engaged in subsistence agriculture and in the production of cash crops. In most countries the proportion of the total population dependent on agriculture is at least 60 percent.

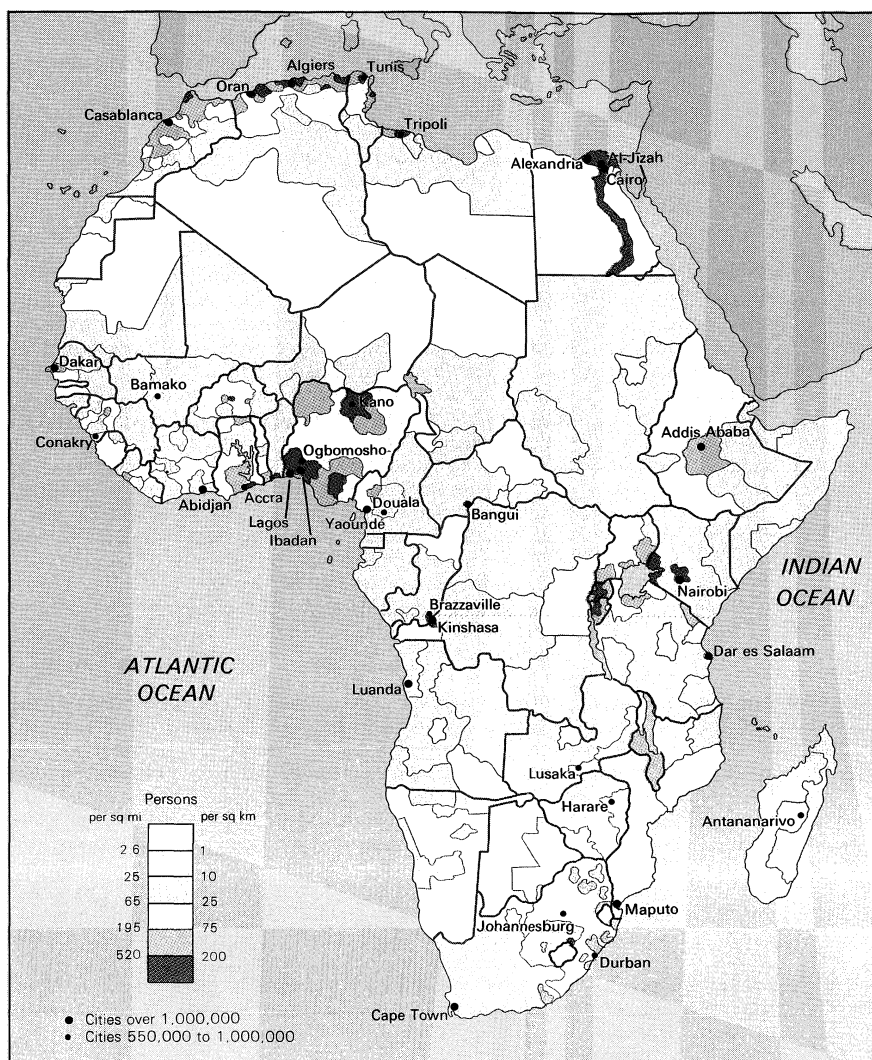

The remainder of the working population is divided mainly between a rapidly growing service sector (including civil servants, members of the armed forces, police, teachers, health workers, and those engaged in commerce and communications) and an increasing number of mining and industrial projects; in only a few countries, however, do these latter activities employ more than 10 percent of the work force. Underemployment, particularly in the agricultural sector, is widespread, and unemployment has risen, especially in urban areas. Participation in labour by women varies considerably from country to country. Women in paid employment are generally fewer than men, though a large proportion of women in sub-Saharan countries are engaged in subsistence agriculture—if only part of the time. Women are also employed in the civil service, in trading (especially in western Africa), in domestic service, and to an increasing extent in light industry.

Population distribution. Africa has more than 10 percent of the total population of the world, distributed over a land area representing slightly more than one-fifth of the total land surface. Such desert areas as the Sahara, Kalahari, and Namib, however, reduce the amount of habitable land, and such factors as climate, vegetation, and disease have tended to limit the evolution of densely populated areas where agriculture is practiced. With the advent of the colonial era the African continent was divided into small geographically and politically based units that took little or no account of ethnic distribution. These political boundaries persisted, and the continent continued to be characterized by a large number of countries with predominantly small populations.

Wide variations in density occur from country to country in Africa and within countries. In general, the most densely populated areas are found bordering the lakes, in the river basins (especially those of the Nile and Niger), along the coastal belts of North and West Africa, and in certain highland areas, while settlement is the most sparse in the desert and savanna areas. Thus, Rwanda and Burundi, situated in the East African highlands, are the most densely populated countries in Africa, while Western Sahara, Mauritania, and Libya in the Sahara and Botswana and Namibia in the Kalahari and Namib are the least densely populated.

Settlement patterns. Traditional African patterns of settlement vary with differences in landscape and ecology, communications, and warfare. The most widespread pattern has been that of scattered villages and hamlets—the homesteads of joint and extended families—large enough for defense and domestic cooperation but rarely permanent because of the requirements of shifting cultivation and the use of short-lived building materials. In much of the western African savanna, large mud-adobe villages are traditional, but over most of Africa housing consists of mud and wattle with roofs of thatch or palm leaves.

Large towns, however, were not widespread in the continent until the 20th century. Towns dating from precolonial times are found mainly along the Nile valley and the Mediterranean fringe of North Africa—where many date from classical times (*e.g.*, Alexandria, Egypt) and the Middle Ages (*e.g.*, Fès, Mor.)—and also in western Africa, in both forest and savanna zones, where they were the seats of governments of kingdoms. Timbuktu, Djenné, Kano, and others date from the Middle Ages; some, such as Benin and the Yoruba cities of Ibadan and Oyo, are more recent but certainly many centuries old. In eastern Africa there are such medieval Arab coastal towns as Mombasa.

The more traditional towns differ in form, function, and even population characteristics from the many towns and cities established under colonial rule as administrative, trading, or industrial centres and ports. These latter cities are found throughout Africa and include Johannesburg, Lusaka, Harare (formerly Salisbury), Kinshasa, Lubumbashi, Nairobi, Dakar, Freetown, Abidjan, and many others; often, as in the case of Lagos or Accra, they are built onto traditional towns. Typically the focus of in-migration

from an impoverished hinterland, they are ethnically heterogeneous. Many have grown to become the largest cities in their respective countries, dominating their national urban hierarchies in size as well as in function.

Mostly rural for centuries, Africa has rapidly become more urbanized. Although it is still the least urbanized of the continents, Africa has the fastest rate of urbanization: about 5 percent annually. Thus, the total population living in towns—which was only about 15 percent in 1950—grew to nearly 35 percent by 1990 and may exceed 40 percent by the year 2000. Generally, the level of urbanization is highest in the north and south, and it is higher in the west than in the east and nearer the coasts than in the interior.

The largest cities include Cairo, Alexandria, and Al-Jizah, Egypt; Kinshasa, Zaire; Lagos, Nigeria; Casablanca, Mor.; Johannesburg, S.Af.; Addis Ababa, Eth.; and Algiers. Many other large cities are seaports along the coasts or central marketing towns, linked by rail or river with a coast. Examples of seaports are Accra, Ghana; Lagos; and Cape Town. Ibadan and Ogbomosho, Nigeria; Nairobi, Kenya; and Addis Ababa are examples of large inland cities.

Migrations. There have been many movements of population within the African continent, from outside into the continent, and from the continent outward. The major movement within the continent in historic times has been that of the Bantu-speaking peoples, who, as a result of a population explosion that is not fully understood, spread over most of the continent south of the equator.

The major movements into the continent in the past few centuries have been of European settlers into northern Africa and of European and Asian settlers in southern

Characteristics of old and new towns

European settlement

Africa. The Dutch migrations into southern Africa began in the mid-17th century. Originally settling on the coast, the Dutch—or Boers—later moved inland to the Highveld region, where a series of military conflicts occurred between them and the Bantu speakers in the 19th century. Other European settlement took place mainly in the 19th century: the British particularly in Natal, but also inland in what are now Zambia and Zimbabwe and in the East African highlands; the Portuguese in Angola and Mozambique; and the Germans in what is now Namibia.

The presence of large settler populations delayed the achievement of self-government by the African peoples of South Africa, Namibia, Zimbabwe, Angola, and Mozambique and has resulted in much bitterness between the races. In North Africa, by contrast, where the extensive settlement of Europeans from France, Italy, and Spain occurred, the growth of Arab nationalism and the emergence of independent states such as Morocco, Algeria, and Tunisia led to the return of between one and two million colonists to their homelands in the late 1950s and early '60s and to the political dominance of the indigenous peoples.

The greatest outward movement of people was that of Africans—particularly from West Africa and, to a lesser extent, Angola—to the Americas and the Caribbean during the period of the slave trade from the 16th to the 19th century. Earlier estimates that between 15 and 20 million Africans were transported across the Atlantic have been revised to a figure of 10 million, which appears more realistic. While their contribution to the development of the New World was of crucial importance, the effect of the loss of manpower to the African continent was considerable and has yet to be satisfactorily analyzed. The slave trade was also active on the east coast of Africa, where it was centred on the island of Zanzibar.

Few permanent movements of population have occurred within Africa in the 20th century, although an extensive settlement of Hausa from northern Nigeria took place in what is now The Sudan. Some significant displacements of population also have resulted from situations of conflict, usually involving minority groups different in religion, ethnicity, or culture from the dominant majority. In 1966 the Igbo people of northern Nigeria, for example, returned en masse to their homeland in eastern Nigeria, the number of refugees being estimated at more than 500,000. The conflicts in the Horn of Africa since the 1960s have caused similar displacements. Indeed, Africa has millions of refugees, especially in Somalia, The Sudan, Zaire, Burundi, and Tanzania. These refugees are among the poorest and most vulnerable people in the world, and their numbers are substantially augmented by those fleeing drought and famine. The countries to which these people flee often find it extremely difficult to cope with them.

Most movement occurs across uncontrolled borders and between people of the same tribal groups. Much is seasonal, in any case, and is restricted to migrant labourers and nomadic herdsmen. Controlled immigration and emigration are generally negligible; contemporary examples, however, include the employment of mine workers in South Africa, the forced emigration of Asians from East Africa, and the expulsion of people from neighbouring West African states caused by such actions as the enforcement of the Alien Compliance Order of 1969 in Ghana.

(R.K.A.G./D.S.H.W.N./J.F.M./J.I.C.)

The economy

With the exception of South Africa and the countries of North Africa, all of which have diversified production systems, the economy of most of Africa can be characterized as underdeveloped. Africa as a whole has abundant natural resources, but much of its economy has remained predominantly agricultural, and subsistence farming still engages more than 60 percent of the population.

Until the beginning of the 20th century this system of farming relied on simple tools and techniques, as well as on traditional organization of the family or community for its labour. Because of poor transport and communications, production was largely for domestic use. There was

little long-distance trade, and wage labour was virtually unknown. The small size and vast heterogeneity of polities at that time also made exchanges very limited. There were, however, notable exceptions, especially in West Africa, where for many centuries societies had engaged in long-distance trade and had elaborate exchange and craft facilities, communications, and a political infrastructure to maintain their trade routes.

Africa has experienced considerable economic development during the 20th century; and, while this has provided many benefits, it also has given rise to a number of serious problems. The first significant changes occurred under colonial rule in the first half of the century: wage labour was introduced, transportation and communications were improved, and resources were widely developed in the colonial territories. The legacy of this, however, has been that the export of two or three major agricultural products or minerals—such as peanuts, petroleum, or copper—has come to provide most of the foreign-exchange earnings for nearly all African nations. Fluctuations in the prices of these commodities have made the economies of these countries vulnerable and fragile. The situation has been exacerbated in countries in the marginal dryland zones, where the increasing frequency of drought conditions have undermined agricultural productivity.

The second major change was the vigorous promotion of industrial development, often with foreign assistance, that took place in the two decades (1960–80) following the political independence of most African countries. The political fragmentation of the continent, however, also became a major constraint to industrial growth, because it created numerous small markets. Consequently, most African countries have become saddled with excess industrial capacity, coupled with enormous foreign debts that were incurred in large part to build this capacity.

In nearly all African countries a poor economic situation has been aggravated by rapid population growth, which has kept per capita gross domestic product low or in some cases has caused it to decline. Thus, any hope for improving economic conditions in most of Africa rests on two factors: population control within individual countries to give their economies the chance to grow; and the organization of groups of states into regional economic blocs in order to create internal markets large enough to sustain growth.

RESOURCES

Mineral resources. Africa's known mineral wealth places it among the world's richest continents. Its very large share of the world's mineral resources includes coal, petroleum, natural gas, uranium, radium, low-cost thorium, iron ores, chromium, cobalt, copper, lead, zinc, tin, bauxite, titanium, antimony, gold, platinum, tantalum, germanium, lithium, phosphates, and diamonds.

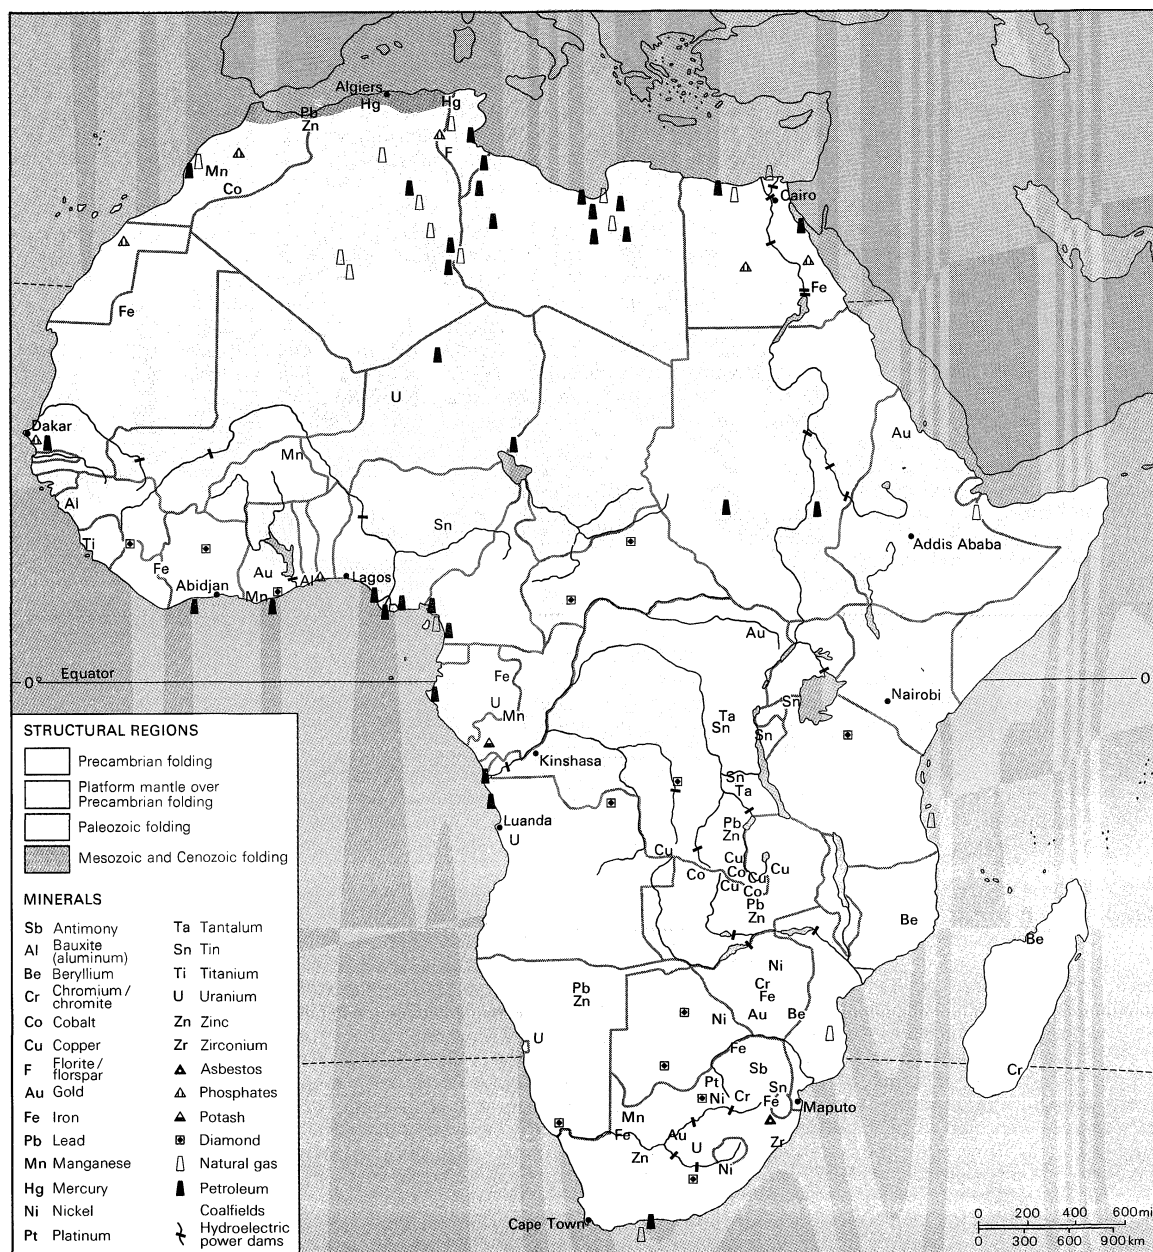

Major deposits of coal are confined to four groups of coal basins—in southern Africa, North Africa, Zaire, and Nigeria. Proved petroleum reserves in North Africa occur in Libya, Algeria, Egypt, and Tunisia. Exploration has been concentrated north of the Aïr–Ahaggar massifs; there may also be major Saharan reserves to the south. The other major oil reserves are in the West African coastal basin—principally in Nigeria and also in Cameroon, Gabon, and the Congo—and in Angola. Africa's natural gas reserves are concentrated in basins of North and coastal central Africa.

Southern Africa is said to be one of the world's seven major uranium provinces. In South Africa the unusual degree of knowledge of reserves derives from the joint occurrence of uranium with gold, a condition that also decreases the cost of production. Other countries with significant uranium deposits are Niger, Gabon, Zaire, and Namibia.

Metallic deposits. In North Africa reserves of iron ore are concentrated in the Atlas Mountains and in western Sahara. Egypt, however, has medium-grade reserves, of which the most important are at the Al-Wāhāt al-Bahriyah Oasis. The ore deposits in Morocco and Tunisia, which were once of considerable importance, have been severely depleted. Africa's most significant iron reserves are to be found in western and southern Africa. It is the sedimen-

Develop-
ment in
the 20th
century

Population
displace-
ments

Basic structural regions and principal mineral and hydroelectric sites of Africa.

tary Precambrian rocks, particularly in western Africa, that have proved the basis of Africa's role as a major world producer of iron ore. The most significant deposits are in Liberia in the Bomi Hills, Bong and Nimba ranges, and the Mano valley; in the extension into Guinea of the Nimba-Simandou ranges, where hematites have been located; in Nigeria and Mauritania, which have large deposits of low-grade ore; and in Gabon, where extensive reserves are present in the northeast. In southern Africa most iron ore reserves lie in South Africa itself. The chief deposits are at Postmasburg, in the Bushveld Complex, at Thabazimbi, and in the vast, low-grade deposits of Pretoria. There are also substantial reserves in Zimbabwe.

Africa's reserves of minerals used as ferroalloys in the steel industry are even more striking than its enormous share of world iron ore reserves. This is particularly true of chromium. Almost the entire world reserve of chromium is found in southern and, to a much lesser extent, in western and northeastern Africa. The highest concentrations are found in Zimbabwe, at Great Dyke. South Africa contains the largest deposits of chromite. As compared with these two sources, reserves elsewhere in Africa are relatively small.

Manganese reserves are also considerable. In South Africa

reserves of contained manganese are found in the Kalahari Manganese Field and elsewhere. The Mouanda deposit in southeastern Gabon is thought to be among the largest in the world. Ghana is another important source of manganese, having both low-grade and high-grade reserves. Elsewhere in West Africa, manganese deposits are situated in Burkina Faso and Côte d'Ivoire, as well as in Zaire and Cameroon. In North Africa manganese is found in Morocco and Algeria.

Africa's contribution to world resources of other ferroalloys is, by comparison, insignificant. Nickel is of some importance, occurring in other metalliferous ores in southern Africa.

Most of Africa's copper is contained in the Central African Copperbelt, stretching across Zambia and into the Shaba area of Zaire. Accompanying minerals vary with the geologic layer, but cobalt dominates. Outside the Copperbelt a number of countries have lesser but still significant reserves of copper.

Only Nigeria, Zaire, and South Africa contain tin reserves of any significance. Although it is difficult to consider Africa's reserves of lead and zinc separately, of the two, lead ores are considerably more widespread. North Africa is the largest traditional producing region. African reserves

of zinc metal are located along the Moroccan-Algerian frontier, in the Copperbelt in Zaire, in Nigeria, in Zambia, and in Namibia.

Africa has about one-fourth of the world's reserves of bauxite, the chief aluminum ore. Virtually all of this occurs in a major belt of tropical laterite stretching some 1,200 miles from Guinea to Togo. The largest reserves are in Guinea.

Half of the world reserves of cobalt can be found in Zaire. A continuation of the geologic formation into Zambia gives the country sizable reserves of cobalt content. The only other deposit of any importance is found in Morocco.

The titanium ores, ilmenite and rutile, are widely distributed in Africa but are rarely considered as minable reserves. A major source is the Sherbro deposit in Sierra Leone. Almost all of Africa's antimony resources lie in the Murchison Range of South Africa. The major concentrations of beryllium are in Madagascar, Mozambique, Zaire, Zimbabwe, Rwanda, Uganda, and South Africa. The principal sources of cadmium are in Namibia and Zaire. Deposits of mercury are restricted to North Africa, notably to Tunisia and, more particularly, Algeria.

Precious
metals

Gold and allied metals are widely disseminated, reaching their greatest concentrations in South Africa, where reserves of gold probably constitute about half of the world total. Gold is also found in Zimbabwe, in the Zaire belt, and in Ghana. There are numerous alluvial sources of gold in Burundi, Côte d'Ivoire, and Gabon. South Africa has the most important deposit of platinum of the world's market economies. Silver reserves of the continent are not important.

Africa contains a major share of world reserves of tantalum, with Zaire having most of these reserves. African reserves of columbium, or niobium (a steel-gray metallic element resembling tantalum in its chemical properties that is used in alloys), are relatively small. Nigeria, however, is an important world producer.

One of Africa's many sources of zirconium (a metallic element resembling titanium chemically) is the Jos Plateau in Nigeria. Greater reserves, however, are contained in deposits on the Senegal coast; on the east coast of South Africa; in Madagascar; at Sherbro, Sierra Leone; and in the Nile delta.

Another rare metal of which Africa contains a majority of world reserves is germanium, concentrated in Zaire and Namibia. Africa also has large deposits of lithium, the largest of which are found in Zaire.

Nonmetallic deposits. Clays are widespread and are found in North Africa, where brick and pottery clays occur in Algeria and in Morocco; in West and central Africa, where clays are located in Togo (ceramic), the Central African Republic, and Côte d'Ivoire (ceramic); and in East and southern Africa.

Kaolin (china clay) occurs in Algeria. Outside North Africa it is widespread. In West Africa it occurs most notably in Nigeria's Jos Plateau, as well as in Mali, in Ghana, and in Guinea. Similar deposits occur in central and East Africa, as well as in southern Africa.

Bentonite (a clay formed from decomposed volcanic ash, which is able to absorb large quantities of water and to expand to several times its usual size) is found in the Moroccan Atlas Mountains and in Tanzania, Kenya, and South Africa. The continent's principal reserve of fuller's earth (an absorbent clay) is in Morocco.

Economically important mica deposits occur primarily in southern Africa (South Africa, Zimbabwe, and Tanzania) and in Madagascar.

Sulfur and
salt

Africa has none of the world's major reserves of sulfur. It reaches economic concentrations only in South Africa's Witwatersrand, in Zambia's Copperbelt, and in Morocco. Large quantities of sodium deposits remain to be evaluated. Sodium chloride is the principal salt, the largest deposit being in the Danakil Plain of Ethiopia. The principal sources of salt in Africa, however, are inland or coastal basins, from which it is extracted by the evaporation of saltwater. Major coastal reserves of this type lie along the North African Mediterranean coast and along Red Sea and Indian Ocean coasts of East Africa and Madagascar. Inland, the chief reserves are in the Oran Sebkhah, a salt-pan

region in Algeria; in Botswana around Lake Makarikari; and in Uganda.

Another important sodium mineral is natron, or sodium carbonate. Natron is more limited in occurrence, but Africa contains several significant deposits. It is found in Lake Magadi, Kenya, and in Lake Natron, Tanz., as well as in western Africa, where beds have been deposited from the waters of Lake Chad.

North Africa has been a traditional exporter of phosphates, and western Africa has large reserves. Morocco and Western Sahara together have vast reserves. The Río de Oro region in Western Sahara contains huge deposits, and a major development at Bu-Craa has been established. Algeria and Tunisia also have reserves. To the east, phosphate-bearing sediments outcrop on the Red Sea coast. The Thiès deposit in Senegal is of particular interest in constituting the world's only source of aluminum (as opposed to calcium) phosphate. Other phosphate deposits occur in Togo, Nigeria, Tanzania, Uganda, and Malawi.

The potash deposits in the Congo are the largest in Africa. The other large reserve is in Ethiopia.

Madagascar has the world's largest known accumulation of flake graphite deposits. Continuations of these high-quality deposits in Mozambique and southeastern Kenya contain further reserves of graphite.

While deposits of low-grade sand suitable for construction and engineering work are widely distributed, reserves of sands with a sufficiently high silica content for glass manufacture are more localized. There are deposits in West Africa (Côte d'Ivoire, Liberia, Nigeria, and Ghana), East Africa (Uganda and Tanzania), and South Africa. Glass sands are also found in Egypt.

Kyanite (cyanite), a mineral aluminum silicate used as a refractory, occurs most typically in southern Africa. Apart from South African reserves, there are deposits in Kenya, Malawi, Ghana, Cameroon, and Liberia.

Of the abrasive substances, industrial diamonds are most closely associated with Africa. The continent contains some 40 percent of the total world reserves. The stones are found in a number of major belts south of the Sahara. The principal known reserves of diamonds in their primary form are in the South African Vaal belt. Elsewhere in Africa, primary deposits are found in Tanzania, Botswana, and Lesotho.

Industrial
diamonds

Another major belt of diamondiferous rocks encircles the Congo River basin and includes the world's largest deposit, located in Zaire, which contains the majority of Africa's reserves of industrial diamonds. The same belt has secondary deposits that occur elsewhere in that country, as well as in the Central African Republic and Angola. In West Africa known reserves are located primarily in alluvial gravel fields. They are found in Sierra Leone, Guinea, Côte d'Ivoire, Liberia, and Ghana.

A considerable proportion of the world reserves of corundum (a common mineral, aluminum oxide, notable for its hardness) is located in southern Africa. The principal deposits are in Zimbabwe, South Africa, Mozambique, Madagascar, and Malawi.

Pumice is found in areas of volcanic activity such as the Atlantic islands, the coastal Atlas Mountains of northeastern Morocco, and in the East African Rift System, notably in Kenya, Tanzania, and Malawi. Joint reserves constitute, however, only a small percentage of the world total.

Reserves of building materials are characterized by their wide distribution, to such an extent that the commercial status of such deposits depends more on their location relative to areas of development than on their extent and quality. While almost all African countries have reserves of building materials, knowledge of such reserves is strictly related to the country's level of development, and no meaningful estimate of the size of reserves can be made.

Granite is located in Morocco and Nigeria, and there are vast reserves in Burkina Faso. Quartzite (a granular rock, consisting essentially of quartz) is important as a building stone in Uganda and Zaire. Dolerite (a coarse-grained basalt) is produced in South Africa, and basalt, which is crushed for use in road construction, in Senegal. Marble is found in Mali, Togo, Nigeria, and South Africa.

Limestone is important because of its use in the cement

industry, and deposits are fairly widespread. North Africa is a particularly important source. In western Africa a belt of limestone runs from the Central African Republic to the Atlantic coasts, with major outcrops in northern Nigeria, Niger, Burkina Faso, and Mali. Elsewhere there are deposits in Nigeria, Benin, Togo, and Ghana. East African deposits include those in Kenya, Tanzania, Uganda, and Zambia; there are also deposits in South Africa.

North Africa has major reserves of gypsum on the Mediterranean coast, as well as in outcrops along the Gulf of Suez and the Red Sea. Somalia has one of the largest known deposits. Eastern Africa and Madagascar have further reserves, and in southern and western Africa superficial deposits are particularly important—for instance, north of Nouakchott, Mauritania.

Gems

Many of the major deposits of the most important commercial gem mineral, the diamond, have already been described above in the discussion of industrial diamonds. One major deposit, however—that of Namibia—consists almost entirely of gem diamonds.

There is no other gem mineral in Africa of comparable importance to these diamond reserves. Deposits of a number of such stones are found, however, especially in southern and eastern Africa, where diamond fields contain beryl, garnets, amethyst, rose quartz, topaz, opal, jasper, emeralds, and other stones. Madagascar contains a large deposit of garnet. Tourmaline is found in Madagascar and Namibia. Agate is particularly associated with the volcanic areas of eastern and southern Africa and malachites with the Shaba Copperbelt, while sapphires are found with diamonds in Ghana.

Africa contains no major world deposits of talc, but the mineral is found in Morocco, Nigeria, The Sudan, Zimbabwe, and South Africa. Reserves of asbestos are much more important, and southern Africa has a number of deposits of world significance.

Major deposits of fluorite, or fluorspar (a common mineral, calcium fluoride, used as a flux in metallurgy), are particularly associated with deposits of lead and zinc. In South Africa the chief deposit is in the Transvaal. North African reserves lie primarily in Tunisia and Morocco.

Africa produces a very small share of the world supply of diatomite (a fine siliceous earth, used as an abrasive). The most important deposit is in Kenya.

Water resources. In general, the seasonal distribution of river flow in Africa reflects the seasonal rainfall pattern; the amount of groundwater entering the river channels during the dry season is comparatively small. Important modifications in the flow of some rivers are caused by the presence of large lakes and swamps, which act as natural storage reservoirs, by the construction of dams on their courses, and by the incidence and severity of drought.

Surface water. Although the surface area of Africa is about one-fifth of the Earth's land surface, the combined annual flow of African rivers is only about 7 percent of the world's river flow reaching the oceans.

North Africa's few perennial rivers originate in the mountains of the Maghrib, and their water is used extensively for irrigation. The large number of wadis, or ephemeral watercourses, to be found throughout the Sahara and the eastern Mediterranean coastal lands become filled with water as a result of the rare and erratic storms that occur over mountainous areas; otherwise they remain dry.

From the relatively well-watered areas of western and equatorial Africa, the Sénégal, the Niger, the Logone-Chari, and the Nile rivers flow through the drier inland zones. Of these, the Niger River, originating in the Fouta Djallon region of Guinea, is retarded in the lake and swamp area south of Timbuktu in Mali, and the Logone-Chari feeds Lake Chad.

The Nile, the world's longest river, receives more than 60 percent of its water from the Ethiopian Plateau, although its source is much farther south in the mountains of Burundi. Since the completion of the Aswan High Dam, only a small proportion of the river's total flow reaching Egypt enters the Mediterranean Sea.

A number of rivers flowing in a more or less southerly direction into the Atlantic Ocean drain the southern part of western Africa. Many flow rapidly over bedrock before

entering the coastal plains, draining into the system of lagoons and creeks along the coast. During the dry season the upper reaches of these rivers are without water; but in Guinea, Sierra Leone, and Liberia, where the dry season is fairly short, the rivers flow throughout the year.

In the well-watered western part of equatorial Africa the total average annual flow of the Congo River is enormous: some 44 trillion cubic feet. River flow at the lower end of the basin has two maxima: one that corresponds with the rainy season north of the equator, the other with the rainy season that occurs when it is summer in the Southern Hemisphere. The waters in the lower reaches of the river are slightly acid after traversing the large swamps situated in the centre of the basin.

East Africa's many lakes stretch along the East African Rift Valley from the Red Sea to the mouth of the Zambezi River. Evaporation from most of them exceeds their surface rainfall, and in consequence their outflow is less than the quantities brought in annually by their tributaries. They often govern river flow by acting as storage reservoirs—decreasing the flood flow and increasing the dry-season flow. A number of the rift valley lakes are situated in closed basins and contain high percentages of dissolved salts. The largest of these are Lakes Rudolf (Turkana), Natron, and Eyasi.

East African lakes

Rainfall over much of southern Africa is small, and the majority of the rivers originating there have an intermittent flow. Some large perennial rivers (e.g., the Okavango, the Zambezi, and the Orange) flow from areas of abundant rainfall into the drier zones.

Groundwater. The conditions under which groundwater is found and the quantity and quality of groundwater reserves are closely related to geologic structure. Large inland depressions in Africa's basement rock, having been filled with sedimentary layers of continental origin, sometimes form important groundwater reservoirs, notably those in the Taoudeni-Niger region, in the central Sahara between the Atlas and Ahaggar mountains; in the Libyan Desert; and in Chad, the Congo basin, the Karoo area of South Africa, and the Kalahari.

The East African plateaus usually contain little or no quantities of groundwater, and aquifers (geologic formations containing water)—generally of local importance—are found only in humid areas where the crystalline rock is weathered or fractured.

The chalky shales (rocks of laminated structure formed by the consolidation of clays) and dolomitic limestones (those containing calcium magnesium carbonate), which sporadically cover the basement rock, may contain important aquifers; those in Zambia and South Africa are major sources of water.

In the Sahara a rock stratum called the Continental Intercalary series, which dates from the early Cretaceous Period and which includes the Nubian sandstones of southern Egypt, is the most important water-bearing layer. It extends over very large areas and reaches a thickness of more than 3,000 feet; in Egypt and Algeria it is a major source of artesian water. In The Sudan it sometimes lies directly on the Precambrian bedrock and contains underground water layers of local importance. Overlaying the Continental Intercalary series, but generally separated from it by a thick marine deposit, is a younger Tertiary layer called the Continental Terminal, which is the second largest aquifer in this area. Both these layers contain "fossil" water—i.e., water that entered the layers when rainfall in and around the Sahara was much more abundant than today. Near the surface, aquifers are found in such geologically recent deposits as alluvial deposits and sand dunes.

"Fossil" water layers

In the coastal areas of Senegal, Côte d'Ivoire, Ghana, Togo, Benin, Nigeria, Cameroon, Gabon, the Congo, Angola, Mozambique, the East African countries, and Madagascar, aquifers are found in sandstone, limestone, and sand and gravel sediments. Intensive exploitation, however, may result in saltwater intrusions.

The Jurassic limestones of the mountainous area of the Maghrib are much more abundant in water sources than are dolomitic limestones. Around the cape in South Africa, sandstones and limestones contain very little water.

Yields from aquifers with good porosity, such as coastal

sedimentary rocks or alluvial deposits, vary from a few cubic feet per hour in the fine-grained sands found in many parts of the continent to 35,000 cubic feet (990 cubic metres) per hour in the coarse gravels of the Nile delta. The capacity of wells in the Continental Terminal is generally somewhat lower, and those in the Continental Intercalary and the Karoo formations can also deliver moderate to high yields.

In North Africa limestones containing many cracks and fissures may yield thousands of cubic feet of water per hour, while in Zaire, Zambia, and South Africa large yields are drawn from dolomitic limestones.

The harder sandstones, sandy shale, and quartzites of Precambrian and Paleozoic age are not generally very porous, and water is obtained only from fractured or weathered deposits. West African, Angolan, and Tanzanian wells in these formations produce only a few cubic feet per hour. Crystalline and metamorphic rocks are almost impermeable except where fractured or weathered. Volcanic rock, especially the basalts, may yield up to 1,060 cubic feet per hour.

Most of the exploited groundwater is generally fit for consumption because the dissolved minerals in water from shallow wells, particularly in the sandy aquifers of West Africa, are quite low. Groundwater from deeper marine layers, however—such as occurs in parts of North Africa, Mozambique, Ethiopia, and South Africa—may have a high content of dissolved salts. In moist, tropical countries water from Precambrian rocks generally contains only small amounts of dissolved minerals, whereas in the volcanic areas of East Africa groundwater may have so high a content of fluorine as to make it unfit for human consumption. There, and elsewhere in Africa, hot (possibly medicinal) springs with high mineral contents occur.

Availability for human use. The pronounced seasonal character of rainfall and the fact that many rivers stop flowing during the dry season have necessitated the development of groundwater for human use, and the tapping of local aquifers has become important in many parts of the continent.

Irrigation

Large-scale irrigation has long been practiced mainly in North Africa, Egypt, The Sudan, South Africa, Mali, Zimbabwe, and Mozambique. Medium-scale irrigation projects have been operated in Madagascar, Senegal, Somalia, and Ethiopia. In Côte d'Ivoire, Burkina Faso, Kenya, Nigeria, Ghana, and Zambia, medium- to small-scale projects have been constructed.

More than 50 river and lake basins are shared by two or more countries, and the development of their resources requires the cooperation of the basin states and several intergovernmental agencies—such as the Organization for the Development of the Sénégal River, the Niger Basin Authority, and the Lake Chad Basin Commission.

Several large reservoirs were built in the late 20th century, such as the Aswan High Dam, Roseires, and Khashm al-Qirbah reservoirs in the Nile basin, Kainji on the Niger, Akosombo on the Volta, Kariba on the Zambezi, Cabora Bassa on the Zambezi in Mozambique, Kossou on the Bandama in Côte d'Ivoire, Kafue on the Kafue in Zambia, and Inga I and II on the Congo River in Zaire. At a number of man-made lakes, research centres have been set up to study resettlement problems, the full use of ecological conditions, and the control of health hazards that sometimes occur.

Biological resources. Africa's naturally occurring biological resources—its immensely varied vegetational cover, vast insect life, and diverse animal life—have been described above. When combined with cultivated crops and domestic animals, these resources represent the great bulk of the continent's economic wealth.

Botanical resources. The two most economically important types of vegetation are forests and grasslands. Among the forested areas, the tropical forests contain much of the valuable timber. The vast equatorial lowland rain forest has the greatest variety of tree species, but the species most commercially in demand are found in the zones of broad-leaved woodlands and tropical highland forests. The true value of the forested areas, however, cannot be ascertained exactly, as original forests are progressively being

converted to farming areas, and few governments have undertaken comprehensive land-use surveys to determine their present extent.

A large proportion of the land surface of Africa bears vegetation in which grass is an essential feature. This abundance of grass has made possible the continent's enormous and varied populations of herbivorous mammals, both wild and domesticated. The tall and fibrous invasive grasses in forest environments and in large tracts of wooded grasslands are seldom very palatable to livestock; but in those parts of the continent where good forage grows naturally or has been introduced, livestock raising is of great economic importance.

The Albida acacia tree of the "farmed parkland" areas of West Africa is of special economic importance. Unlike almost all other dry woodland trees, whose leaf shedding normally occurs at the onset of the dry season, the Albida appears to have a period of partial dormancy during the rainy season and springs to life only at the beginning of the dry season. At such periods its foliage is abundant and—being a palatable leguminous species—is much prized as browse for sheep, goats, and cattle. The smaller leafy branches are frequently fed to stock. The tree flowers and produces fruits, which are harvested, dried, and fed as a protein concentrate to stock at the height of the dry season.

Animal resources. Although water buffalo, oxen, horses, mules, donkeys, and camels are used primarily as draft, pack, or riding animals in Africa, they also provide milk, meat, hides, or skins.

The water buffalo is an offshoot of the Asiatic buffalo (*Bubalus bubalis*); it arrived in Africa in relatively recent times and is now found almost exclusively in Egypt. The domesticated African water buffalo is used to cultivate irrigated land (mainly in the Nile delta) and to provide milk and meat. Because of its intractability and wild nature, however, the African elephant—unlike the Asian elephant—is not used for draft or haulage purposes.

Oxen are widely used in Africa for agricultural purposes, especially for plowing and cultivation; they are also trained to thresh grain, pump water, and act as pack animals. Bullock (castrated oxen) plowing is well developed in the countries of North Africa, in Ethiopia and The Sudan, and farther west in Chad, in northern Nigeria, and in the savanna climatic zone of West Africa. Plowing and cultivation by oxen is also well developed in areas of eastern and southern Africa free of the deadly tsetse fly. Females used for work may also be milked. Work oxen are often used for meat and to provide hides.

Horses and ponies are principally found in Morocco, Algeria, Tunisia, Chad, Ethiopia, Mali, Niger, Nigeria, Senegal, Burkina Faso, Egypt, South Africa, and Lesotho. Horses are used as riding or pack animals and in a number of areas are bred with donkeys to produce mules. Few are kept in areas where tsetse flies are present. Five main types of horses inhabit Africa: the Darfur pony, the Dongola horse, the Ethiopian-Galla horse, the Somalia pony, and the South African horse (including the Basuto pony). In North Africa, types also have evolved as a result of selection and crossing with exotic Arab, Barb (Barbary), and Thoroughbred horses. Arab and Thoroughbred influence may also be noted in southern Africa.

The distribution of the ass roughly corresponds to that of the horse, except that it also extends into the livestock areas of eastern and central Africa. Mules are found in Algeria, Ethiopia, Morocco, Somalia, South Africa, and Tunisia, where they provide farm draft power and are used as pack animals and for riding. The ability of mules to perform work in hot, dry climates is superior to that of most other farm animals.

The Arabian camel, or dromedary, is widely dispersed in the drier regions of northern and eastern Africa. Although used principally as a pack animal, it also is used for land cultivation, water pumping, and human transportation. The camel is essentially a bush browser and, if reasonably well fed and watered, may produce about 11 to 13 pounds (5 to 6 kilograms) of milk daily, in addition to that fed to the calf. The milk is prized by the camel herders and their families. Camel meat and camel hides find a ready market among Muslim communities.

The importance of the Albida acacia tree

Camels

Cattle provide hides, and sheep, goats, and pigs provide skins. Skins of the Maradi, Sokoto, and Kano red goats from Niger and Nigeria are greatly prized by the Morocco leather trade. In the areas north and south of the tropical zone, African sheep are covered with wool, but in the tropics they are hairy. In elevated areas, such as Ethiopia, where temperatures are modified by altitude, some sheep may be partially woolled, at least on the back and buttocks. The woolled sheep of North Africa are largely of the woolly Barbary type, which was originally introduced to Africa from the Middle East.

The great herds of wild African herbivores include the principal game animals. African antelope have been important throughout human history as sources of meat and such by-products as hides and bone; and they, along with other large mammals, became prized by trophy hunters. African elephants have been sought for centuries for the ivory in their tusks, but the severe reduction of their numbers by the late 20th century has led to a total ban on hunting them in most African countries.

The most economically useful fish found in the African waters include many species of freshwater fish. Important among the marine fish are flounder, halibut, sole, redfish, bass, conger, jack, mullet, herring, sardine, and anchovy. Crustaceans are important for local consumption and for export, as are oysters (for pearls), trochus shells, corals, and sponges. The most economically important aquatic mammal is the Southern, or Cape, fur seal.

AGRICULTURE

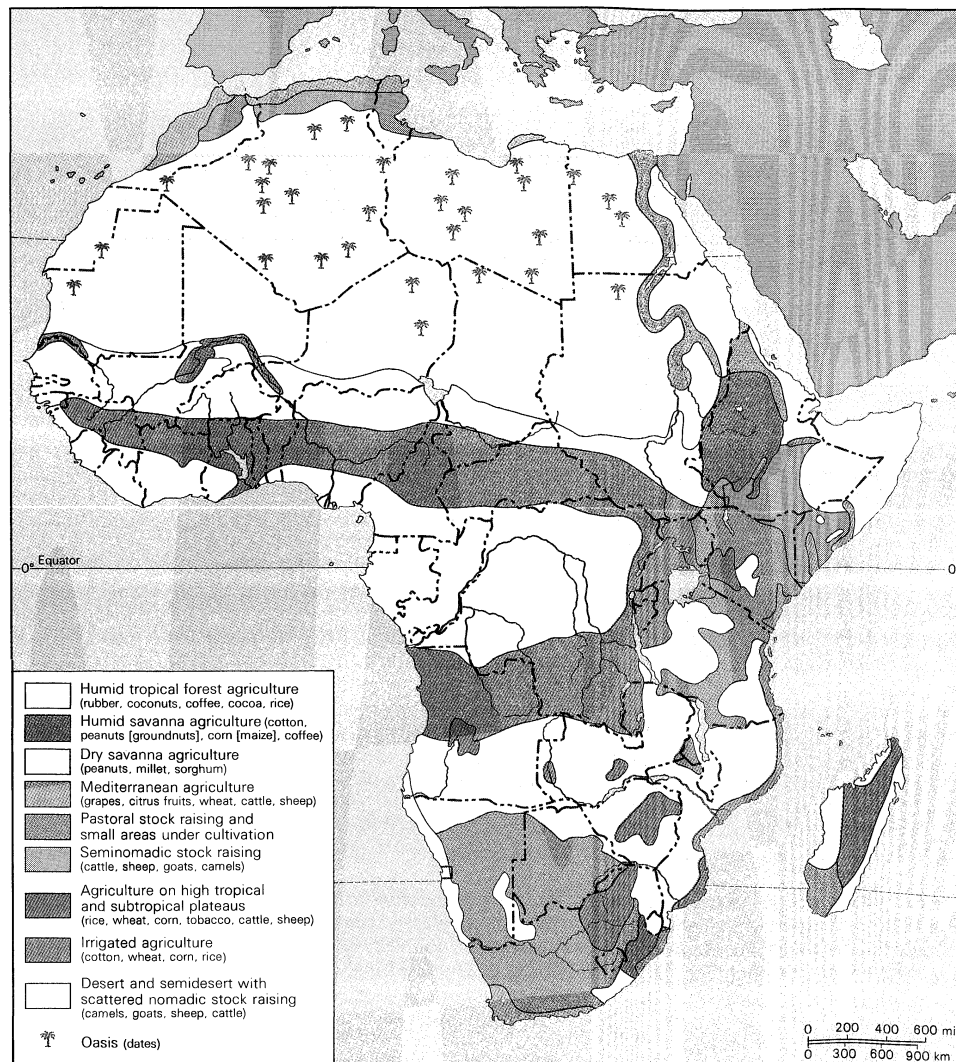

Agriculture is by far the single most important economic activity in Africa. It provides employment for about two-

thirds of the continent's working population and for each country contributes an average of 30 to 60 percent of gross domestic product and about 30 percent of the value of exports. Nonetheless, arable land and land under permanent crops occupy only about 6 percent of Africa's total land area.

Except for countries with sizable populations of European descent—such as South Africa, Zimbabwe, and Kenya—agriculture has been largely confined to subsistence farming and has been considerably dependent on the inefficient system of shifting cultivation, in which land is temporarily cultivated with simple implements until its fertility decreases and then abandoned for a time to allow the soil to regenerate. In addition, over most of Africa arable land generally has been allocated through a complex system of communal tenure and ownership rather than through individually acquired title, and peasant farmers have had rights to use relatively small and scattered holdings. This system of land ownership has tended to keep the intensity of agricultural production low and has inhibited the rate at which capital has been mobilized for modernizing production. A number of countries have made efforts to raise productive levels by selecting better varieties of seeds and planting materials, using tractors and other mechanized equipment, or increasing the use of mineral fertilizers and insecticides. Such measures, however, have been relatively limited, and they have raised concerns about their part in accelerating soil erosion and desertification. In areas of cash-crop production, land has become private rather than community property, and cultivation is intensive.

The persistence of relatively low-productivity agricultural systems over large parts of the continent also stems from

Land
tenure and
ownership

Agricultural regions of Africa.

a lack of integration between crop production and animal husbandry. Traditionally, sedentary cultivators like the Hausa in Nigeria and the Kikuyu in Kenya live apart from their nomadic herdsman neighbours (the Fulani and Masai, respectively), with the result that over large areas of the continent farmers do not have access to animals for draft power or to manure for fertilizer. The incidence of such insect pests as the tsetse fly also discourages mixed farming in many areas.

The need to sharply increase food production to meet the demands of a rapidly growing population, however, has remained paramount. Intense research at such centres as the International Institute of Tropical Agriculture in Ibadan, Nigeria, has been directed at developing high-performing varieties of crops and designing more appropriate cropping systems. One product of such research is a genetically improved strain of corn (maize). Corn is not in itself a balanced food, being deficient in some amino acids; but a scientific breakthrough in the mid-1960s resulted in an increase of the amino acids lysine and tryptophan in certain new varieties of corn called opaque, or high-lysine, strains. These varieties initially produced low yields, were more prone to disease and vermin, and had a soft texture that was not desirable. Breeding programs, however, have since corrected these defects, and the new strains have begun to improve the nutritional value of diets in Africa (which consist mainly of corn preparations).

Principal crops. *Cereals and grains.* Africa produces all the principal grains—corn, wheat, and rice—in that order of importance. Corn has the widest distribution, being grown in virtually all ecological zones. Highest yields per acre are recorded in Egypt and on the Indian Ocean islands of Réunion and Mauritius, areas where production is under irrigation. Millet and sorghum are also produced but principally in the savanna regions of the continent. Rice production and consumption have become increasingly important and are closely associated with areas of rapid urbanization. The most important rice-producing countries are Egypt, Guinea, Senegal, Mali, Sierra Leone, Liberia, Côte d'Ivoire, Nigeria, Tanzania, and Madagascar. Wheat production was once restricted to South Africa, the countries of North Africa, and the highland zones of Ethiopia and Kenya, but new varieties have extended cultivation (under irrigation) to countries in the savanna region such as Nigeria.

Legumes and fodder. Fodder crops are not widely grown except in subtropical areas of North Africa and the highland zones of East and southern Africa, where pure stands of alfalfa (lucerne) are raised. Berseem (a type of clover used for forage) is also grown in Egypt and The Sudan under irrigation. Protein-rich legumes are produced widely, usually sown together with other crops. They include velvet beans, cowpeas, soybeans, and lablab (hyacinth beans). In North Africa broad beans and vetches are also produced. Peanuts (groundnuts) are grown widely in western Africa, both for domestic consumption and for export.

Tubers and root crops. Cultivation of the hardy cassava has expanded tremendously, particularly in West and central Africa; it has displaced the cultivation of yams in many areas and has ceased to be regarded as just famine reserve. Potatoes are cultivated in the higher elevations of such countries as Ethiopia, Kenya, and Madagascar, as well as in areas of Mediterranean climates in North and South Africa. Sweet potatoes have a more tropical and subtropical distribution, while the plantain is grown extensively in the tropical forest zones.

Fruits and vegetables. Among the important fruits are bananas, pineapples, dates, figs, olives, and citrus; the principal vegetables include tomatoes and onions.

The banana is well distributed throughout tropical Africa, but it is intensively cultivated as an irrigated enterprise in Somalia, Uganda, Tanzania, Angola, and Madagascar. Also widely cultivated is the pineapple, which is produced as a cash crop in Côte d'Ivoire, the Congo basin, Kenya, and South Africa.

A typical tree of desert oases, the date palm is most frequently cultivated in Egypt, The Sudan, and the other countries of North Africa. The fig and olive are limited to

North Africa, with about two-thirds of the olive production being processed into olive oil.

The principal orange-growing regions are the southern coast of South Africa and the Mediterranean coast of North Africa, as well as Ghana, Swaziland, Zimbabwe, Zaire, and Madagascar. The largest yields are produced in countries where basin irrigation is practiced. South Africa is the largest producer of grapefruit, followed by The Sudan.

Tomatoes and onions are grown widely, with the largest-producing areas bordering the Mediterranean. Large vegetables, such as cabbages and cauliflowers, are grown in the same region, from where it is possible to export some quantities to southern Europe. Important vegetables of tropical Africa include peppers, okras, eggplants, cucumbers, and watermelons.

Beverage crops. Tea, coffee, cocoa, and grapes are all grown in Africa. Kenya, Tanzania, Malawi, Zimbabwe, and Mozambique are the largest producers of tea, while Ethiopia, Uganda, Côte d'Ivoire, Kenya, Cameroon, Zaire, Tanzania, and Madagascar are the major producers of coffee. Cocoa is essentially a tropical forest crop. Its cultivation is concentrated in West Africa, with the principal producers being Côte d'Ivoire, Ghana, Nigeria, and Cameroon. All of these crops are largely grown for export. Sharp price fluctuations have caused African countries to form international cartels with other producing countries in an effort to regulate the market and negotiate better prices. Grapes are produced in northern Africa and in South Africa, essentially for the making of wine for European markets. The agricultural policy within the European Community (EC), however, has had a restraining effect on the scope of production.

Fibres. Large areas of Africa raise cotton for textile manufacture. The principal producing countries are Egypt, The Sudan (especially the Al-Jazirah Plain), Zimbabwe, and Mali. Sisal production is also important, especially in the eastern African countries of Tanzania, Kenya, and Madagascar, as well as in Angola and South Africa. Some countries, notably Nigeria, promote the cultivation of kenaf (one of the bast fibres).

Other cash crops. The oil palm, producing palm oil and palm kernels, grows widely in secondary bush in the tropical forest zones. There are large plantations in Nigeria, Côte d'Ivoire, and Zaire. Coconuts are important in the Comoros, Ghana, Côte d'Ivoire, Mozambique, Nigeria, and Tanzania. Kola nuts are grown principally in the forested regions of Nigeria, Ghana, Côte d'Ivoire, Sierra Leone, and Liberia. The cashew tree is grown to a limited extent in East Africa and to a lesser extent in the coastal countries of West Africa. Rubber is produced principally in Nigeria and Liberia. Tobacco is widely cultivated as an export crop in Zimbabwe, Malawi, Tanzania, Nigeria, and South Africa. Sugarcane is also widely grown but largely for domestic consumption. Major producers include South Africa, Egypt, Mauritius, and The Sudan.

Livestock and fishing. Cattle, sheep, and goats form the bulk of livestock raised. Except in South Africa, most of these animals are raised essentially for beef. Sheep in the north and south are also kept for their wool; South Africa alone produces half of the entire continental production, much of the clip from merino or crossbred merino sheep. In the tropical areas, however, other livestock products include hides and skins. It is estimated that the annual output of hides is in the range of 10 percent of the total population of cattle, while that of sheepskins and goatskins is approximately 25 percent. The number of game hides and skins processed and sold annually is not accurately known. Except in South Africa, Zimbabwe, and Kenya, production of milk and milk products is grossly insufficient to meet domestic needs. Poultry production, however, has increased tremendously, and everywhere stocks have nearly doubled since the 1960s. Nigeria, Ethiopia, Morocco, South Africa, and The Sudan are the countries with the largest poultry stocks.

Fishing is important on the local level in all countries bordering the sea or inland bodies of water. Commercial ocean fishing is practiced most widely by the countries near the rich fishing grounds of the west coast—South Africa,

Oil and
coconut
palms

Cassava
cultivation

Namibia, Angola, Nigeria, Ghana, Senegal, and Morocco. Herring, sardines, and anchovies contribute most to the ocean catch, followed by jack, mullets, sauries, redfish, bass, and conger in tropical waters and cod, hake, had-dock, tuna, bonitas, and bullfish in northern and southern waters. Inland countries with well-developed fisheries include Malaŵi, Uganda, Chad, Côte d'Ivoire, and Mali; tilapia and other cichlids constitute the largest catch in inland waters. Some countries, such as Nigeria, have developed both marine and freshwater fishing industries. A number of commissions have been established to monitor and control fishery development on the continent.

INDUSTRY

The countries of North Africa, unlike those of the rest of the continent, have wide-ranging and ancient traditions of manufacture. At the end of the 19th century, however, Africa as a whole was regarded solely as a potential source of raw materials or as a natural market for Europe. In the course of time, limited industrialization tended to converge around the relatively large expatriate settlements, where technical considerations operated in favour of the industrialization of some areas and transport costs constituted the dominant development factor in others. Though World War II led to acceleration in the process of industrial development, by 1950 the total factory output of manufacturing industries (excluding South Africa) still remained small.

Industrial
develop-
ment

After 1950 output rapidly increased. The substantial increase and its range were attributable to such factors as increased demand, the substitution of home-produced for imported goods, the encouragement of manufacturing by individual African administrations, and an influx of development capital and petrodollars. Major weaknesses nevertheless were evident, among them high capital costs; the political division of Africa into more than 50 countries, which inhibited mass production and mass marketing; and a scarcity of skilled personnel.

Despite its expansion since about 1950, the relative significance of manufacturing remains considerably smaller than in the more-advanced countries and smaller also than in continental Asia and in Latin America. Furthermore, the share of manufacturing in the gross domestic product varies widely in different African countries. At the lower end of the spectrum are countries such as Equatorial Guinea, Guinea, Zaire, and Niger; at the upper end of the spectrum are countries such as Egypt, Algeria, South Africa, and Zimbabwe. The total output of manufacturing in South Africa alone, however, is nearly 50 percent of the output in the remainder of the continent.

Manufacturing in Africa tends to concentrate on comparatively simple items and on those where some special advantage is available to the African producer, although the range of products has widened. Industrial production includes electric motors, transport equipment, and tractors, while airplanes are also assembled. The leading heavy industries are chemical and petroleum, coal, rubber, and metal manufacture. Most industrial plants, however, are of the relatively simple kind, being engaged in food processing or in manufacturing textiles, leather products, and cement or other building materials.

The mining industry is an increasingly significant source of national income, foreign exchange, and raw materials for the development of local processing industries. The industry is very unevenly distributed: more than half of mineral earnings came from North Africa alone, and nearly one-fourth from southern Africa.

Except in South Africa, iron and steel are used mostly for construction rather than for engineering. There are integrated iron and steel plants in Algeria, Tunisia, Egypt, Zimbabwe, and South Africa, while smaller production facilities—often based on the transformation of scrap—exist in several other countries.

Petroleum
refining

Petroleum-refining capacity is based on domestic crude-oil output in a few cases and on imported crude oil in others. In some countries the development of the petrochemical industry followed the establishment of refineries. In 1965 there were only three major petrochemical complexes in Africa—in Zimbabwe, Egypt, and South Africa; by the

late 20th century several more countries had large refinery capacities, including Algeria, Ghana, Kenya, Libya, Morocco, Nigeria, Senegal, The Sudan, and Tunisia.

Most of the textiles are processed in bleaching, dyeing, and printing establishments that form an integral part of composite spinning and weaving units. With the exception of Egypt, producers have concentrated on the home market and on the manufacture of cotton textiles. Although African countries export textiles, their imports are usually larger. Rayon—synthetic and woolen materials are, for the most part, imported. Ready-made clothing, both domestic and imported, has emerged as a major market factor.

Most African countries have cement plants, the leading producers being South Africa and Algeria. The transport costs of cement make its price variable. Prices are lowest on the North African coast, somewhat higher on the west and east coasts, and highest in the inland countries.

By far most of Africa's wood output is used for fuel. Sawmills, however, are distributed throughout the continent. Plants for the manufacture of plywood, particle-board, and fibreboard have a considerable amount of excess capacity. The pulp and paper industry is concentrated in North Africa and in southern Africa, although a number of small paper mills have been established in other parts of the continent. The main products of the paper industry proper comprise newsprint, printing and writing papers, paper and paperboard, and industrial paper. The bulk of the output of all paper products is directed to national markets.

POWER

A spectacular development in the use of electric energy has taken place in the second half of the 20th century, partly because of the growth of the petroleum industry and partly because of the establishment of large hydroelectric plants and some thermoelectric plants. The increased quantity and quality of electric energy have given rise to problems of transmission and distribution. Unlike thermoelectric plants, which may be sited where the consumer demand is greatest, sites of hydroelectric installations are not flexible, and the type of transmission lines in use has therefore changed. Although in the 1950s it was common practice to use lines with transmission voltages of less than 220 kilovolts, transmission lines were later built that could handle higher voltages. In Nigeria, for example, 330-kilovolt lines were strung; similar lines were used in Zimbabwe's system, which feeds Harare and Bulawayo, in Zimbabwe, as well as the Copperbelt, in Zambia. This same system is interconnected in the north with the large Shaba region hydroelectric power stations in Zaire. The construction of high-tension lines to supply power to the Shaba Copperbelt was completed in 1982. Much of the power for Egypt's population centres is supplied by lines from such hydroelectric power stations as that at the Aswan High Dam. Construction of 533-kilovolt lines to transmit power from the Cabora Bassa hydroelectric station in Mozambique to South Africa was completed in 1974. The possibility of supplying landlocked states with energy from the large hydroelectric plants in the coastal states is more likely to be considered in the future.

A number of steam power stations are located in ports and cities near the coasts. The largest installations of this kind operate in Tunis, Tun.; Casablanca and Oujda, Mor.; Dakar, Senegal; Abidjan, Côte d'Ivoire; and Lagos, Nigeria. Steam power stations using coal are by far the most common, especially in South Africa.

Steam
power
stations

Electric-energy consumption in large urban centres, especially when they are near coastal towns and mining areas where industrial activity has taken shape, has increased considerably. Although some countries have extended networks to the rural areas or have increased the numbers of isolated, low-powered stations and independent networks, progress in rural electrification has not been especially noteworthy.

TRADE

Internal trade. Intra-African trade records frequently understate the amount of trade—partly because of the lack of adequate statistics and partly because of the high rate

of smuggling, which allows a substantial amount of traditional border trade to continue unrecorded. Apart from this, commerce between African states has been handicapped by a tendency for trade to remain concentrated within the common-currency areas and trade zones that developed among African countries during the colonial era, by the often inadequate means of transport and communication, by the lack of complementary agricultural or other products, and by the limited development of manufacturing industries.

Much of the intra-African trade consists of consumables—food, drinks, tobacco, sugar, cattle, and meat. The growth of industrialization in some countries, however, has been accompanied by an increase in the trade of durable and nondurable manufactured goods. There has also been a large amount of reexport trade between the coastal and inland states, especially in machinery, transport equipment, and spare parts.

Common-currency and trade zones that have evolved through the granting of preferences or the operation of common currencies inherited from former colonial powers include: the Customs and Economic Union of Central Africa (UDEAC), comprising Cameroon, Gabon, the Central African Republic, Equatorial Guinea, and the Congo, which since 1985 has become part of the larger Economic Community of Central African States (CEEAC) that also includes Burundi, Rwanda, São Tomé and Príncipe, and Zaire; the Economic Community of West African States (ECOWAS), consisting of Benin, Burkina Faso, Cape Verde, Côte d'Ivoire, The Gambia, Ghana, Guinea, Guinea-Bissau, Liberia, Mali, Mauritania, Niger, Nigeria, Senegal, Sierra Leone, and Togo; the Southern African Development Coordination Conference (SADCC), comprising Angola, Botswana, Lesotho, Malaŵi, Mozambique, Swaziland, Tanzania, Zambia, and Zimbabwe; and the Maghrib Permanent Consultative Committee (CPCM), grouping Algeria, Mauritania, Morocco, and Tunisia.

External trade. Since the outbreak of World War II there has been a considerable expansion in Africa's overall external trade. The growth compares favourably with that of the other developing regions, such as Latin America; the value of imports, however, has outweighed exports for some time, resulting in huge trade imbalances for most African countries. The large expansion in African exports is generally attributed to the increase in the demand for primary commodities during World War II and in the immediate postwar reconstruction period. Subsequently, the attainment of independence by a large number of African countries—especially in the early 1960s—followed by a bid for economic development, strengthened the export-expansion drive. Another reason for the rapid growth in African exports was the temporary increase in the price of primary commodities, although subsequently the general trend, except for petroleum, has been toward depressed commodity prices. The persistence of this situation has been part of the reason the economies of many African countries have become crippled by huge foreign debts.

Exports. An important factor that has influenced the growth of African exports was the discovery of petroleum in several countries, notably Libya, Algeria, Nigeria, Gabon, Angola, the Congo, and Cameroon, and the dramatic price increases brought about by the Organization of Petroleum Exporting Countries (OPEC) in the 1970s. Other factors include the discovery and the increased exploitation of minerals that are in high demand, such as diamonds—especially in Sierra Leone, the Congo, the Central African Republic, and Zaire—and the exploitation of other minerals, such as uranium ore.

Since achieving independence, many African countries have made attempts to diversify external trade relations. The record of achievement has been poor, however, because Africa's trade patterns have continued to reflect the influence of traditional links with the countries of western Europe. These links have been further consolidated through a series of agreements, collectively called the Lomé Conventions, that have guaranteed preferential access to the European Economic Community (EEC) for various export commodities from African states and that have provided European aid and investment funding.

Nonetheless, a significant export trade has developed with the United States and Japan.

In most African states one or two primary commodities dominate the export trade—*e.g.*, petroleum and petroleum products in Libya, Nigeria, Algeria, Egypt, Gabon, the Congo, and Angola; iron ore in Mauritania and Liberia; copper in Zambia and Zaire; cotton in Chad; coffee in Burundi, Uganda, Rwanda, Ethiopia, Madagascar, Kenya, and Côte d'Ivoire; and sugar in Mauritius.

Imports. The tremendous increase of Africa's import trade has meant that the import bill of most African states has exceeded their export earnings; in consequence, many governments have established import restrictions or subsidized many of the required imports. The bulk of imports comes from western Europe, especially the EEC countries, with strong trade ties persisting along former colonial lines. There has, however, been a substantial increase in imports from the United States, Japan, and South Africa. Imports are needed primarily to develop manufacturing industries and are, therefore, confined for the most part to mineral fuels, industrial goods, machinery, transport equipment, and durable consumer goods.

TRANSPORTATION

Although there were highly developed transport networks in many parts of Africa in precolonial times, during the colonial era that followed, these networks were restructured to penetrate into the interior from the seaports and, in the main, to serve the commercial and administrative needs of the colonial powers. Their fragmentation, which led to interregional links being but thinly developed, resulted from the juxtaposition of varied and difficult terrains, the economic artificiality of certain national frontiers, the lack of a developed intra-African trade, and the strong orientation of commodity trade with the administering countries. All of this was further complicated by the existence of vast unpopulated areas lying between the main centres.

The emergence in the 1960s of independent African governments who recognized the need to lift economies from their generally very low levels and, above all, to develop agriculture and embark on industrialization heralded improvements in economic planning, the development of transport networks, and the introduction of cheaper freight rates. But there remained a serious shortage of qualified African labour to plan and manage transport systems at the national or multinational level and, simultaneously, to keep up with the rapid development of transport technology outside Africa.

Animal transport. There is some evidence that before the arrival of the camel, which was introduced into Africa via Egypt at the time of the Arab conquest, bullocks were used either as pack animals or to draw carts from the northern countries across the Sahara to the gold-producing areas of the ancient Sudan. From the 16th century onward, the Portuguese developed transport inland from the coast at Mozambique, and, from the 17th century, first the Dutch and then British settlers from the Cape trekked northward and northeastward with their wagons. Except in such highland areas as Ethiopia, where pack animals were and still are used, the tsetse fly often prevented the use of animal transport. With the steady progress in the development of transport infrastructure in many African countries, the use of bullocks in southern Africa, donkeys in North and western Africa, horses in northern Nigeria, and camels in western and North Africa and the Horn of Africa has been reduced, but the extent of this reduction cannot be accurately gauged.

Motor transport. The arrival and rapid development of the internal-combustion engine in the 1920s transformed the collection and distribution of goods and personal travel. Roads were built, particularly in North and southern Africa, but also in parts of the west and east. World Bank loans since the 1950s, supplementing contributions to road and highway development from national budgets, have financed the building and improvement of road networks in many African countries.

Rail transport. The early railways were constructed partly to facilitate the administration of interior regions and to bring supplies from ports to central consumption or

transport

distribution points and partly—especially in the south—to enable valuable minerals or commodities to reach the coast for export. In Africa, as in Europe and North America, the major period of railway development extended from the end of the 19th century to the end of World War I. This expansion, however, was not coordinated: railways with different gauges of track were built and were operated with rolling stock of different braking and coupling systems. Thus, the colonizing powers left a difficult and costly legacy for independent African countries who wished to link themselves together. As with roads, rail networks have been improved considerably since the 1960s and, as a result, there has been a lowering of transport costs.

Air transport. Air transport is well suited to Africa's geographic vastness, and it has become the primary means of international and sometimes of national travel in Africa. During the late 1940s and the '50s, as great advances were made in the extension and improvement of rail and road services, a new transport factor emerged in the introduction of internal and international scheduled air services. The rapid development of air transport increased the movement of goods and people and began to open up the hitherto largely closed interior of the continent. Transport became much quicker and usually cheaper. Since

then, internal air services have steadily increased, and intercontinental air transport, especially of passengers, has developed greatly. The largest international airports are at Casablanca, Mor.; Las Palmas, Canary Islands; Cairo; Dakar, Senegal; Abidjan, Côte d'Ivoire; Lagos, Nigeria; Douala, Cameroon; Addis Ababa, Eth.; Nairobi, Kenya; and Johannesburg, S.Af.

Navigation. Historically, throughout the vast interior between the Sahara and the Zambezi River, people or goods were transported by canoe or boat on the great river systems of the Nile, Sénégal, Niger, Congo, Ubangi, and Zambezi rivers and on the few but very large lakes. Where conditions allowed, engine-powered craft later supplemented or displaced canoes, but further development of water transport has been slight. Also notable were the construction of lake ports and the installation of rail ferries across Lake Victoria.

Meanwhile, on the coasts, artificial harbours have been developed. New berths have been added to established port facilities, and a number of ports have been constructed. In planning new ports, the choice of site, probable costs, and the possibilities of using containers or other unitized loads have been taken into consideration.

AFRICAN GEOGRAPHIC FEATURES OF SPECIAL INTEREST

Landforms

ATLAS MOUNTAINS

The Atlas Mountains form the geologic backbone of the countries of the Maghrib (the western region of the Arab world)—Morocco, Algeria, and Tunisia. They extend for more than 1,200 miles (2,000 kilometres), from the Moroccan port of Agadir in the southwest, to the Tunisian capital of Tunis in the northeast. Their thick rim rises to form a high sill separating the Mediterranean basin to the north from the Sahara to the south, thus constituting a barrier that hinders, without completely preventing, communication between the two regions. Across the mountains filter both air masses and human migrations. It is, however, only in the east-west direction that the Atlas Mountains facilitate movement. These are the conditions that create at the same time both the individuality and the homogeneity of the Atlas countries. Although the Saharan region is more likely to be described as the archetypal North African habitat, it is the well-watered mountains north of this vast desert that provide the foundation for the livelihood of most of the peoples of North Africa and a striking green or white background for many North African towns.

Physical features. *Physiography.* The Atlas mountain system takes the shape of an extended oblong, enclosing within its ranges a vast complex of plains and plateaus.

Massifs of
the Tell
Atlas

The northern section is formed by the Tell Atlas, which receives enough rainfall to bear fine forests. From west to east several massifs (mountainous masses) occur. The first of these is Er-Rif, which forms a half-moon-shaped arc in Morocco between Ceuta and Melilla; its crest line exceeds 5,000 feet (1,500 metres) above sea level at several points, reaching 8,058 feet at Mount Tidirhine. East of the gap formed by the Moulouya River the Algerian ranges begin, among which the rugged bastion of the Ouarsenis Massif (which reaches a height of 6,512 feet), the Great Kabylia, which reaches 7,572 feet at the peak of Lalla Khedidja, and the mountains of Kroumirie in Tunisia are all prominent.

The southern section, which is subject to desert influences, is appropriately called the Saharan Atlas. It includes in the centre a palisade formed by shorter ranges, such as the Ksour and Ouled-Naïl mountains, grouped into massifs between two mighty ranges—the Moroccan High Atlas to the west and the Aurès Mountains to the east. The High Atlas culminates in Mount Toubkal at 13,665 feet (4,165 metres), the highest point in the Atlas Mountains, which is surrounded by high snowcapped peaks; the Aurès

Mountains are formed of long parallel folds, which reach a height of 7,638 feet at Mount Chelia.

The Tell Atlas and the Saharan Atlas merge in the west into the long folds of the Middle Atlas and in the east join together in the Tébessa and Medjerda mountains.

Geology. If the relief of the Atlas region is relatively simple, its geology is complex. In essence, the two Atlases comprise two different structural regions.

The Tell Atlas originally arose out of a basin filled with sediment, which was dominated to the north by a marginal rim, of which the massifs of Tizi Ouzou, Collo, and Edough are the remnants. Its elevation took place during a lengthy mountain-building process that was marked by upheavals in the Tertiary Period (which began 66.4 million years ago and ended 1.6 million years ago); over the cluster of folds that were uplifted from the rift valley were spread sheets of flysch (deposits of sandstones and clays), which were carried down from the north over the top of the marginal rim. Thus the Tell Atlas represents an example of a young folded mountain range still in the process of formation, as is shown by the earth tremors to which it is subject.

To the south the Saharan Atlas belongs to another structural grouping, that of the vast plateaus of the African continent, which form part of the ancient base rock largely covered by sediments deposited by shallow seas and by alluvial deposits. The Saharan Atlas is the result either of the mighty folding of the substructure that raised up fragments of the base rock—such as the horst (uplifted block of the Earth's crust), which constitutes the Moroccan High Atlas—or else of the crumpling into folds of the Earth's crust during the Jurassic Period (208 to 144 million years ago) and the Cretaceous Period (144 to 66.4 million years ago).

Drainage. The seasonal character of the rains, which fall in torrents, determines the characteristics of drainage in the Atlas: the runoff feeds streams that are of great erosive capacity and that have cut their way down through the thickness of accumulated layers of sediment to form deep narrow gorges difficult to cross. The pre-Roman fortress of Cirta (now called Constantine) in Algeria stands on a rock sculptured out by one such stream, the winding Rhumel River.

The great Maghribian wadis (French: *oueds*; channels of watercourses that are dry except during periods of rain) issue from the Atlas ranges. Among the more perennial rivers are the Moulouya, which rises from the Middle Atlas, and the Chelif, which rises from the Amour Moun-

Wadis

tains. Destructive of the soils of their headstreams, they deposit their loads of silt at the foot of the mountain ranges or else leave a long line of conical deposits locally known as *dirs* ("hills").

Soils. Good soil is sparse at higher altitudes in the Atlas region. Most often nothing is to be found but bare rock, debris, and fallen materials incessantly renewed by landslides. Two materials predominate—limestone, which forms ledges that are half-buried in rough debris, and marls (chalky clays) cut by erosion into a maze of ravines and crumbling gullies. The rarer sandstones favour forest growth. The best soils are the alluvia found on the terraced slopes and on the valley bottoms.

Climate. The Atlas Mountains are the meeting place of two different kinds of air masses—the humid and cold polar air masses that come from the north and the hot and dry tropical air masses that move up from the south. To the influences of altitude and latitude must be added that of aspect or exposure.

Rain is more plentiful in the Tell Atlas than in the Saharan Atlas, and more so to the northeast than to the southwest: the highest rainfall is recorded east of the Tell Atlas. 'Ayn ad-Darāhim in the Kroumirie mountains receives 60 inches (1,524 millimetres) a year; nowhere in the Anti-Atlas Mountains, south of the High Atlas, is the total more than 17 inches a year. In a single massif the slopes with a northern exposure receive more rainfall than those with a southern exposure.

With increased altitude the temperature drops rapidly; despite the proximity of the sea, the coastal massifs are cold regions. At 6,575 feet the summits of Mount Babor in the Little Kabylia region are covered with snow for four or five months, while the Moroccan High Atlas retains its snows until the height of summer. Winter in the Atlas is hard, imposing severe conditions upon the inhabitants.

Plant and animal life. Erosion of the soils in the Atlas region is aggravated by the sparseness of the vegetation covering the landscape; only about 39,000 square miles (101,000 square kilometres) of land are forested. On Er-Rif and the Kabylia and Kroumirie ranges, which experience some rainfall, moist forests of cork oaks cover an undergrowth of arbutus (cane apple) and heather shrub, and carpets of rockroses and lavender are found. When the total annual rainfall is less than about 30 inches and limestone is present, green oak and arborvitae (a species of pine tree) cover the soil, forming light, dry forests with a

thin and bushy undergrowth. Stands of cedar predominate at higher altitudes. On the dry summits of the Saharan Atlas the vegetation is reduced to scattered stands of green oak and juniper trees.

The clearance of land for agriculture has reduced the forest cover in the Atlas ranges; animal life in the mountains is also in retreat. There remain only a few jackals, some tribes of monkeys (Barbary apes) at higher elevations, and occasional herds of wild boars in the oak woods.

The people. The mountains, with their inhospitable environment, have provided a refuge for the original inhabitants, who have fled successive invasions. Here the Berber people have survived, preserving their own languages, traditions, and beliefs, while at the same time accepting Islām to some extent. Village communities still live according to a code of customary law, known as *kanun*, which deals with all questions of property and persons. The family unit traces its descent from a single ancestor, preserving its cohesion by the sense of solidarity that unites its members; an injury to the honour of one affects the group as a whole and demands vengeance.

The concern of Berber society to preserve its individuality is evident in the choice of habitat. Villages, which are fortified, are generally perched high up on mountain crests. Small in size, such villages are composed of the dwellings, a mosque, a threshing floor, and a place for the assembly of the elders (*jamā'ah*, or *djemaa*), which governs the affairs of each community. Families live, each unit apart, in separate rooms that form a square around a closed interior courtyard.

Despite the fundamental homogeneity of Berber society, there is a considerable diversity in different mountain localities. The Shluh of the High Atlas in Morocco inhabit the river valleys that cut down deeply into the massif. Their villages, with populations of several hundred inhabitants in each, are often located at an altitude of more than 6,500 feet. They consist of terraced houses, crowded one against the other, that are often dominated by a communal fortified threshing floor, or else are grouped around the threshing floor-plus-dwelling of the most powerful family. The mountain slopes in the vicinity are divided up for pasturage and cultivation. In some fields dry (*i.e.*, nonirrigated) farming is practiced for growing cereals. Land that is irrigated by diverting water from wadis yields two crops a year—cereals in winter and vegetables in summer. The Shluh use manure from their cattle as fertilizer. Oxen and

goats penned together on the ground floor of dwellings graze on stubble and on fallow lands around the villages. Sheepherders follow a pattern of transhumance (seasonal migration), grazing their sheep on low-lying land in winter and on the uplands in summer.

During the period of the French protectorate in Morocco (1912–56), profound changes occurred, transforming the way of life of the Middle Atlas populations. The dominant pattern of transhumance gave way to the practice of sedentary agriculture. The winter descent to the plains (*azarhar*) pasture has become practically a thing of the past, since the land is now under cultivation. The ascent to high pastures in summer, however, still continues. Stock raising in one location is increasingly practiced. Commercial forest products, mainly cork, also bring in an appreciable income.

Where the mountain and the plain meet, the *dir* lands offer rich potentialities, thanks to a light soil and abundant water. Grouped together in large villages, the *diara* populations (*i.e.*, populations who live on the slope of the *dirts*) constitute prosperous agricultural communities.

The Rif of Morocco and the Kabyle of Algeria resemble each other in many ways. Both Berber tribes, they inhabit the same types of wet-mountain slopes covered with oak forests, are similarly attached to a barren soil, and are both inclined to isolationism. In contrast to the way of life of the Berbers of the High and Middle Atlas, stock raising plays only a secondary role in their village life; they are not so much agriculturalists as arboriculturists, although they grow a little sorgho (a sorghum used for fodder), and women grow vegetables in small gardens adjoining their houses. It is, however, the fig and olive trees covering the mountain slopes they inhabit that constitute their principal resources. The Kabyle are also skilled craftsmen, working with wood, silver, and wool. In the past they were also peddlers, selling carpets and jewelry to the people of the plains.

The Aurès Mountains, standing alone in northeastern Algeria, are perhaps the least developed mountain region in the Maghrib. The Shawia (Chaouïa) populations who inhabit them follow a seminomadic style of life, which is partly agricultural and partly pastoral. They live in terraced stone villages in which the houses are built in tiers, one above the other, the whole being dominated by a *guelaa*, or fortified granary. When winter comes, the inhabitants of the high valleys lead their flocks to the lowlands surrounding the massif, where they pitch tents

or live in caves. Returning to the uplands in summer, they irrigate the land to grow sorghum and vegetables and maintain apricot and apple orchards, while shepherds take the sheep to pastures on the hilltops.

Despite precarious living conditions, the Atlas Mountains are densely populated—overpopulated even, in certain localities. In the area around Tizi Ouzou in the Great Kabylia, for example, densities reach about 700 persons per square mile (270 per square kilometre). Emigration is a necessity: the mountain regions have become a human reservoir upon which the Maghribian countries draw to obtain the labour force needed for development. Commercial agriculture attracts large numbers of farm workers to the plains either on a seasonal or a permanent basis. The Mitidja Plain of Algeria, for example, has been settled by the Kabyle. In Morocco, the Shluh of the High Atlas have provided labour for the phosphate mines.

Urban growth has served to increase the volume of the migratory stream that flows down from the mountains; the cities of Algiers, Constantine, Oran, and Casablanca are to a great extent peopled by mountain folk. The shantytowns of Algiers contain numerous Kabyle, and those of Casablanca many Shluh. Many of these urban immigrants find employment as labourers, while others become shopkeepers.

In Algeria the insecurity that became general in most mountain districts during the nationalist uprising that preceded independence led to the departure of large numbers of people. The exodus from the mountains continued after independence, with many mountain dwellers moving into the plains to occupy houses abandoned by departing Europeans. Rural and urban activities, however, still did not provide employment for all, for many emigrants, mostly from Algeria, sought work in France. To a considerable extent the mountain populations subsist on money sent back by these migratory workers.

The economy. Resources. Despite their inhospitability and relative inaccessibility, the Atlas Mountains have played an important part in the modern development of the Maghribian countries. The mountain massifs constitute catchment areas with considerable potential. The construction of reservoir dams not only has permitted the storage of enormous amounts of water for irrigating the plains but has also made it possible to generate hydroelectric energy. In Morocco efforts have been made in the last half of the 20th century to exploit the potential of the mountain wadis. In addition to the dams across the Wadi

Population density

Minerals

el-Abid and the Wadi el-Rhira on the northern slope of the High Atlas, dams on the southern face have been constructed across the Drâa and Ziz watercourses. In Algeria the Kabylia region has been developed with hydroelectric stations on the Agrioun and Djendjene wadis.

The geologic formations of the Atlas are rich in minerals. The Moroccan High Atlas in particular contains important deposits. Among these the most important economically is phosphate, mined principally in the Khouribga area. Other major deposits include lead and zinc from the Middle Atlas and from the Oujda area and copper, silver, and manganese; the output of manganese mining at Imini and Tiounine is transported to Marrakech by overhead cable cars. Anthracite coal is also mined at Oujda. In Algeria iron ore is extracted from the Siba Chioukh Mountains, from Mount Zaccar Rherbi, and from the areas near Ouenza and Bou Khadra, while phosphate is mined at Mount Onk and El Kouif. Lead and zinc have also become important. In Tunisia the High Tell mountains produce phosphate at Al-Qal'ah al-Jardâ, iron ore from Mount Djerissa, and lead from Sâqiyat Sîdî Yûsuf. These raw materials are often processed in the coastal towns. The iron ore from Ouenza, for example, supplies the iron-smelting industry of Annaba.

Among forest products, cork is more important than timber; production is centred in the Kabylie region of Algeria, notably on the Collo Massif.

The tourist industry is also being developed, particularly in the High Atlas region of Morocco. In the Middle Atlas, long snow-covered slopes suitable for winter sports are located in the vicinity of major towns. In Algeria the establishment of industry in mountain regions is being encouraged, so that employment for the mountain dwellers can be available. At Constantine, the principal city of the mountain regions, as well as at other larger cities, a number of industries have been established. Despite these efforts, however, contrasts between the life-styles of the mountains and those of the plains and cities of the Maghrib have by no means diminished, nor are they soon likely to do so.

Transportation. The Atlas Mountains have their own internal system of communications. Villages are linked by paths that, avoiding the valley bottoms, follow the crest lines of the hills. Travel is on foot or by mule or local bus.

The massifs constitute an obstacle to traffic; roads and railroads traverse them by means of tunnels and viaducts, which are costly to build. Traffic between Algiers and Constantine, for example, is obliged to cross the Kabylia Massif; the route runs through the Isser River gorges and crosses the mountains at the Portes de Fer Pass. The Chiffa Gorge cuts across the route between Blida and Médéa.

The relative impenetrability of the mountains explains why they have been avoided by the main transportation routes, and why, consequently, they constitute strongholds of ancient traditionalism. Obstacles to communication should not, however, be exaggerated; the mountains also offer many natural connecting links, or passes, that facilitate movement. Such topographical accidents localize communication routes: between the desert and the plains the nomads use synclinal corridors (*i.e.*, corridors formed by folds in the rocks in which the strata dip inward from both sides toward the centre) that separate the ridges of the Saharan Atlas range. The Biskra Gap, situated between the Ouled-Naïl and Aurès ranges, provides a natural conduit for traffic between Constantine on the Rhumel River and Touggourt in the Sahara. Between Algeria and Morocco both the road and the railroad pass through the Atlas along the Taza Pass, which breaks the continuity of the mountain system between Er-Rif and the Middle Atlas. Passes are natural routes across the mountain barriers and thus constitute strategic points. The focal point of communication in the Great Kabylia, for example, is Tizi Ouzou, at the Genêt Pass, which has become in effect the capital of the massif. To surmount the obstacle formed by the Ouarsenis Massif, situated between Chelif Plain and the Sersou Plateau, it is necessary to pass by way of Theniet al-Haad. The passes of the Moroccan High Atlas have also played a decisive role in the history of relations between Morocco and the vast region known as the west-

ern Sudan to the south; the ancient caravan route from Marrakech to the Drâa valley used the n'Test Pass, which thus became of great commercial importance.

Study and exploration. Attempts by European powers to gain control of northwestern Africa began in the 15th century. Portuguese activity was confined to the Strait of Gibraltar and the Atlantic coast of Morocco, where several forts were established. Spanish activity, initiated at the beginning of the 16th century, included the capture of Mediterranean ports and a slow penetration first of the Rif region and after 1860 into other parts of Morocco. French influence was more extensive. Beginning in 1830 with the capture of Algiers, French control expanded eventually to encompass all but the Rifian part of the Atlas region, including a protectorate over most of Morocco (1912–56). Road building to control the mountains and to facilitate the movement of peoples and goods enhanced communication in what had been an isolated and fragmented region, often weakly controlled by government authorities based in lowland areas. No longer the focus of European exploration or exploitation, the Atlas Mountains are a conspicuous feature of the independent states of Morocco, Algeria, and Tunisia. (H.Is./M.W.M.)

EAST AFRICAN MOUNTAINS

The East African mountains of Kenya, Tanzania, Uganda, Zaire, Rwanda, and Burundi are intimately related to the East African Rift System, the fractures of which extend discontinuously between the Zambezi River valley and the Red Sea and are flanked in many areas by highlands. Of the major mountains, all but one—the Ruwenzori (Rwenzori) Range—are of volcanic origin. Rising magnificently from the surrounding plateaus to altitudes of over 16,000 feet (4,900 metres), the highest peaks, despite their proximity to the equator, are ice-capped.

Mount Kenya, the Aberdare Range, and the Mau Escarpment are located wholly within Kenya to the north of Nairobi; Mount Elgon lies astride the Uganda-Kenya border; Kilimanjaro extends along Tanzania's northern boundary with Kenya; and Mount Meru is in northern Tanzania. The Ruwenzori Range stretches between Lakes Edward and Albert on the Uganda-Zaire border, and, farther south, the Virunga Mountains extend along the contiguous borders of Uganda, Rwanda, and Zaire.

Physical features. *Physiography.* The Aberdare Range, of which the highest peak is Mount Lesatima (Satima), reaching a height of 13,120 feet, and the Mau Escarpment rise steeply from the eastern portion of the Eastern (Great) Rift Valley. To the west, beyond the Uasin Gishu Plateau, Mount Elgon emerges gently from a level of about 6,200 feet; but the spectacular cliffs of its western face dominate the lower plains of eastern Uganda, which lie at about 3,600 feet. The rim of Elgon's caldera (a vast explosion crater) is approximately five miles (eight kilometres) in diameter and contains several peaks, of which Wagagai, at 14,140 feet, is the highest.

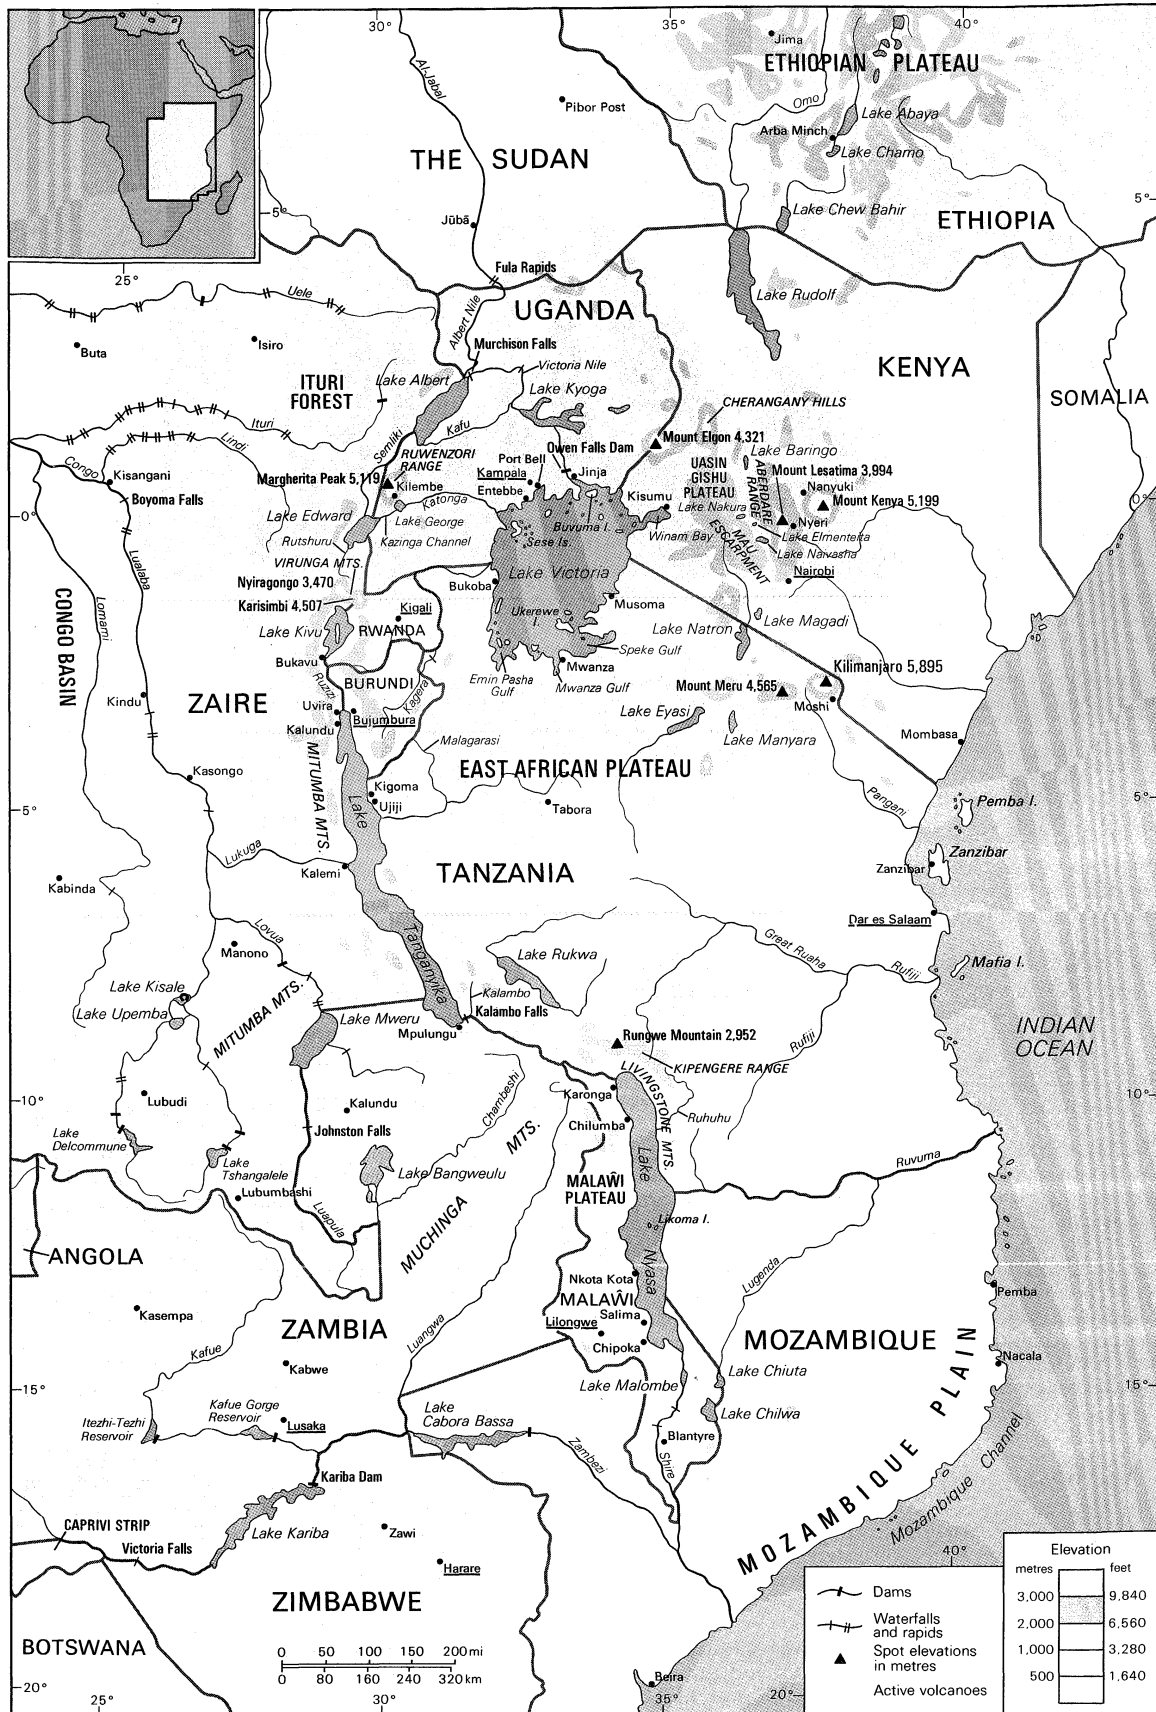

The Nyeri-Nanyuki corridor separates the Aberdare Range from Mount Kenya. The second highest mountain in Africa, Mount Kenya has a girth of about 95 miles at 8,000 feet, from which it rises boldly to its restricted summit zone. The craggy twin peaks of Batian (17,057 feet) and Nelion (17,022 feet) are closely followed in height by Lenana (16,355 feet).

Set amid low plateaus, Kilimanjaro is the highest mountain in Africa, rising to 19,340 feet (5,895 metres) at Uhuru peak on the Kibo cone. The generally smooth outlines of the cratered dome of Kibo are in marked contrast with the jagged form of Mawensi, or Mawenzi (17,564 feet); the two summits are connected by a saddle, seven miles long, that lies at about 14,500 feet. Mount Meru, about 40 miles southwest of Kilimanjaro, attains an altitude of 14,978 feet.

The Ruwenzori Range runs parallel to the Western Rift Valley, to which it drops steeply. The fall to the uplands of western Uganda, however, is more gradual. At its base the range is some 80 miles long, and its greatest width is about 30 miles. The summit zone contains six distinct mountain massifs, which are separated by well-defined passes and deep river valleys. Mounts Baker and Gessi

Principal
mountain
features

The
mountain
passes

lie entirely within Uganda, while Mounts Stanley, Speke, Emin, and Luigi di Savoia form part of the Uganda-Zaire frontier. Of the 10 peaks with heights of more than 16,000 feet, all but one are on Mount Stanley, which includes the highest peak, Margherita, at 16,795 feet.

The Virunga Mountains and their associated lava flows

extend across the Western Rift Valley. In the west, Nyamulagira, Nyiragongo, and Mikeno are in Zaire; Karisimbi—at 14,787 feet the highest of the Virunga volcanoes—and Visoke are centrally placed on the Zaire-Rwanda frontier; and farther east Sabinio (Sabinyo), Mgahinga (Gahinga), and Muhavura, also known as the Mufumbiro Mountains,

Acacia trees on the plain below the summits of Kilimanjaro, Tanz. Uhuru peak is at right, Mawenzi (Mawenzi) at left.

J.S. Wightman—Ardea London

Glaciers

are on the Rwanda-Uganda frontier. Not all of the cones culminate in craters, but several have crater lakes.

The relict glaciers that occur in the summit zones of Kilimanjaro, Mount Kenya, and the Ruwenzori have little erosive force. Their more powerful predecessors, however, extended down to altitudes of between 12,000 and 10,000 feet and even lower and produced arêtes (sharp-edged ridges), cirques (glacial amphitheatres), rock tarns (rock basin lakes), U-shaped valleys, and moraines (boulders and other debris deposited by glacial action). Early glaciation also affected both Mount Elgon and the Aberdare Range. More than 30 small glaciers on the Ruwenzori together cover a surface of approximately 1.5 square miles (4 square kilometres), most of which is on Mounts Stanley and Speke; the lowest valley glacier descends to about 14,000 feet. Of the glaciers remaining on Mount Kenya and covering less than 0.3 square mile, the largest are Lewis and Tyndall; the lowest tongue of ice reaches down to about 15,000 feet. On Kilimanjaro, Kibo crater is strewn with giant blocks of ice, and the outer rims are covered with ice reaching down to about 16,000 feet on the wet southwestern moorlands. The 20th century has been marked in East Africa by a process of glacial retreat that has been rapid but neither constant nor continuous.

Geology. The peneplain of eastern Africa, dating from the Miocene Epoch (between 23.7 and 5.3 million years ago), has been subject to a general elevational movement. The shoulders of the rift valleys have risen intermittently to produce highlands on which lavas that have been ejected from fissures in the Earth's surface have in some instances added considerable height. The most dramatic uplift is that of the Ruwenzori, the only East African mountains that are not volcanic. The ancient plateau surface of gneisses and schists was upfaulted on the west and upwarped on the east. Movements along the faults continue, and the Ruwenzori system is an important earthquake epicentre.

Kilimanjaro is a volcano of complex structure and alkaline lavas situated at an intersection of fault lines. Shira was the first volcano of the group to become inactive, followed in turn by Mawenzi and Kibo. The latter retains its caldera—1.5 miles in diameter and 600 feet deep—within which there are found successive inner cones and craters as well as fumaroles (holes or vents that emit gases).

The long-extinct volcano of Mount Kenya has been much denuded, and the highest peaks consist of the crystalline nepheline-syenite (a granular rock of alkalic feldspar, nepheline, and other minerals), which plugged the former vent. Around this core are gently dipping lavas, agglomerates, and tuffs.

Mount Elgon is part of the Eastern Volcanics in Uganda, which consist of soda-rich lavas and associated fragmental

tuffs and agglomerates. The Western Volcanics are represented by the Virunga Mountains, of which Nyamulagira and Nyiragongo have been active during the 20th century. Major eruptions occurred in 1938 and 1948 and during the 1970s, and on several occasions a lava stream has reached the shores of Lake Kivu.

Drainage. The Virunga Mountains separate the basins of the Nile and the Congo rivers and are the only East African mountains to form a divide of continental stature. The entire system of the Ruwenzori Range drains into the Semliki River, a tributary of the Nile. Because they are relatively young, the mountain systems present good examples of consequent drainage (that is, determined by the initial slope of the land) such as the radial system of Mount Elgon, in which streams radiate from a central area, and the parallel streams of the Aberdare dip slopes. The porous nature of volcanic materials often results in areas devoid of surface drainage.

Soils. The succession of soils is from the raw mineral type of the summit area, through the dark peaty loams of the Afro-Alpine zone and the strong brown loams of high organic content in the forest belt, to the ferruginous (iron-bearing) soils of the lower slopes. Volcanic material presents a range from the unaltered rock of the most recent eruptions to the well-developed fertile soils on surfaces that have been exposed for longer periods of time.

Climate. In a region of predominantly dry climate, the mountains are conspicuous as areas of high rainfall. Affected by the convergence of Indian Ocean and Atlantic airstreams, the Ruwenzori as a whole comprise the wettest and the cloudiest of the mountains, where moist conditions penetrate up to the peaks and about 80 inches (2,000 millimetres) of rain annually fall at 15,000 feet. Kilimanjaro, Mount Kenya, and Mount Elgon are affected by their position in relation to southeasterly and north-easterly airstreams. Below 10,000 feet they are wettest on their southeastern and southern sides, with annual total precipitation rising to 100 inches on Mount Kenya; they are driest on their northern flanks, with less than 40 inches of rainfall yearly. Rainfall decreases above a cloud ceiling at about 10,000 feet, especially on Kilimanjaro, where the Afro-Alpine zone is a veritable desert. On the western and southwestern slopes the diverted southeast trade winds are sucked up each of the mountains as westerlies, creating an increase of cloud and precipitation. At the summit of Mount Kenya, temperatures seldom rise above the freezing point, and above 14,500 feet precipitation mainly occurs in the form of snow.

Plant life. Vegetation in the East African mountains often occurs as a succession of altitudinal zones. This succession is well developed on Mount Kenya, where it

The plant life of Mount Kenya

emerges from the surrounding savanna (grassland with scattered bushes or trees) and begins on the lower slopes with a crescent of cultivated land. The montane forest extends upward from a lower limit of about 6,000 feet to 10,000 feet and includes giant trees, such as camphor and various figs, cedar, yellowwood, and the East African olive. From about 8,000 feet, the forest consists of montane bamboo, and at its upper limit parkland and low thicket fringe the succeeding zone of giant heather. At 11,000 to 12,000 feet, the heather zone gives way to the Afro-Alpine zone in which tree groundsel and the giant lobelia rise out of a ground vegetation of tussocky grassland and everlastings (composite plants, the flowers of which can be dried without loss of colour or form). Mosses and lichens survive up to about 15,000 feet, but bare rock and ice are exposed above that height.

The montane forest of Kilimanjaro is drier than that of Mount Kenya. Bamboo is virtually absent, although it is abundant on neighbouring Mount Meru, and there is no parkland zone. The heather zone is strongly represented, whereas the Alpine semidesert is poor in flowering plants. Mount Elgon reaches into the Afro-Alpine zone, as do the summits of the Aberdare Range. On the northwest of the Ruwenzori, the lower slopes touch upon the equatorial forest, and the vegetation is moister and more luxuriant than that of the eastern mountains. Above the bamboo forest and the wooded parkland, the Virunga Mountains extend into the heather zone and, in the three highest volcanoes, into the Afro-Alpine zone.

The Afro-Alpine vegetation of the East African mountains is unique. With the increase of temperatures in post-Pleistocene times (since about 10,000 years ago), the cold-loving plants retreated to the mountains, where they have been preserved and somewhat transformed. Despite the enormous distances that separate the mountains, plants in the respective Afro-Alpine zones are closely comparable. There are lobelia and *Alchemilla* (lady's mantle) species common to all the mountains, although the tree groundsel species are limited within neighbouring mountains. The phenomenon of gigantism is common, while dwarfism occurs at the highest altitudes.

Animal life. Elephants, rhinoceroses, buffalo, antelope, hyrax, bush pigs, and monkeys, including the black-and-white colobus, are among the main inhabitants of the montane forest. The bongo (forest antelope) and the giant forest hog have not been observed on Kilimanjaro, perhaps because of its lack of bamboo forest and its isolation from the mountains to the north. Mountain gorillas and golden monkeys live in the Virunga Range, and chimpanzees in the Ruwenzori. Trout have been introduced into the streams of the more accessible mountains.

Mammals of the upper forests, including the leopard and antelope such as the duiker and the eland, penetrate into the moorland and Afro-Alpine zones, where the hyrax and the groove-toothed rat are the most obvious inhabitants. Birds include the lammergeier (one of the largest birds of prey, resembling the eagle and vulture), the mountain chat (a songbird), and the scarlet-tufted malachite sunbird (a small, brilliantly coloured songbird). Animal life, like the vegetation, shows resemblances that suggest a retreat of its distribution from the surrounding plateaus to the montane islands of refuge.

The people. Population is confined to the lower slopes, with the upper limit of settlement at about 7,000 feet. Bananas and millet are common subsistence crops, and coffee is an important cash crop. On the southern and eastern slopes of Kilimanjaro the Chaga (Chagga) have long used an effective system of irrigation based on the ridge-and-valley relief of the mountain. High population densities among the Chaga are matched by those among the Kikuyu and related groups on the slopes of the Aberdare Range and around the southern and eastern margins of Mount Kenya. The Gisu have densely settled the western slopes of Mount Elgon below the forest zone.

Population density is high on either side of the northern nose of the Ruwenzori; the Konjo hillmen live mainly on the eastern flank of the range. The Pygmy Twa occupy the forests of the Virunga Mountains, the lower slopes of which are cultivated by the far more numerous Hutu.

The economy. *Mining, forestry, and agriculture.* Copper ore was formerly mined at Kilembe, Uganda, on the south-eastern flank of the Ruwenzori. Other mineral resources include tin deposits also southeast of the Ruwenzori, tungsten deposits in the Virunga Mountains in Uganda, and diatomite in the Aberdare Range.

The closed forests are mainly under forest reserve and are classed as presently productive of timber. The most important output of sawn wood has come from the more accessible mountains of Kenya and Tanzania, where cedar, podo (or yellowwood), and camphorwood are among the principal timbers; the quantities produced, however, are small. Land cleared for cultivation in the lower part of the forests forms rich agricultural zones in which a considerable variety of crops—including coffee, tea, wheat, pyrethrum (a chrysanthemum used in the production of insecticides), bananas, millet, root crops, and vegetables—may be grown. Cattle are raised on the northern slopes of Mounts Kenya and Elgon and on Kilimanjaro. The narrow agricultural belt could be widened, and there has been a tendency for the extension of cultivation into lower altitudes by the use of irrigation.

Tourism. The mountains are an important tourist attraction. Kilimanjaro National Park covers the mountain from 6,000 feet to the summit, and other parks include Mount Kenya above 10,200 feet, the moorland zone of the Aberdares, and a sector of the Kenya portion of Mount Elgon. In the Uganda section of the Virunga Mountains, the Kigezi Gorilla Game Reserve is situated on the northern slopes of Mounts Muhavura and Mgahinga (Gahinga). In the Rwanda and Zaire portions of the Virunga Mountains, gorillas are protected, respectively, in the Volcanoes National Park and the Virunga National Park.

Transportation. The Ruwenzori form a barrier to east-west transport, and road connections between Uganda and Zaire pass south of the range. The Mau Escarpment and the Aberdare Range deflect the main roads to their northern and southern flanks, but each is crossed by a secondary road. The Nyeri col between the Aberdares and Mount Kenya is used as a gateway to the north. There are circular routes around Mounts Kenya and Elgon, and the bases of all the mountains are reasonably accessible.

Study and exploration. In 1848 the snow-covered summit of Kilimanjaro was observed by the German missionary Johannes Rebmann, and the following year Johann L. Krapf obtained a view of the snows of Mount Kenya. In 1888 the Welsh explorer Henry Morton Stanley glimpsed the Ruwenzori through a break in their cloud cover and equated them with the Mountains of the Moon of Ptolemy.

A number of expeditions on Kilimanjaro preceded that of 1889, in which the German geographer Hans Meyer conquered the summit of Kibo. Partial ascents of Mount Kenya were made before the British geographer Halford John Mackinder reached the summit of Batian in 1899. The Ruwenzori awaited the expedition of Luigi, Duke d'Abruzzi, in 1906 for the conquest of their major peaks, and in 1907–08 Adolf Friedrich, Duke of Mecklenburg, made a comprehensive survey of the Virunga Mountains. The southern side of Elgon was visited in 1883 and the caldera was traversed in 1890; in 1911 Wagagai was climbed. In 1932 a Belgian scientific mission explored the western slopes of the Ruwenzori, climbing several peaks.

Since 1931, aerial photography has assisted in the production of excellent maps of the major mountains and their glaciers. Under the stimulus of the International Geophysical Year of 1957–58, glaciological expeditions were mounted on the Ruwenzori, Mount Kenya, and Kilimanjaro.

Kilimanjaro, Kenya, and Ruwenzori are names of African origin; the first two are of somewhat uncertain meaning, and Ruwenzori may come from Nyoro words meaning "place of rain." Elgonyi was the Masai name for Elgon, but the Gisu name Masaba remains current in the Bantu languages. The names Kibo and Mawensi are of African derivation, and the highest peaks of Mount Kenya were named for Masai chiefs. With one exception, Ensonga, the major mountains and peaks of the Ruwenzori have European names, while Virunga nomenclature is African.

ITURI FOREST

The Ituri Forest is an area of dense tropical rain forest that lies on the northeastern lip of the Congo River basin in the central African nation of Zaire. Situated between 0° and 3° N latitude and 27° and 30° E longitude, the precise geographic limits of the Ituri are poorly defined, especially along its southern and western extensions. The Ituri is bounded to the north and northeast by savanna and in the east by the fertile highlands of the Western Rift Valley, while to the south and west it is contiguous with the lowland rain forest, where its rivers drain into the Congo (Zaire) River. The total area of the Ituri Forest is approximately 24,300 square miles (62,900 square kilometres). The forest, which is inhabited by both Bantu-speaking and Pygmy peoples, owes its name to the Ituri River, which flows east-west across the forest into the Aruwimi River and thence to the Congo.

For map coverage of the Ituri Forest, see below *Congo River*.

Physical features. *Physiography.* The magnificence of the tropical rain forest of the Ituri cannot help but inspire the modern-day observer with the same poetic enthusiasm displayed by the famous Welsh explorer Henry Morton Stanley when he described his crossing of the area in 1887–88. The trees of the forest range in size from small saplings just inches in diameter to gigantic hardwoods reaching to heights of 170 feet (52 metres). Like the pillars of a Gothic cathedral, these giant trees are buttressed; roots run down their sides and extend great distances across the forest floor, making the ground a labyrinth of roots that anchor the trees and grab scarce nutrients from the shallow forest soil. In places where the high canopy is nearly continuous, only small, elusive patches of sunlight reach the forest floor. The lack of light at lower levels is accentuated by the darkness of the foliage of the few shrubs and small trees that can grow under such shaded conditions. Where gaps occur in the upper canopy, herbaceous plants with long leaves resembling those of the banana plant take advantage of the available light and grow in dense stands. In many places the forest has been disturbed, either by human activity or by natural treefalls that cut large swathes through the canopy and open up the forest to the strong equatorial sun. There, the vegetation near the ground is a dense tangle of nettles, creepers, and competing species of fast-growing, short-lived trees, which make walking difficult if not impossible. Everywhere on the ground there is a profusion of fallen nuts and fruits, some as large as basketballs and many partially eaten by monkeys, antelope (duikers), and rodents. During certain seasons the air is filled with the nectar of numerous species of flower, including many epiphytes, which cling to the surface of other plants and draw their sustenance from the air. Always there is the sound of myriad insects. Cicadas perch on tree trunks and emit an irritating buzz that seems designed to drive any intruder to madness. Army ants advance in columns, audibly cracking the bodies of their insect prey. Seemingly endless lines of migrating butterflies flutter through the understory and sometimes congregate in colourful displays along streambeds. The buzzing of bees, busily plying the treetops in search of sweet nourishing nectar, is ever present. While magnificent, the forest with its constant high humidity and dark interior may seem oppressive to some. Certainly Joseph Conrad thought so when he referred to the forest as the “heart of darkness.” But the overwhelming impression for even the most squeamish visitor is not of darkness, not of oppressive gloom, but of life in its most vibrant and exciting form.

The Ituri Forest varies in altitude between 2,300 feet (700 metres) in its southern portions to 3,300 feet in the north. The topography is gently undulating in the south, but in the north there are frequent outcroppings of smooth granite that rise several hundred feet above the forest.

Climate and drainage. Steeped in the tannin-rich leaves covering the forest topsoil, the water flowing in the numerous streams that drain the Ituri is the colour of strong tea. Besides the Ituri River itself, there are many broad streams that flow generally from east to west. The most notable are the Nepoko in the north, the Epulu and Nduye in the

centre, and the Ibina in the south. None of these rivers is navigable, even by pirogue, for more than a few miles. The streams are fed by rains that are highly variable from month to month and from year to year. Average annual rainfall is 75 inches (1,900 millimetres), and there are approximately 2,000 hours of sunshine per year. Average temperature at lower elevations is 88° F (31° C). There is a dry season that lasts roughly from December through February, when less than 7 inches of rain normally falls. By the end of the dry season humidity within the forest is reduced, and the smaller forest streams become dry. The heaviest rains fall in October and early November; rivers overflow their banks, and large areas of the forest become flooded, making walking through the forest or driving on the few available roads extremely difficult.

Soils. The soils of the Ituri Forest developed from granites, gneisses, and metamorphosed rock of Precambrian age. In most places the soil is sandy clay or sandy clay loam, ranging in colour from reddish brown through ochre to yellowish brown and even white. The soils are acidic, and the layer of humus is thin. If exposed to the strong equatorial sun and high rainfall, as when the forest vegetation is cleared by Bantu farmers, the soil deteriorates rapidly, recovering only if it is again taken over by secondary forest. Traditionally, farmers have shifted their cultivation sites to allow the fragile soils to regenerate.

Plant and animal life. The climax-forest vegetation left undisturbed by human occupation is characterized by three dominant species of tall, hardwood legumes in the subfamily Caesalpinioidae. In the south and west *Gilbertiodendron deweveriei* dominates and can constitute 90 percent of the standing vegetation. The regions of the forest dominated by only a few plant species have less abundant and diverse animal life than the other, more botanically mixed areas, such as in the north and east. There, *Cynometra alexandrii* and *Brachystegia laurentii*, which together comprise less than 40 percent of the canopy, are interspersed with numerous other tall species (e.g., *Albizia*, *Celtis*, and *Ficus*).

For many generations, people residing in the Ituri have been practicing a form of agriculture that entails clearing and burning the forest, growing their crops, and then moving after several years to allow the forest to regenerate during a long fallow period. This method of shifting slash-and-burn cultivation has created a patchwork of climax vegetation interspersed with various successional stages of secondary forest on the sites of old gardens and abandoned villages. Some areas are a tangle of lianas and shrubs beneath emerging hardwood trees, while others are in less-advanced stages of succession, with large stands of umbrella trees (*Musanga cecropioides*). These various sereal patches—combined with river valleys, swampy waters, rock outcroppings, and the most recent village and garden clearings near the roads—produce a mosaic of diverse habitats that provide cover and food for the greatest abundance of mammals in forested Africa.

Situated near the forest-savanna edge, Ituri fauna include not only species typical of the African equatorial forest but also forms, such as the hyena, that are usually found on the open savanna. The most notable species is the forest giraffe, called okapi, which is endemic to the Ituri. Numerous forest antelopes include five species of duiker, the water chevrotain, and the pygmy antelope. Leopards, genets, and mongooses are the main carnivores. The elephant, buffalo, and bongo (a kind of antelope) are present in forms slightly smaller than their savanna relatives. The Ituri also supports the greatest diversity of primates of any comparable area in the world. The many monkeys include the terrestrial anubis baboon, as well as the leaf-eating imperial black and white colobus and the owl-faced monkey. The only ape is the chimpanzee, which is numerous. Hundreds of species of birds have been recorded, among which the shy Congo peacock, discovered in 1936, is perhaps the most famous.

Efforts to preserve the fauna and flora are largely confined to the Maiko National Park on the southern edge of the Ituri. The park offers some protection for the forest elephant, the okapi, the Congo peacock, the aardvark, and the chimpanzee, but poaching activities and destruction

groups of
Bambuti

of forest habitat seriously threaten these and other species both outside and inside the park boundaries.

The people. Based on their modes of subsistence, there are two principle kinds of inhabitants of the Ituri Forest: the village-living agriculturalists, most of whom are Bantu-speaking, and the nomadic hunting and gathering peoples, often referred to as Pygmies. Neither of these two groups is isolated from the other; in many parts of the Ituri villagers and hunter-gatherers practice a form of mutual interdependence, which includes the sharing of language and many customs.

The Pygmies. There are four populations of Pygmies, collectively called the Bambuti, living in the Ituri Forest. Each Pygmy population is associated with a different tribe of Bantu- or Sudanic-speaking agriculturalists. The Sua are associated with the Budu (Babudu) on the western edge of the Ituri, near Wamba; and the Aka, of whom few remain, are found with the Mangbetu in the north-west. The Efe, having the broadest distribution extending across the northern and eastern portions of the Ituri, are associated with the Sudanic-speaking Mamvu and Lese (Walese). The Mbuti live with the Bila (Babila) in the centre of the forest.

The Bambuti hunt and gather forest resources (meat, honey, fruits, nuts, caterpillars, termites, and mushrooms), which they consume themselves or trade to their neighbouring agriculturalists. In return for these forest products, the Bambuti receive agricultural foods, cloth, pots, pans, ax blades, salt, and other material items not available in the forest. In general, the subsistence activities of men consist of hunting mammals and gathering wild honey. Women supply most of the calories by gathering nuts, fruits, and tubers in the forest or by working for the agriculturalists in the gardens and receiving food as payment.

The Bambuti divide themselves into patrilineal clans, each clan numbering between 10 and 100 members and having one area of forest to which it loosely claims exclusive rights. Marriage occurs through "sister exchange," whereby a prospective husband must give a female clan member in marriage to the wife's clan before a marriage is fully recognized.

In order to hunt and gather in the forest effectively, the Bambuti must remain mobile. They live in beehive-shaped huts, which they can construct in a matter of hours, and they move their camps approximately every three weeks to take advantage of the changing position of edible plants and animals. The Bambuti have few material possessions, no inherited offices or wealth, and no institutionalized headmen or chiefs.

Different Bambuti groups use different technologies to hunt in the forest. The Efe hunt monkeys and forest antelope using bows and arrows, and for large game like

the buffalo, giant forest hog, and elephant they hunt with spears. The Mbuti use only nets, with which they hunt antelope and other small mammals.

The Bambuti are highly skilled musicians, and singing and dancing are important components of their life. Storytelling is highly developed and widely respected by all members of the society. The forest figures prominently in all Mbuti ritual and myth.

The village-living agriculturalists. People practicing shifting cultivation have been present in the Ituri for 2,000 years or more. Most of these peoples, including the Bila, Budu, and Ndaka, speak one of the numerous Bantu languages spoken throughout sub-Saharan Africa, but others, such as the Mamvu and Lese, speak tonal Central Sudanic dialects. In general, the agriculturalists live in small villages with 10 to 150 residents, all members of the same patrilineal clan. Houses are constructed of saplings plastered with mud and leaf thatch for roofing. When Stanley traversed the Ituri, many villages were fortified and distributed more or less evenly throughout the forest. Disputes that sometimes escalated into armed conflict occurred between clans, and people were afraid to travel any great distance from their own villages. Between 1920 and 1940, the Belgian colonial administration created chiefdoms, imposed peaceful relations, constructed roads, and coerced people to move their villages and gardens to the roadsides, where most remain today.

The staple crops of the agriculturalists are cassava and bananas, but they also raise for their own consumption beans, sweet potatoes, a variety of squashes, oil palms, and tobacco; rice, peanuts, and coffee serve as cash crops. Livestock raising is limited to goats and poultry. The agriculturalists also fish, and during the dry season they may camp in the forest to dam up forest streams. They also hunt using traps and snares, which are usually placed within short walking distance of their clearings.

Villager-Bambuti relations. Each clan of Bambuti is associated with a specific clan of villagers, and individual Bambuti have close economic and ritual ties to individual villagers. Such close dyadic relations are often passed from one generation to another, creating a deep sense of kinship between Mbuti and villager families. While they spend most of their time in the forest, Bambuti rarely reside more than an eight-hour walk from "their" villagers, facilitating trade and social relations. While the Bambuti rely upon the villagers for starchy food crops and a few material possessions, the villagers profit by the Bambuti's skill at supplying highly prized forest resources, namely meat and honey. Bambuti also supply much needed labour around the times of planting and harvest, and they provide ritual and curative functions regarded as crucial by the villagers.

crops

The economy. The forest has not played a large part in the Zairian national economy. Only a fraction of its area is exploited for timber because of difficulty of access. A few gold mines operated before the country gained independence, but extraction is now largely restricted to panning by individuals. Cotton growing has all but disappeared. Oil palm cultivation has declined to such an extent that the area is a net importer of palm oil. The larger coffee plantations are being replaced by small independent planters. An illicit ivory trade prospers, despite rapidly declining elephant populations. There are attractions for a tourist industry, but transportation and hotel facilities are poor or absent.

Access to the Ituri Forest is extremely difficult. There are no public transportation facilities. Rivers and streams are unnavigable, and the few existing roads are all dirt and often in poor repair. From the southeast, entrance to the forest can be made from Goma, which lies about 125 miles to the south on the northern shore of Lake Kivu, or from Bunia, which is some 60 miles to the east. From the west the best road is from Kisangani through Nia-Nia.

Study and exploration. The Egyptians knew of the existence of the Pygmies; Pepi II Neferkare, last king of the 6th dynasty (c. 2325–c. 2150 BC), had Pygmies present in his court, and they were depicted on Egyptian pottery some 4,000 years ago. The German botanist Georg Schweinfurth, arriving in the Ituri in 1869 from the north, was the first European to see and write about the Mbuti (*The Heart of Africa*; 1873). Stanley was the first to cross the forest from west to east, following essentially the same route as the present Kisangani to Bunia road. In the 1930s the Jesuit missionary Paul Schebesta performed the first anthropological studies of the people of the Ituri. Since then, many aspects of the behaviour, ecology, and growth and demography of the Bambuti and their villager neighbours have been studied by anthropologists from the United States, Europe, and Japan. (Je.-P.H./R.C.B.)

KALAHARI

The Kalahari is a large, basinlike plain of the interior plateau of southern Africa. It occupies almost all of Botswana, the eastern third of Namibia, and the northernmost part of the Cape of Good Hope province of South Africa. In the southwest it merges with the Namib, the coastal desert of Namibia. The Kalahari's longest north-south extent is roughly 1,000 miles (1,600 kilometres), and its greatest east-west distance is about 600 miles; its area has been estimated at some 360,000 square miles (930,000 square kilometres).

Physical features. *Physiography and geology.* The Kalahari is a featureless, gently undulating, sand-covered plain, which everywhere is 3,000 feet (900 metres) or more above sea level. Bedrock is exposed only in the low but vertical-walled hills, called kopjes, that rarely but conspicuously rise above the general surface. Aside from the kopjes, three surfaces characterize virtually all of the Kalahari: sand sheets, longitudinal dunes, and vleis (pans).

The sand sheets appear to have been formed during the Pleistocene Epoch (1,600,000 to 10,000 years ago), and they have been fixed in place since then. In some areas they appear to have been of fluvial origin, the result of sheet flooding in times of much greater precipitation, but by far the greater part of them were wind-formed. The sheets occupy the eastern part of the Kalahari. Their surface elevation varies only slightly, with relief measured in tens of feet per mile. The depth of the sand there generally exceeds 200 feet. In many areas the sand is red, the result of a thin layer of iron oxide that coats the grains of sand.

The entire western Kalahari is characterized by long chains of dunes, oriented roughly to the north or northwest. The dunes measure at least 1 mile in length, several hundred feet in width, and 20 to 200 feet in height. Each dune is separated from its neighbour by a broad parallel depression locally called a *straat* ("street," or "lane"), because each constitutes the easy way to travel.

Vleis, or pans, are the terminal features of desert drainage systems, the "dry lakes" at the end of ephemeral streams. Many are remnant features from an earlier period of greater precipitation. Very little water ever flowed to the

sea from the Kalahari. Rather, each stream ended its course in a slightly lower depression from which there was no outlet. There, as the stream dried up, the fine silt particles carried in suspension by the sluggish stream were deposited along with soluble calcium minerals and salts precipitated out of the evaporating water. The results are pans—flat surfaces devoid of vegetation that are gleaming white when dry, hardened by the cementing action of the soluble minerals, and, on occasion, covered by a shallow layer of standing water. Where the salt content is low, pans may become covered with grasses after a rain.

Drainage. In the southern and central parts of the Kalahari, surface water is found only in small, widely scattered waterholes, and surface drainage is nonexistent. Nearly all of the rain that falls disappears immediately into the deep sand. Some is absorbed by the underlying rock strata; some is drawn to the surface by capillary action and evaporated into the air; and some, lifted from the depths by tree roots, is transpired from leaf surfaces. A small amount, landing on nonsandy surfaces, may flow short distances into pans, but this occurs only immediately after the infrequent rains. In some parts of the central and southern Kalahari, extensive ancient drainage systems have been detected—some on the ground and others by way of aerial photographs. None of these operate today, even in the wettest of years.

In the northern Kalahari an extraordinary drainage system prevails. During the summer heavy rains fall on the uplands of central Angola, far to the northwest of the Kalahari. Large amounts of runoff water feed a number of south-flowing streams, which merge to form the Okavango and Cuando (Kwando) rivers. The Okavango flows to the southeast and into the northernmost portion of the Kalahari, eventually breaking up into a number of distributary channels and feeding the vast area of swamps in northern Botswana. After an abnormally wet rainy season in Angola, excess water fills the swamps and overflows, filling Lake Ngami farther to the south, and flows eastward through the Boteti River into Lake Xau and the Makgadikgadi Pans. Similarly, the Cuando River flows south from Angola and partly into a northeastern extension of the same swamps. Thus is created the paradoxical situation of an area with an extensive excess of water in a region chronically short of water.

Soils. Soils in the Kalahari are largely based on sand, are reddish in color, and are low in organic material. Chemically, they are relatively alkaline, and they are extremely dry. In and near the pans, the soils tend to be highly calcareous or saline, and frequently they are toxic to most vegetation.

Climate. Traditionally, an area was classed as desert if it received less than 10 inches (250 millimetres) of rain annually. A more accurate definition of a desert is a region in which the potential evaporation rate is twice as great as the precipitation. Both of these criteria are applicable to the southwestern half of the Kalahari. The northeastern portion, however, receives much more rainfall and, climatically, cannot qualify as a desert; and yet, it is totally lacking in surface water. Rain drains instantly through the deep sands of the area, which creates a situation of edaphic drought (*i.e.*, soil completely devoid of moisture).

Moisture-bearing air is derived from the Indian Ocean, and precipitation is greatest in the northeast (with a mean annual precipitation of more than 20 inches) and declines toward the southwest (less than 5 inches on the southern fringe of the Kalahari). Precipitation, however, is highly variable. Most of the rain comes as summer thunderstorms, with great variation from place to place and from year to year. Winters are extremely dry; humidity is very low, and no rain falls for six to eight months.

Great ranges in both diurnal and seasonal temperatures are the rule, the result of the Kalahari's relatively high altitude and predominantly clear, dry air (allowing strong insolation heating in daytime and great radiational heat loss at night). As a result, shade temperatures often reach 110°–115° F (43°–46° C) on summer days but drop to 70°–80° F (21°–27° C) on the same nights; temperatures on winter nights commonly drop to freezing and may go as low as 10° F (–12° C).

Transportation

Vleis

Temperatures

Plant life. The presence of a deep sand cover over most of the area greatly affects the vegetation that grows there. Shallow-rooted plants cannot survive on a perennial basis, although annuals that grow very rapidly after a good rain may be able to sow seeds that will endure until the next good rainy season. Trees with roots deep enough to reach permanently moist sand levels do well.

The southwestern Kalahari, with its very low precipitation, has few trees or large bushes—only scattered xerophytic (drought-tolerant) shrubs and short grasses. The central Kalahari, with more rain, has scattered trees (several species of *Acacia*) and some shrubs and grasses. The northern Kalahari does not have the appearance of a desert at all. It has open woodlands, palm trees growing among thorn brush, and forests of both evergreen and deciduous trees that grow to heights of 50 feet and yield some species suitable for timber; one of the largest and most unusual of these trees is the baobab. The Okavango Swamp supports a dense growth of reeds, papyrus, pond lilies, and other water-loving plants.

Animal life. The animal life of the Kalahari is also richer and more varied in the north than in the south. Yet even in the arid south, many individuals of several species stay for long periods of the year despite the absence of surface water. The principal species found in the south are springbok, gnu (wildebeest), and hartebeest—all of which occasionally are present in great herds—gemsbok (oryx), eland, and many smaller nongregarious species, such as kudu (in areas of denser brush), steenbok, and duiker.

Animals Animals © Anthony Bannister

Springbok in the Kalahari Gemsbok National Park, Cape of Good Hope, S.Af.

The northern Kalahari supports a considerable population of giraffes, zebras, elephants, buffalo, and antelopes (roan, sable, *tsessebe*, and impala); predators such as lions, cheetahs, leopards, wild hunting dogs, and foxes; other large and medium-sized mammals, such as jackals, hyenas, warthogs, baboons, badgers, anteaters, ant bears, hare, and porcupines; and numerous small rodents, several types of snakes and lizards, and a wealth of birdlife. (R.F.Lo.)

The people and the economy. The Kalahari is inhabited primarily by Bantu-speaking Africans and Khoisan-speaking San, with a small number of Europeans.

The Bantu-speaking peoples. The Bantu-speaking peoples—the Tswana, the Kgalagadi, and the Herero—are relative newcomers to the Kalahari. In the late 18th century the Tswana spread west from the Limpopo basin into

the northern and eastern Kalahari; the Kgalagadi moved north and west into the southern and western Kalahari; and the Herero refugees from the German colonial wars in South West Africa (Namibia) fled east into the western and northern Kalahari at the beginning of the 20th century.

Those in the remoter parts of the Kalahari who are unaffected by mining or other industry live in villages of between 200 and 5,000 people. Housing is mostly of the traditional type: single-roomed huts with mud walls and thatched roofs. Water is the limiting factor, confining settlement to places situated near wells or boreholes with potable water.

Cattle, the basis of the economy, are kept on the outskirts of villages, or at distances of up to 50 miles away. Except in the Ghanzi District of Botswana—where most of the livestock raising is done on private ranches, many of them owned by Africans—grazing lands are state-owned, and their use is regulated by local government councils. Wells and boreholes are owned by the councils, syndicates of cattle owners, or private individuals; year-round cattle grazing is limited to their vicinity. In summers of above-average rains, however, pastoralists may trek with their stock to remote pastures, where for a short time water may occur in pools. Cattle and goats feed upon a small range of the available vegetation. Since effective pasture management is little practiced, the grazing of these animals is highly destructive. Pasture loss and subsequent desertification are serious threats to the ecology of the Kalahari. Cattle are prized beyond their economic value, as their ownership is a measure of social status and personal worth. Thus, the desire to possess more cattle puts an increasing load on diminishing pasture, leaving it no chance for recovery. The traditional dangers to livestock—drought, disease, internal parasites, and wild predators—have diminished markedly as more boreholes have been sunk, veterinary care improved, and indigenous fauna have grown scarcer. In addition, wealthier cattle owners have improved their herds by introducing better stock and practicing scientific breeding.

Goats furnish most of the meat and milk for home consumption, and nearly all households cultivate crops of corn (maize), sorghum, and pumpkins. Because of the threat of drought, more crops fail than are successful. Wild food plants and the meat of game animals are important components of diet in the smaller and more remote villages. All villages have trading stores or are visited by hawkers who sell foodstuffs and other commodities.

All but the smallest villages have state-run primary schools, which are attended by the great majority of children, although few proceed to secondary education. State-run health clinics and hospitals in the larger villages supplement the services of herbalists and diviners.

Riding horses and donkeys are the usual means of local travel. Trucks belonging to traders or to the mine labour recruiting agency are used for longer journeys.

Large diamond deposits were discovered in Botswana soon after the country's independence, and the opening of the diamond mine at Orapa in 1971 marked the beginning of the development of mining activities in scattered locations of the Kalahari. In addition, tourism and the sale of handicrafts have become economically important.

San. The San—or Basarwa, as they are called in much of the region—are now either clients of Bantu-speaking pastoralists and work at cattle posts in return for support or they are employees of the cattle ranches of the Ghanzi District or are dependents of such employees. Few San still follow their traditional pattern of hunting and gathering. Many have been resettled by the government of Botswana from their traditional homes in the Central Kalahari Game Reserve to new villages built outside the reserve.

Although all San traditionally were hunter-gatherers, there were significant cultural and social differences between groups. For example, a number of groups had long-standing clientships with Bantu-speaking stockowners, while other groups lived—until the 1970s—solely as autonomous foragers. Of these latter peoples, the Kung (*Kung*), */xong*, and *G/wi* tribes (the “/” and “w” representing click sounds) were intensively studied. While each group was distinct, the *G/wi* of the Central Kalahari Game

Cattle
raising

allowed ranching blocks in the 1890s. Until the 1960s they led a life of isolation and poverty, but since then they have been able to gain ownership of the land and improve their living conditions. Most other whites in the Kalahari are government employees or are engaged in private enterprise. (G.Si.)

Transportation. Because of its sparsely populated expanse, the Kalahari is served by infrequent roads and tracks, the majority of which are passable only by trucks or four-wheel drive vehicles. Maintained roads connect administrative centres, major habitations, and marginal farming areas in the south, southwest, and northwest. Constructed roads now link eastern Botswana with the Okavango Swamp and with mining developments south of the Makgadikgadi Pans.

Study and exploration. The Kalahari's lack of surface water and deep sands constituted a major obstacle to early travelers. The Scottish missionary and explorer David Livingstone, with assistance from local peoples, traversed the Kalahari in 1849 with great effort by utilizing local waterholes. In 1878–79 a party of Boers in the Dorsland ("Thirstland") Trek crossed the Kalahari from the Transvaal to central Angola by a circuitous route, losing along the way about 250 people and 9,000 cattle, largely from thirst. The introduction of motor vehicles in the 20th century greatly improved transport into the Kalahari, but even as late as the 1950s large areas were virtually inaccessible and were never visited by outsiders. By the mid-1970s, however, vehicle mobility had improved to such a degree that the whole of the Kalahari had been opened to study, hunting, and tourist expeditions.

NAMIB

The Namib is a cool coastal desert extending for 1,200 miles (1,900 kilometres) along the Atlantic coast from Namibe (formerly Moçâmedes) in Angola southward across Namibia to the Olifants River in the Cape Province of South Africa. It reaches inland 80 to 100 miles to the foot of the Great Escarpment. The southern portion merges with the Kalahari on the plateau atop the escarpment. Its name is derived from the Nama language, implying "an area where there is nothing."

The Namib is arid and is almost totally uninhabited, except for several towns. It is important because of the trade routes that cross it, its mineral deposits, the fisheries of the bordering sea, and its increasing utilization for recreational purposes.

For map coverage of the Namib, see above *Kalahari*.

Physical features. The Namib is divided into three successive north-south-trending strips: the very narrow coastal region along the Atlantic, strongly subject to marine influences; the Outer Namib, occupying the rest of

the western half of the desert; and the Inner Namib, constituting the eastern portion. The boundaries between them consist of broad transition zones.

Physiography. The desert basically consists of a relatively smooth platform of truncated bedrock of various types and ages. Mica-schist and other metamorphics and granite and similar intrusives predominate. The platform rises gradually from the coast to about 3,000 feet (900 metres) at the foot of the escarpment. Scattered isolated mountains rise steeply and abruptly above the platform, and in the northern half several streams have carved deep, steep-walled gorges into it.

In much of the southern half of the desert the platform is surmounted by a vast expanse of sand—yellow-gray near the coast and brick-red inland—which is derived from the Orange River and from other rivers that flow westward from the escarpment but never reach the sea. The dunes run in lines from north-northwest to south-southeast, with individual dunes having lengths of 10 to 20 miles and reaching heights of 200 to 800 feet. The troughs between these lines of dunes are interrupted by smaller transverse dunes. The extreme southern coastal area consists of wind-scoured bedrock and a few rapidly moving crescent-shaped barchans (*i.e.*, dunes convex to the wind). The northern third—the Kaokoveld region—consists of gravel plains and rock platforms occurring between scattered, rugged mountains, interspersed with a few large dune fields.

Drainage. Being an almost rainless area, the Namib has a poorly developed and fragmentary drainage pattern. Water from the interior plateau flows through or into the desert. In the northern half the larger streams reach the sea, but between the Kuiseb and the Orange rivers, every stream terminates in a vlei (salt pan or mud flat) against or among the dunes.

A portion of the water of major streams seeps through the sands of the streambeds. The underflow of the Kuiseb River has been tapped 25 miles inland to provide water supplies for Walvis Bay and Swakopmund. A pipeline 80 miles long supplies Lüderitz with water from the seepage of the Koichab, a stream that terminates in the dunes. Only the Cunene and the Orange rivers flow permanently on the surface. Other streams have surface flow only after heavy rainfall in the interior plateaus—they normally flow for no more than a few days in several years.

Soils. Large areas of the Namib are completely soilless, with bedrock at the surface. Other areas are covered with shifting sand. Soils that do occur are often highly saline, impregnated with gypsum, or cemented firmly by calcium carbonate, the latter forming a calcrete layer just below the surface. Arable soils in the Namib are limited to floodplains and the terraces of major rivers and are subject to occasional inundation.

Trek

Climate. The coastal area is almost totally rainless, yet its air is almost always at or near the saturation point. The cold Benguela Current flows northward along the coast, chilling the air above it and thus producing fog. This cool air moves inland as a southwest sea breeze, creating a temperature inversion about 1,000 feet thick, with fog below and hot, dry air above.

At the coast, there is little difference in temperature between day and night or between winter and summer. Temperatures are usually between 50° and 60° F (10° and 16° C). Along the inland margins, summer temperatures normally reach about 88° F (31° C); only in areas sheltered from the cooling sea breeze (lee sides of mountains and bottoms of canyons) do temperatures frequently approach those expected in low-latitude deserts—i.e., in excess of 100° F (38° C). Freezing temperatures occur occasionally along the inner edge of the desert. On a few days each year, usually in fall or spring, berg (or mountain) winds, blowing from the east, bring high temperatures (above 100° F), together with dry air and clouds of dust, across the desert to the coast itself. The rare rains occur usually as short-lived torrential thunderstorms.

Average annual precipitation at the coast is generally about 0.5 inch (13 millimetres), increasing inland, until it reaches 2 inches at the foot of the escarpment. In some years, however, no rain falls at all. Dew, on the other hand, is heavy and for some types of vegetation is more important than the rainfall. In the extreme south, some winter precipitation occurs from frontal storms passing farther south over the Cape region; on rare occasions, snow may fall on the higher southern mountains.

Plant life. Six vegetational regions may be identified in the Namib: (1) the coastal region, with highly succulent vegetation, which uses moisture derived from the fog, (2) the almost completely barren Outer Namib, (3) the steppes of the Inner Namib, which in many years are barren but which in wet years are covered with short grasses, both annual and perennial, (4) the dunes of the Inner Namib, which produce a surprisingly rich flora of bushes and tall grasses, (5) the larger river channels, along which large trees, particularly acacias, grow, and (6) the southern winter rainfall area, where a succulent bush growth occurs. A curious Namib plant is the *tumboa*, or *welwitschia* (*Welwitschia mirabilis*), whose two gigantic leaves sprawl over the surface of the ground from the crest of its huge root crown.

Animal life. The plains and dunes of the Inner Namib support large numbers of several varieties of antelope, especially gemsbok (oryx) and springbok, as well as ostriches and some zebras. Elephants, rhinoceroses, lions, hyenas, and jackals are found in the northern Namib, especially along the rivers that flow from the interior highlands to the Atlantic. The dunes of the Outer Namib provide habitats for various types of insects and reptiles, especially beetles, geckos, and snakes, but virtually no mammals. The shore area is densely populated by marine birds (notably flamingos, pelicans, and, in the southern part, penguins), as well as a few jackals, some rodents, and a few colonies of seals. Large quantities of guano are scraped annually from the rocks of several offshore islands.

The people and the economy. A few San roamed the Namib until early in the 20th century, gathering whatever was edible along the shore, hunting in the Inner Namib, and often depending for water upon the bitter juices of the *tsama* (tsamma) melon. A small number of Herero tribesmen continue to herd cattle and goats from waterhole to waterhole in the desert part of the Kaokoveld, living in their traditional manner. A few Topnaar Nama Khoikhoi also graze their sheep and goats on the riverine vegetation along the Kuiseb River. A great part of the Namib is now totally unused and unoccupied, the aboriginal people having left to adopt new homes and new ways of life. A few areas, however, are productive in some way.

The innermost steppes in the southern half of the desert are divided into private "farms" (ranches), which are operated by Europeans using native labour and are devoted to the raising of Karakul sheep; the wavy-haired pelts of newborn lambs of these sheep are used for fur coats in Europe.

Much of the central and northern Namib has been set aside for recreation and conservation. The Namib Desert Park in the central area is a desert range for flocks of antelope, zebra, and ostrich. A strip about 130 miles in length along the coast northwest of Swakopmund constitutes the National West Coast Tourist Area; within it is the Cape Cross Seal Reserve, which protects a breeding area. Farther north is the Skeleton Coast National Park, where entry is restricted in order to preserve the fragile desert environment.

A vast area stretching from the Kuiseb River to the Orange River on the South African border and reaching inland some 80 miles constitutes the Sperrgebiet, or "Forbidden Zone," to which all entry is strictly restricted because of the possible presence of diamonds there. Diamonds are extracted from alluvial beds near the coast by large-scale equipment, chiefly in the area near the mouth of the Orange River.

There are four cities on the Namib coast. Swakopmund, the summer capital for Namibia and a popular coastal resort town, still retains much of the atmosphere from the days when South West Africa was a German colony. From mid-December to mid-February many functions of the government are transferred from Windhoek to Swakopmund to escape the heat of the interior. Swakopmund has been greatly changed by the development of a large uranium mine located some 25 miles inland. Walvis Bay, just to the south of Swakopmund, is a coastal enclave belonging to South Africa that is surrounded by Namibia. It is a modern port city with a mixed population of Europeans, Coloureds, and Africans—the Africans consisting partly of Nama families from south-central Namibia but largely of male Ovambo from Angola and the northern part of Namibia, who have found employment at the port. The port serves as a base for fishing fleets that supply both shore canneries and cannery ships on the open sea. It is also the major transshipment port for Namibia. Lüderitz, a small town on a shallow, rock-strewn harbour, has a small trade with Walvis Bay and Cape Town and is the base of a crayfish (lobster) industry. Oranjemund, a company town of the Consolidated Diamond Mines, is a base for large-scale diamond mining in the alluvial gravels along the southern coast.

The Namib is crossed by rail lines and tarred roads, both from Walvis Bay-Swakopmund and from Lüderitz, which are integrated with the internal rail and road systems of Namibia and South Africa. Except for roads from Swakopmund north for about 130 miles, between Swakopmund and Walvis Bay, and from Lüderitz to Oranjemund, no improved roads exist along the coast, in the Kaokoveld to the northwest, or in the area between Walvis Bay and Lüderitz.

Study and exploration. cursory exploratory voyages were made along the coast from the 15th to 17th century, Walvis ("Whale Fish") Bay was used as a base for New England whaling ships in the early 19th century, and there were direct routes for traders and missionaries from Lüderitz and Walvis Bay into the interior. Otherwise, little was known of the Namib until the latter part of the 19th century. After South West Africa was established as a territory of Germany in the early 1890s, the German military began the detailed exploration and mapping of the desert. (R.F.Lo.)

Parks and reserves

Transportation

Vegetational regions

SAHARA

The Sahara is the largest desert in the world. Filling nearly all of northern Africa, it measures approximately 3,000 miles (4,800 kilometres) from east to west and between 800 and 1,200 miles from north to south and has a total area of some 3,320,000 square miles (8,600,000 square kilometres). The Sahara is bordered in the west by the Atlantic Ocean, in the north by the Atlas Mountains and Mediterranean Sea, in the east by the Red Sea, and in the south by a zone of ancient, immobile sand dunes aligned with latitude 16° N.

Physical features. *Physiography.* The principal topographical features of the Sahara include shallow, seasonally inundated basins (chotts and dayas) and large oasis depressions; extensive gravel-covered plains (serirs or regs);

Climate. The Sahara was established as a climatic desert approximately five million years ago, during the Early Pliocene Epoch. Since the Pliocene, the Sahara has been subject to short- to medium-term oscillations of drier and more humid conditions. Human activity seems to have contributed to the stability of the desert by increasing surface reflectivity and by reducing evapotranspiration. During the past 7,000 years cattle-based animal husbandry in the desert and along its margins apparently has contributed further to the maintenance of these conditions, and the climate of the Sahara has been relatively constant for 2,000 years. A noteworthy departure from existing norms occurred from the 16th to 18th century, the period of the so-called Little Ice Age in Europe: precipitation increased significantly along the tropical margin of the Sahara, in the desert itself, and perhaps along the northern margin as well. By the 19th century, however, a climate similar to that of the present was reestablished.

Two main climatic regimes

The Sahara is dominated by two climatic regimes: a dry subtropical climate in the north and a dry tropical climate in the south. The dry subtropical climate is characterized by unusually high annual and diurnal temperature ranges, cold to cool winters and hot summers, and two precipitation maximums. The dry tropical climate is characterized by a strong annual temperature cycle following the declination of the sun; mild, dry winters; and a hot dry season preceding variable summer rains. A narrow strip of the western coastal zone has a relatively cool, uniform temperature reflecting the influence of the cold Canary Current.

The dry subtropical climate of the northern Sahara is caused by stable high-pressure cells centred over the tropic of Cancer. The annual range of average daily temperatures is about 36° F (20° C). Winters are relatively cold in the northern regions and cool in the central Sahara. For the zone as a whole, average monthly temperatures during the cold season are approximately 55° F (13° C). The summers are hot. The highest temperature ever recorded was 136° F (58° C) at Al-'Aziziyah, Libya, on the northern margin of the Sahara. Daily temperature ranges are considerable during both the winter and summer months. Although precipitation is highly variable, it averages about 3 inches (76 millimetres) per year. Most precipitation falls from December through March. Another maximum occurs in August, characterized by thunderstorms. These storms can cause tremendous flash floods that rush into areas where no precipitation has fallen. Little precipitation falls in May and June. Snowfall occurs occasionally over the northern plateaus. Another feature of the dry subtropics are the hot, southerly winds that often carry dust from the interior. Although they occur at various times of the year, they are especially common during the spring. In Egypt they are known as the khamsin, in Libya as the ghibli, and in Tunisia as the chili. The dust-laden haboob winds of The Sudan are of shorter duration, chiefly occur during the summer months, and often usher in heavy rains.

The dry tropical climate to the south is dominated by the same high-pressure cells, but it is regularly influenced by the seasonal interaction of a stable continental subtropical air mass and a southerly, unstable maritime tropical air mass. The annual range in average daily temperatures in the dry tropical regions of the Sahara is approximately 31.5° F (17.5° C). Average temperatures for the coldest months are essentially the same as they are for the subtropical zone to the north, but the diurnal range is more moderate. In the higher elevations of the zone, the lows approximate those of more northerly, subtropical regions. For example, absolute lows of 5° F (−15° C) have been recorded in the Tibesti Mountains. Late spring and early summer are hot; high temperatures of 122° F (50° C) are not unusual. Although the massifs of the dry tropics often receive small quantities of precipitation throughout the year, the lowlands have a single summer maximum. As in the north, much of this rainfall occurs as thunderstorms. Precipitation averages are about five inches per year, occasionally including some snowfall in the central massifs. In the western margin of the desert the cold Canary Current reduces air temperatures, thereby reducing convective rainfall, but resulting in higher humidity and occasional fogs. In the southern Sahara the winter is the period of the

harmattan, a dry northeasterly wind laden with sand and other easily transported dust particles.

Plant life. Saharan vegetation is generally sparse, with scattered concentrations of grasses, shrubs, and trees in the highlands, in oasis depressions, and along the wadis. Various halophytes (salt-tolerant plants) are found in saline depressions. Some heat- and drought-tolerant grasses, herbs, small shrubs, and trees are found on the less well-watered plains and plateaus of the Sahara.

The vegetation of the Sahara is particularly noteworthy for its many unusual adaptations to unreliable precipitation. These are variously seen in morphology—including root structure, a broad range of physiological adaptations, site preferences, dependency and affinity relationships, and reproductive strategies. Many of the herbaceous plants are ephemerals that may germinate within three days of adequate rainfall and sow their seeds within 10 or 15 days of germination. Sheltered in the Saharan massifs are occasional stands of relict vegetation, often with Mediterranean affinities.

Prominent among the relict woody plants of the Saharan highlands are species of olive, cypress, and mastic trees. Other woody plants found in the highlands and elsewhere in the desert include species of *Acacia* and *Artemisia*, doum palm, oleander, date palm, and thyme. Halophytes such as *Tamarix senegalensis* are found along the western coastal zone. Grasses widely distributed in the Sahara include species of *Aristida*, *Eragrostis*, and *Panicum*. *Aeluropus litoralis* and other salt-tolerant grasses are found along the Atlantic coast. Various combinations of ephemerals form important seasonal pastures called *acheb*.

Animal life. Relict tropical fauna of the northern Sahara include tropical catfish and chromides found at Biskra, Alg., and in isolated oases of the Sahara; cobras and pygmy crocodiles may still exist in remote drainage basins of the Tibesti Mountains. More subtle has been the progressive loss of well-adapted, more mobile species to the advanced firearms and habitat destruction of humans. The North African elephant became extinct during the Roman period, but the lion, ostrich, and other species were established in the desert's northern margins as late as 1830. The last addax in the northern Sahara was killed in the early 1920s; serious depletion of this antelope has also occurred on the southern margins and in the central massifs.

Among the mammal species still found in the Sahara are the gerbil, jerboa, Cape hare, and desert hedgehog; Barbary sheep and scimitar-horned oryx; dorcas gazelle, dama deer, and Nubian wild ass; anubis baboon; spotted hyena, common jackal, and sand fox; and Libyan striped weasel and slender mongoose. Including resident and migratory populations, the birdlife of the Sahara exceeds 300 species. The coastal zones and interior waterways attract many species of water and shore birds. Among the species encountered in the interior regions are ostriches; various raptors; secretary birds, guinea fowl, and Nubian bustards; desert eagle owls and barn owls; sand larks and pale crag martins; and brown-necked and fan-tailed ravens.

Frogs, toads, and crocodiles live in the lakes and pools of the Sahara. Lizards, chameleons, skinks, and cobras are found among the rocks and dunes. The lakes and pools of the Sahara also contain algae and brine shrimp and other crustaceans. The various snails that inhabit the desert are an important source of food for birds and animals. Desert snails survive through aestivation (dormancy), often remaining inactive for several years before being revived by rainfall. (J.A.G.)

The people. Although as large as the United States, the Sahara (excluding the Nile valley) is estimated to contain only some 2.5 million inhabitants—less than 1 person per square mile (0.4 per square kilometre). Huge areas are wholly empty, but wherever meagre vegetation can support grazing animals or reliable water sources occur, scattered clusters of inhabitants have survived in fragile ecological balance with one of the harshest environments on earth.

Long before recorded history, the Sahara was evidently more widely occupied. Stone artifacts, fossils, and rock art, widely scattered through regions now far too dry for occupation, reveal the former human presence, together with

Adaptions of Saharan vegetation

Mammals

Early human occupation

that of game animals, including antelopes, buffalo, giraffe, elephant, rhinoceros, and warthog. Bone harpoons, accumulations of shells, and the remains of fish, crocodiles, and hippopotamuses are associated with prehistoric settlements along the shores of ancient Saharan lakes. Among some groups, hunting and fishing were subordinated to nomadic pastoralism, after domesticated livestock appeared in the Sahara almost 7,000 years ago. The cattle-herding groups of the Ténéré region of Niger are believed to have been either ancestral Berbers or ancestral Zaghawa; sheep and goats were apparently introduced by groups associated with the Capsian culture of northeastern Africa. Direct evidence of agriculture first appears about 6,000 years ago with the cultivation of barley and emmer wheat in Egypt; these appear to have been introduced from Asia. Evidence of the domestication of native African plants is first found in pottery from about 1000 BC discovered in Mauritania. The cultivators have been associated with the Gangara, the ancestors of the modern Soninke.

Archaeological evidence suggests that the Sahara was increasingly inhabited by diverse populations, and plant and animal domestication led to occupational specialization. While the groups lived separately, the proximity of settlements suggests an increasing economic interdependence. External trade also developed. Copper from Mauritania had found its way to the Bronze Age civilizations of the Mediterranean by the 2nd millennium BC. Trade intensified with the emergence of the Iron Age civilizations of the Sahara during the 1st century BC, including the civilization centred in Nubia.

The greater mobility of nomads facilitated their involvement in the trans-Saharan trade. Increasing aridity in the Sahara is documented in the transition from cattle and horses to camels. Although camels were used in Egypt by the 6th century BC, their prominence in the Sahara dates from only the 3rd century AD. Oasis dwellers in the Sahara were increasingly subject to attack by the Sanhaja (a Berber clan) and other camel-mounted nomads—many of whom had entered the desert to avoid the anarchy and warfare of the late Roman period in North Africa. Many of the remaining oasis dwellers, among them the Ḥarāṭīn, were subjugated by the nomads. The expansion of Islām into North Africa between the 7th and 11th centuries prompted additional groups of Berbers, as well as Arab groups wishing to retain traditional beliefs, to move into the Sahara. Islām eventually expanded through the trade routes, becoming the dominant social force in the desert.

Despite considerable cultural diversity, the peoples of the Sahara tend to be categorized as pastoralists, sedentary agriculturalists, or specialists (such as the blacksmiths variously associated with herders and cultivators). Pastoralism, always nomadic to some degree, occurs where sufficient scanty pasturage exists, as in the marginal areas,

on the mountain borders, and in the slightly moister west. Cattle appear along the southern borders with the Sahel, but sheep, goats, and camels are the mainstays in the desert. Major pastoral groups include the Regeibat of the northwestern Sahara and the Chaamba of the northern Algerian Sahara. Hierarchical in structure, the larger pastoral groups formerly dominated the desert. Warfare and raids (*ghazw*) were endemic, and in drought periods wide migrations in search of pasture took place, with heavy loss of animals. The Tuareg (who call themselves Kel Tamasheq) were renowned for their warlike qualities and fierce independence. Although they are Islāmic, they retain a matriarchal organization, and the women of the Tuareg have an unusual degree of freedom. The Moorish groups to the west formerly possessed powerful tribal confederations. The Teda, of the Tibesti and its southern borderlands, are chiefly camel herders, renowned for their independence and for their physical endurance.

In the desert proper, sedentary occupation is confined to the oases, where irrigation permits limited cultivation of the date palm, pomegranate, and other fruit trees; such cereals as millet, barley, and wheat; vegetables; and such specialty crops as henna. Cultivation is in small "gardens," maintained by a great expenditure of hand labour. Irrigation utilizes ephemeral streams in mountain areas, permanent pools (*gueltas*), foggaras (inclined underground tunnels dug to tap dispersed groundwater in the beds of wadis), springs (*ayn*), and wells (*bīr*). Some shallow groundwaters are artesian, but it is often necessary to use water-lifting devices such as the shadoof (a pivoted pole and bucket) and the animal-driven noria (a Persian wheel with buckets). To a limited extent diesel pumps have replaced these ancient means in more accessible oases. Water availability strictly limits oasis expansion, and, in some, overuse of water has produced a serious fall in the water level, as in the oases of the Adrar region of Mauritania. Salinization of the soil by the fierce evaporation, as well as burial by encroaching sand, are further dangers; the latter, as in the Souf oases of Algeria, necessitates constant hand labour in clearing.

The economy. Resources. During the century of colonial dominion over the Sahara, which lasted from the mid-19th to the mid-20th century, there was little fundamental change, except for military pacification; colonial powers were little interested in the economic development of what appeared to be an unpromising region. After World War II, however, the discovery of oil, in particular, attracted international interest and investment. Within a few years major discoveries had been made, particularly in mineral resources.

Metallic minerals are of considerable economic importance. Algeria possesses several major deposits of iron ore, and the reserves at Mount Ijill, in western Mauritania,

Pastoral
groups

Victor Englebert

Kerzaz oasis on Wadi Saoura, western Sahara, Alg.

are substantial; less extensive deposits have been found in Egypt, Tunisia, Morocco, Western Sahara, and Niger. Near Akjoujt, in southwestern Mauritania, lie substantial quantities of copper ore; extensive manganese deposits occur south of Béchar, Alg. Uranium is widely distributed in the Sahara and has been particularly important in Niger. A broad range of other economically significant minerals have been found in the Ahaggar, Aïr, Tibesti, and Eglab regions. Rich phosphate deposits exist in Morocco and Western Sahara, and smaller deposits have been found elsewhere.

Oil and gas reserves

Fuel resources include coal, oil, and natural gas. Sources of coal include anthracite seams in Morocco and bituminous fields near Béchar. Following the discovery of oil near I-n-Salah, Alg., after World War II, major reserves have been found in the Western Desert of Egypt, northeastern Libya, and northeastern Algeria. Minor reserves exist in Tunisia and Morocco, as well as in Chad and Niger in the south. Deposits of oil shale have also been discovered in the Sahara. Major fields of natural gas are exploited in Algeria, and minor fields exist in Egypt, Libya, and Tunisia.

As a result of geologic and oil prospecting, vast underground reserves of water have also been found in a number of sedimentary basins, mainly within sandstone formations. Some recoverable water is also present in surface sand formations.

Economic development of the desert, however, offers enormous difficulties and has not changed the traditional Sahara. Oil and ore extraction have brought modern technology and improved communications to scattered locations, but such activities provide limited opportunities for local employment. Although oil revenues offer the means for desert development, the more immediate and attractive returns possible in inhabited coastal regions tend to take priority. The underground water offers possibilities for major developments in both agriculture and industry; but exploitation on a large scale would be expensive. Heavy exploitation would also result in progressive depletion, and hydrological changes might increase the threat of locust plagues, as locusts congregate into swarms when food supplies are restricted, multiply, and then occupy larger areas when conditions improve.

The desert peoples have benefited little from mineral exploitation—perhaps indeed the reverse. The decline in nomadic pastoralism, started by pacification, has been accelerated by changing economic conditions and official settlement policies (for nomads are administratively inconvenient). Widespread environmental degradation further encourages the drift of nomads to oases and towns, with resultant overcrowding and poverty. High wages in the oil fields attract labour but disrupt traditional life, and the jobs are relatively few and impermanent. Of the traditional desert products—animal skins and wool, surplus fruits, salt—only dates (particularly the *daglet nour* of the northern oases) retain much commercial importance. Salt, although still extracted and sent south to the western Sudan region, now competes with cheap imported salt. Industrial occupations to relieve growing unemployment have as yet made little progress. As manufacturing costs increase in the advanced and overcrowded Western countries, however, the high costs of Saharan development may become more acceptable. It may be possible, for example, to utilize nuclear energy and more efficient solar energy converters to raise deep-seated water (and, if necessary, to remove the salt) for new settlements and to provide power for industries. Tourism has grown considerably since 1950, although the difficulties of transport and of providing accommodations has limited it largely to the Sahara's fringes.

The caravan routes

Transportation. Traditionally, travel in the Sahara was by camel caravan and was slow, arduous, and dangerous. To the hazards of losing the way, excessive heat, stifling sandstorms, and death by starvation—or more probably thirst—were added those of attack by raiders. Despite all this, trans-Saharan trade along caravan routes linking oases has persisted from very early times. Most of the principal routes were west of the Tibesti Mountains and tended to shift somewhat over time, although the easternmost of these—which ran northward from Lake Chad

to Bilma (now in Niger) and through the Fezzan region to Tripoli—was used continuously through the centuries. East of the Tibesti Mountains oases are few, but the *darb al-arba'in* ("road of the forty [days]"), west of the Nile, was a former slave route. Gold, ivory, slaves, and salt were major items of trade in the earlier days, but today camel caravans have almost ceased, except for a residual trade in salt from Mount Ijill, Bilma, and Taoudenni, Mali. The main routes remain in use, however, by specially equipped motor trucks, often traveling in convoys. Year by year modern highways are extended further along the ancient trade routes into the desert. The French initiated a trans-Saharan bus service, which still operates. Off of the main routes a network of recognized tracks are motorable, with care; but in the open desert four-wheel drive is virtually essential, with at least two vehicles, ample spares, and large emergency supplies of fuel, food, and water—particularly in summer, when special regulations apply to all travelers. In large areas maps are inadequate, and navigational methods may be necessary.

To supplement ground travel, numerous international air services cross the Sahara on scheduled flights, while local services link the main inhabited centres to one another. Railways, with the abandonment of the "Trans-Saharan" at Abadla (near Béchar, Alg.), have been little developed except for a line built to transport minerals in Mauritania.

Study and exploration. Classical accounts describe the Sahara much as it is today—a vast and formidable barrier. The Egyptians controlled only their neighbouring oases and, occasionally, lands to the south; the Carthaginians apparently continued the commercial relationships with the interior that had been established during the Bronze Age. Herodotus described a desert crossing by an expedition of Berbers during the 5th century BC, and Roman interest in the Sahara is documented in a series of expeditions between 19 BC and AD 86. The descriptions of the Sahara in the works of Strabo, Pliny the Elder, and Ptolemy reflect growing interest in the desert. Geographic exploration, sponsored by the 'Abbāsids, Fātimids, Mamlūks, and other courts in the Middle East, North Africa, and Moorish Spain, was widespread during the medieval period. Descriptions of the Sahara are contained in the works of numerous Arab writers, including al-Ya'qūbī, ash-Sharīf al-Idrīsī, and Ibn Baṭṭūṭa.

Medieval travelers with religious and commercial motives contributed further to an understanding of the Sahara and its peoples. Abraham Cresque's *Catalan Atlas*, published for Charles V of France in about 1375, renewed European interest in the desert. The atlas contained information based upon the knowledge of Jewish traders active in the Sahara. Its publication was followed by a period of intense Portuguese, Venetian, Genoese, and Florentine activity there. Particularly well documented are the travels of such 15th-century explorers as Alvise Ca' da Mosto, Diogo Gomes, and Pedro de Sintra. Growing interest in the Sahara within northern Europe was reflected in the travels and writings of the 17th-century Dutch geographer Olfert Dapper.

European explorers

Subsequent European exploration of the Sahara, much of it incidental to interest in the major waterways of interior Africa, began in earnest in the 19th century. Attempts to determine the course of the Niger River took the British explorers Joseph Ritchie and George Francis Lyon to the Fezzan area in 1819, and in 1822 the British explorers Dixon Denham, Hugh Clapperton, and Walter Oudney succeeded in crossing the desert and discovering Lake Chad. The Scottish explorer Alexander Gordon Laing crossed the Sahara and reached the fabled city of Timbuktu in 1826, but he was killed there before he could return. The French explorer René Caillié, disguised as an Arab, returned from his visit to Timbuktu by crossing the Sahara from south to north in 1828. Other notable expeditions were undertaken by the German geographer Heinrich Barth (1849–55), the French explorer Henri Duveyrier in 1859–62, and the German explorers Gustav Nachtigal (1869–75) and Gerhard Rohlfs (1862–78).

After the military occupation of the Sahara by the various European colonial powers, more detailed exploration took place; and by the end of the 19th century the main

features of the desert were known. Although 20th-century political, commercial, and scientific activities have greatly increased knowledge of the Sahara, vast tracts remained remote, little known, and difficult to reach.

(R.F.Pe./J.A.G.)

VELD

Veld, an Afrikaans word meaning "field" and pronounced "felt," is the name given to various types of open country in southern Africa. To most South African farmers today the "veld" refers to the land they work, much of which has long since ceased to be "natural."

Various types of veld may be discerned, depending upon local characteristics such as elevation, cultivation, and climate. Thus, there is a high veld, a middle veld, a low veld, a bush veld, a thorn veld, and a grass veld. The boundary between these different varieties of veld is frequently vague, and all of them are usually referred to by the general term veld by the local inhabitants. For convenience, its major regions—Highveld, Middle Veld, and Lowveld—are distinguished on the basis of elevation.

For map coverage of the veld, see above *Kalahari*.

Physical features. *Physiography.* The Highveld comprises most of the high-plateau country of southern Africa. Except in Lesotho, where it extends well above 8,200 feet (2,500 metres) and even above 11,000 feet in places, all of it lies between 4,000 and 6,000 feet above sea level. The South African part of the region is bounded on the east and south by the Great Escarpment, which consists of the Drakensberg and Cape ranges, and by the Lesotho Highlands. Its less clearly defined northern and western boundaries coincide roughly with the 4,000-foot contour. Most of it is underlain by sedimentary strata of the Karoo System (or Karoo Super Group), dating from between 345 to 190 million years ago, and to older pre-Karoo material. Among these are coal-bearing strata. These materials have been eroded over a long period of time to produce generally flat plains, dissected occasionally by deeply carved valleys and including relict mountains and scattered steep-sided hills called kopjes, or koppies. The Highveld plains are thought to have been created by pedimentation, in which the areas around resistant rock are eroded away, leaving mountains of low relief and kopjes. Large areas of the western part of the region are also covered by "pans," which are shallow and ephemeral lakes, often with salty crusts; these are found especially in Orange Free State, eastern and western Transvaal, and northwestern Cape Province in South Africa.

In Zimbabwe the Highveld coincides roughly with the region lying on either side of the central watershed. Like the Highveld of South Africa, it has a remarkably even surface, broken only by kopjes and low ridges. Throughout the Highveld, soils tend to be thin, poor, and powdery and

thus easily carried away by both wind and water erosion.

The Middle Veld is the name given in South Africa to a vast and geologically complex region that lies in the central Transvaal north of Pretoria and Cape Province and in Namibia. Its boundaries are not as well defined as are those for the Highveld, but generally it lies at an altitude between 2,000 and 4,000 feet above sea level. In Zimbabwe to the northeast, the Middle Veld also consists of the land lying roughly between 2,000 and 4,000 feet. Most of the Middle Veld is underlain by Precambrian rocks that have been exposed by erosion. In Transvaal this region is underlain by the unique Bushveld complex, with its wealth of rare minerals. As is the case in the Highveld, the uniformity of the relief is broken by relict mountains and by kopjes. Pans are numerous, especially in the western areas. Middle Veld soils are generally thin and poor.

The Lowveld is the name given to two areas that lie at an altitude of between 500 and 2,000 feet above sea level. One area is in the eastern parts of Transvaal and parts of Swaziland and in northern Natal; and the other is in southeastern Zimbabwe. Both are underlain largely by the soft sediments and basaltic lavas of the Karoo System and by loose gravels. They have been extensively intruded by granites. Other resistant metamorphic rocks also occur; these commonly appear as low ridges or what seem to be archipelagoes of island mountains. The higher western margins of both areas testify to the degree of erosion resulting from the flow of rivers running east or southeast.

The soils of the Lowveld are more varied than those of the other veld regions. Along their higher and wetter western sides, they tend to be deep, leached (percolated by water), acidic, porous, and well drained. In the lower-lying and drier central and eastern portions they tend to be shallow, but they are more fertile and retain moisture better.

Climate. The climate of the veld is highly variable, but its general pattern is mild winters from May to September; hot or very hot summers from November to March, with moderate or considerable variations in daily temperatures; and abundant sunshine. Rainfall mostly occurs in the summer months in the form of high-energy thunderstorms.

Over most of the South African Highveld, the average annual rainfall is between 15 and 30 inches (380 and 760 millimetres), decreasing to about 10 inches near the western border and increasing to nearly 40 inches in some parts of the Lesotho Highlands; the South African Lowveld generally receives more rainfall than the Highveld. Temperature is closely related to altitude. In general, the mean July (winter) temperatures range between 45° F (7° C) in the Lesotho Highlands and 60° F (16° C) in the Lowveld. January (summer) temperatures range between 65° F (18° C) and 80° F (27° C).

In Zimbabwe the rainfall averages around 30 to 35 inches on the Highveld, dropping to less than 15 inches in the

Terrain
of the
Highveld

Rainfall

Gerald Cubitt—Bruce Coleman Ltd.

lowest areas of the Lowveld. Temperatures are slightly higher than in South Africa.

Over the entire veld, seasonal and annual average rainfall variations of up to 40 percent are common. Damaging drought afflicts at least half of the area about once every three or four years. Everywhere the average number of hours of annual sunshine varies from 60 to 80 percent of the total amount possible.

Plant life. The veld regions support an enormous variety of natural vegetation. No particular species is ubiquitous, and many are highly localized. Grassveld is the characteristic vegetation of the South African Highveld, dominated by species of red grass. Where the red grass grows on well-drained, fertile soils subject to comparatively light rainfall, it tends to be sweeter (and is consequently called sweetveld) than elsewhere, where it is commonly called sourveld. Sweetvelds are more palatable to livestock than sourvelds, the latter being usable as fodder only in winter.

The drier South African Middle Veld favours both red grass and drought-resistant species of grasses. These grasses are less luxuriant and the ground cover less complete than those of the Highveld. As the aridity increases to the west and north, the cover becomes sparser, and grassveld gradually loses ground to thornveld (consisting of such types as thorny acacias and aloes), dwarf, drought-resistant bushes, and desert shrub.

In Zimbabwe the Highveld and Middle Veld consist of open woodland savanna, dominated by leguminous, fire-resistant species of trees belonging to the *Brachystegia* genus. Tall perennial grasses and flowering herbs, which readily catch fire during the dry season, occupy most of the open ground.

The Lowveld everywhere supports a parklike plant cover. In the higher areas the characteristic trees are acacias and marula, an intoxicating plumlike fruit. The open ground is dominated by red grass. In the lower areas, such as the Sabi and Limpopo valleys, tufted finger grasses, euphorbias, and other succulents replace red grass; the acacias increase in number; and the mopane tree, the baobab, and the tall fan palm occur.

Animal life. Mass slaughter, trophy hunting, and the encroachments of farmers and pastoralists have thinned out every major species of mammal and reptile and several species of bird in the veld. The South African and Zimbabwean governments have, however, set aside vast tracts of veld, such as the Kruger National Park in Transvaal, as wildlife reserves. The lion, leopard, cheetah, giraffe, elephant, hippopotamus, oryx, kudu, eland, sable antelope, and roan antelope survive only in or near such protected areas. The smaller mammals, most of the reptiles, and almost all of the birds—except the ostrich, which has virtually been eliminated from the veld—are still found wild.

The people and economy. The veld is believed to be one of the world's oldest regions inhabited by humans and their hominid forebears. Fossil evidence indicates that members of the hominid genus *Australopithecus* occupied the Highveld some three million years ago and that various Stone Age peoples lived there hundreds of thousands of years ago. More recently, the San of the Kalahari inhabited parts of the grassveld until driven from it by Bantu-speaking peoples and the Boers. The generally open character, easy gradients, abundant supply of food, and—in the valleys—water of the Highveld have long attracted migrants as well as settlers. It provided the major routes followed by the Bantu-speaking peoples during their recurrent southward migrations; and in the 1830s the Voortrekkers (pioneer Boer farmers), who moved northward from Cape Colony to escape from the power of the British, made the Highveld their home as well as their highway.

Until the Voortrekker era the veld remained largely in a natural state. The San, never very populous, lived solely by hunting and gathering. The animal herding and crop raising done by the Bantu-speaking peoples were solely for subsistence. While much of the veld, especially in Zimbabwe, retains its natural cover—modified by the selective grazing habits of oxen, cattle, and other domesticated animals—millions of acres have been brought under the plow. Most of South Africa's corn (maize) crop is now grown on the grassveld in Transvaal and Orange Free

State. Most of the Zimbabwean corn crop and almost all of its tobacco crop are grown on the Highveld. The major population centres of these two countries and of Botswana, as well as their major commercial and industrial activities, are also located on the Highveld, which, by virtue of terrain, climate, and mineral and ecological endowment, forms one of the areas most suitable for settlement on the African continent.

Study and exploration. Modern study of the veld has centred on its economic, ecological, and archaeological assets. In the economic area, the emphasis has been on conservation and management of ecosystems, the topics including general geography, vegetation, soils, ecology, geology, and geomorphology. One major focus of investigation has been determining the nutritional potential of various natural vegetation forms in terms of their use in livestock raising and wildlife management.

The discovery of australopithecine fossils on the South African Highveld in the first half of the 20th century sparked great anthropological interest in the region. Since then it has become one of the major centres of hominid exploration and research, and many specimens—including those of other hominid species—have been recovered. In addition, the remains of Stone Age cultures have been found on both the Zimbabwean and the South African velds, and thousands of San rock engravings on the kopjes of the Highveld in Zimbabwe, Transvaal, Lesotho, and Botswana are known. (G.H.T.K./Jo.Co./C.E.F.)

Drainage systems and waterways

LAKE CHAD

Lake Chad (French: Lac Tchad) is a freshwater lake located in the Sahelian zone of west-central Africa at the conjunction of four countries: Chad, Cameroon, Nigeria, and Niger. It is situated in an interior basin formerly occupied by a much larger ancient sea that is sometimes called Mega-Chad: While the surface area of Lake Chad varies greatly, its average area of 6,875 square miles (17,800 square kilometres) ranks it as the fourth largest lake in Africa. The surface of the lake is approximately 922 feet (281 metres) above sea level. The hydrologic contributions and biological diversity of Lake Chad are important regional assets. The region is also noteworthy for important archaeological discoveries, its role in trans-Saharan trade, and its association with historic African kingdoms.

For map coverage of Lake Chad, see below *Niger River*.

Physical features. *Geology and physiography.* The Chad basin is a downwarped section of the Precambrian African Shield. Most of the older crystalline rocks are covered by more recent deposits. The most significant physiographic influence on the basin was the ancient sea. At its maximum extent, the sea was more than 600 feet deep, occupied an area of approximately 154,400 square miles, and drained into the Atlantic Ocean through the Benue River system. It experienced four high stages between 41,000 and 2,300 years ago. The history of the sea is documented in the stratigraphic record, which includes thick layers of diatomaceous earth, lacustrine sands, terraced shorelines, and the remains of modern fish and mollusks in now-arid tracts of the basin. The floor of the basin dips to the northeast of the modern lake, reaching its lowest point in the Djourab Depression, some 300 miles away. Lake Chad occasionally overflows into the generally intermittent El-Ghazal River leading into the depression, but it is usually confined by the dune fields of Kanem.

Climate. The climate of the Lake Chad region is strongly influenced by the seasonal migration and interaction of the dominant air masses of the region: a dry, subsiding continental air mass and a humid, unstable maritime air mass. The humid air mass moves northward during the summer, wedging beneath the drier air mass. Precipitation occurs when the depth of humid air is sufficiently great. The depth of the air mass varies daily, as well as seasonally, accounting for variation in rainfall. At the end of the summer the dominance of the dry continental air mass is reasserted. Evaporation and transpirational losses from soil and plants increase, and then they decrease as the surface layers of the soil dry and plants lose their leaves.

The
ancient sea

Effects of
humans

The dry season is also the period of the harmattan, a dust-laden wind that reduces visibility for days at a time. The increased insolation, reduced humidity, and desiccating winds contribute greatly to water loss in the lake.

Rainfall is greatest from July to September. Annual rainfall averages 22 inches (560 millimetres) at the southern margin of Lake Chad and about 10 inches at the northern margin. Variability during the year is high and increases from south to north; variability from year to year is also high, and droughts are frequent. Temperatures during the rainy season are moderate, with highs of about 90° F (32° C). In October and November, during the transition to the dry season, daily highs rise above 90° F, and diurnal ranges are almost double those of the rainy season. During December and January daytime highs are lower, with nighttime lows sometimes falling to about 47° F (8° C). April is usually the hottest month of the year, with temperatures occasionally exceeding 110° F (43° C).

Hydrology. Lake Chad is a variable body of water, with a surface area that fluctuates from approximately 9,950 square miles in late October or early November to 3,800 square miles in late April or early May. The lake is dotted with numerous islands. The volume of the lake reflects local rainfall and the discharge of its catchment area, balanced against losses through evaporation, transpiration, and seepage. The lake is fed chiefly (more than 90 percent) by the Chari (Shari)–Logone river system. Of the remaining inflow, most is contributed by the Ebeji (El-Béid) and Yedseram rivers. Losses to evaporation and the transpiration of aquatic plants amount to approximately 90 inches each year. It is probable that another 10 inches replenish groundwater supplies in the adjacent Manga and Kanem lowlands and pass as underflow through the El-Ghazal.

Two pools
of the lake

The lake is divided into two pools partially separated by a low ridge extending roughly northeast–southwest across the centre of the lake; the ridge was formed during a drought at the beginning of the 20th century. Depths of from 13 to 23 feet are common in the northwestern pool, and depths as great as 33 feet occur among the islands along the eastern margin of the pool. Because of sediment deposition by the Chari River, the southeastern pool is generally shallower—ranging in depth from 10 to 13 feet, but reaching depths of 36 feet along the archipelago. The gentle slope of the lakeshore allows persistent dry-season winds to locally affect water levels for short periods of time. The salt content of Lake Chad is unusually low for a tropical dryland lake with no outlet. As the waters of the lake evaporate during the dry season, the salt content increases, with the highest values recorded along the northeastern shoreline.

Travelers reported high-water levels and overflow into the El-Ghazal during the 13th and 19th centuries. In 1870, for example, Lake Chad covered some 10,800 square miles. At the turn of the 20th century, the lake began to diminish in size, but by the 1920s it had recovered; and in 1956 it again overflowed into the El-Ghazal. During the 1970s and '80s the amplitude of the lake's annual variability was the highest recorded in the 20th century, with average levels falling below long-term norms. The corresponding variability in rainfall appears to have been related to the effects of environmental degradation.

Plant life. The well-drained soils around Lake Chad once supported a relatively dense woodland, including species such as kapok and ebony. Changing patterns of land use and progressive degradation have reduced diversity and resulted in a more open woodland, increasingly composed of species adapted to reduced moisture. They include several acacias, baobab, desert date, palms, African myrrh, and Indian jujube. The periodically inundated lands near the lake are more heavily vegetated. Annual grasses are increasing at the expense of the more economically valuable perennial species. Papyrus, ambatch, water lilies, and reeds dominate aquatic vegetation.

Animal life. Visitors to the medieval kingdom of Kanem in the Lake Chad region described an abundance of wildlife; and until the early 20th century essentially the same faunal assemblages were reported. Since then, however, habitat loss, hunting, and direct competition from livestock have depleted wildlife populations. As with

vegetation, the trend is toward decreased diversity and lower levels of biological productivity. Populations of large carnivores, including lions and leopards, have been eliminated in livestock areas; and such game animals as the rhinoceros have been reduced or eliminated. Nocturnal species have been less affected by these changes; and some species, particularly rodents, have benefited from them.

Hundreds of species of birds reside permanently or seasonally in the Lake Chad region. Included are prominent terrestrial birds—such as the ostrich, secretary bird, Nubian bustard, and ground hornbill—and the water and shore birds for which the region is famous—such as garganey, shoveler, fulvous tree duck, Egyptian goose, pink-backed pelican, marabou stork, glossy ibis, and African spoonbill. Included among the amphibians and reptiles are the Nile crocodile, rock python, and spitting cobra. The Chad basin remains an important fishery, with more than 40 species of commercial importance. Also noteworthy are such ancient species as the lungfish and sailfin.

The people and economy. *Settlement history.* The Chad basin contains the earliest evidence of hominid occupation yet found in western Africa, and it appears that the Lake Chad region has been continuously settled since 500 BC. Among the major archaeological discoveries of the region has been the Sao civilization; it is believed that the modern Kotoko, a fishing people on the Chari near Lake Chad, are descendants of the Sao.

During the medieval period (9th to 16th century) the Lake Chad region was both an important refuge and an area in which diverse populations were consolidated by the authority of powerful kingdoms. The modern Kanembu, for example, are composed of several groups consolidated by Kanem in the 9th century; similarly, the modern Kanuri emerged from the imposed authority of Kanem's successor state, Bornu, located southwest of Lake Chad. Some ethnic groups were not assimilated. The metallurgists of Kanem, for example, were apparently the Danoa (Haddad), who currently serve as blacksmiths among the Kanembu. Other groups resisted integration into the medieval kingdoms. The Yedina (Buduma) established themselves among the inaccessible islands and along the marshy northern shore of Lake Chad, and the Kuri did the same in inaccessible areas along the eastern margin of the lake.

Other ethnic groups established themselves on the shores of Lake Chad in the more recent past. Arab settlement dates from the arrival of the Judam tribes in the 16th century. Some ethnic groups, such as Fulani pastoralists, now enter the Lake Chad lowlands on a seasonal basis; and Hausa agricultural communities can often be found along the lake. The economy of these modern peoples of the Lake Chad region is based primarily on fishing, subsistence and commercial agriculture, and animal husbandry—often in combination.

Agriculture and forestry. Subsistence crops include sorghum, corn (maize), African millet, beans, and vegetables. Bottle gourds are grown widely for making utensils. Polders near Bol, used to grow cash crops, are based on traditional agricultural practices. Cultivated by the Kanembu and Yedina, the polders are devoted chiefly to wheat.

The exploitation of such forest products as gum arabic, honey, beeswax, and firewood is of considerable importance in the region. Production of these, however, has been adversely affected by the decline of the forested areas, aggravated by the explosive growth of cattle populations.

Livestock and fishing. Cattle are the most important livestock raised. Notable breeds include the Kuri (Chad) and several varieties of zebu (Brahman). Milk is a major component of local diets, and cattle are an important export to the tsetse-infested regions to the south. Large numbers of poultry, goats, sheep, camels, horses, and asses are also kept.

Fishing is the most important economic activity for the peoples of the lake. Much of the catch is dried, salted, or smoked. Dried *Alestes* species, known by the Arabic name *salanga*, and pieces of smoked fish called *banda* are marketed, primarily in Nigeria and Cameroon. In addition, fresh Nile perch are often exported to major African and European cities.

Minerals. Petroleum reserves have been discovered in

Birdlife

© Jacques Jangoux—Peter Arnold, Inc.

Chad and Niger. Natron (hydrated sodium carbonate), found in depressions along the northeastern shore of the lake, has long been economically important. Traditionally, it is excavated in blocks and shipped across the lake, where it enters Nigerian commerce.

Transportation. Lake Chad is little used for commercial navigation, although there has been intermittent barge traffic between Bol and N'Djamena since the early 1950s. A variety of watercraft are used in fishing, including the papyrus-reed *kadei* of the Yedina and the sewn-plank boats of the Kotoko.

Study and exploration. For millennia settlement patterns of peoples of Mediterranean and sub-Saharan origin have overlapped in the Sahara, and there is emerging evidence of a long history of interaction between the Lake Chad region and other regions of northern Africa. There are essentially four periods during which the region was strongly affected by external influences. The first is expressed in hints of Egyptian contact with the region; in the sub-Saharan commerce of Carthage and the Garamantes; and in references in Greek, Roman, and Arabic literature.

The second period was precipitated largely by the expansion of Islām in North Africa during the 7th century AD, when groups of Arabs and Berbers who resisted conversion sought refuge in the dry lands of the south. The third period emerged from trade between Kanem or Bornu and Mediterranean Africa, the penetration of Islām into sub-Saharan Africa, and increased Arab interest in geographic exploration. It is documented in the many Arabic works written in the 9th to 14th centuries and is also reflected in Abraham Cresque's *Catalan Atlas* (c. 1375).

The fourth period emerged from growing interest in Africa within European academic and commercial circles and was a prelude to European colonization. Numerous descriptions of the Lake Chad region were written by 19th-century Europeans, and three scientific missions were mounted between 1898 and 1909. (J.A.G.)

CONGO RIVER

The Congo (or Zaire) River, with a length of 2,900 miles (4,700 kilometres), is longer than any other river in Africa except for the Nile. It rises in the highlands of northeastern Zambia between Lakes Tanganyika and Nyasa (Malaŵi) as the Chambeshi River at an altitude of 5,760 feet (1,760 metres) above sea level and at a distance of about 430 miles from the Indian Ocean. Its course then takes the form of a giant counterclockwise arc, flowing to the northwest, west, and southwest before draining into the Atlantic

Ocean at Banana (Banane), Zaire. Its drainage basin, covering an area of 1,335,000 square miles (3,457,000 square kilometres), takes in almost the entire territory of Zaire, as well as most of that of the People's Republic of the Congo, the Central African Republic, eastern Zambia, and northern Angola and parts of Cameroon and Tanzania.

With its many tributaries the Congo forms the continent's largest network of navigable waterways. Navigability, however, is limited by an insurmountable obstacle: a series of 32 cataracts over the river's lower course, including the famous Livingstone (Inga) Falls. These cataracts render the Congo unnavigable between the seaport of Matadi, at the head of the Congo estuary, and Malebo (Stanley) Pool, a lakelike expansion of the river. It was on opposite banks of Malebo Pool—which represents the point of departure of inland navigation—that the capitals of the former states of the French Congo and the Belgian Congo were founded: on the left bank, Kinshasa (formerly Léopoldville), now the capital of Zaire, and on the right bank, Brazzaville, now the capital of the Congo.

The Amazon and Congo are the two great rivers of the world that flow out of equatorial zones where heavy rainfall occurs throughout all or almost all of the year. Upstream from Malebo Pool, the Congo basin receives an average of about 60 inches (1,500 millimetres) of rain a year, of which more than one-quarter is discharged into the Atlantic. The drainage basin of the Congo is, however, only about half the size of that of the Amazon; its rate of flow—1,450,000 cubic feet (41,000 cubic metres) per second at its mouth—is considerably less than the Amazon's flow of more than 6,350,000 cubic feet per second.

While the Chambeshi River, as the remotest source, may form the Congo's original main stream in terms of the river's length, it is another tributary—the Lualaba, which rises near Musofi in the Shaba (formerly Katanga) region of Zaire—that carries the greatest quantity of water and thus may be considered as forming the Congo's original main stream in terms of water volume.

When the river first became known to Europeans at the end of the 15th century, they called it the Zaire, a corruption of a word that is variously given as *nzari*, *nzali*, *njali*, *nzaddi*, and *niadi* and that simply means "river" in many African dialects. It was only in the early years of the 18th century that the river was first called the "Rio Congo," a name taken from the kingdom of Kongo that had been situated on the lower part of the river's course. In 1971, when the Democratic Republic of the Congo changed its name to Zaire, the government also renamed the river as the Zaire. As the river, however, has an international status, it continues to be known throughout the world as the Congo. To the literary-minded the river is evocative of the famous 1902 short story "Heart of Darkness" by Joseph Conrad. His book conjured up an atmosphere of foreboding, treachery, greed, and exploitation. Today, however, the Congo appears as the key to the economic development of the central African interior.

Physical features. *Physiography.* The expression Congo basin refers, strictly speaking, to the hydrographic basin. This is not only vast but is also—with the exception of the sandy plateaus in the southwest—covered with a dense and ramified network of tributaries, subtributaries, and small rivers.

The Congo basin is the most clearly distinguished of the various geographic depressions situated between the Sahara to the north, the Atlantic Ocean to the south and west, and the region of the East African lakes to the east. In this basin, a fan-shaped web of tributaries flows downward along concentric slopes that range from 900 to 1,500 feet in altitude and that enclose a central depression. The basin itself stretches for more than 1,200 miles from north to south (from the Congo–Lake Chad watershed to the interior plateaus of Angola) and also measures about 1,200 miles from the Atlantic in the west to the Nile–Congo watershed in the east.

The central part of the Congo basin—often called the *cuvette* (literally, "saucer," or "shallow bowl")—is an immense depression containing Quaternary alluvial deposits that rest on thick sediments of continental origin, consisting principally of sands and sandstones. These underlying

Comparisons with the Amazon

The *cuvette*

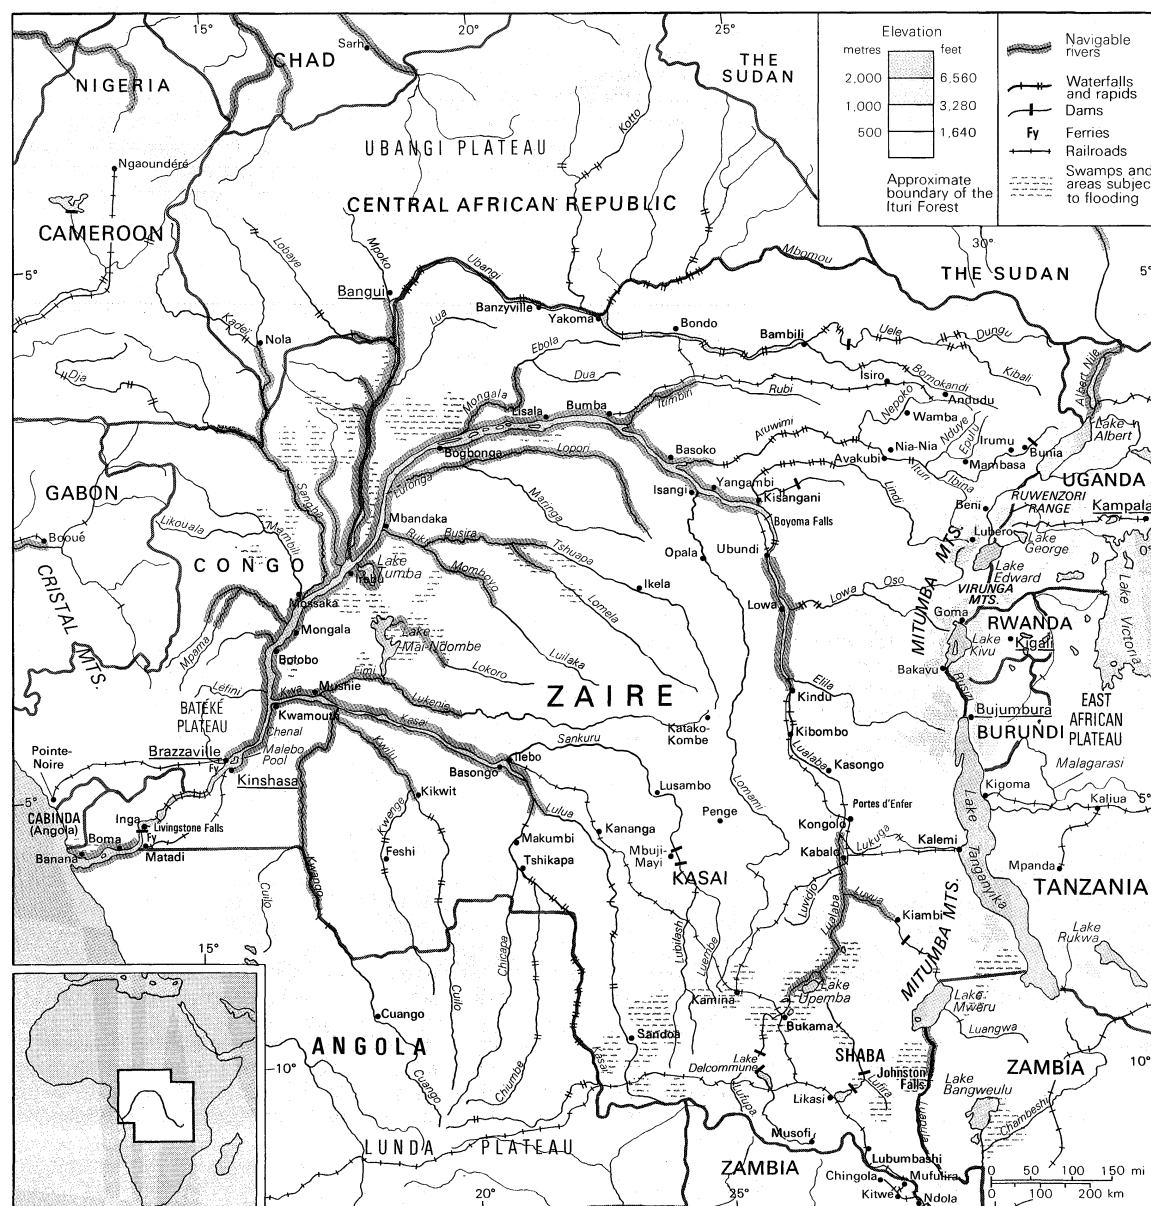

sediments form outcrops in valley floors at the eastern edge of the *cuvette*. The filling of the *cuvette*, however, began much earlier. Boreholes have revealed that since late Precambrian times (*i.e.*, since at least 570 million years ago) considerable sediment has accumulated, derived from the erosion of formations situated around the periphery of the *cuvette*. The arrangement of surface relief, thick depositional strata, and substratum in amphitheatre-like fashion around the main Congo channel, which has been uniform across time, is evidence of a persistent tendency to subsidence in this part of the continent. This subsidence is accompanied by uplifting on the edges of the *cuvette*, principally on its eastern side—which has also been influenced by the formation of the Western Rift Valley.

From its sources to its mouth, the Congo River system has three contrasting sections—the upper Congo, middle Congo, and lower Congo.

The upper reaches are characterized by three features—confluences, lakes, and waterfalls or rapids. To begin with, several streams of approximately equal size unite to form the river. In a little more than 60 miles, the upper Lualaba joins the Luvua and then the Lukuga. Each stream for part of its course undergoes at least a lacustrine type of expansion, even when it does not form a lake. Thus, Lake Upemba occurs on the upper Lualaba; Lakes Bangweulu and Mweru occur on the Chambeshi–Luapula–Luvua sys-

tem; and finally Lake Tanganyika, which is fed by the Ruzizi (flowing from Lake Kivu) and by the Malagarasi, itself flows into the Lukuga. Rapids occur not only along the headstreams but also several times along the course of the main stream. Navigation thus is possible only along sections of the upper Congo by vessels of low tonnage; even so, these stretches are in danger of being overgrown by aquatic vegetation, particularly water hyacinths.

Kisangani (formerly Stanleyville)—located just downstream of the Boyoma (Stanley) Falls, a series of seven cataracts—marks the real beginning, upriver, of the navigable Congo. This central part of the river flows steadily for more than 1,000 miles to within 22 miles of Kinshasa. Its course at first is narrow but soon grows wider, after which many islands occur in midstream. This change in the character of the river corresponds to its entry into its alluvial plain. From that point onward, with the exception of a few rare narrow sections, the Congo divides into several arms, separated by strings of islands. It increases from a width of more than three and a half miles downstream from Isangi (where the Lomami enters the Congo) to a width of from five to seven miles and on occasion—for example, at the mouth of the Mongala—to eight miles. Beyond the natural levees (formed by silt deposits) occurring on either bank, some areas are subjected to extensive flooding that increases the river's bounds still further. (It

The Congo River basin and its drainage network.

is not always easy to distinguish such areas from the "rain swamps" in regions lying between rivers.) The middle course of the Congo ends in a narrow section called the Chenal (Channel), or Couloir (Corridor). Between banks no more than half a mile to a mile wide, the riverbed deepens, and the current becomes rapid, flowing through a valley that cuts down several hundreds of yards deep into the soft sandstone bedrock of the Batéké Plateau. Along this central reach the Congo receives its principal tributaries, primarily the Ubangi and the Sangha on the right bank and the Kwa on the left bank. An enormous increase in the average rate of flow results, rising from less than 250,000 cubic feet a second at Kisangani to nearly its maximum flow at Kinshasa.

Upon leaving the Chenal, the Congo divides into two branches, forming Malebo Pool, a vast lacustrine area about 15 miles by 17 miles, which marks the end of the middle Congo. Immediately downstream occur the first waterfalls of the final section of the river's course. Cataracts and rapids are grouped into two series, separated by a fairly calm central reach, in which the altitude drops from a little less than 900 feet to a few yards above sea level. The Congo's estuary begins at Matadi, downstream from the rapids that close off the interior Congo; 83 miles in length, it forms the border between Angola and Zaire. At first the estuary is narrow (less than half a mile to about a mile and a half in width) with a central channel 65 to 80 feet deep, but it widens downstream of Boma. There, the river, obstructed by islands, divides into several arms, and in some places the depth does not exceed 20 to 25 feet, which makes dredging necessary to allow oceangoing vessels to reach Matadi. Beyond the estuary's mouth, the course of the Congo continues offshore as a deep underwater canyon that extends for a distance of about 125 miles.

Hydrology. The Congo has a regular flow, which is fed by rains throughout the year. At Kinshasa the flow has for years remained between the high level of 2,310,000 cubic feet per second, recorded during the flood of 1908, and the low level of 756,000 cubic feet per second, recorded in 1905. During the unusual flood of 1962, however, by far the highest for a century, the flow probably exceeded 2,600,000 cubic feet per second.

At Brazzaville and Kinshasa, the river's regime is characterized by a main maximum at the end of the year and a secondary maximum in May, as well as by a major low level during July and a secondary low level during March and April. In reality, the downstream regime of the Congo represents climatic influence extending over 20° of latitude on both sides of the equator, a distance of some 1,400 miles. Each tributary in its course modifies the level of the main stream. Thus, for example, the low level in July at Malebo Pool results from two factors: a drought that occurs for several months in the southern part of the basin at that time, as well as a delay before the floods of the Ubangi tributary flowing down from the north arrive, which does not happen before August. The Congo basin is so vast that no single meteorologic circumstance is capable of disturbing the slow movement of the waters' rise and fall. The annual fluctuations may alter drastically, however, when floodwaters from different tributaries that normally coincide with each other arrive at different times.

Lake Tanganyika, apart from brief seiches caused by wind drift and sudden changes in atmospheric pressure, may experience considerable variations in its water level from year to year. In 1960, for example, its waters flooded parts of Kalemie, Zaire, and Bujumbura, Burundi. A series of particularly rainy years, followed by a blocking of the outlet by floating vegetation, may explain this phenomenon.

Climate. Typical of the climate in regions through which the Congo flows is that of Yangambi, a town situated on the river's right bank slightly north of the equator and a little downstream of Kisangani. Humidity remains high throughout the year, and annual rainfall amounts to 67 inches and occurs fairly regularly; even in the driest month the rainfall totals more than 3 inches. Temperatures are also uniformly high throughout the year, and

there is little diurnal variability. The average temperature at Yangambi is 76° F (24° C).

From the pluviometric equator (an imaginary east-west line indicating the region of heaviest rainfall), which is situated slightly to the north of the geographic equator, the amount of rainfall decreases regularly in proportion to the latitude. The northernmost points of the basin, situated in the Central African Republic, receive only from eight to 16 inches less during the course of a year than points near the equator; the dry season, however, lasts for four or five months, and there is only one annual rainfall maximum, which occurs in summer. In the far southern part of the basin—at a latitude of 12° S, in the Shaba region—the climate becomes definitely Sudanic in character, with marked dry and wet seasons of approximately equal length and with rainfall of about 49 inches a year.

Plant life. The equatorial climate that prevails over a significant part of the Congo basin is coextensive with a dense evergreen forest. The Congolese forest spreads out over the central depression, extending continuously from about 4° N to about 5° S; it is interrupted only by clearings, many of which have a natural origin. The forest region is bordered on either side by belts of savanna (grassy parkland). The forest and savanna often meet imperceptibly, blending together in a mosaic pattern; more rarely, strips of forest invade the grassland. Farther away from the equator, and to the extent that the Sudanic features of the climate become evident, the wooded savanna region, with its thin deciduous forest, is progressively reached.

As it courses through the solid mass of the Congolese forest, the Congo and its tributaries are bordered by discontinuous grassy strips. Meadows of *Echinochloa* (barnyard grass), papyrus, and Cyperaceae (sedge) occupy abandoned river channels, fringe the banks, or, behind a curtain of forest, blanket the depressions in the centre of the islands; they also spring up on sandbanks, as well as on the downstream ends of islands that are fertilized by the floods. A shrub, *Alchornea*, frequently marks the transition to the high forest that grows on the levees behind the banks.

Animal life. The animal life of the Congo basin is identified to a certain extent with that of the equatorial forest, which is sharply distinct from the wildlife of the savannas. Within this equatorial domain, the Congo and its principal tributaries form a separate ecological milieu. The animal population of the great waterways often has fewer affinities with the neighbouring marshes or the forests on dry land than it has with other river systems, whether of the coastal region or the savannas.

Numerous species of fish live in the waters of the Congo—more than 230 have been identified in the waters of Malebo Pool and in the waters that flow into it alone. The riverine swamps, which often dry up at low water, are inhabited by lungfish, which survive the dry periods buried and encysted in cocoons of mucus. In the wooded marshlands, where the water is the colour of black tea, the black catfish there assume the colour of their environment. The wildlife of the marshes and that of the little parallel streams do not mix with the wildlife of the river itself.

The waters of the Congo contain various kinds of reptiles, of which crocodiles are the most striking species. Semiaquatic tortoises are also to be found, as are several species of water snakes.

The forest birdlife constitutes, together with the birdlife of the East African mountains, the most specifically indigenous of that to be found on the African continent. In the Congo region more than 265 species typical of the equatorial forest have been recorded. Occasionally or seasonally, however, nontypical birds may be observed. Seabirds, such as the sea swallow, fly upstream from the ocean. Migratory birds from Europe, including the blongios heron and the *Ixobrychus minutus* (little bittern), pass through the region. Species with a wide distribution within Africa, such as the Egyptian duck, also have been noted. Ducks, herons, storks, and pelicans, however, are abundantly represented.

Aquatic mammals are rare, consisting of the hippopotamus, two species of otter, and the manatee (sea cow), which lives entirely in the water. The manatee has been officially identified only on the Sangha tributary but ap-

pears to have given rise to some curious legends on the lower Congo, including its association with a creature called Mami Wata (a kind of siren).

The people and the economy. *Life of the river peoples.* Three types of environment are found, either juxtaposed or in succession, along the river and its tributaries: the narrower sections, bordered by firm ground; the wider stretches, dotted with islands and accompanied by backwaters; and the zones where flooding occurs or where there are extensive marshes.

Almost all the river peoples engage in fishing. Along the narrow sections, where rapids often occur, fishing is only of interest to a small number of villages. The Enya (Wagenia) of Boyoma Falls and the Manyanga living downstream from Malebo Pool attach fish traps to stakes or to dams built in the rapids themselves. Fishing of a very different nature, notably by poison, is conducted in the marshy areas, where the population is more extensive than might be imagined. Among these peoples are the "water people"—the Ngombe—who inhabit the Itimbiri-Ngiri and the triangle formed by the Congo and the Ubangi. Other fisherfolk of the marshes dwell in the lagoons and the drowned forests of the region where the confluence of the Congo and the Alima, Likouala, and Sangha occurs.

Farming

Despite unfavourable conditions, all these peoples are also cultivators. They raise dikes, often of monumental size, to plant cassava on the land thus sheltered from flooding. Other crops, such as sweet potatoes, bananas, and yams, are of little importance. Although the Congo basin has the continent's most important timber resources, the timber industry is still largely undeveloped, mainly because the interior is so inaccessible and because the cost of transporting timber to the coast is so high.

Few modes of existence have undergone such profound changes as a result of contact with the modern world as has that of the river's fisherfolk. The growth of the towns on the banks of Malebo Pool as well as the taste of urban dwellers for river fish have served to stimulate fishing by relating it to a cash economy. It is not just a question of villagers smoking fish that they sell to passing traders. Increasingly numerous fishing crews sail up the Congo, the Ubangi, and the Kasai, well above their confluences, to fish in the shallows.

Transportation. The Congo is the most important navigational system in Africa. Within the territorial limits of Zaire alone, there are some 8,700 miles of navigable waterway. Of this total, 650 miles are accessible at all seasons to barges with capacities of from 800 to 1,100 tons, depending upon the height of the water. The amount of goods transported by water—consisting mainly of agricultural produce, wood, minerals, and fuel—is very modest in comparison to the traffic on European rivers (for example, the commercial traffic from the port of Kinshasa does not

reach a million tons), but river transport remains essential for communications with regions that are inaccessible by road, especially in the *cuvette*. The three principal routes, all of which converge on the downstream terminus at Kinshasa on the Malebo Pool, run from Kisangani, from Ilebo (formerly Port-Francqui) on the Kasai, and from Bangui on the Ubangi. River transport, however, falls short of the role it could play in development. It has actually declined since the states of the Congo became independent in 1960 because of serious problems with aging equipment, a lack of maintenance of the infrastructure, and the poor functioning of the public waterway agencies. In Zaire only the section from Ilebo to Kinshasa is still important, because it constitutes the river link (the other link being a railway between Kinshasa and Matadi) by which part of the copper production of Shaba is conveyed to the coast.

This network has fostered economic development in inland areas, far from the coast. Varied activities include the production of palm oil on the banks of the Kwilu, centred on the port of Kikwit, and the establishment of plantations of robusta coffee in the Kisangani area.

Before such developments could be undertaken, however, it was necessary to overcome the barrier to the sea formed by the Congo's lower course. That feat was accomplished in 1898 with the opening of the railway between Matadi and Léopoldville (now Kinshasa) and in 1934 by the completion of the Congo-Ocean rail line on the right bank between Brazzaville and Pointe-Noire.

Railways

While the river system facilitates navigation, it also hinders land transportation. Only a small number of bridges cross the Congo and its tributaries. The Kongolo rail and road bridge over the Lualaba was reconstructed in 1968, and a bridge over the Congo at Matadi was opened in 1983. Numerous projects to improve the situation nevertheless exist, notably a link between Kinshasa and Brazzaville. This project has long been under discussion, although to financial obstacles are added difficulties caused by political dissension. Several times since the two countries gained independence in 1960, such dissensions have interrupted the ferry traffic between the two capitals.

Power. It has been estimated that the hydroelectric potential of the Congo basin amounts to about one-sixth of the known world resources, but only a fraction of this potential has been harnessed. The single site of Inga, just upriver from Matadi, has a power potential estimated at more than 30,000 megawatts. Two hydroelectric projects, called Inga I and Inga II, have been completed there since Zaire's independence. Although the combined installed capacity of Inga is only a small fraction of the total potential, it is greater than the present power consumption of Zaire. Thus, it will be many years before the Congo region's energy needs equal the potential output of the river.

Study and exploration. The problem of the origin of

the Congo confronted European explorers from the time that the Portuguese navigator Diogo Cão discovered the river's mouth in 1482, which he believed to be a strait providing access to the realm of the mythical Prester John, a Christian priest-king. It is virtually certain that, well before the Welsh explorer Henry Morton Stanley arrived in 1877, some 17th-century Capuchin missionaries reached the shores of Malebo Pool. This exploit, however, was not followed up, even by the amply supplied Tuckey expedition, which was sent out by the British admiralty in 1816. The expedition was decimated and had to retrace its footsteps even before it had surmounted the cataracts. Preposterous hypotheses about the river continued to be entertained, connecting, for example, the upper Niger to the Congo or maintaining that the Congo and the Nile both flowed from a single great lake in the heart of Africa.

Even after the discovery of Lake Tanganyika by the British explorers Richard Burton and John Speke (1858), then of the Lualaba (1867) and of Lake Bangweulu (1868) by the Scottish explorer David Livingstone, uncertainty remained—uncertainty that Stanley was to dissipate in the course of his famous expedition in 1876 and 1877 that took him by water over a period of nine months from the Lualaba to the Congo's mouth. In the interior of the Congo basin, and above all on the right bank, the final blank spaces on the map could not be filled in until about 1890, when the exploration of the upper course of the Ubangi was completed. Stanley's
expedition

EAST AFRICAN LAKES

The majority of East African lakes lie within the East African Rift System, which forms a part of a series of gigantic fissures in the Earth's crust extending northward from the Zambezi River valley through eastern and northeastern Africa and the Red Sea to the Jordan River valley in southwestern Asia. In East Africa itself, the southern, eastern, and western branches of the system can be discerned.

For map coverage of the East African lakes, see above *East African mountains*.

Occupying the Southern Rift Valley is Lake Nyasa (Lake Malaŵi), which drains into the Zambezi River. Marking the course of the Western Rift Valley are Lakes Tanganyika, Kivu, Edward, and Albert (also called Mobutu Sese Seko)—the first two of which are situated within the drainage basin of the Congo River, while the other two constitute part of the Nile River drainage system. With the exception of Lake Rudolf (Lake Turkana), the lakes found in the Eastern (Great) Rift Valley are smaller than those of the Western Rift and constitute several independent inland drainage basins.

Located in a shallow downwarping between the Eastern and Western Rift highlands is Lake Victoria, which among the freshwater lakes of the world has a surface area that is second only to that of Lake Superior in North America. On a smaller scale, East Africa also includes some fine examples of crater lakes, and on Mount Kenya and in the Ruwenzori (Rwenzori) Range are found glacial tarns, small lakes each of which occupies a basin, or cirque, scraped out by a mountain glacier.

Of the eight largest lakes—Victoria, 26,828 square miles (69,485 square kilometres) in area; Tanganyika, 12,700; Nyasa, 11,430; Rudolf, 2,473; Albert, 2,160; Kivu, 1,040; Rukwa, 1,000; and Edward, 830—only one, Rukwa, in Tanzania, lies wholly within a single political entity. The northern shore of Kenya's Lake Rudolf is in Ethiopia; Lake Victoria is divided among Uganda, Tanzania, and Kenya. In the west the international boundary between Uganda and Zaire runs through the centre of Lake Albert; the same boundary places two-thirds of Lake Edward in Zaire and the remainder in Uganda. Lake Kivu lies between Rwanda and Zaire; the waters of Lake Tanganyika are shared among Tanzania, Zaire, Burundi, and Zambia. Malaŵi and Mozambique have territorial waters on Lake Nyasa, and, since its independence, Tanzania has also advanced claims to its territorial waters because it also occupies a part of the lakeshore.

Physical features. *Physiography.* The surface levels of the lakes on the irregular floor of the Eastern Rift Valley

are of varying heights, rising from Lake Rudolf (1,230 feet [375 metres] above sea level) through Lake Baringo (3,200 feet) to Lake Naivasha (6,180 feet), after which there is a decrease in height to Lake Magadi (1,900 feet). The Omo River from the Ethiopian Plateau is the only perennial affluent of Lake Rudolf, which is the lowest of the major East African lakes. Although it has the typical elongated form of a rift lake, Rudolf is relatively shallow (240 feet at its centre, although it reaches about 400 feet in a small depression at the southern end), as are the other lakes of the Eastern Rift. Its eastern and southern shores are bounded by rocky margins of volcanic origin; the lower western and northern shores are mostly composed of sandy sediments. South of Lake Magadi the splaying continuation of the Eastern Rift into northern Tanzania is indicated by Lakes Natron, Manyara, and Eyasi.

In the Western Rift Valley the northwestern and southeastern shores of Lake Albert are flanked by steep escarpments; wild ravines and fine cascades form a conspicuous feature of these geologically young tectonic (fault-formed) landscapes, the scale being greater on the Zaire than on the Uganda side. There is a considerable lowland area at the northern end of the lake, where, about 20 miles below Murchison (Kabalega) Falls, the Victoria Nile enters Lake Albert, to leave almost immediately as the northward-flowing Albert Nile. The southern end of Lake Albert contains an alluvial flat and a papyrus-choked delta formed by the Semliki River, which both carries the outflow from Lake Edward and provides drainage from the rain-soaked Ruwenzori Range.

Lake Edward, of which the deepest part (367 feet) is in the west under the Congo Escarpment, receives the Rutshuru River as its principal affluent. On the northeast it is connected with Lake George by the 3,000-foot-wide Kazinga Channel. At an altitude of approximately 3,000 feet above sea level, the surfaces of both lakes are nearly 1,000 feet higher than that of Lake Albert.

Separating the basins of Lake Edward and Lake Kivu are the Virunga Mountains, which thus divide the drainage system of the Nile River from that of the Congo River. With clear water, a broken shoreline, and a mountainous setting, including the relatively recent volcanoes (Nyamulagira and Nyiragongo) of the Virunga Mountains, Lake Kivu possesses outstanding scenic attractions. Its outflow is southward by the turbulent Ruzizi River, which drops more than 2,200 feet on its way to Lake Tanganyika. This latter lake, long and narrow, is second only to the Soviet Union's Lake Baikal in depth, penetrating at its maximum to 4,710 feet, which is more than 2,400 feet below sea level. Typical, too, are the flanking escarpments, which often rise sheer from the lake; the only sizable lowland is the lower Ruzizi valley. The drainage of the Malagarasi River system enters Lake Tanganyika about 25 miles south of Kigoma, Tanz.; at its southern end, on the frontier with Zambia, the 700-foot Kalambo Falls occur where the Kalambo River tumbles over the escarpment. The overflow to the Lualaba River, a tributary of the Congo, is via the shallow and sometimes obstructed Lukuga River outlet on the western side.

Lake Victoria, with its quadrilateral shape, relative shallowness (maximum depth of about 260 feet), and an area that is more than twice as great, is quite different from Lake Tanganyika. Set in a region of erosion surfaces instead of tectonic escarpments, it is bounded by a shoreline of considerable variety: on the west a straight, cliffed coast gives way to papyrus swamp; headlands and deep indentations mark the intricate northern shores; a major inlet, the Winam (formerly Kavirondo) Bay, is located on the east; and on the southern shores the Speke, Mwanza, and Emin Pasha gulfs lie amid rocky, granitic hills. Ukerewe, situated in the southeast, is the largest island in the lake; in the northwest the Sese Islands constitute a major archipelago. At the entrance to the channel leading to Jinja, Uganda, lies Buvuma Island. There are numerous other islands, most being of ironstone formation overlying quartzite and crystalline schists. The Kagera River, largest of the affluents, may be considered as being the most remote headstream of the Nile. The outlet of the lake and the conventional source of the Nile is at Jinja, where after

The
Virunga
Mountains

The eight
largest
lakes

flowing over the now-submerged Ripon Falls, the Victoria Nile begins its journey toward the Mediterranean Sea through the sluices of the dam at Owen Falls.

Lake Rukwa is situated in a northwest- to southeast-trending side rift, parallel with the southern part of the Lake Tanganyika rift and continuing the structural alignment of the northern end of Lake Nyasa. Lying on flat alluvium (soil, gravel, sand, and stone deposited by running water), Rukwa is extremely shallow (20 feet at the greatest depth), and any change of surface level causes great fluctuations in its area. Southeast of Lake Rukwa, beyond the volcanic mass of Rungwe Mountain, Lake Nyasa, third in size among the East African lakes, has the same characteristics as Lake Tanganyika but in less extreme form. It is deepest in the north (2,310 feet), where, on the Tanzanian side, the Livingstone Mountains rise precipitously from the lake surface. In the northwest, however, there is a well-defined alluvial plain. From the east come the waters of the Ruhuhu River, and numerous streams flow across the Malaŵi Plateau to the western shore. In the shallower, southern part there are several lake plains and sandy beaches. The Shire River outlet at the southernmost end has an extremely small gradient in its upper section, but in its middle course the river is interrupted by cataracts before emptying into the Zambezi.

Formation
of the
lakes

Geology. The East African rifts attained their present form mainly as a result of Pleistocene earth movements from 1,600,000 to 10,000 years ago, and the lakes must have been formed after the landscapes in which they are set. The shallowness of such lakes as Albert (maximum recorded depth 190 feet) and Edward (367 feet) is the result of the thick layers of sediment upon which they rest. In some lakes, too, volcanic activity has played a part in blocking drainage and shaping shorelines. Raised beaches indicate that the lake levels were higher and their surfaces were more extensive during rainy phases of the Pleistocene Epoch. In the Eastern Rift, for instance, Lakes Rudolf and Baringo were formerly part of one lake, from which there was a link via the Sobat River with the White Nile. Subsequent drier conditions caused the eastern lakes gradually to dwindle in size, with many fluctuations, to their present independent status.

The lakes of the Western Rift have experienced their own geologic changes. Before the geologically recent blocking of the rift by the eruption of the Virunga Mountains, the drainage of Lake Kivu was probably northward into the Nile. The fossil record suggests that the organic content of Lakes Edward and George was considerably reduced during a period of intense volcanic activity around their shores, although several species of fish (*e.g.*, *Tilapia nilotica*) appear to have survived. Toward the end of the Middle Pleistocene (about 100,000 years ago), when the

rise in the shoulders of the Western Rift resulted in the reversal of the westward-flowing drainage of such rivers as the Kagera, Katonga, and Kyoga-Kafu, Lakes Victoria and Kyoga were formed by water diverted from the northern section of the rift. Eventually, however, the drainage of most of Uganda returned to the Western Rift and to the Nile. The subsequent reductions in the level of Lake Victoria are indicated by a series of strandlines around its shores.

Climate. Those East African lakes that lie in inland troughs at altitudes of about 2,000 feet or less have a hot, dry climatic environment with a high potential evaporation. In the higher parts of the rift floors, however, climatic conditions approach those of the flanking highlands. In the Western Rift moist air from the Congo basin is a source of the more humid conditions prevailing over Lakes Tanganyika and Kivu. The glacial tarns of Mount Kenya and the Ruwenzori Range are in the frigid zone.

Large lakes tend to create or influence their own climates, and this effect is most marked on the western and northern margins of the immense mass of Lake Victoria. There, in a zone 30 to 50 miles wide, temperatures rarely rise above 80° F (27° C) or fall below 60° F (16° C), and rainfall is well distributed throughout the year. Moreover, annual rainfall is high, being heaviest over the lake and decreasing inland from an average of 50 to 60 inches (1,300 to 1,500 millimetres) at the lake shores. At the northern end of Lake Nyasa, an annual rainfall total of about 120 inches results from similar influences reinforced by air convergence caused by the funnel-shaped relief at the head of the lake. Sudden and dangerous storms are likely to arise over the waters of all the major lakes.

Hydrology. The levels of the East African lakes are perceptibly sensitive to climatic fluctuations. Average seasonal ranges of level are small: no more than a foot on Lake Victoria, 1.3 feet on Lake Albert, and three to four feet on Lake Nyasa. Longer-term fluctuations, with consequential effects on the shorelines, are greater: during the 20th century the extreme range recorded on Lake Victoria has been 10.3 feet, compared with 17.3 feet on Lake Albert and 18.8 feet on Lake Nyasa. In each case the recorded maximum occurred in the early 1960s. The effects of drought are enhanced in small, shallow lakes: Lake Nakuru, in Kenya, dried up completely in 1939–40; at the end of 1949 Lake Rukwa was estimated to be one-fifth its normal size; and Lake Chilwa, in Malaŵi, suffered a drastic reduction of area in 1967–68.

There is a significant correlation between rainfall and variations in the level of Lake Victoria, and Lakes Kyoga and Albert follow—with an appropriate time lag—the conditions of Lake Victoria. In addition to rainfall, other factors affect the longer-term fluctuations of Lakes Tan-

Lake levels

Kay Honkanen—Ostman Agency

Lake Kivu in East Africa between Rwanda and Zaire. The western escarpment of the Western Rift Valley rises on the far side of the lake.

ganyika and Nyasa. The Lukuga River outlet of Lake Tanganyika tends to become blocked intermittently by silting, consolidated by swampy growth. Similarly, in the flat valley of the upper Shire River, periods of erosion alternate with the building of bars of silt and sand reinforced by reeds. As a result, between 1915 and 1935 there was virtually no outflow from Lake Nyasa.

Many of the lakes, especially those in the Eastern Rift, are brackish, but Baringo and Naivasha are exceptions in that they are freshwater lakes and are believed to have subterranean outlets. At the other extreme of salinity, Magadi is a soda lake, in which the continuing source of sodium carbonate (natron) appears to be alkaline waters of deep-seated origin. Lakes Edward and George have the highest salinities among the lakes of the Western Rift, but the alkalinity is not excessive. The problem of the deeper lakes, such as Tanganyika, Nyasa, and Kivu, is that their deeper waters are permanently deoxygenated and thus constitute a biological desert: 75 percent of the volume of Lake Tanganyika and 99 percent of that of Kivu are within this category. Moreover, all three lakes contain lethal amounts of hydrogen sulfide in their deeper waters, and Lake Kivu also contains vast quantities of methane.

Plant life. The vegetation setting of the lakes varies from the semidesert, in which Lake Rudolf is situated, to the patches of closed evergreen forest on the western and northern shores of Lake Victoria. Between the two extremes and in accordance with the position of the individual lakes, bushland and thicket, grassland, savanna, or open woodland occur. The oil palm, which is characteristic of western Africa and of the Congo region, is found on the shores of Lake Tanganyika. Heavily populated and intensively cultivated areas marginal to Lakes Victoria and Nyasa present vegetation types that have been much modified by human activity. The lakeshores may consist of open landscapes of headland or beach or may contain plants associated with swamps, such as the giant sedge, *Cyperus papyrus*, which is the most prevalent.

Fish genera

Animal life. Among the main genera of fish in the East African lakes are the mouthbreeders *Tilapia*, much the most important in number of species and in total quantity; *Haplochromis* (which, like the *Tilapia*, belong to the Cichlidae family), a group of small perchlike fish; *Clarias* (barbel) and *Bagrus* among the catfish; *Hydrocynus* (tiger fish); various carps, including *Labeo*, *Barilius*, and *Barbus*; *Protopterus*, a lungfish; *Mormyrus*, a member of the elephant-snout fish family; and *Stolothrissa tanganicae* (*dagaa*), a small sardineline fish.

The more strongly saline lakes, such as Nakuru, Elmenteita, Manyara, and, above all, Magadi and Natron, have a severely limited fish life. Lake Kivu also has a fish population that is neither varied nor abundant. Although fish are present in enormous quantities in Lake Rukwa, the number of species is not large, and the stock is dominated by the endemic *Tilapia rukwaensis*. Successive droughts such as that of 1949 explain why there are so few species in Lake Rukwa; the years immediately following 1949, on the other hand, provide an excellent example of the amazing recovery powers of tropical fish populations.

The majority of the lakes, though, have a rich and varied fish life, of which a high proportion of species are endemic to the individual lake. The Cichlidae, for example, are especially prone to form new species, and there are between 100 and 200 species of the family in Lakes Victoria and Kyoga.

Lake Albert has a fish life that is related to that of the Nile; it includes Nile perch, tiger fish, and *Polypterus* (bichir). The physical barrier of Murchison Falls, situated near the northern end of Lake Albert, marks the frontier of a separate faunal province formed by Lakes Victoria and Kyoga. Several of the Lake Albert genera are not found in these two lakes, which contain many unique species. Similarly, the rapids on the Semliki River have prevented the introduction of fish species from Lake Albert into Lakes Edward and George, which otherwise are particularly rich in fish. On the other hand, the presence of Nile perch, tiger fish, and bichir in Lake Rudolf serves to indicate its former connection with the Nile. The translocation of fish by humans, however, has caused a man-

made zoogeographic revolution, the full effects of which cannot yet be discerned.

The hippopotamus is ubiquitous around the lakeshores, except those of Lake Kivu; the crocodile is also widespread, although absent from Lakes Edward, George, and Kivu, each of which is sheltered from the spread of this reptile by falls in the outflow river, with cool mountain torrents and sunless forest as additional deterrents. Traditionally there has been an inverse relationship between the density of game and that of human settlement. The establishment of national parks and game reserves, however, has encouraged the increase of game population, although widespread poaching has created serious problems. Among the variety of game to be seen in the neighbourhood of the lakes are elephant, buffalo, and various antelopes.

Waterfowl

Among the resident and migrant birds in evidence, waterfowl are especially noticeable. Several of the Eastern Rift lakes—such as Nakuru, Elmenteita, and Manyara—are famous for their vast congregations of flamingos. Forming the basis of a national park in which the emphasis is on aquatic birds, Lake Nakuru is an ornithologist's paradise; Lake Edward and the Kazinga Channel are also notably rich in birdlife. The fish-eating birds—cormorants, darters, and kingfishers—are also part of the ecology of the lakes.

The people and the economy. Although not all the shores of Lake Victoria are well settled, the lands marginal to the lake are among the most densely populated in Africa. The best-known groups inhabiting these marginal lands are the Ganda, Soga, Luhya, Luo, Sukuma, and Haya, all of whom, except for the Luo (who are Nilo-Saharan speakers), are Bantu-speaking. The eastern margins of Lake Kivu reflect the high population density of Rwanda, and the lowlands at the northern and southern ends of Lake Nyasa are also well populated. In general, though, the shores of the Eastern and Western Rift lakes are sparsely settled.

Resource exploitation. Fish constitute one of the major resources of the East African lakes, but the degree of exploitation varies considerably from lake to lake. Uganda, for example, possesses one of the largest freshwater fishing industries in the world, while production from Kenya is appreciably lower. The potential of Lake Rudolf, well-stocked with Nile perch, has been only partially realized, whereas to the south the waters of the much smaller Lake Baringo have been more strongly exploited. Black bass and several species of *Tilapia*, both of which were introduced, form the basis of the commercial fishery of Lake Naivasha; the lake is also a popular weekend resort for Nairobi residents, many of whom are attracted by the sport fishing. At Lake Magadi, on the other hand, soda ash, which is the leading mineral export of Kenya, is extracted and refined.

The strongly developed Ugandan fishery of Lake Kyoga is largely based on introduced Nile perch; and although Lake Victoria is considered to be essentially a *Tilapia* fishery, there are also important catches of other species, including Nile perch. The fisheries of Lake Victoria are important as a source of protein for the rural and urban population living in the vicinity. The Luo and the Sese Islanders have shown a marked interest in the industry, which is practiced by independent fishermen, typically using planked canoes with outboard motors.

Another important resource at Lake Victoria is the Owen Falls power station at Jinja, which provides electricity for use in Uganda and Kenya. In addition, the dam at the falls enhances the potential of Lake Victoria as a storage reservoir for the Nile River, in the process raising the average level of the lake by three feet. The Lake Victoria region has great potential for economic growth, although greater cooperation among its bordering states is needed to realize this potential.

Hydroelectric power

The varied fish life of Lake Albert includes Nile perch and two genera of tiger fish, of which one, *Alestes*, provides two-thirds of the total weight landed on the Uganda shores of the lake. It is believed, however, that the total catch is below the maximum sustainable yield of the lake. A tourist attraction adjacent to Lake Albert is the Murchison Falls (Kabalega) National Park, which extends down to the narrowing outlet at the northern end of the lake.

Lakes Edward and George support remarkably fertile fisheries. The Zaire shores of Lake Edward are within the Virunga National Park, while the Ugandan portion of the lake lies within the Queen Elizabeth (Ruwenzori) National Park. Close to the northeastern shore of Lake Edward, Lake Katwe, which lies in one of the numerous shallow craters within the Edward-George branch of the Western Rift, is a source of salt.

The fisheries potential of Lake Kivu is more limited than that of the other lakes of the Western Rift, but a large quantity of natural gas is obtained from the lake each year. Tourist attractions are available, and, at the outlet of the lake below Bukavu, Zaire, a hydroelectric station on the Ruzizi River provides power to the Burundi capital of Bujumbura on the northern shores of Lake Tanganyika.

As a whole, the borderlands of Lake Tanganyika are characterized by underdevelopment, although peasant fishermen operate in the northern part of the lake, where fisheries are dominated by the exploitation of *dagaa*. There is a secondary output from other species, but in the absence of shallow, marginal waters *Tilapia* do not form a significant proportion of the catch. Despite the changes in water level to which it is liable and its remoteness from markets, Lake Rukwa is third to Lakes Victoria and Tanganyika among the freshwater fisheries of Tanzania.

In the northern waters of Lake Nyasa the fish caught include catfish and some species of carp, whereas in the southern part of the lake shallow, sheltered waters provide a good habitat for *Tilapia* and for *Labeo mesops* (a species of carp). The majority of the fishermen also practice subsistence agriculture, except on Likoma Island. Commercial fishing, however, has intensified the demand upon the inshore species, resulting in a reduction of the fish population.

Transportation. Most of the East African lakes are reasonably accessible by road and air. Among the major lakes, however, Rudolf remains the least accessible by road. With the exception of Lake Albert, the main lakes of Uganda are well served by surface communications. There are fairly good road communications to Lake Kivu, but considerable stretches of the shores of Lakes Tanganyika and Nyasa have no proper roads. Scheduled inland-waterway services have been developed on Lakes Victoria, Tanganyika, and Nyasa; elsewhere, as on Lake Kivu, there are launch services. Otherwise, canoes and, to a small extent, dhows transport people and goods.

Fluctuations of the lake level and changing economic conditions have brought about the closure of a number of ports on Lake Victoria. The main ports in use are Kisumu in Kenya; Musoma, Mwanza, and Bukoba in Tanzania; and Port Bell (serving the Kampala metropolitan area) and Jinja in Uganda. Entebbe, Uganda, which is no longer a lake port, has an international and regional airport; there is also an international airport at Bujumbura, Burundi's port on Lake Tanganyika. Lake services operate on Victoria, including those from rail-ferry terminals at Jinja, Kisumu, and Mwanza; all three have rail connections with the maritime ports. On Lake Tanganyika, a rail line connects Kigoma, Tanz.—terminus of the rail line from the Tanzanian capital of Dar es Salaam—with the Zambian port of Mpulungu. In Zaire a company based at the railway port of Kalemie maintains links with Kigoma, Bujumbura, and Kalundu (for the town of Uvira). Malaŵi's railway system provides services on Lake Nyasa and has rail connections with Beira and Nacala on the coast of Mozambique, and its major ports are Nkhota Kota, Chilumba, and Karonga.

Study and exploration. Following in the track of earlier Arab trading expeditions, the British explorers Sir Richard Burton and John Hanning Speke reached the eastern shore of Lake Tanganyika in 1858. It was there, at Ujiji, that David Livingstone, the Scottish explorer-missionary who had pioneered the Shire River route to Lake Nyasa in 1859, was met by the Welsh explorer Henry Morton Stanley in 1871, after which the two subsequently made a reconnaissance of the northern part of the lake. Then, in 1874, in the course of his east-west traverse of the continent, the English traveler Verney Lovett Cameron explored the Lukuga River outlet on the western shore of Tanganyika.

While Burton remained at Tabora in 1858, Speke journeyed northward and became the first European to view the waters of Lake Victoria. In 1862, after he returned to East Africa with a fellow countryman, James Augustus Grant, Speke stood above the Ripon Falls, which he proclaimed as the source of the Nile. The details of the Lake Victoria shoreline were filled in by Stanley when he circumnavigated the lake in 1875.

Meanwhile another Englishman, Samuel White Baker, and his wife, Florence, had approached the East African lakes from the north, reaching Lake Albert in 1864. In 1888 to 1889 Stanley, in company with Mehmed Emin Paşa (or Pasha), the German explorer, traced the Semliki River to its source in Lake Edward. Finally, in 1894, a German explorer, Adolf von Götzen, became the first European to visit Lake Kivu.

During the 1880s Europeans explored the lakes of the Eastern Rift. Lakes Magadi and Naivasha were visited by a German traveler, Gustav Fischer, in 1883, and in the same year the Scottish explorer Joseph Thomson reached the shores of Lake Baringo. Five years later Count Sámuel Teleki and Ludwig von Höhnelt reached Lake Rudolf. Considerable scientific study of the lakes region has been conducted since that time. (S.J.K.B.)

NIGER RIVER

The Niger River, with a length of 2,600 miles (4,200 kilometres), is the principal river of western Africa and the third longest in Africa after the Nile and the Congo. It is believed to have been named by the Greeks. Along its course it is known by several names. These include the Joliba (a Malinke word meaning "great river") in its upper course; the Mayo Balleo and the Isa Eghirren in its central reach; and the Kwarra, Kworra, or Quorra in its lower stretch.

Physical features. *Physiography.* The Niger rises in Guinea at 9°05' N and 10°47' W on the eastern side of the Fouta Djallon (Guinea) highlands, only 150 miles inland from the Atlantic Ocean. Issuing as the Tembi from a deep ravine 2,800 feet (850 metres) above sea level, it flows due north over the first 100 miles. It then follows a northeasterly direction, during the course of which it receives its upper tributaries—the Mafou, the Niandan, the Milo, and the Sankarani on the right and the Tinkisso on the left—and enters Mali. Just below Bamako, Mali's capital, the Sotuba Dam marks the end of the upper river. From there the Niger once dropped more than 1,000 feet in about 40 miles into a valley formed by tectonic subsidence; but the rapids in this stretch have been submerged by the waters backed up by the Markala Dam, located some 150 miles downstream of the Sotuba Dam near Sansanding. In this stretch, at Koulikoro, the river takes a more east-northeasterly direction, and its bed becomes fairly free from impediments for about 1,000 miles.

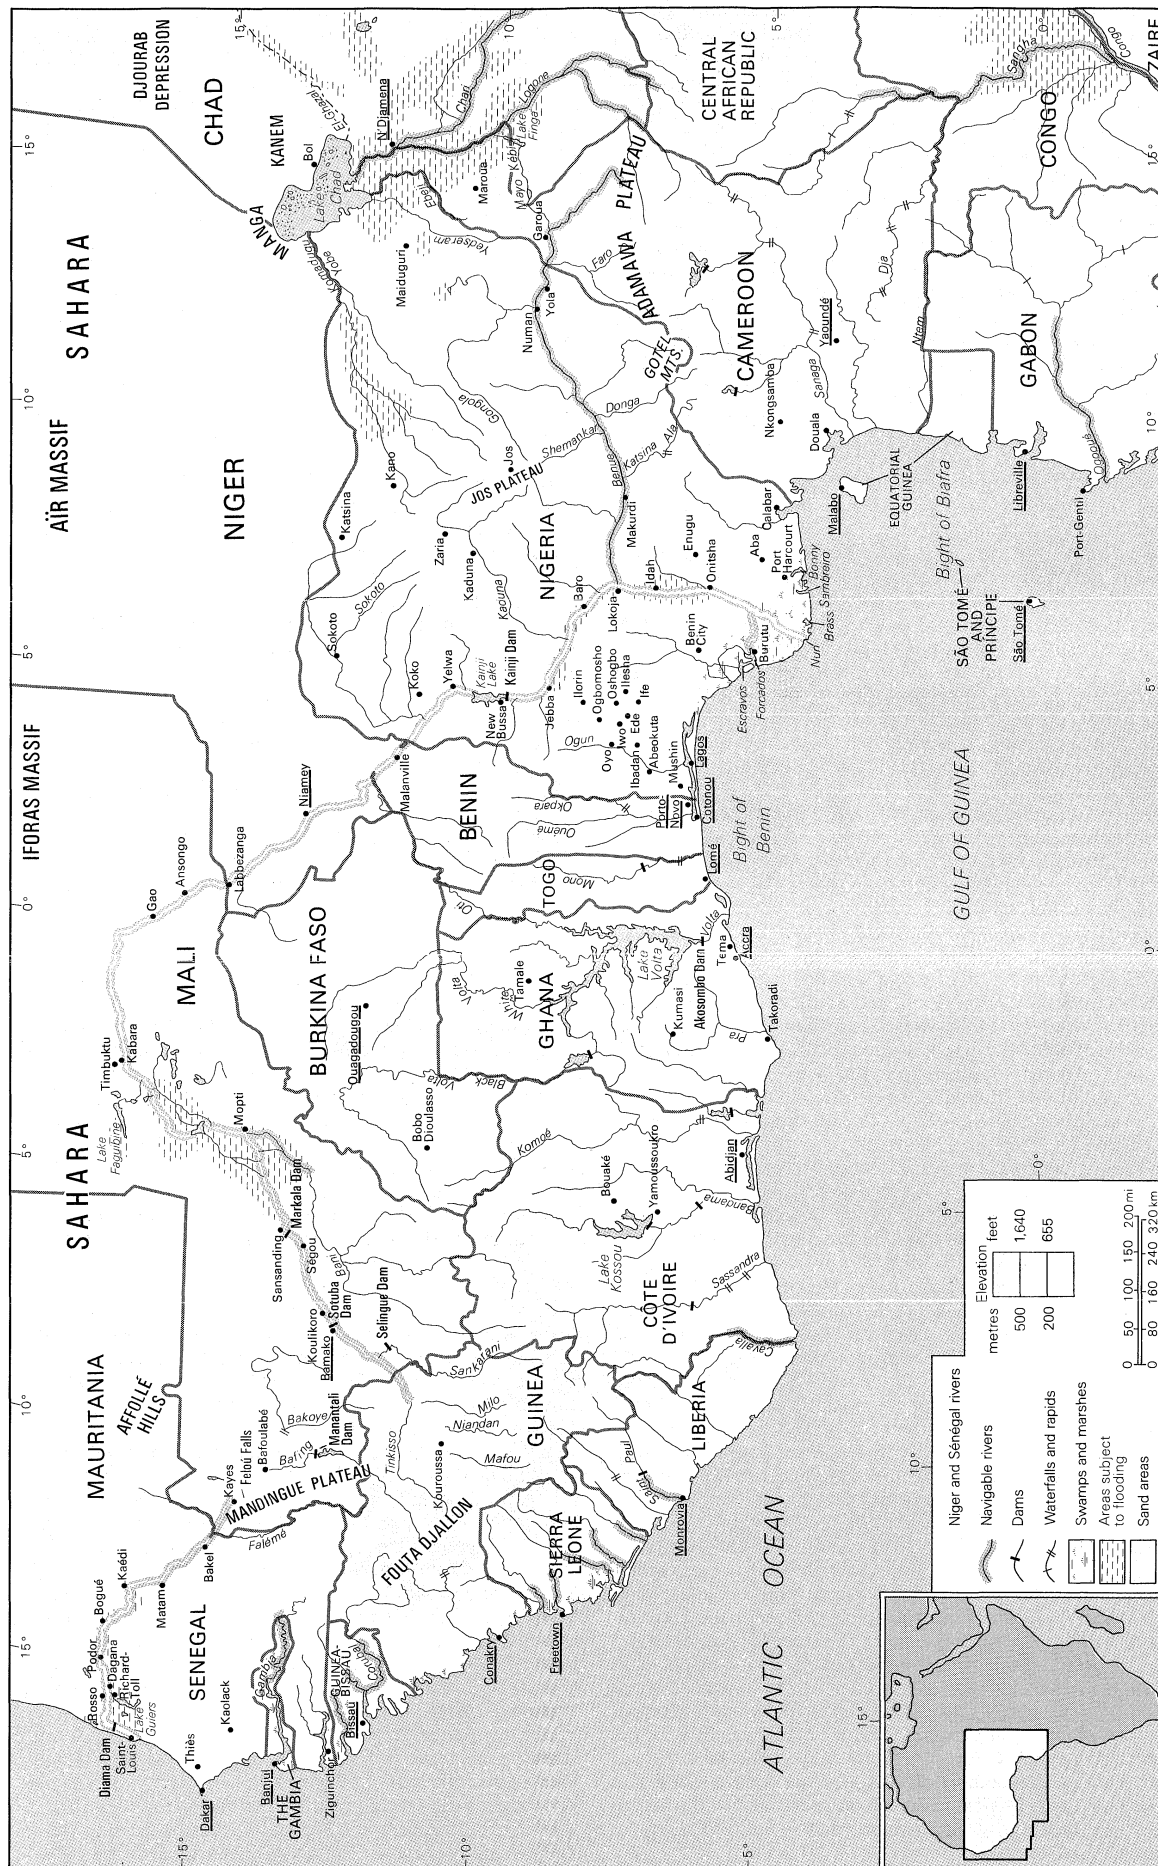

At Mopti the Niger is joined by the Bani, its largest tributary on the right, after which it enters a region of lakes, creeks, and backwaters that is often called the "internal delta" of the Niger. These lakes are chiefly on the left bank and are connected to the river by channels that undergo seasonal changes in the direction of flow. At high water most of the lakes become part of a general inundation. Largest of the lakes in this region is Lake Faguibine, which is nearly 75 miles long, 15 miles wide, and more than 160 feet deep in places.

The labyrinth of lakes, creeks, and backwaters comes to an end at Kabara, the port of Timbuktu (Tombouctou). There, the river turns almost due east, passing its most northern point at latitude 17°05' N. Some 250 miles downstream from Timbuktu, a rocky ridge that obstructs the course of the river is pierced by a defile (narrow gorge) more than a mile long, with an average width of about 800 feet and a depth of more than 100 feet in places. At low water the strong current there endangers navigation. A short way downstream the river turns to the southeast and widens considerably, flowing to Gao across a floodplain three to six miles wide. This most northerly bend of the Niger flows through the southern fringe of the Sahara.

The middle course of the Niger River is navigable to small craft during high water as far downstream as Ansongo—

some 1,100 miles in all. Below Ansongo, 430 miles downstream from Timbuktu, navigability is interrupted by a series of defiles and rapids. The river becomes navigable to small vessels again at Labbezanga—from which it flows into Niger—and continues to be navigable to the Atlantic Ocean. Navigation is seasonal, however, because of the fluctuations in the water level in the rainy and dry seasons.

Downstream from Jebba, in Nigeria, the Niger enters its lower course, flowing east-southeast through a broad and shallow valley 5 to 10 miles wide. About 70 miles from Jebba it is joined by the Kaduna River—an important tributary that contributes about 25 percent to the annual discharge of the river below the Niger-Kaduna confluence—and about 25 miles above Lokoja the river turns to the south. At Lokoja the river receives the water of its greatest tributary, the Benue (see below), thereby approximately doubling the volume of its annual discharge. At their confluence the Niger is about three-quarters of a mile wide, and the Benue more than a mile. Together they form a lakelike stretch of water about two miles wide that is dotted with islands and sandbanks. From Lokoja downstream to the town of Idah, the Niger flows in a restricted valley, enclosed by hills and in some places flanked by sandstone cliffs up to 150 feet high. Between Idah and Onitsha, the largest town on the Niger's banks in Nigeria and the third largest riverine town after Bamako and Niamey (Niger), the valley narrows as the river flows through what is probably a fault in the area's sandstone. It emerges at Aboh, separating into many branches before reaching the Gulf of Guinea via Africa's largest delta.

The Niger delta, which stretches for nearly 150 miles from north to south and spreads along the coast for about 200 miles, extends over an area of 14,000 square miles (36,000 square kilometres). Within the delta the river breaks up into an intricate network of channels called rivers. The Nun River is regarded as the direct continuation of the river, but some of the other important channels include (from west to east) the Forcados, the Brass, the Sambreiro, and the Bonny. The mouths of these channels are almost all obstructed by sandbars. The Forcados, for instance, which supplanted the Nun as the most traveled channel in the early 20th century, was in turn displaced by the Escravos River in 1964. The delta is being gradually extended seaward by the increments of silt brought down by the river, and mangrove swamps extend beyond its outer edge.

The Benue (meaning "Mother of Water" in the Batta language) rises at 4,400 feet above sea level on the Adamawa (Adamaoua) Plateau in northern Cameroon at about 7°40' N and 13°15' E. In its upper course, which extends north-northwest to its confluence with the Mayo Kébi, close to

the town of Garoua, it is a mountain torrent, falling more than 2,000 feet over a distance of 110 miles. The river then turns westward into Nigeria and, for the greater part of its course, flows over a broad and fertile floodplain. At Yola, a town 600 feet above sea level and some 850 miles inland, the width of the river in flood is from 1,000 to 1,500 yards (910 to 1,370 metres). Near Numan, some 30 miles downstream from Yola, the Benue is joined on its north bank by its most important tributary, the Gongola. Other important tributaries include the Shemankar, the Faro, the Donga, and the Katsina Ala.

Together with its tributaries, the Niger drains a total area of some 730,000 square miles. The Niger drainage system is bounded in the south by such highlands as the Fouta Djallon, the Banfora Cliffs in Burkina Faso, the Plateau of Yorubaland, and the Cameroon highlands. This southern rampart forms a watershed separating the rivers of the Niger system from others that flow directly southward to the Atlantic Ocean. With the exception of such highlands as the Jos Plateau, the Iforas and Air massifs, and the Ahaggar Mountains to the north and east, the northern edge of the Niger basin is, however, less clearly defined than the southern edge.

Climate. Within the Niger basin climate shows great variability. Mean annual rainfall decreases northward from more than 160 inches (4,100 millimetres) in the delta area to less than 10 inches in Timbuktu. Both the upper and the lower stretches of the river, however, drain areas with more than 50 inches of rain per year. The middle Niger is an area where rainfall decreases and is also the sector where the greatest amount of evaporation takes place. It is estimated that in the lake region the Niger loses nearly 65 percent of the annual volume of discharge that flows past Mopti.

Hydrology. Because of climatic variations the annual river flood does not occur at the same time in different parts of the basin. In the upper Niger the high-water discharge occurs in June, and the low-water season is in December. In the middle Niger, a first high-water discharge—the white flood (so called because of the light sediment content of the water)—occurs soon after the rainy season between July and October; a second rise—the black flood (so called because of the greater sediment content)—begins in December with the arrival of floodwaters from upstream. May and June are the low-water months in the middle stretch. On the Benue there is only one high-water season. Because of the Benue's more southerly location, this normally occurs from May to October—earlier than on the middle Niger. The lower Niger below its confluence with the Benue consequently has a high-water period that begins in May or June—about a month earlier than on the middle Niger—and a low-water period that is at least

The Niger
delta

The annual
floods

a month shorter, as the rains in the south start earlier. In January a slight rise occurs due to the arrival of floodwaters from the upper Niger. The difference between high and low water often measures as much as 35 feet.

Plant and animal life. Along its course the Niger traverses virtually all the vegetational zones of western Africa. The Fouta Djallon plateau, where the Niger rises, is covered by a type of sedge vegetation consisting of fine, wirelike tufts interspersed with bare rock surfaces. From the Fouta Djallon to well below the Niger's confluence with the Benue, the river flows mainly through savanna grassland country. In the north the grass is short and discontinuous, and thorny shrub and acacia wood occur. In the south of the grassland region, tall, tussocky grass is interspersed with fairly dense wooded vegetation. About the latitude of Onitsha, the river enters the high rain-forest belt, which merges below Aboh with the mangrove swamp vegetation of the delta.

Many varieties of fish are found in the Niger and its tributaries; the chief food species are catfish, carp, and Nile perch. Other Niger fauna include the hippopotamus, at least three different types of crocodile (including the much-feared Nile crocodile), and a variety of lizards. There is a rich collection of birds. Geese are found in the lake region, and heron, egrets, and storks are found both on the river and around the lakes. The striking crown bird is found wherever there is open ground in the grassland zone, and pelicans and flamingos are particularly associated with the upper Benue area. Smaller riverine species include white-headed plover, crocodile bird, sandpiper, curlew, and green-red shank.

The people and the economy. The Niger valley is sparsely settled, although there are population concentrations in the lake region and near the confluence of the Niger and Benue. In medieval times the valley was the heartland of the Mali and Songhai empires, and some of the river towns date from this period. The ethnic pattern along the course of the river includes larger groups—such as the Bambara, the Malinke, the Songhai, and the Zerma (Djerma)—occupying both sides of the river above the Nigerian boundary, below which there are many small ethnic groups.

Fishing is an important activity along the length of the river system, especially during the dry season when the deep-sea and coastal fish catch is smallest. River fishing is a specialized occupation for certain peoples, such as the Bozo and Somono in the lake region, the Sorko on the middle Niger, the Kede and the Kakanda between Jebba and Lokoja, and the Wurbo and the Jukun on the Benue. The discovery and exploitation of petroleum in the delta region, however, has seriously disrupted fishing there; oil pollution has killed most of the fish, undermining the economy of the Ijo (Ijaw) people of the region.

Irrigation. The irrigation of the Niger valley—for the purpose of transforming it into a densely populated, agricultural corridor running through the interior of western Africa—has long been a goal of planners. In the 1930s the French colonial administration, for example, began to plan the irrigation of large areas in the lake region; a barrage at Sansanding that raised the level of the Niger was completed in 1947. Feeder canals were constructed, and huge tracts of irrigated land now produce rice, cotton, sugarcane, and vegetables. The British colonial administration also encouraged irrigated rice cultivation in the Bida region. In Nigeria large-scale irrigation schemes have been developed since the 1960s on the Niger and some of its tributaries, notably the Sokoto, Kaduna, and Benue.

The Niger is also a source of hydroelectricity. The largest project is the Kainji Dam in Nigeria, completed in the late 1960s. A 500-square-mile lake has been created upstream, offering opportunities for fishing and irrigation. Other projects include the Sotuba and Markala dams in Mali and dams at Jebba (on the Niger) and Shiroro (on the Kaduna tributary) in Nigeria.

Transportation. Most of the Niger River—more than 75 percent of its total length—is used by commercial shipping. From the Atlantic Ocean to Onitsha the river is navigable by large vessels throughout the year. From Onitsha to the confluence of the Benue and the Niger large

vessels can move for 10 months of the year (June–March). Navigation in this stretch is made possible by the influx of water from the Benue River, which is at high level in June. From Lokoja to Jebba the Niger is navigable to all craft only from October to mid-November. Thus, Jebba is in effect the head of navigation of the Niger waterway, although extreme fluctuation in water level at times constitutes a major handicap to vessels plying beyond Lokoja. Above Jebba the Niger is navigable only to smaller craft and is dependent locally on periods when water levels are adequate.

Rail and road routes cross the river at many points. Railway bridges span the river at Kouroussa and Jebba, and another crosses the Benue at Makurdi. There are road bridges over the Niger at Ségou, Malanville, Kainji, Jebba, Lokoja, and Onitsha and over the Benue at Makurdi, Numan, and Yola. Ferries cross the Niger at Bamako, Gao, Niamey, Yelwa, and Idah and cross the Benue at Garoua. The main river ports are Koulikoro, Timbuktu, Baro, Onitsha, Burutu, and Koko.

The coordination of multinational efforts to develop the Niger and its tributaries is the responsibility of the Niger River Commission, formed in 1963. The Commission has sponsored a study of the navigational possibilities of the middle Niger from Gao (Mali) to Yelwa (Nigeria). Moreover, in Nigeria several river basin development authorities have been established to develop more irrigation and fishing projects.

Study and exploration. It was not until the late 18th century that Europeans made systematic attempts to find the source, direction, and outlet of the Niger. In 1795 Mungo Park, a Scottish explorer, traveled overland from the Gambia region and reached the Niger near Ségou, where in July 1796 he established that the river flowed eastward. In 1805 Park sailed more than 1,500 miles down the river, seeking to reach its mouth, but he and his party were drowned in the rapids at Bussa (now covered by Lake Kainji). In 1822 another Scottish explorer, Alexander G. Laing, determined but did not visit the source of the river. In 1830 two English explorers, Richard and John Lander, established the lower course of the Niger by canoeing down the river from Yauri (now also covered by Lake Kainji), to the Atlantic Ocean, via the Nun River passage. In the second half of the 19th century two German explorers, Heinrich Barth and Eduard R. Flegel, in separate travels established the course of the Benue from its source to its confluence with the Niger. (A.L.M.)

NILE RIVER

The Nile, the father of African rivers and the longest river in the world, rises south of the equator and flows northward through northeastern Africa to drain into the Mediterranean Sea. It has a length of about 4,132 miles (6,650 kilometres) and drains an area estimated at 1,293,000 square miles (3,349,000 square kilometres). Its basin includes parts of Tanzania, Burundi, Rwanda, Zaire, Kenya, Uganda, and Ethiopia, most of The Sudan, and the cultivated part of Egypt. Its most distant source is the Kagera River in Burundi.

The Nile is formed by three principal streams, the Blue Nile (Arabic: Al-Baḥr al-Azraq; Amharic: Abay) and the Atbara (Arabic: Nahr 'Aṭbarah), which flow from the highlands of Ethiopia, and the White Nile (Arabic: Al-Baḥr al-Abyad), the headstreams of which flow into Lakes Victoria and Albert.

The name Nile is derived from the Greek Neilos (Latin: Nilus), which probably originated from the Semitic root *naḥal*, meaning a valley or river valley, and hence, by an extension of the meaning, a river. The fact that the Nile—unlike other great rivers known to them—flowed from the south northward and was in flood at the warmest time of the year was an unsolved mystery to the ancient Egyptians and Greeks. The ancient Egyptians called the river Ar or Aur (Coptic: Iaro), or "Black," in allusion to the colour of the sediments carried by the river when it is in flood. Nile mud is black enough to have given the land itself its oldest name, Kem or Kemi, which also means "Black" and signifies darkness. In *The Odyssey*, the epic poem written by the Greek poet Homer (7th century BC), Aigyptos is

Origin of
the name

Fishing

the name of the Nile (masculine) as well as the country of Egypt (feminine) through which it flows. The Nile in Egypt and the northern Sudan is now called An-Nil, Al-Bahr, and Bahr an-Nil or Nahr an-Nil.

Physical features. The Nile River basin, which covers about one-tenth of the area of the continent, served as the stage for the evolution and decay of advanced civilizations in the ancient world. On the banks of the river dwelled people who were among the first to cultivate the arts of agriculture and to use the plow. The basin is bordered on the north by the Mediterranean; on the east by the Red Sea Hills and the Ethiopian Plateau; on the south by the East African Highlands, which include Lake Victoria, a

Nile source; and on the west by the less well-defined watershed between the Nile, Chad, and Congo (Zaire) basins, extending northwest to include the Marrah Mountains of The Sudan, the Al-Jilf al-Kabir Plateau of Egypt, and the Libyan Desert (part of the Sahara).

The availability of water from the Nile throughout the year, combined with the area's high temperatures, makes possible intensive cultivation along its banks. Even in some of the regions in which the average rainfall is sufficient for cultivation, such as in The Sudan, marked annual variations in precipitation often make cultivation without irrigation risky. The Nile River is also a vital waterway for transport, especially at times when motor transport is not feasible—e.g., during the flood season. Improvements in air, rail, and highway facilities in the 20th century, however, have greatly reduced dependency on the waterway.

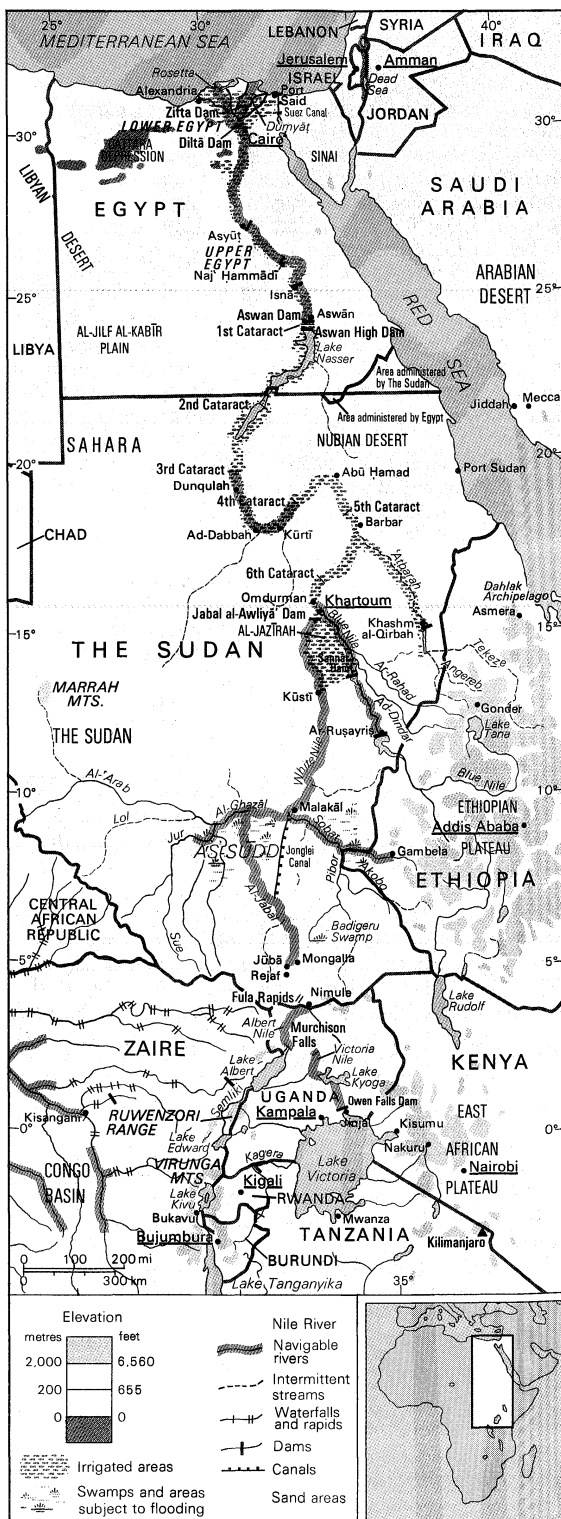

Physiography. It is thought that in the mid-Tertiary Period (approximately 30 million years ago) the early Nile, then a much shorter stream, had its sources about latitude 18° to 20° N. Its main headstream may then have been the present Atbara River. To the south lay the vast enclosed drainage system containing the large Lake Sudd. According to one theory on the evolution of the Nile system, about 25,000 years ago the East African drainage to Lake Victoria developed an outlet to the north, which sent its water into Lake Sudd. With the accumulation of sediments over a long period, the water level of this lake rose gradually; as a result of the overflow, the lake was drained, spilling over to the north. The overflow waters of Lake Sudd, rapidly forming a riverbed, linked the two major parts of the Nile system, thus unifying the drainage from Lake Victoria to the Mediterranean Sea.

The basin of the present-day Nile falls naturally into seven major regions: the Lake Plateau of East Africa, the Al-Jabal (El-Jebel), the White Nile, the Blue Nile, the Atbara, the Nile north of Khartoum in The Sudan and Egypt, and the Nile delta.

The Lake Plateau region of East Africa produces a number of headstreams and lakes that feed the White Nile. It is generally agreed that the Nile has several sources rather than one. The furthest headstream may be regarded as the Kagera River, which rises in the highlands of Burundi near the northern tip of Lake Tanganyika and then flows into Lake Victoria. The Nile proper, however, rises from Lake Victoria, the second largest freshwater lake in the world, which has an area of more than 26,800 square miles and forms a huge but shallow lake. The Nile begins near Jinja, Uganda, on the north shore of the lake, flowing northward over Ripon Falls, which has been submerged since the completion of the Owen Falls Dam in 1954. The northward stretch of the river, known as the Victoria Nile, enters the shallow Lake Kyoga (Kioga) and, passing through its swamp vegetation, flows out in a westerly direction, descending into the East African Rift System over Murchison (Kabalega) Falls before entering the northern end of Lake Albert. Unlike Lake Victoria, Lake Albert is a deep, narrow lake with mountainous sides. There the waters of the Victoria Nile unite with the lake waters, passing northward as the Albert Nile—a portion of the river, somewhat wider and slower, that is fringed with swampy growth and is navigable for steamers.

The Nile enters The Sudan at Nimule, and from there to Juba—a distance of some 120 miles—it is called the Al-Jabal River (Mountain Nile). This section of the river descends through narrow gorges and over a series of rapids, including the Fula (Fola) Rapids, and receives additional water from short tributaries on both banks; it is not commercially navigable. Below Juba the river flows over a large and very level clay plain, which extends through a narrow valley with hill country on either side, lying some 1,200 to 1,500 feet (370 to 460 metres) above sea level, and through the centre of which flows the mainstream. As the gradient of the Nile there is only 1:13,000, the great volume of additional water that arrives during the rainy season cannot be accommodated by the river, and, as a result, during those months almost the entire plain becomes inundated. This circumstance promotes the growth of enormous quantities of aquatic vegetation—including tall grasses and sedges (notably papyrus)—that collectively

Sources of the Nile

The Nile River basin and its drainage network.

is called sudd, literally meaning "barrier," and the region is known as As-Sudd. These great masses of vegetation, the growth of which is exacerbated by the gentle flow of the water, break off and float downstream, effectively choking the mainstream and blocking the navigable channels. Channels have become further choked since the 1950s by the rapid spread of the South American water hyacinth.

This basin receives drainage from numerous other streams. The Al-Ghazāl (Gazelle) River flows in from the southwestern Sudan, joining the Al-Jabal at Lake No, a large lagoon where the mainstream takes an easterly direction. The waters of the Al-Ghazāl undergo extensive loss through evaporation, and only a small proportion of them ever reach the Nile. A short distance above Malakāl the mainstream is joined by the Sobat (Baro in Ethiopia), and downstream from there the river is called the White Nile. The regime of the Sobat is quite different from the steady flowing Al-Jabal, with a maximum flow occurring between July and December; the annual flow of the Sobat is about equal to the water lost through evaporation in the As-Sudd marshes.

The White
and Blue
Nile rivers

The White Nile, about 500 miles in length, supplies some 15 percent of the total volume entering Lake Nasser (called Lake Nubia in The Sudan) downstream. It begins at Malakāl and joins the Blue Nile at Khartoum, receiving no tributaries of importance. Throughout this stretch the White Nile is a wide, placid stream, often having a narrow fringe of swamps. The valley is wide and shallow, however, thus causing a considerable loss of water by both evaporation and seepage.

The Blue Nile drains from the lofty Ethiopian Plateau, where it descends in a north-northwesterly direction from a height of about 6,000 feet above sea level. Its reputed source is a spring, considered holy by the Ethiopian Orthodox Church, from which a small stream, the Abay, flows down to Lake Tana (T'ana), a fairly shallow lake with an area of about 1,400 square miles. The Abay leaves Lake Tana in a southeasterly direction, flowing through a series of rapids and plunging through a deep gorge. It is estimated that the lake supplies the river with only about 7 percent of its total flow, but this water is important since it is silt-free. The river then flows west and northwest through The Sudan to join the White Nile at Khartoum. In the greater part of its course from Lake Tana down to the Sudanese plains, it runs in a canyon that in places is 4,000 feet below the general level of the plateau. All of its tributaries also run in deep ravines. While the White Nile at Khartoum is a river of almost constant volume, the Blue Nile has a pronounced flood season (late July to October) caused by the summer monsoon rains over the Ethiopian Plateau and the rapid runoff from its numerous tributaries; historically, it was this surge that contributed most to the annual Nile floods in Egypt.

The Atbara River, the last tributary of the Nile, flows into the mainstream nearly 200 miles north of Khartoum. It rises in Ethiopia at heights of 6,000 to 10,000 feet above sea level, not far from Gonder, to the north of Lake Tana. The two principal tributaries that feed the Atbara are the Angereb (Arabic: Baḥr as-Salam) and the Tekezo (Amharic: "Terrible"; Arabic: Nahr Satit). The Tekezo is the most important of these, having a basin more than double the area of the Atbara itself. It rises among the high peaks of the Ethiopian highlands and flows north through a spectacular gorge to join the Atbara in The Sudan. For most of its course in The Sudan, the Atbara is well below the general level of the plains. Between the plains and the river, the ground is eroded and cut into by gullies formed by water running off the plains after rainfall. The Atbara rises and falls rapidly, like the Blue Nile. In flood it becomes a large, muddy river, and in the dry season it is a string of pools. The Atbara contributes more than 10 percent of the total annual flow of the Nile, but almost all of this comes in the period of July to October.

Along the stretch of the Nile north of Khartoum, which is sometimes called the United Nile, two parts can be distinguished. The first part, which stretches from Khartoum to Lake Nasser, is about 830 miles in length; there the river flows through a desert region where rainfall is negligible, although some irrigation takes place along its banks. The

second part includes Lake Nasser—which contains the water held back by the Aswan High Dam in Egypt—and below the dam the irrigated Nile valley and delta region.

Below Khartoum, the Nile flows 50 miles northward until it reaches Sablūkah (Sababka), the site of the sixth and highest cataract. There the river cuts through hills for a distance of eight miles. Flowing northward at Barbar, the river takes an S-bend, in the middle of which, from Abū Ḥamad to Kürti and Ad-Dabbah (Debba), the river flows southwestward for about 170 miles; the fourth cataract is in the middle of this stretch. At the end of this bend, at Dunqulah, it again resumes a northerly direction, crossing the third cataract and flowing into Lake Nasser.

The
cataracts

For the 800 miles from the sixth cataract to Lake Nasser, the riverbed alternates between gentle stretches and series of rapids. Outcropping crystalline rocks that cross the course of the Nile cause the five famous cataracts. Because of these cataracts, the river is not completely navigable, although sections between the cataracts are navigable by sailing vessels and by river steamers.

Lake Nasser, the second largest man-made lake in the world, has a potential maximum area of 2,600 square miles; it inundates more than 300 miles of the Nile's course, including the second cataract near the border between Egypt and The Sudan. Immediately below the high dam is the first cataract, which was once an area of rock-strewn rapids that partially obstructed the flow of the river. From the first cataract to Cairo—a distance of about 500 miles—the Nile flows northward in a relatively narrow, flat-bottomed groove, sinuous in outline and generally incised into the underlying limestone plateau, which averages 10 to 14 miles in width and is enclosed by scarps that rise in places to heights of 1,500 feet above the river level. For the last 200 miles of its course before reaching Cairo, the Nile shows a strong tendency to hug the eastern edge of the valley floor, so that the greater part of the cultivated land is found on the left bank.

North of Cairo the Nile enters the delta region, a level, triangular-shaped lowland. In the 1st century AD, the Greek geographer Strabo recorded the Nile as fanning out into seven delta distributaries. The flow has since been controlled and redirected, so that the river now flows across the delta to the sea through two main distributaries, the Rosetta and the Dumyāt (Damietta) branches.

The Nile delta, the prototype of all deltas, comprises a gulf of the prehistoric Mediterranean Sea that has been filled in; it is composed of silt brought mainly from the Ethiopian Plateau. The silt varies in its thickness from 50 to 75 feet and comprises the most fertile soil in Africa. It forms a monotonous plain that extends 100 miles from north to south, its greatest east-west extent being 155 miles between Alexandria and Port Said; altogether it covers an area twice that of the Nile valley in Upper Egypt. The land surface slopes gently to the sea, falling some 52 feet from Cairo in a gentle gradient. In the north, on the seaward border, are a number of shallow brackish lagoons and salt marshes: Lake Marout (Buḥayrat Maryūt), Lake Edku (Buḥayrat Idkū), Lake Burullus (Buḥayrat al-Burullus), and Lake Manzala (Buḥayrat al-Manzilah).

Climate. Almost no area within the Nile basin experiences a true equatorial or a true Mediterranean type of climate. While the Nile basin in The Sudan and Egypt is rainless during the northern winter, its southern parts and the highlands of Ethiopia experience heavy rain—more than 60 inches (1,520 millimetres)—during the northern summer. Most of the region falls under the influence of the northeast trade winds between October and May, which causes the prevailing aridity of most of the basin.

Rainfall

Tropical climates with well-distributed rainfall are found in parts of the East African lakes region and southwestern Ethiopia. In the lake region there is little variation throughout the year in the mean temperature, which ranges from 60° F to 80° F (16° C to 27° C) depending on locality and altitude. Relative humidity, which varies similarly, is about 80 percent on the average. Similar climatic conditions prevail over the extreme southern parts of The Sudan, which receive as much as 50 inches of rain spread over a nine-month period (March to November), with the maximum occurring in August. The humidity

reaches its highest at the peak of the rainy season and reaches its low level between January and March. Maximum temperatures are recorded during the dry season (December to February), with the minimums occurring in July and August.

To the north, the rainy season gets shorter, and the amount of rainfall decreases. The rainy season, which occurs in the south from April to October, is confined to July and August in the northern part of the central Sudan, where three seasons may be distinguished. The first of these is the pleasant, cool, dry winter, which occurs from December to February; this is followed by hot and very dry weather from March to June; and this is followed, in turn, by a hot rainy period from July to October. The minimum temperature occurs in January and the maximum in May or June, when it rises to a daily average of 105° F (41° C) in Khartoum. Only about 10 inches of rainfall occurs annually in the Al-Jazirah area (between the White and Blue Nile rivers), as compared with more than 21 inches at Dakar, Senegal, which is at the same latitude. North of Khartoum less than five inches of rain falls annually, an amount insufficient for permanent settlement. In June and July the central parts of The Sudan are frequently visited by squalls during which strong winds carry large quantities of sand and dust. These storms, which are of three to four hours duration, are called haboobs.

A desert-type climate exists over most of the remainder of the area north to the Mediterranean. The principal characteristics of the northern Sudan and the desert of Egypt are aridity, a dry atmosphere, and a considerable seasonal, as well as diurnal, temperature range in Upper Egypt. Temperatures often surpass 100° F (38° C); in Aswān, for example, the average daily maximum in June is 117° F (47° C). While no low temperatures are recorded anywhere in The Sudan or Egypt, winter temperatures decrease to the north. Thus, only Egypt has what could be called a winter season, which occurs from November to March, when the daily maximum temperature in Cairo is 68° to 75° F (20° to 24° C) and the night minimum is about 50° F (10° C). The rainfall in Egypt is of Mediterranean origin and falls mostly in the winter, with the amount decreasing toward the south. From eight inches on the coast, it falls gradually to a little over an inch in Cairo and to less than an inch in Upper Egypt. During the spring, from March to June, depressions from the Sahara or along the coast travel east, causing dry southerly winds, which sometimes results in a condition called khamsin. These are sandstorms or dust storms during which the atmosphere becomes hazy; on occasion they may persist for three or four days, at the end of which the phenomenon of a "blue" sun may be observed.

Hydrology. The periodic rise of the Nile remained an unsolved mystery until the discovery of the role of the tropical regions in its regime. In effect, there was little detailed knowledge about the hydrology of the Nile before the 20th century, except for early records of the river level that the ancient Egyptians made with the aid of nilometers (gauges formed by graduated scales cut in natural rocks or in stone walls), some of which still remain. Today, however, no other river of comparable size has a regime that is so well known. The discharge of the main stream, as well as the tributaries, is regularly measured.

The Nile swells in the summer, the floods rising as a result of the heavy tropical rains in Ethiopia. In the southern Sudan the flood begins in April, but the effect is not felt at Aswān, Egypt, until July. The water then starts to rise and continues to do so throughout August and September, with the maximum occurring in mid-September. At Cairo the maximum is delayed until October. The level of the river then falls rapidly through November and December. From March to May the level of the river is at its lowest. Although the flood is a fairly regular phenomenon, it occasionally varies in volume and date. Before it was possible to regulate the river, years of high or low flood—particularly a sequence of such years—resulted in crop failure, famine, and disease.

Following the river from its sources, an estimate can be made of the contribution of the various lakes and tributaries in the Nile flood.

Lake Victoria forms the first great natural reservoir of the Nile system. The heavy rainfall over the lake is nearly balanced by surface evaporation, and the outflow from the lake—some 812 billion cubic feet (23 billion cubic metres)—comes mostly from the rivers draining into it, particularly the Kagera. This water then flows via the Victoria Nile into Lake Kyoga, where there is little net loss of water, and then into Lake Albert. Water lost by evaporation is more than balanced by the rainfall over the lake and the inflow from other smaller streams, notably the Semliki. Thus the annual outflow from Lake Albert to the Al-Jabal River is about 918 billion cubic feet.

In addition to the water it receives from the great lakes, the torrential tributaries of the Al-Jabal supply it with nearly 20 percent of its water. The discharge of the Al-Jabal varies little throughout the year because of the regulatory effect of the large swamps and lagoons of the As-Sudd region. About half of its water is lost in this stage by seepage and evaporation, but the flow of the Sobat River into the main stream just upstream of Malakāl nearly makes up for the loss.

The White Nile provides a regular supply of water throughout the year. During April and May, when the main stream is at its lowest level, more than 80 percent of its water comes from the White Nile. The White Nile obtains its water in roughly equal amounts from two main sources. The first source is the rainfall on the East African Plateau of the previous summer. The second source is the drainage of southwestern Ethiopia through the Sobat (contributed mainly by its two headstreams, the Baro and the Pibor) that enters the main stream below As-Sudd. The annual flood of the Sobat, a consequence of the Ethiopian summer rains, is to a great extent responsible for the variations in the level of the White Nile. The rains that swell its upper valley begin in April and cause widespread inundation over the 200 miles of plains through which the river passes, thus delaying the arrival of the rainwater in its lower reaches until November–December. Relatively small amounts of the mud carried by the Sobat's flood reach the White Nile.

The Blue Nile, the most important of the three great Ethiopian affluents, plays an overwhelming part in bringing the Nile flood to Egypt. It receives two tributaries in The Sudan—the Ar-Rahad and the Ad-Dindar—both of which also originate in Ethiopia. The regime of the Blue Nile is distinguished from that of the White Nile by the more rapid passage of its floodwater into the main stream. The river level begins to rise in June, reaching a maximum level at Khartoum in about the first week in September.

The Atbara River draws its floodwater from the rains on the northern part of the Ethiopian Plateau, as does the Blue Nile. While the floods of the two streams occur at the same time, the Blue Nile is a perennial stream, while the Atbara, as mentioned, shrinks to a series of pools in the dry season.

The swelling of the Blue Nile causes the first floodwaters to reach the central Sudan in May. The maximum is reached in August, after which the level falls again. The rise at Khartoum averages more than 20 feet. When the Blue Nile is in flood it holds back the White Nile water, turning it into an extensive lake and delaying its flow. The Jabal al-Awliya' Dam south of Khartoum increases this ponding effect.

The peak of the flood does not enter Lake Nasser until late July or August, when the average daily inflow from the Nile rises to some 25.1 billion cubic feet. Out of this amount the Blue Nile accounts for almost 70 percent, the Atbara more than 20 percent, and the White Nile 10 percent. In early May the inflow drops to its minimum; the total discharge of 1.6 billion cubic feet per day comes mainly from the White Nile and the remainder from the Blue Nile. On the average, about 85 percent of the water in Lake Nasser comes from the Ethiopian Plateau, and the rest is contributed by the East African Lake Plateau system. Lake Nasser has an enormous storage capacity—more than 40 cubic miles (about 168 cubic kilometres)—although the content of the reservoir varies with the extent of the annual flood upstream. Because it is situated in a very hot and dry region, however, Lake Nasser can lose

The Nile
flood

of the Blue
Nile

up to 10 percent of its volume to evaporation annually when it is full, decreasing to about one-third that amount when it is at minimum capacity.

Plant life. In the areas where no irrigation is practiced, different zones of plant life may be roughly divided according to the amount of rainfall.

Tropical rain forest is found along the Nile–Congo divide, in parts of the Lake Plateau, and in southwestern Ethiopia. Heat and copious rainfall produce thick forests with a great variety of tropical trees and plants, including ebony, banana, rubber, bamboo, and coffee shrub. Mixed woodland and grassland (savanna), characterized by a sparse growth of thinly foliated trees of medium height and a ground covering of grass and perennial herbs, occurs in large parts of the Lake Plateau, in parts of the Ethiopian Plateau, in the area that fringes the Blue Nile near Ar-Ruşayriş, and in the southern Al-Ghazāl River region.

On the Sudanese plains, a mixture of thin bush, thorny trees, and open grassland prevails. This area is swampy during the rainy season, particularly in the Sudd region of the south-central Sudan, which has an area of nearly 100,000 square miles. The vegetation there includes papyrus, tall bamboolike grasses, reed mace ambatch, or turor, water lettuce, a species of convolvulus, and the South American water hyacinth.

North of latitude 10° N there occurs a belt of thorny savanna or orchard shrub country characterized by small scattered tree stands, thornbush, and—after rain—grass and herbs. North of this, however, rainfall decreases and the vegetation thins out, so that the countryside is dotted with small thorny shrubs, mostly acacias. From Khartoum northward there is true desert, with scanty and irregular rainfall and no permanent vegetation at all except for a few stunted shrubs. Grasses and small herbs may be scattered along drainage lines after rainfall, but these die away in a few weeks. In Egypt the vegetation near the Nile is almost entirely the result of irrigation and cultivation.

Animal life. Many varieties of fish are found in the Nile system. Notable among those found in the lower Nile system are the Nile perch (which may attain a weight of more than 175 pounds), the boliti (a species of *Tilapia*), the barbel, several species of catfish, the elephant-snout fish, and the tiger fish, or water leopard. Most of these species and the sardinelike *Haplochromis*, the lungfish, and mudfish are found as far upstream as Lake Victoria. The common eel penetrates as far south as Khartoum, and the spiny eel is found in Lake Victoria.

The Nile crocodile, found in most parts of the river, has not yet penetrated the lakes of the upper Nile basin. Other reptiles found in the Nile basin include the soft-shelled turtle, three species of monitor lizard, and some 30 species of snakes, of which more than half are venomous. The hippopotamus, once common throughout the Nile system, is now found only in the As-Sudd region and to the south.

Many schools of fish that fed in the waters of the Nile in Egypt during the flood season have been reduced or have disappeared since the construction of the Aswan High Dam. Most of the species of the Nile fish were migrants, and the dam has prevented many from migrating to Lake Nasser. The diminution in the number of anchovies in the eastern Mediterranean has also been attributed to the serious reduction in the outflow of waterborne nutrients due to the dam. Lake Nasser, however, has been developed into a commercial fishery, where the Nile perch and other species thrive.

The people. The Nile flows through regions inhabited by a wide variety of peoples, from the Bantu-speaking populations of the Lake Victoria area to the Arabs of the Sahara and the Nile delta. The wide ethnic and linguistic diversity is mirrored in the numerous ecological relationships between these peoples and the river.

In the southern Sudan are Nilotic-speaking peoples including the Shilluk, Dinka, and Nuer. The Shilluk are sedentary agriculturists whose land is watered by the Nile. The Dinka and Nuer are pastoralists whose movements are dictated by the Nile's seasonal flow. They migrate with their herds from the river's shores during the dry season, to high ground during the wet season, and back to the river when the dry season returns.

Perhaps nowhere is the relationship between people and the river so intense as in the Nile floodplain. The average population density in the cultivated parts of the floodplain south of the delta is more than 3,320 per square mile (1,280 per square kilometre). This great population, composed mostly of peasant farmers (fellahin), can survive only by making the most careful use of the available land and water.

Before the completion of the Aswan High Dam, the large quantities of silt washed down from the rich highlands of Ethiopia were deposited by the floodwaters in Egypt, where the fertility of the riverine lands was maintained over the centuries, despite intensive cultivation. Thus, a vital feature in the life of the Egyptian people was the river's behaviour, since a good harvest followed a good flood, and a poor flood often meant a later food shortage.

The economy. Irrigation. As an aid to cultivation, irrigation almost certainly originated in Egypt. A particular phenomenon that makes irrigation from the Nile feasible is the slope of the land from south to north—which amounts to about five inches to the mile—as well as the slightly greater slope downward from the riverbanks to the desert on either side.

The first use of the Nile for irrigation in Egypt began when seeds were sown in the mud left after the annual floodwater had subsided. With the passing of time, these practices were refined until a traditional method emerged, known as basin irrigation. Under this system, the fields on the flat floodplain were divided by earth banks into a series of large basins of varying size but some as large as 50,000 acres (20,000 hectares). During the annual Nile flood, the basins were flooded and the water allowed to remain on the fields for up to six weeks. The water was then permitted to drain away as the river level fell, and a thin deposit of rich Nile silt was left on the land each year. Autumn and winter crops were then sown in the waterlogged soil. Under this system only one crop per year could be grown on the land, and the farmer was always at the mercy of annual fluctuations in the size of the flood.

Along the riverbanks and on land above flood level, some perennial irrigation was always possible where water could be lifted directly from the Nile or from irrigation channels by such traditional means as the shadoof (a counterbalanced lever device that uses a long pole); the sakieh, or

reptiles

Persian waterwheel; or the Archimedean screw. Modern mechanical pumps have begun to replace such human- or animal-operated devices.

Because of the limitations of the basin method of irrigation, perennial irrigation—in which the water is controlled so that it can be made to run into the land at regular intervals throughout the year—has largely replaced it. Perennial irrigation was made possible by the completion of several barrages and waterworks before the end of the 19th century. By the beginning of the 20th century, the canal system had been remodeled and the first dam at Aswān had been completed (see below, *Dams and reservoirs*). Since the completion of the Aswan High Dam, virtually all formerly basin-irrigated land in Upper Egypt has been brought under perennial irrigation.

While the people of The Sudan make use of the waters of the Nile for irrigation, reliance on the river is not absolute, as a fair amount of rainfall occurs in the southern parts. Basin irrigation from the Nile floods is used to a small extent, but it is less satisfactory in these areas because the surface is more uneven, with less deposition of silt; the area inundated also varies from year to year. Since about 1950, these traditional methods of irrigation have been largely displaced by diesel-engined pumps, which are used on large tracts on the banks of either the main Nile, or above Khartoum, the White Nile.

Perennial irrigation in The Sudan began with the completion of the combined dam and barrage near Sannār on the Blue Nile in 1925. This made possible the irrigation of the area of the clay plain called Al-Jazīrah between the two Niles south of Khartoum. The success of this attempt encouraged the construction of more dams and barrages for large-scale irrigation schemes.

Dams and reservoirs. In 1843 it was decided to build a series of diversion dams (barrages or weirs) across the Nile at the head of the delta about 12 miles downstream from Cairo, so as to raise the level of water upstream to supply the irrigation canals and to regulate navigation. This delta barrage scheme was not fully completed until 1861, after which it was extended and improved; it may be regarded as marking the beginning of modern irrigation in the Nile valley. The Zifta Barrage, nearly halfway along the Damietta branch of the deltaic Nile, was added to this system in 1901. In 1902 the Asyūt Barrage, more than 200 miles upstream from Cairo, was completed. This was followed in 1909 by the barrage at Isnā (Esna), about 160 miles above Asyūt, and in 1930 by the barrage at Naj' Hammādi, 150 miles above Asyūt.

The Aswan
High Dam

The first dam at Aswān was constructed between 1899 and 1902; it has a series of four locks to allow navigation. The dam has twice been enlarged—first between 1908 and 1911 and again between 1929 and 1934—thus raising the water level and increasing the dam's capacity. It is also equipped with a hydroelectric plant with an installed power of more than 345 megawatts.

The Aswan High Dam is located about 600 miles upstream from Cairo and 4 miles upstream from the first Aswān Dam. It is built at a place where the river is 1,800 feet wide and has steep banks of granite. The dam is designed to control the Nile water for the expansion of cultivation and for the generation of hydroelectric power and to provide protection downstream for both crops and population against unusually high floods. The work began in 1959 and was completed in 1970. The High Dam is 12,562 feet long at crest level and 3,280 feet wide at the base, with a height of 364 feet above the riverbed. It has a hydroelectric plant with an installed capacity of 2,100 megawatts. Lake Nasser stretches some 310 miles upstream from the dam site, extending 125 miles into The Sudan.

The principal objective behind the construction of the High Dam is to store sufficient water in the reservoir in order to protect Egypt from the dangers of a series of years when the Nile flood is above or below the long-term average and thus to guarantee a steady flow of water from the Nile for both Egypt and The Sudan. An agreement concluded in 1959 between the two countries sets a maximum amount that can be drawn per year and apportions it in a ratio of three to one, with Egypt receiving the larger share. The quantities of water maintained and apportioned are

based on the estimated worst possible sequence of flood and drought events over a period of 100 years; and generally, one-fourth of the total capacity of Lake Nasser is reserved as relief storage for the highest anticipated flood during such a period (called "century storage").

The High Dam was a source of considerable controversy during its construction, and since it began operation it has continued to have its critics. Opponents have charged that silt-free water flowing below the dam has caused erosion of the downstream barrages and bridge foundations; that the loss of silt downstream has caused coastal erosion in the delta; that the overall reduction in the flow of the Nile resulting from the construction of the dam has caused the inundation of the lower reaches of the river by saltwater from the Mediterranean Sea, with resulting deposition of salt in the delta soils; and that the creation of Lake Nasser has caused the water table along the river to rise, resulting in waterlogging and an increase in soil salinity in some areas. Already the fish population offshore of the delta has been reduced dramatically by the loss of the nutrient-laden silt. Proponents of the dam have maintained that these harmful effects are worth the security of dependable water and power supplies; and, indeed, Egypt would have suffered a severe water shortage in 1984–88 without the dam.

In The Sudan the Sannār Dam on the Blue Nile provides water for the Al-Jazīrah plain at the time of year when the water level of the Blue Nile is low. It also produces hydroelectric power. Another dam, at Jabal al-Awliya' on the White Nile, was completed in 1937; it was built to increase the water available to Egypt during the period of low water (January to June) and was not intended to provide irrigation water for The Sudan. Other dams—including one on the Atbara at Khashm al-Qirbah (completed in 1964) and the Ar-Ruṣayrīṣ Dam on the Blue Nile (1966)—have enabled The Sudan to take maximum advantage of its allocation of waters from Lake Nasser.

In Uganda, Lake Victoria was made into a reservoir by the completion in 1954 of the Owen Falls Dam; the dam is situated on the Victoria Nile just below the point where the lake waters flow into the river. This permits the storage of surplus water in high-flood years to meet the deficit in years when the waters are low. The fall from the lake is harnessed by a hydroelectric plant that provides power for industries in Uganda and Kenya.

Navigation. As already mentioned, the Nile River is still a vital waterway for the transportation of people and goods, especially in the flood season when motor transport is not feasible; river steamers still provide the only means of transport facilities in most of the area, especially in The Sudan south of latitude 15° N, where motor transport is not usually possible from May to November. Most of the towns in Egypt and The Sudan are situated on or near riverbanks.

In The Sudan steamer service on the Nile and its tributaries extends for about 2,400 miles. Until 1962 the only link between the northern and southern parts of The Sudan was by stern-wheel river steamers of shallow draft. The main service is from Kūsti to Jūbā. There are also seasonal and subsidiary services on the Dunqulah reaches of the main Nile, on the Blue Nile, up the Sobat to Gambela in Ethiopia, and up the Al-Ghazāl River in the high-water season. The Blue Nile is navigable only during the high-water season and then only as far as Ar-Ruṣayrīṣ.

Because of the presence of the cataracts north of Khartoum, the river is navigable in The Sudan only in three stretches. The first of these is from the Egyptian border to the south end of Lake Nasser. The second is the stretch between the third and the fourth cataract. The third and most important stretch extends from Khartoum southward to Jūbā.

In Egypt the Nile is navigable by sailing vessels and shallow-draft river steamers as far south as Aswān; thousands of small boats ply the Nile and delta waterways.

Study and exploration. The ancient Egyptians were probably familiar with the Nile as far as Khartoum and with the Blue Nile as far as its source in Lake Tana, but they showed little or no interest in exploring the White Nile. The source of the Nile was unknown to them. The

Dams in
The Sudan

The Greeks
and
Romans

Greek historian Herodotus, who visited Egypt in 457 BC, traveled up the Nile as far as the first cataract (Aswān). About the second century BC, the Greek scientific writer Eratosthenes sketched a nearly correct route of the Nile to Khartoum, showing the two Ethiopian affluents, and suggested lakes as the source of the river.

In 25 BC, the Greek geographer Strabo and a Roman governor of Egypt, Aelius Gallus, also explored the Nile as far as the first cataract. A Roman expedition to find the source of the Nile that took place in AD 66, during the reign of the emperor Nero, was impeded by the As-Sudd, and the attempt was therefore abandoned. Ptolemy, the Greek astronomer and geographer who lived in Alexandria, wrote in AD 150 that the White Nile originated in the high snow-covered Mountains of the Moon (since identified with the Ruwenzori Range).

From the 17th century onward, several attempts were made to explore the Nile. In 1613, Pedro Páez, a Spanish Jesuit priest, located the source of the Blue Nile. In 1786, the Scottish explorer James Bruce visited Lake Tana as well as the source of the Blue Nile. (M.M.El.-K./C.G.S.)

Modern exploration of the Nile basin began with the conquest of the northern and central Sudan by the Ottoman viceroy of Egypt, Muḥammad 'Alī, and his sons from 1821 onward. As a result of this the Blue Nile was known as far as its exit from the Ethiopian foothills, and the White Nile as far as the Sobat mouth. Three expeditions under a Turkish officer, Selim Bimbashi, were made between 1839 and 1842, and two got to the point about 20 miles (32 kilometres) beyond the present port of Jūba, where the country rises and rapids make navigation very difficult. After these expeditions, traders and missionaries penetrated the country and established stations in the southern Sudan. From an Austrian missionary, Ignaz Knoblecher, in 1850 came reports of lakes farther south. In the 1840s the missionaries Johann Ludwig Krapf, Johannes Rebmann, and Jacob Erhardt, traveling in East Africa, saw the snow-topped mountains Kilimanjaro and Kenya and heard from traders of a great inland sea that might be a lake or lakes.

These reports led to fresh interest in the Nile source and to an expedition by the English explorers Sir Richard Burton and John Hanning Speke, who followed a trade route of the Arabs from the east coast and reached Lake Tanganyika. On the return journey Speke went north and reached the southern end of Lake Victoria, which he thought might be the origin of the Nile. This was followed in 1860 by another expedition by Speke and James A. Grant under the auspices of the Royal Geographical Society. They followed the previous route to Tabora and then turned toward Karagwe, the country west of Lake Victoria. There they saw the Virunga Mountains 100 miles to the west (they thought that they might be the Mountains of the Moon) and discovered the Kagera River. Continuing around the lake, Speke finally reached the Ripon Falls (1862), at which point he wrote, "I saw that old Father Nile without any doubt rises in Victoria Nyanza." Speke then made his way northward with Grant, for part of the way traveling along the Nile, until the two reached Gondokoro, which lies nearly opposite the present Jūba. They heard rumours on the way of another large lake to the west but were unable to visit it and passed the information on to Samuel White Baker, who met them at Gondokoro, having come up from Cairo. Baker then continued his journey south and discovered Lake Albert. Neither Speke nor Baker had followed the Nile completely from the Ripon Falls to Gondokoro; and Baker, who saw the northern half of Lake Albert, was told that it extended a very long way to the south.

The question of the source of the Nile was finally settled when, between 1874 and 1877, General Charles George Gordon and his officers followed the river and mapped part of it. In particular Lake Albert was mapped, and Charles Chaillé-Long, an American, discovered Lake Kyoga. In 1875 Henry Morton Stanley traveled up from the east coast and circumnavigated Lake Victoria. His attempt to get to Lake Albert was not successful, but he marched to Lake Tanganyika and traveled down the Congo (Zaire) River to the sea. In another memorable journey in 1889,

taken in order to relieve the German traveler Mehmed Emin Paşa (Pasha), Stanley traveled up the Congo and across to Lake Albert, where he met Emin and persuaded him to evacuate his Equatorial Province, which had been invaded by the Mahdist forces. They returned to the east coast by way of the Semliki valley and Lake Edward, and Stanley saw the snowy peaks of the Ruwenzori Range for the first time.

Exploration and mapping has continued over the years: it was not until the 1960s, for example, that a detailed study of the upper gorges of the Blue Nile was completed. (H.E.Ht./C.G.S.)

ORANGE RIVER

The Orange River in southern Africa is one of the longest rivers on the continent and one of the longest south of the tropic of Capricorn. After rising in the Lesotho Highlands, less than 125 miles (200 kilometres) from the Indian Ocean, the river flows to the Atlantic Ocean in a generally westerly direction for some 1,300 miles. The Orange traverses the veld region of South Africa, after which it defines the southern limit of the Kalahari and bisects the southern Namib before draining into the Atlantic at Alexander Bay, S. Af. Along its course the river forms the boundary between two of South Africa's provinces, the Orange Free State and Cape Province, as well as that between Namibia and South Africa.

The Orange River—together with the Vaal, its principal tributary—forms a drainage basin with an area of at least 330,000 square miles (855,000 square kilometres). The western part of the basin is generally dry, flat, and unamenable to cultivation without irrigation. The river itself is of vital economic importance to the region through which it flows. Two projects—the Orange River Project and the Lesotho Highland Project, both in various stages of construction—have been designed to meet the water demand for irrigation, urbanization, and economic development in the central industrial areas of South Africa.

For map coverage of the Orange River, see above *Kalahari*.

Physical features. *Physiography.* The headwaters of the Orange River rise at an altitude of about 10,800 feet (3,300 metres) above sea level on a dissected plateau formed by the Lesotho Highlands that extends from the Drakensberg escarpment in the east to the Maloti (Maluti) Mountains in the west. The main source of the Orange River is officially recognized as the Sinqu (Senqu) River, which rises near the plateau's eastern edge. The Seati (Khubedu) headwater rises near Mont aux Sources to the north. Still farther north is the lesser-known Malibamatso headwater, one site of the Lesotho Highland Project. The Lesotho headwaters flow over the turf soil that covers Drakensberg lava and cut through the lava to expose underlying sedimentary rocks; material eroded from these rocks contributes to heavy silt deposits farther down the river's course.

After entering South Africa southwest of Lesotho, the river flows south and west through more open country, where sandstones, shales, and mudstones appear on the surface and where hard dolerite outcrops form small hills and flat-topped mountains. Near Aliwal North, the river has eroded a broad valley with a width of some 30 miles and a depth of more than 1,000 feet. The river's channel, however, varies greatly in both width and depth because of dolerite outcrops that sometimes narrow it to 3,000 or 4,000 feet. The river receives the Caledon as a tributary at the head of the Hendrik Verwoerd Reservoir.

From the Hendrik Verwoerd Dam the Orange swings to the northwest to its confluence with the Vaal River. The Vaal, which rises in the eastern Transvaal, flows west through the major population and industrial core of South Africa before turning south and joining the Orange near the town of Douglas. From there the Orange turns southwest and flows over calcrete and tillite (glacial clayey deposit). At Prieska it makes another sharp bend to the northwest, and this marks the beginning of its middle course. Quartzites and ironstones form a "barrier zone" through which the river has cut deep gorges. At Upington the river—which by then has turned to the west—spreads

Headwaters

out over a granite surface. In this area the Orange splits up into innumerable channels, between which are islands of varying length; and the river attains its greatest width, which may reach nearly four miles in places. About 40 miles downstream from Upington, however, the riverbed is suddenly narrowed to about 2,000 feet.

Some 20 miles below Kakamas the Orange—again flowing in several channels—forms the Augrabies Falls. There, after descending in a series of rapids, the river plunges into a deep pool. The river flows through an almost vertical-sided gorge for about 11 miles, emerging again into more open country. The lower course of the river, from the Augrabies Falls to the sea, is sometimes called the Gorge Tract. Where the rock surface is soft, the river valley is generally open. Where the river traverses harder igneous rock, however, it is confined between almost vertical cliffs more than 1,000 feet high in places. Some of the Orange's most rugged passages are found in the last section of the river, as it flows along the Richtersveld before turning west to the Namib coastal desert.

Mouth of
the Orange

The Orange reaches the sea a few miles north of the little inlet known as Alexander Bay. The mouth is less than three miles wide and is nearly closed by sandbars, which are widely breached during high floods. The gap in the southern end of the bars is maintained by the outflow of water from the river mouth during low tides and by the tidal inflow at high tides.

Climate and hydrology. The rainfall patterns in the Orange basin have a direct effect on the river's rate of flow. In Lesotho, above the confluence with the Caledon, the rainfall averages 28 to 32 inches (700 to 800 millimetres) annually; and, combined with the melted winter snows of the highland areas, this small area contributes nearly 60 percent of the Orange River's total annual flow. From the Caledon to the Vaal annual rainfall decreases to about 11 to 16 inches a year, and below the Vaal confluence it decreases from 9 inches to less than 2 inches in the Namib.

The amount of rainfall reaching the river as runoff decreases from about 16 percent in Lesotho to less than one-half of 1 percent in the lower Orange catchment. Conversely, summer maximum temperatures increase from east to west, the high exceeding 86° F (30° C) on an average 5 days per year in Lesotho and 150 days per year in the west. The result of these phenomena is a tremendous increase in the rate of evaporation from east to west. Wa-

ters lost to evaporation may amount to 12 times the total precipitation in the lower course of the Orange, and the potential storage capacity of reservoirs in the drier regions may be reduced by up to 60 percent.

The people and economy. The high valleys of the Orange River's headwaters are uninhabited, though the adjacent plateaus are used by the southern Sotho (Basuto) people for grazing land. Between the Lesotho border and the town of Aliwal North, corn (maize) is cultivated, and this region is also used as pasturage for cattle and sheep. The dry shrub country farther downstream is in general suitable only for grazing. Irrigated sections, however, occur along the river's course; the largest such area is between Upington and the Augrabies Falls, downstream of the Boegoeberg Dam (located midway between Prieska and Upington), where cotton, alfalfa (lucerne), grapes, and dates are grown. While scattered farms stand within reach of the river's freshwater supply, there are no large towns along the riverbank. This situation remains little changed by the Orange River Project (see below): much of the water accumulated by its dams is diverted to the valleys of the Fish and Sundays rivers and to the cities of Port Elizabeth, Bloemfontein, and Kimberley.

Transportation. Navigation is impossible throughout the river's course because of its irregular flow, its constant interruption by falls and rapids, and the silting that occurs in its channels and at the river mouth. Many bridges cross the river along its course between Aliwal North and Oranjeremund, the largest being at Upington.

Irrigation. Large irrigation and hydroelectric projects have been hampered on much of the Orange by the enormous amount of waterborne silt that clogs up reservoirs and reduces storage capacity. Efforts to combat this problem have included adding sluice gates to the Boegoeberg Dam (completed in 1931), which allow much of the silt to pass through.

In order to obtain comprehensive control of the river, the Orange River Project was located farther upstream, between the Caledon and Vaal confluences. The plan consists of a number of dam and canal projects; work began in 1962. The completed projects include the Hendrik Verwoerd Dam (1972), which has formed the Hendrik Verwoerd Reservoir; the P.K. le Roux Dam (1977), located about 90 miles downstream from the Verwoerd Dam; a tunnel some 50 miles long (1975), which carries water from the Verwoerd Dam to the Great Fish River; and an irrigation canal between the Great Fish and Sundays rivers. Among the projects that were still under construction in the 1990s were the Van der Kloof irrigation canals below the P.K. le Roux Dam.

The two dams have also been equipped to deal with heavy silt accumulation. They have deep dead-storage areas, and their high walls can be raised if necessary to allow for a higher water level. The Verwoerd Dam is the major water-conservation structure of the project. Its main function is to store sufficient water in its reservoir for further distribution via the P.K. le Roux Dam or the Orange-Great Fish tunnel. The maximum height of the dam is 254 feet above the riverbed, it is 3,110 feet long along its crest, and the Verwoerd Reservoir has a maximum surface area of about 140 square miles. The P.K. le Roux Dam has a maximum height of 351 feet, it is 2,510 feet long along its crest, and the reservoir has a maximum surface area of 54 square miles. Both dams have hydroelectric power stations, and their reservoirs provide water-recreation facilities.

Measures to increase the capacity of the Vaal River have also been undertaken. Water has been obtained via the Tugela-Vaal Water Project. More water will be supplied to the Vaal by the Lesotho Highland Project, which, when complete, will consist of several dams and storage reservoirs in the basins of the Sinqu, Malibatso, and Senquyane rivers.

Study and exploration. The first white man known to cross the river to the north bank was an Afrikaner elephant hunter, Jacobus Coetsee, who forded the Groot River, as it was then called, near the river mouth in 1760. Later expeditions across the river in the 18th century were led by the Afrikaner explorer Hendrik Hop; Robert Jacob Gordon, a Dutch officer; William Paterson, an English traveler; and

the French explorer François Le Vaillant. They explored the river from its middle course to its mouth, and Gordon named it in honour of the Dutch house of Orange. Mission stations were established north of the Orange from the late 18th century. In 1813 John Campbell of the London Missionary Society traced the Harts River and from its junction with the Vaal followed the latter stream to its confluence with the Orange, which he explored as far as the Augrabies Falls. The source of the Orange was first reached by the French Protestant missionaries Thomas Arbousset and François Daumas in 1836.

Throughout the 19th century, the Orange River marked the northern limit of British power in southern Africa. Beginning in the 1830s, the Boers crossed it in search of land and freedom from British rule; they named their first republic—the Orange Free State—for the river.

SÉNÉGAL RIVER

The Sénégal River, 1,020 miles (1,641 kilometres) long, is one of western Africa's longest rivers. Its drainage basin encompasses some 174,000 square miles (450,000 square kilometres). Two of the river's three headstreams rise in the Fouta Djallon highlands in Guinea, after which it flows to the northwest and then to the west to drain into the Atlantic Ocean. For some 515 miles of its course it forms the boundary between Mauritania to the north and Senegal to the south.

For map coverage of the Sénégal River, see above *Niger River*.

Physical features. *Physiography and hydrology.* Of the various headstreams of the river, the Falémé and Bafing rise in the sandstones of the Fouta Djallon plateau in Guinea, while the Bakoye rises in western Mali. The Bafing and Bakoye meet at Bafoulabé in Mali to form the Sénégal, 650 miles from its mouth. The stream is then joined by the Falémé near Bakel, Senegal. From there onward the Senegal–Mauritania boundary lies on the right (northern) bank, so that the river belongs to Senegal; Mauritania, however, generally has been permitted to use the river.

From Bakel to Dagana, a distance of 385 miles, the river flows through an alluvial valley as much as 12 miles wide. Floods come in early September at Bakel, reaching Dagana by mid-October. During the flood season the water level rises 12 feet (3.5 metres), the flow is some 300 times greater than in the dry season, and the river occupies the entire valley.

Below Dagana, at Richard-Toll, the Sénégal enters its delta. The river's gradient is extremely slight in the delta, and, until the completion of the Diama Dam near the river's mouth in 1985, salt water was able to flow upstream to Dagana during periods of low water. The mouth of the Sénégal has been deflected southward by the offshore Canary Current and by trade winds blowing from the north; the result has been the formation of a long sandspit, the Barbary Tongue (Langue de Barbarie). Saint-Louis lies in

the river's estuary, which extends for about 10 miles to the river's mouth.

Climate. The Bafing and Falémé sources receive about 80 inches (2,000 millimetres) of rainfall annually, mostly from late March to early November; the Bakoye basin receives less. The Sénégal valley proper receives 10 to 30 inches of rain annually, from late May to mid-October, with mean maximum temperatures of about 105° F (41° C) in April, and mean minimum temperatures of about 62° F (17° C) in January. Rainfall diminishes downstream, and the climate of Saint-Louis is similar to that of Dakar, the capital of Senegal, to the south.

Plant and animal life. Typical trees of the Sénégal valley are acacias, notably *Acacia nilotica*, which grows profusely on banks, and *A. senegal*, which provides the gum arabic of commerce and grows on drier slopes. The grass *Vetiveria nigritiana* grows in tufts in wet depressions. In dry areas near the valley sides *A. albida*, *Balanites aegyptiaca* (a tree with thorny branches), and grasses are common.

The river is overfished, but Nile perch are common. Spoonbills, herons, egrets, and weaverbirds are widespread. Among the animals on the riverbanks hedgehogs, monitor lizards, and warhogs are fairly common.

The people and economy. The Sénégal valley below Dagana is populated by the Wolof; upstream from Dagana to beyond Matam is peopled mainly by the Tukulor (Tokolor), after which Soninke (Serahuli) dominate. Villages average about 300 people except in the delta, which is sparsely settled. Throughout the Sénégal River region small groups of usually nomadic Fulani (Fulbe or Peul) and Mauri (Maure or Moors) are found.

Agriculture and irrigation. The best agricultural land along the Sénégal River is in the alluvial valley between Bakel and Dagana, and this area is the most densely populated part of the valley. As the floods retreat each year, a variety of crops (including millet, rice, and vegetables) are sown, and they grow and mature quickly. Millet is also grown on rain-fed lands. Both areas provide pasture for the livestock of nomads.

Rice cultivation on lands from which floods have retreated has been locally improved by embankments, with sluices constructed mainly on the Senegalese riverbank; diesel pumps have also been used on the Mauritanian bank. At Richard-Toll a large area is irrigated by means of a dam across the Taoué (Taouey), a tributary stream up which Sénégal floods penetrate to Lake Guiers. Rice and, more recently, sugarcane have been grown there by the use of mechanized equipment and paid labour, although rice yields have been lower than expected because of saline soils and the depredations of the quelea bird.

In the delta an embankment 50 miles long controls the entry of floodwater to some 120 square miles, part of which has been prepared for cultivation. The Diama Dam, located about 25 miles upstream from Saint-Louis, permits floodwaters to pass through its sluice gates while preventing the encroachment of salt water; it has im-

Boats on the Sénégal River; Kaédi, Mauritania, is on the far shore.

proved considerably the supply of fresh water in the delta region and at the same time has facilitated navigation. The hydroelectric potential of the Sénégal has also been tapped, with hydroelectric stations at Diama and upstream at Manantali in Mali; these projects have been undertaken jointly by Mali, Mauritania, and Senegal.

Transportation. Extension of a railway from Kayes, Mali, to Dakar (completed in 1923) diverted traffic that previously went by river, after which the valley became an economic backwater. Local traffic, however, is carried by shallow-draft boats from Saint-Louis to Podor, Senegal, year-round, and as far as Kayes from early August to mid-October. Most traffic plies between the Mauritanian river ports of Rosso, Bogué, and Kaédi. Minor ferries exist at Rosso and Kayes; there is a dry season causeway across the river at Kayes. Saint-Louis was once a seaport, but because of the dangerous sandbar there it was supplanted by Dakar, 163 miles to the south, after a Dakar-Saint-Louis railway link opened in 1885.

Study and exploration. In medieval times reports of the Sénégal River's existence as the "River of Gold" reached European navigators. From the 16th to the 20th century the river formed a route of advance for French colonial influence. French ships entered the estuary at least as early as 1558. From a French fort established in 1638, reconnaissance parties went 160 miles upriver to Podor. In 1659 a larger fort was erected on N'Dar Island in the estuary and named Saint-Louis-du-Sénégal for the French king Louis IX (St. Louis). This became a base for French exploration of the river and for trade in slaves, gum, gold, skins, ivory, beeswax, and ostrich feathers. André Brûe built a post, Saint-Joseph-de-Galam, 400 miles upstream in 1698, and parties sent by him reached the Félou Falls above Kayes soon after. Some went up the Falémé, where another fort was built. Pierre David penetrated far up that river in 1744. In the 20th century much of the focus of activity has been on the development of the Sénégal's resources. Since the 1970s this has been undertaken co-operatively by Mali, Mauritania, and Senegal under the auspices of the Organization for the Development of the Sénégal River. (R.J.H.-C./Ca.C.)

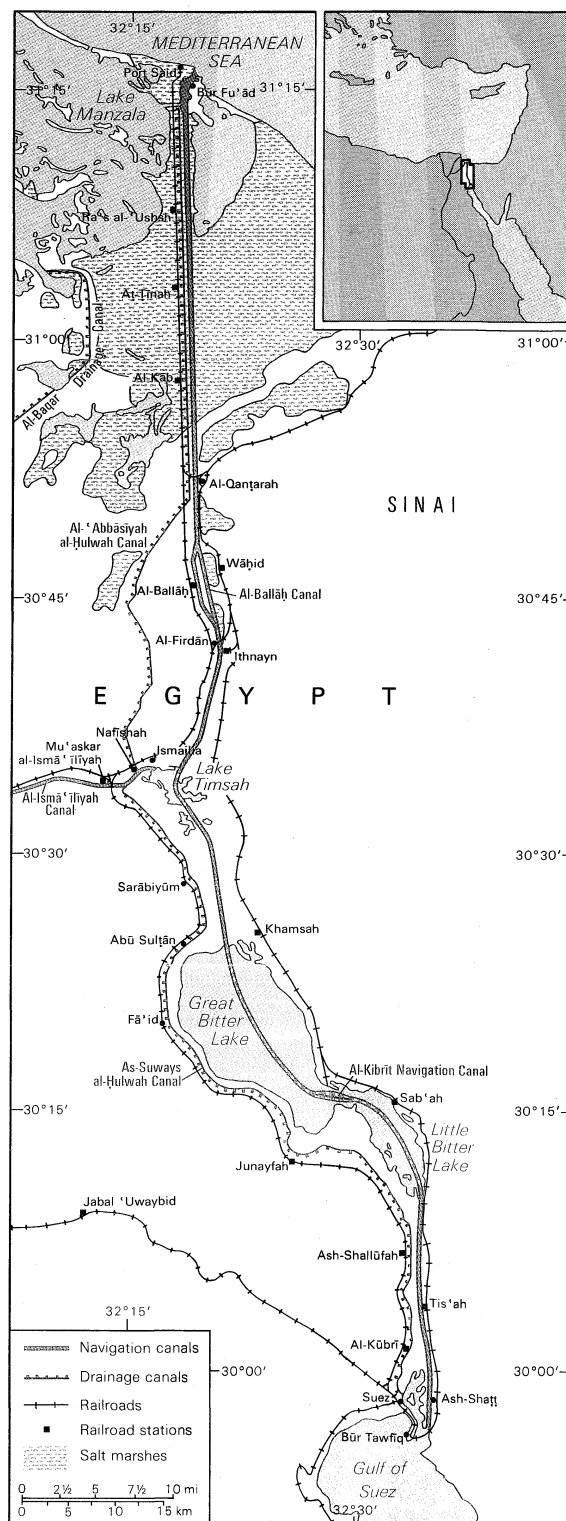

SUEZ CANAL

The Suez Canal (Qanāt as-Suways in Arabic), a sea-level waterway across the Isthmus of Suez in Egypt connecting the Mediterranean and the Red seas, provides the shortest maritime route between Europe and the lands lying around the Indian and western Pacific oceans. It is one of the world's most heavily used shipping lanes. The canal extends 101 miles (163 kilometres) between Port Said (Būr Sa'īd) in the north and Suez in the south, with dredged approach channels north of Port Said into the Mediterranean, and south of Suez. The canal does not take the shortest route across the isthmus, which is only 75 miles, but utilizes several lakes, from north to south, Lake Manzala (Buḥayrat al-Manzilah), Lake Timsah (Buḥayrat at-Timsāh), and the Bitter Lakes: Great Bitter Lake (Al-Buḥayrah al-Murrah al-Kubrā) and Little Bitter Lake (Al-Buḥayrah al-Murrah aṣ-Ṣuḡhrā). The Suez Canal is an open cut, without locks, and, though extensive straight lengths occur, there are eight major bends. To the west of the canal is the low-lying delta of the Nile River; to the east is the higher, rugged, and arid Sinai Peninsula. Prior to construction of the canal (completed in 1869), the only important settlement was Suez, which in 1859 had 3,000 to 4,000 inhabitants. The rest of the towns along its banks have grown up since, with the possible exception of Al-Qanṭarah.

Physical features. *Geology.* The Isthmus of Suez, the sole land bridge between the continents of Africa and Asia, is of relatively recent geologic origin. Both continents once formed a single large continental mass, but during Tertiary times (66.4 to 1.6 million years ago) the great fault structures of the Red Sea and Gulf of Aqaba developed, with the opening and subsequent drowning of the Red Sea trough as far as the Gulf of Suez and the Gulf of Aqaba. In the succeeding Quaternary Period, there was considerable oscillation of sea level, leading finally to the emergence of a low-lying isthmus that broadened north-

ward to a low-lying open coastal plain. There, the Nile delta once extended farther east—as a result of periods of abundant rainfall coincident with the Pleistocene Epoch (1,600,000 to 10,000 years ago)—and two river arms, or distributaries, formerly crossed the northern isthmus, one branch reaching the Mediterranean Sea at the narrowest point of the isthmus and the other entering the sea some nine miles east of present Port Said.

Physiography. Topographically, the Isthmus of Suez is not uniform; there are three shallow, water-filled depressions—Lake Manzala and Timsah, and the Bitter Lakes, the last, though distinguished as Great and Little, forming

The Suez Canal.

Route of
the canal

one continuous sheet of water. A number of more resistant bands of limestone and gypsum obtrude in the south of the isthmus, and another significant feature is a narrow valley leading from Lake Timsah southwestward toward the middle Nile delta and Cairo. The isthmus is composed of marine sediments, coarser sands, and gravels deposited in the early periods of abundant rainfall, Nile alluvium (especially to the north), and windblown sands.

Original
size of the
canal

When first opened in 1869, the canal consisted of a channel barely 26 feet (8 metres) deep, 72 feet wide at the bottom, and 200 to 300 feet wide at the surface. To allow ships to pass each other, passing bays were built every five to six miles. Construction involved the excavation and dredging of 97 million cubic yards (74 million cubic metres) of sediments. Between 1870 and 1884, some 3,000 groundings of ships occurred because of the narrowness and tortuousness of the channel. Major improvements began in 1876, and, after successive widenings and deepening, the canal by the 1960s had a minimum width of 179 feet at a depth of 33 feet along its banks, and a channel depth of 40 feet at low tide. Also in that period, passing bays were greatly enlarged and new bays constructed, bypasses were made in the Bitter Lakes and at Al-Ballāh, stone or cement cladding and steel piling for bank protection were almost entirely completed in areas particularly liable to erosion, tanker anchorages were deepened in Lake Timsah, and new berths were dug at Port Said to facilitate the grouping of ships in convoy. Plans that had been made in 1964 for further enlargement were overtaken by the Arab-Israeli War of June 1967, during which the canal was blocked. The canal remained inoperative until June 1975, when it was reopened and improvements were recommenced.

The economy. *Operation.* In 1870, the canal's first full year of operation, there were 486 transits, or fewer than 2 per day. In 1966 there were 21,250, an average of 58 per day, with net tonnage increasing from 437,000 (1870) to 274,000,000. By the mid-1980s the number of daily transits had fallen to an average of 50, but net annual tonnage was about 350,000,000.

Originally, passing involved one ship entering a passing bay and stopping, but after 1947 a system of convoys was adopted. Transit time at first averaged 40 hours; by 1939 it had been reduced to 13 hours, but as traffic increased after 1942 it went up to 15 hours in 1967, despite convoying, reflecting the great growth in tanker traffic at

Hubertus Kauns/Superstock

Soviet cargo ship in the Suez Canal near Ismailia, Egypt.

that time. Convoys leave daily—two southbound and one northbound. Southbound convoys moor at Port Said, Al-Ballāh, Lake Timsah, and Al-Kabrit, where there are bypasses that allow northbound convoys to proceed without stopping. With reduced overall traffic and some enlargement of the canal, transit time since 1975 has been about 14 hours. Upon entering the canal at Port Said or Suez, ships are assessed for tonnage and cargo (passengers have ridden without charge since 1950) and are handled by one pilot (sometimes two) for actual canal transit, which is increasingly controlled by radar.

The nature of traffic has greatly altered, especially because of the enormous growth in oil shipments from the Persian Gulf since 1950. In 1913, oil in northbound traffic amounted to 291,000 tons; in the peak year of 1966, it amounted to 166,000,000 tons. The closure of the canal from 1967 to 1975 led to the use of large oil tankers on the route around the Cape of Good Hope. Since 1975 the increased size of tankers—the largest of which cannot use the canal—has reduced the canal's importance in the international oil trade. Canal traffic has also been affected by the development of sources of crude oil in Algeria, Libya, Nigeria, the North Sea, and Mexico—all areas outside of the canal route. Competition has also risen from new pipelines to the Mediterranean, including the pipeline from Suez to Alexandria that was opened in 1977.

From an all-time peak in 1945 of 984,000, passenger traffic has declined to negligible numbers because of the competition from aircraft, which also now carry high-value cargoes of small bulk. Further decline in canal traffic resulted from a shift of Australasian trade from Europe to Japan and East Asia. Some movement of oil, however, from refineries in the Soviet Union, southern Europe, and Algeria has continued, chiefly to India, and the shipment of dry cargoes, including grain, ores, and metals, has increased. A more recent feature has been the growth of container (lighter aboard ship, or LASH) and roll-on roll-off traffic through the canal, chiefly destined for the highly congested ports of the Red Sea and Persian Gulf. Asia still receives large quantities of North American wheat, corn (maize), and barley through the canal.

The major northbound cargoes consist of crude petroleum and petroleum products, coal, ores and metals, and fabricated metals, as well as wood, oilseeds and oilseed cake, and cereals. Southbound traffic consists of cement, fertilizers, fabricated metals, and cereals. Much southbound traffic consists of empty oil tankers, for supertankers with a deadweight tonnage of up to 200,000 tons can now transit the canal empty but not laden.

Communications and towns. Construction of the canal led to the growth of settlements in what had been, except for Suez, almost uninhabited arid territory. More than 70,000 acres (28,000 hectares) were brought under cultivation, and about 8 percent of the total population was engaged in agriculture, with approximately 10,000 commercial and industrial activities of various sizes. In 1967 almost all the population was evacuated, and most of the settlements were severely damaged or destroyed during subsequent warfare. With the reopening of the canal in 1975, however, reconstruction of the area was begun, and most of the population had returned by 1978. Port Said was created a customs-free zone in 1975, and tax-free industrial zones have been established along the canal. The major urban centres are Port Said, with its east-bank counterpart, Būr Fu'ād; Ismailia (Al-Ismā'īliyah), on the north shore of Lake Timsah; and Suez, with its west-bank outpost, Būr Tawfiq. Water for irrigation and for domestic and industrial use is supplied by the Nile via the Al-Ismā'īliyah Canal.

There are two roads from the pre-1967 period on the west bank. Ferries have largely been replaced by four underpasses: north of Suez, south and north of Lake Timsah, and at Al-Qanṭarah. From this last, a road continues along the east bank to Būr Fu'ād, and another runs eastward through the Sinai to Israel. Newer roads on the east bank run eastward to the Khutmiyah, Giddi, and Mitla passes, which give access to the central Sinai. The railway on the west side of the canal was restored in the 1970s. In 1980, the Ahmad Hamdi road tunnel was opened, connecting

Nature
of canal
traffic

Road and
railway
connec-
tions

Egypt proper with its governorate (*muḥāfazah*) of Shamāl Sinā'. About one mile of the tunnel passes beneath the canal itself.

History. Construction. The first canal in the region seems to have been dug in about 1850 BC, when an irrigation channel navigable at flood period was constructed into the Wadi Tumelat (aṭ-Ṭumaylāt). This channel was extended by the Ptolemies via the Bitter Lakes as far as the Red Sea. From the region of Lake Timsah a northward arm appears to have reached a former branch of the Nile. Extended under the Romans (who called it Trajan's Canal), neglected by the Byzantines, and reopened by the early Arabs, this canal was deliberately filled in by the 'Abbāsīd caliphs for military reasons in AD 775. Throughout, the reason for these changes appears to have been to facilitate trade from the delta lands to the Red Sea rather than to provide a passage to the Mediterranean.

Among the Venetians in the 15th century and the French in the 17th and 18th centuries were writers who speculated upon the possibility of making a canal through the isthmus. A canal there would make it possible for ships of their nations to sail directly from the Mediterranean to the Indian Ocean and so dispute the monopoly of the East Indian trade that had been won first by the Portuguese, then by the Dutch, and finally by the English, all of whom used the route around the Cape of Good Hope. These schemes came to nothing.

It was not until the French occupation of Egypt (1798–1801) that the first survey was made across the isthmus. Napoleon personally investigated the remains of the ancient canal. J.M. Le Père, his chief lines-of-communication engineer, erroneously calculated that the level of the Red Sea was 33 feet above that of the Mediterranean, and, therefore, locks would be needed. Considering the adverse conditions under which the French surveyors worked, and the prevailing belief in the disparity of levels of the two seas, the error was excusable, and Le Père's conclusion was uncritically accepted by a succession of subsequent authors of canal projects. Studies for a canal were made again in 1834 and in 1846. In 1854 Ferdinand de Lesseps received an Act of Concession from the viceroy (khedive) of Egypt, Sa'id Pasha, to construct a canal; and in 1856 a second act conferred on the Suez Canal Company (Compagnie Universelle du Canal Maritime de Suez) the right to operate a maritime canal for 99 years after completion of the work. Construction began in 1859 and took 10 years instead of the six that had been envisaged; climatic difficulties, a cholera epidemic in 1865, and early labour troubles all slowed down operations. An initial project was the cutting of a small canal (the Al-Ismā'īliyah) from the delta along the Wadi Tumelat, with a southern branch (now called the As-Suways al-Hulwah Canal; the two canals combined were formerly called the Sweet Water Canal) to Suez and a northern one (Al-'Abbāsiyah Canal) to Port Said. This supplied drinking water in an otherwise arid area and was completed in 1863.

At first, digging was done by hand with picks and baskets, peasants being drafted as forced labour. Later, dredgers and steam shovels operated by European labourers took over, and, as dredging proved cheaper than dry excavation, the terrain was artificially flooded and dredged wherever possible. Other than in the few areas where rock strata were met, the entire canal was driven through sand or alluvium. In August 1869 the waterway was completed, and it was officially opened with an elaborate ceremony in November.

Finance. The Suez Canal Company had been incorporated as an Egyptian joint stock company with its head office in Paris. Despite much early official coolness, even hostility, on the part of Great Britain, de Lesseps was anxious for international participation and offered shares widely. Only the French responded, however, buying 52 percent of the shares; of the remainder, 44 percent was taken up by Sa'id Pasha. The first board of directors included representatives of 14 countries.

In 1875, financial troubles compelled the new viceroy, Ismā'il Pasha, to sell his holding, which (at the instigation of the prime minister, Benjamin Disraeli) was at once bought by the British government. Until that year, the shares had

remained below their issue price of 500 francs each. With the British purchase (at 568 francs each), steady appreciation took place, to more than 3,600 francs in 1900.

Originally allocated 15 percent of the net profits, Egypt later relinquished the percentage and, after the sale of Ismā'il's 176,602 shares, remained unrepresented on the board of directors until 1949, when it was, in effect, reinstated as a board member and allotted 7 percent of gross profits. In that year, it was also agreed that 90 percent of new clerical jobs and 80 percent of technical appointments would be offered to Egyptians and that the Canal Company would provide hospitals, schools, and other amenities.

In 1956, 13 years before the concession was due to expire, the canal was nationalized by Egyptian president Gamal Abdel Nasser. Since then, the Egyptian government has exercised complete control, though the original company continues in Paris as a conglomerate.

International status. Although the canal was built to serve, and profit from, international trade, its international status remained undefined for many years. In 1888 the major maritime powers at the time (except Great Britain) signed the Convention of Constantinople, which declared that the canal should be open to ships of all nations in times of both peace and war. In addition, the convention forbade acts of hostility in the waters of the canal and the construction of fortifications on its banks. Great Britain did not sign the convention until 1904.

The history of international use of the canal during wartime includes denial of passage to Spanish warships during the Spanish-American War of 1898 and permission of passage by a squadron of the Russian navy during the Russo-Japanese War in 1905 and of Italian vessels during Italy's invasion of Ethiopia in 1935–36. Theoretically, the canal was open to all belligerents during World Wars I and II, but the naval and military superiority of the Allied forces denied effective use of the canal to the shipping of Germany and its allies.

Following the armistice between Israel and its Arab opponents in 1949, Egypt denied use of the canal to Israel and to all ships trading with Israel. The first of two canal closings occurred during the Suez Crisis of 1956–57, after Israel attacked Egyptian forces and French and British troops occupied part of the canal zone. The second closing was a consequence of the Arab-Israeli War of June 1967, during and after which the canal was the scene of much fighting between Egypt and Israel and for several years formed the front line between the two armies. With the reopening of the canal in June 1975 and the signing of a peace treaty between Egypt and Israel in 1979, all ships (including those of Israeli registration) again had access to the waterway. (W.B.Fi./C.G.S.)

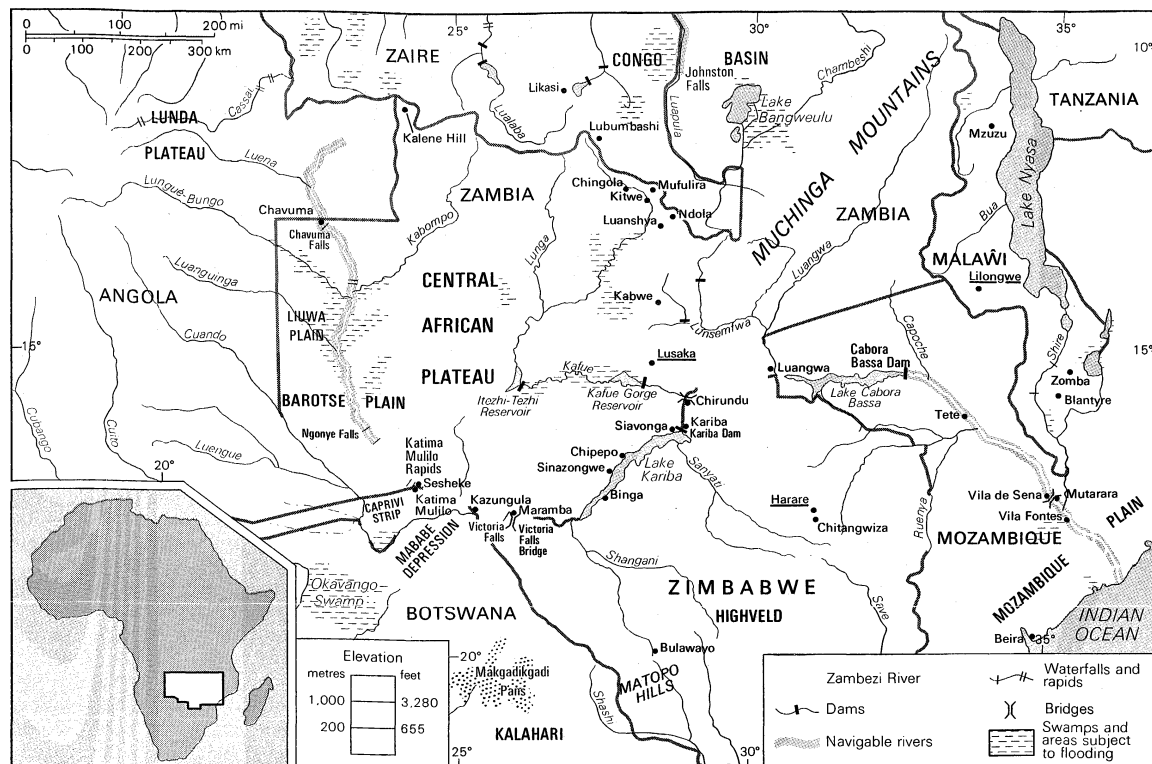

The Suez
Crisis

ZAMBEZI RIVER

The Zambezi, together with its tributaries, forms the fourth largest river basin of Africa and drains a large portion of the south-central region of the continent. It flows eastward for about 2,200 miles (3,540 kilometres) from its source on the Central African Plateau to empty into the Indian Ocean. With its tributaries, it drains an area of more than 500,000 square miles (1,300,000 square kilometres). The Zambezi (meaning "Great River" in the language of the Tonga people) includes along its course the Victoria Falls, one of the world's greatest natural wonders, and the Kariba and Cabora Bassa dams, two of Africa's largest hydroelectric projects. The river either crosses or forms the boundaries of six countries or territories—Angola, Zambia, Namibia, Botswana, Zimbabwe, and Mozambique—and the use of its waters has been the subject of a series of international agreements.

Physical features. *Physiography.* The Zambezi rises out of a marshy bog near Kalene Hill, Zambia, about 4,800 feet (1,460 metres) above sea level, and flows some 20 miles before entering Angola, through which it runs for more than 175 miles. In this first section of its course, the river is met by more than a dozen tributaries of varying sizes. Shortly after reentering Zambia, the river flows over the Chavuma Falls and enters a broad region of hummocky, sand-covered floodplains, the largest of which is

The Suez
Canal
Company

The Zambezi River basin and its drainage network.

the Barotse, or Zambezi, Plain. The region is inundated during the summer floods, when it receives fertile alluvial soils. The main tributaries intersecting the river along the plains are the Kabompo River from the east and the larger Lungué-Bungo (Lungwebungo) River from the west.

The Zambezi then enters a stretch of rapids that extends from Ngonye (Sioma) Falls south to the Katima Mulilo Rapids, after which for about 80 miles it forms the border between Zambia to the north and the eastern Caprivi Strip—an extension of Namibia—to the south. In this stretch the river meanders through the broad grasslands of the Sesheke Plain until it is joined by the Cuando (Kwando) River. Near Kazungula, Zambia, the river, after flowing past Botswana territory to the south, turns almost due east and forms the frontier between Zambia and Zimbabwe. From the Cuando confluence to the Victoria Falls, the Zambezi varies considerably in width, from open reaches with sand islands to stretches of rapids through narrow channels separated by numerous rock islands.

The Victoria Falls mark the end of the upper course of the Zambezi, as its waters tumble with a thunderous roar and an enormous cloud of spray. The area around the falls was once covered by a thick layer of lava, which as it cooled formed wide cracks, or joints, that became filled with softer sediments. As the Zambezi cut its present valley it encountered one of these joints, eroded the sediment, and created a trench, eventually forcing a gap at the lower end of the trench that quickly widened into a gorge. The force of the water also created a second gap at the upper end of the trench that gradually diverted the river until the trench itself was left dry. As the river cut backward it repeated the process, scouring eight successive waterfalls in the last half million years.

The Zambezi's middle course extends about 600 miles from Victoria Falls to the eastern end of Lake Cabora Bassa in Mozambique. It continues to form the boundary between Zambia and Zimbabwe until it crosses the Mozambique border at Luangwa. Below the falls a gorge some 60 miles long has been formed by the trench-scouring process, through which the river descends in a series of rapids. Just upstream of Lake Kariba the river valley widens and is contained by escarpments nearly 2,000 feet high. The middle Zambezi is notable for the two man-made lakes, Kariba and Cabora Bassa (see below), that constitute much of this stretch of the river. Between the

two lakes the Zambezi trends northeast for nearly 40 miles before it turns east below the confluence with the Kafue River, the Zambezi's largest tributary. In this section, the river rushes through two rocky, narrow gorges, the first just below the Kariba Dam, and the other above the confluence with the Luangwa River.

At the dam at the eastern end of Lake Cabora Bassa, the Zambezi begins its lower course, during which it descends from the Central African Plateau to the coastal plain. At first the hilly country is replaced by flat areas at the head of the Tete Basin, and the river becomes more placid. About 40 miles downstream the river has cut the Lupata Gorge through a range of hills, where it emerges onto the Mozambique Plain and occupies a broad valley that spreads out in places to a width of three to five miles. Near Vila Fontes, the river receives its last great tributary, the Shire River, which drains Lake Nyasa (Malaŵi) some 210 miles to the north.

At its mouth the Zambezi splits into a wide, flat, and marshy delta obstructed by sandbars. There are two main channels, each again divided into two. The wider, eastern channel splits into the Muselo River to the north and the main mouth of the Zambezi to the south. The western channel forms both the Inhamissengo River and the smaller Melambe River. North of the main delta, the Chinde River separates from the Zambezi's main stream to form a navigable channel leading to a shallow harbour.

Hydrology. The Zambezi, according to measurements taken at Maramba (formerly Livingstone), Zambia, experiences its maximum flow in March or April. In October or November the discharge diminishes to less than 10 percent of the maximum. The annual average flow reaches about 247,000 cubic feet (7,000 cubic metres) per second. Measurements taken at Kariba Dam reflect the same seasonal pattern; the highest flood recorded there was in March 1958, when the flow reached 565,000 cubic feet per second.

Climate. The Zambezi River lies within the tropics. The upper and middle course of the river is on an upland plateau, and temperatures, modified by altitude, are relatively mild, generally between 64° and 86° F (18° and 30° C). The winter months (May to July) are cool and dry, with temperatures averaging 68° F (20° C). Between August and October there is a considerable rise in average temperatures, particularly in the river valley itself; just be-

fore the rains begin in October temperatures there become excessively hot, often reaching 104° F (40° C). The rainy season lasts from November to April. Rain falls in short, intense thundershowers—the rate sometimes reaching 6 inches (150 millimetres) per hour—with skies clearing between downpours. In these months the upper Zambezi receives nearly all of its total rainfall, and this accounts for the great variation in the flow of the river throughout the year. In all, the upper and middle Zambezi valley receives 22 to 30 inches of rain per year. Studies have suggested that a microclimate in the area of Lake Kariba has created a rise in precipitation, possibly as a result of a lake breeze blocked by the escarpment that produces thunderstorms.

In the lower course of the river in Mozambique the influence of the summer monsoon increases the levels of precipitation and humidity. Temperatures are also higher—determined more by the latitude and less by altitude—as the river descends from the plateau.

Plant life. The vegetation along the upper and middle course of the Zambezi is predominantly savanna, with deciduous trees, grass, and open woodland. Mopane woodland (*Colophospermum mopane*) is predominant on the alluvial flats of the low-lying river valleys and is highly susceptible to fire. Grass, when present, is typically short and sparse. *Baikiaea* forest, found extensively on sandy interfluvies between drainage channels, is economically the most important vegetation type in Zambia, for it is the source of the valuable Rhodesian teak (*Baikiaea plurijuga*). Destruction of the *Baikiaea* forest results in a regression from forest to grassland, a slow process involving intermediate stages of scrub vegetation. The river additionally has a distinct fringing vegetation, mainly riverine forest including ebony (*Diospyros mespiliformis*) and small shrubs and ferns (e.g., *Haemanthus*). In the lower course of the Zambezi dense bush and evergreen forest, with palm trees and patches of mangrove swamp, is the typical vegetation.

Animal life. The tiger fish is one of the few species found both above and below the Victoria Falls. Pike is predominant in the upper course of the river, as are yellowfish and barbel. Bream are now common both above and below the falls. Crocodiles abound in the Zambezi, though they generally avoid stretches of fast-running water. Hippopotamuses are also found in the upper and lower stretches of the Zambezi. Elephants are common over much of the river's course, particularly in areas such as the Sesheke Plain and near the Luangwa confluence. Game animals include buffalo, eland, sable, roan, kudu, waterbuck, impala, duiker, bushbuck, reedbuck, bushpig, and warthog. Of the big cats, lions can be found in the Victoria Falls National Park in Zimbabwe and elsewhere along the river's course; cheetahs, although comparatively

rare, can be sighted; and leopards, rarely seen by daylight, are common, both in the plains and the river gorges. Baboons and monkeys abound throughout.

The people. The Lozi (Barotse), who dominate much of the upper Zambezi, have taken advantage of the seasonal flooding of the Barotse Plain for centuries and have an agricultural economy that is supplemented by animal husbandry, fishing, and trade. The main groups of the middle Zambezi include the Tonga, Shona, Chewa, and Nsenga peoples, all of whom largely practice subsistence agriculture. In Mozambique the riverine population is varied; many engage in commercial agriculture—the growing of sugarcane and cotton in particular—which was established by the Portuguese.

The Lozi

The economy. **Navigation.** Given its numerous natural barriers—sandbars at the mouth, shallowness, and rapids and cataracts—the Zambezi is of little economic significance as a trade route. About 1,620 miles of the river, however, are navigable by shallow-draft steamers. The longest stretch of unbroken water runs from the river delta about 400 miles upstream to the Cabora Bassa Dam. Above the dam Lake Cabora Bassa is navigable to its confluence with the Luangwa River, where navigation is interrupted again to the Kariba Dam. Lake Kariba is navigable, but the river again becomes impassable from the end of the lake to the Ngonye Falls, some 250 miles upstream. It is again navigable by shallow-draft boats for the 300 miles between the Ngonye and Chavuma falls and then for another 120 miles above Chavuma.

The river has four major crossing points. The Victoria Falls Bridge, the first from the head of the river, carries rail, road, and foot traffic between Zambia and Zimbabwe. The dam wall at Kariba is heavily used by road traffic, and a road bridge at Chirundu, Zimb., also connects the two countries. The fourth major crossing is the rail and road bridge between Mutarara (Dona Ana) and Vila de Sena, Mozambique. There are also a number of motor ferries crossing the river at various points.

Kariba and Cabora Bassa schemes. The Kariba Dam harnesses the Zambezi at Kariba, Zimb., 300 miles below Victoria Falls. A concrete-arch dam with a maximum height of 420 feet and a crest length of 1,900 feet carries a road connecting the Zambian and Zimbabwean banks of the gorge. Six floodgates permit a discharge of some 335,000 cubic feet of water per second. Both Zambia and Zimbabwe obtain most of their electricity from the Kariba Dam. Lake Kariba covers an area of about 2,000 square miles. The flooded land was previously inhabited by about 51,000 Tonga agriculturalists, who had to be resettled. The lake stretches for 175 miles from the dam to Devil's Gorge and is 20 miles across at its widest point. Three

townships have been built around lakeshore harbours at Kariba and at Siavonga and Sinazongwe, Zambia. Tourist resorts have also been developed along the lakeshore.

Lake Cabora Bassa was formed by a dam across the Zambezi at the head of Cabora Bassa Gorge, about 80 miles northwest of Tete, Mozambique. The dam, 560 feet high and 1,050 feet wide at its crest, impounds the river for 150 miles to the Mozambique-Zambia border, providing hydroelectric power and water for crop irrigation.

Study and exploration. The first non-Africans to reach the Zambezi were Arab traders, who utilized the river's lower reaches from the 10th century onward. They were followed in the 16th century by the Portuguese, who hoped to use the river to develop a trade in ivory, gold, and slaves. Until the 19th century, the river, then called the Zanbere, was believed to flow south from a vast inland sea that was also thought to be the origin of the Nile River. Accurate mapping of the Zambezi did not take place until the Scottish missionary and explorer David Livingstone charted most of the river's course in the 1850s. Searching for a trade route to the East African coast, he traveled from Sesheke, 150 miles above Victoria Falls, to the Indian Ocean. His map of the river remained the most accurate until the 20th century, when further surveys finally traced the Zambezi to its source. (A.N.L.W./N.J.Mo.)

BIBLIOGRAPHY

General works. Overviews of the continent may be found in R. MANSELL PROTHERO (ed.), *A Geography of Africa*, rev. ed. (1973); JOHN I. CLARKE (ed.), *An Advanced Geography of Africa* (1975); WILLIAM A. HANCE, *The Geography of Modern Africa*, 2nd ed. (1975); ALAN C.G. BEST and HARM J. DE BLIJ, *African Survey* (1977); R.J. HARRISON CHURCH et al., *Africa and the Islands*, 4th ed. (1977); A.T. GROVE, *Africa*, 3rd ed. (1978), and *The Changing Geography of Africa* (1989); J.M. PRITCHARD, *Africa*, rev. 3rd ed. (1979, reissued 1986); PHYLLIS M. MARTIN and PATRICK O'MEARA (eds.), *Africa*, 2nd ed. (1986); PAUL BOHANNAN and PHILIP CURTIN, *Africa and the Africans*, 3rd ed. (1988); and ALAN B. MOUNTJOY and DAVID HILLING, *Africa: Geography and Development* (1988). ROLAND OLIVER and MICHAEL CROWDER (eds.), *The Cambridge Encyclopedia of Africa* (1981), is also useful. REGINE VAN CHI-BONNARDEL, *The Atlas of Africa* (1973), presents general physical and thematic maps, as well as maps and text for each country. JOCELYN MURRAY (ed.), *Cultural Atlas of Africa* (1981), includes maps and text on Africa's physical geography, culture, history, language, and social life. General treatments of European exploration in Africa are contained in HEINRICH SCHIFFERS, *The Quest for Africa: Two Thousand Years of Exploration* (1957; originally published in German, 1954); and ROBERT I. ROTBERG (ed.), *Africa and Its Explorers: Motives, Methods, and Impact* (1970). Useful annuals that contain historical overviews of each African country and updated essays on the continent's political, social, and economic developments include *The Middle East and North Africa*; *Africa South of the Sahara*; and *Africa Contemporary Record*. (D.S.H.W.N./Ed.)

Physical and human geography. *Geologic history:* There are many works on Africa's geology, including RAYMOND FURON, *Geology of Africa* (1963; originally published in French, 2nd ed., 1960); L. CAHEN and N.J. SNELLING, *The Geochronology of Equatorial Africa* (1966), and *The Geochronology and Evolution of Africa* (1984); S.H. HAUGHTON, *Geological History of Southern Africa* (1969); *Tectonics of Africa* (1971), a Unesco publication with contributions in English and French; B.H. BAKER, P.A. MOHR, and L.A.J. WILLIAMS, *Geology of the Eastern Rift System of Africa* (1972); COLIN BUCKLE, *Landforms in Africa* (1978); J.B. WRIGHT (ed.), *Geology and Mineral Resources of West Africa* (1985); ADETOYE FANIRAN, *African Landforms* (1986); and ROBERT BOWEN and ULRICH JUX, *Afro-Arabian Geology* (1987). (R.L.C.F./Ed.)

The land: Descriptions of Africa's physical geography can be found in the general works listed above and in M.F. THOMAS and G.W. WHITTINGTON (eds.), *Environment and Land Use in Africa* (1969). WILLIAM G. MCGINNIES, BRAM J. GOLDMAN, and PATRICIA PAYLORE (eds.), *Deserts of the World* (1968), includes detailed appraisals of research on the physiography, hydrology, soils, weather and climate, vegetation, and fauna of the Kalahari, Namib, and Sahara. A comprehensive account of the geomorphology of Africa is given in LESTER C. KING, *The Morphology of the Earth*, 2nd ed. (1967), pp. 241-309. Regional geographies include JEAN DESPOIS and RENÉ RAYNAL, *Géographie de l'Afrique du nord-ouest* (1967, reissued 1975); R.J. HARRISON CHURCH, *West Africa: A Study of the Environment and of Man's Use of It*, 8th ed. (1980); REUBEN K. UDO, *A Comprehensive Geography of West Africa* (1978), and *The Human*

Geography of Tropical Africa (1982); JACQUES DENIS, PIERRE VENNETIER, and JULES WILMET, *L'Afrique centrale et orientale* (1971); JOHN H. WELLINGTON, *Southern Africa*, 2 vol. (1955); and A.J. CHRISTOPHER, *Southern Africa* (1976). (Ro.W.St.)

H.L. SHANTZ and C.F. MARBUT, *The Vegetation and Soils of Africa* (1923, reprinted 1971), was the first systematic account of major soil groups. Far more modern and useful is the basic text by ZINAIDA SHOKALSKAIA, *Почвенно-географический очерк Африки* (1948), also available in a German translation, *Die Böden Afrikas* (1953). R.P. MOSS (ed.), *The Soil Resources of Tropical Africa* (1968); and PETER M. AHN, *West African Soils* (1970), present discussions of the framework within which tropical soils may be described. B.W. THOMPSON, *The Climate of Africa* (1965), and *Africa: The Climatic Background* (1975), provide general information. GLENN T. TREWARTHA, *The Earth's Problem Climates*, 2nd ed. (1981), gives a more advanced account of the major climatic anomalies in Africa. (K.B.D.)

The undoubted leading survey of African vegetation is F. WHITE, *Vegetation of Africa* (1983), written to explain an accompanying map. The best comprehensive presentation of grasses remains J.M. RATTRAY, *The Grass Cover of Africa* (1960), also with a map. P.W. RICHARDS, *The Tropical Rain Forest: An Ecological Study* (1952, reissued 1979), is a comprehensive classic, with a relevance well beyond its title. BRIAN HOPKINS, *Forest and Savanna* (1965), is a detailed treatment of interactions in western Africa, including the effects of agriculture and pastoralism. MONICA M. COLE, "The Savannas of Africa," part III in her *The Savannas: Biogeography and Geobotany* (1986), pp. 111-290, is also useful. H.L. SHANTZ and B.L. TURNER, *Photographic Documentation of Vegetational Changes in Africa Over a Third of a Century* (1958), presents telling site-by-site comparisons made by two doyens of science in Africa.

Good general treatments of African animal life are to be found in J.L. CLOUDSLEY-THOMPSON, *The Zoology of Tropical Africa* (1969); D.F. OWEN, *Animal Ecology in Tropical Africa*, 2nd ed. (1976); and M.J. DELANY and D.C.D. HAPPOLD, *Ecology of African Mammals* (1979). Two general nature histories, approaching fauna from somewhat different standpoints although complementary to one another, are LESLIE BROWN, *Africa: A Natural History* (1965); and ARCHIE CARR, *The Land and Wildlife of Africa*, rev. ed. (1980), a Time-Life book. Books that provide authoritative surveys of the different forms of animal life include JONATHAN KINGDON, *East African Mammals: An Atlas of Evolution in Africa* (1971-), splendidly artistic and alive in treatment; on hoofed mammals, WALTER LEUTHOLD, *African Ungulates: A Comparative Review of Their Ethology and Behavioral Ecology* (1977); R.E. MOREAU, *The Bird Faunas of Africa and Its Islands* (1966); C.W. MACKWORTH-PRAED and C.H.B. GRANT, *Birds of Eastern and North Eastern Africa*, 2 vol., 2nd ed. (1957-60, reprinted 1980), *Birds of the Southern Third of Africa*, 2 vol. (1962-63, reprinted 1981), and *Birds of West Central and Western Africa*, 2 vol. (1970-73, reprinted 1981); GEOFFREY FRYER and T.D. ILES, *The Cichlid Fishes of the Great Lakes of Africa: Their Biology and Evolution* (1972); MICHAEL HOLDEN and WILLIAM REED, *West African Freshwater Fish* (1972); R.A. JUBB, *Freshwater Fishes of Southern Africa* (1967); VIVIAN F.M. FITZSIMONS, *Snakes of Southern Africa* (1962); and S.H. SKAIFE, *African Insect Life*, new ed. rev. by JOHN LEDGER (1979). JOHN FORD, *The Role of Trypanosomiasis in African Ecology* (1971), studies the problems caused by the tsetse fly; and JEFFREY C. STONE (ed.), *The Exploitation of Animals in Africa* (1988), contains several colloquium papers on wildlife, domesticated stock, and conservation. (D.N.McM.)

The people: GEORGE MURDOCK, *Africa: Its Peoples and Their Culture History* (1959), is a standard text on the diverse peoples of Africa. SIMON OTTENBERG and PHOEBE OTTENBERG (eds.), *Cultures and Societies of Africa* (1960); and JAMES L. GIBBS (ed.), *Peoples of Africa* (1965, reissued 1988), contain essays and readings about African peoples. JOHN MIDDLETON (ed.), *Black Africa* (1970), presents readings about the diversity of peoples and cultural change in sub-Saharan Africa. P.C. LLOYD, *Africa in Social Change* (1967), studies social interaction in West Africa between traditional African institutions and those imported from Europe. ALI A. MAZRUI, *The African Condition* (1980), contains a political diagnosis; and MORAG BELL, *Contemporary Africa: Development, Culture, and the State* (1986), examines the links between the political and economic structures and Africa's cultural variety. JOSEPH H. GREENBERG, *The Languages of Africa*, 2nd ed. (1966), is a basic study of language classification; and EDGAR A. GREGERSEN, *Language in Africa: An Introductory Survey* (1977), is also helpful. JOHN S. MBITI, *Introduction to African Religion* (1975), provides a summary; and GEOFFREY PARRINDER, *Africa's Three Religions*, 2nd ed. (1976), discusses Christianity, Islam, and traditional religion. On Islam in particular, RENÉ A. BRAVMAN, *African Islam* (1983); and J. SPENCER TRIMMINGHAM, *The Influence of Islam Upon Africa*, 2nd ed. (1980), are general introductions.

ETIENNE VAN DE WALLE, PATRICK O. OHADIKE, and MPEMBELE D. SALA-DIAKANDA (eds.), *The State of African Demography* (1988), reviews the state and dynamics of African populations in the late 1980s. JOHN I. CLARKE and LESZEK A. KOSIŃSKI (eds.), *Redistribution of Population in Africa* (1982), provides overviews of population redistribution as well as national case studies and studies of the impact of settlement schemes and redistribution policies; and JOHN I. CLARKE, MUSTAFA KHOGALI, and LESZEK A. KOSIŃSKI (eds.), *Population and Development Projects in Africa* (1985), examines the general and specific impacts of development projects upon population redistribution, with particular emphasis on The Sudan. ROBERT F. GORMAN, *Coping With Africa's Refugee Burden* (1987), attempts to find solutions to the major problems of refugees in Africa since the mid-20th century. WILLIAM A. HANCE, *Population, Migration, and Urbanization in Africa* (1970), contains a major overview of population and urbanization trends. *Population Growth and Policies in Sub-Saharan Africa* (1986), is a study by the World Bank of the fastest-growing population region in the world.

A.T. GROVE and F.M.G. KLEIN, *Rural Africa* (1979), studies the rural environments in which most Africans live; and KENNETH SWINDELL and DAVID J. SIDDLE, *Rural Change and Development in Tropical Africa* (1990), looks at the nature of rural change and the problems of African rural development. JOSEF GUGLER and WILLIAM G. FLANAGAN, *Urbanization and Social Change in West Africa* (1978), analyzes the process of increasing urbanization in West Africa and the related social changes; and MARGARET PEIL and PIUS O. SADA, *African Urban Society* (1984), views changing urban society in West Africa. ANTHONY O'CONNOR, *The African City* (1983), examines the forms, functions, and patterns of growth of African cities, especially in the postindependence period; as does RICHARD E. STREN and RODNEY R. WHITE, *African Cities in Crisis: Managing Rapid Urban Growth* (1989). (J.I.C.)

The economy: The general economic situation is explored in P. ROBSON and D.A. LURY (eds.), *The Economies of Africa* (1969); MICHAEL HODD, *African Economic Handbook* (1986); MELVILLE J. HERSKOVITZ and MITCHELL HARWITZ (eds.), *Economic Transition in Africa* (1964); A.M. O'CONNOR, *The Geography of Tropical African Development*, 2nd ed. (1978); ANDREW M. KAMARCK, *The Economics of African Development*, rev. ed. (1971); RALPH A. AUSTEN, *African Economic History: Internal Development and External Dependency* (1987); WILFRIED KNAPP, *North West Africa: A Political and Economic Survey* (1977); D. HOBART HOUGHTON, *The South African Economy*, 4th ed. (1976); and O. ABOYADE, *Issues in the Development of Tropical Africa* (1976). The problems of regional economic integration are treated by ADEBAYO ADEDEJI and TIMOTHY M. SHAW, *Economic Crisis in Africa* (1985); CAROL LANCASTER and JOHN WILLIAMSON (eds.), *African Debt and Financing* (1986); ARTHUR HAZLEWOOD (ed.), *African Integration and Disintegration: Case Studies in Economic and Political Union* (1967); and B.W.T. MUTHARIKA, *Toward Multinational Economic Cooperation in Africa* (1972). Useful books on mineral resources and industrialization include OYE OGUNBADEJO, *The International Politics of Africa's Strategic Minerals* (1985); and A.F. EWING, *Industry in Africa* (1968). Natural resources and environmental problems are covered by NEVILLE RUBIN and WILLIAM M. WARREN (eds.), *Dams in Africa: An Inter-disciplinary Study of Man-made Lakes in Africa* (1968); D.F. OWEN, *Man in Tropical Africa: The Environmental Predicament* (1973); DAVID DALBY, R.J. HARRISON CHURCH, and FATIMA BEZZAZ (eds.), *Drought in Africa 2*, rev. and expanded ed. (1977); and BONAYA ADHI GODANA, *Africa's Shared Water Resources: Legal and Institutional Aspects of the Nile, Niger, and Senegal River Systems* (1985). Agricultural development and the agrarian crisis are presented by WILLIAM ALLAN, *The African Husbandman* (1965, reprinted 1977); PRABHU PINGALI, YVES BIGOT, and HANS BINSWANGER, *Agricultural Mechanization and the Evolution of Farming Systems in Sub-Saharan Africa* (1987); JOHN W. MELLOR, CHRISTOPHER L. DELGADO, and MALCOLM J. BLACKIE (eds.), *Accelerating Food Production in Sub-Saharan Africa* (1987); PAUL HARRISON, *The Greening of Africa: Breaking Through in the Battle for Land and Food* (1987); STEPHEN K. COMMINIS, MICHAEL F. LOFCHIE, and RHYS PAYNE (eds.), *Africa's Agrarian Crisis: The Roots of Famine* (1986); and ROBERT H. BATES and MICHAEL F. LOFCHIE (eds.), *Agricultural Development in Africa: Issues of Public Policy* (1980). (A.L.M.)

Special geographic features. *Landforms:* The best general treatment of the physical and human geography of the Atlas Mountains is JEAN DESPOIS and RENÉ RAYNAL, *Géographie de l'Afrique du nord-ouest* (1967, reissued 1975). A good overview of the region is also offered by J.M. HOUSTON, *The Western Mediterranean World: An Introduction to Its Regional Landscapes* (1964). Information on livelihood and environmental modifications in the Rif Mountains appears in a short work by MARVIN W. MIKESSELL, *Northern Morocco: A Cultural Geography* (1961, reprinted 1985). The best one-volume survey of the

culture of the peoples of the Atlas region is ERNEST GELLNER and CHARLES MICAUD (eds.), *Arabs and Berbers: From Tribe to Nation in North Africa* (1972). (M.W.M.)

A classic study focused on the East African mountains, including some coverage of Ethiopia, is RENÉ JEANNEL, *Hautes montagnes d'Afrique* (1950). LESLIE BROWN, *East African Mountains and Lakes* (1971), is also useful. WILLIAM C. MAHANEY (ed.), *Quaternary and Environmental Research on East African Mountains* (1989), results from more than 20 years of serious scientific research. STEFAN HASTENRATH, *The Glaciers of Equatorial East Africa* (1984), a specialized study of the mountains' glaciers, has a valuable bibliography. DAVID KEITH JONES, *Faces of Kenya* (1977), includes chapters on the lakes and the mountains. MALCOLM J. COE, *The Ecology of the Alpine Zone of Mount Kenya* (1967), describes the main plant communities and finds them to be more closely related to the mountain's physiography than to altitude. DIAN FOSSEY, *Gorillas in the Mist* (1983), studies the gorillas that inhabit the slopes of the Virunga Mountains. (S.J.K.B.)

An early work on the Ituri Forest is HENRY M. STANLEY, *In Darkest Africa*, 2 vol. (1890, reissued 1913), the tale of his 18-month journey up the Congo (Zaire) River from its mouth, across the Ituri Forest, and across Tanzania to the coast. COLIN M. TURNBULL, *The Forest People* (1961, reissued 1984), contains a beautifully written popular account of the lives and feelings of Mbuti living in the central Ituri Forest, emphasizing the importance of the forest to their subsistence, ritual, and spiritual life. DAVID S. WILKIE, "Hunters and Farmers of the African Forest," in JULIE SLOAN DENSLow and CHRISTINE PADOCH (eds.), *People of the Tropical Rain Forest* (1988), pp. 111-126, summarizes how agriculturalists and Bambuti have adapted to their tropical forest habitat. ROBERT C. BAILEY, "The Efe: Archers of the Rain Forest," *National Geographic*, 176(5):664-686 (November 1989), is a well-illustrated article by an anthropologist who lived in the region for three and a half years. PAUL SCHEBESTA, *My Pygmy and Negro Hosts* (1936, reprinted 1978; originally published in German, 1934), is one of the first true anthropological studies of Pygmies and their relationship with agriculturalists. ROBERT C. BAILEY and N.R. PEACOCK, "Efe Pygmies of Northeast Zaïre: Subsistence Strategies in the Ituri Forest," in I. DE GARINE and G.A. HARRISON (eds.), *Coping with Uncertainty in Food Supply* (1988), pp. 88-117, studies in detail the diet and subsistence ecology of the Efe and discusses the difficulties of living in the tropical forest and the implications for the health of forest-living peoples. LUIGI LUCA CAVALLI-SFORZA (ed.), *African Pygmies* (1986), contains technical articles on demography, health status, growth patterns, genetic composition, and other biomedical aspects. (R.C.B.)

Early descriptions of the Kalahari and Namib include CHARLES JOHN ANDERSSON, *Lake Ngami* (1856), an account of a four-year exploration; SIEGFRIED PASSARGE, *Die Kalahari* (1904), a thorough study; and HEINRICH VEDDER, *South West Africa in Early Times* (1938, reissued 1966; originally published in German, 1934), a detailed history of the region to 1890. FRANK DEBENHAM, *Kalahari Sand* (1953), reports a modern exploring expedition. NICHOLAS LUARD, *The Last Wilderness: A Journey Across the Great Kalahari Desert* (1981), describes a safari trek and includes observations about the desert's ecological balance and the peoples who live there. KAREN ROSS, *Okavango, Jewel of the Kalahari* (1987), describes this river's wildlife. RICHARD F. LOGAN, *The Central Namib Desert*, *South West Africa* (1960), thoroughly studies the area's physical and biological geography. B.J. HUNTLEY (ed.), *The Kuiseb Environment: The Development of a Monitoring Baseline* (1985), contains a set of excellent articles covering all phases of the environment of a transdesert river valley. Studies of the peoples of the Kalahari include ROBERT K. HITCHCOCK, *Kalahari Cattle Posts*, 2 vol. (1978), a general review of Bantu-speaking and San (Basarwa) inhabitants of the western Kalahari. RICHARD B. LEE and IRVEN DEVORE (eds.), *Kalahari Hunter-gatherers: Studies of the !Kung San and Their Neighbors* (1976), collects writings on various aspects of San life, mainly in the northwestern Kalahari. RICHARD B. LEE, *The Dobe !Kung* (1984); and LORNA MARSHALL, *The !Kung of Nyae Nyae* (1976), are also informative and engaging accounts. GEORGE B. SILBERBAUER, *Hunter and Habitat in the Central Kalahari Desert* (1981), provides a detailed description of the life and ecology of central Kalahari San when they lived as autonomous hunter-gatherers. (R.F.Lo./G.Si.)

E.-F. GAUTIER, *Sahara: The Great Desert* (1935, reissued 1987; originally published in French, 2nd ed., 1928), provides a wealth of information by an eminent geographer long acquainted with the desert. A more popular introduction to the Sahara, by a naturalist who traveled there extensively, is JEREMY SWIFT, *The Sahara* (1975), a Time-Life book. Detailed discussions of the geologic past and prehistory of the desert are contained in MARTIN A.J. WILLIAMS and HUGUES FAURE (eds.), *The Sahara and the Nile* (1980). The most comprehensive climatology available for the desert is JEAN DUBIEF, *Le Climat*

du Sahara, 2 vol. (1959–63). An excellent introduction to the vegetation of the desert is P. QUÉZEL, "Analysis of the Flora of Mediterranean and Saharan Africa," *Annals of the Missouri Botanical Garden*, 65:479–534 (1978). Animal life is described in P.-L. DEKEYSER and J. DERIVOT, *La Vie animale au Sahara* (1959). Prehistoric rock art is discussed in HENRI LHOÏE, *The Search for the Tassili Frescoes: The Story of the Prehistoric Rock-paintings*, 2nd ed. (1973; originally published in French, 1973). There are several excellent studies of the peoples of the Sahara: JULIO CARO BAROJA, *Estudios saharianos* (1955), a detailed description of the little-known peoples of the western desert; LLOYD CABOT BRIGGS, *Tribes of the Sahara* (1960), a more general study, focusing on the central regions; and UNESCO, *Nomades et nomadisme au Sahara* (1963), discussing the nomadic peoples. The most detailed 19th-century travelers' reports are by HENRY (HEINRICH) BARTH, *Travels and Discoveries in North and Central Africa*, 5 vol. (1857–58, reissued in 3 vol., 1965; originally published in German, 1857–58); and GUSTAV NACHTIGAL, *Sahara and Sudan*, 4 vol. (1971–83; originally published in German, 3 vol., 1879–89). (J.A.G.)

The geology of the veld is discussed by LESTER C. KING, *South African Scenery*, 3rd ed. rev. (1963), and *The Natal Monocline: Explaining the Origin and Scenery of Natal, South Africa*, 2nd rev. ed. (1982). The veld environment is explored in J.P.H. ACOCKS, *Veld Types of South Africa*, 3rd ed. (1988); R.F. FUGGLE and M.A. RABIE (eds.), *Environmental Concerns in South Africa* (1983); N.K. HOBSON and J.P. JESSOP, *Veld Plants of Southern Africa* (1975); J. STEVENSON-HAMILTON, *The Low-veld: Its Wild Life and Its People*, 2nd ed. (1934); and N.M. TANTON, D.I. BRANSBY, and P. DE V. BOOYSEN, *Common Veld and Pasture Grasses of Natal* (1976). *Veld & Flora* (quarterly) is a useful journal. (Jo.Co./C.E.F.)

Drainage systems and waterways: A general overview of Lake Chad is contained in A.T. GROVE, "Lake Chad," *The Geographical Magazine*, 37(7):524–537 (November 1964). JEAN MALEY, "Histoire de la végétation et du climat de l'Afrique nord-tropicale au Quaternaire récent," *Bothalia*, 14(3–4):377–389 (September 1983), presents a long-term view of climate change in the Chad basin. The annual vegetation of the region is discussed in H. GILLET, "Essai d'évaluation de la biomasse végétale en zone Sahélienne (végétation annuelle)," *Journal d'agriculture tropicale et botanique appliquée*, 14(4–5):123–158 (April–May 1967). J.-P. CARMOUZE, J.-R. DURAND, and C. LÉVÊQUE (eds.), *Lake Chad: Ecology and Productivity of a Shallow Tropical Ecosystem* (1983), is a lengthy study of the lake's environment and productivity. The fish of Lake Chad and its tributaries are described in J. BLACHE and F. MITON, *Les Poissons du bassin du Tchad et du bassin adjacent du Mayo Kebbi* (1964). A particularly useful study of the peoples of the Chad basin is ALBERT LE ROUVREUR, *Sahéliens et Sahariens du Tchad* (1962, reissued 1989). The more recently arrived Arab groups are discussed in J.C. ZELTNER, *Les Arabes dans la région du Lac Tchad: problèmes d'origine et de chronologie* (1977). (J.A.G.)

LESLIE BROWN, *East African Mountains and Lakes* (1971), is a useful introduction to the region's scenery and wildlife. L.C. BEADLE, *The Inland Waters of Tropical Africa*, 2nd ed. (1981), has a strong East African section and contains an extensive bibliography. DAVID KEITH JONES, *Faces of Kenya* (1977), includes chapters on the lakes. PAUL H. TEMPLE, "The Lakes of Uganda," in S.H. OMINDE (ed.), *Studies in East African Geography and Development* (1971), pp. 86–98, classifies the lakes in physical terms. M.J. MANN, "Freshwater Fisheries," in W.T.W. MORGAN (ed.), *East Africa: Its Peoples and Resources*, 2nd ed. (1972), pp. 229–242, gives a brief account of the fisheries of the individual lakes of Kenya, Uganda, and Tanzania. VICTOR C.R. FORD, *The Trade of Lake Victoria: A Geographical Study* (1955), describes against a historical background the international trade achieved within this area in the preindependence period. (S.J.K.B.)

GILLES SAUTTER, *De l'Atlantique au fleuve Congo*, 2 vol. (1966), discusses the Congo basin in general as well as with the river itself, covering hydrology, climate, vegetation, and fishing. G.A. BOULENGER, *Les Poissons du bassin du Congo* (1901), is a classic work on ecology. JAN VANSINA, *Introduction à l'ethnographie du Congo* (1966), synthesizes available knowledge on the subject, with a section on the relationship between fishing and social organization. ANDRÉ HUYBRECHTS, *Les Transports fluviaux au Congo* (1965), analyzes the evolution and organization of traffic on the middle course of the Congo and its affluents in the period 1925–63. Huybrechts' *Transports et structures de développement au Congo* (1970), studies the role of transportation in the economic transformation of the Congo–Zaire region from 1900 to 1970. JEAN-CLAUDE WILLAME, *Zaire, l'épopée d'Inga* (1986), critically analyzes the economic and political

implications of the Inga Dam. ROLAND POURTIER, "Transport et développement au Zaïre," *Afrique contemporaine*, 29(153):3–26 (1990), discusses current transportation in Zaïre. HENRY M. STANLEY, *Through the Dark Continent*, 2 vol. (1878, reissued 1988), and *The Congo and the Founding of Its Free State*, 2 vol. (1885, reissued 1970), are classic works on African exploration, describing the author's famous descent of the Congo to Malebo (Stanley) Pool and the two upper Congo expeditions. An introduction to the river's history can be found in PETER FORBATH, *The River Congo* (1977). (Ro.Po.)

Accounts of the Niger River environment include Y. BRUNET-MONET *et al.*, *Monographie hydrologique du fleuve Niger*, 2 vol. (1986); JEAN GALLAIS, *La Delta intérieur du Niger: étude de géographie régionale*, 2 vol. (1967); and two essays in BRYAN R. DAVIES and KEITH F. WALKER (eds.), *The Ecology of River Systems* (1986), both by R.L. WELCOMME: "The Niger River System," pp. 9–23, and "Fish of the Niger System," pp. 25–48. CHRISTOPHER LLOYD, *The Search for the Niger* (1973); and SANCHE DE GRAMONT (pseud. for TED MORGAN), *The Strong Brown God: The Story of the Niger River* (1975), cover the history of the river's exploration. (A.L.M.)

General works on the Nile River include H.E. HURST, *The Nile*, rev. ed. (1957); and H.E. HURST *et al.*, *The Nile Basin* (1931–). Studies of the river's geology and biology can be found in JULIAN RZÓSKA (ed.) *The Nile: Biology of an Ancient River* (1976); RUSHDI SAID, *The Geological Evolution of the River Nile* (1981); and MARTIN A.J. WILLIAMS and HUGUES FAURE (eds.), *The Sahara and the Nile* (1980), on landforms and human settlement in the region. Hydrology is discussed in A. AZIM ABUL-ATTA, *Egypt and the Nile After the Construction of the High Aswan Dam* (1978); YUSUF A. SHIBL, *The Aswan High Dam* (1971); and JOHN WATERBURY, *Hydropolitics of the Nile Valley* (1979). Early accounts of the sources to find the source of the Nile are described by JOHN HANNING SPEKE, *Journal of the Discovery of the Source of the Nile* (1863, reissued 1971); and RICHARD F. BURTON, *The Nile Basin* (1864, reprinted 1967). ALAN MOOREHEAD, *The White Nile*, rev. ed. (1971, reprinted 1983), and *The Blue Nile*, rev. ed. (1972, reprinted 1983), together offer a study of exploration in the 19th century. Other works on the river's history include KARL W. BUTZER, *Early Hydraulic Civilization in Egypt: A Study in Cultural Ecology* (1976); and TOM LITTLE, *High Dam at Aswan: The Subjugation of the Nile* (1965). (C.G.S.)

Works on the Orange River include DEPARTMENT OF WATER AFFAIRS, *Management of the Water Resources of the Republic of South Africa* (1986); and MONICA M. COLE, *South Africa*, 2nd ed. (1966). (P.S.Ha./Jo.Co.)

PIERRE MICHEL, *Les Bassins des fleuves Sénégal et Gambie: étude géomorphologique*, 3 vol. (1973), is a fundamental work, providing a detailed description of topography, geology, hydrology, and soils. LOUIS PAPY, "La Vallée du Sénégal: agriculture traditionnelle et riziculture mécanisée," *Les Cahiers d'outre-mer*, 4(16):277–324 (October/December 1951), covers hydrology, human exploitation, landscape, cultural traditions, and navigation, with excellent illustrations. *Études sénégalaises*, no. 9, *Connaissance du Sénégal*, fascicle 2, *Hydrographie*, by FÉLIX BRIGAUD (1961), also studies the river's hydrology. COLETTE LE BLANC, "Un Village de la vallée du Sénégal: Amadi-Ounaré," *Les Cahiers d'outre-mer*, 17(66):117–148 (April/June 1964), describes in detail the environment and daily life of a village on the Sénégal River. (Ca.C.)

Studies of the Suez Canal include R.E.B. DUFF, *100 Years of the Suez Canal* (1969); D.A. FARNIE, *East and West of Suez: The Suez Canal in History, 1854–1956* (1969), which traces events from the concession to the nationalization of the canal company; LORD KINROSS (PATRICK BALFOUR, BARON KINROSS), *Between Two Seas: The Creation of the Suez Canal* (1968); JOHN MARLOWE, *World Ditch: The Making of the Suez Canal* (also published as *The Making of the Suez Canal*, 1964), a well-documented account from the canal's inception to the British occupation of Egypt in 1882; HUGH J. SCHONFIELD, *The Suez Canal in Peace and War, 1869–1969*, rev. ed. (1969), a brief, general survey; ANDRÉ SIEGFRIED, *Suez and Panama* (1940; originally published in French, 1940); and ARNOLD T. WILSON, *The Suez Canal: Its Past, Present, and Future* (1933, reprinted 1977), a classic evaluation of the British interest in the canal. (C.G.S.)

Little is written in English specifically on the Zambezi River. Information can be found in B.M. FAGIN (ed.), *The Victoria Falls Handbook*, 2nd ed. (1963); R. MANSELL PROTHERO (ed.), *People and Land in Africa South of the Sahara: Readings in Social Geography* (1972); and N.J. MONEY, *The Geology of Western Zambia* (1972). (N.J.Mo.)

African Arts

African arts usually refers to the works of black, or sub-Saharan, Africa, that part of the continent originally inhabited by Negro peoples who developed cultures quite distinct from those of Caucasian North Africa. Within this huge geographic area are regions of radically different topography, climate, and natural resources. The economies of these regions, therefore, also differ radically from one another, as do the customs, religions, languages, and artistic expressions of their peoples. There is startling diversity within each of the regions as well. It is common to divide sub-Saharan Africa into the following geographic regions: the open grasslands of the Sudan stretching across the continent just south of the Sahara, the woodlands and forests of West Africa, the basin of the Congo River in Central Africa, the East African savannas, and the savannas and deserts of southern Africa. None of these regions has a uniform culture. The western Sudan, for example, is rich in sculptural styles and production, while sculpture has been little developed in the eastern part, where artistic expression is richest in music and oral literature.

The European powers further divided the cultures of black Africa by creating colonies with boundaries that had little regard for traditional ethnic or linguistic groupings. The contemporary literatures of English-, French-, and Portuguese-speaking Africa, therefore, have a uniformity of theme and language that corresponds not to geographic regions or to ethnic affinities but instead to the rather arbitrary manner in which the colonial powers divided the continent. Colonization also introduced European religion, technology, and politics, which, together with the European languages, created a historical division in the development of black African arts that may be deeper than its regional divisions. Since the 19th century some cultural traditions of precolonial origin have disappeared, and, while others survive and indeed flourish, there has been every possible compromise with the cultural forms of the West.

Despite its variety, African arts can be discussed as a whole for several reasons. One reason is that, while the artworks of different peoples may differ in form, the

traditional roles of art and of the artist in the cultural life of the people are quite similar throughout the continent—and quite different from their roles in non-African cultures. Another reason is that the borders of modern African nations do not necessarily correspond to cultural borders, so that it is often necessary to discuss the arts not of one country but of an entire region. In addition, all black African arts, no matter how diverse, went through a common process of adapting to foreign cultures. It is a mistake to think of the subcontinent as having been isolated from the rest of the world until only recently. Trade across the Sahara is probably as ancient as the current stage of desiccation, which began in the 3rd millennium bc. Through this trade, Islām was introduced into and spread throughout much of West Africa, while the trade networks of the Indian Ocean had a comparable effect in East Africa. Coastal trade with Europe, resulting almost immediately in the transatlantic slave trade, began in the late 15th century. This long history of contact means that all discussion of African arts must address a common subject of outside influence.

This article discusses the literature, music, dance, and visual art of black Africa, both in their traditional forms and in their adaptation to modern Western ways of life. Non-African forms of recent adoption are not discussed. For example, this article discusses the thousand-year-old influences of Islām in the literature and architecture of East and West Africa and of Christianity in the painting of Ethiopia, but it does not discuss Christian musical or modernist sculptural forms adopted since the colonial era. For a discussion of North African arts, see the article ISLĀMIC ARTS. For a discussion of white South African writers, see the *Micropædia*, SOUTH AFRICAN LITERATURE. For information on the geographic, economic, and historical background of African arts, see the article SOUTH AFRICA and the articles on the major regions of the continent (e.g., CENTRAL AFRICA, SOUTHERN AFRICA).

For coverage of related topics in the *Macropædia* and *Micropædia*, see the *Propædia*, sections 613, 621, and 624–629, and the *Index*. (J.Pi./Ed.)

General characteristics

It is difficult to give a useful summary of the main characteristics of the arts of sub-Saharan Africa. The variety of forms and practices is so great that the attempt to do so results in a series of statements that turn out to be just as true, for example, of Western art. Thus, some African arts are found to have value as entertainment; some have political or ideological significance; some are instrumental in a ritual context; and some have aesthetic value in themselves. More often than not, a work of African art combines several or all of these elements. Similarly, there are full-time and part-time artists; there are artists who figure in the political establishment and those who are ostracized and despised; and some art forms can be made by anyone, while others demand the devotion of an expert. Claims of an underlying pan-African aesthetic must be viewed as highly contentious.

Some further general points can be made, however, in regard to the status of precolonial sub-Saharan art. The first is that, in any African language, a concept of art as meaning something other than skill would be the exception rather than the rule. This is not because of any inherent limitation of African culture but because of the historical conditions under which European cultures arrived at their concept of art. The Western separation of fine art from the lowlier craft (*i.e.*, useful skill) came out of a sequence of social, economic, and intellectual changes in Europe that did not occur in Africa prior to the colonial period at the very earliest. This separation, therefore, cannot be applied without qualification to African traditions of precolonial origin. Philosophers of art in the West might agree that works of art are simply artifacts made with the intention of possessing aesthetic value, and in that sense art, which would include craft work as well as works of fine art, would indeed be found in all parts of Africa (as indeed it is throughout human culture), but even in this case African art must be understood through the investigation and understanding of local aesthetic values rather than through the imposition of categories of external origin. It may be a field of well-hoed yam heaps (as, for example, among the Tiv people of Nigeria) or a display ox castrated in order to enhance its visual effect (as among the Nuer and Dinka pastoralists of the southern Sudan), rather than a sculpted figure, that constitutes the significant work of art in a given area of Africa.

The popular notion of African art in the West, however, is very different, for it is thought to comprise sculpture and very little else—except, perhaps, “local colour.” This misconception has been caused by the previously mentioned European concept of fine art, but it was also caused by a dependence, during the first period of Western interest in African arts, upon collectible artifacts—some of which (pieces of sculpture, for instance) fitted neatly into the category of fine art, while others (such as textiles and pottery) were dismissed as craft work. Painting in Africa was long presumed not to exist to any significant extent, largely because it was to be found on the skins of human bodies, on the walls of houses, and on rock faces—none of which were collectible items. Clearly, the aesthetic field in Africa is not so limited.

Another misapprehension is that in the West art is created for art's sake, whereas in precolonial Africa art was solely functional. But the motive for the creation of any work of art is inevitably complex, in Africa as elsewhere, and the fact that most of the sculpted artifacts known

from Africa were made with some practical use in mind (whether for ritual or other purposes) does not mean that they could not simultaneously be valued as sources of aesthetic pleasure.

It is also often assumed that the African artist is constrained by tradition in a way contrasting with the freedom given to the Western artist. But, although there are traditions of art in which the expectations of patrons demand repetition of a set form in African art, there are also traditions of precolonial origin that demand a high level of inventive originality—for example, Ashanti silk weaving and Kuba raffia embroidery. There are other traditions in which a standard form can be embellished as elaborately as the artist or patron wishes. The important point is that particular traditions encourage creativity.

STYLE, TRIBE, AND ETHNIC IDENTITY

A commonplace of African art criticism has been to identify particular styles, whether in the performing or visual arts, according to supposedly tribal names—for example, Ashanti, Kuba, or Nuba. The concept of tribe is problematic, however, and has generally been discarded. “Tribal” names, in fact, sometimes refer to the language spoken, sometimes to political entities, and sometimes to other kinds of groupings; yet the boundaries between peoples speaking different languages or acknowledging different chiefs do not necessarily coincide with their respective tribal boundaries. Moreover, the very idea of tribe is an attempt to impose identity from the outside. That this happened is understandable, given the demands of colonial administration, but this historical contingency cannot help in understanding the dynamic of stylistic variation in Africa. The sense of identity that individuals and groups

Identifying
regional
styles

undoubtedly have with others, which was misunderstood as "tribe" but which is better referred to as "ethnic identity," is something that derives from the relationship built up through many different networks: whom one can marry, one's language and religious affiliations, the chief whose authority one acknowledges, who one's ancestors are, the kind of work one does, and so forth. Sometimes African art plays a part in this, as when a religious cult or a chief or a guild employs distinctive artifacts as a mark of uniqueness. Sometimes boundaries are based on linguistic differences, but this may be coincidental.

As to differences of style, regularities of form and tradition do occur such that it is possible to attribute particular African art objects to particular places, regions, or periods. There seem to be four distinct variables making this kind of stylistic identification possible. The first is geography, in that, all other things being equal, people in different places tend to make or do things in different ways. The second is technology, in that in some areas differences of style depend on the material employed. The third is individuality, in that an expert can identify the works of individual artists, inability to do so usually deriving from lack of familiarity. The fourth is institution, in that the creation of works of art takes place under the influence of the social and cultural institutions characteristic of any given location. But artifacts can be traded and then copied; artists themselves can travel; institutions, complete with associated artifacts, can move or spread from one area to another, sometimes because they are copied by a neighbouring people, sometimes because they are purchased, sometimes as a result of conquest. The end result is a stylistic complexity in African art that defies easy classification. The names previously understood as referring to tribes can continue to be used, however, as convenient shorthand as long as it is realized that they all do not represent equivalent categories. One tribal name may refer to a group numbering no more than a few thousand; another may refer to the language spoken in a given area; yet another may describe an empire comprising peoples of distinct historical identities.

AFRICAN ARTS IN THE 20TH CENTURY

African cultures have never been closed to the rest of the world, but the radical developments forced on the continent as a result of colonialism have made the 20th century a period of unusually rapid change. The majority of known "traditional" works are, in fact, products of the colonial period; thus, it is impossible to maintain a rigid distinction between traditional and modern art forms. It is better to think of the 20th century as a period in which the range of options available to the artist has increased as new cultural and social institutions have developed. This process is better understood for literature than it is for the visual arts.

Nevertheless, the continuing development of artistic traditions of precolonial origin is far more widespread in Africa than is commonly realized. In addition, there are roughly three kinds of development in which African artists have drawn on and adapted European forms. The first is when European forms are copied by illiterate or semilliterate artists, or at any rate mediated via the marketplace, as in popular sign painting or the kind of pamphlet writing typified by the Onitsha market literature of Nigeria. The second is when the medium of transmitting Western artistic practice is the university or some other institution of higher education, as is the case with contemporary African sculpture and painting or with African writers using European languages. The third is when traditional forms are revamped, or pseudotraditional forms invented, for the benefit of foreign tourists and other visitors (for example, some of the finest ivory sculptures of West Africa were produced in what is now Sierra Leone by Sherbro artists and in the kingdom of Benin for Portuguese traders in the early 16th century). Although the forms and materials employed in these developments are of external derivation, the subject matter and style are manifestly African. It is the artists working under these influences who are forming the arts distinctive of the particular nation-states of modern-day Africa. (J.Pi.)

Literature and theatre

The term African literatures covers traditional oral and written literatures together with the mainly 20th-century literature written mostly in European languages but also to an increasing extent in the many languages of the sub-Saharan region. Traditional written literature is limited to a smaller geographic area than is oral literature; indeed it is most characteristic of those sub-Saharan cultures that have participated in the cultures of the Mediterranean. In particular, there is literature in both Hausa and Arabic from the scholars of what is now northern Nigeria; the literature of the likewise Muslim Somali people; and literature in Ge'ez (or Ethiopic) and Amharic of Ethiopia, the one part of Africa where Christianity has been practiced long enough to be considered traditional.

The relationship between oral and written traditions and in particular between oral and modern written literatures is one of great complexity and not a matter of simple evolution. Modern African literatures were born in the educational systems imposed by colonialism, with models drawn from Europe rather than existing African traditions. The modern African writer thus uses tradition as subject matter rather than as a means of effecting a continuity with past cultural practice.

ORAL TRADITIONS

The poetic and narrative forms of oral tradition among those peoples living south of the Sahara are immensely rich and varied. They include myths (in the sense of symbolic accounts of the origins of things, whether the world, particular cultures, lineages, political structures, or gods), praise songs, epic poetry, folktales, riddles, proverbs, and magical spells. The content of this material also varies considerably and includes children's rhymes and oral history, as well as symbolic texts of profound intellectual significance.

An important feature of African oral traditions is their close link with music. Poetry exists almost exclusively in chanted form or as song, and, among West African peoples with tonal languages (for example, the Akan and the Yoruba), much poetry is recited in musical form rather than spoken or sung.

Myths. African creation stories are as varied and imaginative as elsewhere in the world. The Kono of Guinea believe that the original force in the world was Death, who existed before God; the Lozi of Zambia see God as retreating helplessly from the cruelty of man; for the Ijo peoples of the Niger Delta, God (there regarded as female) allows a person to choose his own fate before birth. The Pangwa of Tanzania have a fantastic vision of the world as having been created from the excrement of ants. The Yoruba of Nigeria tell of a creator who got drunk on palm wine and so created cripples and albinos. The most detailed cosmology known, requiring seven days for its recitation, is that of the Dogon of Mali. An unusually attractive creation myth is that of the Fulani of Mali, a pastoral, cattle-herding people whose mythology centres on milk.

At the beginning there was a huge drop of milk.
Then Doondari came and created the stone.
Then the stone created iron;
And iron created fire;
And fire created water;
And water created air.
Then Doondari descended the second time. And he took the five elements
And he shaped them into man.
But man was proud.
Then Doondari created blindness and blindness defeated man.
But when blindness became too proud,
Doondari created sleep, and sleep defeated blindness;
But when sleep became too proud,
Doondari created worry, and worry defeated sleep;
But when worry became too proud,
Doondari created death, and death defeated worry.
But when death became too proud,
Doondari descended for the third time.
And he came as Gueno, the eternal one,
And Gueno defeated death.

(Eng. trans. by Ulli Beier in
The Origin of Life and Death, 1966)

Relation of
poetry to
music

According to nearly all African mythologies, God first agreed to give man eternal life, but his message was perverted through the stupidity or malice of the messenger. Several hundred African variants of the myth of the perverted message are known.

The most elaborate pantheons of gods are probably those found among the Yoruba of Nigeria and the Fon of Benin. These deities (*orisha* or *vodun*) are often seen simultaneously as legendary kings and founders of cities, and as supernatural spirits and controllers of the elements. Here the story of a god must often be gleaned from cryptic references embedded in his praise names (*oriki*, or *mlem-len*). These are curious mixtures of praise, description, joking abuse, and prayer; and, although the phrases have been handed down for centuries, the singer is free to add new ones. Thus, Shango (the Yoruba god of thunder and lightning) is compared to the power and rumbling noise of the railway.

Poetry. The praise name is probably the most widely used poetic form in Africa. It is applied not only to gods but to men, animals, plants, and towns. Most important in many African communities are the praise names of chiefs and war leaders, as, for example, those of the great Zulu chieftain Shaka:

He is Shaka the unshakeable,
Thunderer-while-sitting, son of Menzi.
He is the bird that preys on other birds,
The battle-axe that excels over other battle-axes.

(Eng. trans. by Ezekiel Mphahlele)

There are numerous other poetic forms. The Yoruba, for example, distinguish between praise names (*oriki*), the poetry of lineages and towns (*orile*), oracle verse (*ese*), hunters' songs (*ijala*), the poetry of masqueraders (*iwi*), incantations (*ofo*), songs (*orin*), and improvisations (*rara*). Incantations play an important part in all African traditions. The Igbo diviner, for example, invokes truth before consulting his oracular bones or other apparatus.

A common poetic form is the magic formula, in which the meaning of the words is often obscure. These formulas are sacred combinations of words the correct repetition of which, accompanied by the proper ritual, is believed to be effective both in curing and cursing.

Probably the most elaborate body of poetry is that of the Ifa oracle among the Yoruba. Even the most learned priest is not expected to know it all, and the recital of the most important parts takes a whole night. The poems are accompanied by stories that constitute the mythological or historical precedents by which the diviner judges his client's case.

Every situation in African life is accompanied by poetry and song. The herdsman praises his bull ("My bull is dark like the rain cloud in a storm" [Dinka]); the young warrior sings of his bride ("Neither her heel nor her palm are rough, but sweet to the touch like liver" [Fulani]); children invent a song to comment on an important event ("Europeans are little children, at the riverbank they shot an elephant, its blood became a canoe and it sank" [Nyasa, Malawi]); the widower mourns the death of his wife ("What are your wares that they sold out so quickly?" [Akan, Guinea Coast]).

Folktales. The best-known type of African folktale is the animal-trickster tale. In Bantu Africa (East, Central, and southern Africa) and the western Sudan, the trickster is the hare; in West Africa, the spider (Ghana, Liberia, Sierra Leone) or the tortoise (Benin, Nigeria). The Yoruba consciously poke fun at their own faults when they tell stories of the tortoise-trickster. Sometimes the tortoise's cunning defeats itself, as, for example, in the tale in which the tortoise steals from the gods a calabash that contains all the wisdom in the world. He hangs it around his neck and is so eager to get home with it that, when he comes to a tree trunk lying across the road, he is unable to cross it because the calabash gets in his way; in his anxiety he fails to think of putting it on his back. Frustrated, the tortoise smashes the calabash, and so, ever since that day, wisdom has been scattered all over the world in tiny pieces. Anansi (the spider-trickster, of whom stories are told among the Akan and, as Anancy, in Jamaica) often appears as a mythological figure, the fiendish opponent of

the sky god, who steals the sky god's stories or tricks him into allowing disease to enter the world. In this function he shows some similarity with the Yoruba trickster god, Eshu, who consistently opposes the other gods and thwarts their intentions. There are a number of African peoples who also have story cycles about human tricksters—for example, the stories of Yo in Benin, the Lay cycle of the Iraqw in Tanzania, and the Zulu Uhlakanyana stories.

A variant of the trickster tale is the escape story, in which the hero extricates himself from an impossible task by imposing an impossible condition. One such story tells how a cruel king of Benin ordered his subjects on pain of death to build a new palace but to start at the top and build downward. All were in despair until one wise old man went to the King and said that they were now ready to begin and asked him, according to tradition, to lay the foundation stone.

Stories of another kind, told for entertainment, usually on moonlit nights, are dilemma tales, in which the audience is invited to supply the ending or solution. An example of a dilemma tale told among the Wolof (Senegal, The Gambia) is as follows. Three brothers journey to a strange land and are all married to the same girl, with whom they sleep in turn. One night she is murdered by a robber, and the eldest brother, with whom she is sleeping, is condemned to death on suspicion. He begs leave to visit his father before he dies. When he is late in returning, the second brother offers to die in place of him. As he is about to be executed, the third brother steps forward and "confesses" that he is the murderer. But, at that moment, the eldest brother rides in, just in time to embrace his fate. Which of the brothers (the listeners are asked) is the most noble?

In another group of tales, prominent features of animals are explained (e.g., "... so that is why the tortoise has a broken back").

Proverbs and riddles. "Proverbs are the palm oil with which words are eaten," an Igbo proverb says. The art of conversation and argument depends, in fact, on their use. By them the speaker shows his learning. Use of proverbs also enables the speaker to attack an opponent obliquely, without mentioning his name or the subject of the dispute. Proverbs express not only a people's inherited wisdom and code of behaviour ("If a child washes his hands, he will eat with kings" [Igbo]) but also imagination and sense of humour ("If the earthworm does not dance in front of the cock, he will still be eaten, but at least the cock cannot say that he was provoked" [Yoruba]). The largest collection of African proverbs, made by a Swiss Lutheran missionary, J.G. Christaller, and published at Basel in 1879, contains 3,600 in the Twi language of Ghana.

Riddles usually take the form of a statement, not a question. In the riddle "People run away from her when she is pregnant, but they rejoice when she has delivered" (the answer is a gun), the question "What is it?" is understood. Often the riddle is an exercise in metaphorical speech, intended to display the questioner's imagination rather than to test the cleverness of the audience (e.g., the Yoruba "We tie a horse in the house, but its mane flies above the roof," to which is answered "fire" and "smoke").

Survival of oral tradition. Many oral traditions, particularly those associated with traditional ritual, are disappearing, and poetic forms are gaining new content and application (e.g., praise names, applied to politicians; songs of abuse during elections, often taking the form of incantations). Nationalism and higher education tend to make Africans more conscious of their cultural heritage, and the collection and conservation of oral traditions is no longer left to foreign anthropologists. Some of the best collections are by African writers and scholars, and many universities in Africa are engaged in recording and interpolating this material.

African folklore has come most powerfully alive in modern writing in the works of Amos Tutuola. *The Palm-Wine Drinkard* (1952) and *My Life in the Bush of Ghosts* (1954) are inspired re-creations of the world of Yoruba folklore. Tutuola, whose long rambling tales are improvisations on traditional themes, is a born storyteller. Better than any exact translation, his books convey the rich inventiveness

of traditional Yoruba folktales, the rather grim humour of which is often mingled with fear, pain, and other extremes of sense or impression.

MODERN LITERATURES IN EUROPEAN LANGUAGES

Though the written literatures in African languages antedate in origin those in European languages, they are discussed after the more widespread modern literatures in French, Portuguese, and English—the so-called metropolitan languages of Africa.

The body of published African literature written in European languages is sufficient to be studied in its own right. Critical opinion within Africa remains divided about how authentically African experience can be rendered in a language of European origin, but, despite the growth of indigenous language publications, there is no serious threat to the survival of literatures in the metropolitan languages.

French. The first contemporary literature was born as a protest against French rule and the policy of assimilation. Its leading figure was Léopold Senghor, who in 1960 was elected first president of the Republic of Senegal. In Paris during the 1930s he met Negro writers from the French Caribbean, such as the poets Aimé Césaire of Martinique and Léon Damas of French Guiana. Together, they began an examination of Western values and a reassessment of African culture, and in 1947 they founded *Présence Africaine*, Africa's leading literary journal. Senghor's *Anthologie de la nouvelle poésie nègre et malgache* (1948; "Anthology of the New Negro and Madagascan Poetry") was an important influence in the formation of the idea of a Negritude (a term first used by Césaire) that should include poets outside Africa—in the French Caribbean territories and in Madagascar, for example. Senghor's poems are sometimes regarded as examples of 20th-century French poetry in the manner of Paul Claudel or St. John Perse, but they are, in fact, essentially African: his love poetry, in particular, is intensely so in structure and tempo. Senghor's themes are those of Negritude: he attacks what he sees as the soullessness of Western civilization ("no mother's breast, but only nylon legs") and proclaims that African culture alone has preserved the mystic warmth of a life that could still revive "the world that has died of machines and cannons." This culture, says Senghor, gains strength from its closeness to nature and constant contact with "the ancestors"; Western culture is out of step with the world's natural and ancient rhythm. Therefore, he proclaims, "[We are] the leaven that the white flour needs." In his long rhapsodic lines he tries to make the French language swing and dance in the rhythms of his native Serer language.

Another Senegalese, Birago Diop, has similarly explored the mystique of African life in a volume of poems, *Leures et lueurs* (1960). His fellow countryman David Diop wrote the most violent and full-blooded protest poetry to be produced by the Negritude movement: "When civilization kicked us in the face, when holy water slapped our cringing brows. . . ."

Two of the most important Francophone novelists are the Cameroonians Mongo Beti (pseudonym of Alexandre Biyidi), who wrote *Le Pauvre Christ de Bomba* (1956; *The Poor Christ of Bomba*), and Ferdinand Oyono, author of *Une Vie de boy* (1956; *Houseboy*) and *Le Vieux Nègre et la médaille* (1956; *The Old Man and the Medal*). All three novels aim to explode the French colonial myth of France Outre-Mer: that the French West African possessions were not really colonies and that educated Africans are thus simply "black Frenchmen."

The second generation of French African writers was less concerned with the public rhetoric of Negritude. Thus, though the Congolese poet Tchicaya U Tam'si sometimes speaks of his people's sufferings ("My race remembers the taste of bronze drunk hot"), he does not claim to be the spokesman of his race. In *Le Mauvais Sang* (1955; "Bad Blood"), *Feu de brousse* (1957; *Brush-Fire*), *A triche-cœur* (1960; "A Game of Cheat-Heart"), *Épitomé* (1962), and *Le Ventre* (1964; "The Belly"), he explores his personal agonies in Surrealist poems in the dense texture of which mythological, Christian, and sexual imagery are juxtaposed.

Camara Laye became famous with his romantic autobiography *L'Enfant noir* (1953; *The Dark Child*), which draws a poetic, idyllic picture of life in a traditional African town. His most important work, however, is the novel *Le Regard du roi* (1954; *The Radiance of the King*), which describes a white man's quest for personal salvation in the mysterious atmosphere of the West African jungle. It is regarded as among the most imaginative novels to have come from Africa. In a third novel, *Dramouss* (1966; *A Dream of Africa*), Laye, who in 1965 became a political refugee in Senegal, attacks the harsh methods of Guinea's ruling party. Among Africa's Socialist intellectuals, Senegal's Sembène Ousmane is best known as a film director, but his *Les Bouts de bois de Dieu* (1960; *God's Bits of Wood*) is a classic novel about the poor.

In the 1960s there was an important development of the philosophical novel in French-speaking Africa, notably by Sheikh Hamidou Kane in *L'Aventure ambiguë* (1961; *Ambiguous Adventure*) and by Yambo Ouologuem in *Le Devoir de violence* (1968; *Bound to Violence*). Both writers belong to the Islāmic western Sudan and present their novels partly in the form of "dialogues," either between Islām and Western materialism or between traditional autocracy and Christian compassion. Remarkable as women writers in a hitherto male world were Mariama Bâ, recipient of the first Noma Award for publishing in Africa for *Une Si Longue Lettre* (1980; *So Long a Letter*), and Aminata Sow Fall, a fellow Senegalese, who earned praise for *La Grève des battus ou les déchets humains* (1979; *The Beggar's Strike*), an ironic novella of great skill.

Portuguese. The 20th-century poetry of former Portuguese Africa, first widely known through the Angolan Mário de Andrade's *Antologia da Poesia Negra de Expressão Portuguesa* (1958), is mainly extremely militant. Both Andrade and the more important Agostinho Neto became actively engaged in the Angolan liberation movement, Neto serving as the first president of the People's Republic of Angola from 1975 until his death in 1979.

The Mozambican José Craveirinha, an *assimilado* (i.e., assimilated to Portuguese culture and Roman Catholicism), like all the African writers who have published work in former Portuguese Africa, is yet deeply concerned with problems of race and discrimination. Mozambique's capital of Maputo (Lourenço Marques), the centre of a considerable literary and artistic activity, has also produced Luís Bernardo Honwana, one of Africa's outstanding short-story writers. In 1980 an Angolan writer of stature emerged, Pepetela (Artur Carlos Mauricio Pestana dos Santos), whose novel *Mayombe* is regarded as the major work of African fiction to have derived from guerrilla experience.

English. Although a genuine African literature in English did not emerge until the 1950s, writing in English by Africans goes back to the 18th century. Perhaps the most remarkable of the works published in England by West Africans sold into or born in slavery and later freed is *The Interesting Narrative of the Life and Adventures of Olaudah Equiano or Gustavus Vassa, the African* (1789; 3rd ed., enlarged, 1790), the first known English account by an African of his native country. In the 19th century, with the spread of missionary schools, several Africans published prose works in English, among them Samuel Adjai Crowther (who in 1844 translated part of the Gospel According to Luke), Africanus Horton, and Edward Blyden. In the early 20th century, the Ghanaian minister of religion the Reverend Carl Christian Reindorf wrote one of the first works by an African to make use of oral traditions, *The History of the Gold Coast and Asante* (c. 1911); and Joseph E. Casely-Hayford, also a Ghanaian, wrote *Ethiopia Unbound* (1911), a mixture of novel, autobiography, and pamphlet that is a forerunner of Negritude.

In the 1940s the popular novelettes of the Onitsha market literature, named after the famous market where they were sold, began to be written, and a number of pioneer writers—among them Michael Dei-Anang and Raphael Armattoe of Ghana, Dennis Osadebay of Nigeria, and Edwin Barclay of Liberia—began to publish poems that, technically often crude and somewhat didactic in theme, prepared the way for later poets.

Literary
activity in
Nigeria

The institution in 1948 of university colleges at Accra, Ghana, and Ibadan, Nigeria, gave impetus to poetry, the novel, and drama in the 1950s and '60s. The most intense activity was in Nigeria, the Igbo proving particularly prolific. Cyprian Ekwensi, who began as an Onitsha pamphleteer, enjoyed great popularity with *Jagua Nana* (1961), the story of a prostitute. Onuora Nzekwu explored the relationship of the educated Igbo to his traditional culture in *Wand of Noble Wood* (1961), *Blade Among the Boys* (1962), and *Highlife for Lizards* (1965). Nkem Nwankwo created the comic figure of *Danda* (1964), the irreverent antihero of a novel perhaps inspired by trickster tales. The outstanding Igbo novelist was Chinua Achebe. All his novels present the conflict of emergent Africa: in *Things Fall Apart* (1958) he showed the impact of British rule on Igbo village life; in *No Longer at Ease* (1960) he analyzed the conflict in the mind of an African civil servant in Lagos who is torn between the social pressures of upper-class urban life and the demands of his village union; in *Arrow of God* (1964) he explored the breakup of traditional values and the struggle for political power in an Igbo village. *A Man of the People* (1966) is a bitter, disillusioned story of political corruption and intimidation in independent Nigeria. The same themes emerge in *Anthills of the Savannah* (1987).

The development of Nigerian literature owed much to two related centres in Ibadan. The journal *Black Orpheus*, founded in 1957 with Ulli Beier and Janheinz Jahn as its first coeditors, took its name from Jean-Paul Sartre's famous "Orphée noir" (1948), the introduction to Senghor's anthology (see above), and from Jahn's anthology, *Schwarzer Orpheus* (1954). Inspired by *Présence Africaine* and the First Congress of African Writers (Paris, 1956), *Black Orpheus* published the earliest efforts of African writers in English to find a literary mode of expression. A second influence on the establishment of an independent Nigerian culture was the foundation (1961) of the Mbari Club (also called the Mbari Mbayo Club), a meeting place for new writers and artists that also published the work of many poets and playwrights.

Among poets published by Mbari was Christopher Okigbo, who, until his early death in 1967 while fighting for Biafran independence, was the most polished and prolific Nigerian poet. In *Heavensgate* (1962) and *Limits* (1964) he developed a sensuous verse using styles borrowed from African and Western sources.

Like Okigbo, John Pepper Clark was graduated from the University of Ibadan. His passionate *Poems* (1962) and *Song of a Goat* (1961) were first published by Mbari. Clark is the most urgent and immediate of the Nigerian poets. Less reflective than Wole Soyinka, less meticulous than Okigbo, he works out each poem on the impetus of a single lyrical impulse. He has also written successful plays: *Song of a Goat* (performed in London at the 1965 Commonwealth Festival) is the tragedy of a childless woman. *The Ozidi of Atazi* (performed in the early 1960s; published, 1966) is a stage version of a traditional Ijo ritual play.

One of Nigeria's most sensitive poets is Gabriel Okara, whose novel *The Voice* (1964) is a fascinating linguistic experiment. Okara forces English into the straitjacket of Ijo syntax, producing an extraordinary and archaic effect that is often as beautiful as it is bizarre.

Africa's most famous playwright is the Nigerian Wole Soyinka (see below *African theatre*). Apart from his plays, Soyinka's tragic view of life is also expressed in his novel *The Interpreters* (1965). Publication in 1967 of *Idanre and Other Poems*, his first anthology, established him as a poet of distinction. Here, too, he explored his tragic sense of the difficulties and cost of human progress. Soyinka's autobiography of childhood, *Aké* (1981), was masterly in its tender recollections of his early years.

Nigerian writing in the 1970s lost some of its momentum. While many writers were coming to terms with the effects of the civil war of 1967–70, new writers emerged dealing with other preoccupations. These included Buchi Emecheta, who documented the position of women in Nigeria and Britain; Festus Iyayi and Ben Okri, who showed the stresses within urban African society; and playwrights such as Zulu Sofola.

Among the most important poets outside Nigeria in the late 1960s were a Gambian, Lenrie Peters, and a Ghanaian, George Awoonor Williams (later known as Kofi Awoonor). The early work of both was published by Mbari: Peters' *Poems* and Awoonor Williams' *Rediscovery and Other Poems* (both 1964). Peters brings an unusual scientific intelligence to bear in his poetry, while Awoonor is deeply concerned with his native Ewe poetic tradition and the means of extending this in English.

In 1968 the Ghanaian Ayi Kwei Armah's novel *The Beautiful Ones Are Not Yet Born* was published. On the surface it deals with the dying days of Kwame Nkrumah's government, but, on a more universal level, it sums up the drift and despair of many African writers in the years after the stilling of the drums that celebrated independence. Armah's later work included *The Healers* (1978), a novel set in the 19th century that, like those of many other writers, uses the past as a key to understanding the present.

In East Africa in the 1960s, written literature was only just coming to birth; and the literary review *Transition* (Kampala, Uganda, 1961–68) played an important part in encouraging young writers. In the late 1960s the most original talent in East Africa was that of a Ugandan, Okot p'Bitek, whose long poem *Song of Lawino* (1966) treats the conflict of cultures with freshness and imagination, using the device of a lament by an illiterate woman. Already, however, Ngugi wa Thiong'o of Kenya had emerged as East Africa's leading novelist, with two novels—*Weep Not, Child* (1964) and *The River Between* (1965)—in which he tried to do for his native people, the Kikuyu, what Achebe had done for the Igbo. In a third novel, *A Grain of Wheat* (1967), he reflected profoundly on the meaning of heroism and of national independence. His *Petals of Blood* (1977) is complex in its narrative technique and explicit in its call for popular rebellion against the injustices of external domination. Ngugi's plays in particular were sufficiently outspoken to result in his spending a year in detention. He turned to writing in Kikuyu as well as in English, notably in his novel *Devil on the Cross* (1982), a scathing satirical fantasy.

The emergent work of African and Coloured writers born in, though often living in exile from, the Republic of South Africa has been dominated by the political fact of apartheid. Many found the short story the best medium of protest, among the most successful writers being Bloke Modisane; Todd Matshikiza; Ezekiel Mphahlele; Richard Rive; a Coloured writer, Alex La Guma; a journalist, Can Themba; and Arthur Maimane. In the late 1950s *Drum* magazine provided an important forum for these writers. Autobiographies are among the most moving and significant works by black South Africans. Mphahlele's *Down Second Avenue* (1959) has become a South African classic; and Alfred Hutchinson's *Road to Ghana* (1960) and Bloke Modisane's *Blame Me on History* (1963) are passionate documents in which the authors try to overcome the humiliation of their experience as blacks living in white-dominated South Africa.

The outstanding nonwhite novelist in South Africa in the 1960s was Alex La Guma. His superb eye for detail makes it possible for him to let the horror of a situation speak for itself, so that he never becomes sentimental, prolix, or overemotional in describing it. His short novels, including *A Walk in the Night* (1962), *And a Threefold Cord* (1964), *The Stone-Country* (1965), and *Time of the Butcherbird* (1979), are tense works of protest. The subtlest treatment of the recurrent theme of race relations, however, was perhaps that by Lewis Nkosi in his extraordinary play *The Rhythm of Violence* (1964).

The leading South African poets of the 1960s were Mazisi Kunene, K.A. Noortje, and Dennis Brutus. Many writers went into exile, but the country continued to produce, as a main focus of opposition to apartheid, some of the outstanding black writers on the continent. Prominent prose writers in the 1980s included Njabulo Ndebele and Mbululo Mzamane; poets included Sipho Sepamla, Oswald Mtshali, and Mongane Serote. A notable playwright was Maïshe Maponya.

The 1980s saw the emergence of Zimbabwean fiction (represented notably by Dambudzo Marechera and Charles

Mungoshi), at least one major Malaŵian poet (Jack Mapanje), the Botswanan (formerly South African) novelist and short-story writer Bessie Head, and a brilliant Somali novelist, Nuruddin Farah. The last two were perhaps Africa's most profound interpreters of women.

(U.Be./Ge.Mo./A.N.R.N.)

LITERATURES IN AFRICAN LANGUAGES

Evidence of the indigenous written literatures of Africa is in some regions ancient and in others comparatively recent. The earliest written African language known is the now-dead language of Ge'ez, from Ethiopia (see below). The Latin and Arabic alphabets have had marked influence on developments in written African literature. Arabic was brought to the continent in the 7th century, when the Arabs conquered North Africa, while the Latin alphabet was introduced by Christian missionaries largely in the 19th century.

In West Africa the beginnings of indigenous written literature are linked to the campaigns in the early 1800s of the Fulani reformer Shaykh Usman dan Fodio; in East Africa the earliest extant Swahili text dates from 1652. In southern Africa the history of the earliest written literature, Xhosa, is linked to the printing press of the Lovedale Missionary Institution set up by the Glasgow mission in the 1820s.

There was a great development in both quantity and quality of literary output after World War II, but in many cases, because they saw their own career advancement as being in English and French and perhaps because they regarded those languages as more advanced than their own, African elites tended to be indifferent to indigenous literatures. Indeed, it is only since the 1970s that the dominance of literatures in the metropolitan languages has been challenged and that writers such as Ngugi wa Thiong'o have begun to write in African languages, with translations into English, Swahili, and other languages following publication in the mother tongue. There is in the literary, political, and educational circles of some African countries a growing sense that the fostering of literature in indigenous African languages is important, especially in the drive to create new national models closer to the culture and history of the people.

The success of such a venture depends greatly on government policy. Somalia is a striking example of a country in which such a policy has been successfully applied. The role of publishers is also crucial; in spite of the severe financial constraints that operate in most African countries, some—such as Nigeria, Ghana, Tanzania, and Zimbabwe—now have indigenous publishing houses serving local readers. In some cases international publishing houses with African interests also participate in publishing African-language texts. The rate of illiteracy in Africa is still high, which limits the potential readership for texts in African as well as other languages. However, the huge popularity of stage and radio dramas in a number of countries (for instance, Nigeria, South Africa, Kenya, Somalia, and Tanzania) makes clear the great popular interest in forms of verbal art that both entertain and comment on contemporary life.

The dominant theme in much of the literature in African languages is the conflict between traditional cultures and modernization. In the novel and the short story, although the influence of modern European literary forms is clear, so too is that of the oral narrative. Sharp political comment on corruption and inefficiency is also prevalent. In general the role of public comment on national problems, and on wider topics such as African unity and racism, is a highly developed and important one, just as it is in the metropolitan languages.

West Africa. *Yoruba.* The rich oral literature of the Yoruba, who live mainly in Nigeria and Benin, consists of myths, legends, folktales, and song. It is still flourishing, particularly in the rural areas, and has exerted a considerable influence on the written literature. Yoruba orthography was standardized in 1875 by the Church Missionary Society, in Lagos. The Bible was translated in 1900 and was widely used in Yorubaland. It was followed in 1911 by a translation of John Bunyan's *The Pilgrim's Progress*, which has probably exerted more influence on African-

language writers than any other English work. The first written poetry, *Iwe Ekini Sobo* ("Sobo's First Book"), came in 1905 from the pen of the prolific and popular J. Sobowole Sowande. Sowande wrote several more collections (the last in 1934), publishing most of them himself. The first Yoruba novel did not appear until 1938, although a few novelettes appeared before then. Daniel Olorunfemi Fagunwa's allegorical novel *Ogboju Ode Ninu Igbo Irunmale* (1950; *The Forest of a Thousand Daemons*) was widely read and enjoyed. It uses the traditional Yoruba themes of virtue, courage, and perseverance and focuses on the vices of cruelty and greed. Fagunwa's first novel was *Igbo Olodumare* (1947; "The Forest of God"). Two others in a similar style followed, but his fifth and last novel, published in 1961, was considerably more realistic. Fagunwa's allegorical and fantastic adventure tales, full of folkloric elements—spirits, monsters, transformation flights, gods, magic, and witchcraft—provided a model for other writers.

A literary competition held at the time of Nigerian independence in 1960 was won by Femi Jeboda's realistic novel *Olowolaiyemo* ("Mr. People-Rally-Only-Around-the-Well-To-Do"), which deals with the hardships of urban life in Yorubaland. The trend of contemporary realism continued with Afolabi Olabimtan's novels. His first, *Kekere Ekun* (1967; "[Lad Nicknamed] Leopard Cub"), depicts the intrigues of a typically polygamous Yoruba home and the role of the church and school in a rural community. His second novel, *Ayanmo* (1973; "Predestination"), follows a village schoolmaster who studies hard to become a medical doctor. Various tempting and sophisticated women almost prevent him from achieving his ambition, but in the end he marries a girl from his hometown. Another successful writer was Akinwunmi Isola. His popular novel, *O Le Ku* (1974; "Heart-Rending Incidents Occurred"), depicts love and tragedy in a contemporary context.

Hausa. There has been a tradition of Arabic writing in Hausaland (northern Nigeria and Niger) since the end of the 15th century. The Hausa language has been written in the Arabic alphabet since the early 19th century and in the Roman alphabet since the early 20th century. Islamic influence is still strong. A key feature of Hausa literature is the interaction of the oral and written traditions, and the emphasis (as in other literatures, such as Somali) is on recitation. Comment on religious, political, and social life has always been central to Hausa poetry. Its importance as a vehicle for comment is fostered by radio, the press, and television.

A key role in the history of Hausa poetry was played in the late 18th and early 19th centuries by the Islamic warrior and reformer Shaykh Usman dan Fodio. He wrote poetry in both Arabic and Hausa, using it to exhort the Hausa to follow Islam. Early religious poetry included the mystical writings of the Islamic Sufi brotherhoods. Of political and religious importance were the praise poems to Muhammad and to secular leaders and the chronicles of the city-states, such as Sokoto and Kano. One of the best known of early 20th-century poets is Alhaji Umaru. His *Zuwan Nasara* (1903; "Arrival of the Christians") describes the chaos caused to traditional life by the British occupation. The tradition of religious poetry has continued through the custom of public recitations, often by blind beggars who learn by heart the texts of manuscript poems.

Secular poetry flourished after World War II. It remained deeply influenced by Islam, but poets tended to be drawn from a wider range of occupations, and poetry became far less the preserve of Muslim functionaries. A number of well-known poems were composed by the political leader Sa'adu Zungur; among the best known is *Wakar maraba da soja* (1957; "Song of Welcome to the Soldiers [on Their Return from Burma and India]"). Other eminent poets who followed the tradition of commenting on contemporary life are Mudi Sipikin and Hamisa Yadudu Funtuwa. The latter wrote poems on social evils such as drink. In his *Wakar uwar mugu* (1957; "Song of the Mother of Evil") he wrote on the attraction of prostitution as an emancipated alternative for women facing the tedium and constriction of polygamous marriage. International political relations have also been the subject of poetry, as in

Garba Gwandu's "Julius Nyerere" (1971). Akilu Aliyu, like many of his fellow poets, wrote and recited poetry on the Nigerian civil war and on contemporary politics.

Novel writing in Hausa is more recent than the tradition of written poetry. The first clutch of novels was published as the result of a competition held in 1933. Dominant interests were heroic figures of the past and aspects of traditional life. As in Fagunwa's fiction, much use was made of fantastic figures and allegorical elements from oral narrative. Interest in social comment has been less marked in fiction than in poetry, but it is still present. A theme that occurs often is that of childlessness in marriage and its disastrous effects on those involved. Trenchant comment on political corruption is featured in Sulaiman Ibrahim Katsina's *Turmin Danya* (1983; "Hog-Plum Mortar"). Science fiction is particularly popular with youth; an example is *Tauraruwa maiwutsiya* (1969; "The Comet"), by Umaru Dembo.

Travel writing and biography have also featured in Hausa prose. An interesting comment on the individualism of European society viewed through African eyes is provided by the playwright and biographer Aminu Kano, whose *Motsi ya fizama* (1955; "Moving Is Better than Sitting") is an account of his visit to Europe in 1946.

East Africa. *Ethiopian languages.* The oldest literary language in Ethiopia, Ge'ez, which is related to classical Arabic, was first used for the writing of Christian texts in the 4th century AD. It was the literary language of Ethiopia until the 19th century and was used for recording the lives of saints (hagiography) and for writing royal chronicles. A great deal of religious poetry was also written in Ge'ez.

Amharic

In Amharic, the official language of Ethiopia, one of the founders of modern literature was Blattengeta Hiruy Walda Silläse. His two novels, addressed to a new generation educated in European-style schools, criticized outmoded social customs and dubious religious practices. Thus, he focused on child marriage and on the venality of some of the lower clergy. Hiruy argued for the adoption of Western technology and for a return to uncorrupted Christian ethics. Equally important as a founder of modern writing was Afawarq Gabra Iyasus, author of the first Ethiopian novel, *Libb Wallad Tārik* (1908; "Imaginative Story").

The critical thrust of the new Ethiopian literary trend was disrupted by the Italian conquest of 1936. However, a novel in the same critical vein, *Ar'āyā*, was published in 1948–49 by Girmācchaw Takla Hāwāryāt. The Western-educated hero of this work is thwarted by intrigues in court and government circles when he returns home and tries to put his newly learned Western skills at the service of his people. Historical fiction, based mainly on the complex and commanding figure of the 19th-century emperor Tewodros II, is also well represented, particularly in *And Lammātu* (1967; "His Mother's Only Child"), by Abbe Gubaññā, and *Ya-Tewodros Inbā* (1966; "The Tears of Theodore"), by Birhānu Zarihun. Didactic and socially committed writing is common: some touches on social issues such as prostitution, as in the short story "Abbonas," by Tāddasa Libān, in his collection *Lelāw Mangad* (1959; "Another Way"). A novel that sympathetically examines the dilemma of a woman faced with the challenge of survival is *Setiññā Adāri* (1963; "Fallen Woman"), by Innānu Ḍgonāfir (pseudonym of Nagāsh Gabra Māryām). Hād-dis Ḍlamāyayahu's novel *Wanjalaññāw Dāññā* (1974; "The Crooked Judge") depicts corruption in the government of Emperor Haile Selassie I, while *Fiqir Iska Maqābir* (1958; "Love unto the Grave") is a love story of two people from different social backgrounds.

The conflict between old and new and the antagonisms in Ethiopian society are explored by writers such as playwright Mangistu Lammā (see below *African theatre*). Acculturation and alienation are explored in Tāddasa Libān's short story "Yatabaṭṭasa Fire" ("The Seed of the Sundering") in his collection *Maskaram* (1956). Writing since the proclamation of socialist Ethiopia is best represented by Birhanu Zarihun's trilogy, *Mā'ibal* (1979–82; "Storm"), which describes the revolution and its effects. Political problems such as apartheid, Pan-Africanism, and the conflict between Somalia and Ethiopia have also been featured.

Somali. Besides the centuries-old practice of composing religious verse in Arabic, Somalia has a very old and rich tradition of oral literature in Somali, which still flourishes and influences the modern written forms. Written Somali literature really did not begin until after World War II—and even then did not flourish until after 1973, when the government introduced a standard orthography based on the Roman alphabet. Two periodicals, *Sahan* ("Reconnaissance") and *Horseed* ("Vanguard"), fostered Somali writing in the 1960s. The first poet to commit his poems to writing was Cali Xuseen Xirsi. Two of his poems appeared in *Sahan* and *Horseed*, although most reached the public in oral form. Cali wrote often on public themes; one of his poems, for instance, commented on the political plight of Somalis in the late 1950s, and another, composed in 1962, protested the importation of foreign automobiles when the mass of the people were still living in poverty. The emphasis on oral performance and transmission has continued in the era of print and amid a strong campaign for adult literacy under the socialist government established by the military in 1969. Poems may now be written down, but they are subsequently recited on the radio or at public or private recitals, or they are circulated on audiocassettes. Cabdulqaadir Xirsi "Yamyam" became one of the leading poets of socialist Somalia. The themes of his and of his contemporaries' poems tend to be public, stressing, for example, dedication to the country and its new order and support for the feminist stance of the government.

In prose, the fiction of Faarax M.I. Cawl, which incorporates oral historical narratives and poems, marks a transition from oral to written form. His novel *Aqoondarro waa u nacab jacayl* (1974) is highly didactic, exhorting the virtue of literacy. It is about an illiterate Dervish warrior who is unable to read a vital love letter from a young girl, and so the love affair ends tragically—hence the title of the novel, translated as *Ignorance Is the Enemy of Love*.

Swahili. Written poetry in Swahili—which drew inspiration from the Islāmic literatures in Arabic, Persian, and Urdu taken to the east coast of Africa by Oriental traders and scribes—goes back at least to the mid-17th century. Until the mid-19th century, Arabic script was used, but thereafter Latin script became more common and is now standard. The oldest extant epic is the *Hamziya* (1749), a court poem written by Sayyid Aidarusi, who was assigned the task by Bwana Mkuw II, ruler of the island of Pate off the coast in what is now Kenya. It was written in Arabic script in the old Kingozi dialect of Swahili.

Possibly because of the didactic thrust of Islāmic poetry, Swahili poetry has a strong tradition of public and religious commentary. The first well-known poet writing in this didactic vein was Mwana Kupona binti Msham, from Lamu Island, Kenya. His *Utendi wa Mwana Kupona* ("Poem of Mwana Kupona") dates from 1858. Another poet of the 19th century is Muyaka bin Haji al-Ghassany, from Mombasa, Kenya. Using a variety of styles—including lyrical, satiric, and panegyric—his poems presented a social and political commentary on urban life.

The acknowledged father of contemporary Swahili literature is Shaaban Robert, a Tanganyikan, best known as a poet (e.g., for *Almazi za Afrika* [1960; "African Diamonds"]) but also as a novelist and essayist. Robert's later style moved away from fantasy to the realistic portrayal of contemporary problems in novels such as *Siku ya Watenzi Wote* (1968; "The Day of Reckoning") and *Utubora Mkulima* (1968; "Utubora the Farmer"). The next generation of poets, among whom the best known are the Kenyans Ahmad Nassir and Abdillatif Abdalla, continued to focus on public themes.

Social change and the confusion caused by the clash of tradition with modernity feature strongly in the contemporary novel. The Tanzanian Euphrase Kezilahabi's third novel, *Dunia Uwanja wa Fujo* (1975; "The World Is a Chaotic Place"), exemplifies this preoccupation. The general mood of contemporary novels is pessimistic. Heroes are often unsympathetic characters whose decline and fall reflect the difficulties of maintaining a moral stance in modern urban society.

Like other African-language literatures, Swahili suffers from a publishing and book famine. Poems on a wide

Recital
of written
literature

Didactic
origin of
Swahili
poetry

range of topical subjects appear regularly in the local Swahili-language newspapers, but the publication of novels is hindered by the lack of strong indigenous publishing houses, despite a large potential readership.

Southern Africa. *Shona.* Writing in Shona, the major African language group of Zimbabwe, is fairly recent, little of note appearing before the 1950s. In the novel a dominant trend has been the imaginative exploration of a heroic past. An example is Solomon Mutswairo's popular novel *Feso* (1956; English translation 1974). Patrick Chakaipa's *Pfumo reropa* (1961; *The Spear of Blood*) also explores the workings of Shona society before the appearance of whites, while his *Rudo ibofu* (1962; "Love Is Blind") and *Garan dichanya* (1963; "I Shall Return") treat the conflict between values of the two cultures. Other writers have focused on the harmful effects of urban life and the alienation that Western education may cause. John Marangwanda's *Kumazi vandadzoke* (1959; "Who Goes to a Place Perhaps Never Comes Back") and Mutswairo's novel *Murambiwa Goredema* (1959; "Murambiwa, Son of Goredema") focus on this urban theme.

Zulu. Early Zulu writing at the beginning of the 20th century comprised mostly historical and religious works. Magma Fuze's reconstruction of the Zulu past, *Abantu abamnyama lapha bavela ngakhona* ("The Black People and Whence They Came") was published in 1922. The Zulu-language newspaper, *Ilanga lase Natal* ("The Natal Sun"), founded in Durban, S.Af., in 1903 by John L. Dube, helped shape the Zulu readership. One of the paper's later editors, R.R.R. Dhlomo, wrote a series of novels on the Zulu kings of the 19th and early 20th centuries: *UShaka* (1936), *UDingane* (1936), *UMpande* (1938), *UCetshwayo* (1952), and *UDinuzulu* (1968). Dube wrote *Insila kaShaka* (1933; *Jeje, the Bodyservant of King Shaka*), a historical novel on the powerful theme of Zulu royalty, and *UShembe* (1936), a biography of the charismatic Zulu prophet Isaiah Shembe. Fascination with the heroic Zulu past continued in works by later writers—for example, Leonard Mncwango's *Ngenzeni?* (1959; "What Have I Done?"), Muntu Xulu's *Simpofu* (1969; "We Are Poor") focuses on the struggle between the Zulu king Cetshwayo and the white Natal politician Theophilus Shepstone.

The question of how to accept westernization without abandoning tradition has always been a dominant theme in Zulu fiction. Dhlomo's novel *Indlela yababi* (1946; "The Way of the Wicked") shows the disastrous effects of urban life on people from the village. J.K. Ngubane's *Uvalo lwezinhlonzi* (1957; "The Fear of Authority") touches on the same theme, and C.L.S. Nyembezi's masterly *Inkin-sela yaseMgungundlovu* (1961; "The Wealthy Man from Pietermaritzburg") portrays the wiles of a city man set against the upright morality of country people. Nyembezi's earlier *Mntanami! Mntanami!* (1950; "My Child! My Child!") depicts a boy caught in the crime of the city who finally returns to his mourning family. A variety of themes covering the Zulu past, the clash between tradition and modernity, and the benefits and dangers of education feature in the short story collections *Uthingo lwenkosazana* (1971; "The Rainbow"), by D.B.Z. Ntuli, and *Amawisa* (1982; "Fighting Sticks"), by D.B.Z. and C.S.Z. Ntuli.

The finest Zulu poet to date is B.W. Vilakazi, who wrote passionately about nature, the Zulu past, and the injustice and degradation of apartheid in South Africa (see, for example, his famous poem "Ezinkomponi" ["In the Mines"]). Vilakazi's two volumes of poetry, *Inkondlo kaZulu* (1935) and *Amal'ezulu* (1945), are translated together as *Zulu Horizons*. In some instances the traditional praise poem has been effectively used to express contemporary experience, as in J.C. Dlamini's collection *Inzululwane* (1959; "Giddiness") and Phumasilwe Myeni's *Hayani maZulu* (1969; "Sing Zulus!"). A poet who uses traditional and modern styles, covering both public and private themes, is N.J. Makhaye in his collection *Isoka lakwaZulu* (1972; "The Popular Young Man of Zululand").

Xhosa. As in Zulu literature, the themes of the heroic past and of the opposition between beneficent tradition and harsh modernity are much in evidence. The question of how best to come to terms with change is also central in Xhosa literature. Much important early writing,

expressing Xhosa aspirations and views on Christianity and tradition, appeared in the Xhosa-language newspapers and journals of the mid- and late 19th century: *Ikhwezi* ("The Morning Star"), *Isigidimi samaXhosa* ("The Xhosa Messenger"), *Imvo zabantsundu* ("Opinions of the Black People") and *Izwi labantu* ("Voice of the People"). Xhosa writers were also concerned with contemporary political themes, particularly the struggle against the loss of their land and power and their economic subjugation by the white South Africans.

The earliest exponents of written poetry were Samuel E.K. Mqhayi and J.J.R. Jolobe. While Mqhayi modeled his verse on traditional praise poetry, Jolobe experimented with such European-inspired forms as rhyme and descriptions of nature, thereby laying the foundations of modern Xhosa poetry. Mqhayi's important novel, *Ityala lamawele* (1914; "The Lawsuit of the Twins") demonstrated how native justice had operated quite successfully before whites arrived. It was, however, A.C. Jordan's *Ingqumbo Yeminyanya* (1940; *The Wrath of the Ancestors*) that set the principal theme of later Xhosa prose: how to retain the strengths of tradition in the face of inevitable change. Some writers, such as Z.S. Qangule and K.S. Bongela, set the rural-versus-urban conflict in stark polarities. Qangule's *Izagwebwa* (1972; "Weapons") depicts the conflict between uncompromising traditionalists and westernized, urbanized individuals. Bongela's *Alishoni lingenandaba* (1971; "The Sun Does Not Set Without News") deals with the squalor and corruption of life in the black townships surrounding the affluent white cities of South Africa. Some works look critically at tradition—particularly at the custom of the bride-price; others, such as Godfrey Mzamane's *Izinto zodidi* (1959; "Things of Value") suggest that synthesis can be achieved. In Mzamane's novel a strong and clever son succeeds in the new urban world, whereas his less well-prepared father has been corrupted by it and forced to return home. (E.A.W.G.)

The theme of changing traditions

AFRICAN THEATRE

The content and style of urban African theatre are influenced by both African dramatic traditions and Western theatre. The influence of Western styles is the result of a colonial presence, education in European languages, and the training of artists abroad. The degree and manner of foreign influence differ greatly from country to country, however. Such influence has hindered the development of African theatre in Zimbabwe, for example, where a minority continues to produce predominantly commercial Western theatre. The accent on Negritude in the theatre of French-speaking West Africa in the 1960s, on the other hand, was a reaction to the control of French directors, who clearly left their mark on production styles, e.g., in the Daniel Surano Theatre in Senegal, where the works of Aimé Césaire and other leading playwrights are staged. The plays of Bernard Dadié of Côte d'Ivoire reflect French comic traditions, and Jean Pliya of Benin is one of a number of playwrights obsessed by colonial history. The texts of Western-educated writers have built a literary style of theatre, appealing to an elite audience, in which dance and music play, if anything, a subsidiary role.

On the other hand, at a popular level, village theatre throughout Africa is based on the traditions of music, song, dance, and spectacle and has offered a rich platform for the development of contemporary urban theatre. Theatre innovators built onto village traditions of storytelling, some borrowing production styles from the colonial music-hall entertainment staged in West African cities in the 1920s and '30s. Concert parties toured Togo and Ghana, and in the 1950s the Ghanaian "Trios" emerged, with Bob Cole and his company delighting audiences in Accra with comic dramatizations of local events.

West Africa. The first professional theatres in Nigeria were companies created by actor-managers. The three most successful—Hubert Ogunde, Kola Ogunmola, and Duro Ladipo—were all Yoruba, and all started work as teachers involved in dramatizing Bible stories in African Christian churches. Ogunde's first production was *The Garden of Eden* (1944), staged in the Church of the Lord in Lagos. It was followed in 1945 by a secular satire, *Strike and*

Western influence

Historical fiction

Hunger, inspired by a clash between Nigerian workers and their colonial bosses. Ogunde's success led him to form the Ogunde Concert Party, which, in a style borrowed from the current British concert parties, staged domestic comedies and astute political satires between opening and closing "glees" of song and dance unrelated to the plot.

The euphoria of Nigerian independence in 1960 brought with it an explosion of creativity in the urban arts oriented toward new African forms and a rejection of colonial influences. This resulted in a creative confidence in literary and popular theatre that was to be influential throughout Africa. Traveling theatres, loosely known as Yoruba Opera companies, took to the road. Duro Ladipo created spectacular productions dramatizing themes from Yoruba mythology and history. His trilogy on the history of the Kingdom of Oyo, published in 1964 as *Three Yoruba Plays* (*Oba Koso* ["The King Did Not Hang"], *Oba Moro* ["The King of Ghosts"], and *Oba Waja* ["The King Is Dead"]), has the power and serenity of ancient Greek tragedy.

Kola Ogunmola specialized in domestic comedies featuring himself as a brilliant actor and mime. He refined Ogunde's techniques, replacing saxophones with Yoruba drums and writing tightly constructed yet gentle social satires. His most typical play is *Ife Owo* (c. 1950; *Love of Money*), but his greatest success was with *Omuti Apa Kini* (1963), an adaptation of Amos Tutuola's *The Palm-Wine Drinkard*. Though Ogunmola and Ladipo died in the early 1970s, their influence continued through the next decade as decorated trucks carried Yoruba Opera companies to one-night stands in towns and villages. The Yoruba music-drama *Obaluyaye* (1970), by the composer Akin Euba, added a theatrical sophistication to their idiom, and they had a profound influence on the work of literary playwrights, particularly Wole Soyinka and Ola Rotimi. Soyinka and Rotimi spent years as university playwright-directors, and their skills at staging their own works gave them a theatrical viability lacking in the more poetic work of John Pepper Clark.

Wole Soyinka, a brilliant critic and satirist who in 1986 was the first African to win the Nobel Prize for Literature, is regarded as Africa's leading writer. His work reflects the complexities facing an African playwright writing in English, moving from naturalistic treatment of his subjects to a profoundly Yoruba view of universal themes. His early comic satires *The Lion and the Jewel* (first performed at Ibadan in 1959; published 1963) and *The Trials of Brother Jero* (1960) are popular with all levels of English-speaking audiences, but the verbal and philosophical complexities of his later works are for an intellectual elite. *The Strong Breed* (1963) and *Death and the King's Horseman* (1975) are powerful statements of cultural conflict, while Soyinka's political satires, such as *Kongi's Harvest* (1965), are both savage and entertaining. *The Road* (1965) and *A Dance of the Forests* (1963) delve into the dramatic contrasts of life in Africa through the complexities of Yoruba mythology. In the latter, written for and performed to celebrate Nigerian independence in October 1960, Soyinka criticized the myth of the glorious African past, rejecting the Negritude concept that the revival of African culture must be inspired by African cultural heritage alone. His drama became increasingly pessimistic—as well as more obscure—after the Nigerian civil war, notably in *Madmen and Specialists* (1970). He also turned to past events—for example, in *Death and the King's Horseman*—and to new versions of old plays. His version of the *Bacchae* of Euripides was staged by the National Theatre in London in 1973, and *Opera Wonyosi*, a version of John Gay's *The Beggar's Opera*, appeared at the University of Ife in 1977.

Ola Rotimi evolved a theatrical English enriched by African proverbs and idioms. His style of directing made brilliant use of dramatic movement and drew an enthusiastic response from both university and popular audiences. Rotimi excelled at historical tragedies: *Kurunmi* (1969) deals with the Yoruba wars and *Ovonramwen Nogbaisi* (1971) with the sack of Benin. He also had a flair for satirical comedy, as shown in *Our Husband Is Gone Mad Again* (1966). As directors, both Soyinka and Rotimi made creative use of music and dance.

In Ghana, intercultural exchange had mixed results. In

the 1960s Saka Acquaye's *The Lost Fisherman*, a musical based on "highlife" (see below *Dance*), was a popular success, as was Efua Sutherland's traveling theatre, for which she created productions based on village storytelling and local themes. Her plays in English use Greek models, as do those of Joe de Graaft. Ama Ata Aidoo was the most successful Ghanaian playwright after the 1960s. Her *The Dilemma of a Ghost* (1964) explores the complex cultural conflict arising in a Ghanaian village when a young man returns from his studies abroad with an Afro-American wife. *Anowa* (1970) deals with African involvement in the slave trade and the subservience of women.

Hausa drama generally has a popular appeal and owes much to the dramatic style of traditional storytelling; it has focused on social problems, particularly those involving the Hausa family, with its tradition of polygamy. This practice has been criticized in many plays—for example, *Tabarmar Kunya* (1969; "Matter of Shame") by Adamu dan Gogo and Dauda Kano. Some plays satirize the dependence of uneducated people on Muslim scholars, and some—for example, Umaru Balarme Ahmed's *Buleke* (1970)—depict characters who lead a hectic modern life but are nevertheless still rooted in tradition. Plays are performed often in schools and are featured frequently on radio and television.

East Africa. An important Ethiopian playwright is Kabbada Mikael, whose historical play *Hannibal* was performed at the Festival of Arts in Dakar, Senegal, in 1966. The best-known work of Mangistu Lammā is *Yalaccha Gabbiccha* ("Marriage of Unequals"), which deals with social inequality; it was staged for the first time in Addis Ababa in 1964. A play depicting a family in transition from old rural ways to the bleak uncertainty of city life is the Pinteresque *Yakarmo-saw* (1958; "The Origin of Man-made Taboo"), by Saggāye Gabra Madhin.

Somali theatre has been firmly established since the 1950s and is very popular; many scripts still remain to be published, however. *Shabeelnagood* (*Leopard Among the Women*), by Xasan Sheikh Mumin, a play depicting a heartless, wily trickster who marries naive young women, was published in Somali with an English translation in 1974; it was first performed in Mogadishu in 1968 and also had a long provincial tour and radio serialization. Somali theatre has been compared to that of the Elizabethan era in England in its combination of popular entertainment with high art and its ability to excite the interest of a broad cross section of society.

Swahili drama is particularly popular with school and college students, especially when it explores the conflicting pressures of traditional and modern values. Penina O. Mlama's popular play *Pambo* (1975; "Decoration"), depicting this conflict, ends with the central character's reluctant rejection of self-seeking careerism in the interest of his family and community.

Southern Africa. Zulu drama is most successful in serialized radio plays, which are immensely popular and have huge audiences. One of the best-known examples, which has been published, is D.B.Z. Ntuli's *Indandathoyesithembiso* (1971; "The Engagement Ring").

Protest theatre in South Africa emerged under inventive and dedicated directors—Athol Fugard working through improvisation with John Kani and Winston Ntshona; Barney Simons, the artist behind the Market Theatre for Black Artists in Johannesburg; and Maishe Maponya and his versatile Soweto company. The works of these directors have no sophisticated sets and may be staged in any venue. They speak of the tragedy of South Africa, with twists of humour touching on the most dire of situations—a quality found throughout Africa in village and urban drama. A stark contrast is provided by the officially sponsored vapid extravaganza of the musical *Ipi-Tombi*. An unofficial musical was *Poppie Nongena*, starring Thuli Dumakude in successful seasons in London and New York City in 1984.

In Zimbabwe the most effective theatre was in the hands of small semiprofessional companies such as The People's Theatre, directed by Ben Sibenke in Harare. In Zambia Stephen Chifunyise toured villages with his company, setting up a dramatic dialogue with his audiences.

Music

The term African music refers to the musical practices of all indigenous peoples of Africa, including the Berber in the Sahara and the San (Bushmen) and Khoikhoi (Hottentot) in southern Africa. Not included is the music of European settler communities or that of Arab North Africa.

HISTORY

It is widely acknowledged that African music has undergone frequent and decisive changes throughout the centuries. What is termed traditional music today is probably very different from African music in former times. Nor has African music in the past been rigidly linked to specific ethnic groups. The individual musician, his style and creativity, have always played an important role.

The material sources for the study of African music history include archaeological and other objects; pictorial sources (rock paintings, petroglyphs, book illustrations, drawings, paintings); oral historical sources; written sources (travelers' accounts, field notes, inscriptions in Arabic and in African and European languages); musical notations; sound recordings; photographs and motion pictures; and videotape.

Neolithic
origins

In ancient times the musical cultures of sub-Saharan Africa extended into North Africa. Between c. 8000 and 3000 BC, climatic changes in the Sahara, with a marked wet trend, extended the flora and fauna of the savanna into the southern Sahara and its central highlands. During this period human occupation of the Sahara greatly increased, and along rivers and small lakes Neolithic, or New Stone Age, cultures with a so-called aquatic life-style extended from the western Sahara into the Nile Valley region. The aquatic cultures began to break up gradually between 5000 and 3000 BC, once the peak of the wet period had passed. The wet climate became more and more restricted to shrunken lakes and rivers and, to a greater extent, to the region of the Upper Nile. Today remnants survive perhaps in the Lake Chad area and in the Nile swamps.

The cultures of the "Green Sahara" left behind a vast gallery of iconographic documents in the form of rock paintings, among which are some of the earliest internal sources on African music. One is a vivid dance scene discovered in 1956 by the French ethnologist Henri Lhote in the Tassili-n-Ajjer plateau of Algeria. Attributed on stylistic grounds to the Saharan period of the Neolithic hunters (c. 6000–4000 BC), this painting is probably one of the oldest extant testimonies to music and dance in Africa (see Figure 2). The body adornment and movement

style are reminiscent of dance styles still found in many African societies.

Some of the earliest sources on African music are archaeological. Although musical instruments made of vegetable materials have not survived in the deposits of sub-Saharan climatic zones, archaeological source material on Nigerian music has been supplied by the representations of musical instruments on stone or terra-cotta from Ife, Yorubaland. These representations show considerable agreement with traditional accounts of their origins. From the 10th to the 14th century AD, *Igbín* drums (a set of footed cylindrical drums) seem to have been used. The *dùndún* pressure drum, now associated with Yoruba culture and known in a broad belt across the savanna region, may have been introduced around the 15th century, since it appears in plaques made during that period in the Kingdom of Benin. The Yoruba *dùndún* drums are now used as "talking drums" in accompaniment to *oriki* (praise name) poetry (see above *Literature and theatre: Oral traditions*). The double iron clapperless bell seems to have preceded the talking drum. Pellet bells and tubular bells with clappers were known by the 15th century.

Other archaeological finds relating to music include iron bells excavated in the Shaba region of Zaire and at several sites in Zimbabwe. Benin bronze plaques represent a further, almost inexhaustible source for music history, since musical instruments—such as horns, bells, drums, and even bow lutes—are often depicted on them in ceremonial contexts.

Among the most important written sources (though superficial analytically) are accounts from the 14th-century Arab travelers Ibn Baṭṭūṭah and Ibn Khaldūn and from the European navigators and explorers Vasco da Gama, Jan Huyghen van Linschoten, João dos Santos, François Froger, and Peter Kolbe. Early attempts at notating African music were made by T.E. Bowdich (1819) for Ghana, Karl Mauch (1872) for Zimbabwe, and Brito Capelo and Roberto Ivens (1882) for inner Angola.

Major and minor migrations of African peoples brought musical styles and instruments to new areas. The single and double iron bells, which probably originated in Kwa-speaking West Africa, spread to western Central Africa with Iron Age Bantu-speaking peoples, and from there to Zimbabwe and the Zambezi River valley. Earlier migrating groups moving eastward from eastern Nigeria and central Cameroon to the East African lakes did not know the iron bells or the time-line patterns associated with them. Consequently, both traits were absent in East African music until the recent introduction of the time-line patterns of Congolese and Zairian electric guitar-based music. With

Jean-Dominique Lajoux

the intensifying ivory and slave trades during the 19th century, the *zeze* (or *sese*) flatbar zither, a stringed instrument long known along the East African coast, spread into the interior to Zambia, the eastern half of Zaire, and Malaŵi.

Beginning in the 17th and 18th centuries, lamellaphones with iron keys, a prominent feature of ancient Zimbabwe and neighbouring kingdoms and chieftainships, spread from the Zambezi Valley northward to the kingdoms of Kazembe and Lunda and to the Katangan and Angolan cultures. In the course of migration, some models became smaller, because they were used as travel instruments; others were modified and gave rise to the numerous types present in western Central Africa during the first half of the 20th century. (For a description of the lamellaphone, see below *Musical instruments: Idiophones*.)

A small box-resonated lamellaphone, called the *likembe* in Zaire, traveled in the other direction, from the west to the east, northeast, and southeast. It was invented in the Lower Congo region probably not earlier than the mid-19th century, and thereafter it spread upriver with Lingala-speaking porters and colonial servants to the northern Bantu borderland. The Azande, Ngbandi, and Baya, who speak Adamawa-Eastern languages, adopted the *likembe*.

Stylistic traits of *likembe* music linking it to its region of origin were only gradually modified in the new areas to suit local styles. At the beginning of the 20th century the *likembe* distribution area extended farther to the northeast into Uganda, where the Nilotic Alur, Acholi, and Lango adopted it. It was later introduced to southern Uganda by northern Ugandan workers; there the Bantu-speaking Soga and Gwere adopted it and began to construct models entirely from metal, even with a metal resonator. The *likembe* also spread southward from the Lower Congo, penetrating Angola from the Kasai region of Zaire and being adopted as recently as the 1950s by the Khoisan-speaking /Kung of Kwando Kubango Province in south-eastern Angola.

As a result of migrations and the exchange of musical fashions both within Africa and with foreign cultures, specific traits of African music often show a puzzling distribution. Extremely distant areas in Africa may have similar, even identical, traits, while adjacent areas may have quite different styles. The multipart singing style in triads within an equiheptatonic tone system of the Baule of Côte d'Ivoire (Ivory Coast) is so close, if not identical, to the part singing style of Ngangela-, Chokwe-, and Luvala-speaking peoples in eastern Angola that the similarity is immediately recognized by informants from both cultures. Why this is so is a riddle. The two areas are separated by several countries with different approaches to multipart singing. Another historical riddle is the presence of practically identical xylophone playing styles and instruments among Makonde- and Makua-speaking peoples of northern Mozambique and among certain peoples of Côte d'Ivoire and Liberia, notably the Baule and the Kru. The *jomolo* of the Baule and the log xylophones of northern Mozambique—for example, the *dimbila* of the Makonde or the *mangwilo* of the Shirima—are virtually identical instruments.

Diffusionist theories of various kinds have been offered to resolve such riddles. The English ethnomusicologist A.M. Jones proposed that Indonesian settlers in certain areas of East, Central, and West Africa during the early centuries AD could have introduced xylophones and certain tonal-harmonic systems (equipentatonic, equiheptatonic, and *pelog* scales) into Africa. Ethnohistorians, on the other hand, have tended to accentuate the importance of coastal navigation (implying the traveling of hired or forced African labour on European ships) as an agent of cultural contact between such areas as Mozambique, Angola and Zaire, and the West African coast.

Existing historical sources on African music and dance are more abundant than might be expected. Sometimes historical data can be obtained indirectly from contemporary observation outside Africa, especially in Latin America. It was a rule rather than an exception that people brought as slaves from Africa to the New World often came from the hinterland of the African coastal areas. Between the European slave traders established on the

coast and the hinterland areas were buffer zones inhabited by African "merchant tribes," such as the Ovimbundu of Angola, who are still remembered by eastern Angolan peoples as *vimbali*, or collaborators of the Portuguese. In the 18th and 19th centuries the inland areas of Angola were not directly accessible to Europeans. But the music and dance of these areas became accessible indirectly, as European observers saw African captives playing musical instruments in New World countries. In Brazil the music of the Candomblé religious cult, for example, can be directly linked to 18th- and 19th-century forms of *orisha* worship among the Yoruba. In a similar manner, Umbanda religious ceremonies are an extension of traditional healing sessions still practiced in Angola, and Vodun religious music among the Fon of Benin has extensions in the Voodoo of Haiti and elsewhere in the Caribbean. African instruments have also been modified and sometimes further developed in the New World; examples are the Central African friction drum and the lamellaphone (in the Cuban *marimbula*).

African music as it is known today was also shaped by changes in the ecology of the continent, which drove people into other lands, thus producing changes in their art. With the drying of the Sahara, for example, populations tended to shift southward. When settled populations accepted the intruders, they often adopted musical styles from them. Thus, the choral singing style of the Masai had a fundamental influence on vocal music of the Gogo of central Tanzania, as is audible in their *nindo* and *msun-yunho* chants.

It is only relatively recently that scholarly attention has focused on the various urban popular styles, reflecting a blend of local and foreign ingredients, that have emerged during the last 50 years or so. The best known of these are West African "highlife," Congolese (or Zairian) dance music, *tarabu* of East Africa, and South African styles. With the widespread adoption of Christianity in Africa since the 19th century, many new varieties of African church music have risen and continue to evolve. For example, with altered words, hymns—as well as secular songs—are quite often adapted as protest songs in order to rally opposition to political oppression. (G.K./D.K.R.)

MUSICAL INSTRUMENTS

Outsiders have often overlooked the enormous variety of musical instruments in Africa in the mistaken belief that Africans play only drums. Yet even Hanno the Carthaginian, who recorded a brief visit to the west coast of Africa in the 5th century BC during a naval expedition, noted wind instruments as well as percussion. Of an island within the gulf of "Hesperon Keras" he wrote:

By day we saw nothing but woods, but by night we saw many fires burning, and heard the sound of flutes and cymbals, and the beating of drums, and an immense shouting. Fear therefore seized on us, and the soothsayers bid us quit the island.

Ensembles fitting this description may be found over a wide area of West Africa today, serving as accompaniment to dancing and merrymaking or as an essential ingredient of ceremonial or cultic activities.

Besides the percussion and wind instruments noted by Hanno, there are also stringed instruments of many kinds, ranging from the simple mouth bow to more complex varieties of zithers, harps, lutes, and lyres. While the aggregate of instrumental resources distributed over the continent is vast, each society tends to specialize in a limited assortment, and there is a wide variety from region to region. In some areas interesting new hybrid varieties emerged in the 20th century in response to outside influence, notably the *endingidi* spike fiddle of Uganda, *malipenga* gourd kazoos of Tanzania and Malaŵi, and chordophones such as the *ramkie* and *segankuru* of South Africa.

Musical instruments in African societies serve a variety of roles. Some instruments may be confined to religious or cultic rituals or to social occasions. Among some peoples there may also be restrictions as to the age, sex, or social status of the player. Among the Xhosa, for example, only girls play the imported Jew's harp, a modern replacement for the traditional mouth bow, which was formerly their prerogative.

Non-musical function of instruments

Besides recreational applications, or as accompaniment for dancing, instruments may serve many other roles. In Lesotho it is claimed that cattle graze more contentedly when entertained by the sound of the *lesiba* mouth bow. Among the Shona in Zimbabwe, a local form of lamellaphone known as *likembe dza vadzimu* serves in rituals of ancestor worship, while in the kingdom of Buganda the royal drums formerly held higher status than the king. In West and Central Africa, pressure drums may serve for the transmission of messages or, together with trumpets, for the declamation of praises, by mimicking the tonal and rhythmic patterns of speech. All sub-Saharan languages (except Swahili) are "tone languages," in the sense that the meaning of words depends on the tone or pitch in which they are said. Consequently, instrumental music—or even natural sounds such as birdsong—often imitates or suggests meaningful phrases of the spoken language. Sometimes this is intentional and sometimes it is merely fortuitous, but in either case it escapes the notice of uninformed outsiders.

Certain instruments are used solely for song accompaniment. Here the interplay between voice and instrument is often intricate and delicately balanced. Zulu solo songs, in earlier times, were often self-accompanied on the *ugubhu* gourd bow. In such bow songs, while the instrumental melody was influenced by the tone requirements of the song's lyrics, the tuning of the bow determined the vocal scale to which the singer conformed. Today, when Zulus use the modern Western guitar, precisely the same antiphonal relationship and mutual interdependence between voice and instrument is maintained.

Of the principal instruments found in sub-Saharan Africa, the following is a brief sampling.

Idiophones. In this class the substance of the instrument itself, owing to its solidity and elasticity, yields sound without requiring strings or stretched membranes. Some are sounded by striking, others by shaking, scraping, plucking, or friction. Idiophones are numerous and widely distributed throughout the continent. On musical grounds they may be divided into instruments used mainly for rhythm and several varieties tuned and used melodically.

Rhythmic idiophones. Among the vast array of non-melodic, rhythmic idiophones, the most common and widespread are probably rattles, sounded by shaking. One type, the *sistrum*, which has small metal disks loosely suspended on rods, is important in the Ethiopian church and is also used in Guinea. More widespread are hollow rattles, consisting of a gourd enveloped in a net of shells or beads or of a container such as a calabash with seeds or pebbles inside. Besides hand-held varieties, there are many other kinds of rattles, often strung on cords, which may be attached to the limbs or other parts of the body and shaken while dancing or playing another instrument, or which may be fastened onto another instrument, such as the lamellaphone, to serve as a supplementary jingling device. In Zimbabwe, bottle tops, instead of the traditional snail shells, serve this purpose on the *likembe dza vadzimu* of the Shona.

Struck and concussion-sounded idiophones are found everywhere. These include stone clappers and multiple rock gongs (in Nigeria); wooden clappers and percussion beams; and implements such as hoe blades, weapons, and shields (in fact, all kinds of domestic items serve as temporary idiophones when required). Further examples are metal or wooden bells, either with internal pellets or clappers or externally struck; inverted half calabashes; bottles; and clay pots, partially water-filled, which in West Africa are struck with fanlike beaters. Stamping sticks are also used in West and Central Africa, as are stamping tubes made from bamboo or from long, open-ended gourds. In Ghana and Nigeria the latter are used for accompanying certain women's songs. Scraped and friction idiophones are quite widely distributed, the most common form being a notched stick or piece of bamboo that is scraped by another stick.

Slit drums. Falling between rhythmic and melodic instruments, the largest and most distinctive member of the African struck-idiophone family is the slit drum, made from a hollowed log. By careful thinning of the flanks

at certain places, the instrument may be tuned so as to yield as many as four distinct pitches. Besides their use for transmitting messages, West and Central African slit drums are often played in combination with membrane drums and other instruments.

Xylophones. Two markedly different species of xylophone are distinguishable in Africa: one has free, unattached keys, and the other has fixed keys. With free-key xylophones, found in parts of West and East Africa, loose slabs may be laid across the player's outstretched legs or supported on logs or straw bundles, sometimes above a resonating pit. In Uganda and Zaire, from two to six players may perform together on the same instrument.

Fixed-key xylophones are more elaborate. Mounted below each key, there is usually an individually tuned calabash resonator, often with a mirliton (a vibrating membrane) attached to add a buzzing quality to the sound. A mid-14th-century account mentions a calabash-resonated xylophone in the West African kingdom of Mali, and similar instruments were reported on the east coast in the 16th century. Xylophone ensembles are common in some areas, notably among the Chopi of Mozambique, where *timbila* orchestras of up to 40 xylophones, of six different sizes, have been reported.

Lamellaphones. These "thumb pianos" are plucked idiophones unique to Africa and widely distributed throughout the continent. In construction they consist basically of a set of tuned metal or bamboo tongues of varying length fitted to a board, box, or calabash resonator, their free ends being twanged by the player's thumbs and fingers. Supplementary rattling or buzzing devices are often added, and board-mounted varieties are often played inside a half calabash or bowl to enhance the resonance. They serve mainly for song accompaniment. Some common names for regional varieties of the instrument are *likembe*, *mbira*, and *timbrh* (see Figure 3).

G. Kubik

Figure 3: *Timbrh* lamellaphones of the Vute people of central Cameroon.

Membranophones. All African drums except the slit drum fall within this class, sharing the basic feature of having a stretched animal skin as their sounding medium. The mirliton, or small "singing membrane," is often added to the bodies of drums and xylophone resonators as a supplementary buzzing device. It is an essential component of the *malipenga* gourd kazoos used in Tanzania and Malaŵi to simulate military band music.

Africa has a wide variety of drums, which may serve in a number of different roles, some of them not primarily musical. Their manufacture is often steeped in ritual and symbolism, and their use may be restricted to specific contexts. In many societies only men may play them; in others, certain drums are used only by women (as among the Venda, Sotho, and Tswana of southern

Variety of drums

Clappers and bells

Africa). Playing techniques differ widely: some drums are beaten with the bare hands, others with straight or curved sticks. Friction drums are also occasionally found, such as the *ingungu* used in Zulu girls' nubility rites. Except in the extreme south, drums of contrasting pitch and timbre are frequently played in ensembles, with or without other instruments, to accompany dancing. Though the role of drums is usually rhythmic, the *entenga* drum chime in Uganda, comprising a set of tuned drums, plays vocally derived melodies.

The body of a drum may be either bowl-shaped, tubular, or shallow-framed. Bowl-shaped drums include those made from gourds and pots as well as the small and large kettledrums found in and around Uganda. Tubular and frame drums may have either one skin or two, which are either pegged, pinned, glued, or laced onto the body. Tubular drums come in many sizes and shapes, such as cylindrical, conical, barrel-shaped, goblet-shaped, footed, and hourglass-shaped. The *atumpan* talking drums of the Ashanti are barrel-shaped with a narrow, cylindrical, open foot at the base. East African hourglass drums are single-skinned. In West Africa double-skinned hourglass drums are held under one arm, their pitch rapidly and continually changed by as much as an octave by squeezing the lacing that joins the two heads. In some areas wax may be applied to the centre of the drum skin, and a mirliton, shells, or jingles may be attached to the body to modify the tone.

Chordophones. This class, comprising instruments that produce sound from strings stretched between fixed points, is well represented in Africa. There is an abundance of specimens in the form of zithers, lutes, and harps.

Musical bows. These consist of a string stretched between the two ends of a flexible stave. There are three types: bows with a separate resonator; bows with attached resonators; and mouth bows, which use the player's mouth for resonance. Though it is conjectural whether all varieties evolved from the shooting bow, the San of the Kalahari often convert their hunting bows to musical use. Sometimes it is held against the mouth, yielding a range of mouth-resonated harmonics, as with the Jew's harp, or it is pressed against a hollow container. Apart from adapted shooting bows, more specialized types of musical bows are widespread. Most are sounded by plucking or striking the string, but the Xhosa *umrubhe* is bowed with a friction stick, the *xizambi* of the Tsonga has serrations along the stave that are scraped with a rattle stick, and the Sotho *lesiba* (like the *gora* of the Khoikhoi) is sounded by exhaling and inhaling across a piece of quill connecting the string to the stave. Bows with more than one string are rare, but the *tingle apho* of the Kara people in southern Ethiopia has three.

Besides mouth-resonated bows, the gourd bow, which has an attached gourd resonator, is commonly used in southern, Central, and East Africa for self-accompanied solo singing. The string is struck with a thin stick or grass stem. The Zulu *ugubhu* is a typical example. Harmonic tones are selectively resonated by moving the mouth of the gourd closer to or farther from the player's chest. The fundamental pitch of the string can be altered by finger stopping; with other types, like the Swazi *makhweyane*, a noose or brace divides the string so as to yield two different "open" notes, and resonated harmonics are selected in the same way.

While all the above types of musical bow are simple forms of the zither, the so-called ground bow or earth bow of Equatorial Africa, which has one end planted in the ground, qualifies as a ground harp.

Lutes. Characterized by strings that lie parallel to the neck, the lute is found in Africa in several varieties. The multiple-necked bow lute, or pluriarc, of central and southwestern Africa is the oldest. This has a separate flexible neck for each string and resembles a set of musical bows fixed at one end to a sounding box. West African plucked lutes such as the *konting*, *khalam*, and the *nkoni* (which was noted by Ibn Battūṭah in 1353) may have originated in ancient Egypt. The *khalam* is claimed to be the ancestor of the banjo. Another long-necked lute is the *ramkie* of South Africa.

Fiddles. The bowed-lute family is represented by three types of one-string fiddle, as exemplified by the rebeclike *goje* of Nigeria and the spike fiddles *masengo* of Ethiopia and *endingidi* of Uganda—the last being a 20th-century invention.

Harp lutes. The sophisticated *kora* of the Malinke people of West Africa is classified as a harp lute. Its strings lie in two parallel ranks, rising on either side of a vertical bridge, which has a notch for each string. The long neck passes through a large, hemispherical gourd resonator covered with a leather sounding table.

Lyres. These have been termed yoke lutes, the strings running from a yoke supported by two side arms. Their distribution in Africa is confined to the northeast. In Ethiopia two types occur: the large *beganna*, with eight to 10 strings and a box-shaped body (corresponding to the ancient Greek kithara); and the smaller six-string *krar*, with a bowl-shaped body (resembling the Greek lyra). The latter type, with from four to eight strings and varying in size, is also used in The Sudan, Uganda, and Kenya. The *litungu* is a typical specimen.

Harps. These are confined to a belt, north of the Equator, running from Uganda to Mauritania. All African harps (like those of ancient Egypt) are classed as open harps, as they have a neck and a resonator with a string holder but lack a supporting pillar to complete the triangle. In most cases some form of buzzing device is incorporated. Examples are the *ennanga* (Uganda), *ardin* (Mauritania), *kinde* (Lake Chad region), and *ngombi* (Gabon).

Aerophones. The archaic bull-roarer (a board attached by rope to a stick and whirled about in the air) survives in various localities, notably in southern Africa among the San and neighbouring peoples. Of the wind instruments proper, the three main divisions—flutes, reed pipes, and trumpets—are all well represented, though the second of these is more restricted in distribution than the others.

Flutes. At the southernmost tip of the continent the navigator Vasco da Gama in 1497 encountered a band of Khoi people (Khoikhoi, later called the Hottentots) "playing upon four or five flutes of reed." Ensembles of single-note stopped flutes playing on the hocket principle, with each flute blowing its note in rotation, have been reported from various regions, ranging from southern Africa through eastern Zaire, Uganda, and The Sudan to southern Ethiopia. Panpipe ensembles are less common, but notable examples have been witnessed in Central Africa, and particularly among the Nyungwe of Mozambique. There are many other types of open and stopped flutes—cylindrical and conical; transverse and end-blown; made from bamboo, reed, roots, stems, wood, clay, bone, and horn. Globular flutes made from small spherical gourds or from hard-shelled fruits such as the *Oncoba spinosa* are found in southern Africa, Zaire, Mozambique, Uganda, Guinea, and elsewhere. End-blown notched flutes, with a U- or V-shaped embouchure, either with or without finger holes, are widely distributed across the continent. The long Zulu *umshingo* has an obliquely cut embouchure; there are no finger holes, but a double range of overblown harmonics is produced by alternately stopping and un-stopping the lower end with a finger. Such instruments and many others throughout the continent are played singly, but in many areas flutes are played in pairs or in combination with other instruments.

Reed pipes. Transverse clarinets are used throughout the West African savanna region, from Guinea to Cameroon. These are single-reed pipes made from hollow guinea corn or sorghum stems, the reed being a flap partially cut from the stem near one end. Single and double clarinets are found in The Sudan among the Dinka people. Conical double-reed instruments of the oboe or shawm type have spread around the northeastern and northwestern fringes of Africa wherever Islām has taken root. Despite local variations, they are basically related to the Arab *zūrānā*, having a disk (or pirouette) below the reed that supports the player's lips.

Trumpets. Lip-vibrated aerophones made from a variety of materials are widespread in Africa. Apart from musical uses, some serve for signaling. In West Africa, side-blown ivory or horn instruments may transmit verbal

praises of chiefs and rulers. Among the Hausa, the long metal *kakaki* and wooden *farai*, both end-blown, fulfill this role in combination with drums (see Figure 4). In East and Central Africa the instruments are often made from gourds, wood, hide, horn, or a combination of these materials. In Buganda, trumpet sets were part of the royal regalia. Throughout Africa, more than one or two notes are seldom produced from a single trumpet, but trumpet ensembles are common, playing in hocket fashion.

(D.K.R.)

MUSICAL STRUCTURE

Complexity
of African
music

In Africa it is unrealistic to separate music from dance or from bodily movement. In Europe the body tends to be used as a single block, while in African and Afro-American dance it seems to be "polycentric," that is, split into several independent body areas or "centres." Likewise, the playing of African musical instruments involves a whole combination of body movements. This is one reason African music is less amenable to notation than Western music; for analytical purposes, sound filming, rather than just sound recording, is essential.

In Africa music making is very often collective, involving organized collaboration in which performers contribute not identical, but complementary, constituents. Besides polyrhythmic and polymetric procedures, melodic phrases are frequently offset against one another, with different starting and ending points, either in an antiphonal "call-and-response" relationship or in an overlapping relationship that yields polyphony. In addition, melodic phrasing and instrumental accompaniment may be deliberately out of step—a displacement technique described in 1952 by American anthropologist Richard Waterman as "offbeat phrasing of melodic accents." Complementary participation is also evident in drumming and in flute or trumpet ensembles where each player in turn sounds a different, single note. The Ghanaian musicologist J.H. Kwabena Nketia pointed out the function of this African form of hocket technique in "achieving overall effects of continuity, [and] for building up interlocking, and sometimes complex structures, out of relatively simple elements."

Timing. In a great many African music and dance cultures, movement organization rigidly follows certain principles of timing that cannot be equated with Western metrical systems. African systems of timing are generally based on at least four fundamental concepts:

(1) There is an overall presence of a mental background pulsation, or "metronome sense," consisting of equally spaced pulse units continuing ad infinitum and often at great speed. These so-called elementary pulses serve as a basic orientation screen; they are two or three times faster than the beat rate, or gross pulse.

(2) Musical form is organized so that recurring patterns and themes are timed against a regular number of elementary pulses—usually 8, 12, 16, 24, or their multiples (more

rarely, 9, 18, or 27). The recurring sequences are called strophes, or cycles; the number of pulses they contain are referred to as their form numbers, or cycle numbers.

(3) Such strophes or cycles are often divisible in more than one way, allowing simultaneous combinations of contradictory metrical units. For example, 12 pulses—12 is the most important form number in African music—can be divided by 2, 3, 4, and 6.

(4) Patterns with the same form number can be shifted out of phase, so that their starting points and main accents do not coincide, resulting in "cross rhythms." In some cases they cross in such a way that they interlock, or fall between one another, with no two notes ever sounding together.

Interlocking. Interlocking techniques are a prominent feature of many instrumental styles in East and southeastern Africa. From regions in Tanzania and Mozambique come the *ng'oma* drumming of Gogo women and such log xylophone styles as the *dimbila* of the Makonde, the *mangwilo* of the Shirima, and the *mangolongondo* of the Yao people. The drumming in the *ngwayi* dance of northeastern Zambia, the *timbrh* lamellaphone music of the Vute people of central Cameroon, and many other traditions also use interlocking techniques.

A basic characteristic of interlocking is the absence of a common guide pulse to be taken as a reference point by all players. In a Western music ensemble or a jazz band all the players share a "beat," one common metric point of departure. They may even beat their feet to mark it. While there are many traditional African musics in which such a common reference pulse does exist, in several others the musicians in a group relate their parts to individual reference pulses, which can stand in various relations to one another.

In one type of relation the pulse of one performer or group of performers falls exactly in the middle of the other's pulse. This type of interlocking occurs, for example, in the music of the *amadinda* and *embaire* xylophones of southern Uganda. A special type of notation is now used for these xylophones, consisting of numbers and periods. A number indicates that a player strikes a note; the number refers to the note in the scale, as 5, for example, the fifth note of the scale. An underlined number should be read an octave down; in other words, 5 is an octave below 5. A period indicates that no note is struck. Numbers and periods both occupy one elementary pulse.

The following is an example of interlocking as played on the *amadinda*. The melodies are actually played in parallel octaves; that is, each melody is played at the notated pitch and also at the pitch an octave below:

Musician A plays:	4.3.4.1.3.3.4.2.3.4.2.1.4.3., etc.
(in parallel octaves)	↑
Musician B plays:	...5.3.3.5.5.3.5.2.3.5.1.1., etc.
(in parallel octaves)	
	↑ = place of entrance for musician B

In interlocking music of this type, one musician's positive action of striking a note always coincides with a negative action, or "non-strike," of his fellow musician, who at that moment lifts his beater. The effect is such that both series of equally spaced notes seem to interlock like the teeth of a cogwheel. Each of the two musicians, however, feels his own series of notes as "on beat."

In the very fast *mangwilo* xylophone music, the interlocking technique is exploited further. In some compositions by two virtuoso players, each musician interlocks with the right hand only. The left hands play different rhythm patterns superimposed over the interlocking pattern.

Triple interlocking is another type, used, for instance, in Zambia in drum music and also in southern Uganda in the music of the *akadinda* xylophone. Here a group of three musicians plays a short pattern of equally spaced notes in parallel octaves. Three musicians sitting opposite them interlock with another pattern that fits two equally spaced notes between each note of the first group's pattern. In numerical notation it looks like this:

Three musicians play:	2 . . 4 . . 2 . . 2 . . 1 . . 1 . . 2 . . 5 . .
(in three octaves)	↑
Three opposite musicians play:	. 14.35.14.35.14.35.14.35.
(in three octaves)

a performance

Interlocking techniques allow African instrumentalists to produce resultant patterns—overall patterns formed by all the players—that are unbelievably rapid. The resultant pattern of the above *akadinda* musical example is: 214435214235114135214535. This series of 24 notes, when played by expert musicians, is at a speed of approximately 600 notes per minute. But each musician, for himself, plays one-third that fast.

Time-line patterns. In certain areas there is yet another principle of timing, known as time-line patterns. These are struck motional patterns that make up a rhythmic ostinato with an asymmetrical inner structure (such as 5 + 7 or 7 + 9), against which the melodic and rhythmic phrasing of other performers is juxtaposed. They are percussive patterns, produced either by hand clapping or on some musical instrument of penetrating sound quality, such as a bell, a high-pitched drum, the rim or body of a drum, a bottle, an ax blade, a calabash, a percussion beam, concussion sticks, or a high-pitched xylophone key. Time-line patterns are a regulative element in many kinds of African music, especially dance music along the West African coast, in western Central Africa, and in a broad belt along the Zambezi River Valley from Zambia into Mozambique. Broadly speaking, they are found in those parts of Africa covered by the Kwa and Benue-Congo subgroups of the Niger-Congo group of languages—with the notable exception that they are not found in most areas of East Africa or in South Africa.

A time-line pattern represents the structural core of a musical piece, something like a condensed and extremely concentrated representation of the rhythmic and motional possibilities open to the musicians and dancers. Singers, drummers, and dancers in the group find their bearings by listening to the strokes of the time-line pattern, which is repeated at a steady tempo throughout the performance. The following are some of the most important time-line patterns:

- (1) The 12-pulse seven-stroke pattern
Version a (mainly West African)

⑫ [x . x . x x . x . x .]

- Version b (mainly Central African)

⑫ [x . x . x x x . x .]

(Distribution: mostly along the West African coast—for example, in the music of the Yoruba, Fon, and Ewe—but also in Zaire, Angola, and Zambia.)

- (2) The 12-pulse five-stroke pattern

⑫ [x . x . x . x . x .]

(Distribution: Central Africa, especially in the Congo and Zaire; southern Africa, including Zambia and Malawi; West Africa—for instance, among the Baule of Côte d'Ivoire.)

- (3) A 16-pulse time-line pattern

⑮ [x . x . x . x x . x . x x .]

(Distribution: mostly southern Zaire, Angola, and north-western Zambia; an isolated occurrence in xylophone music on the Kenya coast.)

The longest time-line pattern is found among the Pygmies of the upper Sangha River in the Central African Republic. It is a 24-pulse pattern of the following structure:

②④ [x . x . x . x . x x . x . x . x . x x .]

This pattern is struck on a percussion beam, and the dance style accompanying it emphasizes motions of the pelvis.

The asymmetrical time-line patterns of African music are, no doubt, an ancient cultural heritage along the Guinea Coast and in western Central Africa. They were most likely invented by peoples who spoke ancestral forms of Niger-Congo languages. It is likely that the area of origin was the Guinea Coast. One explanation for the absence of time-line patterns in the northern half of East Africa is that they were unknown among the first wave of Bantu-language speakers moving eastward from the Cross River area in eastern Nigeria along the fringes of the equatorial forest toward the East African lakes region c. 100–400 BC. Another explanation could be the influence in East Africa of Nilotic cultures. The knowledge of time-line patterns might have been brought to western Central Africa with a

second migration of Benue-Congo speakers from eastern Nigeria during the Early Iron Age, a time when time-line patterns had already spread eastward across the Niger River. This second migration could have been responsible for the introduction into western Central Africa of a set of cultural traits that include asymmetrical time-line patterns, the single and double bells, masked dancing, secret societies, and certain initiation ceremonies.

With the beginning of the Later Iron Age in Central Africa (c. AD 1000), a second nuclear area for time-line patterns apparently developed in southern Zaire; both the 12- and 16-pulse patterns still play an enormous role in the musical traditions of that region. With the third Bantu dispersal, this time from southern Zaire and carrying with it trade connections, the practice of time-line patterns could have reached the Zambezi Valley and the Nyasa-Ruvuma culture area of Tanzania, Malawi, and Mozambique—the only areas in the eastern part of the continent where time-line patterns are prominent today.

Inherent note patterns. Closely associated with interlocking techniques but not necessarily depending on them is the composition of inherent note patterns. These are rhythmic and melodic patterns that emerge when series of notes in distinct intervals are played at high speed.

The human ear perceives not isolated particles of sound but a “gestalt.” When sequences of many notes are played rapidly, the ear cannot follow each note. As a result, the hearing tends to pick out and regroup the material, forming several melodic-rhythmic patterns that seem independent of one another. Thus, the heard image of the music differs from the pattern of notes actually played. In a series of notes that are large intervals apart, for example, the ear picks out the notes of about the same pitch level and perceives them as a group. This psychological perception of a gestalt—an inherent note pattern—is an important element in listening to and composing some kinds of African instrumental music, particularly in Central and East Africa.

Inherent note patterns are not accidental or coincidental; they are recognized and consciously employed by African musicians. In southern Uganda there are even specific terms referring to them. The main function of inherent note patterns is to suggest words—text passages of a song that is outlined by instrumental accompaniment. Thus, in the music of the *ennanga* harp of Uganda, the inherent note patterns suggest certain phrases of the vocal part. In a performance of the traditional harp song “Olutalo olw’e Nsinsi” (“The Battle of the Nsinsi”) by the former court musician Evaristo Muyinda, one inherent pattern seemed to speak the words “Batulwanako ab’edda!” (“How They Forget Those Ancients!”) long before they were actually sung. Muyinda often introduces a new phrase of text by first accentuating the corresponding inherent rhythm on the *ennanga*. Once the melody is firmly established as a gestalt, it is sung. By slight accentuation or melodic variation during performance, the harpist may bring one or another of the already existing inherent patterns into prominence. This results in a musical development of the song’s text.

Tone systems and multipart patterns. Tone systems and multipart patterns have a functional interrelationship in African music. In other words, the kind of multipart pattern occurring in singing or instrumental music is conditional on the type of tone system, and vice versa.

The tonal material used in African musical traditions varies considerably from region to region. Tonal organization, tuning procedures, and intervallic structure depend upon a broad range of human experience. Several factors have determined the shape of tone systems actually in use. One factor mentioned above (see *Musical instruments*) is language, especially with regard to the semantic and grammatical importance of speech tone. Another is the principle of equidistance, the measuring of space or time in equal steps. In addition, in some cross-perceptual associations, such as from aural to visual and vice versa, pitch may be graded in terms of magnitude or altitude. In African music different pitches are not conceptualized as “high” or “low,” as they are in English and some other Germanic languages of Europe, but as “small” and “big”

Function
of inherent
note
patterns

Origins of
time-line
patterns

or "tiny" and "fat." Consequently, a lamellaphone of middle size, producing middle-range notes, is called *endongo* in Lusoga, a Bantu language spoken in an area of Uganda east of the former Kingdom of Buganda. *Kadongo* (with the diminutive prefix *ka-*) is a high-tuned lamellaphone, while *gadongo* (with the augmentative prefix *ga-*) is a bass instrument. Finally, tonal structure may be influenced by the human experience of sound in nature and the discovery of acoustics.

Broadly speaking, African tone systems may be divided into the following families and subfamilies: (1) equi-tonal systems, based on the principle of equal intervals; (2) monophonic systems, based on octaves, fifths, and fourths; and (3) systems based on the experience of instrumental harmonics.

Equi-tonal systems. Two varieties are found: (1) equi-pentatonic (for example, in southern Uganda); and (2) equi-heptatonic (for example, in the lower Zambezi Valley and in eastern Angola). These tone systems, with either five or seven notes per octave, differ radically from the two Western equal-interval scales, namely the chromatic scale of 12 semitones to the octave (which is equi-dodecatonic) and the whole-tone scale (which is equi-hexatonic). Each step in the whole-tone scale involves an interval of 200 cents (a cent is a measure of frequency, with each semitone in the Western scale equal to 100 cents). In equi-pentatonic systems, on the other hand, the recurrent interval is theoretically 240 cents (*i.e.*, 2.4 semitones of the Western scale), and in equi-heptatonic systems it is 171 cents (or 1.71 semitones).

In practice, the intervals in African equi-tonal systems are only approximately equal. For example, there is evidence that the tonal basis of music in southern Uganda, although equi-pentatonic in principle, accommodates a relatively wide deviation from the ideal equidistant interval of 240 cents. The term *pen-equidistant* has been coined for such a system. The cause of deviation is the presence in the music of that region of certain consonance principles, based on the recognition of simple ratios of fourths and fifths. Thus, the southern Ugandan tone system seems to have two disparate roots, accommodating both the principle of equidistance and the experience of simple ratios. In particular, the natural fourth is the only interval (besides octaves) recognized as consonant; it is therefore used extensively as "harmonic filler" in the interlocking-composition method of that region. No simultaneous fourths occur, and yet the semblance of a fourth-, fifth-, and octave-based "harmony" is established by durational overlapping of the notes struck. Consequently, seconds (240 cents), in contrast to fourths (480 cents), are avoided to a great extent in interlocking composition.

Similarly, in equi-heptatonic systems the desire for harmonic sound may dictate constant adjustments of intonation away from the theoretical interval of 171 cents. One of the most impressive areas in Africa in which a *pen-equidistant* heptatonic scale is combined with a distinctively harmonic style based on singing in intervals of thirds plus fifths, or thirds plus fourths, is the eastern Angolan culture area. This music is heptatonic and non-modal; *i.e.*, there is no concept of major or minor thirds as distinctive intervals. In principle all the thirds are neutral, but in practice the thirds rendered by the singers often approximate natural major thirds (386 cents), especially at points of rest. In this manner, the principles of equidistance and harmonic euphony are accommodated within one tonal-harmonic system. For the notation of such music, a seven-line staff is most appropriate, with each horizontal line representing one pitch level.

Monophonic systems. These tonal systems, based on octaves, fifths, and fourths (*i.e.*, on the simple ratios 1:2, 2:3, and 3:4), are found in the western Sudanic belt. There are also many pentatonic systems of this kind in the Sahel zone and on the Guinea Coast (such as those of the Fon and Oyo-Yoruba peoples), where no simultaneous sounds occur except octaves.

Systems based on instrumental harmonics. These tone systems may be divided into two subfamilies: (1) that based on the selective use of harmonics from a single fundamental (for example, the system of the Gogo of cen-

tral Tanzania); and (2) that based on the selective use of harmonics from two or more fundamentals (for example, the systems of the Fang in Gabon and of the /Kung in southwestern Africa, based on harmonics from two fundamentals, and the hexatonic systems of the Lala, Nsenga, Swaka, and Shona in southern and Central Africa, based on more than two fundamentals). All musical cultures employing this type of tone system practice multipart singing. The regions involved are southern Africa, central and southwestern Tanzania, and much of western Central Africa.

The actual shape of the system depends upon whether the tonal material derives from one fundamental or more, upon the conventionalized intervals between these fundamentals (if there is more than one), and upon which section of the natural harmonic series is selected to form the tone system. Depending upon these variables, completely different tonal-harmonic systems may be encountered. The Gogo tone system, illustrated below, is basically tetratonic (within one octave) with a pentatonic extension. It is based on selective use of the sequence of natural harmonics from partials 4 to 9, over a single fundamental.

Variety of tonal-harmonic systems

The old tone system (now obsolete) of the Kisi people of Tanzania was hexatonic. It was based on the selective exploitation of the sequence of natural harmonics from partials 6 to 11 over a single fundamental.

Tone systems based on the use of harmonics from two fundamentals are frequently encountered in areas where the musical bow, particularly the mouth bow in its varieties, is or was an important instrument. Western Central Africa and the whole of southern Africa are the most prominent distribution areas for mouth bows; they are also found in some areas of West Africa.

The tone system of the /Kung people is tetratonic. It may manifest itself, however, in three different versions with different intervals, leading, as in the first of the tunings shown below, to a semitone interval (shown as F-E). Because the melodic and harmonic results of these particular tunings are unique, they provide strong evidence of San heritage in any southern African music in which they occur. In /Kung music the natural harmonic series of each fundamental is not used beyond the fourth partial. This is why fourths, fifths, and octaves are the characteristic simultaneous sounds in /Kung polyphony.

(a) musical-bow tuning at intervals of about 400 cents

Where, in addition to the second, third, and fourth partials, the fifth partials of each fundamental are also used, hexatonic tone systems arise. The tonal-harmonic system of the Handa-Nkhumbe group in southwestern Angola is one example, based on two fundamentals tuned about 200 cents apart. The resultant chords are thirds and fourths in characteristic positions:

This system also underlies the music of the Xhosa in South Africa. It occurs, too, in some of the music of their neighbours, the Zulu and Swazi, although these latter use a different hexatonic system, based on fundamentals tuned about 100 cents apart. This tuning, used on the Zulu *ugubhu* gourd bow, has three semitone intervals:

Multipart singing. Multipart singing and harmonic concepts are basic traits of many African musical traditions and have been observed by Western travelers since the earliest periods of contact. Contrary to earlier opinions, "harmony" in African music is now seen to be not a result of acculturation but rather indigenous to many parts of the continent. Polyphonic singing styles were almost certainly used by prehistoric hunters in Central and southern Africa. Among the San, the discovery of the use of the hunting bow as a musical instrument, and with it the discovery of the harmonics of a stretched string, constituted a cluster of traits that were probably interdependent. Questions raised in the 19th and early 20th centuries as to whether the hunting bow or the musical bow was invented first are certainly irrelevant in the culture of southern African prehistoric hunters.

Multipart singing in African music embraces two entirely different approaches, homophonic and polyphonic, with the definition of these words adapted to African cultures.

Homophonic vocal styles. In these styles all melodic lines, though at different pitch levels, are rhythmically the same, and they begin and end together. Individual singers conceive of their voice lines—all carrying the same text—as identical in principle, only sung at different levels. Men sing "with a big voice" (*i.e.*, in low voices), women

and children "with small voices" (*i.e.*, high voices). Their voices may stand a third, a fourth, a fifth, or an octave apart, but they are considered to sing the same tune. In practice, though, not only parallel, but also oblique and contrary, motion may occur. To what extent the latter is permitted depends upon the tolerance within the tonality of the particular language. For example, in eastern Angola contrary motion is normal practice. In other cultures movement is strictly parallel within the structure of the tone system concerned.

Homophonic multipart singing is found in particular concentration along the Guinea Coast. It is also found throughout western Central Africa, among most peoples of Angola, Zambia, and Malawi, and in many parts of East Africa. In northern Central Africa it is found among the Azande and related peoples. In southwestern parts of the Central African Republic there is three-part harmonic singing with vocal parts shifting chromatically between two roots one semitone apart. Homophonic vocal styles are often linked to a call-and-response (leader-chorus) form.

Polyphonic vocal styles. In these styles the complementary individual lines differ in their rhythm and phrasing and carry different texts or syllables. They may be of different length, and their starting and ending points do not coincide. Such styles are more restricted geographically. The vocal music of the San communities in southwestern Africa is predominantly polyphonic, as are the vocal styles of Pygmy groups in the Ituri Forest and the upper Sangha River area of the Congo and the Central African Republic. (The San and Pygmy peoples, whose polyphonic styles and tone systems are based on different principles, have often mistakenly been lumped together in evolutionist theories.) In other parts of Africa, isolated islands of polyphonic singing occur among or between largely homophonic communities. Thus, the otherwise homophonic Gogo people employ polyphonic techniques in their *saigwa* and *msunyunho* songs, and Nyakyusa children of southwestern Tanzania use yodel and polyphony in a song type called *kibota*.

A distinct style of polyphonic singing is found in much of the music of the peoples of the lower Zambezi Valley, in parts of Mozambique, and also in Zimbabwe, as exemplified by the Karanga-Shona threshing song shown here:

This is a diagrammatic transcription showing the relationships between the five male voice parts (here transposed one octave and five semitones higher). In actual performance the voices enter consecutively, each starting from the double bar in his particular line and then repeatedly backtracking to the beginning of the line. The entry point for voices 2 and 3 is one pulse after the commencement of the last note of voice 1. When voice 1 repeats his line, his second syllable signals the entry point for voices 4 and 5. The cycle (which is continually repeated) is 18 pulses long. The harmonic scheme comprises a sequence of bichords in fourths and fifths, characteristic of much Shona music. The roots of these bichords, E A C / E G C, are shown above the top staff. The tone system here is hexatonic.

Polyphony is also prevalent in South Africa and Swazi-

Geographic
distribution

land. In the dance-songs of the Nguni people (including the Zulu, Xhosa, Swazi, and Ndebele), two or more voice parts, commencing at different points in the cycle, often overlap extensively. At least two parts, solo and chorus, are always regarded as essential. In fact, a solo vocalist singing the entire song usually does not complete a single voice part but instead shifts from one part to another when he arrives at the entry point of each part.

The Zulu bow song transcribed below begins with the bow phrase, which simulates a chorus part. During repetitions of this ostinato, the voices (sung in this transcription by Zulu princess Constance Magogo kaDinuzulu, her son Chief Mangosuthu Gatsha Buthelezi, and several of his young children) enter in turn, each beginning at its double bar: first, voice 1, then, in subsequent repetitions of the 16-pulse cycle, voices 2 and 3. The lines shown below the song may be rendered by additional singers or by voices 2 and 3 as occasional variants.

Similar structures underlying different tone systems

This song sounds very different indeed from the previous Shona example, mainly on account of its tone system, which has two semitone intervals. A pentatonic variant of the Zulu hexatonic system cited above, it is based on two instrumental roots a semitone apart. The melodic line produced on the *ugubhu* gourd bow employs harmonic partials 3 and 4 of the two fundamentals B and C, these harmonics being selectively resonated by moving the open end of the gourd resonator closer to or farther from the player's chest.

Despite the marked tonal dissimilarity between the Shona and Zulu songs, they clearly share an almost identical underlying formal structure, based on the principle of deliberately nonaligned, overlapping voice parts that retain the same relationship to one another through all successive repetitions of the song. The relationships of their parts can be demonstrated by concentric circles, in which clockwise rotation represents a cycle, or strophe, of the song, which is continually repeated.

All the vocal music considered above has as its basis some kind of tone system. Among the Zulu and other Nguni peoples, however, certain non-melodic forms of chanting coexist alongside melodic styles of performance—even among items that fit the same category of “dance-song”—

Karanga-Shona threshing song (18-pulse cycle)

Zulu part-song (16-pulse cycle)

just as some English nursery rhymes are sung while others are recited or chanted. In such cases, fixed musical pitches are absent, and a singsong form of rhythmical recitation is used instead. The close affinity of such pieces with melodic songs is confirmed by their sharing of the same circular, multipart formal structure.

There is indeed evidence from many different parts of Africa of the use of intermediate vocal styles, falling somewhere between the extremes of speech and song. In many African cultures the boundary between the two does not tally exactly with the Western, demonstrating that definitions of music and song are culture-specific.

(G.K./D.K.R.)

Dance

THE CULTURAL POSITION OF DANCE

In African societies, dance serves a complex diversity of social purposes. Within an indigenous dance tradition, each performance usually has a principal as well as a number of subsidiary purposes, which may express or reflect the communal values and social relationships of the people. In order to distinguish between the variety of dance styles, therefore, it is necessary to establish the purpose for which each dance is performed.

Often there is no clear distinction between ritual celebration and social recreation in dance performances; one purpose can merge into the other, as in the appearance of the great Efe mask at the height of the Gelede ritual festival in the Ketu-Yoruba villages of Nigeria and Benin (see Figure 5). At midnight the mask dramatically appears

Merging of ritual and recreation

Figure 5: A Gelede masquerader dancing in the courtyard of the Ibara palace in Abeokuta, Nigeria.

to the expectant community, its wearer uttering potent incantations to placate witches. The dancer then moves into a powerful stamping dance in honour of the great Earth Mother and the women elders of the community. The dance continues as the performer pauses to sing the praises of people of rank, carefully observing their order of seniority. In this way a ritual act becomes a social statement, which then flows into recreation as the formal dancing by the Gelede team gives way to free participation by spectators until sunrise. The great Efe holds a central position, entertaining his audience with tales that make comic and satiric reference to irregular behaviour within the community over the past year.

The more significant the concept expressed in a dance, the greater the appreciation of the audience and the more insistent their demands for a skillful performance and for movements that fit its purpose. Dance is appreciated as a social occasion but is simultaneously enjoyed as an activity in its own right, entertaining and giving pleasure as an expression of communal life.

The religious context. Thought systems traditional to African cultures are rooted in a world view in which there is continuous interaction between spiritual forces and the community. Spiritual beings may inhabit natural elements or animals and may also take possession of human mediums. This possession of persons is usually temporary and confined to ritual, as when the priest of the Yoruba god Shango dances into a state of deep trance at the annual festival, expressing the wrath of the god of thunder with the lightning speed of his arm gestures and the powerful roll of his shoulders (see Figure 6, top). In Zimbabwe the Mhondora spirit mediums, who relate the Shona people to the guardian spirits of the dead, enter a trance through the music of the *mbira* lamellaphone (or thumb piano), to which they sing while performing simple, repetitive foot patterns. Thus, the dances of priests and mediums confirm their ritual leadership.

Dance is used as therapy by ritual societies in many cultures. Hausa women, for example, find healing through dance and spirit possession in the Bori cult. Among the Jukun of Nigeria, a similar organization is called the Ajun, whose elders deal with hysterical disorders in women by exorcising evil spirits in initiation ceremonies. During a three-month period in a house shrine, the sufferer is taught songs and dances that have a therapeutic function culminating in a ceremony in which the initiate publicly joins the members of the society to perform the Ajun-Kpa dance (see Figure 6, bottom). The female spirit mediums of the Kalabari in the Niger Delta, using dance and song as an essential part of their therapy, are also credited with powers of healing.

Many African religions are based on a bond of continuity between the living and their dead ancestors, who, in some cultures, return as masquerade performers to guide and judge the living. The complex web of human relationships is continuously renewed and restated at ritual festivals through the arts.

Masquerade dancers. Masquerade dancers are a feature of religious societies in many areas. Four main types of masquerader are identified by the roles they play: those who embody deities or nature spirits and to whom sacrifice is made to assure the fertility of land and people, those who embody the ancestral spirits, those who placate the spirits through their dance, and those who perform principally as entertainers.

Animal masks are a common feature of masking societies throughout Africa. In Mali the Tiwiwara spirit masqueraders of the Bambara people carry formalized carvings of antelopes and other wild animals, dancing in imitation of their movements to promote the fertility of land and community (see Figure 15). The Isinyaso masked dancers of the Yao and Maku peoples of Tanzania carry elaborate bamboo structures covered with cloth and raffia, which sway rhythmically while their Nteepana mask elongates to great heights as the embodiment of a powerful animal spirit.

The type of mask influences the style of the masquerade dance. The Ikpelweme ancestral masqueraders of the Afe-mai people of Bendel State, Nigeria, wear richly coloured,

Figure 6: Ritual dancing in Nigeria.

(Top) Yoruba performing a dance in honour of the god Shango. (Bottom) Jukun women dancing the Ajun-Kpa, which exorcises evil spirits and heals members of their cult.

Frank Speed

close-fitting costumes with face masks and elaborate headpieces of embroidered cloth, which allow for a dance that accelerates into a climax of rapid, abrupt movement. The Nago and Akakayi ancestral masqueraders of the Gwari wear close-fitting head and body coverings, which permit rapid, staccato movements while dancing at the "second burial" (*i.e.*, the post-burial celebrations) of a leader of the community. The Egungun ancestral masqueraders of Yorubaland appear in a wide variety of loosely flowing cloth or palm-leaf costumes, often with carved headpieces. The heavier the mask, the less freedom for dance. For example, Epa masqueraders of the Ekiti-Yoruba carry carved helmet masks with elaborate superstructures whose weight allows only the type of movement fitting the stately processional dances that confirm the masqueraders' role of ritual leadership. Masked stilt dancers, such as those of the Makonde of Tanzania, are largely restricted to rhythmic strides and gestures; in contrast, the simple cloth costumes of ancestral Egungun Elewe of the Igbomina-Yoruba allow for a dance of acrobatic skill, and the light raffia Igo masks of the neighbouring Edo people enable them to lift their costumes above their heads in a dance of whirling turns.

Secular masqueraders who perform as entertainers have emerged from the ritual societies. The Egungun entertainers of the Oyo-Yoruba, for example, perform at Egungun ancestral festivals, but they may be invited to perform for a fee as entertainers, often traveling to neighbouring towns to earn money (although they are obliged to offer sacrifices to their ancestors before performing). The company members usually start with popular acrobatic dances and then display their magic powers by changing into a series of animal and masked figures. They use an inventive range of mime and dance to praise gods and heroes, to satirize politicians and wrongdoers, and to ridicule strangers,

Figure 7: Mask representing the *mwana-pwo*, a mythical figure of a young woman who died. It is one of the prominent figures in masked performances by the Chokwe and related peoples in the eastern Angolan-northwestern Zambian culture area.

G. Kubik

such as visiting Hausa traders or Europeans, with wit and humour. Accompanied by singers and led by a drum ensemble, they present a form of communal or folk theatre.

Masqueraders may play an individual role, as with the circumciser during the initiation rites of the young Nyanga men in eastern Zaire. Initially he dances as a masquerade to send the boys out of the village to their ritual seclusion, where he taunts the initiates before and after the rites of circumcision. As an authoritative figure, he inspires awe in women and children. In some cultures masquerade performance is not allowed to be seen by women, and nocturnal performances are often used to control women and even threaten them into accepting their social role. This is aided by the fact that in many forms of masquerade the body of the carrier is entirely covered in order to hide his identity, and his voice may be distorted by a kazoo (or voice disguiser).

The social context. In all African cultures, dance, music, and song help define the role of the individual and the group within the community. In hierarchical societies a ruler is expected to state his authority in formal dances, and failure to meet the required standard may seriously damage his prestige.

At the crowning of an *oba* (king) in Yorubaland, for example, the ruler leads a procession through the town as he dances with upright carriage and dignified step, his gestures dictated by the nature of his kingly role and the insignia he carries. His wives follow, interpreting the rhythms in a style suitable to their rank, inclining forward from the waist with their attention respectfully directed toward the earth. When the *oba* is seated in state, his war chiefs greet him, each with his appropriate dance rhythm. The hunters then dance to their rapid and complex beat. Palace chiefs and women market chiefs have their own distinctive music, song, and dance to praise the ruler, and girls, young men, and children honour him with dances appropriate to their status.

Children's dances

Dance is also important as an educational tool. Repetitive dances teach children physical control and stress accepted standards of conduct. Children may form their own dance and masquerade groups, join adults at the end of a dance line, or simply have a space allocated to them in a performing area at the time of a festival. In some places, particularly in West Africa, boys have their own masked dances in training for membership in adult societies. Throughout Africa children enjoy dance games, as when Makindu boys of Kenya sing as they play leapfrog to a dance rhythm (see Figure 8, top).

In societies that stress horizontal stratification into age sets, the qualities proper to a particular age are expressed in dances, as in those that keep young men physically fit and

teach them the discipline necessary in warfare. The dances of young Zulu and Ndebele men in southern Africa recall the victories of past warriors. Among the Owo-Yoruba the stately Totorigi dance is for senior men and women, while adolescent boys perform the lively Ajabure with ceremonial swords. The transition from one age grade to the next may be marked by rites and festivities. In initiation rites for adolescents, dances may stress sexual fertility as well as customary behaviour between the sexes. In the Otufu initiation rites for girls among the Ga of Ghana, dance is part of their preparation for womanhood and enables them to display their charms to suitors. Young Kaka men of Cameroon perform their Midimu dance after the circumcision rites as a formal precondition of admission into the society of adults.

In some areas dances are designed to be performed during funeral rites, after burial ceremonies, and at anniversaries. Dances may be created for a specific purpose, as in the Igogo dance of the Owo-Yoruba, when young men use stamping movements to pack the earth of the grave into place. In Fulani communities in Cameroon, the corpse is placed in a sitting position in a prominent place, and solo and communal dances are performed in the deceased's honour. In some areas a circle dance surrounds the men performing the required ritual autopsy.

Thus, dance plays a cathartic role during the key transition from one social state to another: a child is welcomed into the community at his naming ceremony; an adolescent is initiated into the responsibilities of adult life; a woman moves from her paternal home to join her husband's family; an elder receives recognition for service in the form of a title; a member leaves the community to join the world of the spirits. The individual is not left alone to bear the emotions that accompany critical change, as members of the community carry him and his family through the crisis with appropriate ceremonies containing the emotions of the moment in music, song, and dance.

Division between the sexes. Within traditions of long standing in many cultures, it is unusual for men and women to dance in direct relation to each other, and they seldom perform the same style of dance—though combination of the sexes is more common in areas where the original dance has been disrupted by non-African forms. Idealized male and female qualities are normally expressed in the movement patterns of their separate dances: for example, Tiv men dance with an attack of rapid, forceful movements expressing masculinity, whereas the women dance with a sustained grace reflecting their femininity. If men and women join a common dance circle, their dance patterns are usually distinct, as with the Kambari of Nigeria: men and women dance to the same musical rhythm, but they hold different postures, with the women singing and using a simpler foot pattern than the men.

Idealized male and female dance styles

Dance occasions for formalized flirtation between the sexes before marriage are common, as in the Sikya dance of the Akan of Ghana. The Bororo of western Cameroon celebrate the coming of the dry season with a dance for young men and women, and couples pair off at the climax of the performance. Among the Nupe of Nigeria ribald songs and joking insults between the sexes have replaced performances allowing for sexual license at harvest festivals. The dances of Ika men and girls (western Igbo, Nigeria) have become openly erotic since the early 1960s, when a master dancer brought the sexes together in a single dance team to entertain visitors to the palace of the *oba* of Agbor in Nigeria. Thus, erotic patterns of dance movement are encouraged in some societies, usually with bawdy humour, whereas the limits of flirtation are clearly defined in others for the sake of social decorum.

Work dances. Men who work together often celebrate a successful project with beer drinking and vigorous dances expressing their occupational skills. In Nigeria, Nupe fishermen are renowned for their net throwing, which they formalize into dance patterns, and young Irigwe farmers on the Jos Plateau leap to encourage the growth of crops at festivals related to the agricultural cycle. Occupational guilds and professional organizations of experts, such as blacksmiths, hunters, or wood-carvers, have their own expressive dances.

Figure 8: Play and work dances.

(Top) Bill Horman—FPG, (bottom) George Holton—Photo Researchers, Inc./EB Inc.

Hunters may reenact their exploits or mime the movements of animals as a ritual means of controlling wild beasts and allaying their own fears. The Akan of Ghana perform the Abofor dance, a dance-mime staged after the killing of a dangerous animal. This is meant to placate the spirit of the beast and inform the community of the manner in which it was killed. Tutsi hunters in Zaire commemorate a successful hunt in their lion dance (see Figure 8, bottom).

Dance as recreation. Dance is the most popular form of recreation in Africa. In towns, men and women of all ages meet informally in dance clubs to dance to the rhythms of popular musicians. In villages there may be opportunities in the evenings for informal dancing, but relations between the sexes there are more tightly controlled.

Highlife and other westernized dances Highlife was a style of urban recreational dance popular in West Africa in the 1950s. It originated in Ghana, where musicians adopted Western dance-band instruments at open-air nightclubs to celebrate the exuberant spirit of independence. In Nigeria, local instruments were used as the Yoruba created *juju* rhythms, while the Tiv danced the Swange. Francophone countries elaborated the Latin-American rhythms of the cha-cha, while southern Africans danced to the modern African beats of the *kwela*. Zairian dance bands excelled in the creation of their own popular dance music. These have given way to styles influenced by Caribbean reggae and Western pop music, but they retain a distinctly African character.

DANCE STYLE

Although often similar in social purpose, dances are realized in radically different styles in the multitude of diverse cultures of Africa. Movement patterns vary greatly from one culture to another, depending upon the way in which environmental, historical, and social circumstances have been articulated in working, social, and recreational movements.

People living on dry, spacious farmlands, for exam-

ple, have different movement habits from those living in swamplands. For farmers of the savanna, the ground is solid and their space open to the far horizon. They place their feet firmly on the sunbaked earth as they follow their team leader on the circular path of their dance, performing simple foot patterns at a steady tempo.

The Ijo people, who live in the mangrove swamps of the Niger Delta, traditionally wrest an uneasy living by fishing creeks and rivers. As they dance, they lean forward from the hips, their torsos almost parallel with the earth as they use a precision of light, rapid foot beats, moving their weight from heel to toe to side of foot in a variety of rhythmic patterns, as though balancing on an unsteady canoe or picking their way through the swamp. Many other riverine peoples mime paddling in their dances.

Manipulating their flowing gowns as an extension of gesture in stately, measured dances, the Kanuri of Maiduguri in northeastern Nigeria conserve energy with economy of movement—a common feature in the dance of desert peoples. By contrast, some forest dwellers dance freely. The southern Yoruba continuously alter their foot patterns and sequence of movements at the dictates of the leading drummer. Their movements suggest finding a way through forest undergrowth, which necessitates reactions ever alert to the unexpected.

Working movements feed into styles of dance. The bend of the knees accompanying the swing of a farmer's machete may be elaborated in a dance pattern. Architecture, furniture, and dress are among features that also influence posture and gesture, producing a distinctive use of energy. The Kambari of Nigeria continuously bend forward to enter their low doors, and their dance posture reflects this habit. The Jukun sit on low stools or on the floor with legs crossed or extended; their flexible knees and strong leg tendons allow for the performance of continuous deep knee bends in their dance movements.

These cultural influences in the development of dance style have been offset by such historical events as migrations, wars, and slave trading, which have displaced people as refugees over the centuries, changed their habitation patterns, and brought them in touch with new environments. The development of trade routes introduced influences from Arabic and other cultures. Conversion to Christian and Muslim faiths severely disrupted ritual and ceremonial life and thus often disturbed the traditional patterns sustaining music and dance. Colonialism also resulted in the dissipation of cultural homogeneity and the gathering of disparate dance patterns into new styles.

Dance formations. There are four principal African dance formations: a dance team using a formalized floor pattern; a group using a free-flow floor pattern; a group using a formation from which solo dancers emerge to display their individual skills; and the performance of a solo dancer—usually a ruler, ritual specialist, herbalist, or comic entertainer—who may be supported by a group of musicians.

The most common form of dance within the indigenous traditions of Africa is a team dance performed either in a closed circle, with the dancers facing the centre, or in a line following a circular path that is often centred on the musicians. The dancers usually move along the circle line in a counterclockwise direction. In egalitarian societies the circular team dances are a marked expression of the close-knit fraternity within an age grade, as with Tiv men, while Tiv women express their relationship within the extended family through their own circle dance.

Dance teams using straight linear formations are common in cultures with a strong warrior tradition, where a strict spatial discipline is required, as in the Shangani war dances in Zimbabwe. They also are common with people prone to borrow from other cultures, as with the Igbo boys' dances in eastern Nigeria, in which the formation of a number of lines suggests Western patterns of drill. Some migratory cultures favour the line, as do Fulani girls, who form a tightly knit unit with their arms around one another's waists as they perform simple step rhythms from side to side, and the Masai, with their high-jumping dance pattern.

A linear or circular floor pattern is used in cultures

Change and disruption of traditional styles

employing a combination of team and soloist. The Olu Kanaanwa dance for unmarried Igbo girls is done in unison in a circular formation, from which each dancer breaks away to perform individually in the centre. Among Ijo women, the dance starts in a loosely knit semicircular line from which virtuoso performers move out toward the spectators. The Urhobo of Nigeria use a loose, linear formation, the soloists dancing toward and away from the musicians. As the tempo of the drumming mounts, individuals dance into an ecstatic trance in which they are caught and controlled by dance organizers. A more ordered line-and-soloist pattern is used by Ashanti women in the Kumasi district of Ghana in their Adua dance, which is notable for elaborating expressive hand movements into a language of gestures.

Dance team organization

The members of dance teams who perform on occasions of social importance are related within an age grade, an extended family, a working guild, a social club, or a ritual society whose elders provide sponsorship, respond to invitations, settle financial arrangements with external bodies, and discipline spectators and dancers at performances. A woman elder is usually the "mother" of the dance, attending to the comfort of the dancers and encouraging them by ululating during the performance. The elders select the team leader on the basis of skill, organizing ability, and creative flair. The leader selects the dancers, arranges and runs rehearsals, and is responsible to the elders for the appropriate dress of the performers. In some cultures the leader may compose songs requiring an elaboration of gesture or new movement patterns, which he or she will then choreograph. In cultures in which the dancers sing either before or during the dance, the leader initiates the singing.

In performance the leader heads the dance line or performs alone in a clearly defined space. The leader responds to the musicians and takes artistic responsibility for the dance interpretation of the music on behalf of the team, which usually follows the leader's movements in unison. In formal team dancing, creative innovations are planned and practiced in rehearsals.

Dance posture. There are three characteristic dance postures. An upright posture with a straight back is used as an expression of authority in the dance of chiefs and priests. In the second posture the dancer inclines forward from the hips, moving his attention and gestures toward the ground. In the third posture the dancer holds the torso nearly parallel to the ground, taking the body weight onto the balls of the feet. Many riverine people use this posture. The downward stress toward the earth does not necessarily imply that the dancer is heavy-footed. In some cultures the dancers use the full foot in stamping out the rhythms, while in others they may leap or perform light foot movements.

Rhythm. African dances are earth-centred. Dancers repeatedly return to the earth as they give themselves to the rhythmic pulses of their dance, interpreting the percussive patterns of the music through their postures, gestures, and steps. They externalize rhythmic patterns in the surrounding space by moving through, rather than to, fixed positions in the space surrounding the body. Thus, the criteria for assessing skill are based on rhythmic rather than spatial precision. Rhythm is provided for the dancer by musicians playing percussive instruments, by singers, or by a combination of music and song. In some cultures the dancers themselves sing or play musical instruments as they perform. Normally the musicians lead the dancers, although there are cultures in which the dancer takes over the initiative and sets up a dialogue of rhythmic exchange.

A dancer is assessed primarily on his ability to follow the percussive musical rhythm, "to play the drums with his feet" or with whatever part of the body articulates the rhythm. Each dance style is immediately identified by its characteristic rhythmic pattern. In some cultures the rhythmic patterns are expressed in foot patterns, in others in contractions of the torso, strong shoulder beats, rapid vibrations or twists of the buttocks, or acrobatic leaps.

A wide variety of rhythmic patterns form the basis of dance in Africa. The most basic is the continuous repetition of a simple beat at a steady tempo for the duration of a dance. This may continue for days, as in the Akbia

women's funeral dance in the southern Sudan and the dances of the Mbuti Pygmies of Central Africa.

Teams of savanna farmers on the Jos Plateau play instruments as they dance, using simple, repetitive rhythmic phrases. Angas men of West Africa blow 14 large buffalo horns as they perform the repetitive step pattern of the Rumada dance in a circle, following the line or moving in and out of the centre. Neighbouring Chip men perform a light run, playing flutes of four different pitches that combine to form a rhythmic melody. At the end of each phrase the dancers turn toward the centre of their circle to perform a climax of light hopping movements as they play. In many styles of circle dance the music is divided into a number of separate sections, each with its own distinct rhythm and related dance pattern, as in the Lmele le dag Chun dance of the Birom girls of the Jos Plateau.

The Igbo dance to a complex of sophisticated rhythms. In the Ubi-Ogazu dance, a version of the popular Atilogwu performed by a boys' team, the adult leader dances while playing a small flute to lead the rhythm. He is supported by a single-membrane drum, a pot drum, two simple xylophones, and a bamboo gong. The dance has at least 10 variations, each with a distinct rhythm dictating its own movement pattern. As in most African dances, the rhythm gives the name to the dance steps: in the Ikpo Okme, the performers hop from one foot to the other; for Ebenebe, a stamping pattern leads into a cartwheel; Iza requires an upright carriage with high kicks; Nkpopi is a leaping dance; Etukwa requires the torso to be inclined to the earth as the feet drum a staccato beat; Nzaukwu Nabi is a stamping step with sudden pauses.

In the Ubi-Ogazu ("Guinea Fowl"; named for the bird that inspired a hunter to create the dance), the performers hold bird-topped, carved staves for an initial dance in which they execute birdlike hops in a circle. They then drop the staves in favour of horse-tail switches held in both hands as they form two lines facing each other for the main performance. The performers wear brief skirts with girdles of brass bells and seedpod rattles around their ankles to accentuate their movements. The regular introduction of new themes calls for innovation in the dance rhythms. The girls' and women's teams use a more flowing quality of movement that elaborates the intertwining rhythms played by an ensemble or sung by a choir at varying tempos.

While months of practice are required before an Igbo dance team is permitted by the elders to perform on a public occasion, a Yoruba dancer may develop new patterns within the dance style during performance. The Yoruba Apala dance allows individuals to move on a free-flow floor pattern. Each dancer competes with his fellows in the interpretation of the rhythm and in his swift response to change. The leading drummer leaves the ensemble to join an outstanding dancer in a rhythmic exchange in which he praises and urges him into yet greater feats of invention, the drum's tones speaking recognizable proverbs from the tonal Yoruba language. The dancer performs a variety of subtle foot patterns leading into turns, kicks, or small, neat jumps. He flourishes his horse-tail switch and swirls or holds his flowing robe as he continuously alters his tempo at the dictates of the drum.

The Swange is a form of urban recreational dance among the Tiv in which men and women dance together. This dance uses the circle formation familiar in village dances and adapts traditional musical themes to highlife rhythms played on a combination of Tiv and Hausa instruments. The climax of the evening is provided by a solo dancer who improvises freely, using movements from many styles of Tiv dance in a rhythmic dialogue with the lead drummer.

Change and tradition. Scholars studying the emergence of new styles of dance in Africa have distinguished three related forms: traditional, neo-traditional, and contemporary. The last two categories have become increasingly evident as the result of radical social changes since World War II.

Changes in traditional dance styles within a village usually occur gradually, under the creative leadership of master dancers. But major social changes in the community, such as the introduction of formal primary education,

Instru-
mental
accompani-
ment

radically alter the pattern of life—including children's attitudes toward their dances, which they no longer have time to learn in the inherited manner. Modern transport and communication bring together people of diverse cultures, resulting in cross-cultural influences on dance performance. The spread of transistor radios in villages has caused young people to turn to new styles of dance, with an accent on entertainment. When a master dancer dies, there is often no one to replace him, but the changing patterns of life stimulate creative individuals to build new expressive patterns.

An example of change can be seen in the Sogoni Koun masquerade dancers of the Dogon in Mali, who carry a wide range of carved wooden masks, some surmounted by geometric shapes up to 12 feet high. The masks are so lightly constructed that they do not hamper the vigorous dances of the carriers as they bend to touch the earth, traditionally to honour the dead during funeral rites. According to one theory, the geographic isolation of the Dogon protected the masking societies from changes affecting other Malian cultures, until the introduction of a cash economy forced the young men who carried the masks to migrate to labour markets. They returned with urban tastes and habits, altering the social pattern on which the masking traditions were based. The traditions were further threatened by the spread of Islām.

In the 1930s the establishment of the Malian Tourist Office created a new role for the dancers as entertainers for colonial officers. This later developed into regular paid performances for tourists visiting the villages. Dance leaders tailored performances to run for a limited time, using a performing area unrelated to the funeral rites and therefore necessitating a different pattern of movement and positioning of performers. The dances stressed spectacular movements but lost the social purpose that had infused them with dramatic vitality. The masks are now decorated with commercial paints and the dancers concerned with commercial reward. As members of the Malian National Folk Lore Troupe, they gain prestige as ambassadors for their country at international festivals. Radical changes continue as dancers travel to work in urban centres, where Western forms of entertainment on radio, film, and television have become part of life.

A major catalyst of change is the staging of civic arts festivals organized by government ministries to promote the traditional arts as a means of enhancing national unity. Cultural officers visit villages and hold competitions to select the best dancers to compete against performers of other styles within their own culture. The winners are then taken to urban centres to compete with dancers from other cultures. If successful, they proceed to the capital to compete at the national level for prestigious trophies.

When a village dance is taken out of its original context to be performed for an audience whose members regard it purely as entertainment or as a taste of exotic culture, however, the motivation of the dancers changes radically. The dance's original purpose is replaced by the pursuit of financial gain and prestige. Cultural officers rearrange the performances by stipulating their duration and by concentrating spectacular movements from a number of dances into a single performance. Costumes are changed to suit the occasion or express national sentiment. Exits, entrances, and floor patterns are altered to accommodate the design of a modern stage. In this way, the original social purpose of the dance as understood by an acculturated audience is destroyed, and a style of neo-traditional dance emerges.

Ritual dances are usually unsuccessful at national festivals. The performance of a priest, whose dance movements are part of a ritual context, loses the vitality that is dependent on response from members of his own culture. On the other hand, the highly organized dance teams of the Tiv are accustomed to performing on a variety of social occasions within their village tradition. Their well-established discipline of rehearsal makes the transition to a modern stage possible and has had spectacular results.

Thus, some cultures, particularly the more egalitarian, welcome new experiences and can adjust to fresh challenges—though, with continuous repetition for predomi-

nantly commercial motives, even spectacular dances like the Igbo Atilogwu or the Zulu war dance can become hackneyed and faded. Other cultures are more conservative toward change, particularly those whose way of life is based on highly structured, hierarchical social and ritual patterns. (P.H.)

Architecture

Compared with the immense literature on African art, particularly sculpture, published since 1920, remarkably little attention has been paid to indigenous African architecture. Of the buildings of the continent south of the Sahara, only the ruins of Great Zimbabwe are widely known. This complex of stone enclosures, particularly those popularly termed the elliptical building and the acropolis, was built on sites established as early as the 3rd century AD. The first Shona phase of building was probably begun six centuries later, continuing until the 15th century when, under the Mwene Matapa, or "Ravager of Nations," in this gold-bearing district, Zimbabwe reached its peak.

Important though Great Zimbabwe is, in many ways it is not representative of African architecture. First, it is built of stone. As an archaeological site, it has a massive defensive wall and, included in the elliptical building, a conical tower of unknown purpose. It is also monumental in scale, having functioned as a royal citadel, and has become a national symbol. While some of these features can be found in other examples of African building, they are rare, and the emphasis on Zimbabwe has been at the expense of other architectural forms.

Arab and Berber architecture of Egypt and North Africa have had an impact on African architecture south of the Sahara. Similarly, the states of the Persian Gulf and the Red Sea have influenced architectural types in the Sudan, the Horn of Africa, and the coasts of Kenya and Tanzania, where the Muslim presence has also been strong. These influences are discussed below (see *Influences of Islām and Christianity*).

GEOGRAPHIC INFLUENCES

African architectural types reflect the interaction of environmental factors—such as natural resources, climate, and vegetation—with the economies and population densities of the continent's various regions. As the most durable of building materials, stone survives from the past, while other materials have succumbed to rain, rot, or termites. Stone-walled kraals from early Sotho and Tswana settlements (Transvaal; Botswana), and stone-lined pit circles with sunken kraals for pygmy cattle (Zimbabwe), have been the subject of archaeological study. Stone-corbeled shelters and circular huts with thatched roofs have also been recorded in the 20th century among the southern Sotho. Rectangular and circular stone farmhouses, unusual in being two-story, have been built by the Tigre of Ethiopia for centuries, while in Niger the sedentary Tuareg build square houses in stone.

Such exceptions apart, the overwhelming majority of Africa's 5,000 peoples build in grasses, wood, and clay. Constructions tend to be light, with much of the material for building transportable. Owing to the impermanence of many of these materials, the dwellings, though based on forms many centuries old, are of relatively recent date. Where vegetation is largely confined to thin grazing, peoples are often nomadic, using animal skins and woven hair for cover. In the veld and less-forested areas, grasses are used as building material as well, being employed widely for thatch and mat roof coverings. Hardwoods in the forest regions are used for building, though bamboo and raffia palm are also often used. Earth and clay constitute a major building resource, the characteristic soils of much of Africa being semidesert chestnut earths and laterites (reddish residuals of rock decay), which are often low in fertility but easily compacted. Earth-sheltered housing is made by the Iraqw of Tanzania, and a number of peoples in Mali and Burkina Faso have partly sunken dwellings. In general, however, Africans do not excavate.

Ecological and demographic factors play an important part in building design. Nomads are in decline, while

ZEFA

the prevalence of the tsetse fly limits the extent of pastoralism. Past migrations have had a profound effect on the dispersal of house types. Large African populations in cities have developed only in the 20th century, especially after the 1960s. Soil erosion and overgrazing, increasing pressure on land as a result of population growth, and the attractions of the city have all contributed to migratory movements.

Nomads and pastoralists. A hunting and gathering economy obliges the San (Bushmen) of the Kalahari Desert to move camp frequently. Some San *schermes* (shelters) may be little more than a depression in the ground, but groups such as the /Kung build light-framed shelters of sticks and saplings covered with grass. Other hunter-gatherers, such as the Hadza of Tanzania, live amid relative plenty; their dry savanna territory has a wide range of game animals. Their domed huts of tied branches may be given a thick thatch in winter. Some forest dwellers, such as the Mbuti Pygmies of the Ituri Forest, Zaire, are also hunter-gatherers. Their similarly constructed temporary shelters are interlaced with crossed sticks, over which *mongongo* leaves are layered.

Pastoral nomads follow defined routes, which reduces the risk of overgrazing and enables them to contact other nomadic groups. Camel nomads such as the Kababish of the central Sudan use the traditional Bedouin tent, which consists of a rectangular membrane of strips of woven camel hair that is strained on webbing straps and secured with guys over a rectangle of poles. A central row of four poles supporting curved ridge pieces reduces the possibility of damage to the tent. In Niger the Tuareg of the desert use a tent of superficially similar form, though the strips are made of goat skins sewn together. As many as 40 skins are required to complete a tent membrane. Farther south, Tuareg subgroups employ a structure similar to that used by many camel nomads, such as the Afar, from as far away as Ethiopia. Common to these people is the use of the pole frame in the form of a humped dome over which woven mats of grass or palm fronds are secured. Dum palm leaves are split by the Galla of Somalia, the women of which weave strips of coloured cloth into the mat, the patterned side being laid over the frame so as to be visible within the tent, while the shaggy, rough fibres are exposed like thatch on the outside.

The cattle pastoralists of southern and East Africa may settle for some years in one location. The Masai of Kenya and Tanzania construct an oblong, or sometimes square, low-domed hut some six metres long and at shoulder height from closely woven frames of thin *leleshwa* sticks and saplings. Arranged in a circle around the cattle en-

sure, or manyatta, the frames are packed with leaves and plastered over with cattle dung, which acts as a deterrent to termites. The huts are aerodynamically proof against high winds, and the manyatta thicket boundary acts as a defensive barrier. A number of other tribes use a similar structure; the Barabaig of Tanzania, for example, build thornbush enclosures in the form of a figure eight, with one loop used as a kraal for the cattle, and the other lined with huts with flat roof frames.

In southern Africa, frame domes are constructed by the Zulu, Swazi, and, in Natal, the Nguni using concentric hoops. Others make a ring of poles inserted into the ground and brought together in a crest, either as a continuous curve (early Xhosa) or to a point (Sotho). These structures are expertly thatched, the Zulu domes, or *indlu*, having finely detailed entrances. Some Nguni types have layers of mats beneath for insulation, the covering thatch being brought to a decorative finial and the whole held down with a grass rope net to withstand strong winds.

Savanna kraals and compounds. Later houses of the Xhosa have tended toward a consistent form, the rondavel, or cylindrical, single-cell house with conical thatched roof. This type is prevalent throughout southern Africa. Variants in the region include a low plinth or curb supporting a domed roof (some Swazi, Zulu), flattened domes or low-pitched cones on head-height cylinders, and high, conical roofs. The methods of construction also vary, though a common method is a wall with a ring of posts and infilling of wattles or basket weave packed and plastered with mud. Rings of posts may have packed earth infilling, and in more wooded regions walls may consist mainly of timber posts. Some southern peoples, including the Venda of the Transvaal and the Tswana of Botswana, build veranda houses, with deep, thatched eaves supported by an outer ring of posts. Traditionally the units are single-cell and undivided and are illuminated only from the doorway. Additional living space may be claimed from the exterior, with a semipublic space to the fore, and a private space, with hard-packed earthen floor, to the rear of the dwelling being used for food preparation, cooking, and domestic occupations. Both spaces are bounded by a low wall. In many areas houses are dispersed, but in others the kraal, with huts ranged around the perimeter of a large cattle enclosure (as among the Ba-Ila of Zambia), serves a defensive function against raiders and predators. In South West Africa/Namibia the kraal of the Ambo people had an outer concentric ring leading to cattle pens, an inner fenced meeting place, and subdivisions for wives', visitors', and headman's quarters.

Similar houses are constructed in the East African lakes

of the
savanna

region, where the form probably originated. Houses of considerable size are built by some Luo (near Lake Victoria) and Kuria (Tanzania) people, the former making extensive use of papyrus reeds from lake borders, using the thicker stems structurally and the leaves for thatching material. Luo homesteads are frequently ringed with hedges within which cattle are penned; fields extend beyond for the growing of cereals. Most of these Central African peoples construct granaries, often basket-shaped and basket-woven, raised on stilts to keep away rodents, and beneath a thatched roof to keep them dry. Veranda houses are also built, and secondary thatched roof crests permitting ventilation and the escape of smoke are not uncommon.

Cylindrical houses are built by the majority of peoples in the savanna and semidesert regions of the Sudan and West Africa. With less wood available, these are often constructed of mud in a coil pottery technique. It is customary to lay the mud spirally in "lifts" of approximately half a metre, allowing each lift to dry before adding the next. Among the Matakam of Cameroon, conical roofs are covered with thatch or woven mats, often terminating in decorative finials (see Figure 10). Many houses, as among the Sudanese Nuba, have molded doorways shaped to accept the shoulders.

Figure 10: Thatch-covered conical roofs of cylindrical houses in a Matakam compound, Cameroon.

Layout
of the
compound

The characteristic settlement form in West Africa is the compound, a cluster of units linked by walls. Many compounds are circular in plan, but others, conditioned sometimes by the uneven terrain, are more complex. Earthen wall and floor surfaces are plastered smooth and dried to a rocklike hardness. These surfaces are often decorated with coloured clays (as done, for example, by the Bobo in Burkina Faso) and, in some instances, sculpted with ancestral motifs (as the Kassena do in Burkina Faso). Flat roofs with parapets are also built, sometimes in the same compound, supported either independently by a log frame of forked posts and crossmembers or by joists inserted into the clay walls; hollowed half-log gargoyles throw off water during seasonal rains. Dwelling huts, granaries and other stores, and pens for goats and fowl are built within the same compound.

Dwellings of approximately rectangular plan, though often with curved and molded corners, are also found among the cylindrical units, and some peoples, such as the Lobi of Côte d'Ivoire, build compounds with straight walls. Throughout the western savanna region the trend has been toward rectangular-plan houses, largely owing to

Islamic influence from the north (see below *Influences of Islam and Christianity*) and to contact with rain forest peoples from the south.

Forest dwellings. To the south of the savanna is a thinly populated strip, possibly depleted by the slave trade, beyond which lie the rain forests. These regions, especially in Nigeria, are among the most densely populated parts of sub-Saharan Africa and have had contact with European traders since the 16th century. The rectangular-plan houses of the Akan peoples, including those of the Ashanti in Ghana, date from before this, but they may have replaced an earlier savanna form. Until the 20th century Ashanti houses were mainly of pole frames with mud infilling. Frequently they were finely decorated, in mud molded over grass armature, with spiral motifs of a symbolic significance akin to those found on weights used for measuring gold. Today, however, the Ashanti house is constructed of "swish," or *pisé de terre* (earth rammed into a wooden formwork), raised in lifts. The pitched or hipped roof is covered in thatch or, more frequently, with corrugated iron. Though the materials have changed, the basic form remains in the village compounds: four independently constructed, rectangular-plan huts forming the sides of a courtyard. Yorubā compounds in Nigeria are somewhat similar, but the four sides are often under one continuous roof. Rain is collected from the roofs, so that the plan has frequently been compared with the Roman impluvium house. Farther south in Nigeria, the Igbo and related peoples traditionally built rectangular houses, often with open fronts facing a courtyard and surrounded by enclosing mud walls. Similar rectangular buildings with thatched, hipped roofs are used by other rain forest peoples, including some groups of the Fon in Benin and the Baule and Dan of Côte d'Ivoire. But in regions where widely dispersed peoples, such as the Senufo of Côte d'Ivoire, border the savanna, cylinder-and-cone houses with deep thatched eaves are common.

Closer to the coast of West Africa, some peoples build houses raised on stilts; the most notable are those built in the lakeside village of Ganvié in Benin. The buildings are constructed of mangrove poles, a material also used by coastal Swahili-speaking people in Kenya. In some coastal regions, such as that occupied by the Duala in Cameroon, houses are of bamboo, though they are mud-plastered. Bamboo, which grows to heights of over 15 metres in Angola, Congo, and parts of Central Africa, is used by many peoples as a building material. Its straight stalks, used as screen walls, are lashed with thin wood strips to produce crisp, rectangular houses with peaked, thatched roofs, as among the Nyakyusa of Tanzania. Bamboo construction reached its apogee in the tall houses of the Bamileke and other peoples of western Cameroon, who constructed steep, prefabricated pyramidal roofs raised on platforms with verandas; the whole structure frequently reached 10 metres or more, with male and female ancestor figures often flanking the doors (see Figure 11). Tall, conical houses, made of bamboo poles joined at the crest and then leaf-thatched, were built by the Ngelima and the Panga of Zaïre.

Raffia palm is also used by the Bamileke and the neighbouring Bafut and is an important material among the Kongo of Angola and the Bushongo of Zaïre. The most impressive of these structures are the rectangular, pitched-roofed meeting halls of the Mangbetu in Zaïre; their houses are of the cylinder-and-cone type, mud-plastered and geometrically decorated. Large meeting houses are found in Nigeria among the Yakō and other peoples. On special occasions pole-frame shelters are constructed with monopitch roofs loosely covered with grass or palm fronds. Awnings are also used, and among the Ashanti immense umbrellas shade dignitaries and members of royal families.

PALACES AND SHRINES

In the 19th century the earth-and-stone palace of the Asantehene (divine king) of the Ashanti empire at the capital city of Kumasi covered some five acres. It had many courtyards with verandas and open screens and more than 60 rooms with steep, thatched roofs. However, little of the palace survived the Ashanti wars and a punitive ex-

pedition by the British in 1874. More extensive was the great palace of the *oba* of Benin City, Nigeria. In the 16th and 17th centuries it was as large as a European town, with many courts surrounded by galleried buildings, their pillars encased in bronze plaques. Roofs were shingled, and there were numerous high towers topped with bronze birds. Benin City was burned by the British in 1897. The Yoruba of western Nigeria are also an urban people. Their towns traditionally have as their centre the *afin* (palace) of the *oba*, from which radiate broad roads dividing the town into quarters, each with its compound of a subordinate chief. Some *afins* in the precolonial era were of great size, encompassing much of the surrounding bush; that at Oyo, the capital of the Oyo empire (17th and 18th centuries), was reported to cover 260 hectares (640 acres). The palace buildings were substantially built, and the open verandas were supported by carved caryatid pillars. Yoruba towns still have *oba*'s palaces; though the architecture of many is Westernized, the traditional courtyards, recreation grounds, and high surrounding walls persist.

The *zimbabwes* ("stone houses") built in the 17th and

18th centuries by the Rozwi kings of southern Central Africa were royal kraals, an example being the citadel of Chief Changamire at Khami, modern Zimbabwe. Ruins at Regina, Nalatali, and Dhlodhlo (also in Zimbabwe) all display fine mortarless stonemasonry worked with chevron patterns and banded colours. Many African palaces were larger and often better crafted versions of the traditional dwelling type, raised on hillocks or plinths. Such were the palaces of the kabaka (king) of the kingdom of Buganda, including the great barnlike thatched dome with an open reception veranda at Mengo, near present-day Kampala, Uganda. Other palaces were royal compounds, such as that of the *fon* (chief) of Bafut, Cameroon, which within a high fenced enclosure comprised separate quarters for the older and younger wives, dormitories for the adolescent sons, houses for retainers, stores, meeting places, a shrine house and medicine house, burial huts for former chiefs, and huts for secret societies.

While many African peoples have or have had kings, not all have resided in palaces and not all have been divine. Some peoples have no recognized chiefs or leaders at all. Religion, however, plays an essential part in the life of all African societies. Among some, such as the Fali of Cameroon or the Nankani of Burkina Faso, spiritual symbolism informs every part of their dwelling types. Among the most-studied peoples in this respect are the Dogon who live on the rockfall of the Bandiagara escarpment in Mali. The Dogon perceive each dwelling compound anthropomorphically as a man on his side in the act of procreation. The man's head is associated with the hearth, the stores with his arms, the stables with his legs, the central workroom with his belly, and the grinding stones with his genitalia. From the individual parts of the house to the entire village plan, each element has a religiously symbolic association, and totemic sanctuaries with markedly zoomorphic form are built and dedicated to the ancestors of the living.

Monumental temple architecture is virtually nonexistent in Africa, for in animist religions spirits may reside in trees, carved figures, or small, simple shrines. Cult houses and shrine rooms containing votive objects and dedicated to spirits or ancestors are common, though, like the fetish house of the Ashanti, with its rooms for orchestra and officiating priest, these may be similar to the dwelling compound. A more notable structure is the elaborate *mbari* house of the Owerri Igbo of Nigeria. A large open-sided shelter, square in plan, it houses many life-sized, painted figures sculpted in mud and intended to placate the figure of Ala, the earth goddess, who is supported by other deities of thunder and water. The remaining witty sculptures are of craftsmen, officials, Europeans, animals, and imaginary beasts. Because the process of building is regarded as a sacred act, *mbari* houses, which take years to build, are left to decay, new ones being constructed

rather than old ones maintained. This cycle encourages the continuance of a lively tradition.

INFLUENCES OF ISLĀM AND CHRISTIANITY

Early civilizations in the western Sudan region had strong trading links across the Sahara, and an Islāmic presence south of the desert was established 1,000 years ago. In the 11th century, Kumbi, the capital of the kingdom of Ghana (actually in present-day Mali), was described as having a dozen mosques. Subsequently the kingdoms of Mali and Songhai superseded ancient Ghana, with Timbuktu and Gao on the Niger River becoming major centres of learning and commerce. Excavations have revealed that these

towns were large, prosperous, and well constructed. Muslim builders introduced a type of dwelling reflecting their Arab and North African traditions: rectilinear in plan, flat-roofed, and often two stories or more in height, these dwellings were built of sun-dried mud brick or of mud and stone. By the 16th century this form had penetrated the Nigerian savanna with the establishment of the Hausa states. Kano, Katsina, Sokoto, and Zaria today present an appearance probably comparable with that of earlier centuries, but with the former cylindrical huts replaced by those of square plan, reflecting the changing size of families (see Figure 13). New houses are built from *ta-bali*, or pear-shaped mud bricks, and the large palaces of the *amīrs* (emirs) are often richly decorated within, with spaces spanned by palm ribs.

Prominent in many West African towns are the mosques, which frequently display a formal conjunction between Islāmic structure and indigenous conical ancestral pillars and shrines. The earliest surviving of these is probably the ziggurat at Gao, but more typical of the savanna form are the mosques, bristling with wood reinforcement, of Agadez (Niger) and Djénné (Mali) and the great mosque at Mopti (Mali), which was greatly restored under the French administration.

On the east coast of Africa, Islāmic influence began with the establishment of the *dhow* trade, which, relying on the trade winds, linked East Africa with the Arabian and Persian Gulf ports, and with India. Kilwa, an island port that flourished between the 12th and 15th centuries, was built largely of stone, as were Zanzibar (where the mosque at Kizimkazi has a 12th-century inscription), Dar es Salaam, Malindi, Mombasa, and other ports and city-states built by Swahili- and Arabic-speaking traders along the Tanzanian and Kenyan coast. With the coming of the Portuguese at the close of the 15th century, the east coast towns were plundered and burned. Only the northerly island port of Lamu, Kenya, retains the character of the Swahili town. Built of coral rag stone, roofed with mangrove poles, and covered with rag and lime mortar, the houses have fine plasterwork, decorative rows of niches, and deeply carved doors.

Until the late 19th century, Christian influence on African architecture was minimal, with the remarkable exception of the rock churches of Lalibela, Ethiopia. Following the Islāmization of Egypt, the Ethiopian church was isolated for many centuries, but, during the reign of the ascetic Zagwe king Lalibela in the 13th century, 11 churches were carved out of the red tufa, including the cruciform Church of St. George excavated out of bedrock. Some of the churches, among them St. Mary and St. Mercurius, were richly painted with biblical murals. Throughout the

Tigre region of Ethiopia, there are many other rock-carved and cave churches, such as those at Cherkos, Wik'ro, Abraha Azba, and the great mountain monastery at Debre Damo Debir.

CHANGE IN THE 20TH CENTURY

Churches built by Christian missionaries, sometimes with imported stone, generally followed modified Gothic forms and had no impact on African building, but the growth of colonial towns encouraged the adoption of European styles, including the use of the rectangular-plan house. This trend was reinforced by the infiltration into the hinterland of the indigenous Swahili-style house in East Africa, the rain forest house type in West Africa, and the Islamic house type of North African origin in the western Sudan—all of which have rectangular plans. Though the effect has been to reduce the variety of house forms and to regimentalize settlement patterns, the trend has not been without interesting hybrids. In particular, the decorated *lapa* (courtyard) walls and facades of the southern African Sotho, Pedi, and Ndebele, with their ziggurat details, have a colourful vitality (see Figure 14). Elsewhere, in Laputo, in Mozambique, and in Johannesburg, owner-built houses and resettlement townships have been erected, extended, or decorated, often with originality, within the limitations of economy and space.

With the westernizing of African cities, much indigenous architecture has been lost, though not necessarily in street life or surface enrichment. Two- and three-story houses and shops have become commonplace with the use of reinforced concrete and steel frame construction. Since World War II, a number of African architects have gained prominence, including Oluwole Olumuyiwa of Nigeria and David Mutiso of Kenya. Their work is immaculately designed and responsive to climate and environment, but it is firmly in the modernist International Style.

While these and other African architects have shown themselves to be effective designers of major buildings in the urban centres, the greatest challenge to African designers lies in the burgeoning suburbs of African cities. Unserviced, unsanitary, and often in locations subject to disease and flood, the squatter settlements of, for example, Lagos, Nigeria, or Lusaka, Zambia, underline the importance of economical housing that is responsive to the diversity of cultural needs in urban contexts. It is here that the African genius for building unpretentious, functional, and environmentally appropriate housing from indigenous resources can make its most important contribution to the future of its architecture. (P.O.)

Sculpture and associated arts

Although wood is the best-known medium of African sculpture, many others are employed: copper alloys, iron, ivory, pottery, unfired clay, and, infrequently, stone. Unfired clay is and probably always was the most widely used medium in the whole continent, but, partly because it is so fragile and therefore difficult to collect, it has been largely ignored in the literature. Small figurines of fired clay were excavated in a mound at Daima near Lake Chad in levels dating from the 5th century BC or earlier, while others were found in Zimbabwe in deposits of the later part of the 1st millennium AD. These imply an even earlier stage of unfired clay modeling. About the time of these lower levels at Daima (which represent a Neolithic, or New Stone Age, pastoral economy), there was flourishing farther to the west the fully Iron Age Nok culture, producing large, hollow sculptures in well-fired pottery, some of the stylistic features of which imply yet earlier prototypes in wood.

Copper-alloy castings using the *cire perdue* technique afford evidence of great sculptural achievements from as early as the 9th century AD, when the smiths of Igbo Ukwu, Nigeria, were casting leaded bronze, which is highly ductile, and smithing copper, which is not (see Figure 23). Some three or four centuries later the smiths of Ife, seemingly unaware that unalloyed copper was not suitable for casting (or perhaps wishing to demonstrate their virtuosity), used it to produce masterpieces such as the seated

figure in a shrine at Tada and the so-called Obalufon mask in the Ife Museum. In fact, however, zinc brasses were used more than unalloyed copper. The largest corpus of this work is from Benin, where zinc brasses were used almost exclusively. These copper-alloy castings, together with pottery sculptures the traceable history of which goes back even further, are the main evidence for the early history of sculpture in sub-Saharan Africa.

Wrought-iron sculptures are found in a number of traditions, mostly in West Africa, including the Dogon, Bambara, Fon, and Yoruba peoples.

Stone sculpture occurs in several separate centres, employing both hard and soft rock, but there is usually not much evidence of a development through time in a single place. Ivory is a highly prized medium in many parts of Africa. Its fine texture makes it suitable for delicate sculpture, while its rarity leads to its employment in many societies for items of great prestige.

African wood sculptures are carved with similar tools throughout the continent. An *ax* may be used to fell the tree, but an *adz*, with its cutting edge at right angles to the shaft, is used for the substantive work of carving. The skill achieved with this tool is astonishing to the Western observer. Thin shavings can be removed with speed and accuracy, creating a surface (especially when the form is convex) that shows slight facets that catch the light and add to the visual interest. More intricate work is done with knives. A pointed iron rod heated in the fire may be employed to bore holes in a mask for attachment to the costume and to permit the wearer to see. The surface of the sculpture is sometimes polished with the side of a knife or sanded down with rough leaves. Details are commonly picked out by a method involving charring with a red-hot knife (as among the Ibibio of Nigeria), or the carving is immersed in mud to darken its surface before oiling (as among the Dan people of Côte d'Ivoire).

WEST AFRICA

Scholars divide the visual arts of West Africa into three broad areas: the western Sudan, the Guinea Coast, and Nigeria. This is done partly to enable the outsider to comprehend the diversity of styles and traditions within the region, while recognizing that there are themes common to all of the areas.

Western Sudan. This is the name conventionally given to the savanna region of West Africa. It is an area dominated by Islamic states situated at the southern ends of the trans-Saharan trade routes. The sculpture here is characterized by schematic styles of representation. Some commentators have interpreted these styles as an accommodation to the Islamic domination of the area, but this is probably not an adequate explanation since Islam in West Africa has either merely tolerated or actually destroyed such traditions while exerting other influences.

Among the better-known sculptural traditions of the western Sudan are those of the following peoples.

Dogon and Tellem. The Dogon inhabit the Bandiagara escarpment in Mali. Dogon sculpture is intimately linked with the cult of the ancestors. Figures are made to house the spirits of the deceased on the family shrine, and masks are used to drive the spirits away at the end of the mourning period. One type of mask, called *sirige*, has a tall, flat projection above the face (a feature found also in the masks of the neighbouring Mossi and Bobo), which is said to represent a multistory house. The Great Mask, never worn and made anew every 60 years, represents the primordial ancestor who met death while he was in the form of a serpent. Iron staffs topped with human figures are also made, and some personal ornaments are cast in brass.

Also found in Dogon territory are, possibly, the oldest wood sculptures to survive (three have been dated by carbon-14 to the 15th to 17th century AD). They were found in caves in the Bandiagara escarpment. The Dogon attribute them to an earlier population, the Tellem. These figures, usually of simplified and elongated form, often with hands raised, seem to be the prototype of the ancestor figures that the Dogon carve on the doors and locks of their houses and granaries; investigations have confirmed that the Tellem were ethnically a different people from the

Bambara
masks

Dogon, though the art style appears to have been handed on from one people to the other.

Bambara. The Bambara live in the region around Bamako, the capital of Mali. Their traditions include six male societies, each with its own type of mask. The Ntomo is for young boys before circumcision. Their masks have a line of vertical projections placed transversely over the human face, representing man as God first created him. The Komo is the custodian of tradition and is concerned with all aspects of community life—agriculture, judicial processes, and passage rites. Its masks are of elongated animal form decorated with actual horns of antelope, quills of porcupine, bird skulls, and other objects. Masks of the Kono, which enforces civic morality, are also elongated and encrusted with sacrificial material. The Tyiwara uses a headdress representing, in the form of an antelope, the mythical being who taught men how to farm (see Figure 15). The Kore, concerned with the sky and with the bringing of rain to make the crops grow, employs masks representing the hyena, lion, monkey, antelope, and horse. In addition there are masks of the Nama, which protect against sorcerers. Ancestor figures of the Bambara clearly derive from the same artistic tradition as do many of those of the Dogon; so also do their sculptures in wrought iron. Rectangular intersection of flat planes is a stylistic feature common to Bambara and Dogon sculpture.

These headdresses, attached to a wickerwork cap, are worn by farmers who, at the time of planting and harvest, dance in imitation of leaping antelope. In the National Museum, Copenhagen. Height 50 cm.

Djénné-Mopti. These are two towns situated on the inland delta of the Niger River, Mali. They are notable as centres of the cloth trade and for their architecture. Moreover, in their immediate vicinity many sculptures in pottery of uncertain age have been found. They may have some association with the empires of Ghana and Mali (7th–13th and 13th–16th centuries, respectively). For all their extensive trade contacts across the Sahara, these medieval empires did not significantly change the basic structure of society in the western Sudan.

Senufo. The Senufo of northern Côte d'Ivoire produce a rich variety of sculptures, mainly associated with the Lo society (known more widely as the Poro), to which all

adult men belong and which maintains the continuity of religious and historical traditions, especially through the cult of the ancestors. During initiations, headpieces are worn that have a flat, vertical, round or rectangular board on top, decorated with paint or pierced work. Many wood carvings of male figures depict these headpieces, sometimes on rhythm pounders used by young initiates, who beat the earth to call upon the ancestors to take part in the ceremony and purify the earth. Several types of mask are used. The *kpelie*, a human face with projections all around, is said to remind initiates of human imperfection. Animal-head masks usually combine characteristics of several creatures—hyena, warthog, and antelope. A type of animal mask called *waniugo* has a cup for a magical substance on top; these masks blow sparks from their muzzles in a nighttime ritual protecting the village from sorcerers. Among the Naffara group of the Senufo, masks of similar form but with an interior cavity too small for a human head are carried on the top corner of a rectangular, tent-like costume called *kagba*. This mask is the symbol of the Lo, which only initiates may see. In the Korhogo region, *deguele* masks appear in pairs at funerals. They are of plain helmet shapes topped with figures whose bodies are carved to resemble a pile of rings. Figures of the hornbill are used in initiation, and groups of birds on a pole are trophies for the best farmer. Figures of male and female twins and of horsemen are used in divination. These represent the spirit familiars enabling the divination process. The diviners themselves are women, forming the Sandogo society. Shrine doors and drums are carved in relief, and small figures and ritual rings are cast in bronze. For many years the Senufo have been producing large quantities of carvings for the Western market.

Guinea Coast. This is the forested region of West Africa, where Islām was not a dominant influence until recent years. Political organizations in the past tended to be small in scale, with government sometimes in the hands of chiefs, sometimes by assemblies of men, sometimes by secret associations manifesting their attributes in masquerade ceremonies. State systems developed toward the eastern end of the region, particularly in areas inhabited by the Ashanti (in present-day Ghana) and Fon (Benin) and in the Yoruba Oyo empire and the Edo kingdom of Benin (Nigeria). These states capitalized on trade both with peoples of the savanna and, from the late 15th century onward, with Europeans.

Guinea Coast sculpture displays a greater tendency to naturalistic styles of representation. Some of the best-known traditions of the area are the following.

Bidyogo. In the Bijagós Islands of Guinea-Bissau, the Bidyogo carve rather simplified human figures seated on stools, bowls supported by human figures with human and animal forms on the lids, and staffs with figures on them. They also carve naturalistic masks of wild bulls, which are carried on the prow of the royal war canoe and also used in dances. Their buildings are round and often painted.

Baga. The Baga, 15th- or 16th-century migrants from the Sudan now occupying the coastal region of Guinea, carve *anok*, or *elek*, bird heads with human features styled in a manner resembling western Sudanic work. They had rich traditions of mask and figure sculpture, many of which were suppressed with the advent of Islām. The best known of these is the massive *dumba* mask (see Figure 16), with its great cantilevered head supported on the upper part of a female torso, carved so as to rest on the shoulders of the wearer, who sees out through a hole between the breasts, his body hidden in raffia fibre. This mask appears at the harvest and threshing of the rice crop. Tall drums supported by a human figure are also carved.

Mende. The Mende of Sierra Leone are best known for smooth, black, helmet-shaped masks (see Figure 17), representing the Sande society, which is responsible for initiating girls into womanhood. This is the only women's society on the continent known to use masks. Because the mask is "found" beside a stream deep in the forest, where the Sande spirit is said to live, and is supposed not to be an artifact at all, the carver in this case is anonymous. Members of the corresponding male society, Poro, also wear masks, although they are of differing form. The women's

Yasse, a divination and healing society, employs slender human figures called *minseré*. Large, ugly *gongoli* masks are also used, but entirely for entertainment. In preparing their rice farms, the Mende often uncover figures carved in soapstone and known as *nomoli*, which they set up in shelters to protect the crop. The figures are similar in style and are thought to be similar in date to ivories carved in the 16th century for Portuguese traders in the adjacent Sherbro area.

Dan-Ngere. The Dan-Ngere complex of styles is named after two extremes of stylistic variation: the smooth, restrained style of the Dan, De, and Diomande; and the grotesque style of the Ngere (or Guere), Wobe, Kran, and Bete, a less extreme form of which is found among the Kru and Grebo, who inhabit adjacent regions of Liberia, Guinea, and Côte d'Ivoire. A single carver will produce masks in both of the extreme modes of the range of style. Miniature, easily portable masks, representing and sharing in the power of the larger masks, protect the owner when he is away from home. The carvers also produce the large anthropomorphic rice ladles used by the mother of the heir apparent at the harvest feast; chiefs' staffs; and female figures that seem to be prestige items, as are small figures cast in brass among the Dan and Kpelle.

Ashanti and Baule. The Ashanti region of southern Ghana is a remnant of the Ashanti empire, which was founded in the early 17th century when, according to legend, a golden stool descended from heaven into the lap of the first king, Osei Tutu. The stool is believed to house the spirit of the Ashanti people in the same way that an individual's stool houses his spirit after death. The Ashanti also carve *akua-ba* (dolls with disk-shaped heads embodying their concept of beauty and carried by women who want to become pregnant) as well as staffs for royal spokesmen, which, like the handles of state swords, are covered in gold foil. The success of the Ashanti empire depended on the trade in gold not only with Europeans at the coast but also with the Muslim north. Gold dust was the currency, weighed against small brass weights that

were often geometric or were representations recalling well-known proverbs. Ashanti weavers developed a style of weaving of great technical mastery, incorporating imported silk (see Figure 18). Cast-brass ritual vessels, *kuduo*, used in funeral ceremonies, bear indications of Islamic inspiration. The Ashanti also cast fine gold jewelry, as do the Baule of Côte d'Ivoire, who separated from them in the mid-18th century.

Baule gold weights are similar to those of the Ashanti, but the Baule also have types of sculpture that none of the other Akan peoples possess: masks (which, like their low-relief doors, seem to indicate Senufo influence) and standing human figures, apparently sometimes used as ancestor figures. The figures and human masks, the latter reported to be portraits used in commemorating the dead, are elegant—well polished, with elaborate hairdressings and scarification. More roughly finished are the *gbekre* figures, representing minor divinities in human form with animal heads. Masks are made also to represent the spirits of the bush: antelope, bush cow, elephant, monkey, and leopard. Boxes for the mouse oracle (in which sticks are disturbed by a live mouse, to give the augury) are unique to the Baule, whose carvers also produce heddle pulleys, combs, hairpins, and gong mallets.

Fon. The Fon Kingdom of Dahomey, with its capital at Abomey (now in the People's Republic of Benin), was also founded in the early 17th century. The palace is decorated with painted relief panels modeled in clay, representing the different kings and the events of their reigns. The kings are represented also by iron staffs and messengers' staffs with openwork iron symbols on a wooden haft, as well as by a small number of large wooden statues combining human and animal attributes. The thrones of the kings are similar in form to Ashanti stools but are much taller and are preserved as cult objects. Small figures cast in brass, often in groups, are prestige items employed also to decorate the royal tombs. Brightly coloured appliqué cloth is used on state umbrellas and chiefs' caps. A popular art is calabash carving. The greatest achievements of Fon art, however, are the large sculptures for Gun, the god of iron and war, made from sheets of copper or iron (see Figure 19).

Nigeria. The northern and southern parts of Nigeria can be considered part of the western Sudan and Guinea Coast, respectively; but, because of the wealth of evidence for an artistic tradition of some 2,000 years, it is convenient to consider Nigeria separately.

Stylized
pottery
sculpture
of the Nok

Nok. The earliest known sculpture of large size in the Sudan is that produced in pottery by the Nok culture, which flourished extensively in northern Nigeria from the 5th century BC into the early centuries AD (see Figure 20). These people were the first known manufacturers of iron in western Africa, furnaces at Taruga having been dated between the 5th and early 3rd centuries BC; they continued, however, to use stone tools. Of well-fired clay, their sculptures represent animals naturalistically; human figures, however, are depicted with heads that are usually

By courtesy of the Musée de l'Homme, Paris

Figure 19: Fon iron image of Gun, the god of iron and war, Dahomey. In the Musée de l'Homme, Paris. Height 1.65 m.

tubular, but sometimes conical or spherical, and with simple tubular trunks and limbs. The art of Nok indicates the antiquity of many basic canons of West African sculpture, but the precise relationship between ancient and modern forms is obscure.

Daima and Sao. Not far from the Nok area but very different in style, at Daima near Lake Chad, small, simple clay animal figures were by the 6th century BC being made by a population of Neolithic herdsmen. A little later they began making animals with more extended legs, and sometime after AD 1000 they started to make animals covered with little spikes. The last are similar to examples found on sites of the Sao culture in the Chari Valley, Cameroon, where more elaborate human figure sculptures, thought to represent ancestors and probably spirits, have been found. Carbon-14 dates for these sites range from the 5th century BC to the 18th century AD.

Ife and Yoruba. The Yoruba peoples inhabit a large part of southwestern Nigeria. Their art traditions are of considerable antiquity. Excavations at Ife, in central Yorubaland (the site of the creation of the world in some Yoruba myths), have shown that naturalistic sculpture in brass and pottery was being produced sometime between 1100 and 1450 AD. The sculptures may represent royal figures and their attendants, and life-size portrait heads in brass were perhaps used as part of funerary effigies. During this time, Ife appears to have had widespread importance, and the naturalism of its art seems to have influenced the basic development of Yoruba sculptural style. Throughout Yorubaland, human figures (see Figure 21) are represented in a fundamentally naturalistic way, except for bulging eyes; flat, protruding, and usually parallel lips; and stylized ears. The evolution of these characteristics can be observed in a number of pottery sculptures at Ife, which, on stylistic grounds, are considered to be relatively late.

Frank Willett

Figure 20: Pottery head found at Nok, Nigeria. In the Jos Museum, Nigeria. Height 21 cm.

Within the basic canon of Yoruba sculpture, many local styles can be distinguished, down to the hand of the individual artist. Individual cults, too, have their own characteristic requirements of form and ethnography. Staffs for Shango, the thunder god, bear the symbol of a double ax. On his altars are placed carved mortars, for the pounding of food in a mortar sounds like thunder; on the wall behind hangs his leather bag, with a motif based on the extensive gesture of a Shango dancer. Because Shango was king of Oyo, largest of the Yoruba kingdoms, his cult is mainly restricted to areas that were once under Oyo domination.

Typical of Ekiti is the Epa cult, which is connected with both the ancestors and agriculture. The mask proper,

Figure 21: Brass figure of an *oni* (king) of Ife, Nigeria. In the Museum of Ife Antiquities, Nigeria. Height 46.7 cm.

Frank Willett

Mask of
the Epa
cult

roughly globular, has highly stylized features that vary little; but the superstructure, which may be four feet (122 centimetres) or more in height, is often of very great complexity—for example, a king on horseback, surrounded by two tiers of attendant warriors and musicians. The most widely distributed cult is of twins, *ibéji*, whose birth among the Yoruba is unusually frequent. Their effigies (Figure 22), made on the instructions of the oracle, are among the most numerous of all classes of African sculpture. Carved doors and house posts are found in shrines and palaces and in the houses of important men. Fulfilling purely secular functions are bowls for kola nuts, offered in welcoming a guest; *ayo* boards for the game, known also as *wari*, played with seeds or pebbles in two rows of cuplike depressions; and stools, spoons, combs, and heddle pulleys.

To the north is Esie, where about 800 sculptures in soapstone were found by the local Yoruba population some centuries ago. Their origin is obscure; they are by no means certainly Yoruba. The city of Owo, to the southeast of Yorubaland near the frontier with the Edo-speaking peoples, developed an art style—indeed, a whole culture—that is a blend of Yoruba and Benin traditions. Ivory carving is especially important, and wooden heads of rams and of humans with rams' horns are used on ancestral altars. Second-burial effigies, life-size and naturalistically carved in wood, have been made during the 20th century but were developed from wickerwork forms such as are still used in Benin and in Igbo towns that were formerly under Benin influence. Excavations in 1971 revealed a large number of pottery sculptures that are clearly related to those of Ife but with some Benin features. The site was dated by carbon-14 to about the 15th century AD.

Edo peoples. According to tradition, the Kingdom of Benin was founded from Ife, whence, in the late 14th century, knowledge of brass casting may have been introduced into Benin City for the manufacture of commemorative heads for royal altars. These heads have been grouped in stylistic sequence from moderate naturalism through increasing stylization. The brasses also include figures in the round, groups on a common base, and plaques. The rectangular shape of the plaques, their narrative content, and in some cases their attempt at perspective have been attributed to the influence of illustrations in books carried by the Portuguese, who were in contact with Benin from

the late 15th century. The technique of brass casting, however, had been introduced at least a century earlier. Bronze bars had been imported, probably from the interior, as early as the 13th century, but these were made into bracelets in Benin City only by smithing and chasing techniques, not by casting. There were certain limitations on the use of brass, and also ivory. Cult objects (such as memorial beads) were made of wood when intended for non-royal purposes but of brass for the king. Regalia, if made for the king, were of ivory, but otherwise of brass. The regalia of king and chiefs also included coral beads and red cloth, the colour red signifying a mystical threat to the enemies of the kingdom. Wood was used for staffs commemorating ancestors, and these were placed on their altars. Pottery heads were made for shrines in the brass casters' quarter; and life-size groups of royal figures in mud are still made for the cult of Olokun, divinity of the sea and of wealth.

Outside Benin City, the Edo peoples live in villages that have many localized cults of nearby topographical features and founder heroes. The *ekpo* masquerade, occurring to the south and east of Benin, is performed by the warrior age group in ceremonies to purify the village ritually and to maintain health. At Ughoton, to the southwest of Benin, a different type of mask is used, in the cult of the water spirit Igibile. Both the cult and the sculptural style seem to have derived from the Ijo.

A number of bronze castings found in Benin have been classified tentatively as the Lower Niger bronze industries. They include pieces from Tada and Jebba in the region now inhabited by the Nupe people, who regard them as relics associated with their own mythical ancestor, and other pieces from various parts of the delta of the Niger River.

Ijo. The Niger Delta is occupied by Ijo fishermen, whose masks for the cults of the water spirits are made in the form of aquatic animals, especially hippopotamus and crocodile. The western Ijo use *ejiri* figures, in which the head of the household is represented upon a highly schematic quadruped that is said to represent the guardian spirit of the family. Similar objects are made by the Edo-speaking Urhobo, to the north of the Ijo, where they are used in a cult of aggressiveness by the warriors. Among the eastern Ijo, shrines for the water spirits have figures that are often large though frequently kept hidden. They also have masks, similar to those of the western Ijo, worn by men of the Ekine society. In addition, there are shrines that contain sculptures for the village heroes and ancestors. In some Kalabari communities, rectangular screens are fashioned by carpentry into a low-relief frontal group in which a commemorated ancestor is flanked by supporting

the Ijo

figures—much like the king in Benin plaques, by which the screens may have been inspired about two centuries ago. All Ijo sculpture exhibits a four-square schematic style that contrasts starkly with the relative naturalism of surrounding styles, such as those of Yorubaland or Benin.

Igbo. On both sides of the Niger, but mainly to the east, live the Igbo. Traditionally, they have lived in small and often isolated settlements scattered through the forest. Only on the northern and western edges of the area, under influence from Igala and Benin, are hereditary rulers found. In Igbo society there is strong social pressure toward individual distinction, and men can move upward through successive grades by demonstrating their achievements and their generosity. One of the traditional representations of this was the *ikenga*, that part of oneself enabling personal achievement, with cult figures representing the attributes of distinction.

The lack of overall centralization among the Igbo-speaking peoples has been conducive to the development of a great variety of art styles and cultural practices. The earliest sculpture known from Igboland is from the village of Igbo Ukwu, where the grave of a man of distinction and a ritual store, dating from the 9th century AD, contained both chased copper objects and elaborate castings of leaded bronze (see Figure 23). The earliest artistic castings from black Africa, these pieces consist of ritual vessels and other ceremonial objects with intricate surface decoration, often small animals and insects represented in the round.

A very great variety of masks is found among the Igbo. The masks, of wood or fabric, are employed in a variety of dramas: social satires, sacred rituals (for ancestors and invocation of the gods), initiation, second burials, and public festivals, which now include Christmas and Independence Day. Some masks appear at only one festival, but the majority appear at many or all. Best known are those of the Northern Igbo Mmo society, which represents the spirits of deceased maidens and their mothers with masks symbolizing beauty. Among the Southern Igbo, the Ekpe society, introduced from the Cross River area, uses contrasting masks to represent the maiden spirit and the elephant spirit, the latter representing ugliness and aggression and the former representing beauty and peacefulness (see Figure 24). A similar contrast is found in their Okorosia masks, which correspond to the Mmo of the Northern Igbo. The Eastern Igbo are best known for masquerades associated with the Iko okochi harvest festival, in which the forms of the masks are determined by tradition, though the content of the play varies from year to year. Stock characters include Mbeke, the European; Mkpi, the he-goat; and Mba, which appear in pairs, one representing a boy dressed as a girl mimicking the behaviour of a girl, the other representing the girl being satirized.

Most impressive are the *ijele* masks of the Northern Igbo,

Frank Willett

which are 12 feet (366 centimetres) high. Consisting of platforms six feet in diameter, supporting tiers of figures made of coloured cloth and representing everyday scenes, they honour the dead to ensure the continuity and well-being of the community.

Wooden figures are carved for ancestors of both sexes, varying from less than one to more than five feet in height. Those representing founders of the village are kept in a central shrine and sometimes become patrons of the market. A great many other decorative wooden objects are made, including musical instruments, doors, stools, mirror frames, trays for offering kola nuts to guests, dolls, and a variety of small figures used in divination. Shrines called *mbari*, which contain elaborate tableaux of painted, unfired earth, are made in honour of the earth spirit in villages near Owerri in southern Nigeria; and in Igbo communities to the west of the Niger, elaborate pottery groups representing a man and his family are made for the yam cult. There seems to be no tradition of pottery sculpture in other Igbo groups.

Ibibio. Among the oldest sculptures of tropical Africa are several hundred ancestor figures, called *ekpu*, of the Ibibio coastal trade centre of Oron, some of which are thought to date from the late 18th century. They are bearded figures, three to four feet high, and are so individual as to suggest portraiture, despite their schematic style. Oron is one group of Ibibio-speaking villages. As with the Igbo, Ibibio is not a single group but several networks of independent communities, with local unity represented by secret associations and their masquerades. The Ekpo society uses black masks, often of naturalistic appearance and with movable jaws, to maintain social order and propitiate the ancestors; some of these masks represent disease and deformity.

Ekoi. The Ekoi-speaking peoples (Anyang, Boki, Ejagham, Keaka, and Yako) are best known for their large, skin-covered masks, which have two or even three faces, and for their smaller headpieces, which represent a head or an entire figure. The headpieces and masks have metal teeth, inlaid eyes, and frequently pegs to represent hair, which, alternatively, may be carved in elaborate coils. They are used by several masking associations. In the northern Ekoi area, around Ikom, are found circles of large stones, *akwanshi*, from one to six feet high, carved in low relief to represent human figures. They are thought to be no earlier than the 16th century.

Fulani. The Fulani are in origin nomadic pastoralists who range from Senegal to the Cameroon grasslands. They are particularly known for their body decoration (see below *Other visual arts: Personal decoration*) and for their engraved milk gourds. In addition, in Mali they have set-

Ancestor
figures of
the 18th
century

bled groups of artists such as goldsmiths, leatherworkers, blacksmiths, weavers, and potters.

Hausa. Northern Nigeria has long been dominated by the Muslim Hausa who, since the 19th century, have been ruled by Fulani *amirs* (emirs). For centuries their buildings have been decorated inside with molded and painted low-relief decorations, which have more recently been applied to the exteriors (see Figure 13). Both decorative and of a high technical standard are their crafts: leatherwork for saddles, bags, hilts, and sheaths; gold and silver jewelry; ironwork; pottery; weaving and embroidery.

Nupe. The Nupe have been Muslim for some centuries and are best known for their weaving, embroidery, bead-making, wood carving, and sheet metalwork. They have produced many doors carved in low relief in a blend of decorative designs. Carved and painted masks are made for the *elo*, a purely secular performance intended only to entertain (nowadays on the Prophet's birthday). The *elo* mask has a human face with a motif (sometimes a human figure) rising above it, flanked with stylized horns. The *gugu* masquerader wears a cloth mask decorated with cowrie shells, but sometimes Yoruba masks are used. The *ndako gboya* appears to be indigenous; a spirit that affords protection from witches, it is controlled by a small secret society that cleanses communities by invitation. The mask consists of a tall tube of white cotton supported inside on a bamboo pole about 12 feet long.

That Nupe art should have been influenced by the Yoruba is not surprising. Yoruba live among the Nupe, and there are bronzes in the Nupe villages of Tada and Jebba—one of them apparently an Ife work, and another in a more recent Yoruba style. Others of this group, which include the largest castings ever made in black Africa, share features with Benin sculpture and have other elements that are widely distributed in time and space on the Lower Niger. Nupe tradition says these sculptures were taken from Idah, the Igala capital, in the early 16th century. Many were probably already ancient, but nothing is known of ancient Igala bronze casting.

Other groups in northern Nigeria. There is a great diversity of sculptural tradition among peoples inhabiting the Niger and Benue valleys, the mountainous regions around the Jos Plateau in the centre of the area, and Adamawa to the east. This is altogether an area of astonishing diversity little understood beyond a confusing list of "tribal" names. Some of the better known traditions include the Igala, Idoma, Afo, Tiv, and Jukun, all of the Benue Valley.

CENTRAL AFRICA

Cameroon grasslands. The Cameroon grasslands area can be divided into three stylistic regions. The Bamileke area is composed of a number of separate chiefdoms, the best known being the Bangwa and the Bacham. Here sculptured human figures are composed of a highly expressive blend of rounded and angular forms. The Bamum kingdom developed roundness of form almost to its extreme, producing figures with big, inflated cheeks. Among the Tikar, Bekom, and Babanki, the forms are rounded but not exaggerated. Throughout the grasslands there have been exchanges of art objects and diffusion of the brass-casting technique, confusing the more detailed stylistic picture. In general, however, all of these societies are hierarchical, with sculpture mainly intended to reflect the power and importance of the king. (F.Wi./J.Pi.)

Gabon. Three major groups live in the equatorial rain forests of Gabon: the Fang and related peoples; the Ogowe (Ogooué) group, including the Ashira and Mpongwe; and the Kota.

Fang masks and figures are characterized by schematic simplicity. Typical of Fang work are *bieri*, boxes containing the skulls and bones of deceased ancestors and carved with figures intended to represent their protective influence (see Figure 26). Fang masks, such as those worn by itinerant troubadours and for hunting and punishing sorcerers, are painted white with facial features outlined in black.

The art of the Ogowe tribes, particularly the Mpongwe, is closely tied to death rituals. Their masks, painted white to symbolize death, represent dead female ancestors, though they are worn by male relatives of the deceased.

Figure 25: Bamum beaded throne of a king, Cameroon grasslands. In the Museum für Völkerkunde, West Berlin. Height 83.2 cm.

Holle Bildarchiv, Baden-Baden, West Germany

The Kota create stylistically unique reliquary figures, called *mbulu-ngulu*, which are covered with a sheet of brass or copper. Like the Fang, the Kota keep the skulls and bones of ancestors in containers, which consist here of a basket surmounted by the carved figure.

(P.Wa./J.Pi.)

Zaire and Congo. The region formerly referred to as the "Congo" consists of the modern republics of Zaire and the Congo, which are separated by the Congo River. The area falls into two major geographic divisions: the northern half is an equatorial rain forest inhabited by peoples who hunt, farm, and fish; the southern half is a savanna. It is in the villages of this southern region that the most highly developed political, social, and artistic culture has evolved.

In general, the styles of Zaire and the Congo can be characterized as a combination of symbolism and realism, wherein naturalistic forms—predominantly human and animal figures—are rendered not in precise imitation of nature but in an exaggerated manner. It is this "non-naturalistic reality" that distinguishes the art of this region from West African art.

The sculptural forms are most commonly wood carvings: masks (see Figure 27), ancestor figures, fetishes, bowls, boxes, cups, staffs, pots and lids, pipes, combs, tools, weapons, and musical instruments. Similar objects are also carved in ivory, and in some cases copper, brass, and iron are used. In rare instances, stone figures have been found.

Painting is not utilized greatly as a separate medium, but carved pieces frequently are painted. Masks and other pieces are covered with polychrome (see Figure 28), the colours applied in wide patches and often in planes and angles upon smooth surfaces. In the huts in which rituals take place, wooden figures are hung on brightly painted walls.

Reeds are woven into decorated mats, used for sleeping and for wrapping the dead, and into baskets and boxes, which are used to contain foodstuffs as well as ritual objects. Basketry patterns and sometimes container forms have been imitated by wood carvers; textile weavers, too, use decorative motifs derived from basketry.

Pottery making has depended on four forming techniques: molding, ring building, modeling on a board, and, more recently, throwing on the potter's wheel. Pottery forms are influenced by those of basketry and wood carving as well as by vegetal forms such as the calabash; deco-

ration consists of traditional geometric incised or painted patterns. The pots are used for cooking and for carrying and storing food or as ceremonial objects.

Pottery and embroidery are arts practiced by women, whereas sculpture and weaving are male activities.

Stylistic differences within the two major regions of the southern savanna and the northern rain forest can best be seen by subdividing the areas according to the kingdoms that have determined the social, political, and artistic lives of the people. The savanna falls into the Lower Congo, Kuba, and Luba cultural areas; and the rain forest into the northern, northeast, and northwest areas.

Lower Congo (Kongo) cultural area. In the Lower Congo area three sub-styles can be identified: the areas known as the coastal region, the Kwango River area, and the Teke region.

Seated mother-and-child figures are found throughout the Lower Congo region. The human figure is used by the peoples of the Lower Congo in the decoration of almost every work—from ceremonial objects and domestic utensils to pieces of furniture and architectural ornament. Although the majority of carved figures are made of wood, many important pieces in metal and ivory have been found. Among them are numerous metal figures clearly influenced by the Portuguese missionaries—statuettes of Christian saints, for example. In addition to the figures, crucifixes were also produced, in brass or bronze (using the lost-wax, or *cire perdue*, method of casting).

Ancestor figures and fetishes carved by the Kongo and related peoples, who live along the coast and in the Mayombé forest, are more realistically expressive than the figures of other areas. Every detail rendered, the deceased ancestor is portrayed standing, seated, or kneeling, each attitude revealing the dignity and pride with which he is viewed. The fetishes are less realistically portrayed; although the head is treated in great detail, the arms and legs are stylized, appearing to be of equal size, and often the sex of the figure is not indicated. Whereas the ancestor figure typically appears serene, the countenance of the fetish can be protective or malevolent.

The *nkongi*, a group of fetishes characteristic of the coast and the Mayombé forest, consist mainly of human figures, but there are some that combine the forms of a dog and a leopard, sometimes with two heads. The *nkongi* fetish is often completely covered by nails and other sharply pointed metal objects driven into its surface (see Figure 29); these objects mark each appeal made to the spirit embodied in it. All fetishes, whether they represent humans or animals, whether made of wood, horn, ivory, or even calabash, must contain a number of magical substances such as blood along with animal, vegetable, and mineral matter. These ingredients, called *bilongo*, are placed in a cavity, usually in the figure's stomach but sometimes in the back or head. The opening of the cavity is covered by a shell or, in some modern fetishes, by a piece of mirror. The magical substances are believed to invest the fetish figure with power and make it possible for the devotee to establish contact with the spirit (*nkisi*).

Another object common to the Lower Congo area, produced primarily by the coastal peoples, especially the Woyo, is a wooden pot lid carved with pictorial narratives representing proverbs. The pot lid, which covered the meal served by a wife to her husband, illustrates a particular complaint about their marital relationship—a wife's displeasure with her husband, for example; when that lid was used, the husband was obliged to discuss and resolve the problem publicly with the help of mealtime witnesses. This manner of family arbitration was traditional, and each woman was given a variety of carved pot lids on the occasion of her marriage.

The Kwango River area is the home of the Yaka, Suku, Mbala, and Pende, whose masks, figures, and other carved objects show a dynamic stylization. Characterized by geometric patterns formed by the relationship of stylized body parts, Yaka figures lack the organic integration of naturalistic forms produced by the neighbouring Kongo. The turned-up nose is a characteristic of Yaka figures and masks. Large, life-size carved figures stand at the entrances of Yaka initiation huts, the inside walls of which are covered with painted bark panels. *Tudansi* masks, worn by the young men at their initiation into manhood and decorated with polychrome and raffia collars, are topped with animal figures. The dramatically painted *kakungu* mask worn by the leader of the initiation rite represents a gaunt face with exaggerated nose and cheeks. This mask is thought to embody terrific powers and is kept in its own hut. Similar to the Yaka *tudansi* mask is the *hemba* mask of the nearby Suku, which is only slightly less grotesque. Carved Suku figures show more rounded forms than do the Yaka.

Mbala figures have three different types of faces: elongated, wide, and lozenge-shaped. The features (especially the forehead and chin) project forcefully, and the head is surmounted by a crestlike coiffure. Mbala mother-and-

child figures are much more powerfully rigid in style than others in the Congo.

Pende masks, made in a realistic style, are among the most dramatic works of all African art. Like the Yaka, small Pende masks fit over the head, helmet style. Representing the mysterious powers to which boys are introduced at initiation, Pende masks are worn in comic entertainments performed during the ceremonies. The masks have facial forms that repeat the angular pattern established by the heavy triangular eyelids, and they are topped by a bushy coif of raffia. Smaller versions of these masks are made as amulets in ivory or wood. The Pende fashion their figures in a style identical to that of their masks. One type of figure, called *tungunlungu*, representing the female ancestry of the tribe, is placed in front of the chief's house.

The Teke live on the banks of the Congo River. They are best known for their fetishes, called *butti*, which serve in the cult of a wide range of supernatural forces sent by the ancestors, who are not worshiped directly. Each figure has its own specific purpose not related directly to its appearance. When a figure is carved for a newborn child, part of the placenta is placed in the stomach cavity of the figure while the rest is buried inside the father's hut (where the family's fetish figures are kept). The figure serves to protect the child until puberty. Figures of identical appearance serve also for success in hunting, trading, and other activities, each figure's specific purpose being known only to the owner. Teke figures are characterized by an angular, geometric form with linear ornamentation. Teke face masks, flat disks painted in bright polychrome, are highly schematic forms bearing no naturalistic associations (see Figure 28).

Kuba cultural area. The art of the Kuba is one of the most highly developed of all African traditions, and significant cultural accomplishments are part of their heritage. Mucu Mushanga, their 27th king, was credited with the invention of fire, and he was the first to make clothing out of bark cloth. Shamba Bolongongo (c. 1600), the 93rd king, who introduced weaving and textile manufacture to his people, was also the first ruler to have his portrait carved in wood. Shamba Bolongongo's portrait established a tradition of such portraiture among the Kuba people. The kings typically sit facing forward with legs crossed, the left in front of the right; the right hand, with fingers extended, rests on the right knee, and the left hand holds the royal dagger. Geometric patterns cover the stomach and are continued on the back of the figure. The sculptures also include objects significant to each particular king, identifying his own personal accomplishments. Developing from the court style was a popular style, which utilized geometric forms instead of the well-modeled, full-volumed forms of the court figures. Kuba fetishes, em-

phasizing only essential organs, are highly schematic. The popular style can also be found in the utensils and textiles produced by the Kuba.

The Kuba metalsmith worked with copper, iron, and brass, making weapons and tools to be admired as well as used. In some cases, one metal was inlaid with another. *Mashambo* and other masks—made of raffia and decorated with shells, beads, and even bells and feathers—were traditionally used to dramatize the founding of the royal dynasty and its matrilineal system of descent (see Figure 30).

Luba cultural area. Although the history of the Luba people (southeast Zaire) is one of violence and warfare, their artistic style is characterized by harmonious integration of organically related forms. Female figures are carved more often than are male figures. Some are freestanding, almost always in a frontal position with their hands on their breasts; others are kneeling, sitting, or standing figures whose upraised hands serve as supports for bowls, seats, and neck rests (see Figure 31). A popular form consists of a kneeling or sitting female figure holding a bowl. Such mendicant figures are used to appeal to spirits for health and aid for pregnant women; neighbours, seeing the figure in front of a woman's hut, will fill it with gifts to help her avoid hardship in pregnancy. The female figures are modeled in rounded forms and have what is called *dodu*; that is, a stylistic tendency toward plumpness.

One well-known Luba sub-style has been called the "long-face style" of Buli. It contrasts strongly with the roundness of other Luba figures. The faces are elongated, with angular, elegant features.

"Long-face style" of Buli

The Songe, who conquered and were conquered by the Luba, created a sculptural style of intense dynamism and vitality. The style of their fetishes, carved from wood or horn and decorated with shells and polychrome, is not as realistic as the classic Luba style, and their integration of non-naturalistic, more geometric forms is impressive. The Songe also produce ceremonial axes, made of iron and copper and decorated with interlaced patterns. One group is known for its *kifwebe* masks, which combine human and animal features painted in red, black, and white.

Frank Willett

In the 19th century the Chokwe and Lunda conquered the Luba kingdom; today these hunters and farmers live in an area that includes part of northern Angola as well as southern Zaire. Their styles are often indistinguishable from one another. The forms they create are monumental and weighty, and both male and female figures are carved in an impressively vigorous style. Also made by these peoples are chairs decorated with figures posed in genre and legendary scenes. Zoomorphic motifs are found on all objects—even utensils such as combs and knives. In ceremonial rites of initiation, men wear painted bark cloth masks and net costumes.

Northern cultural area. The Lega, who inhabit the area between the Luba and the northernmost peoples, have produced figures and masks, mostly carved from ivory in a schematic style (see Figure 32). These objects are used, together with a vast assemblage of artifacts and natural objects, in the initiation to successive grades of the Bwami association.

Northeast cultural area. In the northeast area live the Mangbetu and the Azande. Mangbetu sculpture—in wood, ivory, and pottery—is often characterized by the elongated skull forms produced by binding the heads of young children. Azande sculpture seems largely of Mangbetu derivation.

Northwest cultural area. The Ngbaka and Ngbandi are the peoples whose sculptures are of major significance in the northwest area. There is no single Ngbaka sculptural style: at times the figures are fleshy and rounded; at other times they are considerably more angular. Small animal figures are used as fetishes in hunting. The masks used in circumcision ceremonies are roughly executed. Both the Ngbaka and the Ngbandi make clay images to be used in funeral rituals. The Ngbandi are also known for wooden fetishes and figures. Small carved ivory or wood figures were worn by Ngbandi warriors, who carried shields made of decorated woven fibre. It is often impossible to distinguish the few Ngbandi masks from those of the Ngbaka.

(P.Wa./J.Pi.)

EAST AFRICA

Southern Republic of The Sudan. Agriculture and cattle raising are widespread in this part of The Sudan, though the former is often despised and is engaged in with great reluctance. Among peoples such as the Nuer and Dinka, cattle are a source of aesthetic satisfaction. The prize ox could indeed be regarded as their sculpture.

There is little scope for differentiating local styles of surviving wood carvings, all of which are highly schematic in

form. Some of the larger ones, three feet or more in height, are attributed to the Bongo and appear on the graves of important people. The Bongo also made smaller figures, used in murder trials to identify criminals by oracular divination. Other peoples, especially the Bari, also made figures, of uncertain significance.

The Shilluk made life-size representations of their first king, Nyikang; clay figurines of bulls; clay pipe bowls and figurines in hyena form; and masks, typically fashioned of a piece of gourd with applied facial features made of cattle dung and fishbone teeth.

Some peoples decorate their houses with wall paintings and reliefs; the Burun, for example, paint animal murals reminiscent of rock paintings. The Nuba make mural paintings and fine pottery of clay or cow dung, sometimes embellished with finely painted geometric patterns. The southeast Nuba are particularly famous for the body painting of their young men (see Figure 37). Artistic taste appears in weapons, such as throwing knives, and in domestic utensils, elaborate coiffures, and personal ornaments.

Horn of Africa. The Amhara people of Ethiopia have inherited a Christian art and architecture with its roots in Coptic and Byzantine traditions. The Somali, on the other hand, are Muslim, with rich traditions of decorative art.

The Konso and other peoples of southern Ethiopia carve wooden tomb posts about six feet, six inches high surmounted by carved heads and shoulders, representing deceased nobles or warriors. The Arusi, also of southern Ethiopia, make tombstones of like height, ornamented with engravings filled in with red or black, sometimes showing the deceased in rough relief. Similarly shaped gravestones occur in Somalia, sometimes plain, sometimes adorned with decoration.

The pastoral way of life of the people of this area affects the applied arts; for example, pottery is less used than wood (see Figure 34) or coiled basketry for making containers and dishes for food and liquids. Baskets may be waterproofed and are often patterned in many colours and ornamented with cowrie shells and leather bands. Weaving and leatherwork sometimes reach a high standard; handsome jewelry is made from silver and amber; wooden

spoons and combs may be elaborately carved. The Somali have circular shields that are made of antelope hide and have embossed designs; and their swords, daggers, and spears combine utility with artistry.

Region of Lakes Victoria and Tanganyika. A pottery head and torso from Luzira in Uganda (now in the British Museum) is generally regarded as the oldest work of art known from this region, though its age is in fact unknown. Surviving from the treasure of Chief Rumanika of the Karagwe (on the western shore of Lake Victoria), seen by the explorer Henry Morton Stanley in 1876, are wrought-iron figures of two bulls and an eland, a bird of copper foil, and other metal objects that may have formed part of the chief's regalia. Compared to copper and its alloys, iron is little used as an art medium in Africa, and these iron figures are the only such known from East Africa.

The Kerewe of Ukerewe Island in Lake Victoria carved large wooden figures, about three feet high, which appear to have been effigies of deceased chiefs. Other examples of wood sculpture, including figures and masks, are known, some showing possible influences from the Luba of Zaire. In general, however, this is an area in which other artistic mediums clearly dominate.

Decorative arts among the Ganda and Tutsi

The peoples around Lake Victoria, notably the Ganda and Tutsi, have brought the decorative arts to a high peak of excellence. Mats and screens used on house walls are pale, straw-coloured ground. Fine baskets, with a variety of motifs in the same colours, come from the same area, as well as fine black pottery burnished to a high lustre. The domestic equipment is made in great variety and is of high artistic merit. Also made are shields, painted or straw-covered and patterned in black or natural colour. Bark cloth robes are printed or painted in black on a rust-red ground colour.

Coastal East Africa. The area of the Eastern Bantu covers Kenya and part of Tanzania, including the Swahili coast. The trade between East Africa, Arabia, and India in the past 1,000 years has had some effect on the decorative art traditions of the region. Swahili art includes wood carving (especially of doors), silversmithing and other metalworking, and finely plaited polychrome mats. Farther inland, direct Arab cultural contact is less obvious. Like the Konso, the Giryama of Kenya produced grave

posts surmounted by schematic heads. Notable among the remaining peoples who produce sculpture are the Kamba, who have spontaneously developed a style of wood carving, embellished with coiled-wire jewelry ornament, now sold in gift shops; formerly their art was applied to engraving gourds and inlaying stools with coiled-wire patterns.

Clay figures were made throughout the region for a variety of purposes, including initiation ceremonies at which they had the didactic role of visual aids in traditional education. Murals occur on the mud walls of houses—sometimes decorative, sometimes for ritual and magical purposes. Pottery is normally simple in form and decoration; gourds ornamented with engravings or covered with beadwork are widespread. Stools may be elaborately made, as by the Kamba; shields painted with distinctive polychrome designs occur especially among the Kikuyu and Masai. Traders' beads and coiled brass or iron wire are the raw materials for elaborate personal ornaments in a variety of designs and colour combinations.

SOUTHERN AFRICA

Makonde. The Makonde, living on either side of the Tanzania–Mozambique border, are the most prolific wood-carvers in the area. Masks are more numerous than figures and may be face masks, worn only over the face, or helmet masks, worn over the entire head. Makonde carvers have also developed a new style of spirit-figure carving in ebony (not a wood that is used traditionally).

Mbunda and others. In Zambia the Mbunda, Luvale, and Chokwe make masks; those of the former are made of wood, and those of the latter two are made of painted coarse bark cloth on a wicker frame. Each type is worn with a netted string costume or a fibre skirt. As with the Makonde, the masks may be worn at *makishi* dances (held at the new moon), in initiation ceremonies, or for public entertainments.

Small figure carvings are made in Zambia, mostly in the west. Decoratively carved food dishes, stools, headrests, *mbira* lamellaphones, and snuff bottles come from Zambia, Malaŵi, and Zimbabwe, together with distinctive baskets and clay pipe bowls carved in animal form, excellent pottery, and fine brass, copper, and aluminum wire intricately wound and plaited to embellish ax handles, hilts and sheaths, and snuff bottles.

Southern Bantu. The Zulu and related peoples of the southern Bantu made wooden figures that are mostly undistinguished and may have been executed under European influence. Attractive small clay models of cattle, made by children, occur here, as they do through much of eastern and southern Africa. Much artistic feeling is revealed in such decorative arts as basketry, pottery, the carving of wooden vessels, stools and headrests, ceremo-

Preeminence of the decorative arts in southern Africa

Other visual arts

POTTERY

Most peoples of sub-Saharan Africa use pottery, many making it themselves. Today, although traditions of pottery-making survive in many rural areas, town dwellers switching from firewood to other sources of fuel are also turning to industrially manufactured wares. The preindustrial traditions involve the molding of fairly coarse-textured clay by hand, either building the clay up in rings or by some variation of the hammer-and-anvil techniques found in preindustrial technologies worldwide. The pots so formed are then fired in open bonfires at a relatively low temperature. The variety of form and design is almost endless.

Pottery techniques are also used in a few places for sculpture, as, for example, in the grave memorials of the

Ashanti in Ghana; they are also presumed to have been the means used to form the pottery sculptures of antiquity, such as those of Ife and Nok, in Nigeria, and of Djenné and Mopti, in Mali. In most modern cases, potters are women.

TEXTILES

In both East and West Africa, cloth traditionally was woven of locally grown and hand-spun cotton. In West Africa today most cotton is factory-spun (producing a more regular and easier-to-weave fibre), while in East Africa weaving traditions have virtually disappeared in the face of competition from ready-made fabrics. Woolen yarn is woven in rural Berber areas of North Africa and by Fulani weavers of the inland Niger delta region of West Africa. Silk is also woven in West Africa. Hausa, Nupe, and Yoruba weavers in Nigeria use a locally gathered wild silk; Ashanti and Ewe weavers in southern Ghana use imported silk, a practice begun by Ashanti weavers unraveling imported fabrics in the 17th century. Fibres prepared from the leaves of the raffia palm are woven into cloth principally in Central Africa, especially Zaire, though also in parts of West Africa.

Throughout most of the continent men are the weavers, though in some areas (Nigeria, The Sudan) women also weave. If in any place both sexes weave, each uses a different type of loom. The looms are of two basic types, according to whether one or both sets of warp (the lengths of yarn mounted on the loom) are leashed to a heddle. Each type has more than one version, especially the single-heddle, of which there are various upright and horizontal versions in different regions of Africa.

Textiles are designed either as part of the weaving process—in which case colour, texture, and weave structure are significant—or by a range of techniques employed on the already woven cloth.

Weaving the yarn. The cultures that have developed the greatest skill and creative variety in woven design are undoubtedly the Ashanti and Ewe, with the Fulani and other weavers of the middle Niger, on each side of Timbuktu, following closely in expertise. Three types of woven pattern are common: In the first, yarn of different colours is used for the warp, creating stripes along the length of the cloth. The variety of patterns is almost infinite; most are decorative embellishments of what would otherwise be a plain, naturally coloured textile, but certain patterns can have additional significance, indicating, for example, a corpse, a rich person, or a girl about to be married. This kind of patterning is most developed in West Africa.

In the second type of pattern, the loom is set up in such a way as to allow the weft (the yarn interwoven with the warp) to predominate in the finished cloth, so that the use of different colours gives patterns across the width of the cloth. This type of patterning is typical of North African and of certain types of West African cloth. The third type of patterning employs an extra weft. This second yarn is woven in a different way from the basic weft, using a

technique known as float weaving. This type of pattern is also common in West Africa.

A further design element is provided by the unusual way in which the double-heddle loom has evolved in West Africa. The construction of the loom is so narrow that it weaves strips of cloth of considerable length; these strips are then sewn together edge to edge to make the finished textile. (The strips range from half an inch in one tradition of Hausa weaving to less than a yard in another; cloth about four inches wide is typical of much of West Africa.) This process can create a repeated pattern of stripes or a juxtaposition of varied patterns.

Embellishing the woven cloth. The most widespread technique of embellishing already woven cloth is dyeing—particularly with indigo but also with other dye colours, all of which are obtained from local vegetable and mineral sources as well as in ready-made, industrially produced form. Another pattern-making technique is known as resist-dyeing, in which parts of the cloth to be embellished are either tied, stitched, or painted with starch to prevent the dye's colouring those parts. Women of the Soninke (Senegal), Guro and Baule (Côte d'Ivoire), and Yoruba peoples have developed contrasting styles in the use of this technique.

Other techniques of embellishing woven cloth are embroidery and appliqué. Embroidery is especially common in two areas. In the first, the savanna stretching across West Africa, male embroiderers give pattern to the wide-sleeved gowns (historically of Saharan origin) typical of that region. The embroidery of the Hausa (see Figure 35) and Nupe are the best-known examples. In the second area, Zaire, women of the Kuba people in particular embroider raffia cloth dyed and woven in complicated geometric motifs (see Figure 36, right). Appliqué, mostly for flags, banners, and tent hangings, is practiced mostly along the Nile and in the savanna region immediately south of the Sahara. It often takes the form of Islamic texts cut out in cloth of one colour and sewn to cloth of a contrasting colour. An exception to this practice was the Fon Kingdom of Dahomey (present-day Benin), in which banners displayed the attributes of successive kings (see Figure 36, left). In many places appliqué is presently employed in the preparation of masquerade costumes. A related technique is the stitching of glass beads onto a cloth backing, for example, to make royal regalia and sometimes other ceremonial objects. Those practicing this technique are the Yoruba and the Kuba and the various peoples of the Cameroon grasslands.

Other fabrics. Textiles are not traditionally woven throughout sub-Saharan Africa; in some areas other fabrics are used. The stitching of beads to hide is found

among some peoples of East and southern Africa—as, for example, in the clothing of Masai women in Kenya. Animal hides are also treated to produce leather, the working of which is an art associated with many of the Islamic peoples south of the Sahara (for example, the Tuareg and the Hausa), each with its distinctive style. In Uganda bark cloth is prepared by felting and dyeing certain tree barks, which are often then painted or stenciled. The use of vegetable fibres for matting and basketry is universal throughout this region, with particular peoples noted for their styles of pattern and design.

PERSONAL DECORATION

The adornment of the human body involves all aspects of the arts as practiced in Africa. The body may be altered in ways that are permanent, especially by scarification, or the cutting of scars. Among the Yoruba, scarification indicates lineage affiliation. Among Nuba women in The Sudan, it is sometimes a mark of physiological status: patterns indicate such stages as the onset of menstruation and the birth of the first child. Sometimes the body is scarified for the aesthetic value of the patterns, as among the Tiv of Nigeria.

The body may be altered in ways that are semipermanent, in the sense that a person is not normally seen in public without certain effects, although they can be removed or adjusted in private. Royal regalia are an example, as are the heavily beaded ornaments worn by Masai women. The body may also be altered in ways that are essentially

ephemeral. For example, some young Nuba men celebrate their youthful vigour in extensive body painting (see Figure 37). Hairdressing is done sometimes for its aesthetic value (as among the Yoruba), sometimes to signal age status (East African pastoral peoples such as the Pokot and Samburu). Perhaps the most striking example of body decoration is that of the pastoral Fulani of Nigeria. It reaches its height in the annual *gerewol*, a beauty contest between men whose faces are painted and who wear metal bracelets, bead necklaces, and head ornaments. The women regularly wear elaborate hairstyles (often featuring golden rings around separate locks of hair), together with a profusion of jewelry. The varieties of dress and jewelry found throughout the continent are invariably matters of aesthetic concern whatever social purposes may also be served.

PAINTING

Painting in some form or another is found throughout most of the sub-Saharan region. Besides the paintings and engravings on rock surfaces (see below) and the many traditions of body painting, there are the painting and decorating of houses and other buildings. In any given area numerous art forms may exist, often as completely independent traditions with little obvious relationship to one another in style or content. The purposes fulfilled are equally varied, as seen in personal decoration. Other forms of graphic design are noteworthy as well: the most obvious is calabash (or gourd) decoration, notable traditions

of which exist among the Fulani and in Kenya among the Kamba.

There is also the painting of sculpture, whether masks or other forms. Sometimes this is the final stage of the work of the carver, but, as often as not, sculptures are painted and repainted by their owners. For example, mask headpieces among the Kalabari Ijo of Nigeria provide a temporary embodiment of spirits, and the painting of the masks before each performance is part of the ritual by means of which the spirits are summoned.

Paintings and engravings on the surfaces of rocks are found extensively in the Sahara and in southern Africa. The Saharan works were evidently done by successive populations, as is indicated by the different styles and subject matter. Most of the southern African work was probably done by ancestors of the San (Bushmen), the hunter-gatherer peoples of the region. (J.Pi.)

The Sahara. The earliest known African rock art consists of more than 30,000 engravings and paintings on rocks in the Sahara. At the time most of these works were executed (from about the beginning of the 5th millennium BC into the 2nd), the area was open savanna, supporting animals no longer found in the desert but represented in the art. Representation of the changing fauna makes it possible to divide the art into a succession of periods, the divisions being confirmed by changes in style and in the economy and artifacts possessed by the artists.

The earliest engravings (in southern Oran and in Tassili-n-Ajjer, Algeria, and in Fezzan, Libya) reflect a hunting economy and represent such wild animals as the extinct buffalo *Homoioceras antiquus* (formerly called *Bubalus*, hence the name Bubalus period assigned to these earliest engravings), the elephant, rhinoceros, hippopotamus, giraffe, ostrich, and large antelope (see Figure 38, left). The human figures are armed with clubs, throwing-sticks, axes, and bows.

Carbon-14 dating indicates that there was human occupation (if not drawing) in Tassili-n-Ajjer from the mid-6th millennium BC. Paintings seem to begin a little later than the engravings. These paintings, in which some 30 styles have been distinguished, often represent men and women with globular heads or apparently wearing masks.

There follows, both in painting and in engraving, the Cattle period, in which the depiction of domestic cattle indicates that pastoralism had by then become the basis for human life. The bow is the principal weapon. Bones of domestic cattle and of *Homoioceras* were found together in a deposit dated by carbon-14 to the mid-4th

owners, in some cases the nomadic Tuareg, still paint and engrave on rocks, as well as on the occasional truck or airplane, representations of camels in the Sahara.

(F.Wi./J.Pi.)

Southern Africa. In southern Africa, rock paintings and engravings occur in abundance (see Figure 39). Most surviving paintings were probably made during the last two millennia. The tradition seems to be much older, but no southern African site with either paintings or engravings has been satisfactorily dated to before the time of Christ. The San were still making such paintings in the 19th century, but some of the surviving examples may be the work of Khoikhoi (Hottentots) and Bantu-speakers. The way of life represented is mainly that of Neolithic, or New Stone Age, hunters (which is also more or less the way of life of the San), living off a fauna that has not changed in the area since the middle of the Late Pleistocene Epoch. Many of

Rock painting and engraving

millennium BC, thus dating this transitional phase of the art. The style of engraving is less naturalistic than in the Bubalus period, the poses stiffer; in contrast, the paintings are more naturalistic, with compositions and a sense of space if not strictly of perspective (see Figure 38, top). The Cattle period ended with the introduction of the horse about 1200 BC.

The Horse period is divided into three sub-periods. The first is the Chariot sub-period, in which the elephant was the only pachyderm still depicted, cattle continued to be represented, and mouflons, or wild sheep, and domesticated dogs appeared. The earliest chariots were carefully rendered with a single shaft and a horse on each side; later chariots consist only of a shaft with two wheels, and human figures are reduced to two isosceles triangles set apex to apex. Spears and shields are introduced and, later, daggers. The distribution of these representations of chariots conforms remarkably to the trans-Saharan trade routes of the more recent past and can be seen as the earliest evidence of them. The Horseman sub-period reflects a change from horse driving to horse riding, though chariots continue. Next, the camel was introduced, possibly as early as 700 BC and certainly by Roman times, producing the Horse and Camel sub-period. Cattle had now become very rare.

Because continuing desiccation led to restricted distribution of the horse (represented mainly in Mauritania), the Camel period reflects only present-day fauna: camel, antelope, oryx, gazelle, mouflon, ostrich, humped cattle, and goat. At first the spear was the only weapon depicted, but later the sword and firearms, weapons that are still in use, were added. The style is highly schematic. The Camel period has continued up to the present time, for their

the paintings depict a peaceful existence; others, perhaps from the 17th century onward, reveal the pressures created by incoming Bantu and Europeans, with scenes of cattle raiding and subsequent fighting between groups (which are recognizable by their stature, dress, and weapons).

The paintings are in three main styles: monochrome, bichrome, and polychrome. The last style has a restricted distribution in the southeast of southern Africa, an area to which the eastern San were confined by incoming Bantu in the early 17th century; yet works in this style are the finest achievements of the art, showing foreshortening and carefully composed groups. Ostrich eggshells (see Figure 40), engraved with linear patterns, are the only recent graphic art form produced by the San, who discontinued rock painting and rock engraving during the 19th century.

(F.Wi./Ma.A.C./J.Pi.)

BIBLIOGRAPHY. No attempt has been made in the literature to bring together the arts of Africa as a whole. There is only one journal expressly devoted to all the arts of Africa, *African Arts* (quarterly), and even this concentrates primarily on the visual arts and secondarily on the dramatic context of many visual forms. It is, nevertheless, invaluable as a guide to research, exhibitions, and publications, and it is extremely well illustrated. Otherwise information about the arts has to be culled from a variety of journals concerned either with African studies as a whole—*Africa* (monthly); *Journal of African History* (quarterly); *Odu* (semiannual), mainly Nigerian in content—or with part of the continent only—*Nigeria Magazine* (irregular); *Sudan Notes and Records* (annual)—or from journals devoted to a discipline—*Journal for Ethnomusicology* (3/year); *Yearbook for Traditional Music* (annual); *Objets et Mondes* (quarterly); *Man* (quarterly); and *Research in African Literatures* (quarterly).

(J.Pi.)

Literature and theatre: (*Oral traditions*): The single most authoritative work on oral literature is still the full and lucid work by RUTH FINNEGAN, *Oral Literature in Africa* (1970, reissued 1976), covering all the major genres (except epic) and discussing social context, function, and the aesthetic qualities of a wide variety of oral art forms. There are two scholarly bibliographies on oral literatures: VERONIKA GÖRÖG, *Littérature orale d'Afrique noire: Bibliographie analytique* (1981); and HAROLD SCHEUB, *African Oral Narratives, Proverbs, Riddles, Poetry, and Song* (1977). A handbook providing extensive annotated bibliographies on written and (to a lesser extent) oral African literatures is HANS M. ZELL, CAROL BUNDY, and VIRGINIA COULON (eds.), *A New Reader's Guide to African Literature*, 2nd rev. and expanded ed. (1983).

The following works cover and analyze some of the best and most representative collections of oral art forms from many parts of Africa: UCHEGBULAM N. ABALOGU, GARBA ASHIWAJU, and REGINA AMADI-TSHIWALA, *Oral Poetry in Nigeria* (1981), containing articles on a number of different oral genres in contemporary Nigeria; B.W. ANDRZEJEWSKI and I.M. LEWIS, *Somali Poetry: An Introduction* (1964), a detailed and authoritative account of the main genres and their social context by a linguist and a sociologist; ULLI BEIER (comp. and ed.), *Yoruba Poetry: An Anthology of Traditional Poems* (1970), a good introduction to the rich and complex Yoruba oral traditions; JAMES STUART (comp.), *Izibongo: Zulu Praise-Poems* (1968), long poems to kings and chiefs, rich in imagery and allusions, with a discussion of their form, function, and social context; A. COUPEZ and TH. KAMANZI, *Littérature de cour au Rwanda* (1970), analysis and texts of the royal poetry of the kings of Rwanda and accounts of the poets responsible for them; PIERRE SMITH (ed.), *Le Récit populaire au Rwanda* (1975), 30 popular tales from Rwanda that interpret the history of the region in a different way from the royal praises; M. DAMANE and P.B. SANDERS (eds. and trans.), *Lithoko: Sotho Praise-Poems* (1974), an authoritative anthology of praise poems of Basotho chiefs, covering 200 years; FRANCIS MADING DENG, *The Dinka and Their Songs* (1973), a careful account of the performed poetry of the Dinka people of The Sudan; RUTH FINNEGAN (comp. and trans.), *Limba Stories and Story-Telling* (1967, reprinted 1981), stories from the Limba of Sierra Leone, with attention to the creative role of individual narrators; VERONIKA GÖRÖG-KARADY, *Noirs et blancs: Leur Image dans la littérature orale africaine: Étude-anthologie* (1976), an analysis of a large number of tales exploring the different perceptions of the relations between races that the stories reveal; QLATUNDE O. QLATUNJI, *Features of Yorùbá Oral Poetry* (1984), a full account of the oral genres from the point of view of Yoruba poetics; DENISE PAULME, *La Mère dévorante: Essai sur le morphologie des contes africains* (1976), essays that discuss the social role of the tale and analyze eight archetypal African tales; JEFF OPLAND, *Xhosa Oral Poetry: Aspects of a Black South African Tradition* (1983), an

analysis primarily of Xhosa praise poetry and poets, incorporating discussion of the interplay of print, literacy, and orality; and HAROLD SCHEUB, *The Xhosa Ntsomi* (1975), an important collection of Xhosa and Zulu stories with an emphasis on the creative role of the storyteller.

(*Modern literatures in European languages*): The two fullest bibliographies are JANHEINZ JAHN and CLAUS PETER DRESSLER, *Bibliography of Creative African Writing* (1971, reprinted 1975), a list of more than 2,800 books, plays, articles, and anthologies, including works in African languages; and BERNTH LINDFORS, *Black African Literature in English: A Guide to Information Sources* (1979), a list of more than 3,300 critical books and essays on more than 400 African authors, complemented by a 1977–81 supplement (1986), with an additional 2,800 entries. An excellent collection of criticism is ALBERT S. GÉRARD (ed.), *European-Language Writing in Sub-Saharan Africa*, 2 vol. (1986).

Anthologies include CHINUA ACHEBE and C.L. INNES (eds.), *African Short Stories* (1985), stories by major figures such as Ngugi and Ousmane but also containing new writers' work; MARIO DE ANDRADE (ed.), *Antologia da Poesia Negra de Expressão Portuguesa*, prefaced by his essay "Cultura Negro-Africana e Assimilação" (1958, reprinted 1970); GERALD MOORE and ULLI BEIER (eds.), *Modern Poetry from Africa*, rev. ed. (1966, reprinted 1978); JACQUES CHEVRIER (ed.), *Anthologie africaine d'expression française*, vol. 1, *Le Roman et la nouvelle* (1981), prose writing from Francophone Africa, including established and new writers and organized thematically; STEPHEN GRAY (ed.), *The Penguin Book of Southern African Short Stories* (1985, reprinted 1986), a representative selection with translations from Afrikaans and Zulu; MBULELO VIZIKHUNGO MZAMANE (ed.), *Hungry Flames: And Other Black South African Short Stories* (1986), short stories by black South African writers with an introduction by Mzamane; AGOSTINHO NETO, *Sacred Hope* (1974; originally published in Portuguese, 1974), collected poems depicting the struggle for independence; JOHN REED and CLIVE WAKE (comps.), *French African Verse* (1972), poems presented chronologically with parallel French-English texts; K.E. SENANU and T. VINCENT (comps.), *A Selection of African Poetry* (1976), a wide selection, including some oral poetry, with excellent commentary; L.S. SENGHOR (ed.), *Anthologie de la nouvelle poésie nègre et malgache de langue française* (1948, reprinted 1985); *Présence Africaine*, vol. 57 (1966), also called *Nouvelle Somme de poésie du monde noir*, an anthology of poetry by black writers, including Africans; WOLE SOYINKA (ed.), *Poems of Black Africa* (1975), a wide-ranging thematic anthology compiled by one of Africa's major writers; and MICHAEL WOLFERS (comp. and trans.), *Poems from Angola* (1979).

Critical works on writing in French include DOROTHY S. BLAIR, *African Literature in French: A History of Creative Writing in French from West and Equatorial Africa* (1976), an authoritative and thorough coverage of the literature, and *Senegalese Literature: A Critical History* (1984); JACQUES CHEVRIER, *Littérature nègre: Afrique, Antilles, Madagascar*, 3rd ed. rev. and updated (1979, reissued 1984), with chapters on poetry, the novel, and the theatre, and discussing the writers Senghor, Césaire, Jacques Rabemananjara, and Frantz Fanon; MOHAMADOU K. KANE, *Roman africain et traditions* (1982), an examination of the major novelists with attention to social and cultural contexts; LILYAN KESTELOOT, *Black Writers in French: A Literary History of Negritude* (1974; originally published in French, 1963), a detailed account of the major writers of the Negritude school; and LOCHA MATEO, *Littérature africaine et sa critique* (1986), which argues for a critical approach that accepts an African worldview.

Critical works on writings in Portuguese include DONALD BURNES, *Fire: Six Writers from Angola, Mozambique, and Cape Verde* (1977), a study of Neto, Luandino Vieira, Geraldo Bessa Victor, Mário António, Baltasar Lopes, and Honwana, with frequent comparisons between Lusophone, Francophone, and Anglophone writing, and *Critical Perspectives on Lusophone Literature from Africa* (1981), 22 essays in English and Portuguese on Lusophone African literature; RUSSELL G. HAMILTON, *Voices from an Empire: A History of Afro-Portuguese Literature* (1975); GERALD M. MOSER, *Essays in Portuguese-African Literature* (1969), the first major work in English on Lusophone African writing; and FERNANDO AUGUSTO ALBUQUERQUE MOURÃO, *A Sociedade Angolana Através da Literatura* (1978), on literary life in Luanda over more than a century and on the novelist Castro Soromenho.

Critical works on writings in English include ULLI BEIER (ed.), *Introduction to African Literature: An Anthology of Critical Writing*, new ed. (1979), still an important collection, with seminal essays on Yoruba and Hausa oral literature and on Francophone, Lusophone, and Anglophone writing; MICHAEL CHAPMAN (ed.), *Soweto Poetry* (1982), a collection of reviews, interviews, and critical essays on the black South African poets

of the 1970s; DAVID COOK, *African Literature: A Critical View* (1977), which discusses the links and contrasts between English and African literatures, with studies of Achebe and other key African writers; O.R. DATHORNE, *The Black Mind: A History of African Literature* (1974), a broad survey of major contemporary writers and discussion of oral art, early written literature, and work in African languages; GEORG M. GUGELBERGER (ed.), *Marxism and African Literature* (1985), important essays on major writers such as Ngugi and on new developments in African literary criticism; CHRISTOPHER HEYWOOD (ed.), *Aspects of South African Literature* (1976), valuable papers from a critical and historical perspective, including contributions from Nadine Gordimer, Mtshali, and Alan Paton; ABIOLA IRELE, *The African Experience in Literature and Ideology* (1981), critical wide-ranging essays by a distinguished Nigerian critic; and BERNTH LINDFORS (ed.), *Critical Perspectives on Nigerian Literatures* (1976, reissued 1979), essays on oral literatures in the Hausa, Yoruba, and Igbo languages and on the major Nigerian authors. OLADELE TAIWO, *Female Novelists of Modern Africa* (1985); and ELDRED DUROSIMI JONES, *Women in African Literature Today: A Review* (1987), explore a topic largely ignored in earlier criticism. See also G.D. KILLAM (ed.), *The Writing of East and Central Africa* (1984); and BERNTH LINDFORS, *Early Nigerian Literature* (1982).

(Literatures in African languages): Two indispensable general references are ALBERT S. GÉRARD, *African Language Literatures: An Introduction to the Literary History of Sub-Saharan Africa* (1981); and B.W. ANDRZEJEWSKI, S. PIŁASZEWICZ, and W. TYŁOCH (eds.), *Literatures in African Languages: Theoretical Issues and Sample Surveys* (1985), containing essays on literature in more than 15 different languages, especially Yoruba, Hausa, Amharic, Somali, and Swahili. Also informative is *Review of National Literatures*, vol. 2, no. 2 (Fall 1971), a special issue devoted to black African literatures.

Writings on specific language literatures include ADEBOYE BABALOLA, "A Survey of Modern Literature in the Yoruba, Efik and Hausa Languages," in BRUCE KING (ed.), *Introduction to Nigerian Literature* (1971), pp. 50–63; PIERRE COMBA, "Le Roman dans la littérature éthiopienne de langue amharique," *Journal of Semitic Studies*, 9(1):173–186 (1964); ALBERT S. GÉRARD, *Four African Literatures: Xhosa, Sotho, Zulu, Amharic* (1971), including a critical study and literary history of Amharic; PAUL E. HUNTSBERGER (comp.), *Highland Mosaic: A Critical Anthology of Ethiopian Literature in English* (1973), extracts from ancient and modern Ethiopian literature with a critical overview; THOMAS LEIPER KANE, *Ethiopian Literature in Amharic* (1975), an indispensable introduction to the literature; MARGARET LAURENCE (comp.), *A Tree for Poverty: Somali Poetry and Prose* (1954, reissued 1970); J.W.T. ALLEN (comp. and trans.), *Tendi: Six Examples of a Swahili Classical Verse Form* (1971); LYNDON HARRIES (ed. and trans.), *Swahili Poetry* (1962), a descriptive survey outlining the themes and forms of early Swahili poetry; JAN KNAPPERT (comp.), *Four Swahili Epics* (1964), and *Four Centuries of Swahili Verse: A Literary History and Anthology* (1979), a scholarly account covering verse in manuscripts and oral traditions; RAJMUND OHLY, *Aggressive Prose: A Case Study in Kiswahili Prose of the Seventies* (1975); G. FORTUNE (ed.), *African Languages in Schools* (1964), containing a number of papers on Shona prose and poetry, and "75 Years of Writing in Shona," *Zambezia*, 1(1):55–67 (January 1969); RUDO GAIDZANWA, *Images of Women in Zimbabwean Literature* (1985), an analysis of women in books in Shona, Ndebele, and English; *Zimbabwe: Prose and Poetry* (1974, reprinted 1979), a collection of Shona prose and poetry in translation, including a translation of the short historical novel *Feso* by Mutsauro; GEORGE P. KAHARI, *Aspects of the Shona Novel and Other Related Genres* (1986), a comprehensive survey of Shona prose writing to date; ABRAHAM KRIEL, *An African Horizon* (1971), a discussion of the ethical and philosophical significance of a number of Shona novels; A.C. JORDAN, *Towards an African Literature: The Emergence of Literary Form in Xhosa* (1973), 12 authoritative essays on oral and written Xhosa literature; and B.W. VILAKAZI, "The Conception and Development of Poetry in Zulu," *Bantu Studies*, 12:105–134 (1938, reprinted 1968), a pioneering critical essay on oral and written Zulu poetry.

(African theatre): Studies on contemporary African drama and on theatre in African languages include B.W. ANDRZEJEWSKI, "Modern and Traditional Aspects of Somali Drama," in RICHARD M. DORSON (ed.), *Folklore in the Modern World* (1978), pp. 87–101; MICHAEL ETHELTON, *The Development of African Drama* (1982), which analyzes the literary and traditional roots of African drama from East and West Africa and draws on a wide range of plays; BIODUN JEIFO, *The Truthful Lie: Essays in a Sociology of African Drama* (1985), a work setting plays by such diverse figures as Soyinka and Fugard in their sociological context and including an essay on the social and dramatic significance of Yoruba popular theatre; ELDRED

DUROSIMI JONES, *The Writings of Wole Soyinka*, rev. ed. (1983), a major critical introduction to Soyinka's drama; ROBERT MSHENGU KAVANAGH, *Theatre and Cultural Struggle in South Africa* (1985), a stimulating study of the cultural and political context of South African drama by Gibson Kente and other black South African playwrights and including plays by Fugard, Ntshona, and Kani; OYIN OGUNBA and ABIOLA IRELE (eds.), *Theatre in Africa* (1976, reprinted 1978), a collection of 10 essays on traditional and modern drama in Africa; YENI OGUNBIYI (ed.), *Drama and Theatre in Nigeria: A Critical Source Book* (1981), an excellent survey and overview of Nigerian theatre, both traditional and modern; BAKARY TRAORÉ, *The Black African Theatre and Its Social Functions* (1972; originally published in French, 1958), focusing on a particular variety of theatre in traditional societies in former French colonies and covering the plays of Keita Fodeba; and HAROLD A. WATERS, *Black Theatre in French: A Guide* (1978), including a general introduction and covering the plots of some 150 plays, grouping them thematically.

(E.A.W.G.)

Music: Works dealing with the distribution of style areas and the history of African music include FRANCIS BEBEY, *African Music: A People's Art* (1975; originally published in French, 1969); WOLFGANG BENDER, *Sweet Mother: Moderne Afrikanische Musik* (1985), dealing with highlife and related popular styles; BILLY BERGMAN, *Goodtime Kings: Emerging African Pop* (1985), a discussion of eight styles of popular music; O. BOONE, *Les Xylophones du Congo Belge* (1936); DAVID COPLAN, *In Township Tonight! South Africa's Black City Music and Theatre* (1985), a survey of South African popular music and its history; E.M. VON HORNOSTEL, "African Negro Music," *Africa*, 1(1):30–62 (January 1928), a pioneer survey in the field; A.M. JONES, *African Music in Northern Rhodesia and Some Other Places*, rev. ed. (1958); GERHARD KUBIK, *The Kachamba Brothers' Band: A Study of Neo-Traditional Music in Malaŵi* (1974; originally published in German, 1972); ALAN P. MERRIAM, "African Music," in WILLIAM R. BASCOM and MELVILLE J. HERSKOVITS (eds.), *Continuity and Change in African Cultures* (1959, reprinted 1970), pp. 49–86, a valuable and concise survey of salient features; PAUL OLIVER, *Savannah Syncopators: African Retentions in the Blues* (1970), which traces African roots of the blues; JOHN STORM ROBERTS, *Black Music of Two Worlds* (1972, reissued 1974), which surveys black popular music in Africa and the Americas; GILBERT ROUGET, "La Musique d'Afrique noire," in ROLAND-MANUEL (ed.), *Histoire de la musique*, vol. 1 (1960), pp. 215–237; KLAUS P. WACHSMANN (ed.), *Essays on Music and History in Africa* (1971); and KLAUS WACHSMANN and PETER COOKE, "Africa," in STANLEY SADIE (ed.), *The New Grove Dictionary of Music and Musicians*, vol. 1 (1981), pp. 144–153. See also L.J.P. GASKIN (comp.), *A Select Bibliography of Music in Africa* (1965), an annotated work useful for locating earlier sources.

The following deal more specifically with musical instruments of Africa: DAVID W. AMES and ANTHONY V. KING, *Glossary of Hausa Music and Its Social Contexts* (1971); JOHN F. CARRINGTON, *Talking Drums of Africa* (1949, reprinted 1969), describing how drums are used to transmit messages in Central Africa; E.M. VON HORNOSTEL, "The Ethnology of African Sound-Instruments," *Africa*, 6(2):129–157 (April 1933), a survey of types, their distribution, and prehistory; A.M. JONES, "African Drumming: A Study in the Combination of Rhythms in African Music," *Bantu Studies*, 8:1–16 (1934, reprinted 1967), a pioneer study of cross-rhythms in Zambia; PERCIVAL R. KIRBY, *The Musical Instruments of the Native Races of South Africa*, 2nd ed. (1965), the standard work on this subject; GERHARD KUBIK, *Ostafrika* (1982), a well-illustrated survey of East African music and instruments, with a wealth of detailed information; J.S. LAURENTY, *Les Cordophones du Congo Belge et du Ruanda-Urundi* (1960); STANLEY SADIE (ed.), *The New Grove Dictionary of Musical Instruments*, 3 vol. (1984, reprinted 1985), which extensively covers African instruments; HUGH TRACEY, *Chopi Musicians: Their Music, Poetry, and Instruments* (1948, reprinted 1970), about the Chopi of Mozambique, who are famous for their *timbila* xylophone orchestras; MARGARET TROWELL and KLAUS P. WACHSMANN, *Tribal Crafts of Uganda* (1953), including a discussion of musical instruments; KLAUS P. WACHSMANN, "The Primitive Musical Instruments," in ANTHONY BAINES (ed.), *Musical Instruments Through the Ages* (1961, reprinted 1978), pp. 23–54; and ULRICH WEGNER, *Afrikanische Saiteninstrumente* (1984). See also two works in *Essays for a Humanist: An Offering to Klaus Wachsmann* (1977): DAVID K. RYECROFT, "Evidence of Stylistic Continuity in Zulu 'Town' Music," pp. 216–260; and FRANK WILLET, "A Contribution to the History of Musical Instruments Among the Yoruba," pp. 350–389.

Theoretical and practical aspects of African musical structure are to be found in the following: PAUL BERLINER, *The Soul of Mbira: Music and Traditions of the Shona People of Zimbabwe*

(1978, reprinted 1981); A.M. JONES, "African Rhythm," *Africa*, 24(1):26-47 (January 1954), and *Studies in African Music*, 2 vol. (1959, reprinted 1978), based mainly on Ghana and Zambia but also with much general discussion; JOSEPH KYAGAMBIDWA, *African Music from the Source of the Nile* (1955); J.H. KWABENA NKETIA, *African Music in Ghana: A Survey of Traditional Forms* (1962), *Drumming in Akan Communities of Ghana* (1963), *Folk Songs of Ghana* (1963), and *The Music of Africa* (1974, reprinted 1986), the last a useful survey dealing mainly but not exclusively with West Africa; DAVID RYCROFT, "Nguni Vocal Polyphony," *Journal of the International Folk Music Council*, 19:88-103 (1967), an examination of overlapping antiphonal parts in polyphony among the Zulu and their neighbours; ARTUR SIMON (ed.), *Musik in Afrika* (1983); KWESI YANKAH, "Beyond the Spoken Word: Aural Literature in Africa," *Cross Rhythms*, 2:114-146 (1985); and HUGO ZEMP, *Musique Dan: La Musique dans la pensée et la vie sociale d'une société africaine* (1971), an in-depth study of music and its context among the Dan of Côte d'Ivoire.

The journal *African Music* (irregular), the only periodical devoted solely to African music, has published a great number of valuable and scholarly articles in this field, including, on the history of African music, GERHARD KUBIK, "Harp Music of the Azande and Related Peoples in the Central African Republic," 3(3):37-76 (1964); and ANDREW TRACEY, "The Original African Mbira?" 5(2):85-104 (1972); on musical instruments, K.A. GOURLAY, "Long Trumpets of Northern Nigeria—In History and Today," 6(2):48-72 (1982); DAVID K. RYCROFT, "The Zulu Bow Songs of Princess Magogo," 5(4):41-97 (1975/76), the late princess having been an expert performer and a leading authority on Zulu music and its history; and ANDREW TRACEY, "The Nyanga Panpipe Dance," 5(1):73-89 (1971); and, on theoretical and practical aspects, ROSEMARY JOSEPH, "Zulu Women's Music," 6(3):53-89 (1983); GERHARD KUBIK, "The Structure of Kiganda Xylophone Music," 2(3):6-30 (1960), a detailed analysis of performance and output, "The Phenomenon of Inherent Rhythms in East and Central African Instrumental Music," 3(1):33-42 (1962), and "Composition Techniques in Kiganda Xylophone Music," 4(3):22-72 (1969); and ANDREW TRACEY, "Mbira Music of Jeje A. Taper," 2(4):44-63 (1961), and "The Matepe Mbira Music of Rhodesia," 4(4):37-61 (1970).

(G.K./D.K.R.)

Dance and dance theatre: Among the studies of particular traditions are JAMES W. FERNANDEZ, *Bwiti: An Ethnography of the Religious Imagination in Africa* (1982), concerned with Gabon; W.D. HAMBLBY, *Tribal Dancing and Social Development* (1926, reprinted 1974), material on dances of southern, East, and West Africa; PEGGY HARPER, "Dance," in SABURI O. BIOBAKU (ed.), *Living Culture of Nigeria* (1976), pp. 25-32, an analysis of tradition and change in a wide range of Nigerian cultures; ROBIN HORTON, *The Gods as Guests: An Aspect of Kalabari Religious Life* (1960), which describes a cycle of Kalabari ritual festivals in the Niger Delta and the central role played by masquerade dancers; T.O. RANGER, *Dance and Society in Eastern Africa, 1890-1970: The Beni Ngoma* (1975); PAUL SPENCER (ed.), *Society and the Dance: The Social Anthropology of Process and Performance* (1985); ROBERT FARRIS THOMPSON, *African Art in Motion* (1974, reissued 1979), a book on African sculpture that contains interesting writing on mime and dance as features of masquerade performance; HUGH TRACEY, "The Dancers and Dances," ch. 3 in his *Chopi Musicians: Their Music, Poetry, and Instruments* (1948, reprinted 1970), pp. 84-105, an excellent descriptive account, and *African Dances of the Witwatersrand Gold Mines* (1952), an illustrated description of Bantu dances as performed by workers in the gold mines of South Africa; and ARCHIBALD NORMAN TUCKER, *Tribal Music and Dancing in the Southern Sudan (Africa) at Social and Ceremonial Gatherings* (1933), a useful study of music and rhythms in the dance.

Selected articles in the journal *African Arts* (quarterly) include PAULA BEN-AMOS and OSARENREN OMOREGIE, "Ekpo Ritual in Avbiama Village," 2(4):8-13, 79 (Summer 1969), describing the role of masquerades in a ritual festival of the rural Bini of Nigeria; JEAN M. BORGATTI, "Age Grades, Masquerades, and Leadership Among the Northern Edo," 16(1):36-51 (November 1982), on the masquerade ceremonies of the Edo in the Bendel state of Nigeria; PAUL GEBAUER, "Dances of Cameroon," 4(4):8-15 (Summer 1971), a study of the dance traditions of a number of cultures in Cameroon; PEGGY HARPER, "Dance in a Changing Society," 1(1):10-13, 76-77, 79-80 (Autumn 1967), a study of ethnic traditions of dance within Nigerian cultures and the emergence of theatrical forms in urban centres; PASCAL JAMES IMPERATO, "Contemporary Adapted Dances of the Dogon," 5(1):28-33, 68-72 (Autumn 1971), dealing with tradition and change in the masquerade dances of the Dogon, and "Dances of the Tyi Wara," 4(1):8-13, 71-80 (Autumn 1970), a study of the use of animal masks by the Tyi Wara masqueraders of the

Bambara; and J.A.R. WEMBAH-RASHID, "Isinyago and Midimu: Masked Dancers of Tanzania and Mozambique," 4(2):38-44 (Winter 1971). Also useful are the following articles: PEGGY HARPER, "Dance in Nigeria," *Ethnomusicology*, 13(2):280-295 (May 1969), on the form and social function of the dance of the Yoruba in Nigeria, "The Kambari People and Their Dances," *Odu*, 7:83-96 (April 1972), a study of dance as an expression of the way of life of rural Kambari in Nigeria, and "The Role of Dance in Gèlèdè Ceremonies of the Village of Ijibé," *Odu*, 4:67-94 (October 1970), a study of dance and dancing masquerades.

Few works exist on dance drama of Africa as a special study, and most of them are in French. Additional descriptive material can often be found in more general works by anthropologists, cultural historians, and travelers. See especially SAKA ACQUAYE, "Modern Folk Opera in Ghana," *African Arts*, 4(2):60-63 (Winter 1971); KÉÏTA GODEBA, "La Danse africaine et la scène," *Présence Africaine*, 14-15:202-209 (June-September 1975), on traditional dance forms; PEGGY HARPER, "African Tradition in Theatre and Liturgy," *Theoria to Theory*, 11(3):185-193 (December 1977); BIODUN JEIFO, *The Yoruba Popular Travelling Theatre of Nigeria* (1984), an excellent account; BAKARY TRAORÉ, *The Black African Theatre and Its Social Functions* (1972; originally published in French, 1958), the standard work; and PIERRE VERGER, *Dieux d'Afrique* (1954), on the nature and forms of ritual and mime.

(P.H./J.Pi.)

Architecture: A general introduction to building in Africa is SUSAN DENYER, *African Traditional Architecture: An Historical and Geographical Perspective* (1978). See also PAUL OLIVER (ed.), *Shelter in Africa* (1971, reissued 1976), case studies, and *Dwellings: The House Across the World* (1987). Early stages of African urbanism are discussed in BASIL DAVIDSON, *The Lost Cities of Africa* (U.K. title, *Old Africa Rediscovered*, 1959, reissued 1970); and RICHARD W. HULL, *African Cities and Towns Before the European Conquest* (1976).

Of the regional studies, the most notable is JAMES WALTON, *African Village* (1956), which deals with southern and East Africa; it is brought up-to-date in FRANCO FRESCURA, *Rural Shelter in Southern Africa: A Survey of the Architecture, House Forms, and Constructional Methods of the Black Rural Peoples of Southern Africa* (1981). Visually impressive, though with less substantial research, is RENÉ GARDI, *Indigenous African Architecture* (1974; originally published in German, 1973), which deals with savanna forms of West Africa; other fine examples are to be found in JEAN-LOUIS BOURGEOIS, *Spectacular Vernacular: A New Appreciation of Traditional Desert Architecture* (1983), with photographs by CAROLLEE PELOS; and JEAN DETHIER, *Down to Earth: Mud Architecture* (1982; originally published in French, 1981).

Of the local studies, the early and influential one by JEAN-PIERRE BÉGUIN et al., *L'Habitat au Cameroun: Présentation des principaux type d'habitat: Essai d'adaptation aux problèmes actuels* (1952), records the styles of former French Cameroun with immaculate drawings and photography. A noteworthy successor, JEAN-PAUL BOURDIER and TRINH T. MINH-HA, *African Spaces: Designs for Living in Upper Volta* (1985), examines comparatively a number of compounds in Burkina Faso. Also important is LABELLE PRUSSIN, *Architecture in Northern Ghana* (1969), in which the forms and functions of six compounds are compared. Four villages in eastern Botswana are discussed in ANITA LARSSON and VIERA LARSSON, *Traditional Tswana Housing* (1984). See also KAJ BLEGVAD ANDERSEN, *African Traditional Architecture: A Study of the Housing and Settlement Patterns of Rural Kenya* (1977).

Perhaps the most exhaustive anthropological study is FRIEDRICH W. SCHWERTFEGGER, *Traditional Housing in African Cities* (1982), comparing the architecture of Zaria and Ibadan, Nigeria, with that of Marrakech, Mor. Hausa mosques and palaces are discussed in J.C. MOUGHTIN, *Hausa Architecture* (1985). The symbolism of built forms is movingly described in MARCEL GRIAULE, *Conversations with Ogotemméli: An Introduction to Dogon Religious Ideas* (1965, reprinted 1980; originally published in French, 1948). Cult houses or shrines are the subject of MICHAEL SWITHEBANK, *Ashanti Fetish Houses* (1969); while ULLI BEIER, *African Mud Sculpture* (1963), is largely devoted to Igbo *mbiri* houses and Yoruba palace reliefs. Studies of palaces include G.J. AFOLABI OJO, *Yoruba Palaces: A Study of the Afins of Yorubaland* (1966); JACOB EGHAREVBA, *A Short History of Benin*, 4th ed. (1968); and JAMES S. KIRKMAN, *Gedi: The Palace* (1963), a study of a number of Arab-Swahili centres. Of these, Lamu survives and is examined in USAM GHADAN, *Lamu: A Study of the Swahili Town* (1975). A detailed study of the influence of Islamic forms on sub-Saharan architecture is to be found in LABELLE PRUSSIN, *Hatumere: Islamic Design in West Africa* (1986). RUTH PLANT, *Architecture of the Tigre, Ethiopia* (1985), surveys the rock-cut Ethiopian Christian cave churches, many dating from the 13th century. Colonial influence on African town form is discussed especially

with reference to Lagos in AKIN L. MABOGUNJE, *Urbanization in Nigeria* (1968). Problems in rapid urban growth are the subject of JOSEF GUGLER and WILLIAM G. FLANAGAN, *Urbanization and Social Change in West Africa* (1978); while design by contemporary African architects is included in UDO KULTERMANN, *New Architecture in Africa* (1963; originally published in German, 1963), and *New Directions in African Architecture*, trans. from German (1969). In addition, a number of journals, including *Tribus* (annual), occasionally publish articles on African architecture.

(P.O.)

Visual arts: Recommended general accounts are FRANK WILLET, *African Art: An Introduction* (1971, reprinted 1985); J. VANSINA, *Art History in Africa: An Introduction to Method* (1984); WERNER GILLON, *A Short History of African Art* (1984, reissued 1986); and ROBERT LAYTON, *The Anthropology of Art* (1981), in part about Africa. For a survey of modern developments, see ULLI BEIER, *Contemporary Art in Africa* (1968).

The best account of sculptural traditions is still ELIOT ELISOFFON, *The Sculpture of Africa* (1958, reissued 1978), with text by WILLIAM B. FAGG; while for other visual media, see JOHN PICTON and JOHN MACK, *African Textiles: Looms, Weaving and Design* (1979); JOHN PICTON (ed.), *Earthenware in Asia and Africa* (1984); PHILIP ALLISON, *African Stone Sculpture* (1968); MARGARET TROWELL, *African Design*, 3rd ed. (1971); EUGENIA W. HERBERT, *The Red Gold of Africa: Copper in Precolonial History and Culture* (1984); T.J.H. CHAPPEL, *Decorated Gourds in North-Eastern Nigeria* (1977); and ROY SIEBER, *African Textiles and Decorative Arts* (1972), and *African Furniture and Household Objects* (1980).

For studies of particular traditions, see WARREN L. D'AZEVEDO (ed.), *The Traditional Artist in African Societies* (1973); PAULA BEN-AMOS, *The Art of Benin* (1980); DANIEL P. BIEBUYCK, *The Arts of Central Africa: An Annotated Bibliography* (1987), on Zaire, and *Lega Culture: Art, Initiation, and Moral Philosophy Among a Central African People* (1973); R.E. BRADBURY, "Ezomo's Ikegobo and the Benin Cult of the Hand," *Man*, 61:129-138 (1961); ROBERT BRAIN and ADAM POLLOCK, *Bangwa Funerary Sculpture* (1971); EUGENE C. BURT, *An Annotated Bibliography of the Visual Arts of East Africa* (1980), concentrating

on Kenya, Tanzania, Uganda, and the Makonde; KEVIN CARROLL, *Yoruba Religious Carving: Pagan & Christian Religious Sculpture in Nigeria and Dahomey* (1967); HERBERT M. COLE, *Mbari: Art and Life Among the Owerri Igbo* (1982); HENRY JOHN DREWAL and MARGARET THOMPSON DREWAL, *Gẹ̀lẹ̀de: Art and Female Power Among the Yoruba* (1983); WILLIAM FAGG, *Yoruba, Sculpture of West Africa* (1982); JAMES C. FARIS, *Nuba Personal Art* (1972); EVERHARD FISCHER and HANS HIMMELHEBER, *The Arts of the Dan in West Africa* (1984; originally published in German, 1976); DOUGLAS FRASER and HERBERT M. COLE (eds.), *African Art & Leadership* (1972); ANITA J. GLAZE, *Art and Death in a Senufo Village* (1981); ROBIN HORTON, "The Kalabari Ekine Society: A Borderland of Religion and Art," *Africa*, 33(2):94-114 (April 1963), *Kalabari Sculpture* (1965), and "Igbo: An Ordeal for Aristocrats," *Nigeria Magazine*, 90:168-183 (September 1966); KATHERYNE S. LOUGHRAN (ed.), *Somalia in Word and Image* (1986); JOHN MACK, "Bakuba Embroidery Patterns: A Commentary on Their Social and Political Implications," *Textile History*, 11:163-174 (1980), and "Animal Representation in Kuba Art: An Anthropological Interpretation of Sculpture," *Oxford Art Journal*, 4(1):50-56 (November 1981); KATHERYNE S. LOUGHRAN et al., *Somalia in Word and Image* (1986); SIMON OTTENBERG, *Masked Rituals of Afikpo: The Contexts of an African Art* (1975); and SUSAN MULLIN VOGEL, *African Aesthetics* (1986).

For antiquities and rock art, see PETER S. GARLAKE, *Great Zimbabwe* (1973), and *The Kingdoms of Africa* (1978); JEAN-DOMINIQUE LAJOUX, *The Rock Paintings of Tassili* (1963; originally published in French, 1962); J. DAVID LEWIS-WILLIAMS, *The Rock Art of Southern Africa* (1983); HENRI LHOTE, *The Search for the Tassili Frescoes: The Story of the Prehistoric Rock-Paintings of the Sahara*, 2nd ed. (1973); DAVID W. PHILLIPSON, *African Archaeology* (1985); THURSTON SHAW, *Nigeria: Its Archaeology and Early History* (1978), and *Unearthing Igbo-Ukwu: Archaeological Discoveries in Eastern Nigeria* (1977); PATRICIA VINNICOMBE, *People of the Eland: Rock Paintings of the Drakensberg Bushmen as a Reflection of Their Life and Thought* (1976); and A.R. WILLCOX, *The Rock Art of Africa* (1984).

(J.Pi.)

Agricultural Sciences

The agricultural sciences deal with the challenges of food and fibre production and processing. They include the technologies of soil cultivation, crop cultivation and harvesting, animal production, and the processing of plant and animal products for human consumption and use.

Food is the most basic human need. The domestication and cultivation of plants and animals beginning almost 10,000 years ago were aimed at ensuring that this need was met, and then as now these activities also fit with the relentless human drive to understand and control the Earth's biosphere. Over the last century and a half, many of the world's political leaders have recognized what India's Jawaharlal Nehru did, that "Most things except agriculture can wait." Scientific methods have been applied widely, and the results have revolutionized agricultural production. Under the conditions of prescientific agriculture, in a good harvest year, six people can produce barely enough food for themselves and four others. Advanced technologies have made it possible for one farmer in the United States, for example, to produce food for more than 100 people. The farmer has been enabled to increase yields per acre and per animal; reduce losses from diseases, pests, and spoilage; and augment net production by improved processing methods.

Until the 1930s, the benefits of agricultural research derived mostly from labour-saving inventions. Once the yield potentials of the major economic crops were increased through agricultural research, however, crop production per acre increased dramatically. Between 1940 and 1980 in the United States, for example, per-acre yields of corn tripled, those of wheat and soybeans doubled, and farm output per hour of farm work increased almost 10-fold as capital was substituted for labour. New techniques of preserving food products made it possible to transport them over greater distances, in turn facilitating adjustments among locations of production and consumption, with further benefits to production efficiency (see FOOD PROCESSING).

From a global perspective, the international flow of agricultural technology allows for the increase of agricultural productivity in developed and developing countries alike. From 1965 to 1985, for example, world trade in grains tripled, as did net exports from the United States. In fact, by the 1980s more than two-fifths of U.S. crop production was exported, making U.S. agriculture heavily dependent upon international markets.

This article is divided into the following sections:

HISTORY

Early knowledge of agriculture was a collection of experiences verbally transmitted from farmer to farmer. Some of this ancient lore had been preserved in religious commandments, but the traditional sciences rarely dealt with a subject seemingly considered so commonplace. Although

much was written about agriculture during the Middle Ages, the agricultural sciences did not then gain a place in the academic structure. Eventually, a movement began in central Europe to educate farmers in special academies, the earliest of which was established at Keszthely, Hungary, in 1796. Students were still taught only the experiences of farmers, however.

Liebig's contribution. The scientific approach was inaugurated in 1840 by Justus von Liebig of Darmstadt, Germany. His classic work, *Die organische Chemie in ihrer Anwendung auf Agrikulturchemie und Physiologie* (1840; *Organic Chemistry in Its Applications to Agriculture and Physiology*), launched the systematic development of the agricultural sciences. In Europe, a system of agricultural education soon developed that comprised secondary and postsecondary instruction. The old empirical-training centres were replaced by agricultural schools throughout Europe and North America. Under Liebig's continuing influence, academic agriculture came to concentrate on the natural sciences.

U.S. agricultural education and research. Agricultural colleges came into being in the United States during the second half of the 19th century. In 1862 Pres. Abraham Lincoln signed the Morrill Act, under which Congress granted to each state 30,000 acres (12,141 hectares) of land for each representative and senator "for the endowment, support and maintenance of at least one college where the leading object shall be—without excluding other scientific and classical studies and including military tactics—to teach branches of learning as are related to agriculture and mechanic arts." Thus the stage was set for the remarkably successful land-grant system of agricultural education and research in the United States. That same year Iowa became the first state to accept the provisions of the act, and all the other states have followed. Now, land-grant colleges of agriculture offer programs of study leading to both baccalaureate and postgraduate degrees in the various agricultural sciences. These institutions have served as models for colleges established in many nations.

In 1887 Congress passed the Hatch Act, which provided for necessary basic and applied agricultural research to be conducted by the state colleges of agriculture in cooperation with the U.S. Department of Agriculture (USDA). Agricultural experiment stations were established in 16 states between 1875 and 1885, and they now exist in all 50 states. These stations, together with USDA research centres around the country, comprise a network of coordinated research installations in the agricultural sciences. Slightly more than half of the agricultural research in the United States, however, is conducted by the private sector.

Congress passed the Smith-Lever Act in 1914, providing for, among other things, the teaching of improved agricultural practices to farmers. Thus the agricultural extension service—now recognized as an outstanding example of adult vocational education—was established.

The demand for instruction in agriculture at the secondary level gained momentum around the beginning of the 20th century. Some private agricultural schools had already been founded in the East, and by 1916 agriculture was being taught in more than 3,000 high schools. Federally aided programs of vocational agriculture education began with the passage of the Smith-Hughes Vocational Education Act in 1917. By the second half of the 20th century, an average of 750,000 high-school, young farmer, and adult farmer students were enrolled annually in classes offered by about 10,000 vocational agriculture departments in the United States. Since passage of the Vocational Education Act of 1963, further expansion of agricultural education has occurred in vocational schools and in courses offered at junior and senior colleges.

Morrill Act

The
Hatch Act

MAJOR DIVISIONS

Theory of
soil fertility

The agricultural sciences can be divided into six groups. In all fields, the general pattern of progress toward the solution of specific problems or the realization of opportunities is: (1) research to more accurately define the functional requirements to be served; (2) design and development of products, processes, and other means of better serving these requirements; and (3) extension of this information to introduce improved technologies to the agricultural industries. This has proved to be a tremendously successful approach and is being used the world over.

Soil and water sciences. Soil and water sciences deal with the geological generation of soil, soil and water physics and chemistry, and all other factors relevant to soil fertility. Soil science began with the formulation of the theory of humus in 1809. A generation later, Liebig introduced experimental science, including a theory of the supply of soil with mineral nutrients. In the 20th century, a general theory of soil fertility has developed, embracing soil cultivation, the enrichment of soil with humus and nutrients, and the preparation of soil in accordance with crop demands. Water regulation, principally drainage and irrigation, is also included.

Soil and water research have made possible the use of all classes of land in more effective ways, while the control of soil erosion and deterioration has made other advances even more striking. Because the amount of water available for plant growth is one of the major limiting factors in crop production, improved tillage and terracing practices have been devised to conserve soil moisture, and soil-management and land-use practices have been developed to increase the infiltration of snow, rain, and irrigation water, thereby reducing losses caused by runoff.

Public and private research into chemical fertilizers and soil management have made it possible for farmers to aid nature in making specific soils more productive. Much has been learned about using crop rotation, legumes, and green manure for replenishing soil humus and nitrogen; determining and supplying the major and minor nutrient needs of crops; and managing soil under irrigation, including salt control. Techniques based on these findings have been put to use on farms to improve soil fertility and increase crop yields. Between 1940 and 1965, for example, farmers in the United States more than tripled their use of chemical fertilizers, resulting in increases of 50 to 150 percent in crop yields.

Scientists have used many sophisticated techniques to unlock a vast storehouse of knowledge about plants. In one case, chemicals tagged with radioactive isotopes were employed to follow the processes by which plants take up soil nutrients to synthesize their fruits, grains, vegetables, nuts, flowers, and fibres.

Plant sciences. The plant sciences include applied plant physiology, nutrition, ecology, breeding and genetics, pathology, and weed science, as well as crop management. They deal primarily with two major types of crops: (1) those that represent direct human food, such as cereals, vegetables, fruits, and nuts; and (2) those that serve as feed and forage for food, companion, laboratory, and recreational animals. Special branches of these sciences have developed to deal with each of the numerous classes of plant crops—*e.g.*, vegetables, small fruits, citrus fruits and other tree fruits, and flowers and other ornamental plants. Other specialties concern the production of raw materials for industry—cotton, hemp, sisal, and silk—although some of these are losing economic importance in the face of competition from synthetic fibres. Branches of the plant sciences that deal with such tropical crops as coffee, tea, cocoa, bananas, coconuts, sugarcane, and pineapples, to the contrary, promise to retain their importance.

Although scientifically based plant production came of age at the end of the 19th century, it started much earlier. Instructions on sowing dates are reported in Egypt by 2000 BC. Throughout the centuries, numerous treatises have included recommendations on how to achieve higher and more efficient yields.

The stimulus for the development of the plant sciences did not come from botany but from agricultural chemistry, the application of which led to the development

of plant physiology. Field experiments were started in Rothamsted, England, in 1834, and elsewhere in Europe soon after. Improved methods of experiment design and statistical analysis made possible the comparative study of plants and their cultivation systems.

Cultivation of plants by varieties had already led in the late 18th century to the systematic selection of cereal varieties according to predicted yield. The rediscovery at the start of the 20th century of Gregor Mendel's laws of heredity and later of ways to cause mutations led to modern plant breeding, with momentous results that included the tailoring of crop varieties for regions of climatic extremes. Agronomist Norman E. Borlaug was awarded the Nobel Prize for Peace for 1970 for the development of short-stemmed wheat, a key element in the so-called Green Revolution in developing countries.

Major advances in the study of plant diseases were recorded in the 19th century, and the science of plant nutrition matured in the second quarter of the 1900s. Serious calamities resulting from the introduction of plant diseases into regions where the indigenous plants had no immunity against them, and the invasion of grapes by insects and of potatoes by fungi, stimulated research efforts. During the 20th century, all diseases have become objects of systematic plant pathology research. Plant pathologists search for chemicals effective against microbial diseases, weeds, and various pests and seek to adjust the biotic balance to reduce losses. That chemical residues have created some problems has led to further scientific activity. Biological control measures may ultimately be less harmful to the environment and more specific and effective in pest and weed management.

Other research has been undertaken because consumers want better fruits and vegetables. New varieties have been developed, methods found to ensure that fresh and processed foods arrive at retail stores in prime condition, and grocers taught to care for these foods so that consumers receive them in the most attractive and nutritious state.

(G.P./B.T.Sh./J.R.C./S.E.Cu.)

Animal sciences. In modern civilizations, people rely on meat, milk, and eggs as major sources of numerous nutrients. To satisfy this demand, sheep, goats, cattle, water buffalo, swine, chickens, ducks, geese, and turkeys are produced on farms all over the world. To understand how agricultural animals convert feedstuffs into the food and other commodities consumers demand, animal scientists have undertaken broad investigations using highly sophisticated techniques. The animal sciences comprise applied animal physiology, nutrition, breeding and genetics, ecology and ethology, and livestock and poultry management. In addition, diseases of food animals are the focus of many veterinary scientists.

Animal nutrition research was well-established in several centres around the world by the turn of the 20th century, and it began to flourish during the second quarter of the 1900s. Many discoveries have been made about animal metabolism and consequent nutrient requirements; the usefulness of hundreds of feedstuffs as sources of essential amino acids, vitamins, and minerals, as well as lipids and carbohydrates; the proper balance of available nutrients in the diet; nutrient supplements and feed-processing technologies; and metabolite-partitioning and growth-promoting compounds. These fundamental findings have been applied widely since 1950, bringing about improved animal feeding. Studies of life processes in farm animals have helped in developing the optimal nutriment for each animal, and human nutrition has benefitted enormously from the knowledge that has come from these investigations.

The notion that "like begets like" was already current in biblical times. Long before the science of animal genetics developed, all species of agricultural animals were subjected to selective breeding to some extent. Modifying livestock and poultry to meet consumer demands requires the application of scientific principles to the selection of superior breeding animals and planned matings. For example, consumers have come to prefer more lean tissue and less fat in meat, and so the meat-type hog was developed in two decades of intensive selection and crossbreeding

Plant
breeding

Animal
nutrition

animal
feeding
and repro-
duction

starting in the 1950s. Swine now yield more lean pork, grow faster, and require less feed to reach market weight than before. By the 1980s, a laying hen of any popular genetic strain, if managed properly, could be expected to produce more than 250 eggs annually, while special meat-producing strains of chickens gain body weight at a rate of 1 : 2 in ratio with feed intake. (J.R.C./S.E.Cu.)

Some of the most significant research in animal breeding has been done with dairy cattle and has established the proved sire system, in which bulls are ranked according to the performance of their offspring. The use of sires proved in this way together with artificial insemination has enabled dairymen to improve their herds by greatly expanding the influence of genetically superior bulls. Along with increased emphasis on performance testing, efforts have been made to predict at a young age whether an individual animal will be an efficient meat, milk, or egg producer. Such success has made for earlier culling and for herds and flocks of higher genetic merit.

(G.P./B.T.Sh./J.R.C./S.E.Cu.)

Animals represent renewable agricultural resources because they reproduce, and animal scientists have studied animal reproduction assiduously since the 1930s. These investigations began in the United Kingdom but were soon joined by scientists in the United States, where the work blossomed. Basic discoveries have been put to use quickly in the animal industries. Elucidation of reproductive structures and mechanisms made it possible to refine reproductive management in the 1940s, and artificial insemination made possible the widespread use of proved sires in the 1950s. Additional basic knowledge and later technological developments made practical the control of the estrous cycle and of parturition by exogenous hormones and the serial harvesting and transplantation of embryos from donor females of high merit. The result of these changes has been an increase in the reproductive rate and efficiency of all species of farm animals.

Animal ecology and ethology are young branches of the animal sciences. Around the middle of the 20th century, environmental physiologists in the United States and the United Kingdom began to study agricultural animals' relations with their environment, including temperature, air, light, and diet. Interactions among environmental temperature, diet, and the animals' genetic makeup have been characterized, and great strides have been made in improving thermal-environmental management on farms. Lighting management is now essential to profitable poultry production, and the light environment is being controlled in livestock houses as well. Since the 1970s emphasis has shifted to include the behavioral adaptability of animals to their surroundings and the effects of environmental stress on the immune status of livestock and poultry. Farmers have widely adopted intensive systems of animal production, and these systems continue to present opportunities and problems to animal scientists concerned with discovering and accommodating the environmental and ethological needs of food animals.

Animal
health
science

Animal health is essential to the efficient production of wholesome animal products. An example of the economic effect of animal-disease research conducted by veterinary scientists is the control of Marek's disease, a highly contagious disease affecting the nerves and visceral organs of chickens, which resulted in a loss of more than \$200,000,000 annually to the U.S. poultry industry alone. The disease was studied for more than 30 years before it was learned that it is caused by a herpes virus. Within three years of this discovery, a vaccine was developed that reduced the frequency of Marek's disease and the resultant meat condemnations in vaccinated chickens by 90 percent and increased egg production by 4 percent. Veterinary scientists also investigate the chronic infectious diseases associated with high morbidity rates and various metabolic disorders.

Food sciences and other post-harvest technologies. A group of sciences and technologies underlie the processing, storage, distribution, and marketing of agricultural commodities and by-products. Modern post-harvest technology helps provide inexpensive and various food supplies for consumers, meets the demands of a variety of indus-

trial users, and even creates replacements for fossil fuels.

Research having particular significance to post-harvest technology includes genetic engineering techniques that increase the efficiency of various chemical and biological processes and fermentations for converting biomass to feedstock and for use in producing chemicals (including alcohols) that can replace petroleum-based products. Among the expected outcomes are the manufacture of new products from reconstituted ones and the recovery of by-products that would otherwise be considered waste.

Agricultural engineering. Agricultural engineering includes appropriate areas of mechanical, electrical, environmental, and civil engineering, construction technology, hydraulics, and soil mechanics.

The use of mechanized power and machinery on the farm has increased greatly throughout the world, fourfold in the United States since 1930. Research in energy use, fluid power, machinery development, laser and microprocessor control for maintaining grain quality, and farm structures is expected to result in further gains in the efficiency with which food and fibre are produced and processed.

Agricultural production presents many engineering problems and opportunities. Agricultural operations—soil conservation and preparation; crop cultivation and harvesting; animal production; and commodities transportation, processing, packaging, and storage—are precision operations involving large tonnages, heavy power, and critical factors of time and place. Facilities designed to aid farm operations help farm workers to minimize the time and energy requirements of routine jobs. (J.R.C./S.E.Cu.)

Four primary branches have developed within agricultural engineering, based on the problems encountered. Farm power and machinery engineering is concerned with advances in farm mechanization—tractors, field machinery, and other mechanical equipment. Farm structures engineering studies the problems of providing shelter for animals and human beings, crop storage, and other special-purpose facilities. Soil and water control engineering deals with soil drainage, irrigation, conservation, hydrology, and flood control. Electric power and processing engineering is concerned with the distribution of electric power on the farm and its application to a variety of uses, such as lighting to control plant growth and certain animal production operations. (R.A.Pr./J.R.C./S.E.Cu.)

Agricultural economics. The field of agricultural economics includes agricultural finance, policy, marketing, farm and agribusiness management, rural sociology, and agricultural law. The idea that the individual farm enterprise forms a unit—affected by location, production techniques, and market factors—originated during the 19th century. It was later supplemented by the theory of optimum utilization of production factors by the selection of production lines. Further refinement came about through applications of modern accounting methods. Research into farm and agribusiness management led to mathematical planning systems and statistical computation of farm-enterprise data, and interest has been drawn to decision-making behaviour studies of farm managers.

Agricultural policy is concerned with the relations between agriculture, economics, and society. Land ownership and the structure of farm enterprises were traditionally regarded as primarily social problems. The growth of agricultural production in the 20th century, accompanied by a decline in size of the rural population, however, has given impetus to research in agricultural policy. In the capitalist countries, this policy has concentrated on the influence of prices and market mechanisms; in the centrally planned countries, emphasis has been placed on artificially created market structures.

Research in agricultural marketing was originally limited to the problem of supply and demand, but the crises of the Great Depression in the 1930s brought new analytical studies. In Europe, the growth of the cooperative movement—began in Germany in the 19th century as a response to capital shortage and farm indebtedness—brought satisfactory solutions to problems of distribution of products from farmer to processor. Consequently, little interest in market research developed in Europe until the mid-20th century. Today, agricultural marketing studies

Agri-
cultural
marketing

focus on statistical computations of past market trends to supply data for forecasting.

Agricultural law concentrates on legal issues of both theoretical and practical significance to agriculture such as land tenure, land tenancy, farm labour, farm management, and taxation. From its beginnings at the University of Illinois in the 1940s, modern agricultural law has evolved to become a distinct field of law practice and scholarship.

Rural sociology, a young discipline, involves a variety of research methods, including behaviour study developed from studies in decision making in farm management.

(G.P./B.T.Sh./J.R.C./S.E.Cu.)

OTHER AGRICULTURAL SCIENCES

Agricultural work science arose in response to the rural social problems experienced in Germany during the Great Depression. The improvement of work procedures, appropriate use of labour, analysis of human capacity for work, and adjustment of mechanized production methods and labour requirements represent the main objects of this branch of ergonomics research. Studies of the influence of mechanization on the worker and of worker training came later.

(G.P./J.R.C./S.E.Cu.)

Agricultural meteorology deals with the effects of weather events, and especially the effects of their variations in time and space, on plant and animal agriculture. Atmospheric factors such as cloud type and solar radiation, temperature, vapour pressure, and precipitation are of vital interest to agriculturalists. Agricultural meteorologists use weather and climatic data in enterprise risk analysis as well as in short- and long-range forecasting of crop yields and animal performance.

EMERGING AGRICULTURAL SCIENCES

The agricultural sciences are poised to enter a new era, armed with ever more sophisticated research technologies, such as monoclonal antibodies and gene splicing, in their continuing drive to better harness nature for the ultimate benefit of human beings everywhere. Although broad and deep scientific investigations have been made in the biological, physical, and social realms related to agriculture, the need persists for additional research to close remaining gaps in knowledge, especially in molecular biology and the environmental, social, and economic effects of its fruits.

From results of experiments already conducted, it is clear that molecular biology will influence plant genetics and crop production. Plant genetic engineers are working to improve specific economically important plant varieties by increasing their photosynthetic efficiency, improving their nutritional quality, and transferring to them such favourable properties as the ability to fix atmospheric nitrogen, as do legumes, and to better resist diseases and tolerate herbicides and natural environmental stress.

Animal scientists also are using new research methods in biotechnology, including the micromanipulation of embryos to produce multiple clones. Monoclonal antibodies are used in studies of specific factors in immune mecha-

nisms, and recombinant DNA (deoxyribonucleic acid) technology is used in the genetic engineering of microbes so that they can synthesize specific antigenic proteins useful in vaccine production. The ultimate goal of this research is to improve dramatically the health and productivity of agricultural animals.

(J.R.C./S.E.Cu.)

(G.P./J.R.C./S.E.Cu.)

The History of Agriculture

Agriculture, or the practice of cultivating the soil, harvesting crops, and raising livestock, was long believed to have begun in a single centre in the Middle East, about 4000 BC. Modern dating techniques have since disproved this hypothesis; they indicate agriculture already in progress around 7000 BC, and archaeologists have uncovered evidence of animal domestication thousands of years earlier. It has also been shown that some plants were probably cultivated in the New World, which suggests that agricultural development took place simultaneously in many areas and thus did not spread from a single originating centre.

This article discusses developments in crop and stock farming in the ancient societies of the Middle East and Mediterranean; in China and India; in Roman and medieval Europe; and in more recent times, after the introduction of power machinery and scientific farming in the 19th and 20th centuries. For information on the techniques of modern agriculture, see the article **FARMING AND AGRICULTURAL TECHNOLOGY**. For further treatment of the modern disciplines of agricultural research, engineering, and management, see the article **AGRICULTURAL SCIENCES**.

Origins of agriculture

Agriculture has no single, simple origin. At different times and in numerous places, many plants and animals have been domesticated. How many species passed into or out of domestication in prehistory is not known. Cultivation of foxtail millet in America and domestication of the elk in Scandinavia and the gazelle in the Middle East were abandoned long ago. In the 20th century, cultivation of bottle gourds, finger millet, and Galla potatoes is on the decline, while efforts proceed to tame the eland, musk ox, and fox. Cultivation of rice, wheat, barley, potatoes, and corn (maize) met with great success in the favourable climate that followed the last Ice Age, while reindeer husbandry, by contrast, found these climatic changes unfavourable and lost importance.

EARLIEST BEGINNINGS

Nineteenth-century scholars hypothesized four stages in human development: (1) a savage stage in which all people were hunter-gatherers; (2) a herdsman or nomad stage during which man domesticated some animals; (3) a farming stage; and (4) civilization. Researchers have since attempted to determine when and where man first changed from hunter-gatherer to pastoralist or agriculturist.

Many authorities have come to think that man's domestication of plants and animals caused changes in their form and that the presence or absence of such changes may indicate whether the animal or plant was domesticated at some time in the past. On the basis of such evidence, some scholars have hypothesized a preliminary agricultural phase of intensive food gathering in the Middle East about 9000–7000 BC, when man passed from hunting and gathering to food producing or agriculture. The Natufians of Palestine, who possessed sickles, lived at this time; whether the grain they harvested was sown or wild is not known. Cattle were probably domesticated during this period or slightly earlier from the wild ox (*Bos taurus*), which stood six to seven feet (1.8 to 2.1 metres) high at the withers (the ridge between the shoulder bones).

At Shanidar, in Iraq, it is claimed that sheep, similar to wild varieties in form and structure, were kept in herds. Furthermore, it has been suggested on somewhat speculative grounds that einkorn wheat (*Triticum monococcum*), emmer wheat (*Triticum turgidum*), and wild barley (*Hordeum spontaneum*) were cultivated about 7000 BC at Ali Kosh on the borders of Iraq and Iran.

There seems no compelling reason, however, why these instances should be regarded as the first of their kind. It is possible that domesticated beans (*Phaseolus*), peas (*Pisum*), bottle gourds (*Lagenaria siceraria*), and water chestnuts (*Trapa*) may have been grown at the Spirit Cave in northern Thailand about 9000 BC. In the Americas, pumpkins (*Cucurbita*) and gourds (*Lagenaria*) are known to have existed in domesticated form in northeast Mexico about 7000 BC, and probably beans in the Tehuacán Valley. The bones of a dog, possibly used for hunting about 8500 BC, were discovered in the western United States. In sum, it now seems unlikely that there was either a single or even a very limited number of places of origin of plant and animal domestication and, therefore, of agriculture.

EARLY DEVELOPMENT

The development of agriculture was an intensification by man of his food extractive processes. More food could be obtained from a given area of land by encouraging plant and animal species found useful and discouraging others. This provided for an increased population and gave better opportunity for settled life. Durable houses, as well as tools such as pestles, mortars, and grindstones, all of which had long been known in scattered places, came into more general use. There had even been villages in Stone Age times, among them the hunters' villages at Mezin in the Soviet Union, at Mallaha in Israel, and at Suberde in Turkey. These produced scant archaeological records, however; there exists no satisfactory evidence that they were inhabited by hunter-gatherers.

The Middle East. In the 7th millennium BC, with heightened agricultural development, villages in the Middle East became more numerous. Called the "effective"

“Effective”
village
stage

Effect of
domestica-
tion on
animals

Figure 1: Wild and cultivated wheats. (Left to right) wild einkorn, einkorn, wild emmer, emmer, bread wheat. Scales: Ears, about $\frac{1}{2}$; grains, about $\frac{9}{10}$.

From E.C. Curwen and G. Hatt, *Plough and Pasture* (copyright 1953); Murnat Publications, Inc.

village stage of development, this period was accompanied by increasingly diversified agriculture, which led to more productive and efficient exploitation of available resources. The earliest known domesticated pigs have been recorded, in association with einkorn, at the village site of Jarmo (Iraq), dated about 6750 BC. The earliest known domesticated cattle date from about 6000 BC, at Argissa and Nea Nikomedeia, in Greece, in association with cultivated einkorn, emmer wheat, and lentils (*Lens culinaris*); and at Knossós on Crete in association with bread wheat (*Triticum aestivum*), emmer, and barley. Hoes or digging sticks were still used to break the ground where necessary. Seeding by treading in with flocks and herds was probably employed at this time. Techniques of food storage, a practice that man shares with many other animals, grew in sophistication; there were pit silos and granaries, sometimes of quite substantial nature. In drier areas, crop irrigation, which greatly increased yield, was developed; and, with the increasing population, more labour was available to carry out wider irrigation projects.

Nitrogen-fixing (fertilizing) crops were also grown; a form of crop rotation came into use either by accident or by design. By this particular means, soil fertility was maintained, and thus additional plant protein was added to the diet.

The Americas. Although domesticates such as peppers,

avocados, and amaranths were being grown in the Americas around 7000–5000 BC, villages were not numerous until widespread corn production began about 3500 BC. By then, common beans (*Phaseolus vulgaris*), chili pepper (*Capsicum annuum*), and black and white zapotes were also widely cultivated. An early cereal, the foxtail millet, was probably domesticated around 4000 BC in Tamaulipas, Mex., but was superseded by corn, and its cultivation was abandoned.

China. In China, millet was cultivated by the 5th millennium BC; rice was probably grown by the 4th millennium. Wheat was introduced before 1300 BC, but the arid nature of the uplands made progress slow. In the wetter lowlands, wheat could scarcely compete with already domesticated rice. Barley apparently was not introduced until after 1300 BC, nor was the soybean cultivated until perhaps 1100 BC.

Europe. In Europe, archaeologists have given so much attention to domesticates that are today outstandingly successful, such as wheat, barley, cattle, sheep, and pigs, that other species, possibly of major significance in the past, have largely been ignored.

It is generally assumed—apart from the earliest known incidence in the Old World of the domesticated dog at Star Carr in Yorkshire, England (about 7500 BC), cattle in Greece (about 6000 BC), and a possibility of domesticated pigs in the Crimea at an earlier date—that Europe prior to the introduction of agriculture from the East was inhabited by hunter-gatherers. It has indeed been suggested that the grain called fat hen (*Chenopodium album*) was cultivated at Iron Age settlements in Denmark, as well as Gold of Pleasure (*Camelina sativa*) and curl-topped lady's thumb (*Polygonum lapathifolium*). Since cultivation of these grains is regarded as typifying a late form of agricultural development, it follows that agriculture must have taken about 3,000 years to spread from Greece to Denmark and the British Isles. Furthermore, considerable adaptations to new environments must have taken place in human technology and in the Asian species of sheep, goats, and cereals after their introduction into Europe. The effective village stage appears to have begun as soon as cereals and sheep or goats became important in Europe. In some areas, such as Hungary and Switzerland, many villages for thousands of years continued to rely upon indigenous animals for their animal protein.

Along the Danube River, the great postglacial European forest was penetrated by slash-and-burn agriculture based on cereals. In the more arid regions along the Mediterranean coast, fewer modifications were necessary. The incorporation of indigenous wild stock, wherever available, into domesticated herds doubtless aided their acclimatization, for this practice continued into historic times, in Hungary until the invasion of the Mongols.

Early agricultural societies

In the Old World, settled life had developed on higher ground from Iran to Anatolia (site of modern Turkey) and the Levant, and in China in the semiarid loess plains, but the earliest civilizations based on complex and productive agriculture developed on the alluviums of the Tigris, Euphrates, and Nile rivers. When the first villages appeared there is not certain. It is known, however, that villages and townships existed in the Euphrates Valley in the latter part of the 5th millennium BC. Soon the population was dispersed over the available area in agricultural units based upon hamlets and villages. Townships provided additional services that the hamlets themselves could not provide. On this basis, Sumerian civilization developed.

Sumer. The Sumerian civilization was marked by an overall increase in wealth rather than by technical or agricultural innovations. The necessary foundations had already been laid. The Early Dynastic Phase began about 3000 BC. In Sumer, barley was the main crop, but wheat, flax, dates, apples, plums, and grapes were also grown. The earliest known white woolly, and therefore carefully bred, sheep and goats were herded and were more numerous than cattle. The sheep were kept mainly for meat and milk; butter and cheese were made. It has been es-

Spread of agriculture in Europe

Earliest sheep breeding

timated that at Ur, a large town covering some 50 acres (20 hectares) within a cultivated enclave, there were 10,000 animals confined in sheepfolds and stables, of which 3,000 were slaughtered each year. Ur's population of about 6,000 included a labour force of 2,500 who annually cultivated 3,000 acres of land, leaving 3,000 acres fallow. The work force included storehouse recorders, work foremen, overseers, and harvest supervisors, as well as labourers. Agricultural produce was allocated to temple personnel in return for their services, to important people in the community, and to small farmers.

The land was plowed by teams of oxen pulling light un-wheeled plows, and the grain was harvested with sickles in the spring. Wagons had solid wheels with leather tires held in position by copper nails. They were drawn by oxen or the now-extinct Syrian onager (wild ass), harnessed by collars, yokes, and headstalls, and controlled by reins and a ring through the nose or upper lip and a strap under the jaw. As many as four animals, harnessed abreast to a central pole, pulled a wagon. The horse, which was probably domesticated about 2700 bc by pastoral nomads in the Ukraine, did not in fact displace the onager as a draft animal in Mesopotamia until about 2300 bc, when bridles and bits were also introduced. Soon after, written instructions appeared for the grooming, exercising, and medication of horses; presumably for breeding purposes, horses were named and records of sires kept. The upper highland areas continued to be exploited by transhumant nomads.

The Nile Valley. In Egypt, intensified agricultural exploitation apparently did not take place until domesticated animals from the Middle East were introduced. By the first quarter of the 5th millennium bc in al-Fayyūm, there existed villages that kept sheep, goats, and swine and cultivated wheat (emmer), barley, cotton, and flax, which was woven into linen. In this dry climate, village silos consisted of pits lined with coiled basketry; crops were harvested with reaping knives slotted with sharp flints. Elsewhere, at al-Badāri in Upper Egypt, animals were also kept; the fact that domesticated animals were wrapped in linen and buried close to villages perhaps indicates that agriculture was closely associated with some form of religious belief.

By predynastic Amratian times, about 3600 bc, agriculture appears to have begun in the valley alluviums of the Nile. By late predynastic times, about 3100 bc, there is evidence of a considerable growth in wealth consequent upon the earlier agricultural development and accompanied by a more integrated social system.

From depictions on the tombs and other artifacts in dynastic times, it is known that, in addition to present-day domesticates, other animals, such as deer, gazelles, hyenas, and Barbary sheep, were kept either in captivity or under some form of control. Whether or not this man-animal relationship can be regarded as domestication is a matter of semantics, but certainly some aspects of animal husbandry were practiced with these unusual animals. Though it is not known how far back in time such practices existed, some early villages in Egypt were dependent upon gazelles for their source of animal protein, as was the

township of Jericho, in Palestine, about 7000 bc. Indeed, such a dependence on the gazelle is known to go back to Upper Paleolithic times in Palestine, and the question arises whether this was due to earlier forms of domestication. Discoveries at Nahal Oren, in Israel, indicate that this may be true. It has also been suggested that millet was a staple crop in early times in Egypt.

By the 4th dynasty, about 3000 bc, agriculture was developed and sophisticated. In contrast to Mesopotamia, where the tendency had been to develop urbanized communities, the inhabitants going out of the towns to work in the fields, in Egypt the cities tended to be no more than market towns to serve the surrounding countryside. A whole bureaucracy dealt with agriculture. The grand vizier, second only to the pharaoh, stood at its head, the ministry of agriculture under him. There was a chief of the fields and a master of largesse, who looked after the livestock. There were royal domains and temple estates. Between landlord and tenant there was a patriarchal relationship, which, although despotic, was underlain by a strong sense of responsibility to the land. Rent was three and a half bushels of grain to the acre. Irrigation and the waters of the Nile were carefully controlled. Records show that King Menes, who lived around 3100 bc, had a large masonry dam built to control the Nile River and provide water for irrigation. A millennium later, the Nile at flood was diverted through a channel, 12 miles (19 kilometres) long, into Lake Moeris, so that, after the flood, water in the lake could be released for irrigation. Seed grain was lent to tenants, and teams of oxen were lent or hired to them. The land was tilled with a wooden plow drawn by ox or ass traction (Figure 2). The land was plowed twice, once to break the ground, after which the clods were broken up by heavy hoes, and a second time to cover the seed. Six-rowed barley and emmer wheat were the main crops. The seed was sown by a funnel on the plow or, alternatively, was trodden in by sheep. The crops were cut with sickles, which had been improved by the introduction of a curved handle. The harvest produced 11 times the sowing, but it is not known whether or not two crops were grown within the year. The grain was threshed by asses or cattle treading on it on the threshing floor. It was winnowed by tossing in the wind, the chaff blowing away and the grain falling back into the basket, and was then stored in great silos (Figure 3). Lentils, onions, beans, and flax were other important Egyptian field crops.

Production of animal protein was also given attention. The wetter areas were exploited by domesticated ducks and geese. The marshes, swamps, wasteland, and stubbles were grazed by numerous herds of cattle (black, piebald, and white), sheep with kempy (coarse) coats, goats, and pigs. One wealthy landlord in the 6th dynasty owned 1,000 cattle, 760 asses, 2,200 goats, and 1,000 sheep. Animal breeding for specialized purposes was developed; one breed of cattle was kept for meat and another for milk; a Saluki-like hunting dog was bred, as were fat-tailed sheep with tails so heavy they were carried by a small cart drawn behind.

Domestication of corn

mals were domesticated in the Americas until a comparatively late date. Available evidence seems to indicate that, in spite of the early domestication of some plants, village life did not begin to develop on any scale until 3500 BC or possibly somewhat earlier in Mexico, following domestication of corn. The process of agricultural development was therefore rather slow, occurring in widely dispersed centres, often in areas of poor fertility, sometimes even in deserts. Cacao (chocolate used to make a beverage), toma-

Figure 4: Inca cultivation with fire-hardened digging sticks. Drawing from "Nueva Crónica y Buen Gobierno" by Felipe Guaman Poma de Ayala. In Det Kongelige Bibliotek, Copenhagen.

toes, and avocados were cultivated. Irrigation, terracing, and the construction of islands in lakes increased land usage in drier areas. The land was cleared by chopping and burning, and the seeds were sown with the aid of fire-hardened digging sticks (Figure 4). Crops were stored in pits or granaries. The corn was prepared by boiling in limewater and by wet grinding. Cornmeal paste was then made into tortillas or flat cakes and gruel. Fine textiles were woven of cotton, and paper was made from tree bark. Village life was based on the extended family, composed of parents and their children's families, which provided the labour force. Villages were organized into larger territorial units based on ceremonial centres commonly in the form of flat-topped pyramids. Larger territorial units developed early in the 1st millennium AD.

Much less is known about the formative stage in Peru. Indeed, a civilization based on agricultural production may have begun there hundreds of years before it did in Meso-America, about the beginning of the Christian Era. Corn did not become important as a main crop in Peru until the 9th century BC, after perhaps 1,000 years of root crop, bean, and cotton agriculture. Corn was not extensively cultivated until irrigation developed; the potato, domesticated since about 2500 BC, was the chief crop in many areas until the 16th century AD.

At some time before the Inca civilization, the guanaco, ancestor of the llama and alpaca, was domesticated. The llama may have been domesticated as early as 2000 BC. Though the llama was essentially a beast of burden, the alpaca's main product was its fine wool. Another animal, raised for food, was the guinea pig. (E.S.H.)

Agriculture in Peru

Agriculture in ancient Asia

On his way across the Pamirs in search of Buddhist texts (AD 518) the Chinese pilgrim Sung Yün noted that the crest of the bare, cold, snowy highlands was commonly believed to be "the middle point of heaven and earth":

The people of this region use the water of the rivers for irrigating their lands; and when they were told that in the middle country (China) the fields were watered by the rain, they laughed and said, "How could heaven provide enough for all?"

Yet, heaven provided. It has long supported more than one-half of humanity on less than a seventh of the Earth's land surface along the continental rim to the south and east of the high interior mass with its festoons of mountains. In the so-called "golden fringe of a beggar's mantle"—from Pakistan through India, Burma, Thailand, Indochina, and eastern China up to the Gulf of Chihli, and the offshore island groups of Japan, Indonesia, the Philippines, and Sri Lanka (formerly Ceylon)—lives the vast majority of the population of Asia. Some 1,800,000,000 people are concentrated in two countries, China and India.

There is no consensus on the origin and progress of plant and animal domestication. The Soviet plant geneticist Nikolay Ivanovich Vavilov postulated several world centres of plant origin, of which,

an unusual wealth of original genera, species, and varieties of plants is found in India and China, countries which have contributed almost half of our crop plants. . . .

CHINA

Vavilov thought that the mountainous regions of central and western China, together with the adjacent lowlands, constituted the earliest and largest independent centre of the world's agriculture. From earliest times, land use has been divided into two major regions by the Tsinling Mountains, with wheat predominant in the northern realm and rice in the south. At different periods and places, subsidiary crops have included soybean, kaoliang (a grain sorghum), millet, corn, barley, sweet potatoes, peanuts, fruits, and vegetables. Cotton, tobacco, sugarcane, tea, and sericulture (silkworms) have been the important cash crops.

Early history. Archaeological information is comparatively scanty. It does not reveal when and how the first farmers settled down to cultivate food crops. Written records, available from about 1750 BC, are more conclusive.

Two growing areas of China

Tradition accords the honour of inventing agriculture to the legendary emperor Shen Nung, who is said to have carved a piece of wood into a plowshare and bent another piece to make a handle and taught the world the advantages of plowing and weeding. The chronicle *Pai-hu t'ung* relates that he did so out of necessity, because "the ancient people ate meat of animals and birds." At the time of Shen Nung, there were so many people that the wild animals and birds became inadequate for people's wants, and therefore Shen Nung taught the people to cultivate. As for the origin of cultivated plants, the problem was resolved by divinity: "Millet rained from heaven. Shen Nung collected the grains and cultivated them." Pigs are believed to have been domesticated in eastern Asia as early as 2900 bc.

Apparently the "millet from heaven" rained over the North China Plain in the central region of the Yellow River Valley, which is regarded as the birthplace of agriculture-based civilization in China. From there it spread throughout the country, but it failed to penetrate the northern grassland and plateaus. The Great Wall may be taken to demarcate the approximate frontier between the two basically different ways of life—the agrarian to the south and the pastoral nomadic of the steppes and deserts on the other side.

It is thought likely that the practice of irrigation spread to China from Babylonia. The Chinese are known to have had irrigation before 2200 bc. Notable Chinese irrigation works include the Tu-kiang Dam, built about 200 bc, which provided water for about 500,000 acres, and the Grand Canal, built in stages over several centuries and eventually extending for more than 1,000 miles.

The classical-imperial era. In about 335 bc, the Chinese philosopher Mencius wrote that, "If the farmer's seasons are not interfered with, there will be more grain in the land than can be consumed." By the 1st century bc, however, wastelands were being reclaimed for cultivation, and there was a demand for limitation of landholdings. In about ad 9, the first (unsuccessful) attempt was made to "nationalize" the land and distribute it among the peasants. By the end of the 2nd century ad, severe agrarian crises culminating generally in the downfall of the ruling dynasty had become a recurrent theme of history. Through the centuries, Chinese agriculture has been a continual struggle between man and land to raise more food.

By the 4th century ad cultivation was more intensive in China than in Europe or the rest of Asia. The major cereal-producing region and the population, however, were shifting rapidly from the wheat and millet area of the North China Plain to the paddies of the lower Yangtze Valley. By the 8th century the lower Yangtze was exporting enormous quantities of grain into the old Northwest by way of a unified system of canals linking the large rivers.

By about ad 1100 the population of South China had probably tripled, while that of the whole country may have exceeded 100,000,000. Consequently, cultivation became extremely intensive, with a family of 10 crowded, for example, onto a farm of about 14 acres. Again, more new lands were opened to cultivation. Even tanks, ponds, reservoirs, streams, and creeks were reclaimed to be turned into farms. At the same time, complex water-driven machinery came into use for pumping irrigation water onto fields, for draining them, and for threshing and milling grain. A large variety of improved and complicated field implements were also employed; these are described and illustrated in the agricultural literature of the day.

Tools and techniques. The first significant revolution in Chinese agricultural technology had occurred when iron agricultural implements became available to the Chinese peasantry. The earliest iron plow found in northern Honan dates from the Warring States period (475–221 bc) and is a flat V-shaped iron piece that must have been mounted somewhat insecurely on wooden blades and handles to serve as working edges. It was small, and there is no evidence that draft animals were used. Cattle-drawn plows do not appear until the 1st century bc.

Several improvements and innovations, such as the three-shared plow, the *lou-li* (plow-and-sow) implement, and the harrow, were developed subsequently. By the end of the

Sung dynasty in 1279, Chinese agricultural engineering had reached a high state of development.

The common farmers continued to use these early medieval techniques into modern times. Their unfenced fields were cultivated by a wooden plow, with or without a cast-iron share and usually drawn by a water buffalo. Harvesting was by sickle or billhook (a cutting tool consisting of a blade with a hooked point fitted with a handle). Sheaves carried from the field were slung at the ends of a pole across an individual's shoulders. The grain was threshed by beating on a frame of slats or by flails on the ground. Winnowing was accomplished by tossing the grain in the wind. Rice was dehusked by hand pounding in a mortar or with a hand-turned mill. Irrigation techniques varied. The most common perhaps was a wooden, square-paddle chain pump with a radial treadle operated by foot. Fields were drained by open ditches and diking. Night soil, oil cakes, and ash fertilized the soil.

Over the past millennium, in fact, the revolution in Chinese agriculture has not been in mechanical or chemical technology but rather in the biological sphere: in crops, cropping systems, and land utilization. Under increasing population pressures, cultivation was forced to become more labour intensive and also to expand into the sandy loams, arid hills, and the upper reaches of lofty mountains. Lacking major technological inventions, the Chinese peasant had to expand the area under cultivation by finding suitable crops for inferior land.

Land use. A "three fields in two years" rotation system for wheat and millet was being practiced by the 6th century ad. Revolutionary changes in land utilization, however, started with the introduction in Fukien Province of an early-maturing and relatively drought-resistant rice from Champa, in central Indochina. In 1012, when there was a drought in the lower Yangtze and Huai Ho regions, 30,000 bushels of Champa seeds were distributed. Usually a summer crop, the native rice plant required 150 days to mature after transplanting. Not only did this make a second crop difficult, but, because of the plant's soil and water requirements, cultivation was confined largely to the deltas, basins, and valleys of the Yangtze. The original Champa rice, on the other hand, ripened in 100 days after transplanting and required less water.

The success of Champa rice initiated the development and dissemination of many more varieties suited to the local peculiarities of soil, temperature, and crop rotation. The first new early-ripening strain to develop required 60 days after transplantation. By the 18th century, there was a 50-day Champa and a 40-day Champa. In 1834, a 30-day variety was available—probably the quickest ripening rice ever recorded. The effect was revolutionary. By the 13th century, much of the hilly land of the lower Yangtze region and Fukien had been turned into terraced paddies. At the close of the 16th century, Champa rice had made double, and sometimes triple, rice cropping common.

A second revolution in land utilization began in the 16th century, with adoption of food crops from the New World, such as corn, sweet potatoes, potatoes, and peanuts (groundnuts). These could be grown at drier altitudes and in sandy loams too light for rice and other indigenous cereals. Virgin heights of the Yangtze region and North China were turned into corn and sweet-potato farms. As the population in the mountain districts increased, the potato took over the soils too poor for corn and sweet potatoes. By the middle of the 19th century, even ravines and remote mountains were being cultivated. Similarly, peanuts penetrated the remote and agriculturally backward areas of Kwantung, Kwangsi, and Yunnan provinces and the sandbars of Szechwan. Gradually, they brought about a revolution in the utilization of sandy soils along the lower Yangtze, the lower Yellow River, the southeast coast, particularly Fukien and Kwantung, and numerous inland rivers and streams.

Even so, the revolution in land use failed to alter the basic man-land relationship in China. Again in the 18th century, the emperor Ch'ien-lung rejected demands for limitation of landownership. In an edict (1740), however, he noted that "the population is constantly increasing, while the land does not become any more extensive." He

directed his subjects, therefore, to cultivate all and every odd piece of soil,

on top of the mountains or at the corners of the land. All these soils are suitable either for rice or for miscellaneous crops. . . . no matter how little return the people may receive from cultivation of these lands, it will be always helpful in supplying food provisions for the people.

THE INDIAN SUBCONTINENT

India's most important contribution to world agriculture is rice (*Oryza sativa*), the staple food and crop of most of southern, Southeast, and East Asia. Sugarcane, varieties of legumes, and several kinds of tropical fruit, such as the mango and the muskmelon (*Cucumis melo*), also are native to the Indian subcontinent.

Archaeological records of this region's prehistory are still incomplete and uneven. Evidence of how the transition from pastoralism to crop farming took place is lacking. Toward the close of the 3rd millennium bc, in the alluvial plains of the Indus River in Pakistan, ruins of the twin cities of Mohenjo-daro and Harappā reveal an apparently sudden explosion of an organized, sophisticated urban culture. This society, known as the Indus Valley, or Harappan, Civilization, flourished until around 1750 bc, and was much more extensive than those of Egypt or Babylonia, and earlier than that of northern China. Peculiarly Indian, Harappan society was remarkably homogeneous, thoroughly individual and independent, and technically the peer of China and Egypt. Nothing is known, however, about the farm communities that must have produced a surplus of agricultural products sufficient to sustain the population and fill the granaries of the metropolitan centres. At Harappā, for instance, the granary consisted of two blocks of six chambers each. The floor space of the 12 units covered an area of more than 90,000 square feet (about 8,100 square metres).

Barley (*Hordeum vulgare*), a small-seeded, six-rowed variety, and two types of wheat—club wheat (*Triticum aestivum*) and an Indian dwarf variety (*T. sphaerococcum*)—were evidently the main cereal crops, supplemented by dates, sesame, field peas, and lentils. Humped Indian cattle and a humpless breed, goats, sheep, fowl, and the elephant had been domesticated. In addition to the domestication of a great variety of animals, fragments of dyed and woven cotton fabric attest to the antiquity of the cultivation of cotton plants and of the textile industry for which India was to become famous the world over.

No archaeological or pictorial evidence of farm implements has survived, and the Harappan script is yet to be deciphered. It has been surmised, however, that the cereals could have been sown in the fall on inundated land after the annual flooding of the rivers had receded and then harvested in spring. The system is still in use and involves minimal skill, labour, and equipment. The land does not have to be plowed, fertilized, or irrigated.

It was clearly more than a subsistence economy, for there is proof of river and sea traffic. There was a trading post at Lothal on the Gulf of Cambay with a brick dockyard and elaborate channel and spillway. Two-wheeled bullock carts and light, covered wagons—forms of transportation still common—were used for local travel. Caravans of pack oxen were the principal mode of transportation over longer distances.

South India, centre of the later distinctive Tamil culture, constituted a second, initially independent agricultural region. Crops were being raised there during the first half of the 2nd millennium bc. Two varieties of pulses (legumes) and finger millet (also called raggee) were cultivated.

To the north and west of the Deccan Plateau lay a third intermediate area. There, at Lothal and Rangpur, has been found the earliest evidence of rice cultivation, in the later Harappan period. Subsequently, wheat, cotton, flax, and lentils spread into the region from the Indus Valley, and pulses and millets from the south.

In all the three regions the basic cropping pattern of the 2nd millennium bc, except the pattern for rice, has continued into the 20th century.

Early historic period. A fourth agricultural region developed during the 1st millennium bc in the Gangetic

Valley. Waves of invading Indo-Aryan tribes presumably destroyed the Harappan cities and penetrated deep into Hindustān proper, the principal seat of the classical Indian civilization. With the Aryans came the horse, coinage, the Brāhmī script, and the whole corpus of Vedic literature. Sources of information henceforth are literary rather than archaeological. The plow, for example, figures in a hymn of the most ancient of the texts, the Rigveda: "Harness the plows, fit on the yokes, now that the womb of the earth is ready to sow the seed therein. . . ."

Apparently, rice played an important role in growth of population and new settlements. They had spread eastward to the Ganges Delta by the 7th century bc.

In the later Vedic texts (c. 1000–500 bc), there are repeated references to iron. Cultivation of a wide range of cereals, vegetables, and fruits is described. Meat and milk products were part of the diet; animal husbandry was important. The soil was plowed several times. Seeds were broadcast. Fallowing and a certain sequence of cropping were recommended. Cow dung provided the manure. Irrigation was practiced.

A more secular eyewitness account is available from Megasthenes (c. 300 bc), a Greek envoy to the court of the Mauryan Empire. In his four-volume *Indica*, he wrote:

India has many huge mountains which abound in fruit-trees of every kind, and many vast plains of great fertility. . . . The greater part of the soil, moreover, is under irrigation, and consequently bears two crops in the course of the year. . . . In addition to cereals, there grows throughout India much millet . . . and much pulse of different sorts, and rice also, and what is called *bosporum* [Indian millet].

And again,

Since there is a double rainfall [*i.e.*, the two monsoons] in the course of each year. . . . the inhabitants of India almost always gather in two harvests annually.

Other sources reveal that the soils and seasons had been classified and meteorological observations of rainfall charted for the different regions of the Mauryan Empire, which comprised nearly the whole subcontinent and territory to the northwest.

A special department of the state supervised construction and maintenance of the irrigation system. The best known work of the period is the Sudarshana Lake in Kāthiāwār, created by an artificial dam and furnished with conduits. Roads, too, were the government's responsibility. The swifter horse-drawn chariot provided greater mobility than the bullock cart.

The Mughal century (c. 1600). At the climax of the Mughal Empire, with the arrival and presence of the Western powers, a commercial economy based on oceanic trade was evolving. But no technological revolution in cultivating tools or techniques had occurred since roughly the time of the *Upaniṣads* (c. 600–300 bc).

The crops were broadly divided into rice zones and wheat and millet zones. Rice predominated in the eastern states, the southwest coast, and in Kashmir. Aside from its original home in Gujarāt, it had spread also to the Punjab and Sind with the aid of irrigation. Wheat grew throughout its "natural" region in north and central India. Millets were cultivated in the wheat areas and in the drier districts of Gujarāt and Khāndesh as well.

Cotton, sugarcane, indigo, and opium were major cash crops; the last two have since passed out of cultivation. Introduced by the Portuguese, cultivation of tobacco spread rapidly. The Malabar coast was the home of spices, especially black pepper, that had stimulated the first European adventures in the East. Coffee had been imported from Abyssinia and became a popular beverage in aristocratic circles by the end of the century. Tea, which was to become the common man's drink and a major export, was yet undiscovered, though it was growing wild in the hills of Assam. Vegetables were cultivated mainly in the vicinity of towns. New species of fruit, such as the pineapple, papaya, and cashew nut, also were introduced by the Portuguese. The quality of mango and citrus fruits was greatly improved.

Cattle continued to be important for draft and milk. According to a Dutch observer, however, the cows gave far less milk than in his country. Land use never became

Gangetic
Valley
culture

Spices,
coffee, tea,
and fruit

Indus
Valley
Civilization

as intensive as in China and the Far East, although, as noted by Megasthenes, double (and even triple) cropping was fairly common in regions favoured with irrigation or adequate double rainfall. Though the population must have increased many times over since Mauryan times, in the 17th century virgin land was still abundant; peasants were scarce.

Irrigation from wells, tanks, and canals, however, had greatly expanded. Some new water-lifting devices—such as the *sakia*, or Persian wheel, which consisted of a series of leather buckets on an endless rope yoked to oxen—had been adopted and are still widely used.

Traditional
implements

The plow was the principal implement for tillage. Drawn by oxen, the traditional Indian plow has never had a wheel or a moldboard. The part that penetrates the soil is a wedge-shaped block of hardwood. The draft pole projects in front, where it is attached to the neck yoke of the bullocks. A short, upright stilt in the rear serves as a guiding handle. The point of the wedge, to which an iron share may or may not be attached, does not invert the soil. Some plows are so light that the cultivator can carry them daily on his shoulder to and from the fields. Others are heavy, requiring teams of four to six pairs of oxen. Levelers and clod crushers, generally consisting of a rectangular beam of wood drawn by bullocks, are used to smooth the surface before sowing. Among hand tools, the most common is the *kodali*, an iron blade fitted to a wooden handle with which it makes an acute angle.

Drill sowing and dibbling (making small holes in the ground for seeds or plants) are old practices in India. An early 17th-century writer notes that cotton cultivators “push down a pointed peg into the ground, put the seed into the hole, and cover it with earth—it grows better thus.” Another simple device was a bamboo tube attached to the plow. The seed was dropped through the tube into the furrow as the plow worked and was covered by the soil in making the next furrow.

Operations of reaping, threshing, and winnowing have continued to be performed almost exactly as described in the Vedic texts. Thus, grain is harvested with a sickle. It is bound in bundles and threshed by bullocks treading on it or by hand pounding. To separate the grain from the chaff, it is either sieved with sieves made of stalks of grass or of bamboo, or it is winnowed by pouring by hand at a height from a *supa* (winnowing scoop). The grain is then measured and stored. The sickle, sieve, and *supa* remain today as they were more than two millennia ago.

SOUTHEAST AND EAST ASIA

The Chinese agrarian system could not conquer the northern steppes and deserts nor could it cultivate the barren heights of the Tibetan plateau to the west. It did reach out, however, to areas with less extreme environmental factors—to the plains of Manchuria, Inner Mongolia, the lower valleys of eastern Tibet, and Chinese Turkistan, wherever conditions were favourable. It encountered no comparable barriers to the east. As a result, crops and cultivation techniques, especially of rice culture, spread to Korea and Japan, where they enjoyed notable success. Japan achieved higher yields per acre of rice than did China and most of the world.

Southeast Asia, on the other hand, constitutes an agricultural subcentre supplementing that of the Indian subcontinent. Though it has a wealth of tropical wild and cultivated flora, rice became the staple and predominantly subsistence crop of the region after its introduction probably by Indian colonists around the middle of the 1st millennium BC. Most of the other key farm products, such as sugar, tea, coffee, cotton, rubber, and corn, also were introduced to this area from the outside by the European colonizers.

Shifting
cultivation

Historically, shifting cultivation has been native to all the countries and still survives. As in South Asia, most of the rice is rain fed, and multiple cropping is infrequent, probably because of relatively low population densities in most of the region. With the exception of small pockets, as on the island of Java and in the Red River Delta of northern Vietnam, even wet-rice cultivation techniques have never been as intensive as in South China and Japan, nor have the yields been nearly as high.

(K.Na.)

Improvements in agriculture in the West: c. 200 BC to AD 1600

THE ROMAN EPOCH

Crop farming and domestication of animals were well established in western Europe by Roman times. Yields per acre were small by 20th-century standards, and nearly half the annual crop had to be used as seed, but quantities of grain were still exported from Britain to Gaul. Where feasible, Roman farming methods were adopted.

Greek and Roman farming techniques are known from contemporary textbooks that have survived. Methods were dictated to some degree by the Mediterranean climate and by the contours of the area. The majority of the crops cultivated today on the Mediterranean coast, wheat, spelt, barley, some millet, and the legumes (beans, peas, vetches, chick-peas, alfalfa [*lucerne*], and lupines), were known at that time. The olive, the vine, and fruit trees were grown, as were turnips and radishes.

The farm. Roman holdings were commonly as small as 1¼ acres; the ground was prepared with hand tools, hoes, and mattocks, doubtless edged with bronze or iron. Later, as farming developed, and estates of different sizes came into existence, two writers set out catalogs of the tools, implements, and labour required to exploit a given-size holding. These were Marcus Porcius Cato (234–149 BC) and Marcus Terentius Varro (116–27 BC). Already in Cato's time, emphasis was on production of wine and oil for sale, rather than cultivation of cereal crops, beyond the volume required to feed animals and slaves.

For an olive grove of 240 jugers (150 acres), Cato estimated necessary equipment as three large carts, six plows and plowshares, three yokes, six sets of ox harness, one harrow, manure hampers and baskets, three pack saddles, and three pads for the asses. Required tools included eight heavy spades, four smaller spades, shovels, rakes, scythes, axes, and wedges. Some 13 people, including an overseer, a housekeeper, five labourers, three teamsters, a muleteer, a swineherd, and a shepherd responsible for 100 sheep, would do the work. Other livestock included three yokes of oxen, three donkeys to carry manure, and one for the olive-crushing mill. The farm was also to be equipped with oil presses and containers for the oil.

Equipment
and labour
for an olive
grove

Farm implements. Most Roman-era hand tools were similar in shape to their modern counterparts. The wooden plow was fitted with an iron share and, later, with a coulter (cutter). Though it had no moldboard to turn the soil over, it was sometimes fitted with two small ears that helped to make a more distinct rut. Though it could not turn a furrow, it could invert some of the soil if held sideways. It was usually followed by a man with a mattock who broke up clods and cleared the row so seed would fall into it. Two or three such plowings were given each year to land intended for cereals. Manure was spread only after the second plowing. If spread earlier, it would be buried too deep to do any good. The farm included a compost pit where human and animal excrement were placed along with leaves, weeds, and household waste. Water was added from time to time to rot the mass, and an oak pole was driven into the middle to keep snakes away. Various animal and bird droppings were believed to have different effects on growing plants. Pigeon's dung was valued, but that of aquatic birds was avoided. Marl—earth containing lime, clay, and sand—was used in Gaul and possibly in Britain.

Seeds were sown by hand, broadcast, or dropped. They were covered with a harrow, which may have had iron teeth or may simply have been a thornbush. A more complex plow, fitted with a wheeled forecarriage, may have been used in Cisalpine Gaul (northern Italy) as early as the 1st century AD. Traction normally was supplied by a pair of oxen; the Roman historian Pliny the Elder (AD 23–79) mentions as many as eight being used on heavy land. In light soil, only one was necessary, and sometimes asses were used.

Cropping systems. Olive groves and vineyards were permanent; grain and pulses were annuals. Although it was realized that different soils were better suited to some crops than to others, the same piece of land was used for

all crops. A specific crop, however, was grown in alternate years in what is known as the two-field, or crop-and-fallow, system. The fallow land was plowed two or three times during the fallow year to kill the weeds, which typically accumulate where cereal crops are continuously cultivated. Wetland was drained by digging V-shaped trenches, the bottom of which, usually four feet deep, was paved with loose stones, willow branches, or bundles of brushwood placed lengthwise, and covered with the replaced soil. Soil was judged by colour, taste, smell, adhesion to the fingers when rubbed, and whether it filled up a hole from which it had been dug or proved too loose.

Then as now, wheat was mostly sown in autumn, though a species known as *Triticum trimestre* was sometimes planted in spring; it ripened in three months. Barley was a spring-sown crop, as were most others. Though the Romans knew that growing alfalfa and clover was in some way good for the succeeding crop, they did not know why. Similarly, a crop of lupines was sometimes planted for plowing in as green manure, and occasionally a crop of beans was used in the same way.

Harvesting and processing. The harvest was reaped with a curved sickle, a tool that has changed little since Roman times. In some places, the ears of grain were cut and carried in wicker baskets to the threshing floor. The straw was cut and stacked later. In other areas, the plant was cut lower down, and the grain was threshed from the straw. Another set of tools was used, consisting of a short-handled sickle held in the right hand, with the blade at right angles to the handle. A short-handled hooklike implement held in the left hand was used to draw together enough grain to be cut at one stroke. In Gaul, a reaper was used, a cart with an open back pushed by an animal reversed in the shafts. On the edge of the back, a comb-like device was fixed to tear off the ears as the vehicle was pushed through the crop. The grain was threshed in the long-established way, by animals treading it on a firm floor, or by an implement known as a *tribulum*, a wooden framework with bits of flint or metal fixed to the underside, hauled over the grain by an animal. Winnowing was still done by tossing in the air from a winnowing basket when there was a favourable wind to blow away the chaff.

Grain was ground with a quern, a hand implement made of two stones, a concave base with a convex upper stone fitted into it. Some querns turned in a circle, while others merely rubbed up and down on the grain. Though designed before the end of the Roman period, water mills were uncommon.

Some forage crops were necessary to feed the plow animals and the cattle, sheep, and pigs. Grass was cut for hay, and many hours must have been spent in the woods collecting acorns for winterfeed for the swine. Alfalfa was the best fodder; it helped fertility as well. Lupines and a mixed crop of beans, vetch, and chick-peas and another mixture of barley, vetch, and legumes were also employed. Turnips were grown for human and animal consumption in some regions, notably Gaul.

Livestock. Little attempt was made at selective breeding, and little was possible, for most of the animals spent their time at open range or in the woods. Nevertheless, different breeds of cattle were recognized as native to particular places. They were bred between the ages of two and 10 years; two bulls to 60 or 70 cows was the usual proportion. Greek shepherds garbed some of the very fine woolled sheep in skin coats to keep their fleece clean. Ewes were bred at three years old, two if essential. They fed on the stubble after harvest. Transhumance, or seasonal migration in search of pasture, was normal. A supply of clear water near the grazing ground was necessary.

Goats were kept in large herds, with 50 to 100 the optimum. Swine were also important. Very fat animals were preferred, and large numbers of these, whose meat was frequently seen on the Roman table, were kept. Sows were covered (bred) at from 12 to 20 months of age; it was desirable for them to pig in July or August. The best proportion of boars to sows was 10 to 100. Herds of 100 to 150 ranged the woods. The bacon produced in Gaul had a reputation for quality; swine also flourished in northern Italy and eastern Spain.

The methods of the Roman farmer produced only limited yields, and cereals were regularly imported to Italy from lands more naturally favourable to grain growing: Egypt, Sicily, Sardinia, and Gaul. Yet the Roman methods were basically sound and, with the help of modern mechanical aids, remain to a large extent in force today.

THE MEDIEVAL PERIOD: 600–1600

In 1,000 years of medieval history, many details of farming in the Western world changed. The period falls into two divisions: the first, one of development, lasted until the end of the 13th century; the second, a time of recession, was followed by two centuries of recovery.

Agricultural advances. The most important agricultural advances took place in the countries north of the Alps, in spite of the large population changes and warfare that accompanied the great migrations and the later onslaughts of Northmen and Saracens. Agriculture had, of course, been practiced regularly in Gaul and Britain and sporadically elsewhere in Europe both before and during the Roman epoch. The climate and soils and, perhaps, the social organization compelled different arrangements of land division and the use of more complex tools as more and more land was reclaimed from forest, marsh, and heath to meet the needs of a rising population.

Open-field system. The precise origin of the open-field arrangement (Figure 5), which involves long scattered strips of arable land separated from each other by a furrow, balk (ridge of land left after plowing), or mere (boundary), is obscure. The earliest examples of this system date from about 800, the year Charlemagne was crowned emperor of the West. Usually these strips of land, normally about one

Figure 5: Ridges of the English open-field system as seen today in Leicestershire.

acre in size, were laid out in two or three large fields. Each farmer in the village worked a number of these acres; the units forming his holding were scattered among those of other men. The open-field system continued as more land was reclaimed and lasted for many centuries—longer, of course, in some places than in others. It has been suggested that the length of each strip was determined by the distance a draft animal, usually an ox, could haul a plow before stopping for a rest. The intermingling of the strips was said to have been the result of a jointly owned

The quern

Swine raising

plow team and plow supplied by a number of farmers working together, each being allotted a strip in turn. A subsequent theory holds that in some places the division of fields, which may have originally been rectangular or square, among a number of heirs led to the creation of long, narrow acres.

In theory each person's holding totaled 30 acres, comprising strips equally divided among the three arable fields. With the passage of time, wide variations in the size of holdings came about; many became very small.

Plows and plowing. Besides the different arrangement of the plowland, there were other changes, some of them important. Though Pliny the Elder claimed a wheeled plow was used in Cisalpine Gaul about the time of Christ, there is a good deal of doubt about this. A wheeled asymmetrical plow was certainly in use in some parts of western Europe by the late 10th century. Illuminations of manuscripts and calendars a little later in date show a plow with two wheels fitted with a rudimentary moldboard and a coulter (Figure 6). This plow could invert the soil and turn a true furrow, thus making a better seedbed. Its use left high ridges on the land, traces of which can still be seen in some places.

The horse collar, which replaced the old harness band that pressed upon the animal's windpipe, severely restricting its tractive power, was one of the most important inventions in the history of agriculture. Apparently invented in China, the rigid, padded horse collar allowed the animal to exert its full strength, enabling it to do heavier work, plowing as well as haulage. Many peasants continued to use oxen, however, because horses were more expensive to buy and to keep. Some plowing was done by two oxen as in former times; four, eight, or more were occasionally necessary in very difficult land.

Hand tools. Modifications, slight but important, had been introduced into the design of hand tools. A more effective ax made forest clearance easier and faster. The jointed flail supplanted the straight stick. The scythe was more frequently in use for mowing grass, reaping barley, and performing similar tasks. Wind power was applied to the grinding of grain by the earliest windmills. All these changes and adaptations helped expand the cultivated area and supply food for the growing population.

New lands and crops. Not only were forests cleared and heavy land cultivated but, in the Netherlands, reclamation from marsh and from the sea was extended. In the midst of the marshes, terps, artificially made patches of higher land on which houses and barns could be built, were made at a very early date. Ditches to drain the fens were dug in the 10th century. Polders, land reclaimed from the sea, are first recorded in the 12th century.

In Spain, the Moors had introduced new crops and a new breed of sheep, the Merino, that was to make Spanish wool famous throughout Europe. New crops included sugarcane, rice, cotton, and some subtropical fruits, especially citrus. Grapevines and olive groves flourished in the south, as did the vines the Romans had introduced to the valleys of the Moselle and Rhine rivers. In the 12th century, Venice became a major cotton-manufacturing city, processing cotton from the Mediterranean area into cloth for sale in central Europe; and in the Middle Ages Germany became a cotton-manufacturing centre.

Widespread expansion of farmed land occurred throughout western Europe between the 10th century and the later years of the 13th. German and Dutch settlers were encouraged to take up holdings eastward toward the Baltic countries and south to the Carpathians. In France, new villages were built and new farms carved out of the forest and the waste, while, in England, a great deal of land on the boundaries of the open fields was taken in and cultivated. All this new cultivation was carried out with the same old implements and tools; the same crops were cultivated and animals bred as before. In remote and desolate places, monastic organizations created great estates. These estates were formed to feed growing populations rather than to improve technical skills. A new literature of farming arose, directed to the attention of great lords and ecclesiastical magnates rather than to the illiterate majority of husbandmen. These bright prospects, how-

ever, were dimmed in the 14th century by a combination of calamities.

Agricultural recession. What is now called a recession began toward the end of the 13th century. The disasters of the 14th, climatic, pestilential, and military, followed. Famine resulted from excessively bad weather in 1314, 1315, and 1316; a small recovery followed in 1317. Yields, never high (from six to 10 bushels of wheat per acre; a little more for barley, rye, and oats), were reduced to nothing by the weather. Floods wiped out the reclaimed land in the Netherlands. Plague followed famine, bringing suffering to both animals and humans. The Black Death broke out in 1347 and is estimated to have killed approximately one-third of the population of Europe. Renewed outbreaks followed throughout the remainder of the century. The Hundred Years' War desolated much of France; other conflicts, accompanied by similar pillage and destruction, broke out elsewhere. The result of all these misfortunes was to be seen in the landscape throughout western Europe. Much of the arable land could not be cultivated for lack of labourers; in some regions the countryside was inhabited by a few scattered peasants grubbing a scanty living in the grimmest isolation. Many of the newer settlements and some of the established ones were abandoned and became deserted villages.

The Netherlands. The Netherlands was not as seriously affected as most other countries. The flood destruction was repaired, and a system developed that was to become an example to all Europe. Leguminous and root crops were introduced into the rotation at least as early as the 15th century, and long continuous rotations almost without fallow breaks were employed. Town refuse was added to the supplies of animal manure. The size and milk yield of the Dutch cattle became famous, though possibly exaggerated. Some say that they owed part of their distinction to crosses with animals from Lombardy and Piedmont, which also enjoyed a great reputation. Flemish horses were already renowned for size and strength.

England. In England, when agricultural recovery began in the 15th century, there was no immediate improvement in technique. During this period, England became known as the home of most medium- and long-wooled mutton breeds. The profits of the wool trade and, later, of the

Effects of
the Black
Death and
Hundred
Years' War

The
wheeled
plow

woolen manufacture induced landowners to increase the size of their flocks. This led to some difficulties. Not only had some arable land fallen down to rough grazing because of labour scarcity after the diseases and bad seasons of the 14th century, but the profit of wool encouraged enclosure of formerly open fields for grazing; some villages were even destroyed to increase the area of grazing land. Though there was a considerable outcry against enclosure in the 16th and early 17th centuries, the practice was too profitable to halt. At the same time, farmers began exchanging their scattered plots of land in order to consolidate individual holdings. These consolidated plots were then enclosed with a hedge or fence to prevent them from being subjected to the regulations that governed the use of the remaining strips. Land was also acquired by purchase for this purpose. None of these changes, however, involved any technological advances in farming.

Spain. In Spain, the shepherds, whose organization, the Mesta, was a powerful body with great political influence, came into conflict with the farmers. The annual journey of sheep from their northern grazing area to the south carried them along an established route; this route steadily broadened, with the sheep trespassing upon the farmers' lands and consuming crops. At the same time, the Mesta successfully opposed any expansion in the amount of arable land until the mid-16th century.

Persistence
of Roman
farming

Italy. In the 14th century the city-states of Italy were devoted to commerce. There was little emphasis on farming, though some attempts at draining marshes were made, and, in spite of the introduction of rice culture in the north, Italian farming on the whole remained much as it had been in Roman times. In the south great flocks were kept and moved up to the mountains for the summer along well-defined paths.

France. In the 15th century French farmers made substantial progress toward recovery, but even in France there was little advance in technology. The open-field system was prevalent in the north, and a type of Roman farming suited to the environment was practiced in the south, with alfalfa, clover, lupines, and other legumes grown for fodder and to maintain fertility. A fodder crop called Burgundy grass was grown in Burgundy toward the end of the 16th century.

Germany. Many of the German villages depopulated by the disasters of the 14th century were never resettled. Some of them had been established on marginal land, such as sandy heaths or high in the mountains. By the middle of the 16th century, the advanced farming of the Netherlands penetrated into the north at the mouth of the Rhine and in Schleswig-Holstein. This is clear from one of the earliest printed books on farming, by a German, Conrad Heresbach. Heresbach described and recommended many of the methods used by the Romans, including raising lupines for green manure and rotating fallow-manured, winter-sown rape with wheat, rye, and spring barley. For the preparation of the seedbed, the destruction of weeds, manuring, sowing, and harvesting, implements that derived from the Roman pattern were used.

Heresbach's book followed somewhat the pattern of Crescentius, who wrote in the 13th century, and in that respect was similar to the growing number of agricultural treatises that appeared in Spain and France. These were often encyclopaedias of rural life presumably intended for the landowning public. In the late 16th century, Henry IV of France and his minister, Sully, tried to stimulate interest among the lesser nobility in the management of their estates. In England, translations were made of continental works.

Crop-farming changes in western Europe: 1600-1800

THE NORFOLK FOUR-COURSE SYSTEM

Of the many changes that took place during this period in agricultural history, few were more important than the Norfolk four-course system, characterized by the disappearance of the fallow year and by a new emphasis on fodder crops. The movement toward change was further intensified by the invention of new farm machines, im-

provements in farm implements, and scientific interest and new biological theories relating to farm and animal life.

In the Norfolk four-course system, wheat was grown in the first year, followed by turnips in the second, then barley, with clover and ryegrass undersown, in the third. The clover and ryegrass were grazed or cut for feed in the fourth year. The turnips were either employed for feeding cattle in open yards during the winter (some covered yards were built) or for feeding sheep confined in folds set up on the ground. This new system was cumulative in effect, for the fodder crops eaten by the livestock produced large supplies of previously scarce animal manure, and that was richer in nature because the animals were better fed. When the sheep grazed the fields, their urine and droppings fertilized the soil, so that heavier cereal yields were obtained in following years.

Increased
use of
animal
manure

Established in Norfolk County, England, and in several other counties before the end of the 17th century, the Norfolk four-course system became fairly general on the newly enclosed farms by 1800, remaining almost standard practice on most British farms for the best part of the following century. The system was used in the Lothians and some other parts of Scotland by about 1800 and, during the first three quarters of the 19th century, was adopted in much of continental Europe.

Enclosure. In order to adopt the Norfolk four-course system, it was first necessary to alter the thousand-year-old layout of the arable fields. It was virtually impossible for an individual farmer to grow fodder crops on his strips of land in open fields, for at certain seasons (after harvest, for example) these fields were opened to grazing by the livestock of the whole community. The improving farmer, who grew clover and ryegrass or other legumes or a root crop, would simply have provided additional feed for his neighbours' as well as his own animals. Such an arrangement was possible, of course, if all the farmers cooperated, a rather unlikely but not absolutely unknown state of affairs. On enclosed land, however, a farmer could cultivate these crops and benefit from his own efforts.

Consequently there was a rapid acceleration of the enclosure movement in England, sometimes by local agreement, by Chancery decree (late 17th century), and by private acts of Parliament in growing numbers (18th century). Some 6,000,000 acres of English fields were enclosed between 1700 and 1845. On the Continent, the change, where it was made, took place slightly later. Some farms are still worked in strips, though communal regulation has vanished.

Livestock. Where new fodder crops were introduced into the rotation, more and better livestock were bred and kept. Animal size increased, and meat development was greater. In cows, milk yield improved. Better breeding increased fleece and flesh production in sheep and improved the size of pigs. Horses, essential to transport, were carefully bred. There were disastrous outbreaks of cattle plague, however, that spread throughout Europe in the second and fourth decades of the 18th century, possibly introduced from eastern Europe by cattle driven to markets in the west. As a result of these calamities, a veterinary school was founded at Lyon, in 1762, and a second at Alfort, Fr., in 1767. Denmark established its first veterinary school in 1773, and England followed in 1791.

An interesting aspect of livestock breeding was the admiration of all Europe for the Spanish Merino sheep, which were forbidden from export for fear of competition. It proved impossible to maintain the prohibition. Merinos were obtained by Louis XVI of France in 1786. Some had been imported into Sweden even earlier, before 1765. Both Prussia and Saxony raised them by midcentury, the Saxon Merino becoming famous. Austria also secured Merinos, and George III of England obtained a few by the end of the century. Merinos were not a success in England, however.

Spread of
the Merino
sheep

Though a major source of meat since Roman times, pigs had been raised half wild, feeding in the woods under the care of a swineherd and his dogs. Over a large part of western Europe, this system continued, especially where open-field farming prevailed. In England, however, where population doubled during the 18th century from about

5,000,000 to about 10,000,000, more care was taken in breeding productive swine. Several different breeds could already be distinguished; some were crossed with Chinese animals possibly brought from that distant country in vessels carrying spices and tea.

IMPROVEMENTS IN TECHNOLOGY

Plows and farm machinery. Probably of Dutch origin, the Rotherham plow, the main design of which has remained virtually unchanged to this day, was first put into use in the Netherlands, England, and Scotland during the first half of the 18th century. Details of design varied from area to area. Some Rotherham plows were wheeled, and some were not; some were made of timber; others of iron. The first factory for making plows was established in England in 1783.

Though the problem of mechanizing harvest work was not solved until the 19th century, a few fairly simple threshing machines were designed and put in use by 1800. Similarly, a variety of machines for such tasks as preparing animal feed, chopping turnips, and cutting chaff were designed and used.

The English gentleman Jethro Tull made important contributions during this period, among them the horse-drawn hoe and the seed drill. To save expensive hand labour, Tull designed and fabricated horse-drawn hoes that destroyed the weeds and kept the soil between the rows in good crumbly (friable) condition. Tull believed that friable soil would supply all the nutrients a plant required, and he was so convinced of his theory that he planted wheat in rows spaced widely enough to allow for horse hoeing while the plant was growing. Tull also believed that placing the seed into the ground in small holes (drilling) would permit a much lighter rate of seeding than hand broadcast methods and still get high yields. To place the seeds, he designed and used a seed drill.

Tull was not the first man to invent a seed drill. A seed dropper, consisting of a tube attached to a plow through which seed could be dropped by hand at regular intervals, had been attached to an ancient Babylonian plow. A similar system, but with two tubes behind two plowshares set in a rectangular frame, was employed in 17th-century China, and probably at a very much earlier date. An Italian described a modern form of seed drill in the late 16th century. An Austrian, Locatelli, described a *semlador*, or seed drill attached to a plow, which was either used or proposed for use in Spain. After Tull, inventors were numerous, and, at the end of the 18th century, the drilling of seed, though not commonplace, was accepted. Throughout this period, however, the ordinary farmer continued to prepare his seedbed by plowing three times a year, occasionally more, and broadcasting seed by hand and harrowing it in. All these techniques were thousands of years old.

Irrigation and drainage. Walter Blith, a captain in Cromwell's army, was interested in land drainage and irrigation in the form of water meadows, pieces of low, flat land capable of being kept in fertility by being overflowed from some adjoining stream. During his lifetime considerable drainage work was carried out in eastern England, where it has continued to the present day. At the same time, water meadows were constructed in southwest England. This system was well known and of long standing in Germany. Similarly, there were sporadic attempts to drain wetlands in France and Italy; maintenance of the drainage system was essential to parts of the Netherlands. Colonization of reclaimed lands in eastern England by Dutch settlers also introduced some novel crops to that area, especially rape and cole.

Importance of the New World. The age of exploration that began in the mid-15th century led to discovery of edible plants previously unknown to Europeans. The Arabs had introduced sugarcane and rice to some parts of southern Europe. The voyagers to North America returned with corn (maize), tobacco, and the turkey. South America supplied the potato, cocoa, quinine, and some vegetable drugs, while coffee, tea, and indigo came from the Orient.

Though the tropical plants could not be cultivated in the temperate European climate, corn was rapidly adopted

in southern Europe. Imported first to Ireland, the potato came into general use elsewhere by the end of the 18th century.

These novel crops expanded the dietary range in some places, and importation of the new beverages may have helped reduce the very large consumption of alcoholic drinks. Tea drinking was regarded as harmful by some fervent propagandists at the end of the 17th century and later, and, in the 1820s, William Cobbett even condemned the potato. By that time, however, the crop had become the staple food of the Irish rural population and was raised on a moderate scale in Lancashire and Cheshire for consumption by their growing manufacturing population, as it was in some parts of Germany, France, the Low Countries, and Italy.

In the 16th and 17th centuries the introduction of sheep into such New World countries as Argentina, with suitable climate and grazing land, proved highly successful.

Agricultural textbooks and improvement societies. The small number of vernacular farming textbooks printed in Europe during the 16th century increased in the 17th and became much larger in the 18th, indicating a developing interest in commercial farming. Population growth, especially in the urban centres, and the rise of industry opened new opportunities for the enterprising landlord and farmer, even though transport was difficult. English writers on farming were more numerous than those in other countries. The French paid more attention to gardening, and the Thirty Years' War (1618–48) brought a long interruption in agricultural development in Germany and adjacent countries.

The Flemish and Dutch produced no agricultural texts, declaring that they were more interested in farming than in writing about it. Indeed, the system of crop rotation in Brabant and Flanders became the pattern for the rest of Europe. In 1645 an Englishman, Sir Richard Weston, wrote the first description of this system, which featured crops such as clover or roots, rotating with industrial crops such as flax, with no fallow break. Adoption in England and other parts of western Europe increased agricultural production between 1600 and 1800.

The problem of educating the ordinary farmer occupied the minds of improving landlords who were the governing class in every European country. Improvement societies formed in Great Britain, and a semiofficial Board of Agriculture, financed in part by a government grant, was established there in 1793. It lasted until 1822. One of the first tasks it undertook was to make and publish a survey of each county in the kingdom in order to make the best local methods known to other districts. A similar plan had been tried in France in 1759. Other countries in western Europe engaged in similar activities. A Royal Society was established in Denmark in 1769 and made practical researches. The Italian Società di Geogofili, founded in 1753, tried to stimulate technical improvement and planned large drainage schemes. The first similar Swiss society was established at Zürich in 1747. Frederick William I of Germany founded an agricultural school at Halle in 1727; and the first agricultural high school was begun, with royal encouragement, at Möglin, near Berlin, in 1806.

PROGRESS IN DIFFERENT COUNTRIES

Italy. Although Italy was the first country where a four-course rotation was advocated, traditional farming persisted there into the 18th century and even later. Italian farmers, however, had accepted corn, potatoes, tomatoes, and tobacco and relied upon these and other subtropical products for subsistence and sale. The vine continued to be important, as did the olive. The north was more advanced than the less fertile south; a wide variety of crops was grown there, often in long rotations with a reduction of the proportion of fallow. An occasional fodder crop of turnips, clover, and ryegrass was cultivated. Shortages of fodder encouraged adoption of the Norfolk four-course system. Plows and other implements, however, remained primitive. The mulberry tree, the leaves of which provided food for silkworms, was important in the Milanese and Piedmont area. Rice was also grown on irrigated land in that area. High-yielding milch cows were also kept. Trans-

Crop rotation in Brabant and Flanders

Water meadows

humance was practiced, with sheep on the lower lands in winter and on the mountain pastures in summer.

Spain. Spain remained backward, partly because of its physical and climatic conditions and partly from social pressure. The Merino sheep, fine horses, and mules continued to deserve their high repute. Some subtropical crops were cultivated in the south and east—sugarcane, cotton, grapes, olives, figs, raisins, and oranges—but the arid and stony land of the centre and elsewhere remained substantially unproductive and thinly populated by a poor class of *métayers* (sharecroppers).

Britain. The Industrial Revolution in Great Britain drew many people from food production; this had happened before in the mercantile and manufacturing Low Countries. Since these people still had to be fed, there existed a strong incentive toward increased farm productivity. These countries could not, however, satisfy local demands, and they sought to import food, especially grain. Thus, industrialization in England stimulated cereal growing in Prussia, Poland, and parts of Russia.

Germany. Increased grain production in Prussia was also stimulated by the personal efforts of Frederick II the Great, who set out to repair some of the damage caused by the Thirty Years' War and generally to improve conditions in his country. He ordered the rearrangement of the open-field farms into separate enclosed holdings and did away with common grazing, doubtless to encourage better animal selection and breeding. He bred horses for the army and gave bulls and rams to favoured landowners. Elsewhere in the German congeries of small states, the princes enforced improvements by royal edicts. Fodder crops were introduced. In addition to keeping the animals indoors in winter, summer stall feeding was introduced in some areas, resulting in preservation of the animal manure formerly dropped on the commons.

Sugar beets had been grown for feed in Germany, but it was not until 1747 that sugar was successfully extracted and not until 1802 that the first factory for making beet sugar was built. This industry, however, did not really begin to grow until the time of the Napoleonic Wars.

Scandinavia. The countries of Scandinavia were influenced by the spirit of improvement, but less spectacularly. Danish farmers were somewhat hindered in the introduction of novel methods by political restrictions, and it was not until the end of the 19th century that serious advances in technique took place. Sweden had some improvers who imported Merino sheep, English cattle, and Angora goats and who studied plow design. Nevertheless, Swedish farming in general remained almost static until after 1757, when some exchange of strips made enclosed farms possible. Potatoes became a staple.

North America. Changes in farming technique that increased productivity, introduced primarily in Great Britain and the Netherlands before 1800, made British farming the example to the world, even the distant lands of America. That continent, north and south, had indeed supplied Europe with very valuable plants. By the end of the 18th century, the production of North America was sufficient to supply some of the necessities of a warring Europe. The New England settlements, like those of the Southern states, were expanding toward the west, as land was claimed from the forest. Agriculture produced small surpluses for export. The Southern states had, of course, always exported staples like tobacco, cotton, and (Louisiana) sugar; but the processes by which these plants were cultivated remained primitive.

Cattle raising expanded rapidly in the New World. The need for fresh and larger grazing areas drew cattle farming west into Ohio and Kentucky, where corn for fattening purposes could be raised at low cost. Cattle were being driven overland to seaboard markets by 1805.

The 19th-century power revolution on the farm: c. 1792–1914

The development of agriculture between the close of the 18th century and the early years of the 20th century was characterized by the partial mechanization of agriculture in western Europe—especially in Great Britain—and in

the previously untapped lands of Australia, New Zealand, and North America, where wild, uncultivated, and virtually unoccupied land was made to yield vast quantities of plant and animal crops.

MECHANIZATION

Though the first steps had been taken earlier, it was not until after 1850 that mechanization took hold in western Europe and the newly settled countries. A variety of machines were slowly coming into use when the French revolutionary wars broke out in the 1790s. An efficient seed drill had been devised but still required demonstration in the 1830s to convince farmers of its value. A few threshing machines were in use before 1800, and they became steadily more popular until, in the 1830s, farm labourers in England rebelled against them because the machine robbed them of their winter employment. The speed with which the thresher was adopted is rather surprising, as there was a surplus rather than a shortage of labour at the time.

The reaper. Yet even an ample supply of labour could not always cope with the harvest by hand methods. Local labour frequently had to be supplemented by traveling

By courtesy of the Library of Congress, Washington, D.C.

Figure 7: The original McCormick reaper, 1831; from R.L. Ardrey, "American Agricultural Implements," 1894.

gangs or by small tradesmen from neighbouring towns. This unsatisfactory situation proved an incentive to invention. Reaping machines had been proposed before, but not until Patrick Bell in Scotland and Cyrus Hall McCormick (Figure 7) in the United States produced their designs did this machine become a practical reality. After the Great Exhibition of London in 1851, the reaper slowly came into general use. About this time an animal-pushed combine harvester, which stripped the grain from the plant like the Gallo-Roman reaper of classical times, was devised. This machine was used successfully in South Australia, where more grain was grown than could be harvested manually by the few labourers available there.

Plows and plowing. Before harvesting machines could be used, however, the ground had to be prepared, and the fundamental instrument for this purpose was the plow. Though attempts had been made in the 17th and 18th centuries to develop a mathematical theory of plow design, in a less esoteric way practical men had made significant improvements. Prominent among these was the English inventor Robert Ransome, who patented a cast-iron share in 1785 and a self-sharpening share in 1803. Later he designed a plow with standard parts that could be removed and replaced in the field, a double plow (*i.e.*, with two shares), and other patterns.

As settlers in the United States moved westward, plowing of the black prairie soils, high in organic matter, posed a special problem to the farmers who had cast-iron and iron-patched plows. The ingenuity of John Deere, an Illi-

The combine harvester

Plowing the Great Plains

Rehabilitation by Frederick the Great

nois blacksmith and plow maker of the 1830s, resulted in a new kind of plow that was made entirely of steel except for the braces, beam, and handles. The one-piece share and moldboard of his first steel plow was cut from a mill-saw blade and shaped over a wooden form. This greatly improved implement not only made possible the effective plowing of the black prairie soils but also considerably lessened the animal power needed to turn the soil.

A mole plow, characterized by a cartridge-shaped “mole” attached to the bottom of its wide cutting blade, and intended for plowing a drain in heavy wetland, was successfully fabricated and used in the late 18th century. The plow, pulled by a capstan or team of animals, was a great help in draining wetland. Invention of a method for manufacturing tubular clay pipes also aided and simplified drainage. Use of these pipes spread rapidly beginning about 1850; large areas of land were thus drained all over Europe. Drainage by this method continues today.

Steam-powered equipment. The first attempts at steam-powered plowing took place in the 1830s. Though ingenious, the early apparatus was impractically heavy and cumbersome. A successful steam plow was made in the 1860s, after which steam power was widely adopted, especially on large farms (Figure 8). Supplementary implements helpful to the farmer were also produced about this time. They include hay rakes, hay-loaders, and potato spinners. Barn machinery, housed in especially designed buildings, was driven by a steam engine through a system of belts and pulleys or in more primitive style by horses. Threshing drums and supplementary machines were often hauled about the countryside by steam traction engines and worked on a contract basis by itinerant gangs of agricultural labourers.

Steam power spread rapidly but thinly over Europe. The first steam plow was worked in The Netherlands in 1862. Though milking machines were built, they were not really successful until the end of the century. The cream separator and milk cooler, both little changed since the time of their invention, were introduced in the 1880s.

Progress in mechanization in the second half of the 19th century was not, of course, confined to agriculture. Transport and communications improved enormously. Steamships facilitated the movement of goods and the spread of ideas. Railroads were built throughout the world, making agriculture possible in areas where farmers previously had no way to carry their goods to market. The first shipment of cattle marketed by rail originated in Lexington, Ky., in 1852. These cattle were driven to Cincinnati, Ohio, freighted to Cleveland on Lake Erie, boated to Buffalo, freighted to Albany, N.Y., and then boated down the Hudson River to New York City. By 1860 railroads had extended beyond the Mississippi River, opening the Southwest to range production and the Middle West to cattle feeding.

APPLYING SCIENCE TO FARMING

New fertilizers. Mechanical developments were paralleled by scientific discovery. Research in plant physiology and nutrition, begun in the 18th century, continued and grew in scope. The brilliant English chemist Sir Humphry Davy summarized the current state of agricultural knowledge in a series of lectures, published as *Elements of Agricultural Chemistry* in 1813. Though Davy's lectures probably had little impact on the ordinary farmer, a few enterprising pioneers were soon conducting field experiments with new fertilizers. The beneficial effects of saltpetre (potassium nitrate) had been known since the 17th century. When a firm began to import saltpetre from India in the 1820s, interested farmers bought and used it. Imported Chilean nitrate of soda was more plentiful, however, and more often used. Peruvian guano, an organic fertilizer, was imported and extensively used, even though sellers often diluted it with useless material to increase its bulk. Ground bones and other kinds of waste had been used in the late 18th century for restoring phosphate to pastures in dairy areas. Perhaps it was the use of these bones and their cracking and soaking in sulfuric acid that led to the production of superphosphate of lime in the 1840s. As the 19th century continued, more mineral fertilizers were discovered and marketed. With the development of the chemical industry, other fertilizers were manufactured. Basic slag, a waste product of the iron industry, was applied to grasslands with success. Gypsum was also tried but was later superseded by more effective products.

guano

Agricultural research and education. Scientists of the 18th century had established the principles that governed plant life. About 1837 the English agriculturist Sir John Bennet Lawes began to experiment with the effects of manures on plants and crops. In 1842 he patented a process for treating phosphate rock to produce superphosphate and thus initiated the synthetic fertilizer industry. In the following year, Lawes enlisted the services of the English scientist J.H. (later Sir Henry) Gilbert, with whom he worked for more than half a century, performing experiments on crop and animal nutrition. The work of Rothamsted Experimental Station, which Lawes founded and endowed, became world renowned. At the same time similar work was carried out in France, Germany, and the United States.

Though a considerable number of books on agricultural subjects appeared during the 19th century, their effect was perhaps less than that of the measures taken to promote agricultural education in most European countries. Though schools for farmers had been established in some German states in the 18th century, the first professorships of rural agriculture and economy were established at Oxford (1790) and Edinburgh (1797). Though similar events took place in France and Germany in the 19th century, a key date in the history of agricultural research

and education is 1862, when the U.S. Congress set up the Department of Agriculture and provided for colleges of agricultural and mechanical arts in each state.

Disease. An important spur to research was the great prevalence of plant disease, which at intervals became epidemic. Two crops—the potato and the grapevine—were virulently attacked in the 1840s, and irreparable damage resulted. When the potato blight struck Ireland, where the potato was a staple food crop, it caused widespread famine. The vine growers of southern Europe suffered several disastrous epidemics of the vine fungus. Later in the century, infestation by the vine louse grape phylloxera nearly put an end to European viticulture.

FARMING OUTSIDE EUROPE

European colonies. In the 19th century, European colonial expansion and plantation farming spread to many areas of the world. Coffee was grown widely in Ceylon (Sri Lanka) until disease destroyed the plants and they were replaced by tea bushes. Sugarcane was raised on a large scale in the East and West Indies, in the United States, and the Hawaiian Islands. Cocoa was carried from South America to colonies in West Africa, where it prospered. Natural rubber was tapped in the Congo and Brazil and was later cultivated in well-designed plantations in the Malay Peninsula. Palm oil was collected from trees in West Africa and the South Seas. Yet these spectacular developments had little impact on the native agriculture of the underdeveloped regions in general; ancient patterns of cultivation remained largely unchanged.

America and Australia. By 1900 much of the western United States had been settled; great livestock ranches and wheat farms had been established there and in Argentina. A large dairy and sheep industry had grown up in Australia and New Zealand. Imported Merinos were the foundation stock of the vast flocks that grazed the Australian hinterland. Devon cattle were exported from England to South Africa, where sheep were also a significant economic factor.

The Great Plains of the United States, lying between the Mississippi River and the Rocky Mountains, were first used by the open-range cattle industry, the heyday of which lasted from about 1866 to 1886. To improve their lean, lanky longhorn, breeders imported Herefords, Durham Shorthorns, and other fine European cattle. As the range became more and more heavily occupied, and as wheat farmers began to till the soil of the Great Plains, it became necessary to put up fences. This was accomplished with a remarkable invention, barbed wire, a new, cheap, and rapidly erected kind of fencing, used in preference to the post and rail fences or the sod and stone walls that had been common in Europe for centuries.

Grain farmers rapidly followed the ranchers, and farming spread from Oklahoma north into Canada. Because hand labour was scarce, cultivation and harvesting were rapidly mechanized. A combine harvester hauled by a large team of mules was used in California in the late 1880s. Different from the combine harvester used in South Australia, this was a prototype of today's machine. Iron and steel plows were produced in large numbers, and steam traction engines were used as power units for many mechanized operations such as threshing. Though seed was usually drilled, yields were often low because manure was in short supply. Furthermore, with manure scarce, a three-year rotation was practiced to prevent soil depletion: two crop plantings were followed by a fallow year. In the Southern states, export staples were produced in addition to subsistence crops.

America's prodigious new supplies of meat and grain were generally exported from the wide ranges of the Western states to the more populous Eastern states and to Europe, where they lowered prices paid to European farmers but played an important role in feeding populations in industrial centres. Fresh meat and dairy produce from Argentina and Australia were carried thousands of miles in newly developed refrigerator ships.

The huge quantities of inexpensive food produced by the newly settled countries created a difficult problem for the European farmer. The arable and mixed farming common

in most European countries simply could not compete. In Great Britain, much cropland was planted with grass, and farmers began to raise pedigree animals and dairy produce. On the Continent, where many farmers occupied peasant holdings, a kind of subsistence farming continued. Denmark and The Netherlands turned to production of dairy produce and high-quality bacon, feeding pigs on waste dairy materials. (G.E.F.)

Scientific agriculture: the 20th century

Agricultural technology has developed more rapidly in the 20th century than in all previous history. Though the most important developments during the first half of this century took place in the industrial countries, especially the United States, the picture has changed somewhat since the 1950s. With the coming of independence, former colonies in Africa and Asia have initiated large-scale efforts to improve their agriculture. In many cases they have used considerable ingenuity in adapting Western methods to their own climates, soils, and crops (see also FARMING AND AGRICULTURAL TECHNOLOGY).

DEVELOPMENTS IN POWER:

THE INTERNAL-COMBUSTION ENGINE

The internal-combustion engine brought major changes to agriculture in most of the world. In advanced regions it soon became the chief power source for the farm.

The tractor. The first applications to agriculture of the four-stroke-cycle gasoline engine were as stationary engines, at first in Germany, later elsewhere. By the 1890s stationary engines were mounted on wheels to make them portable, and soon a drive was added to make them self-propelled. The first successful gasoline tractor was built in the United States in 1892. Within a few years several companies were manufacturing tractors in Germany, the United Kingdom, and the United States. The number of tractors in the more developed countries increased dramatically during the 20th century, especially in the United States: in 1907 some 600 tractors were in use, but the figure had grown to almost 3,400,000 by 1950.

Major changes in tractor design throughout the century have produced a much more efficient and useful machine. Principal among these were the power takeoff, introduced in 1918, in which power from the tractor's engine could be transmitted directly to an implement through the use of a special shaft; the all-purpose, or tricycle-type, tractor (1924), which enabled farmers to cultivate planted crops mechanically; rubber tires (1932), which facilitated faster operating speeds; and the switch to four-wheel drives and diesel power in the 1950s and 1960s, which greatly increased the tractor's pulling power. The last innovations have led to the development of enormous tractors—usually having double tires on each wheel and enclosed, air-conditioned cabs—that can pull several gangs of plows.

Unit machinery. Since World War II, there has been an increase in the use of self-propelled machines in which the motive power and the equipment for performing a particular task form one unit. Though the grain combine is the most important of these single-unit machines, self-propelled units are also in use for spraying, picking cotton, baling hay, picking corn, and harvesting tomatoes, lettuce, sugar beets, and many other crops. These machines are faster, easier to operate, and above all, have lower labour requirements than those that are powered by a separate tractor.

Grain combine. The first successful grain combine, a machine that cuts ripe grain and separates the kernels from the straw, was built in the United States in 1836. Lack of an adequate power unit and the tendency of combined grain to spoil because of excessive moisture limited its development, however. Large combines, powered by as many as 40 horses, were used in California in the latter part of the 19th century. Steam engines replaced horses on some units as a power source, but, about 1912, the gasoline engine began to replace both horses and steam for pulling the combine and operating its mechanism. A one-man combine, powered by a two-plow-sized tractor (*i.e.*, one large enough to pull two plows), was developed

Design
changes

Barbed
wire

in 1935. This was followed by a self-propelled machine in 1938.

Mechanized equipment for corn. Corn, the most important single crop in the United States and extremely important in many other countries, is grown commercially with the aid of equipment operated by tractors or by internal-combustion engines mounted on the machines. Corn pickers came into use in the U.S. Corn Belt after World War I and have been even more widely adopted since World War II. Corn pickers vary in complexity from the snapper-type harvester, which removes the ears from the stalks but does not husk them, to the picker-sheller, which not only removes the husk but shells the grain from the ear. The latter is often used in conjunction with dryers. Modern machines can harvest as many as 12 rows of corn at a time.

Mechanized equipment for cotton. Mechanization has also reduced substantially the labour needed to grow cotton. Equipment includes tractor, two-row stalk-cutter, disk (to shred the stalks), bedder (to shape the soil into ridges or seedbeds), planter, cultivator, sprayer, and harvester. Cotton fibre is harvested by a stripper-type harvester, developed in the 1920s, or by a picker. The stripper strips the entire plant of both open and unopened bolls and collects many leaves and stems. Though a successful cotton picker that removed the seed cotton from the open bolls and left the burrs on the plant was invented in 1927, it did not come into use until after World War II. Strippers are used mostly in dry regions, while pickers are employed in humid, warm areas. The pickers are either single-row machines mounted on tractors or two-row self-propelled machines.

Tomato-harvesting equipment. The self-propelled mechanical tomato harvester, developed in the early 1960s by engineers working in cooperation with plant breeders, handles virtually all packing tomatoes grown in California. Harvesters using electronic sorters can further reduce labour requirements.

Automobiles, trucks, and airplanes. The automobile and truck have also had a profound effect upon agriculture and farm life. Since their appearance on American farms between 1913 and 1920, trucks have changed patterns of production and marketing of farm products. Trucks deliver such items as fertilizer, feed, and fuels; go into the fields as part of the harvest equipment; and haul the crops to markets, warehouses, or packing and processing plants. Most of the livestock is trucked to market.

The airplane may have been used agriculturally in the United States as early as 1918 to distribute poison dust over cotton fields that were afflicted with the pink bollworm. While records of this experiment are fragmentary, it is known that airplanes were used to locate and map cotton fields in Texas in 1919. In 1921 a widely publicized dusting experiment took place near Dayton, Ohio. Army pilots, working with Ohio entomologists, dusted a six-acre grove of catalpa trees with arsenate of lead to control the sphinx caterpillar. The experiment was successful. It and others encouraged the development of dusting and spraying, mainly to control insects, disease, weeds, and brush. In recognition of the possible long-term harmful effects of some of the chemicals, aerial dusting and spraying have been subject to various controls since the 1960s.

Airplanes are also used to distribute fertilizer, to re-seed forest terrain, and to control forest fires. Many rice growers use planes to seed, fertilize, and spray pesticides, and even to hasten crop ripening by spraying hormones from the air.

During heavy storms, airplanes have dropped baled hay to cattle stranded in snow. Airplanes have also been used to transport valuable breeding stock, particularly in Europe. Valuable and perishable farm products are frequently transported by air. Airplanes are especially valuable in such large agricultural regions as western Canada and Australia, where they provide almost every type of service to isolated farmers.

NEW CROPS AND TECHNIQUES

New crops and techniques are, in reality, modifications of the old. Soybeans, sugar beets, and grain sorghums, for

example, all regarded as "new" crops, are new only in the sense that they are now grown in wider areas and have different uses from those of earlier times. Such techniques as terracing, dry farming, and irrigation are nearly as old as the practice of agriculture itself, but their widespread application is still increasing productivity in many parts of the world.

New crops. *The soybean.* This is an outstanding example of an ages-old crop that, because of the development of new processes to make its oil and meal more useful, is widely produced today. In the Orient, where the soybean originated long ago, more than half the crop is used directly for food, and less than a third is pressed for oil. Its high protein and fat content make it a staple in the diet, replacing or supplementing meat for millions of people.

Though first reported grown in America in 1804, the soybean remained a rare garden plant for nearly 100 years. Around the beginning of the 20th century, when three new varieties were introduced from Japan, farmers began growing it for hay, pasture, and green manure. In the early 1930s a soybean oil processing method that eliminated a disagreeable odour from the finished product was developed. World War II brought an increased demand for edible oil. The food industry began using soybean oil for margarine, shortening, salad oil, mayonnaise, and other food products and continues to be its chief user. Manufacturers of paints, varnishes, and other drying oil products are the most important nonfood users.

Development of the solvent process of extracting soybean oil has greatly increased the yield. A 60-pound bushel of soybeans processed by this method yields 10½ pounds of oil and 45 pounds of meal. Soybean meal and cake are used chiefly for livestock feed in the United States. The high protein content of the meal has made it an attractive source of industrial protein, and, with proper processing, it is an excellent source of protein for humans.

Development of new soybean varieties suited for different parts of the world is possible by means of hybridization. This permits isolating types superior in yielding ability, resistance to lodging (breakage of the plant by wind and rain) and shattering (of the bean), adaptation to suit various requirements for maturity, and resistance to disease. Hybridization, however, has not yet led to spectacular gains in yields.

Sorghum. Just as the soybean was used for many centuries in Asia before its introduction into the Western world, so sorghum was a major crop in Africa. Sorghum is fifth in importance among the world's cereals, coming after wheat, rice, corn, and barley. It is called Guinea corn in West Africa, kafir corn in South Africa, durra in The Sudan, and mtama in East Africa. In India it is known as jowar, cholam, and great millet, and it is called kaoliang in China. In America it is often called milo, while the sweet-stemmed varieties are referred to as sweet sorghum, or sorgo.

Sorghum probably had been domesticated in Ethiopia by 3000 B.C. From there, it spread to West and East Africa, and then southward. Traders from Africa to the East carried sorghum as provisions on their dhows. It is likely that sorghum thus reached India, where cultivation began between 1500 and 1000 B.C. Other traders carried sorghum to China and the Far East. The amber sorghums or sorgos, useful for forage and syrup, may have moved by sea, while the grain sorghums probably moved overland. The movement to the Mediterranean and the Middle East also began through traders.

Sorghum reached the New World through the slave trade. Guinea corn and chicken corn came from West Africa to America as provisions for the slaves. Other types were introduced into the United States by seedsmen and scientists from about 1870 to 1910. Seed was sometimes sold to farmers as a new, highly productive variety of corn. It was not until the 1930s, after the value of the plant as grain, forage, and silage for livestock feeding had been recognized, that acreage began to increase. Yields rose markedly in the late 1950s, after successful hybridization of the crop. Better yields led in turn to increased acreage.

Chinese amercane was brought from France to the United States in 1854 and was distributed to farmers.

Sorghum
sugar

While the cane provided good forage for livestock, promoters of the new crop were most interested in refining sugar from the sorghum molasses, a goal that persisted for many years. While refining technology has been perfected, the present cost of sorghum sugar does not permit it to compete with sugar from other sources.

Large amounts of sorghum grain are eaten every year by people of many countries. If the world population continues to grow as projected, food is likely to be sorghum's most important use. Most of the sorghum is ground into flour, often at home. Some is consumed as a whole-kernel food. Some of the grain is used for brewing beer, particularly in Africa.

The sugar beet. The sugar beet as a crop is much newer than either soybeans or sorghum. Although beets had been a source of sweets among ancient Egyptians, Indians, Chinese, Greeks, and Romans, it was not until 1747 that a German apothecary, Andreas Marggraf, obtained sugar crystals from the beet. Some 50 years later, Franz Karl Achard, son of a French refugee in Prussia and student of Marggraf, improved the Silesian stock beet—probably a mangel-wurzel—as a source of sugar. He erected the first pilot beet-sugar factory at Cunern, Silesia (now Poland), in 1802. Thus began the new use for sugar of a crop traditionally used as animal feed.

Napoleonic
experimen-
tation with
beet sugar

When during the Napoleonic Wars continental Europe was cut off from West Indies cane sugar, further experimentation with beet sugar was stimulated. In 1808 a French scientist, Benjamin Delessert, used charcoal in clarification, which insured the technical success of beet sugar. On March 25, 1811, Napoleon issued a decree that set aside 80,000 acres of land for the production of beets, established six special sugar-beet schools to which 100 select students were given scholarships, directed construction of 10 new factories, and appropriated substantial bounties to encourage the peasants to grow beets. By 1814, 40 small factories were in operation in France, Belgium, Germany, and Austria. Although the industry declined sharply after Napoleon's defeat, it was soon revived. For the last third of the 19th century, beets replaced cane as the leading source of sugar.

Since World War II, major changes have taken place in sugar-beet production in the United States and, to a lesser extent, in the Soviet Union, Germany, and other nations with a substantial production. These changes may be illustrated by developments in the United States.

In 1931 the California Agricultural Experiment Station and the U.S. Department of Agriculture undertook a cooperative study of the mechanization of sugar-beet growing and harvesting. The goal in harvesting was a combine that would perform all the harvesting operations—lifting from the soil, cutting the tops, and loading—in one trip down the row. By the end of World War II, four different types of harvesters were being manufactured.

The spring and summer operations—planting, blocking (cutting out all plants except for clumps standing 10 or 12 inches [25 or 30 centimetres] apart), thinning, and weeding—did not yield so easily to mechanization, largely because the beet seed, a multigerm seedball, produced several seedlings, resulting in dense, clumpy, and somewhat irregular stands. In 1941 a machine for segmenting the seedball was developed. The problem was solved in 1948, when a plant with a true single-germ seed was discovered in Oregon. Now precision seed drills could be used, and plants could be first blocked and then cultivated mechanically using a cross-cultivating technique; that is, cultivating the rows up and down and then across the field. During World War I, 11.2 hours of labour were required to produce a ton of sugar beets; in 1964, 2.7 hours were needed.

New techniques. As the development of the sugar beet shows, new techniques may bring particular crops into prominence. This discussion, however, is confined to three that, in some forms, are old yet today are transforming agriculture in many parts of the world.

Terracing. Terracing, which is basically grading steep land, such as hillsides, into a series of level benches, was known in antiquity and was practiced thousands of years ago in such divergent areas as the Philippines, Peru, and Central Africa. Today, terracing is of major importance

in Japan, Mexico, and parts of the United States, while many other nations, including Israel, Australia, South Africa, Colombia, and Brazil, are increasing productivity through the inauguration of this and other soil-conserving practices.

Colombia provides an example of the modern need for terracing. For many years the steep slopes used for producing the world-renowned Colombian coffee have been slowly eroding. During the 1960s experimental work showed that contour planting and terracing would help preserve the land. Farther south, the Brazilian state of São Paulo created a terracing service in 1938. Since then, the program has become a full conservation service.

Irrigation. The usefulness of a full-scale conservation project is seen in the Snowy Mountains Project of Australia, where three river systems have been diverted to convert hundreds of miles of arid but fertile plains to productive land. Intensive soil conservation methods have been undertaken wherever the natural vegetation and soil surface have been disturbed. Drainage is controlled by stone and steel drains, grassed waterways, absorption and contour terraces, and settling ponds. Steep slopes are stabilized by woven wickerwork fences, brush matting, and bitumen sprays, followed by revegetation with white clover and willow and poplar trees. Grazing is strictly controlled to prevent silting of the reservoirs and damage to slopes. The two main products of the plan are power for new industries and irrigation water for agriculture, with recreation and a tourist industry as important by-products.

Snowy
Mountains
Project

The Snowy Mountains Project of Australia is a modern successor, so far as irrigation is concerned, to practices that have provided water for crops almost from the beginnings of agriculture. The simplest method of irrigation was to dip water from a well or spring and pour it on the land. Many types of buckets, ropes, and, later, pulleys were employed. The ancient shaduf, which consists of a long pole pivoted from a beam that has a weight at one end to lift a full bucket of water at the other, is still in use. Conduction of water through ditches from streams was practiced widely in the Middle East, in Africa, and in America, where ancient canal systems can be seen. A conduit the Romans built 2,000 years ago to provide a water supply to Tunis is still in use.

Sufficient water at the proper time makes possible the full use of technology in farming—including the proper application of fertilizers, suitable crop rotations, and the use of more productive varieties of crops. Expanding irrigation is an absolute necessity to extend crop acreage in significant amounts; it may be the most productive of possible improvements on present cropland. First, there is the possibility of making wider use of irrigation in districts that already have a high rate of output. Second, there is the possibility of irrigating nonproductive land, especially in arid zones. The greatest immediate economic returns might well come from irrigating productive districts, but irrigation of arid zones has a larger long-range appeal. Most of the arid zones, occupying more than one-third of the landmass of the globe, are in the tropics. Generally, they are rich in solar energy, and their soils are rich in nutrients, but they lack water.

Supplemental irrigation in the United States, used primarily to make up for poor distribution of rainfall during the growing season, has increased substantially since the late 1930s. This irrigation is carried on in the humid areas of the United States almost exclusively with sprinkler systems. The water is conveyed in pipes, usually laid on the surface of the field, and the soil acts as a storage reservoir. The water itself is pumped from a stream, lake, well, or reservoir. American farmers first used sprinkler irrigation in about 1900, but the development of lightweight aluminum pipe with quick couplers meant that the pipe could be moved easily and quickly from one location to another, resulting in a notable increase in the use of sprinklers after World War II.

India, where irrigation has been practiced since ancient times, illustrates some of the problems. During the late 20th century, more than 20 percent of the country's cultivated area was under irrigation. Both large dams, with canals to distribute the water, and small tube, or driven,

Irrigation
problems

wells, made by driving a pipe into water or water-bearing sand, controlled by individual farmers, have been used. Some have been affected by salinity, however, as water containing dissolved salts has been allowed to evaporate in the field. Tube wells have helped in these instances by lowering the water table and by providing sufficient water to flush away the salts. The other major problem has been to persuade Indian farmers to level their lands and build the small canals needed to carry the water over the farms. In Egypt, impounding of the Nile River with the Aswān High Dam has been a great boon to agriculture, but it has also reduced the flow of silt into the Nile Valley and adversely affected fishing in the Mediterranean Sea. In arid areas such as the U.S. Southwest, tapping subterranean water supplies has resulted in a lowered water table and, in some instances, land subsidence.

Dry farming. The problem of educating farmers to make effective use of irrigation water is found in many areas. An even greater educational effort is required for dry farming; that is, crop production without irrigation where annual precipitation is less than 20 inches.

Dry farming as a system of agriculture was developed in the Great Plains of the United States early in the 20th century. It depended on the efficient storage of the limited moisture in the soil and the selection of crops and growing methods that made best use of this moisture. The system included deep fall plowing, subsurface packing of the soil, thorough cultivation both before and after seeding, light seeding, and alternating-summer fallow, with the land tilled during the season of fallow as well as in crop years. In certain latitudes stubble was left in the fields after harvest to trap snow. Though none of the steps were novel, their systematic combination was new. Systematic dry farming has continued, with substantial modifications, in the Great Plains of Canada and the United States, in Brazil, in South Africa, in Australia, and elsewhere. It is under continuing research by the Food and Agriculture Organization of the United Nations.

The direction of change. While no truly new crop has been developed by modern man, new uses and new methods of cultivation of known plants may be regarded as new crops. For example, subsistence and special-use plants, such as the members of the genus *Atriplex* that are salt-tolerant, have the potential for being developed into new crops. New techniques, too, are the elaboration and systematization of practices from the past.

NEW STRAINS: GENETICS

The use of genetics to develop new strains of plants and animals has brought major changes in agriculture since the 1920s. Genetics as the science dealing with the principles of heredity and variation in plants and animals was established only at the beginning of the 20th century. Its application to practical problems came later.

Early work in genetics. The modern science of genetics and its application to agriculture has a complicated background, built up from the work of many individuals. Nevertheless, Gregor Mendel is generally credited with its founding. Mendel, a monk in Brūnn, Moravia (now Brno, Czech.), purposefully crossed garden peas in his monastery garden. He carefully sorted the progeny of his parent plants according to their characteristics and counted the number that had inherited each quality. He discovered that when the qualities he was studying, including flower colour and shape of seeds, were handed on by the parent plants, they were distributed among the offspring in definite mathematical ratios, from which there was never a significant variation. Definite laws of inheritance were thus established for the first time. Though Mendel reported his discoveries in an obscure Austrian journal in 1866, his work was not followed up for a third of a century. Then in 1900, investigators in The Netherlands, Germany, and Austria, all working on inheritance, independently rediscovered Mendel's paper.

By the time Mendel's work was again brought to light, the science of genetics was in its first stages of development. The word genetics comes from "genes," the name given to the minute quantities of living matter that transmit characteristics from parent to offspring. By 1903, scientists in

the United States and Germany had concluded that genes are carried in the chromosomes, nuclear structures visible under the microscope. In 1911 a theory that the genes are arranged in a linear file on the chromosomes and that changes in this conformation are reflected in changes in heredity was announced.

Genes are highly stable. During the processes of sexual reproduction, however, means are present for assortment, segregation, and recombination of genetic factors. Thus, tremendous genetic variability is provided within a species. This variability makes possible the changes that man can bring about within a species to adapt it to his specific uses. Occasional mutations (spontaneous changes) of genes also contribute to variability.

Development of new strains of plants and animals did not, of course, await the science of genetics, and some advances were made by empirical methods even after the application of genetic science to agriculture. The U.S. experimenter Luther Burbank, without any formal knowledge of genetic principles, developed the Burbank potato as early as 1873 and continued his plant-breeding research, which produced numerous new varieties of fruits and vegetables. In some instances, both practical experience and scientific knowledge contributed to major technological achievements. An example is the development of hybrid corn (maize).

Corn. Corn originated in America, probably having been first developed by Indians in the highlands of Mexico. It was quickly adopted by the European settlers, Spanish, English, and French. The first English settlers found the northern Indians growing a hard-kerneled, early-maturing flint variety that kept well, though its yield was low. The Indians in the south central area of English settlement grew a soft-kerneled, high-yielding, late-maturing dent corn. There were doubtless many haphazard crosses of the two varieties. In 1812, however, John Lorain, a farmer living near Philipsburg, Pa., consciously mixed the two and demonstrated that certain mixtures would result in a yield much greater than that of the flint, yet with many of the flint's desirable qualities. Other farmers and breeders followed Lorain's example, some aware of his pioneer work, some not. The most widely grown variety of the Corn Belt for many years was Reid's Yellow Dent, which originated from a fortuitous mixture of a dent and a flint variety.

At the same time, other scientists besides Mendel were conducting experiments and developing theories that were to lead directly to hybrid corn. In 1876 Charles Darwin published the results of experiments on cross- and self-fertilization in plants. Carrying out his work in a small greenhouse in his native England, the man who is best known for his theory of evolution found that inbreeding usually reduced plant vigour and that crossbreeding restored it.

Darwin's work was studied by a young American botanist, William James Beal, who probably made the first controlled crosses between varieties of corn for the sole purpose of increasing yields through hybrid vigour. Beal worked successfully without knowledge of the genetic principle involved. In 1908 George Harrison Shull concluded that self-fertilization tended to separate and purify strains while weakening the plants but that vigour could be restored by crossbreeding the inbred strains. Another scientist found that inbreeding could increase the protein content of corn, but with a marked decline in yield. With knowledge of inbreeding and hybridization at hand, there was yet to be developed a technique whereby hybrid corn with the desired characteristics of the inbred lines and hybrid vigour could be combined in a practical manner. In 1917 Donald F. Jones of the Connecticut Agricultural Experiment Station discovered the answer, the "double cross."

The double cross was the basic technique used in developing modern hybrid corn and has been used by commercial firms since. Jones's invention was to use four inbred lines instead of two in crossing. Simply, inbred lines A and B made one cross, lines C and D another. Then AB and CD were crossed, and a double-cross hybrid, ABCD, was the result. This hybrid became the seed that changed much of

Origins of
corn

Mendel's
experi-
ments

The double
cross

American agriculture. Each inbred line was constant both for certain desirable and for certain undesirable traits, but the practical breeder could balance his four or more inbred lines in such a way that the desirable traits outweighed the undesirable. Foundation inbred lines were developed to meet the needs of varying climates, growing seasons, soils, and other factors. The large hybrid seed-corn companies undertook complex applied-research programs, while state experiment stations and the U.S. Department of Agriculture tended to concentrate on basic research.

The first hybrid corn involving inbred lines to be produced commercially was sold by the Connecticut Agricultural Experiment Station in 1921. The second was developed by Henry A. Wallace, a future secretary of agriculture and vice president of the United States. He sold a small quantity in 1924 and, in 1926, organized the first seed company devoted to the commercial production of hybrid corn.

Many Midwestern farmers began growing hybrid corn in the late 1920s and 1930s, but it did not dominate corn production until World War II. In 1933, 1 percent of the total corn acreage was planted with hybrid seed. By 1939 the figure was 15 percent, and in 1946 it rose to 69. The percentage was 96 in 1960. The average per acre yield of corn rose from 23 bushels (2,000 litres per hectare) in 1933, to 83 bushels (7,220 litres per hectare) by 1980.

The techniques used in breeding hybrid corn have been successfully applied to grain sorghum and several other crops. New strains of most major crops are developed through plant introductions, crossbreeding, and selection, however, because hybridization in the sense used with corn and grain sorghums has not been successful.

Wheat. Advances in wheat production during the 20th century include improvements through the introduction of new varieties and strains; careful selection by farmers and seedsmen, as well as by scientists; and crossbreeding to combine desirable characteristics (see Figure 1 for a comparison between wild and cultivated wheat). The adaptability of wheat enables it to be grown in almost every country of the world. In most of the developed nations producing wheat, endeavours of both government and wheat growers have been directed toward scientific wheat breeding.

The development of the world-famous Marquis wheat in Canada, released to farmers in 1900, came about through sustained scientific effort. Sir Charles Saunders, its discoverer, followed five principles of plant breeding: (1) the use of plant introductions; (2) a planned crossbreeding program; (3) the rigid selection of material; (4) evaluation of all characteristics in replicated trials; and (5) testing varieties for local use. Marquis was the result of crossing a wheat long grown in Canada with a variety introduced from India. For 50 years, Marquis and varieties crossbred from Marquis dominated hard red spring wheat growing in the high plains of Canada and the United States and were used in other parts of the world.

In the late 1940s a short-stemmed wheat was introduced from Japan into a more favourable wheat-growing region of the U.S. Pacific Northwest. The potential advantage of the short, heavy-stemmed plant was that it could carry a heavy head of grain, generated by the use of fertilizer, without falling over or "lodging" (being knocked down). Early work with the variety was unsuccessful; it was not adaptable directly into American fields. Finally, by crossing the Japanese wheat with acceptable varieties in the Palouse Valley in Washington, there resulted the first true semidwarf wheat in the United States to be commercially grown under irrigation and heavy applications of fertilizer. This first variety, Gaines, was introduced in 1962, followed by Nugaines in 1966. The varieties now grown in the United States commonly produce 100 bushels per acre (8,700 litres per hectare), and world records of more than 200 bushels per acre have been established.

The Rockefeller Foundation in 1943 entered into a cooperative agricultural research program with the government of Mexico, where wheat yields were well below the world average. By 1956 per acre yield had doubled, mainly because of newly developed varieties sown in the fall instead of spring and the use of fertilizers and irrigation. The

short-stemmed varieties developed in the Pacific Northwest from the Japanese strains were then crossed with various Mexican and Colombian wheats. By 1965 the new Mexican wheats were established and were gaining an international reputation.

Rice. The success of the wheat program led the Rockefeller and Ford foundations in 1962 to establish the International Rice Research Institute at Los Baños in the Philippines. A research team assembled some 10,000 strains of rice from all parts of the world and began outbreeding. Success came early with the combination of a tall, vigorous variety from Indonesia and a dwarf rice from Taiwan. The strain IR-8 has proved capable of doubling the yield obtained from most local rices in Asia.

The Green Revolution. The introduction into developing countries of new strains of wheat and rice was a major aspect of what became known as the Green Revolution. Given adequate water and ample amounts of the required chemical fertilizers and pesticides, these varieties have resulted in significantly higher yields. Poorer farmers, however, often have not been able to provide the required growing conditions and therefore have obtained even lower yields with "improved" grains than they had gotten with the older strains that were better adapted to local conditions and that had some resistance to pests and diseases. Where chemicals are used, concern has been voiced about their cost—since they generally must be imported—and about their potentially harmful effects on the environment.

Genetic engineering. The application of genetics to agriculture since World War II has resulted in substantial increases in the production of many crops. This has been most notable in hybrid strains of corn and grain sorghum. At the same time, crossbreeding has resulted in much more productive strains of wheat and rice. Called artificial selection, or selective breeding, these techniques have become aspects of a larger field called genetic engineering. Of particular interest to plant breeders has been the development of techniques for deliberately altering the functions of genes by manipulating the recombination of DNA. This has made it possible for researchers to concentrate on creating plants that possess attributes—such as the ability to use free nitrogen or to resist diseases—that they did not have naturally.

ANIMAL BREEDING

The goal of animal breeders in the 20th century has been to develop types of animals that will meet market demands, be productive under adverse climatic conditions, and be efficient in converting feed to animal products. At the same time, producers have increased meat production by improved range management, better feeding practices, and the eradication of diseases and harmful insects. The world production of meat has been increasing steadily since World War II.

While the number of livestock in relation to the human population is not significantly lower in less developed than in more developed regions, there is much lower productivity per animal and thus a much lower percentage of livestock products in diets. Less scientific breeding practices usually prevail in the less developed regions, while great care is given to animal breeding in the more developed regions of North America, Europe, Australia, and New Zealand.

The advances made in developing new, highly productive strains of crops through the application of genetics have not been matched by similar advances in livestock. Except for broiler chickens in the United States, little progress has been made in improving the efficiency with which animals convert feed to animal products. Research on the breeding and nutrition of poultry, for example, makes it possible to produce chickens for market in about 30 percent less time than it took before the research findings were applied.

Hogs. Advances in animal breeding have been made by careful selection and crossbreeding. These techniques are not new. The major breeds of English cattle, for example, were developed in the 18th and early 19th centuries by selection and crossbreeding. The Poland China and Duroc Jersey breeds of swine were developed in the United States

Canadian
Marquis
wheat

Improving
Mexican
wheat

in the latter part of the 19th century by the same means.

The hogs developed in the United States in the latter part of the 19th and first part of the 20th century were heavy, fat-producing animals that met the demands for lard. During the 1920s lard became less important as a source of fat because of increasing use of cheaper vegetable oils. Meat-packers then sought hogs yielding more lean meat and less fat, even though market prices moved rather slowly toward making their production profitable.

Breeding
leaner hogs

At the same time, Danish, Polish, and other European breeders were crossbreeding swine to obtain lean meat and vigorous animals. An outstanding new breed was the Danish Landrace, which in the 1930s was crossed with several older American breeds, eventually giving rise to several new, mildly inbred lines. These lines produced more lean meat and less fat, as well as larger litters and bigger pigs.

Sheep. Similar crossbreeding, followed by intermating and selection with the crossbreeds, brought major changes in the sheep industries of New Zealand and the United States. The goal in New Zealand was to produce more acceptable meat animals, while that in the United States was to produce animals suited to Western range conditions and acceptable both for wool and mutton.

During the late 19th century, several New Zealand sheep breeders began crossing Lincoln and Leicester rams with Merino ewes. Early in the 20th century, the Corriedale had become established as a breed, carrying approximately 50 percent Australian Merino, with Leicester and Lincoln blood making up the remainder. The Corriedale was successfully introduced into the United States in 1914. Since World War II, a more uniform lamb carcass has been developed in New Zealand by crossing Southdown rams with Romney ewes.

With different objectives in view, breeders in the United States in 1912 made initial crosses between the long-wool mutton breed, the Lincoln, and fine-wool Rambouillets. Subsequent intermating and selection within the crossbreeds led to a new breed, the Columbia. Both the Columbia and the Targhee, another breed developed in the same way as the Columbia, have been widely used. They are suited to the Western ranges, and they serve reasonably well both as wool and meat animals.

Beef cattle. Changes in beef cattle, particularly the establishment of new breeds, have resulted from selective linebreeding and from crossbreeding. The Polled Shorthorn and the Polled Hereford breeds were established by locating and breeding the few naturally hornless animals to be found among the horned herds of Shorthorns and Herefords, first established as distinctive breeds in England. It is of particular note that the originator of the Polled Herefords made an effort to locate naturally hornless Herefords and begin linebreeding with them after he had studied Darwin's work on mutations and variations and how they could be made permanent by systematic mating.

New breeds
of beef
cattle

Three new breeds originating in the United States were developed for parts of the South where the standard breeds lacked resistance to heat and insects and did not thrive on the native grasses. The first of these breeds, the Santa Gertrudis, was developed on the King Ranch in Texas by crossbreeding Shorthorns and Brahmans, a heat- and insect-resistant breed from India. The Santa Gertrudis cattle carry approximately five-eighths Shorthorn blood and three-eighths Brahman. They are heavy beef cattle and thrive in hot climates and have been exported to South and Central America in order to upgrade the native cattle.

The Brangus breed was developed in the 1930s and 1940s by crossing Brahman and Angus cattle. The breed has been standardized with three-eighths Brahman and five-eighths Angus breeding. The Brangus generally have the hardiness of the Brahman for Southern conditions but the improved carcass qualities of the Angus.

The Beefmaster was developed in Texas and Colorado by crossbreeding and careful selection, with the cattle carrying about one-half Brahman blood and about one-fourth each of Hereford and Shorthorn breeding. Emphasis was given to careful selection, major points being disposition, fertility, weight, conformation, hardiness, and milk production.

Artificial breeding. An increase in milk production per cow in the 20th century has come through better nutrition and artificial breeding. Artificial breeding permits the use of proved sires, developed through successive crosses of animals of proved merit. An Italian scientist experimented successfully with artificial insemination in 1780, but its practical usefulness was not demonstrated until the 20th century. The Soviet biologist Ilya Ivanov established the Central Experimental Breeding Station in Moscow in 1919 to continue work that he had begun some 20 years earlier. As early as 1936, more than 6,000,000 cattle and sheep were artificially inseminated in the Soviet Union.

After the Soviets reported their successes, scientists in many nations experimented with artificial breeding. Denmark began with dairy cattle in the 1930s. The first group in the United States began work in 1938. Statistics show that the milk and butterfat production of proved sires' daughters, resulting from artificial breeding, is higher than that of other improved dairy cattle. Furthermore, a single sire can be used to inseminate 2,000 cows a year, as compared with 30 to 50 in natural breeding.

In summary, crossbreeding and careful selection, combined with such techniques as artificial insemination, better feeding, and control of diseases and pests, have made substantial contributions to livestock production in the 20th century. More intensified research, particularly in hybridization, offers promise of help to livestock producers in meeting increasing world demands for their products.

(W.D.R./K.Me.)

ELECTRICITY IN AGRICULTURE

Electric power has had an impact on modern agriculture that has been at least as significant as that of either steam or gasoline, because electricity in its nature is far more versatile than the earlier power sources. Although there had long been scientific interest on the effects electricity had on plant growth, especially after the development of electric lamps, it was the development of the electric motor that really gained the interest of the farming community. Some authorities saw its value to farmers as early as 1870.

Electrical cooperatives. Despite the obvious advantages of the other, more available power sources, progressive farmers in a number of countries were determined to exploit the possibilities of electricity on their farms. To get electricity, farmers formed cooperatives that either bought bulk power from existing facilities or built their own generating stations.

It is believed that the first such cooperatives were formed in Japan in 1900, followed by similar organizations in Germany in 1901. Multiplying at a considerable rate, these farmer cooperatives not only initiated rural electrification as such but provided the basis for its future development.

From these small beginnings the progress of rural electrification, though necessarily slow, steadily gained impetus until, in the 1920s, public opinion eventually compelled governments to consider the development of rural electrification on a national basis. Today in the most advanced countries virtually all rural premises—domestic, commercial, industrial, and farms—have an adequate supply of electricity.

Early applications of electricity were of necessity restricted to power and some lighting, although the full value of lighting was not completely realized for years. Electric motors were used to drive barn machinery, chaff-cutters and root cutters, cattle cake and grain crushers, and water pumps. Electricity's ease of operation and low maintenance showed savings in time and labour. It was not long before the electric motor began to replace the mobile steam engine on threshing, winnowing, and other crop-processing equipment outside the barn.

In the fields, a number of electrically driven, rope-haulage plowing installations, some of them quite large, came into use in several European countries. These systems, however, did not stand the test of time or competition from the mobile internal-combustion-driven tractor.

Applications of electricity in agriculture did not increase greatly until the 1920s, when economic pressures and the increasing drift of labour from the land brought about a change in the whole structure of agriculture. This change,

Rural
electrifi-
cation

based on new techniques of intensive crop production resulting from the development of a wide range of mechanical, electrical, and electromechanical equipment, was the start of the evolution of agriculture from a labour-intensive industry to the present capital-intensive industry, and in this electricity played a major part.

Modern applications. Modern applications of electricity in farming range from the comparatively simple to some as complex as those in the manufacturing industries. They include conditioning and storage of grain and grass; preparation and rationing of animal feed; and provision of a controlled environment in stock-rearing houses for intensive pig and poultry rearing and in greenhouses for horticultural crops. Electricity plays an equally important part in the dairy farm for feed rationing, milking, and milk cooling; all these applications are automatically controlled. Computers have increasingly been employed to aid in farm management and to directly control automated equipment.

The engineer and farmer have combined to develop electrically powered equipment for crop conservation and storage to help overcome weather hazards at harvesttime and to reduce labour requirements to a minimum. Grain can now be harvested in a matter of days instead of months and dried to required moisture content for prolonged storage by means of electrically driven fans and, in many installations, gas or electrical heaters. Wilted grass, cut at the stage of maximum feeding value, can be turned into high-quality hay in the barn by means of forced ventilation and with very little risk of spoilage loss from inclement weather.

Control-
ling storage
tempera-
tures

Conditioning and storage of such root crops as potatoes, onions, carrots, and beets, in especially designed stores with forced ventilation and temperature control, and of fruit in refrigerated stores are all electrically based techniques that minimize waste and maintain top quality over longer periods than was possible with traditional methods of storage.

The two most significant changes in the pattern of agricultural development since the end of World War II have been the degree to which specialization has been adopted and the increased scale of farm enterprises. Large numbers of beef cattle are raised in enclosures and fed carefully balanced rations by automatic equipment. Pigs by the thousands and poultry by the tens of thousands are housed in special buildings with controlled environments and are fed automatically with complex rations. Dairy herds of up to 1,000 cows are machine-milked in milking parlours, and the cows are then individually identified and fed appropriate rations by complex electronic equipment. The milk passes directly from the cow into refrigerated bulk milk tanks and is ready for immediate shipment.

(A.W.Gr./K.Me.)

PEST AND DISEASE CONTROL IN CROPS

Beginnings of pest control. Wherever agriculture has been practiced, pests have attacked, destroying part or even all of the crop. In modern usage, the term pest includes animals (mostly insects), fungi, plants, bacteria, and viruses. Man's efforts to control pests have a long history. Even in Neolithic times (about 7000 BC), farmers practiced a crude form of biological pest control involving the more or less unconscious selection of seed from resistant plants. Severe locust attacks in the Nile Valley during the 13th century BC are dramatically described in the Bible, and, in his *Natural History*, the Roman author Pliny the Elder describes picking insects by hand from plants and spraying. The scientific study of pests was not undertaken until the 17th and 18th centuries. The first successful large-scale conquest of a pest by chemical means was the control of the vine powdery mildew (*Uncinula necator*) in Europe in the 1840s. The disease, brought from the New World, was controlled first by spraying with lime sulfur and, subsequently, by sulfur dusting.

First
successful
chemical
pest
control

Another serious epidemic was the potato blight that caused famine in Ireland in 1845 and some subsequent years and severe losses in many other parts of Europe and the United States. Insects and fungi from Europe became serious pests in the United States, too. Among these were

the European corn borer, the gypsy moth, and the chestnut blight, which practically annihilated that tree.

The first book to deal with pests in a scientific way was John Curtis' *Farm Insects*, published in 1860. Though farmers were well aware that insects caused losses, Curtis was the first writer to call attention to their significant economic impact. The successful battle for control of the Colorado potato beetle (*Leptinotarsa decemlineata*) of the western United States also occurred in the 19th century. When miners and pioneers brought the potato into the Colorado region, the beetle fell upon this crop and became a severe pest, spreading steadily eastward and devastating crops, until it reached the Atlantic. It crossed the ocean and eventually established itself in Europe. But an American entomologist in 1877 found a practical control method consisting of spraying with water-insoluble chemicals such as London Purple, paris green, and calcium and lead arsenates.

Other pesticides that were developed soon thereafter included nicotine, pyrethrum, derris, quassia, and tar oils, first used, albeit unsuccessfully, in 1870 against the winter eggs of the *Phylloxera* plant louse. The Bordeaux mixture fungicide (copper sulfate and lime), discovered accidentally in 1882, was used successfully against vine downy mildew; this compound is still employed to combat it and potato blight. Since many insecticides available in the 19th century were comparatively weak, other pest-control methods were used as well. A species of ladybird beetle, *Rodolia cardinalis*, was imported from Australia to California, where it controlled the cottony-cushion scale then threatening to destroy the citrus industry. A moth introduced into Australia destroyed the prickly pear, which had made millions of acres of pasture useless for grazing. In the 1880s the European grapevine was saved from destruction by grape phylloxera through the simple expedient of grafting it onto certain resistant American rootstocks.

This period of the late 19th and early 20th centuries was thus characterized by increasing awareness of the possibilities of avoiding losses from pests, by the rise of firms specializing in pesticide manufacture, and by development of better application machinery.

Pesticides as a panacea: 1942-62. In 1942 Paul Hermann Müller of Switzerland discovered the insecticidal properties of a synthetic chlorinated organic chemical, dichlorodiphenyltrichloroethane, which was first synthesized in 1874 and subsequently became known as DDT. Müller received the Nobel Prize for Physiology or Medicine in 1948 for his discovery. DDT was far more persistent and effective than any previously known insecticide. Originally a mothproofing agent for clothes, it soon found use among the armies of World War II for killing body lice and fleas. It stopped a typhus epidemic threatening Naples. Müller's work led to discovery of other chlorinated insecticides, including aldrin, introduced in 1948; chlordane (1945); dieldrin (1948); endrin (1951); heptachlor (1948); methoxychlor (1945); and Toxaphene (1948).

Origin
of DDT

Research on poison gas in Germany during World War II led to the discovery of another group of yet more powerful insecticides and acaricides (killers of ticks and mites)—the organophosphorus compounds, some of which had systemic properties; that is, the plant absorbed them without harm and became itself toxic to insects. The first systemic was octamethylpyrophosphoramide, trade named Schradan. Other organophosphorus insecticides of enormous power were also made, the most common being diethyl-*p*-nitrophenyl monothiophosphate, named parathion. Though low in cost, these compounds were toxic to humans and other warm-blooded animals. The products could poison by absorption through the skin, as well as through the mouth or lungs, thus, spray operators must wear respirators and special clothing. Systemic insecticides need not be carefully sprayed, however; the compound may be absorbed by watering the plant.

Though the advances made in the fungicide field in the first half of the 20th century were not as spectacular as those made with insecticides and herbicides, certain dithiocarbamates, methylthiuram disulfides, and thaladimides were found to have special uses. It began to seem that almost any pest, disease, or weed problem could be mas-

Figure 9: Low-volume spraying of pesticide on a field of corn.

Grant Heilman

tered by suitable chemical treatment. Farmers foresaw a pest-free millennium. Crop losses were cut sharply; locust attack was reduced to a manageable problem; and the new chemicals, by killing carriers of human disease, saved the lives of millions of people.

Problems appeared in the early 1950s. In cotton crops standard doses of DDT, parathion, and similar pesticides were found ineffective and had to be doubled or trebled. Resistant races of insects had developed. In addition, the powerful insecticides often destroyed natural predators and helpful parasites along with harmful insects. Insects and mites can reproduce at such a rapid rate that often when natural predators were destroyed by a pesticide treatment, a few pest survivors from the treatment, unchecked in breeding, soon produced worse outbreaks of pests than there had been before the treatment; sometimes the result was a population explosion to pest status of previously harmless insects.

At about the same time, concern also began to be expressed about the presence of pesticide residues in food, humans, and wildlife. It was found that many birds and wild mammals retained considerable quantities of DDT in their bodies, accumulated along their natural food chains. The disquiet caused by this discovery was epitomized in 1962 by the publication in the United States of a book entitled *Silent Spring*, whose author, Rachel Carson, attacked the indiscriminate use of pesticides, drew attention to various abuses, and stimulated a reappraisal of pest control. Thus began a new "integrated" approach, which was in effect a return to the use of all methods of control in place of a reliance on chemicals alone.

Integrated control. Some research into biological methods was undertaken by governments, and in many countries plant breeders began to develop and patent new pest-resistant plant varieties.

Biological
pest
control

One method of biological control involved the breeding and release of males sterilized by means of gamma rays. Though sexually potent, such insects have inactive sperm. Released among the wild population, they mate with the females, who either lay sterile eggs or none at all. The method was used with considerable success against the screwworm, a pest of cattle, in Texas. A second method of biological control employed lethal genes. It is sometimes possible to introduce a lethal or weakening gene into a pest population, leading to the breeding of intersex (effectively neuter) moths or a predominance of males. Various studies have also been made on the chemical identification of substances attracting pests to the opposite sex or to food. With such substances traps can be devised that attract only a specific pest species. Finally, certain chemicals have

been fed to insects to sterilize them. Used in connection with a food lure, these can lead to the elimination of a pest from an area. Chemicals tested so far, however, have been considered too dangerous to humans and other mammals for any general use.

Some countries (notably the United States, Sweden, and the United Kingdom) have partly or wholly banned the use of DDT because of its persistence and accumulation in human body fat and its effect on wildlife. New pesticides of lesser human toxicity have been found, one of the most used being mercaptosuccinate, trade named Malathion. A more recent important discovery was the systemic fungicide, absorbed by the plant and transmitted throughout it, making it resistant to certain diseases.

The majority of pesticides are sprayed on crops as solutions or suspensions in water. Spraying machinery has developed from the small hand syringes and "garden engines" of the 18th century to the very powerful "autoblast machines" of the 1950s that were capable of applying up to some 400 gallons per acre (4,000 litres per hectare). Though spraying suspended or dissolved pesticide was effective, it involved moving a great quantity of inert material for only a relatively small amount of active ingredient. Low-volume spraying was invented about 1950, particularly for the application of herbicides, in which 10 or 20 gallons of water, transformed into fine drops, would carry the pesticide. Ultralow-volume spraying has also been introduced; four ounces (about 110 grams) of the active ingredient itself (usually Malathion) are applied to an acre from aircraft. The spray as applied is invisible to the naked eye. (G.O.)

ECONOMICS, POLITICS, AND AGRICULTURE

As the 20th century opened, western Europe was recovering from an economic depression during which most of the nations had turned to protecting agriculture through tariffs. The major exceptions were Great Britain, Denmark, and The Netherlands. In the first decade of the century there was an increasing demand for agricultural products, a result of industrialization and population growth, while agriculture in the United States, France, Germany, and many other nations reached a state of equilibrium in relation to the rest of the economy.

During World War I farmers benefited from high prices, which persisted for a short period after the war because of a shortage of food supplies. European agriculture recovered from wartime losses in land fertility, livestock, and capital and by the early 1920s was fully productive. Elsewhere, production had expanded greatly during the war and afterward continued to rise. After the war prices declined,

and, as farmers sought to compensate by expanding their output, the fall in prices was aggravated.

Agricultural tariffs, generally suspended during the war, were gradually reintroduced. The Great Depression of the 1930s brought a new wave of protectionism, leading some industrial nations to look toward self-sufficiency in food supplies. In countries such as France, Germany, and Italy, where agriculture was already protected, the tariff structure was reinforced by new and more drastic measures, while countries such as Britain, Denmark, The Netherlands, and Belgium abandoned free trade and began to support their farmers in a variety of ways. The United States first raised tariffs and then undertook to maintain the prices of farm products. Major exporters of farm products, such as Argentina, Brazil, Australia, Canada, and New Zealand, tried a number of plans to maintain prices.

The
milling
ratio

One of the most effective of the nontariff measures was the "milling ratio" for wheat or, less often, rye, under which millers were legally obliged to use a certain minimum percentage of domestically produced grain in their grist. This device was first used in Norway in 1927. In 1929 both France and Germany adopted it, and, from 1930 on, it became customary in Europe and in some non-European nations as well. Milling ratios continued in many nations up to World War II and have been reintroduced in several since that time.

Import quotas, although used earlier in a limited way, became a major protective device during the 1930s. Starting with France, by 1939 they had been adopted on a large scale, mainly for agricultural products, by most European and several non-European nations.

The most radical measures were undertaken in Germany under Hitler, where the Nazi government, seeking self-sufficiency in food, fixed farm prices at relatively high levels and maintained complete control over imports.

In the fall of 1931, Great Britain abandoned the free-trade policies followed for nearly a century and turned to protectionism. The new policies emphasized industrial rather than agricultural products. A commodity-by-commodity approach for agriculture through subsidies, marketing schemes, and import restrictions provided help for some farmers. Competition from the Dominions, however, was strong.

In 1932 Great Britain negotiated the Ottawa Agreements with the Dominions, which included comparatively free access of Dominion agricultural products to the British market. The agreement helped considerably to alleviate the difficulties the Dominions faced during the Depression. In addition, export subsidies were adopted by several of the Dominions: for wheat by Canada and Australia; for dairy products by New Zealand; and for several products by South Africa.

In the United States the Agricultural Marketing Act of 1929 established the Federal Farm Board to promote orderly marketing through cooperatives. The Tariff Act of 1930 imposed virtually exclusive tariffs on many products, including those of the farm. These acts, comparatively ineffective in meeting the pressures of the Great Depression, were followed by the Agricultural Adjustment Act of 1933 and subsequent legislation that included restoring the balance between production and consumption, restoration of farm purchasing power, and the attainment of parity, the ratio between prices farmers paid and those they received during the period 1910-14.

Some of the exporting nations adopted extreme measures during the Depression in an attempt to maintain prices for their commodities. Brazil burned surplus coffee stocks, destroying more than 8,000,000 pounds of coffee over 10 years beginning in 1931. An Inter-American Coffee Agreement, signed in 1940, assigned export quotas to producer nations for shipment to the United States and other consuming nations and was effective during World War II. Other commodity agreements have met with very limited success.

During World War II, agricultural production declined in most of the European countries, shipping became difficult, and trade channels shifted.

In contrast, agriculture in the United States, undisturbed by military action and with assurance of full demand

and relatively high prices, increased productivity. The United States, Great Britain, and Canada cooperated in a combined food board to allocate available supplies. The United Nations Relief and Rehabilitation Administration (UNRRA) was organized in 1943 to administer postwar relief, while the Food and Agriculture Organization (FAO) of the United Nations was established in 1945 to provide education and technical assistance for agricultural development throughout the world.

United
Nations
activity

By the end of World War II, food production in most of the countries of Europe had fallen below the prewar level. Through assistance given primarily by the United States and the United Nations, recovery was rapid. Western Europe was greatly helped from 1948 on by U.S. aid under the Marshall Plan, administered through the Organisation for European Economic Co-operation (OEEC). In September 1961, this organization was replaced by the Organisation for Economic Co-operation and Development (OECD), with Canada and the United States, and later other non-European developed nations, as full members. Its agricultural programs have dealt, for example, with economic policies, standardization, manpower, and development.

From the 1950s on, agricultural production increased markedly in western Europe, in the United States, and in most of the nations that ordinarily export large quantities of agricultural products. The Soviet Union, which in the 1930s had organized agricultural production into state-run collective farms, has increased its output substantially, in part by opening new lands. It has been hampered, however, by periodic crop failures that have made it necessary to import large quantities of grain. Agricultural production in China, though adversely affected by the social and economic upheavals caused by the policies of the Great Leap Forward (1958-60) and the chaotic atmosphere of the Cultural Revolution (1966-76), has steadily improved, especially since the Cultural Revolution.

Most of the Western nations offer some type of protection to their farmers—price supports, import quotas, and plans for handling surplus production. Notable examples are the agricultural programs run by the U.S. Department of Agriculture and by the European Communities. On the other hand, many of the developing nations have had food deficits, with little in the way of exportable goods to pay for food imports. Several national and international organizations have been established in an effort to deal with the problems of the developing nations, and direct assistance has also been provided by the governments of developed countries.

Individual farmers in the nations where commercial agriculture is important have been forced to make changes to meet the problems of world surpluses and low world prices for farm products. Thus, in many nations, farmers have increased productivity through adopting advanced technology. This has permitted each worker, generally speaking, to farm larger areas and has thus reduced the number of farmers. In some nations, commercialization has led to farming by large-scale corporations. Thus, the world tendency is toward larger farms. The farm operated by a single family, however, is still the dominant unit of production in most of the world. (W.D.R./K.Me.)

Albania

Albania, officially the People's Socialist Republic of Albania (Republika Popullore Socialiste e Shqipërisë), is located in the western part of the Balkan Peninsula on the Strait of Otranto, the southern entrance to the Adriatic Sea. The smallest of the Balkan countries, Albania encompasses an area of 11,100 square miles (28,748 square kilometres), with a maximum length from north to south of about 210 miles (340 kilometres) and a maximum width of about 95 miles. It is bounded to the north and east by Yugoslavia and to the south by Greece. To the west and southwest, Albania is bordered by the Adriatic and Ionian seas. The border with Yugoslavia runs generally northward from Lake Prespa to the Albanian Alps, then southwest to the Adriatic, west of Shkodër. The border with Greece runs southwest from Lake Prespa to the Ionian Sea. Albania's immediate western neighbour, Italy, lies some 50 miles away. The capital is Tiranë.

Albanians refer to themselves as *shqiptarë*, meaning "sons of eagles," and to their country as Shqipëria. Descended from the ancient Illyrians, they have lived in relative isolation and obscurity through most of their difficult history, in part because of the rugged terrain of their mountainous land but also because of a complex of historical, cultural, and social factors. Owing to its location on the Adriatic Sea, Albania has long served as a bridgehead for various nations and empires seeking conquest abroad. As a result, Albanians have often faced extinction as a people. In 168 BC the Illyrians were conquered by the Romans, and from AD 395 they were ruled by the Byzantine Empire. After suffering centuries of invasion by Visigoths, Huns, Bulgars, and Slavs, the Albanians were finally conquered by the Ottoman Turks in the 15th century. But before this conquest was completed, there occurred one of the most stirring moments in Albanian history, when for 25 years Albanians struggled for their independence under the leadership of Gjergj Kastrioti, known to posterity as

Skanderbeg. As an embodiment of the familial loyalty, love of country, and martial skill often attributed to his people, Skanderbeg has lived on in the imagination of Albanians as their greatest national hero.

Turkish rule cut off Albania from Western civilization for more than four centuries, but in the late 19th century the country began to remove itself from Ottoman Orientalism and to rediscover old affinities and common interests with the West. Albania was declared independent in 1912, but the following year the demarcation of its boundaries by the Great Powers of Europe assigned about half of its territory and people to neighbouring states. This division, still in effect, has entered deeply into the political psychology of Albanians. In particular, the people of Albania proper and the ethnic Albanians of the Yugoslav region of Kosovo view themselves as members of the same nation, at times severely straining the relations of their two states.

Ruled as a monarchy between the world wars, Albania fell under the dominance of Italy. It emerged from the violence of World War II as a communist state that has fiercely protected its sovereignty and in which almost all aspects of life have been controlled by the government. Nevertheless, although the ruling Albanian Party of Labour has rejected the Western political and economic model, it has used Western technology and science in its efforts to modernize the country. In addition, the Albanian people have long shown great appreciation for the cultural achievements of western Europe, even while retaining their own ethnic identity, cultural heritage, and individuality. (E.Bi./P.R.P.)

This article covers the land, people, economy, government, culture, and history of Albania. The Albanian-speaking region of Kosovo is covered in YUGOSLAVIA. For discussion of Albania and Albanians within the broader context of their region, see BALKANS.

Physical and human geography

THE LAND

Relief. Albania is predominantly a mountainous country. About three-quarters of its territory consists of mountains and hills with elevations of more than 650 feet (200 metres) above sea level; the remainder consists of coastal and alluvial lowlands. The North Albanian Alps, an extension of the Dinaric mountain system, extend over the northern part of the country, with elevations approaching 8,900 feet. The most rugged part of the country, the

Alps have limited arable land and are sparsely populated. Forestry and animal husbandry form the main economic activities.

The central mountain region, extending from the valley of the Drin River in the north to the central Devoll and the lower Osum valleys in the south, has a generally less rugged terrain and is more densely populated than the Alps region. In the easternmost portion, the imposing gypsum block of Albania's highest peak, Korab, rises to 9,025 feet (2,751 metres). The region is characterized by substantial mineral deposits such as chromium, iron-nickel,

and copper. Forestry, animal husbandry, mining, and, to an extent, agriculture are the main economic activities of the region.

South of the central mountain region there is a series of northwest-southeast-trending mountain ranges, with elevations of up to 8,200 feet. Composed of limestone rock, the ranges are separated by wide valleys. While the Alps and the mountains of the central region are covered with dense forests, the mountains of the southern region are either bare or have a thin covering of Mediterranean shrubs, oaks, and Mediterranean pines. They serve essentially as pasture grounds for livestock.

In contrast to the three mountain regions, western Albania, stretching along the Adriatic coast, consists of low, fertile plains. The most densely populated region in the country, this area extends over a distance of nearly 125 miles from north to south and penetrates some 30 miles into the interior from the coast. It is the most important agricultural and industrial region of the country. The 290 miles of coastline along the Adriatic are well known for their splendid beaches and surrounding landscape.

Drainage. The longest river (175 miles in Albania) is the Drin, which originates in Yugoslavia. Other main rivers are the Seman, Shkumbin, and Vjosë, all of which drain the central part of the western plain. Albania also has many lakes, the most important of which are Liqeni i Shkodrës (Lake Scutari) in the northwest and Lakes Ohrid and Prespa along the eastern border.

Climate. Albania has a Mediterranean type of climate, with characteristically warm, dry summers and mild, wet winters. Local climatic variation is considerable, however, from one region to another. The western part, which is under the influence of warm maritime air from the Adriatic and Ionian seas, has more moderate temperatures than the rest of the country. For example, Sarandë, on the southern coast, has average daily temperatures of 75° F (24° C) in July and 48° F (9° C) in January. The eastern part of the country, on the other hand, is mainly under the influence of continental air and is characterized by mild summers (owing to the high elevations) and cold winters. Peshkopi, in the eastern mountains, averages 73° F in July and 30° F in January.

Rainfall in Albania is abundant but irregularly distributed throughout the year. Average annual precipitation varies from more than 100 inches (2,500 mm) in the Albanian Alps to less than 30 inches along much of the eastern border. Some 40 percent of the annual precipitation falls in the winter. Summer droughts are common, especially in the southwest of the country.

Plant and animal life. Only a small part of Albania is completely without vegetation, and forests cover more than one-third of the total area. The coastal lowlands are characterized by Mediterranean shrubs such as laurel and myrtle. Citrus fruits are grown on the southern coast, with figs and olives wherever there is sufficient irrigation. Above the lowlands, oak forests predominate. Cultivated fruits in this zone include apples, plums, and grapes, and walnuts and chestnuts are also grown. Above the oak belt, beginning at about 3,000 feet, is a belt of beeches and pines, and Alpine pastures lie above the timberline.

Old customs of weapon carrying and unrestricted shooting took a heavy toll of Albanian wildlife, but hunting laws have been introduced and nature preserves established to protect the remaining jackals, wolves, and foxes and the even rarer wild boars, bears, and chamois. The mild coastal climate attracts great numbers of migratory birds, such as swallows, storks, ducks, geese, and pelicans. Sardines and mullet are among the fishes that swim Albanian coastal waters, and trout are found in the streams and lakes of the mountains.

Settlement patterns. The west is the most densely populated part of Albania. About one-third of the people live in urban centres, but they are evenly distributed among the country's major cities.

The mountain regions, being suitable mainly for pasture, traditionally saw sparse settlement, with small, often almost inaccessible villages of only a few dozen families. Houses, built of stone, consisted of one or two rooms around a hearth. In the mountain valleys or basins, towns such as Elbasan, Korçë, and Berat grew up as centres of local farming and trading.

Under the legacy of Ottoman rule, even such centres of the coastal plain as Tiranë, Durrës, and Vlorë were small towns with virtually no industry, but, with the growth of industry under socialism, the urban population has more than doubled. Large apartment blocks, often with several units sharing kitchens and toilets, are typical of the new sections. In the countryside are planned communities that house the workers of huge collective farms, many of which have been built around formerly private estates.

THE PEOPLE

There are an estimated seven million ethnic Albanians in the world, but fewer than half of them live within the boundaries of the Albanian state. On almost all its frontiers with Yugoslavia, Albania borders on Albanian-speaking regions, which, in the opinion of most Albanians, should have been incorporated within the borders of the Albanian state when the Great Powers delimited its national boundaries. The ethnic Albanians in Yugoslavia number more than two million, making them that country's third largest ethnic group. There are large Albanian communities in Italy, Greece, Turkey, and, to a lesser extent, Bulgaria and Romania. There is also a sizable community in the United States.

Albania itself has one of the most ethnically homogeneous populations in the world, with non-Albanians accounting for only 2 percent of the total population. Greeks, concentrated mainly in the southeast, and Slavs, almost all of them Macedonians, constitute the largest minorities.

Population growth. The Albanian government has actively encouraged population growth, and the population has been increasing four to five times faster than the average annual rate in other European countries. Nearly all of the growth has been due to natural increase rather than migration. The birth rate has consistently been the highest in Europe since the end of World War II, while the death rate has been one of the continent's lowest. Albania's population, consequently, is the youngest in Europe, with more than one-third of the total under 15 years of age.

Language. The Albanian language (called Shqip by Albanians) is of interest to linguists because, as a descendant of the extinct Illyrian tongue, it is the only surviving member of its branch of the Indo-European language family. Owing to centuries of rule by foreigners, its vocabulary has adopted many words from the Latin, Greek, Turkish, Italian, and Slavic tongues. There are two principal dialects: Geg, spoken north of the Shkumbin River, and Tosk, spoken in the south. Geg dialects are also spoken in Yugoslavia, and Tosk dialects in the Albanian communities of Greece and Italy. Although there are variations even within these two dialects, all Albanians can understand one another with little difficulty.

Because official business and ecclesiastical functions were carried on in foreign languages, Albanian did not acquire a definitive orthography until 1908, when a writing system was adopted based on the Roman alphabet. Attempts were then made in following decades to create a unified language based on the Geg dialect of the central Elbasan region, but after 1944 the communist regime established Tosk as the official standard. Since 1952 all printed Albanian works have been published in Tosk.

Northerners and southerners. Differences in dialects used by Glegs and Tosks, as well as their different outlooks and ways of life, were quite pronounced before World War II, but the communist regime has sought to integrate the two groups and has therefore banished the terms Geg and Tosk from the political vocabulary.

Before 1945 the more numerous Glegs traditionally dominated Albanian politics. Well known for their independent spirit and fighting abilities, they managed to enjoy a great degree of independence and opposed the authority of foreign invaders and, subsequently, that of the Alba-

Albanians
outside the
Albanian
state

Traditional
Geg society

nian government. Before the communist takeover, Geg society was organized according to tribal groups, with the clan chieftain, or *bajraktar*, playing an important political and social role. While the clan system and the traditional Geg way of life have largely disappeared from Albania, the patriarchal family system is still evident among ethnic Albanians in Yugoslavia.

Because their territories were easily accessible, the Tosks had substantial contacts with the outside world; as a result, foreign influences among them were more pronounced than among the Gëgs. Before World War II the south was characterized by a semifeudal society. The peasantry, which made up most of the population, was exploited by a small group of large landowners who controlled about two-thirds of the rich land. The communist movement was largely based in the south.

Religion. Albania is Europe's only predominantly Muslim country—a legacy of nearly five centuries of Ottoman rule. At the end of World War II, some 70 percent of the population was Muslim, 20 percent Eastern Orthodox, and 10 percent Roman Catholic. The Roman Catholics were located in the northern part of the country, particularly in the city of Shkodër, while Orthodox Christians lived in the southern districts of Gjirokastrë, Korçë, Berat, and Vlorë. The Muslims were spread throughout the land, although they particularly dominated the centre. Most of them were traditional Sunnites, but about one-quarter were members of the liberal, pantheistic Bektashi sect, which for a time had its headquarters in Tiranë.

Albanians traditionally displayed a high degree of religious tolerance, and religious diversity did not obstruct national unity since the Albanians' main identification was ethnic and national rather than religious. Nevertheless, soon after seizing power, the communist regime launched a campaign against religious institutions. In 1967 Albania became the world's first self-proclaimed atheistic country. All religious institutions were closed, church property confiscated, and religious practices prohibited. The government's policy of supplanting religion with communist ideology, however, has largely failed, and officials have acknowledged that Albania has experienced a religious revival.

THE ECONOMY

Albania has a centrally planned economy, with all means of production under state control, agriculture fully collectivized, industry nationalized, private enterprise strictly prohibited, and the administrative structure highly centralized. Since the break in relations with China in 1978, the main element in Albania's development program has been the policy of self-reliance, which promotes the maximum utilization of internal human, material, and monetary resources. The government is prohibited by a constitutional provision from seeking foreign aid, accepting loans, or allowing foreign investments. The Albanian Party of Labour (APL) directs the country's entire economic activity through a single five-year plan.

Resources. For a small country, Albania is endowed with considerable resources. The southwestern part of the country is rich in petroleum and natural gas. The northeastern region has substantial reserves of metallic mineral deposits, including chromium, copper, and iron-nickel. Large deposits of lignite (soft coal) are found near Tiranë, and natural asphalt is mined near Selenicë.

Albania is also rich in rivers and streams with significant hydroelectric potential. These have been exploited quite effectively, making the country an energy exporter. A number of huge hydroelectric power plants have been built, mainly on the Drin River, and more than half of the country's arable land is irrigated, largely from the artificial reservoirs created upstream of the dams.

Industry. The government has pursued an ambitious policy of rapid industrialization aimed at making the country economically self-sufficient in as many fields as possible. This policy has led to the creation of a relatively modern multibranch industry, which now generates more than half of the total national income. Priority has been given to the exploitation of the country's considerable natural resources. Albania is the world's third largest producer of chromium. Electrification of the entire coun-

try was completed in 1971, and by the late 1980s Albania was exporting electricity to several surrounding countries.

Albania processes most of its minerals domestically. Machinery and industrial equipment sufficient to outfit complete factories and plants, as well as Albanian-brand tractors, are produced domestically. The engineering industry reportedly met 95 percent of the country's needs for spare parts in the late 1980s. Besides selling hydroelectricity abroad, Albania also exports oil and petroleum products.

Despite this progress, Albania experiences difficulties in industrial production, particularly in the extraction of oil and the production of electricity. The exploitation of natural resources has been hampered by obsolete machinery and equipment, a lack of technical expertise, poor organization, and an inability fully to assimilate imported technology. Also, because most state investment has gone into heavy industry, the economy is unable to meet the population's demands for various consumer goods.

Agriculture. About one-half of the economically active population is employed in agriculture. Arable land amounts to only one-fourth of the total land area, yet the country meets nearly all of its food needs from domestic production. In the mid-1970s, moreover, Albania became self-sufficient in bread grains. Main crops are wheat, corn (maize), sugar beets, cotton, sunflower seeds, tobacco, potatoes, and fruits. Major livestock are sheep, goats, cattle, and pigs.

The government claims that Albania has achieved the stage of development of an agricultural-industrial country and is on the way to becoming an industrial country with an advanced agriculture. Large-scale programs of land reclamation, soil improvement, and irrigation, the introduction of new farm techniques and mechanization, and increased use of fertilizers have all contributed to a significant expansion and modernization of agricultural production.

But, despite impressive gains, agriculture is a problem sector of the economy, consistently failing to meet planned targets. The government apparently has never been able to overcome the resentment caused by its violent and all-out assault on peasant agriculture, which, when completed in 1967, resulted in the full collectivization of farmland and the reduction of private plots allowed to individuals. In addition, agricultural production continues to be hindered by the persistence of traditional agricultural methods, a low level of mechanization, and a lack of material incentives.

Trade. Albania's major trading partners are Yugoslavia, Romania, Italy, Czechoslovakia, and West Germany. It exports crude petroleum, chromium ore and iron ore, copper wire, vegetables and fruits, tobacco, and wine. The principal imports are machinery and equipment, spare parts, minerals and metals, construction materials, and food products.

Transportation. Albania built its first railroad in 1947, and 40 years later Tiranë was linked to all other major industrial centres in the country. The highway network has been extended even to remote mountain villages. Air transport, however, remains largely underdeveloped. There is no scheduled domestic air service.

ADMINISTRATION AND SOCIAL CONDITIONS

Government. Albania's constitution recognizes the Albanian Party of Labour (until 1948 known as the Albanian Communist Party) as "the sole leading political force of the state and the society" and proclaims Marxism-Leninism as the official ideology. The party has set as its immediate objective the complete construction of a socialist society and as its ultimate objective the construction of a communist society, in which the principle "from each according to his abilities, to each according to his needs" will be applied. In the late 1980s the party had some 147,000 members, or about 8 percent of the adult population. Workers accounted for about 40 percent of the total membership, peasants 25 percent, and white-collar workers 30 percent. Women constituted one-third of the membership.

The APL operates on the principle of democratic centralism, which provides for strict party discipline and the

Achievements in agriculture

Economic self-reliance

The Albanian Party of Labour

subordination of the minority to the majority. The highest body of the party is the Congress, which meets every five years. Between congresses, the Central Committee directs party activities. The Politburo is the party's policy-making body and the real locus of power, while the Secretariat is in charge of the day-to-day functioning of the party.

In 1976 the Albanian People's Assembly approved a new constitution, replacing the one adopted in 1946 and revised in 1950. This document sanctions the one-party system and designates the first secretary of the APL as commander in chief of the armed forces. Albanian citizens are guaranteed such inalienable rights as freedom of speech, press, organization, association, assembly, and public demonstration. The constitution stresses, however, that citizens cannot exercise their rights in opposition to the socialist order, and the penal code contains enough provisions to provide a legal basis for suppressing any signs of dissident opinion.

The People's Assembly is the legislative branch of the government. Its 250 deputies are elected by direct suffrage of all citizens over 18 to four-year terms and meet in regular session twice a year. The 15-member Presidium of the People's Assembly acts on behalf of the assembly between sessions. The Council of Ministers, appointed by the People's Assembly, is the executive branch of the government. It is in charge of the country's social, economic, and cultural activities. The country is divided into 26 *rrethe*, (districts). Government at the district, regional, and city levels operates through people's councils. Elected for three-year terms, people's councils administer all the affairs of their geographic areas. The Supreme Court is the country's highest judicial organ, and its members are elected by the People's Assembly. Albania abolished its ministry of justice in the 1960s, and the Office of the Attorney General supervises the implementation of the country's laws.

The APL supervises government work. Although the constitution officially grants the People's Assembly considerable power, the composition of its Presidium as well as that of the Council of Ministers is actually decided by the party's Politburo. The chairman of the Council of Ministers (the prime minister), his deputies, and the ministers in charge of the most important ministries are usually members of the Politburo.

Since only a small percentage of Albania's total population are members of the APL, the party relies heavily on mass organizations to achieve its objectives. The Democratic Front is an umbrella organization for cultural, professional, and political groups. It also serves as a school for mass political education. As an instrument of the party, the Democratic Front nominates and campaigns for candidates for local and national elective posts. The list of candidates, however, is approved by the party. The Union of Albanian Women helps the party supervise the political and social activities of women. Other mass organizations include the United Trade Unions of Albania and the Union of Albanian Working Youth.

Education. The government has devoted considerable resources to the educational development of the country. Schooling is compulsory between ages 7 and 15. Education at the primary and secondary levels is free, and higher education fees are based on family income. Upper-level studies are combined with work in factories or collective farms and military service. Enver Hoxha University of Tiranë (1957) is the country's major institution of higher education. The government has also built an impressive network of professional and vocational schools.

From the outset, the communist authorities have emphasized the necessity of raising the cultural level of the population. Indeed, the rapid expansion of educational and occupational opportunities, especially for the previously unprivileged sectors of Albanian society, helped strengthen the APL's popular support and legitimacy. Whereas in 1945 about 80 percent of the population was illiterate, by the end of the 1980s the authorities could claim that illiteracy had been eliminated.

Education, like other aspects of life in socialist Albania, has been subjected to rigid centralized planning, with the emphasis on technical education and the training of tech-

nicians and skilled workers. Enrollment past secondary school is strictly regulated by the APL, with priority given to children of party members. Moreover, the educational system serves the government's ideological and political objectives, which include the education of the "new" man with appropriate communist traits, morality, and atheistic ideas, as well as the eradication of the country's past "bourgeois" cultural traits. With the APL controlling every facet of the school system, educational institutions have little say regarding their programs, curricula, administration, and teaching staffs.

Health. Albania has a relatively well-developed health system, with all services reported to be provided free of charge. There are about 20 doctors for every 10,000 inhabitants. There has been a considerable reduction in the incidence of most infectious diseases, with malaria and syphilis having been especially widespread in the past. Nevertheless, despite real improvements in health care, Albania still has a high infant-mortality rate, about 25 deaths per 1,000 live-born children. This is a result of poor nutrition and the difficulty of obtaining medical treatment in many rural areas. Life expectancy, at 69 years for men and 74 years for women, is slightly below the average for southern Europe.

CULTURAL LIFE

The government has made a conscious effort to enrich the population's cultural life, and it has particularly encouraged and preserved the nation's rich folk life. There are some 4,300 cultural institutions of various sorts in the country. The National Library, as well as the State Choir and the Opera and Ballet Theatre, are located in Tiranë. Albania's best-known writer is Ismail Kadare, a novelist and poet whose writings have been translated into some 30 foreign languages.

Cultural development in general, however, is handicapped by restrictions on freedom. All means of information and communication are under state ownership, and the authorities impose strict censorship on the press, publications, and the performing arts. The writers' union serves as a supplemental instrument for the implementation of the APL's policies.

The most widely circulated newspapers are *Zëri i Popullit*, the organ of the APL, and *Bashkimi*, published by the Democratic Front. Other important publications are: *Rruga e Partisë* (monthly), an ideological journal; *Ylli* (monthly), a social and literary review; *Studime Politiko-Shoqërore* (quarterly), an academic journal; *Nentori* (monthly) and *Drita* (weekly), both published by the Union of Writers and Artists of Albania; and *Puna* (weekly), the organ of the Central Council of Albanian Trade Unions.

History

ANTIQUITY

The Illyrians. The origins of the Albanian people are not definitely known, but data drawn from history and from linguistic, archaeological, and anthropological studies have led to the conclusion that Albanians are the direct descendants of the ancient Illyrians and that the latter were natives of the lands they inhabited. Similarly, the Albanian language derives from the language of the Illyrians, the transition from Illyrian to Albanian apparently occurring between the 4th and 6th centuries AD. (Some scholars, however, dispute these theses, arguing that Illyrians were not autochthonous and that Albanian derives from a dialect of the now-extinct Thracian language.)

Illyrian culture is believed to have evolved from the Stone Age and to have manifested itself in the territory of Albania toward the beginning of the Bronze Age, about 2000 BC. The Illyrians were not a uniform body of people but a conglomeration of many tribes that inhabited the western part of the Balkans, from what is now the Yugoslav republic of Slovenia in the northwest to (and including) the region of Epirus, which extends about halfway down the

cultures
of the
lowlands
and
highlands

mainland of modern Greece. By the beginning of the Iron Age, about 1000–800 BC, the majority of Illyrian tribes had abandoned migratory life and settled down, mostly as agrarian communities in the plains and as pastoral societies in the highlands. In general, Illyrians in the highlands of Albania were more isolated than those in the lowlands, and their culture evolved more slowly—a distinction that persisted throughout Albania's history.

Authors of antiquity relate that Illyrians were a sociable and hospitable people, renowned for their daring and bravery at war. Illyrian women were fairly equal in status to the men, even to the point of becoming heads of tribal federations. In matters of religion, Illyrians were pagans who believed in an afterlife and buried their dead along with arms and various articles intended for personal use.

The land of Illyria was rich in minerals—iron, copper, gold, silver—and Illyrians became skillful in the mining and processing of metals. They were highly skilled boat builders and sailors as well; indeed, one of their boats, the *Liburna*, was of such superior design that the Romans incorporated it into their own fleet as a type of warship called the Liburnian galley.

The Greeks. From the 8th to the 6th century BC the Greeks founded a string of colonies on Illyrian soil, two of the most prominent of which were Epidamnus (modern Durrës) and Apollonia (near modern Vlora). These colonies carried on a prosperous trade with Illyrian natives and served as channels for Italic trade with southern Illyria. The presence of Greek colonies on their soil brought the Illyrians into contact with a more advanced civilization, which helped them to develop their own culture, while they in turn influenced the economic and political life of the colonies. In the 3rd century BC the colonies began to decline and eventually perished.

Roughly parallel with the rise of Greek colonies, Illyrian tribes began to evolve politically from relatively small and simple entities into larger and more complex ones. At first they formed temporary alliances with one another for defensive or offensive purposes, then federations and, still later, kingdoms. The most important of these kingdoms, which flourished from the 5th to the 2nd century BC, were those of the Enkalayes, the Taulantes, the Epirotes, and the Ardiannes.

After warring for the better part of the 4th century BC against the expansionist Macedonian state of Philip II and Alexander the Great, the Illyrians faced a greater threat from the growing power of the Romans. Seeing Illyrian territory as a bridgehead for conquests east of the Adriatic, in 229 BC Rome attacked and defeated the Illyrians, led by Queen Teuta, and by 168 BC established effective control over Illyria.

The Roman Empire. The Romans ruled Illyria—which now became the province of Illyricum—for about six centuries. Under Roman rule Illyrian society underwent great change, especially in its outward, material aspect. The use of new tools and techniques led to notable advancements in agriculture, the crafts, mining, trade, and construction. Art and culture flourished, particularly in Apollonia, whose school of philosophy became celebrated in antiquity. To a great extent, though, the Illyrians resisted assimilation into Roman culture. Illyrian culture survived, along with the Illyrian tongue, though many Latin words entered the language and later became a part of the Albanian language.

The advent
of Chris-
tianity

Christianity manifested itself in Illyria during Roman rule, about the middle of the 1st century AD. At first the new religion had to compete with a number of Oriental cults—among them that of Mithra, Persian god of light—which had entered the land in the wake of Illyria's growing interaction with eastern regions of the empire. For a long time it also had to compete with scores of gods worshiped by Illyrian pagans. The new faith initially made converts along the coast, then spread into the hinterland. The steady growth of the Christian community in Dyrrachium (the Roman name for Epidamnus) led to the creation there of a bishopric in AD 58. Later, episcopal seats were established in Apollonia, Buthrotum (modern Butrint), and Scodra (modern Shkodër).

By the time the empire began to decline, the Illyrians,

profiting from a long tradition of martial habits and skills, had acquired great influence in the Roman military hierarchy. Indeed, several of them went on from there to become emperors. From the mid-3rd to the mid-4th century AD the reins of the empire were almost continuously in the hands of emperors of Illyrian origin: Gaius Decius, Claudius Gothicus, Aurelian, Probus, Diocletian, and Constantine the Great.

THE BYZANTINE EMPIRE

From Illyria to Albania. When the Roman Empire divided into east and west in 395, the territories of modern Albania became part of the Byzantine Empire. As in the Roman Empire, some Illyrians rose to positions of eminence in the new empire. Three of the emperors who shaped the early history of Byzantium (reigning from 491 to 565) were of Illyrian origin: Anastasius I, Justin I, and—the most celebrated of Byzantine emperors—Justinian I.

In the first decades under Byzantine rule (until 461), Illyria suffered the devastation of raids by Visigoths, Huns, and Ostrogoths. Not long after these barbarian invaders swept through the Balkans, the Slavs appeared. Between the 6th and 8th centuries they settled in Illyrian territories and proceeded to assimilate Illyrian tribes in much of what is now Yugoslavia. The tribes of southern Illyria, however—including modern Albania as well as Kosovo and western Macedonia in Yugoslavia—averted assimilation and preserved their native tongue.

In the course of several centuries, under the impact of Roman, Byzantine, and Slavic cultures, the tribes of southern Illyria underwent a transformation, and a transition occurred from the old Illyrian population to a new one, Albanian. As a consequence, from the 8th to the 11th century, the name Illyria gradually gave way to the name, first mentioned in the 2nd century AD by the geographer Ptolemy of Alexandria, of the Albanoi tribe, which inhabited what is now central Albania. From a single tribe the name spread to include the rest of the country as Arbëri and, finally, Albania. The genesis of the Albanian nationality apparently occurred at this time as the Albanian people became aware that they shared a common territory, name, language, and cultural heritage. (Scholars have not been able to determine the origin of *Shqipëria*, the Albanians' own name for their land, which is believed to have supplanted the name Albania during the 16th and 17th centuries. It probably was derived from *shqipe*, or "eagle," which, modified into *shqipëria*, became "the land of the eagle.")

Long before that event, Christianity had become the established religion in Albania, supplanting pagan polytheism and eclipsing for the most part the humanistic world outlook and institutions inherited from the Greek and Roman civilizations. But, though the country was in the fold of Byzantium, Albanian Christians remained under the jurisdiction of the Roman pope until 732. In that year the iconoclast Byzantine emperor Leo III, angered by Albanian archbishops because they had supported Rome in the Iconoclastic Controversy, detached the Albanian church from the Roman pope and placed it under the patriarch of Constantinople. When the Christian church split in 1054 between the East and Rome, southern Albania retained its tie to Constantinople while northern Albania reverted to the jurisdiction of Rome. This split in the Albanian church marked the first significant religious fragmentation of the country.

Medieval culture. In the latter part of the Middle Ages, Albanian urban society reached a high point of development. Artisans continued the country's tradition of skilled workmanship in metals, gaining esteem as well for their fine silk fabrics and carvings in stone and wood. Foreign commerce flourished to such an extent that leading Albanian merchants had their own agencies in Venice, Ragusa (modern Dubrovnik, Yugos.), and Thessalonica (now Thessaloniki, Greece). The prosperity of the cities also stimulated the development of education and the arts.

Albanian, however, was not the language used in schools, churches, and official government transactions. Instead, Greek and Latin, which had the powerful support of the state and the church, were the official languages of culture

The
genesis of
Albanian
nationality

and literature. In this respect, the country was divided linguistically and culturally, although Albanian was the everyday language of the people.

The new administrative system of the *themes*, or military provinces created by the Byzantine Empire, contributed to the eventual rise of feudalism in Albania, as peasant soldiers who served military lords became serfs on their landed estates. Among the leading families of the Albanian feudal nobility were the Thopias, Balshas, Shpatas, Muzakas, Aranitis, Dukagjinis, and Kastriotis. The first three of these rose to become principalities that were practically independent of Byzantium. In the 14th century, quarrels among the feudal lords as they competed for power and wealth plunged Albania into anarchy, rendering it more vulnerable to foreign intrigue and penetration.

The decline of Byzantium. Owing partly to the weakness of the Byzantine Empire, Albania, beginning in the 9th century, came under the domination, in whole or in part, of a succession of foreign powers: Bulgarians, Norman crusaders, the Angevins of southern Italy, Serbs, and Venetians. The final occupation of the country in 1347 by the Serbs, led by Stefan Dušan, caused massive migrations of Albanians abroad, especially southward to Greece and the Aegean islands. By the mid-14th century, Byzantine rule had come to an end in Albania, after nearly 1,000 years.

A few decades later the country was confronted with a new threat, that of the Turks, who at this juncture were expanding their power in the Balkans. The Ottoman Turks invaded Albania in 1388 and completed the occupation of the country about four decades later (1430). But after 1443 an Albanian of military genius—Gjergj Kastrioti (1405–68), known as Skanderbeg—rallied the Albanian princes and succeeded in driving the occupiers out. For the next 25 years, operating out of his stronghold in the mountain town of Krujë, Skanderbeg frustrated every attempt by the Turks to regain Albania, which they envisioned as a springboard for the invasion of Italy and western Europe. His unequal fight against the mightiest power of the time won the esteem of Europe as well as some support in the form of money and military aid from Naples, the papacy, Venice, and Ragusa. After he died, Albanian resistance gradually collapsed, enabling the Turks to reoccupy the country by 1506.

Skanderbeg's long struggle to keep Albania free became highly significant to the Albanian people, as it strengthened their solidarity, made them more conscious of their national identity, and served later as a great source of inspiration in their struggle for national unity, freedom, and independence.

THE OTTOMAN EMPIRE

The nature of Turkish rule. The Turks established their dominion over Albania just as the Renaissance began to unfold in Europe, so that, cut off from contact and exchanges with western Europe, Albania had no chance to participate in, or benefit from, the humanistic achievements of that era. Conquest also caused great suffering and vast destruction to the country's economy, commerce, art, and culture. Moreover, to escape persecution by their conquerors, about one-fourth of the country's population fled abroad to southern Italy, Sicily, and the Dalmatian coast.

Although the Turks ruled Albania for more than four centuries, they were unable to extend their authority throughout the country. In the highland regions Turkish authorities exercised only a formal sovereignty, as the highlanders refused to pay taxes, serve in the army, or surrender their arms—although they did pay an annual tribute to Istanbul.

Albanians rose in rebellion time and again against Ottoman occupation. In order to check the ravages of Albanian resistance—which was partly motivated by religious feelings, namely, to defend the Christian faith—as well as to bring Albania spiritually closer to Turkey, the Ottomans initiated a systematic drive toward the end of the 16th century to Islāmize the population. This drive continued through the following century, by the end of which two-thirds of the people had converted to Islām. A major reason Albanians became Muslims was to escape

Turkish violence and exploitation, an instance of which was a crushing tax that Christians would have to pay if they refused to convert.

Islāmization aggravated the religious fragmentation of Albanian society, which had first appeared in the Middle Ages and which was later used by Istanbul and Albania's neighbours in attempts to divide and denationalize the Albanian people. Hence, leaders of the Albanian national movement in the 19th century used the rallying cry "The religion of Albanians is Albanianism" in order to overcome religious divisions and foster national consciousness and unity.

The basis of Ottoman rule in Albania was a feudal-military system of landed estates, called *timars*, which were awarded to military lords for loyalty and service to the empire. As Ottoman power began to decline in the 18th century, the central authority of the empire in Albania gave way to the local authority of autonomy-minded lords, and in time, under conditions of instability and lawlessness, more and more power gravitated into the hands of a few of them. The most successful of these lords were three generations of pashas of the Bushati family, who dominated most of northern Albania from 1757 to 1831, and Ali Paşa Tepelenë of Janina (now Ioánnina, Greece), a colourful Oriental-type despot who ruled over southern Albania and northern Greece from 1788 to 1822. These pashas created separate states within the Ottoman state until they were overthrown by the sultan.

After the fall of the pashas, in 1831 Turkey officially abolished the *timar* system. In the wake of its collapse, economic and social power passed from the feudal lords to private landowning beys and, in the northern highlands, to tribal chieftains called *bajraktars*, who presided over given territories with rigid patriarchal societies that were often torn by blood feuds. Peasants who were formerly serfs now worked on the estates of the beys as tenant farmers. The production of goods and commercial life began to be influenced by the market forces of free enterprise, but only minimally and superficially, as Albanian society continued to operate under the legacy of feudalism.

Ottoman rule in Albania remained backward and oppressive to the end. In these circumstances, many Albanians went abroad in search of careers and advancement within the empire, and an unusually large number of them, in proportion to Albania's population, rose to positions of prominence as government and military leaders. More than two dozen grand viziers (similar to prime ministers) of Turkey were of Albanian origin.

Albanian nationalism. By the mid-19th century Turkey was in the throes of the Eastern Question, as the peoples of the Balkans, including Albanians, sought to realize their national aspirations. To defend and promote their national interests, Albanians met in Prizren, a town in Kosovo, in 1878 and founded the Albanian League. The league had two main goals, one political and the other cultural: First, it strove (unsuccessfully) to unify all Albanian territories—at the time divided among the four vilayets, or provinces, of Kosovo, Shkodër, Monastir, and Janina—into one autonomous state within the framework of the Ottoman Empire. Second, it spearheaded a movement to develop Albanian language, literature, education, and culture. In line with the second program, in 1908 Albanian leaders met in the town of Monastir (now Bitola, Yugos.) and adopted a national alphabet. Based mostly on the Latin script, this supplanted several other alphabets, including Arabic and Greek, that were in use until then.

The Albanian League was suppressed by the Turks in 1881, in part because they were alarmed by its strong nationalistic orientation. By then, however, the league had become a powerful symbol of Albania's national awakening, and its ideas and objectives fueled the drive that culminated later in national independence.

When the Young Turks, who seized power in Istanbul in 1908, ignored their commitments to Albanians to institute democratic reforms and grant autonomy, Albanians embarked on an armed struggle, which, at the end of three years (1910–12), forced the Turks to agree, in effect, to grant their demand. Alarmed at the prospect of Albanian autonomy, Albania's Balkan neighbours, who had already

Skanderbeg

Beys and
bajraktars

Declaration of Albanian independence

made plans to partition the region, declared war on Turkey in October 1912, and Greek, Serbian, and Montenegrin armies advanced into Albanian territories.

To prevent the annihilation of the country, Albanian national delegates met at a congress in Vlorë. They were led by Ismail Qemal, an Albanian who had held several high positions in the Ottoman government. On Nov. 28, 1912, the congress issued the Vlorë proclamation, which declared Albania's independence.

INDEPENDENT ALBANIA

Creating the new state. Shortly after the defeat of Turkey by the Balkan allies, a conference of ambassadors of the Great Powers (Britain, Germany, Russia, Austria-Hungary, France, and Italy) convened in London in December 1912 to settle the outstanding issues raised by the conflict. With support given to the Albanians by Austria-Hungary and Italy, the conference agreed to create an independent state of Albania. But, in drawing the borders of the new state, owing to strong pressure from Albania's neighbours, the Great Powers largely ignored demographic realities and ceded the vast region of Kosovo to Serbia, while, in the south, Greece was given the greater part of Çamëria, a part of the old region of Epirus centred on the Thíamis River. As a result, about one-half of Albania's lands and population were left outside its borders. On the other hand, a small community of about 35,000 ethnic Greeks was included within Albania's borders. (Greece, however, which counted all Albanians of the Orthodox faith—20 percent of the population—as Greeks, claimed that the number of ethnic Greeks was considerably larger.) Thereafter, Kosovo and the Greek minority remained troublesome issues in Albanian-Greek and Albanian-Yugoslav relations.

The Great Powers also appointed a German prince, Wilhelm zu Wied, as ruler of Albania, a decision that conformed to the sentiment of those Albanians who wished to align their country with the West. Wilhelm arrived in Albania in March 1914, but his unfamiliarity with Albania and its problems, compounded by complications arising from the outbreak of World War I, led him to depart from Albania six months later. The war plunged the country into a new crisis, as the armies of Austria-Hungary, France, Italy, Greece, Montenegro, and Serbia invaded and occupied it. Left without any political leadership or authority, the country was in chaos, and its very fate hung in the balance. At the Paris Peace Conference after the war, the extinction of Albania was averted largely through the efforts of U.S. President Woodrow Wilson, who vetoed a plan of Britain, France, and Italy to partition Albania among its neighbours.

A national congress held in Lushnje in January 1920 laid the foundations of a new government. In December of that year Albania, this time with the help of Britain, gained admission to the League of Nations, thereby winning for the first time international recognition as a sovereign nation and state. The road ahead nevertheless proved difficult for the new state, mainly because of the Ottoman legacy of backwardness and the vestiges of feudalism in the country.

Bishop Noli and King Zog. At the start of the 1920s, Albanian society was divided by two apparently irreconcilable forces. One, made up mainly of deeply conservative landowning beys and tribal *bajraktars* who were tied to the Ottoman and feudal past, was led by Ahmed Bey Zogu, a chieftain from the Mat region of north-central Albania. The other, made up of liberal intellectuals, democratic politicians, and progressive merchants who looked to the West and wanted to modernize and Westernize Albania, was led by Fan S. Noli, an American-educated bishop of the Orthodox church. In the event, this East-West polarization of Albanian society was of such magnitude and complexity that neither leader could master and overcome it.

In an unusually open and free political, social, and cultural climate that prevailed in Albania between 1920 and 1924, the liberal forces gathered strength, and, by mid-1924, a popular revolt forced Zogu to flee to Yugoslavia. Installed as prime minister of the new government in June 1924, Noli set out to build a Western-style democracy in

Albania, and toward that end he announced a radical program of land reform and modernization. But his vacillation in carrying out the program, coupled with a depleted state treasury and a failure to obtain international recognition for his revolutionary, left-of-centre government, quickly alienated most of Noli's supporters, and six months later he was overthrown by an armed assault led by Zogu and aided by Yugoslavia.

Zogu began his 14-year reign in Albania—first as president (1925–28), then as King Zog I (1928–39)—in a country rife with political and social instability. Greatly in need of foreign aid and credit in order to stabilize the country, Zog signed a number of accords with Italy. These provided transitory financial relief to Albania, but they effected no basic change in its economy, especially under the conditions of the Great Depression of the 1930s. Italy, on the other hand, viewed Albania primarily as a bridgehead for military expansion into the Balkans. To this end, Benito Mussolini applied pressure on Zog to the point where Albania lost control over its own affairs. On April 7, 1939, Italy invaded and shortly after occupied the country. King Zog fled to Greece.

The social base of Zog's power was a coalition of southern beys and northern *bajraktars*. With the support of this coalition, plus a vast Oriental bureaucracy, an efficient police force, and Italian money, King Zog brought a large measure of stability to Albania. He extended the authority of the government to the highlands, reduced the brigandage that had formerly plagued the country, laid the foundations of a modern educational system, and took a few steps to Westernize Albanian social life. On balance, however, his achievements were outweighed by his failures. Although formally a constitutional monarch, in reality Zog was a dictator, and Albania under him experienced the fragile stability of a dictatorship. Zog failed to resolve Albania's fundamental problem, that of land reform, leaving the peasantry as impoverished as before. Moreover, he denied democratic freedoms to Albanians and created conditions that spawned periodic revolts against his regime, alienated most of the educated class, fomented labour unrest, and led to the formation of the first communist groups in the country.

World War II. Using Albania as a military base, in October 1940, Italian forces invaded Greece, but they were quickly thrown back into Albania. After Nazi Germany defeated Greece and Yugoslavia in 1941, the regions of Kosovo and Çamëria were joined to Albania, thus creating an ethnically united Albanian state. The new state lasted until November 1944, when the Germans—who had replaced the Italian occupation forces following Italy's surrender in 1943—withdrew from Albania. Kosovo was then reincorporated into Yugoslavia, and Çamëria into Greece.

Meanwhile, the various communist groups, which had germinated in Zog's Albania, merged in November 1941 to form the Albanian Communist Party and began to fight the occupiers as a unified resistance force. After a successful struggle against the fascists and two other resistance groups, the National Front (Balli Kombëtar) and the pro-Zog Legality Party (Legaliteti), which contended for power with them, the communists seized control of the country on Nov. 29, 1944. Enver Hoxha, a college instructor who had led the resistance struggle of communist forces, became the leader of Albania by virtue of his post as secretary general of the party. Albania, which before the war had been under the personal dictatorship of King Zog, now fell under the collective dictatorship of the Albanian Communist Party. The country became officially the People's Republic of Albania in 1946 and, in 1976, the People's Socialist Republic of Albania.

Socialist Albania. The new rulers inherited an Albania plagued by a host of ills: pervasive poverty, overwhelming illiteracy, blood feuds, epidemics of disease, gross subjugation of women. In order to eradicate these ills, the communists drafted a radical modernization program intended to bring social and economic liberation to Albania, thus completing the political liberation won in 1912. The government's first major act to "build socialism" was a swift, uncompromising agrarian reform, which broke up

Liberal experiment under Fan Noli

The Albanian Communist Party

the large landed estates of the beys and distributed the parcels to landless and other peasants. This destroyed the powerful class of the beys. The government also moved to nationalize industry, banks, and all commercial and foreign properties.

In order to obtain the economic aid needed for modernization, as well as the political and military support to enhance its security, Albania turned to the communist world. Over the next three decades, Hoxha formed a succession of alliances with socialist countries: Yugoslavia (1944–48), the Soviet Union (1948–61), and China (1961–78). Economically, Albania benefited greatly from these alliances: with hundreds of millions of dollars in aid and credits, and with the assistance of a large number of technicians and specialists sent by its allies, Albania was able to build the foundations of a modern industry. Politically, however, it was disillusioned each time. Hoxha broke with Yugoslavia when Soviet premier Josef Stalin expelled that country from the Soviet bloc, with the Soviet Union when Nikita Khrushchev demanded that Albania accept without question the ideological and political authority of Moscow, and with China following Peking's rapprochement with the United States and Yugoslavia after the death of Mao Zedong. Alone among eastern European leaders, Hoxha professed continued loyalty to Stalinism, and at each break he denounced his former allies as revisionists of truly revolutionary socialism. After breaking with China, he adopted a "go-it-alone" road for Albania; thereafter, the country was isolated ideologically and avoided participation in multilateral organizations or endeavours such as the Warsaw Pact military alliance and the Conference on Security and Cooperation in Europe. Nevertheless, Albania maintained normal diplomatic, economic, and cultural relations with scores of countries.

Social
changes
under
communist
rule

Shortly after the agrarian reform, the Albanian government started to collectivize agriculture, completing the job in 1967. As a result, peasants lost title to their land, but the change enabled Albania to become practically self-sufficient in the production of food crops, solving the chronic problem of hunger. The Hoxha leadership also extended the new socialist order to the northern highlands, bringing down the age-old institution of the blood feud and the patriarchal structure of the family and clans, thus destroying the semifeudal class of *bajraktars*. The traditional role of women—namely, confinement to the home and farm—changed radically as they gained legal equality with men and became active participants in all areas of society. In 1967 the religious establishment, which party leaders and other atheistic Albanians viewed as a backward medieval institution that hampered national unity and progress, was officially banned, and all Christian and Muslim houses of worship were closed.

Albania's extremist foreign policy and radical domestic policy for modernization met with resistance at each step along the way from those who questioned the wisdom of these policies and from others whose interests suffered directly from the changes and dislocations that occurred. To eliminate dissent, the government resorted periodically to purges, in which opponents in the party hierarchy, the military, the intellectual community, and other segments of society were subjected to public criticism, dismissed from their jobs, imprisoned in forced-labour camps, or executed. Travel abroad was forbidden to all but those on official business, artists and intellectuals were required to infuse their works with a zeal for socialism and nationalism, and, in almost all aspects of its daily life, the Albanian populace was watched over by agents of the Directorate of State Security, known as the Sigurimi.

Hoxha's program for modernization aimed at transforming Albania from a backward agrarian country into a modern industrial society, and indeed, within four decades, Albania had made respectable—in some cases historic—strides in the development of industry, agriculture, education, the arts, and culture. The standard of living improved

to the point where chronic poverty, like chronic hunger, disappeared. Likewise, illiteracy and epidemics were relegated to the past, as education and health care became available to all citizens at almost no cost. Nevertheless, the per capita income of Albania remained low compared to the rest of Europe.

When Enver Hoxha died in 1985, his handpicked successor, Ramiz Alia, took over as leader of Albania. Unlike the doctrinaire and orthodox Hoxha, Alia was a less dictatorial pragmatist who somewhat loosened Hoxha's controls over Albanian society. Moreover, Albania began to participate in multilateral conferences of Balkan countries, and it expanded its network of diplomatic ties to include nearly every nation of Europe. This broadening of contacts was the continuation of a process begun under Hoxha, but it also reflected new forces at work. Among these were stronger pressures by a younger generation of Albanians to open up to the outside, a need to strengthen the economy through greater commercial exchange with other countries, and the example of such regional endeavours as the European Economic Community as a means of achieving prosperity and security through cooperation and understanding rather than the animosities and conflicts of the past. (P.R.P.)

For later developments in the history of Albania, see the *Britannica Book of the Year* section in the BRITANNICA WORLD DATA ANNUAL.

For coverage of related topics in the *Macropædia* and *Micropædia*, see the *Propædia*, sections 912, 921, 924, 961, 962, 963, and 972, and the *Index*.

BIBLIOGRAPHY

Physical and human geography: A most useful guide and encyclopaedic reference source is *Fjalori enciklopedik shqiptar* (1985), published by the Academy of Sciences of the People's Socialist Republic of Albania, covering diverse subjects and providing information from ancient times up to the mid-1980s. *Albania: General Information* (1984), which was prepared by the editorial board of the magazine *New Albania*, provides basic information on such subjects as government, party, administration, institutions, economy, social services, and foreign policy. *40 Years of Socialist Albania: Statistical Data on the Development of the Economy and Culture* (1984), is a useful reference work, prepared by the Directory of Statistics at the State Planning Commission, that gives figures, facts, and data on Albania's development since 1945. ADI SCHNYTZER, *Stalinist Economic Strategy in Practice: The Case of Albania* (1982), provides an excellent review of Albanian economic development under communist rule. WILLIAM E. GRIFFITH, *Albania and the Sino-Soviet Rift* (1963), is an excellent overview of Tiranë's break with Moscow and subsequent alliance with Peking. ELEZ BIBERAJ, *Albania and China: A Study of an Unequal Alliance* (1986), analyzes the formation, development, and disintegration of the Albanian-Chinese alliance, based on primary sources from Albania, while his *Albania: The Socialist Maverick* (1990), gives an overview of Albania from 1945 to 1990, focusing on trends in Albanian politics, economics, and diplomacy during the 1980s. (E.B.)

History: Despite the Marxist bias of its theoretical premises, the standard work on the history of Albania is STEFANAQ POLLO *et al.*, *Historia e Shqipërisë*, rev. and expanded ed. (1983–), with 3 vol. published by 1989. KRISTO FRASHËRI, *The History of Albania* (1964), is a rather short but informative book, useful as an introduction. RAMADAN MARMULLAKU, *Albania and the Albanians*, trans. from Serbo-Croatian (1975), by an ethnic Albanian in Yugoslavia, includes a chapter on the Albanian minority in that country. STAVRO SKENDI, *The Albanian National Awakening, 1878–1912* (1967), provides a comprehensive study of the rise and development of Albanian nationalism. BERND JÜRGEN FISCHER, *King Zog and the Struggle for Stability in Albania* (1984), is an absorbing account of Albania between the world wars, although it suffers from some inconsistencies. ANTON LOGORECI, *The Albanians: Europe's Forgotten Survivors* (1977), is mostly about postwar Albania and strongly critical of the government. PETER R. PRIFTI, *Socialist Albania Since 1944: Domestic and Foreign Developments* (1978), is especially useful for readers who are mainly interested in domestic developments in postwar Albania. NICHOLAS C. PANO, *The People's Republic of Albania* (1968), is a pioneer work on socialist Albania, with the accent on foreign affairs. (P.R.P.)

Alcohol and Drug Consumption

Human beings have been experimenting for thousands of years with a variety of naturally occurring substances that act on nervous tissues: alcohol to intoxicate a weary mind, belladonna to calm an angry intestine or to poison an adversary, opium to overcome worry and strain. The relief of pain, in particular, is an age-old aim of humankind, and various narcotic and sleep-producing agents were probably used by primitive people. But for many human beings there is another kind of pain—the pain of being—and from time immemorial some people have been trying to expand their vision, enhance their appreciation of their world, change their mood, alter their inner existence, or stupefy their awareness with the use of such drugs as alcohol, opium, and cannabis.

It is written in Genesis (9:20) that Noah planted a vine-

yard, “and he drank of the wine, and became drunk, and lay uncovered in his tent.” Alcohol has been used by many cultures and has been worshipped as a god. Opium has also been used extensively, at least since the time of ancient Greece. Homer tells how some of Odysseus’ crew succumbed to forgetfulness in the land of the Lotus-eaters, and the ancient Vedic philosophers of India spoke of soma, a mysterious and probably mythical plant. Coca, coffee, and tobacco have also played their parts in history.

ALCOHOL

People do not usually drink pure alcohol but a beverage containing alcohol, specifically ethyl alcohol. This article deals with most aspects of such drinking, from the chemical and the physiological to the medical and social.

Alcoholic beverages include wines, beers, and spirits. Wines are fermented from the sugars in fruits or berries (most commonly grapes), from various plants or their saps, from honey, and even from milk. Beers are fermented from grains after the starch in them is first converted to sugar. Spirits are distilled from wines or beers (see BEVERAGE PRODUCTION). The alcohol in all these beverages is ethyl alcohol, or ethanol ($\text{CH}_3\text{CH}_2\text{OH}$). Extremely small amounts of other alcohols, such as amyl, butyl, propyl, and methyl alcohol, also occur in alcoholic beverages,

along with other so-called congeners that include acids, aldehydes, esters, ketones, phenols, and tannins; there are also numerous inorganic substances, including vitamins and minerals. Some of these ingredients are derived from primary plant materials; some are produced during the fermentation process and may be reduced by purification; and some are introduced during the aging process—for example, by continuous contact with containers such as wooden barrels. The combinations and exact amounts of congeners vary with the type of beverage, ranging from as few as 33 milligrams per litre in vodka, which is purified diluted alcohol, to averages of 500 milligrams per litre in some whiskies and as many as 2,600 milligrams per litre in specially aged whiskies or brandies. Congeners contrib-

ute special characteristics of taste, aroma, and colour to the beverages. Some have nutrient and medicinal effects. Some, in spite of their small quantity, slow the rate at which the body disposes of ethyl alcohol and may have toxic effects if very large amounts of alcoholic beverages are consumed. But the main ingredient that characterizes alcoholic beverages and the chief contributor of the effects sought by people who drink them is ethyl alcohol (hereafter referred to simply as alcohol).

In beers the alcohol content varies from about 2 percent in some mild Scandinavian varieties to about 8 percent in especially strong types; most U.S. beers contain between 4 and 5 percent. Natural or unfortified wines (the so-called dry wines, such as burgundy, chianti, and sauterne) usually contain between 8 and 12 percent alcohol, although most U.S. varieties have a somewhat higher content, ranging from 12 to 14 percent. Vermouths and aperitif wines usually contain 18 percent, and dessert, sweet, and cocktail wines (such as sherry, port, and muscatel) contain 20 to 21 percent. These percentages are by volume; *i.e.*, the proportion of alcohol in the fluid volume of an average American beer is 4.5 percent. Since fermentation yields only 14 percent alcohol, the extra strength of fortified wines comes from the addition of alcohol or brandy. Spirits, including vodka, gin, and whiskies (rye, Scotch, bourbon), rum (distilled from sugarcane or molasses), brandies (distilled from fruit wines), and liqueurs (flavoured syrupy spirits) usually contain between 40 and 50 percent alcohol. Cordials, made of flavoured spirits, such as anisette, blackberry, curaçao, maraschino, and sloe gin, usually contain between 25 and 40 percent. The Asiatic beverage kumiss (made from mare's milk) and the Russian kvass rarely contain more than 2 percent alcohol.

Physiological and psychological effects of alcohol

WHAT THE BODY DOES WITH ALCOHOL

When an alcoholic beverage is swallowed, it is diluted by the stomach juices—it may first undergo some dilution in the mouth—and very quickly distributed throughout the body. Alcohol does not require digestion before its absorption into the bloodstream. A small portion is diffused into the bloodstream directly from the stomach wall. Most of the alcohol passes through the pyloric junction into the small intestine, where it is very rapidly absorbed and circulated. The rate of absorption will vary according to the particular beverage and the state of the individual consumer's stomach. A strong alcohol solution, when taken into an empty stomach, may cause a spasm of the pylorus that will impede its passage into the small intestine, resulting in a slower rate of absorption. The presence of food in the stomach, especially some fatty foods, will delay absorption. On the other hand, alcohol taken together with carbonated beverages will ordinarily be absorbed more rapidly. Other factors, such as the emotional state of the drinker, may also affect the rate of absorption. Probably cocktails and highballs, many of which contain carbonated water or other beverage, provide the most rapidly absorbed forms of alcoholic beverage that people consume.

Alcohol is diffused in the body in proportion to the water content of the various tissues and organs, appearing in greater concentration in the blood and brain than in fat or muscle tissue. The absorbed alcohol is greatly diluted by the body fluids. Thus, the alcohol in an ounce (29.57 millilitres) of whiskey at 50 percent strength (100 U.S. proof, 87.6 British proof) will be diluted, in a man of average build, to a concentration of about 2 parts per 10,000 in the blood (0.02 percent). In a larger person the blood alcohol concentration will be proportionately smaller; and, in a smaller person, of course, the concentration will be proportionately greater.

The importance of the rate of absorption, distribution, and dilution of alcohol in the body lies in their relation to the achieved alcohol concentration in various organs, particularly the brain. After rapid intake of a large amount of alcohol that is quickly absorbed, a relatively early "high," or sensation of intoxication will occur. Figure 1 shows a set of probable average curves of blood alcohol concen-

trations in an average-size man after rapid absorption of various amounts of alcohol. It shows also the average rate of decline of the blood alcohol concentration over time as a result of the disposal of the alcohol by the body through the processes of metabolism (oxidation) and excretion.

The body begins to dispose of alcohol immediately after it has been absorbed. An insignificantly small proportion of alcohol is exhaled through the lungs, and a tiny amount is excreted in sweat. A small proportion is secreted by the kidneys and will be accumulated and retained in the bladder until eliminated in the urine. Only between 2 and 10 percent of the alcohol is eliminated by these means. The remainder, 90 percent or more of the absorbed alco-

Figure 1: Percent of blood alcohol concentration in an average man at hourly intervals after drinking one, two, four, or six ounces of spirits containing 50 percent alcohol.

hol, is disposed of by metabolic processes, mainly in the liver. Other organs are capable of metabolizing only small amounts of alcohol.

As absorbed alcohol is passed through the liver by the circulating blood, it is acted upon by ADH (alcohol dehydrogenase), a zinc-containing enzyme found chiefly in the liver cells. The alcohol molecule is converted by this action to acetaldehyde, itself a highly toxic substance, but this is immediately acted upon by another enzyme, aldehyde dehydrogenase, and converted to acetate, most of which enters the bloodstream and is ultimately oxidized to carbon dioxide and water. Considerable utilizable energy—7.1 calories from each gram of alcohol (about 200 calories per ounce)—is made available to the organism during these processes, and in this sense alcohol serves as a nutrient.

The two enzymatic reactions—that of ADH and aldehyde dehydrogenase—require a co-enzyme, NAD (nicotinamide adenine dinucleotide), the acceptor of hydrogen from the alcohol molecule, for their effects. The NAD is thus changed to NADH and becomes available again for the same reaction only after its own further oxidation. While adequate ADH seems always present for the first step of alcohol metabolism, the temporary reduction of the available NAD apparently acts as a limit on the rate at which alcohol can be metabolized. That rate is about half an ounce of alcohol (equal to about an ounce of spirits, a 12-ounce bottle of beer, a four-ounce glass of dry wine, or a 2.5-ounce glass of fortified wine) per hour in an average-size man.

The limit on the rate at which the body can dispose of alcohol results in its accumulation in the organism if drinking proceeds at a faster rate than the alcohol is metabolized. The average-size man who drinks and absorbs four ounces of whiskey (at 50 percent alcohol) rapidly will have 1½ ounces of alcohol in his body at the end of an hour and a blood alcohol concentration near to 0.07 percent (Figure 1). If he drinks eight ounces within two hours, he will have a blood alcohol concentration of about 0.11 percent. The continued accumulation of alcohol in the organism faster than it can be metabolized leads to increas-

Absorption and distribution

How alcohol is metabolized

ing degrees of intoxication. This is illustrated in Figure 2, Curve A, which shows what happens if an average man drinks two ounces of spirits each hour for four hours. At the end of the first hour, the blood alcohol concentration has passed its peak and begun to decline, but with the next drink the concentration starts rising again; this is repeated after each drink. Only at the end of four hours—an hour after the last drink—is the highest blood alcohol concentration reached; and, with no more drinking, it declines steadily thereafter. Curve A thus illustrates the combined effects of repeated alcohol absorption and its continuous metabolism. Curve B in Figure 2 shows what the course of blood alcohol concentration would be if the eight ounces of spirits were drunk and absorbed all at once.

Figure 2: Percent of blood alcohol concentration in an average man at hourly intervals after drinking two ounces of spirits each hour for four hours (curve A) and eight ounces all at once (curve B).

INTOXICATION

The drinking of small amounts of alcohol, even if this is done regularly over a long period of time, does not have any conclusively demonstrated pathological effect. A mild infrequent intoxication produces a variety of temporary biochemical disturbances in the body: the adrenal glands may discharge hormones, sugar may be mobilized from stores in the liver, the electrolyte balance may be slightly upset, the metabolism and equilibrium of the liver may be disturbed. But these changes leave no chronic aftereffects, and the body rapidly returns to normal. A severe intoxication, on the other hand, may produce more serious disturbances, including temporary extensive imbalance in the body chemistry, an acute hepatitis and numerous "hang-over" effects: nausea, headache, gastritis, thirst because of the shift of water from cellular to extracellular spaces, and a generalized residual malaise and physical and mental incompetence that may last as long as 24 hours after all the alcohol consumed has been metabolized. Some drinkers are satisfied to suffer the mild and even the severer aftereffects of occasional intoxication for the sake of the temporary dissociation, euphoria, or socialization that the drinking allows. But frequent intoxication, even of moderate degree, imposes a severe and debilitating burden on the organism.

The irritating effects of alcohol, especially in undiluted strong beverages, can result in damage to the tissues of the mouth, esophagus, and stomach, perhaps with increased susceptibility to cancer. The liver is likely to suffer serious damage if it must cope lengthily with the detoxication of large amounts of alcohol. There may also be damage to the heart muscle.

Frequent heavy drinking to severe degrees of intoxication or the prolonged steady maintenance of a high alcohol concentration in the organism has been shown to be linked to many impairments or injuries of many organs. The most common linkage is with diseases caused by defects of nutrition.

Effects on the brain. Alcohol as a drug affecting the

central nervous system belongs in a class with the barbiturates, minor tranquillizers, and general anesthetics and is commonly classified as a depressant. Its effect on the brain is rather biphasic: at quite low concentrations it can serve as an excitant or stimulant of some functions, but, as the concentration increases, the effect is constantly more depressant, going on to sedation, stupor, and coma. The excitement phase exhibits the well-known signs of exhilaration, loss of socially expected restraints, loquaciousness, unexpected changes of mood, and occasionally uncontrolled emotional displays. This excitement phase may result from an indirect effect of alcohol in suppressing the function of inhibitory brain centres rather than from a direct stimulation of the manifest behaviour. The physical counterparts of this state of relatively mild intoxication are slurred speech, unsteady gait, disturbed sensory perceptions, and inability to make fine discriminations. These effects are produced not by the direct action of alcohol on the misbehaving muscles and senses but by its effect on the brain centres that control their activity.

Because brain alcohol concentrations can rarely be measured in people, blood alcohol concentrations are used as the standard against which performances are compared. Most people exhibit some degree of functional depression or incapacitation at blood alcohol concentrations of 0.10 percent. Inefficiency in performing some tasks may begin at much lower concentrations, even at 0.03 percent. The majority of drinkers begin to show measurable impairment at just above 0.05 percent, and most people are considered intoxicated at 0.15 percent. In determining the intoxication of automobile drivers, most jurisdictions in Western countries use a blood alcohol concentration of 0.15 percent as the criterion; in some, a presumption of impairment is made at the much lower concentrations of 0.10, 0.08, or 0.05 percent.

The impairments at these concentrations may not be manifested superficially by all individuals, but laboratory tests show diminished alertness, visual acuity, and capacity to distinguish between signals. Reflex responses and the time of reaction to a signal, as well as neuromuscular functions, are slowed. Complex reactions, those that require the brain to process more than one type of incoming information simultaneously, are impaired at blood alcohol concentrations too low to affect simple reflexes and reaction times.

The most important immediate actions of alcohol are on the highest functions of the brain—those of thinking, learning, remembering, and making judgments. The biphasic action of alcohol is evident in its effect on thinking. One group of experiments revealed that at low blood alcohol concentrations, after the equivalent of two drinks (two ounces of spirits), well-trained and highly intelligent young men performed better at solving problems in symbolic logic than they had without alcohol. At medium concentrations, the equivalent of four drinks, their performance was about normal. But, at concentrations equivalent to six drinks, their ability to solve such problems definitely deteriorated. Similar effects were observed in tests of memorizing. More recent experiments indicate the dependence of learning on the state in which it occurs:—*i.e.*, what is learned under the influence of alcohol is better recalled under the influence of alcohol than when sober, but what is learned in the sober state is better recalled when sober. The function of judgment is difficult to define; when evaluated by such a task as willingness to drive a bus through a more or less adequate gateway, judgment progressively deteriorates with increasing blood alcohol concentrations; when evaluated by willingness to take risks, as shown in responses to hypothetical problem situations, the results are similar, although more so in younger than in older people.

As blood alcohol concentrations continue to rise above 0.15 percent, intoxication steadily increases. Well-adapted, very heavy drinkers may continue to function fairly well in some motor and mental tasks even up to concentrations of 0.3 percent, but most people will appear visibly drunk, manifesting the common symptoms of slurred speech, unsteadiness of gait, and confusion of thinking long before this level is reached. At 0.4 percent most people will be

Effects on
mental
processes

eneral
fects of
itoxica-
on

anesthetized to the extent that they will be asleep, difficult to arouse, incapable of voluntary activity—indeed, in a state in which they could undergo surgery. At higher blood alcohol levels, deep coma sets in, and, if the intoxicated person is long unattended, death may ensue by accidental stoppage of the breathing passages. Between 0.5 and 1 percent the breathing centre in the brain or the action of the heart may be anesthetized, and then death directly from alcohol intoxication will quickly follow. Ordinarily, the achievement of blood alcohol concentrations above 0.4 percent by drinking is unlikely; in a man of average build it would require the ingestion and absorption, unmetabolized, of almost a fifth of a gallon of spirits (0.757 litre) at 50 percent alcohol.

Effects on emotional behaviour. People ordinarily drink alcohol to obtain effects that they have been taught to expect. Small amounts are drunk in the expectation of reducing feelings of tension, relieving feelings of anxiety, and, conversely, obtaining feelings of gaiety and exhilaration. A sufficient amount of alcohol will usually serve the desired purpose. It is likely, however, that alcohol itself is not solely responsible: the state of expectation combines with the pharmacological action of the drug to produce the desired effect. In favourable circumstances, alcohol will not merely reduce tension and anxiety but suppress them entirely, even allowing a shift of the emotional state to one of indifference or euphoria or elation. The anxiety-suppressing action of alcohol is commonly seen in the gradual removal of social inhibitions. Shy people become outgoing or bold; well-behaved people become disorderly; the sexually repressed become amorous; the fearful become brave; the quiescent or peaceful become verbally or physically aggressive. All these reactions may be the result of the stimulating effect of small amounts of alcohol or the control-anesthetizing (disinhibiting) effects of larger amounts. But they are, in part, also made possible by the social and cultural permissiveness typical of drinking situations. Alcohol is not only a psychoactive but a socioactive drug. These effects apparently occur in most normal drinkers; in alcoholics, the consumption of huge quantities apparently evokes different states of feeling and even an increase of anxiety or tension.

Alcohol
and thera-
peutics

Alcohol is often used for medicinal and therapeutic purposes. Whiskey is popular for treating colds and snakebites, brandy for treating faintness, wine for blood building, beer for lactation, and any alcoholic beverage for treating sleeplessness or overexcitement. Many of these uses survive from folk medicine of many cultures. Alcohol is administered by physicians in hospitals, usually by vein, sometimes for anesthesia before minor surgery; more often it is given for sedation after surgery and as a source of easily absorbed calories when it is desirable to bypass the patient's digestive system. Physicians often prescribe "a drink" for a variety of purposes: to stimulate a sluggish appetite, as a sedative to induce sleep, as an anxiolytic in premenstrual tension in women, as a vasodilator (an agent used to widen the lumen of the blood vessels) in arteriosclerosis, to relieve the vague aches and pains that beset the elderly, and as a supplement in special diets.

Direct effects on organs. After being considerably diluted upon absorption into the bloodstream, alcohol reaches the body organs in extremely small concentrations. A pint (0.473 litre) of whiskey (at 50 percent alcohol), fully absorbed and not metabolized, will produce in a man of average build and weight a concentration of about 0.32 percent in the blood. The concentration in any organ is likely to be less. Concentrations of 1 percent are hardly sufficient to irritate the most delicate tissue. Even with very heavy continuous drinking, a post-absorptive concentration above 0.5 percent in any organ is extremely unlikely. Such small alcohol concentrations cannot be expected to inflict direct damage on the liver, the kidneys, the generative organs, the heart, or the brain, though they may cause temporary derangements of biochemistry and function. A concentration of 0.5 percent in the brain will cause coma and may be lethal. Most of the damage to these and other organs in long-time heavy drinkers consists apparently of side effects related to disturbances of metabolism or to malnutrition and poor hygiene. Some experimental work

has suggested that alcohol has a directly adverse effect on the liver and on muscle tissue, and clinical observations have suggested a direct chronic pathological effect on the heart muscle. But the manner in which alcohol produces such direct damages is still unexplained.

The acute diseases. Excessive users of alcohol have been shown to suffer in varying degrees from both acute and chronic diseases. The acute diseases include, first of all, intoxication, with its wide variety of disturbances of neuromuscular and mental functions and of body chemistry. In addition, the intoxicated person is abnormally liable to accidents and injuries. Those who experience severe intoxication chronically, the alcoholics, are said to be seven times as liable to fatal accidents as persons in the general population. They are 30 times more liable to fatal poisoning, 16 times more liable to death from a fall, and 4.5 times more liable to death in a motor-vehicle accident. These liabilities obviously reflect not only the disablements of immediate intoxication but the whole life-style and state of alcoholics.

Another range of diseases associated with intoxication are those that occur in the post-intoxication state, the alcohol-withdrawal syndromes. The commonest and least debilitating of these syndromes is the hangover. After a prolonged bout of drunkenness, however, severe withdrawal phenomena often supervene, consisting of tremulousness, loss of appetite, inability to retain food, sweating, restlessness, sleep disturbances, sometimes epileptiform seizures, and abnormal changes in body chemistry, especially in the electrolyte balance.

With-
drawal
syndromes

In extreme cases of alcohol withdrawal syndrome, delirium tremens will develop. Delirium tremens involves a gross trembling of the whole body, sometimes with seizures, mental clouding, disorientation, and hallucinations both visual and auditory. Depending on the amount and quality of care and treatment, as well as the possible occurrence of intercurrent diseases, delirium tremens lasts from three to 10 days, with a reported fatality rate ranging from 1 to 20 percent. Acute alcoholic hallucinosis may develop with or without preceding delirium tremens and may last days to weeks. Other brain disorders that may follow a prolonged bout include Wernicke's disease, resulting from an acute complete deficiency of thiamine (vitamin B₁) and marked by clouding of consciousness and paralysis of the optic nerves; the acute form of Korsakoff's syndrome, marked by loss of recent memory, with a tendency to make up for the defect by confabulation; and Jolliffe's encephalopathy, resulting from an acute complete deficiency of nicotinic acid and marked by delirium, together with rigidities of the extremities and sucking and grasping reflexes.

Early signs of polyneuropathy, a degenerative disease of the peripheral nerves, include tenderness of calf muscles, diminished tendon reflexes, and loss of vibratory sensation. Acute hepatitis (inflammation of the liver) is common. Less often seen are severe pancreatitis and Zieve's syndrome, the latter being a combination of jaundice with hemolytic anemia, hyperlipemia, and hepatic tenderness. Numerous other disturbances, for example, severe muscle cramps and defects in nerve conduction, are occasionally observed.

The disorders of the brain and nervous system and possibly many of the symptoms in the other acute consequences of alcoholism are caused largely by dietary deficiencies. Alcohol provides large numbers of calories, but they are empty calories—such as those of refined sugar—devoid of vitamins and other essential microelements of nutrition, including minerals and amino acids. The small amounts of vitamins and minerals present in beers and wines—rarely in spirits—are insufficient for dietary needs. In heavy bouts of drinking, alcoholics neglect normal eating or, because of digestive difficulties, cannot absorb enough of the essential food elements. These nutritional defects are the cause of many of the chronic diseases associated with alcoholism.

Another acute disorder associated with alcohol is sometimes misnamed pathological intoxication in which, after downing a small amount of drink, a person suddenly breaks into a maniacal fury, smashing furniture and attacking people. The seizure ends as suddenly as it began,

and the victim usually falls into a stuporous sleep, from which he awakens after some hours—usually without memory of the events. The cause is uncertain; personality factors combined with a temporary deficiency of blood sugar have been suspected.

degenerative
diseases

The chronic diseases. In long-lasting alcoholism, one or more of the chronic nutritional deficiency diseases may develop. The severer effects of vitamin B₁ deficiency are probably commonest—degeneration of the peripheral nerves, with permanent damage in extreme cases, and beriberi heart disease; another common disease is pellagra, due chiefly to deficiency of nicotinic acid. Other diseases include scurvy, resulting from ascorbic acid deficiency; hypochromic microcytic anemia, caused by iron deficiency; and anemia resulting from vitamin B₁₂ deficiency. Severe open sores on the skin of alcoholic derelicts whose usual drink is the cheapest form of alcohol—low-quality fortified wines—are sometimes misnamed wine sores, but they result from a combination of multiple nutritional deficiencies and poor hygiene.

The classical disease associated with alcoholism is cirrhosis of the liver (Laënnec's type), frequently preceded by a fatty enlargement of the organ. The exact mechanism by which this cirrhosis develops is still unclear; it appears to involve the consequences both of the metabolism of excessive amounts of alcohol and of defective nutrition. In its severest form, Laënnec's cirrhosis is often fatal; its successful treatment or the retardation of its progress is impossible in an alcoholic who cannot be stopped from drinking.

Besides the mental symptoms that may accompany pellagra, other mental disorders that are more specifically related to the consumption of alcohol include chronic hallucinations and Korsakoff's psychosis, which may last months to years. A relatively uncommon chronic brain disorder is Marchiafava-Bignami's disease; because the symptoms are not specific, this degeneration of the corpus callosum in the brain is usually diagnosed only at autopsy. Other brain damage occasionally reported in alcoholism includes cortical laminar sclerosis, cerebellar degeneration, central pontine myelinolysis, and enlargement of the ventricles as a result of atrophy of brain substance. Alcoholics, especially older ones, frequently show signs of neurological defect and impaired brain function, and these are sometimes blamed on direct damage to the central nervous system by alcohol; it is possible, however, that they are the result of brain damage caused by accidents and blows. Many of those who survive long years of alcoholism show a generalized deterioration involving the brain, muscles, endocrine system, and vital organs, giving an impression of premature old age. Alcoholics die more frequently in all types of accidents and from numerous diseases; their average life span is reduced by about 10 or 12 years.

(M.Ke.)

Fetal alcohol syndrome. The effect that the problem drinker or alcoholic has on others may be generational. There is evidence that habitual or even occasional drinking by an expectant mother can endanger the health of the fetus. Studies have indicated that babies of heavy drinkers may be small in terms of length and weigh less than other babies. The babies may have a high incidence of small heads, defective joints in their hands and feet, cleft palates, and heart abnormalities. Researchers studying such infants have termed their abnormalities "fetal alcohol syndrome." Some babies may be so severely affected that they die after birth; and, when their brains are studied, they are found to be poorly developed; some portions may actually be missing. The infants that survive may show impaired intellectual development as well as decreased ability to use certain muscles. It is believed that fetal alcohol syndrome is not a rare occurrence. It may exist in many degrees of severity, but its most common manifestation is mental impairment.

Opinion is varied in regard to what a pregnant woman should do about the use of alcohol. Some scientists feel that it should be totally avoided because of the possibility that the fetus may be affected by even very low or infrequent doses; others feel that one or two drinks a day may be safe.

(Ed.)

Social conditions of alcohol consumption

HISTORY OF THE USE OF ALCOHOL

In early societies. The origin of alcoholic beverages is lost in the mists of prehistory. Fermentation can occur in any sugar-containing mishmash, such as one of grapes, fruits, berries, or honey, if left exposed in a warm atmosphere. Airborne yeasts will act on the sugar, converting it to alcohol and carbon dioxide. This is the process of fermentation. Alcoholic beverages were thus probably discovered accidentally in the pre-agricultural gathering stage. Early man presumably liked the effects, if not the taste, and proceeded to purposeful production; from merely gathering the wild-growing raw materials, he went on to regular cultivation of the vine and other suitable crops. Few preliterate people did not learn to convert some of the fruit of the earth into alcohol. In the case of starchy vegetation, quite primitive agriculturists learned how to convert the starch to fermentable sugar by providing the necessary zymase from their saliva through such a simple process as preliminary mastication.

The making of wines and beers has been reported from several hundred preliterate societies. Their importance is evident in the multiplicity of customs and regulations that developed around their production and uses. They often became central in the most valued personal and social ceremonies, especially in the rites of passage, and are ubiquitous in such activities as births, initiations, marriages, compacts, feasts, conclaves, crownings, magic, medicine, worship, hospitality, war making, peace making, and funerals. Alcohol is thus the oldest and still probably the most widely used drug.

The manufacture and sale of alcoholic beverages was already common and commercialized and regulated by government in the earliest civilizations. The oldest known code of laws, that of Hammurabi of Babylonia (c. 1770 BC), regulated drinking houses. Sumerian physician-pharmacists prescribed beer (c. 2100 BC) in relatively sophisticated pharmacopoeias found on clay tablets. The later Egyptian doctors, in their medical papyri (c. 1500 BC), included beer or wine in about 15 percent of their prescriptions. The recently discovered Semitic cuneiform literature of the northern Canaanites, in pre-Biblical Ugarit, contains abundant references to the ubiquitous religious and household uses of the intoxicating fluid.

Water, a precious commodity in the earliest agricultural dependent civilizations, was probably the original fluid used as offering in worship rites. In time, other fluids—milk, honey, and later wine (in some religions, beer)—were substituted. That alcoholic beverages should have displaced other fluids in early religions, both as offering and drink, is not surprising: its capacity to help the shaman or priest and other participants reach a desired state of ecstasy or frenzy could not long have escaped observation, and its appreciation was naturally attributed to supernatural spirits and gods. The red wine in religious uses was eventually perceived as symbolizing the blood of life and, in this spiritual sense, ultimately passed into the Christian Eucharist. The records of the Egyptian as well as of the Mesopotamian civilizations attest that drinking and drunkenness had passed from the state of religious rite to common practice, often troublesome to government and accompanied by acute and chronic illnesses. There are ample indications that some people so loved drink and were so abandoned to drunkenness that they must be presumed to have been alcoholics.

Among classical peoples. The significance of the classical history of drinking arises from the fact that after about 300 BC the Greek, Hebrew, and Roman cultures became mingled in a mix that was to influence powerfully the development of European culture. The surviving records of ancient Greek and Roman culture, in classic pictorial and plastic art as well as in the literature transmitting prehistoric memories enshrined in myths, reveal the common and copious use of wine by the gods, as well as by people of all classes. The worship of Dionysus, or Bacchus, the wine god, was the most popular; his festival, the Bacchanalia, has given English one of its literary names for a drunken orgy. His female devotees, the Maenads,

Universal-
ity of
alcohol
production

Early reli-
gious uses
of alcohol

Religious
sanctions
against
drunken-
ness or
drinking

worshipped him in drunken frenzies. The Greco-Roman classics abound with descriptions of fulsome drinking and often drunkenness. The wine of the ancient Greeks, like that of the Hebrews of the same time, was usually drunk diluted with an equal part or two parts of water, and, thus, the alcohol strength of the beverage was presumably between 4 and 7 percent. But, as a standard drink, diluted wine was apparently more common than plain water, and there were toppers who preferred their wine straight.

The literature of the Greeks does not lack warnings of the evil effects of excess in drinking, but in this they are excelled by the classics of the Hebrew Canaanites. The earliest references in the Bible show that abundant wine was regarded as a blessing, on a par with ample milk and honey, grain and fruit. The eyes of the Judaeans were to be bright from wine, which also was known to gladden the heart of man and to bring relief to those who were bitter of heart or ready to perish. In the national religious culture that developed into the Judaism that has survived to the present, drinking was intertwined with all important ceremonial occasions—from the celebration of the eight-day-old boy's circumcision to the toasting of the soul of the departed and, in between, the wedding, the arrival and departure of every Sabbath and festival, and, indeed, any sort of celebration. The purpose of drinking thus became integrated with an attitude of reverence for the sanctity or the importance of the occasion, to the extent that over-drinking, becoming tipsy, would manifestly be inappropriate and disapproved. Drunkenness then became a culturally negative, an alien and rejected behaviour and generally vanished from the Jewish communities. In contemporary terms, drinking was under effective social control, and the result has been the seeming paradox, fascinating to modern students of sociocultural phenomena, that a people with the highest proportion of drinkers exhibit the lowest rates of alcoholism and other alcohol-related problems.

Quite a different kind of religious control was adopted later (in the 7th century) in Islām: the Qur'an simply condemned wine, and the result was an effective prohibition wherever the devout followers of Muḥammad in Arabia and other lands prevailed. (The same process occurred some 1,000 years later in Europe, after the Reformation, and later still in the United States, when a number of ascetic Christian sects, resting their ideology on the Bible, made abstinence a fundamental tenet.)

Like the early agriculturists of the Near East, the people of the Far East discovered the technology of manufacturing alcoholic beverages in prehistoric times. Barley and rice were the chief crops and the raw materials for producing the drink that, here too, was incorporated into religious ceremonial, both as drink and libation, with festivals featuring divine states of drunkenness. Here too, in time, the sacred drink became secularized, even while its religious uses survived, and evoked public as well as private disorders. The history of China includes several abortive efforts at control or prohibition. But, in the Far East, prohibition was effective only when religiously motivated. The Hindu Ayurvedic texts (c. 1000 BC) skillfully describe both the beneficent uses of alcoholic beverages and the consequences of intoxication and the diseases of alcoholism. The devout adherents of Buddhism, however, which arose in India in the 5th and 6th centuries BC and spread over southern and eastern Asia, abstain to this day, as do the members of the Hindu Brahmin caste. But most of the peoples in India, as well as in Ceylon and the Philippines, in China and Japan, have continued, throughout, to ferment a portion of their crops and nourish as well as pleasure themselves with the alcoholic product.

In Africa, maize, millet, bananas, honey, the saps of the palm and the bamboo, and many fruits (including that of the sausage tree) have been used to ferment nutrient beers and wines, the best known being Kafir beer and palm wines. Most of the peoples of Oceania, on the other hand, seem to have missed the discovery of fermentation. Many of the pre-Columbian Indians of North America are also exceptional in lacking alcoholic beverages until introduced to firewater by Europeans, with explosive and disastrous consequences. But the Papago Indians of the southwestern

United States made a cactus wine, and the Tarahumara of northern Mexico made beers from corn and species of agave, while throughout Central and South America the aborigines made chicha and other alcoholic beverages from maize, tubers, fruits, flowers, and saps. For the most part, their drinking appears to have been regulated so as to inhibit individual alcoholism and limit drunkenness to communal fiestas.

Alcohol in complex societies. *Contrasts and similarities between primitive and modern uses.* In primitive societies the uses of alcoholic beverages were multiply motivated. These beverages had important nutritional value. They were the best medicine available for some illnesses and especially in relieving pain (in any case, a patient given a prescription to be taken in beer or wine, with the instruction to drink it liberally, was likely to feel better, regardless of whether the various ingredients affected his disease). They facilitated religious ecstasy and communion with the mystical super-mundane powers thought to control tribal and individual fate. They enabled periodic social festivity and the personal jollification of the participants, thus also serving as the mediator of popular recreation. They helped reduce anxiety, tension, and fears connected with concerns over subsistence, safety, or with the need to engage in aggressive or dangerous activities, such as warfare. They could calm anger or tranquilize hostility so as to allow pacification and reduce suspicion, making possible peaceful associations and commercial or ceremonial relations. And, in individuals with extraordinary responsibilities, such as chiefs, shamans, medicine men, they helped to assuage the personal anxieties and tensions connected with those exceptional roles. In some cases the formalized public binge could serve as the permissive loosener of interpersonal aggressions, allow an interlude of verbal or even physical hostility within the family or clan group, which otherwise the mores of the cohesive small society necessarily forbade. The insults and wounds of the discordant interlude could easily be forgiven by blaming them on the alcohol-induced irresponsibility. Under these circumstances drunkenness could be approved or even mandatory and still serve an integrative social function. In short, the most general effect of alcohol, suggested by its very equivocal uses, appears to be as a facilitator of mood change in any desired direction.

The conditions of primitive or early societies foreshadow the conditions of complex societies, including the contemporary highly industrialized ones. As food, hardly anything but the caloric value of alcohol remains, and this is essentially of no importance in modern diets, unless such large amounts are consumed that the value becomes negative, since the carbohydrate calories in modern beverages are deficient in other necessary nutrients, such as vitamins and minerals, provided by other foods. As medicament, alcohol has a limited surviving value in the practice of contemporary physicians equipped with more efficient anesthetics and taught to prescribe more variegated analgesics and tranquilizers. In religion, wine has been relegated to a highly specific, essentially symbolic role, where not completely eliminated. What remains is the satisfaction of personal and group needs that have particular urgency arising out of the very complexity of modern life.

The most distinctive features of the complex technological society, in contrast to the simple primitive type, consist of specialization of functions; membership in limited interest groups (though often with conflicting roles); inequalities of earnings and prestige; social and economic stratification, in addition to religious differentiation; and an irreconcilable disharmony of individualism and interdependence, marked by the fact that individuals command skills and privileges indispensable for the welfare of others (only a baker can produce bread for the supermarket's customers; only a licensed physician can write a prescription), yet the same individuals are totally dependent on others for their own vital needs. All these factors contribute to competitiveness, distrust, insecurity, anxiety, alienation. Those who have abundant goods or positions of power and prestige are not thereby freed of these troubles. The result is, if anything, a more intense need for relief from tension,

Variety of
uses for
alcohol

for relaxation from anxiety, for tranquillization from the effects of competitive effort.

It is not that the ancient uses have been forgotten: a drink is still the symbolic announcer of friendship, peace, agreement, in personal as well as in business or political relations. But in the complex society many people discover that many drinks often help them to suppress the overwhelming inhibitions, shynesses, anxieties, tensions that interfere with urgent needs to function effectively, either socially or economically. In the complex society, characterized by multifarious frustrations of gratifying interpersonal relationships, the capacity of alcohol to serve as socio-activating medicine comes into high value.

Conflicts over drinking. Modern complex societies are troubled by a lack of consensus around many issues of right and wrong or proper and improper behaviour; and drinking, since the latter part of the 18th century, has been a focus of disagreement, sometimes amounting to political warfare among subgroups making up larger national societies. In the United States, the late 18th-century temperance movement became, by the middle of the 19th century, an anti-alcohol movement that culminated in national Prohibition (enacted by constitutional amendment in 1919 and repealed in 1933). Echo movements in other countries had somewhat similar histories. The lack of consensus regarding who may drink how much of what and where and when and with whom is illustrated by the crazy quilt of local regulations extant in the United States. In some localities there is total prohibition or prohibition only of distilled spirits and strong wines; in some, only those over 18 or over 21 years of age may buy drinks; in some, married women under age may buy but not married under-age men; in some, until recently, Indians might not buy; in some, liquor may be sold only by the bottle, not by the drink; in some, drinks may be served only together with food, in others only without food; in some, drinking in public places is permitted only if the drinkers are curtained or only if they are uncurtained or only when they are seated; or men may stand to drink, but women must be seated. Dissonant attitudes toward a custom as common as drinking are believed by many sociologists to account for the inability of the society to establish firm rules inhibiting immoderate behaviour, with a resulting high incidence of damaging use, drunkenness, and many other problems related to alcohol. The Chinese and the Italians, as well as the Jews, are cited as examples of groups having well-developed cultural consensus against drinking to drunkenness, with resulting low rates of alcohol problems. In parallel, France is cited as a country with a consensus favouring steady copious drinking, with a resulting high rate of alcoholism.

The modern conflict over drinking reflects the complex interactions of individual man and small group and larger society. Small groups, formed by common interests in business or occupation or recreation or neighbourhood or politics or ethnicity or religion, use drinking together to facilitate mixing, to engender solidarity, to reduce normal inhibitions against trust in and collaboration with "strangers," to symbolize and ratify accord, to ensure that gatherings for celebration will succeed as festive occasions. Individuals use alcoholic beverages as an agreeable effector of desired mood alteration, such as moderate relief from anxiety or depression or masking of unease and pain, and to enable participation in the various small groups with which they are required to associate. Given favourable contexts, moderate amounts of alcohol apparently function well in fulfilling these purposes. Given consensual practices, moderate amounts of drink function integratively within families and in common-interest groups. This is thought to account for the survival of the drinking custom from early times, in spite of the problems it has engendered and the opposition it has provoked. But individuals and, sometimes, groups, whether formally or informally organized, also indulge in immoderate, self-injurious, and socially damaging drinking. These dysfunctional behaviours account, in part, for the organized societal opposition to any drinking although the antagonism is sometimes based in more fundamental perspectives of the anti-alcohol sentiment: alcohol is, from olden times, the facilitator of

pleasurable, morally lax, hedonistic behaviour; as such, it evokes the displeasure and condemnation of those favouring moral strictness and an ascetic way of life.

DRINKING PATTERNS

The universal and general functions of drinking are displayed in a great variety of ways and customs in different parts of the world and among various subgroups and subcultures within larger societies. The places of drinking vary infinitely: home may be the only place to drink or the one place where it is forbidden. Drinking may be a ceremonial or informal family affair, with or before meals. It may be a lone practice at home, in commercial drinking places, or in private hideaways or a group practice in membership clubs, neighbourhood taverns, beer gardens, sidewalk cafés, or skid-row alleys. The purposes and occasions are infinitely disparate. It may be the benign drunkenness of the men in the quasi-religious fiestas of Central and South American natives, the festal abandonment in song and dance—after relatively little drinking—of the members of the Jewish sect of Hasidim, the socializing celebrations of fraternal collegians, or the exhibitionistic libationism of business meetings and professional conventions. Or it may be the repeated "killing" of bottles by men or women fixed mindlessly before the television set, or the quick potations of cocktail parties, or the gulping of forbidden liquors by defiant, rebellious youth groups needing to assert their grownupness. Not only an individual's taste, predilection, or psychological need but also his sex, age, residential neighbourhood, education, associations, church and other memberships, and socio-economic status may determine whether, when, what, how much, or with whom he shall drink. In the United States, where nearly one-third of adults are abstainers, the better educated and the economically advantaged are more likely to be drinkers than the poor, though, among the poor who do drink, the proportions of heavy drinkers are higher. By contrast, in France, where abstainers are in a very small minority, they are more likely to be found among the better educated and upwardly mobile. The attitudes toward drinking and abstaining, among or within different countries, are as varied as the practices.

Kinds and distributions. The worldwide pattern of total alcohol consumption on a per capita basis increased generally during the period after 1950. The per capita consumption of distilled spirits, beer, and wine also rose during most of this period, with beer consumption increasing more than spirits or wine. Although the consumption of all alcoholic beverages generally rose during this period, deviations from this general tendency were evident in many countries; countries with traditionally high levels of total alcohol consumption (e.g., France, Italy, Portugal, Spain, and Switzerland) exhibited stable or slightly increased per capita levels; beer consumption in traditionally heavy beer-drinking countries (e.g., West Germany, Belgium, Australia, New Zealand, Ireland, the United Kingdom, and Denmark) did not increase as much as the worldwide pattern; and wine consumption on a per capita basis actually declined in some countries with traditionally high consumption levels (e.g., France and Italy).

Many factors are believed to affect these recent patterns in total alcohol consumption. One factor has been the increased use of alcohol with meals, primarily beer and wine, in part a result of long-term increases in per capita income in many countries and in part a result of fermentation technology that has kept the price of alcoholic beverages relatively low, permitting the purchase of beer and wine more readily for meals. Another factor has been the increased consumption of alcoholic beverages considered to be nontraditional to a specific nation—e.g., increased consumption of wine in traditionally beer- and spirits-drinking countries or vice versa. This increased consumption has followed a pattern in some countries of new nontraditional beverage consumption in addition to the continued consumption of traditional alcoholic beverages. In some other countries with high levels of total alcohol consumption, such as France, Italy, Portugal, and Spain, there has been a substitution pattern: substantial increases in per capita beer consumption have involved concom-

itant declines or stabilizations in wine consumption per capita. While the substitution pattern was exhibited primarily in countries with traditionally high levels of total alcohol consumption, the first pattern of new nontraditional beverage consumption was the more prevalent and was experienced by nations with more moderate levels of alcohol consumption. The countries of Scandinavia, the British Isles, North America, and Oceania, traditionally beer- and spirits-drinking societies, sustained substantial increases in per capita wine consumption but experienced fairly stable or slightly increasing consumption of traditional beverages. In North America, particularly in the United States, the introduction of low-calorie beer and wine in the early 1970s was instrumental in the increased per capita consumption of alcohol in the late 20th century.

During the late 20th century the leading countries in total alcohol consumed per capita were France, Portugal, Spain, Italy, West Germany, and Austria. Except for West Germany, these same countries were also the leading per capita consumers of wine. West Germany and Ireland emerged as the leading consumers of beer per capita, along with the more traditionally heavy beer-drinking countries of Australia, New Zealand, Belgium, and the United Kingdom. The United States, Canada, France, Belgium, and The Netherlands were the leading per capita consumers of distilled spirits.

Kinds and customs. In both France and Italy, wine consumption is high, but attitudes as well as patterns and amounts differ in the two countries in many ways. French parents tend to exhibit strong attitudes, either favourable or negative, to their children's drinking; Italian parents typically introduce their children to wine drinking without any emotional overtones. Italian standards of safe limits for drinking are lower than those of the French, and the Italians typically regard getting drunk with disdain, while the French look on it with good humour or even, in men, as a mark of virility; also, as already noted, the French are heavily given to the use of spirits. Although these generalized patterns are not consistent among the various regional populations and socioeconomic groupings of either country, they are thought to be significant in accounting for the much higher mortality and morbidity from alcoholism in France.

Among the Scandinavian countries (including Finland),

the alcohol consumption pattern is not one of drinking daily or with meals but rather of telescoped drinking on weekends or special occasions; this is believed to account for the relatively high rate of alcohol-connected problems, such as intoxication, even in a country such as Finland, where the total alcohol consumption is relatively very low. The Scandinavian countries have also had strong anti-alcohol movements, often supported by government funds, and have had abstainer societies with large memberships. It is possible, therefore, that alcohol is consumed by a smaller number of drinkers than is represented by the drinking-age population; in Norway, for example, it is reported that more than 20 percent of men and nearly 40 percent of women are abstainers.

In England and Ireland, the pub has maintained its popularity as a main locus of drinking. In both countries, beer is by far the most popular beverage—in the United Kingdom accounting for more than three-fourths of the total alcohol consumed and in Ireland for two-thirds. The marked preference for beer is seen in other countries overwhelmingly settled and influenced by British populations—Australia, New Zealand, and much of Canada. In these countries, too, the pub tends to dominate the drinking style, apparently allowing an agreeable pattern of prolonged but not necessarily intimate socializing, while preserving the degree of independence that individual drinkers may prefer. Drinking to a moderate grade of intoxication appears to be acceptable and in some of these countries is thought to constitute the permissive societal attitude that partly underlies the development of alcoholism.

The drinking patterns of very few total populations in European countries have been subject to formal examination by social scientists. Studies have been focussed, for the most part, on segments of the population regarded as problem giving, such as alcoholics, traffic offenders, criminals, inmates of mental hospitals, or youths, especially students. Information from eastern European countries tends to be of the same order. There are indications that, in Poland, the shifting of a young population from rural-farm to new urban-industrial centres, with higher cash incomes and few outlets, has resulted in what the authorities regard as an increase in heavy drinking or alcoholism; vodka is the common drink. Somewhat similar reports emanate from Yugoslavia, where old village customs, while permissive of

Drinking

and Italy

Drinking
in eastern
Europe

much drinking, nevertheless used to curb gross excesses. In the Soviet Union the growing program of establishing sobering-up stations and treatment clinics in many cities, often with research-oriented staffs, indicates a recognition that alcoholism is a serious problem. Vodka is the national drink, though native wines are increasingly being promoted. But the situation is evidently quite varied in different parts of the country. In the Soviet republic of Georgia, a viticultural region, wine is the favoured drink, and the drinking patterns are much more like the Italian than those of western Russia, with, apparently, a decidedly low rate of problems.

Much of the description of drinking patterns in South and Central America, as in Africa and Oceania, has consisted of anthropologists' observations of small, preliterate groups, with occasional notations on the effects of acculturation. Studies of national patterns do not exist, although, as in Europe, there are occasional reports on special, either local or problem-giving, populations. In Chile, a middle class population is described as similar to some European populations in drinking patterns—moderate consumption, drinking at home with meals, and frowning on drunkenness being typical. The much larger working class customarily drinks outside the home, in male company, on weekends or paydays, seeking intoxication that is valued as signalling both friendship and virility. A third population, identified as Indian, has a pattern such as that of the working class. The favoured drinks are pisco, a strong native brandy, and wine. Drinking accompanies all secular and religious fiestas, as well as the celebrations of births, baptisms, marriages, funerals; women, however, are expected to drink very moderately. Similar patterns have been reported from various areas in Bolivia and Peru.

In Japan, traditional drinking, still practiced in large circles, allowed heavy drinking and drunkenness in well-delimited social situations and was socially integrative. The traditional beverage was sake, often called rice wine but, more properly, a beer, brewed by highly skilled methods up to a strength of at least 14 percent alcohol and possibly up to 16 or 17 percent. A great many drinking customs and rituals involving sake were connected with religious and social occasions. Next to sake the common beverage was a distillate from sake mash, *shōchū*, containing about 25 percent alcohol. There are evidences of heavy drinking and alcoholism and various attempts to impose prohibition, as well as the practice of abstinence by the followers of Buddhism and of some revered Japanese philosophers. Modernization was accompanied in the last quarter of the 19th century by a temperance movement stimulated, in part, by the Woman's Christian Temperance Union and the Salvation Army. Since World War II, the widespread Americanization has included a growing popularity of beer and an increased use of imported beverages, especially whiskey, for which younger people express a preference. Among the young, the development of an ambivalence toward drinking, also characteristic of U.S. attitudes, has been reported.

Drinking patterns and attitudes in the United States have been studied more systematically and completely than those of any other country. The results indicate that there is no pattern or set of attitudes typical of the nation as a whole; instead, there is a variety of patterns, customs, and attitudes. U.S. drinking patterns are a conglomerate of customs brought over by repeated waves of immigrants from different places and of diverse ethnic stocks, modified over time by intermixture, economic circumstances, political developments, and the emergence of some indigenous ways. Nevertheless, certain generalizations are possible. In the post-Prohibition and post-World War II era, several changes in U.S. drinking practices and attitudes have been observed and confirmed by formal systematic studies. The proportion of abstainers has declined, especially among women. In recent years, approximately 77 percent of adult men and 60 percent of adult women are drinkers. Men, however, as is almost the universal custom, drink substantially larger amounts, on average, than women. Among adolescents, about 57 percent of boys and 43 percent of girls are drinkers; these percentages rise with

age, and the age class 21–29 contains the highest proportion of drinkers; drinking appears to be associated with separation from home and with courtship behaviour. As they continue to age, apparently many Americans become abstainers, perhaps settling down to living as they were brought up to do by their parents or as they would like to exemplify to their children. Rural populations, those with fewer years of education, lower income, more frequent religious attendance, and membership in fundamentalist Protestant denominations, contain larger proportions of abstainers. Among drinkers, beer tends to be the preferred drink of men and, to a lesser extent, of unskilled and blue-collar workers. Spirits are preferred by middle and upper class drinkers and by women—especially in the form of mixed drinks, such as cocktails. Repeal of Prohibition was advocated with the promise of no return of the saloon. Its successors, the bar, tavern, or cocktail lounge, are a ubiquitous U.S. institution. A good deal of drinking, however, takes place at home—though not, most commonly, with meals—and at parties, especially at the second indigenous U.S. drinking way, the cocktail party, now sometimes a substitute for the vanished frontier drinking style. The popularity of the cocktail party and, more specifically, the cocktail on coming home from work and before the evening meal has been attributed to its function as a separator between the working day and the relaxing evening—a sort of rite of passage, easing the way from one into the other. Whether or not this is the actual reason, the cocktail hour has become increasingly adopted in many countries, like other U.S. customs that are paradoxically sneered at while being assiduously imitated.

Although, in general, styles and customs of drinking are influenced by geographic and ethnic backgrounds, Americans tend to be members of multiple small societies, and, to some extent, they drink differently within each of these societies. People from diverse origins may drink alike when joined in some special association—as fellow collegians, members of a business convention, comrades in one of the armed services, or guests at a special kind of social function. Even then, the expected way and amount of drinking is likely to be at least modified by an individual's background. Even within a situation where drinking—indeed, drunkenness—is institutionalized (that is, on the skid rows), patterned differences are discernible to the systematic observer, giving rise to named classes, such as luses, bums, winos, and rubby-dubs (habitual drinkers of non-beverage alcohols, such as rubbing alcohol and canned heat), and distinct consequences. The fact that most Americans drink, that drinking rather than abstinence is the norm, does not prevent the paradoxical existence of ambiguous attitudes about the behaviour among the drinkers themselves, many of whom express such views as that which maintains that alcohol, or drinking, is more harmful than beneficent, more wrong than right. These ambivalences account for the massive array of regulations on the sale and distribution of alcohol, most of them intended to interfere with the availability of beverages at certain times, in certain places, or to certain classes of persons.

Alcoholism

The conception of inveterate drunkenness as a disease appears to be rooted in antiquity. The Roman philosopher Seneca classified it as a form of insanity. The term alcoholism, however, appears first in the classical essay "Alcoholismus chronicus" (1849) by the Swedish physician Magnus Huss. The phrase chronic alcoholism rapidly became a medical term for the condition of habitual inebriety conceived as a disease; and the bearer of the disease was called an alcoholic or alcoholicist (e.g., Italian *alcolisto*, French *alcoolique*, German *Alkoholiker*, Spanish *alcohólico*, Swedish *alkoholist*).

DEFINITIONS AND CAUSAL FACTORS OF ALCOHOLISM

Alcoholism consists of a repetitive intake of alcoholic beverages to an extent that causes repeated or continued harm to the drinker. The harm may be physical or mental; it may also be social or economic. Implicit in the conception

of alcoholism as a disease is the idea that the person experiencing repeated or long-lasting injury from his drinking would alter his behaviour if he could. His failure to do so shows that he cannot help himself, that he has "lost control over drinking." This conception incorporates the idea of addiction or dependence.

Formal definitions of alcoholism vary according to the point of view of the definer. A simplistic old-fashioned medical definition calls alcoholism a disease caused by chronic excessive drinking. A purely pharmacological-physiological definition of alcoholism classifies it as a drug addiction recognizable by the need for increasing doses to produce desired effects and by the occurrence of a withdrawal syndrome when drinking is stopped. This definition is inadequate, since alcoholism does not resemble other addictions in the need for increased doses. Opium addicts become adapted to and require as much as hundreds of times the normal lethal dose, but the increased amounts to which alcoholics become adapted are well below the normal single lethal dose. Moreover, the withdrawal syndromes in alcoholism occur inconsistently, sometimes failing to appear in the same persons who experienced them previously and apparently never occurring in some persons who cannot be distinguished from confirmed alcoholics.

A comprehensive definition of alcoholism

Behavioral rather than pharmacological-physiological signs are much more consistent and reliable in defining and diagnosing alcoholism. A sophisticated definition representing modern conceptions of comprehensive medicine classifies alcoholism as a disease of unknown cause, without recognizable anatomical signs, manifested by addiction to or dependence on alcohol. A more comprehensive definition incorporating the perspectives of both psychological and physical medicine recognizes that alcoholism may be either a symptom of another underlying, possibly psychological, disorder or a disease itself: alcoholism, in this view, is a chronic and usually progressive disease or a symptom of an underlying psychological or physical disorder, characterized by dependence on alcohol (manifested by loss of control over drinking) for relief from psychological or physical distress or for gratification from alcohol intoxication itself, and characterized also by a consumption of alcoholic beverages sufficiently great and consistent to cause physical or mental or social or economic disability. Here, the conception of disease undoubtedly rests on the evidence of disablement.

The various definitions that rely on the symptom of loss of control over drinking often consider the loss of control to consist of an inability to stop drinking once it is started, implying that the alcoholic can choose not to take the first drink. But the more comprehensive definition sees the alcoholic as starting a drinking episode because he cannot refrain. Nor does the loss of control over drinking hold true all the time. As with symptoms in many diseases, the loss of control is active in most alcoholics only inconsistently. This means that an alcoholic is not always under internal pressure to drink and can sometimes resist drinking, or, if he drinks, he can sometimes drink in a controlled way. The inconsistency of the loss of control is, however, consistent with a definition of alcoholism based on learning psychology: alcoholism, in this definition, is a learned (or conditioned) dependence on (or addiction to) alcohol that irresistibly activates resort to drinking whenever a critical internal or environmental stimulus (or cue) presents itself. This definition leaves room for the conception that alcoholism may start as a symptom of an underlying disorder, which induces the learning of the alcoholismic pattern, and that once the pattern is fixed or conditioned it may become a disease in its own right (that is, an addiction), capable of surviving even the disappearance of the original underlying cause. Some theorists who regard alcoholism as primarily a symptom do not necessarily subscribe to the idea that it is learned, although they recognize that it may progress to the state of a primary disease.

Alcoholism is a multifarious phenomenon requiring more than one definition. Epidemiologists need a definition that will enable them to identify alcoholics within a population not available for individual examination. Such a definition may rely on a quantity-and-frequency measurement of

drinking and also on behavioral features, including injurious effects measurable by instrumental indexes, such as a formula resting on the relation of alcoholism to diseases of known frequency among alcoholics or a drinking-history questionnaire or a preoccupation-with-alcohol scale. Sociological-behavioral definitions emphasize deviance from a norm, especially drinking that exceeds customary dietary use or diverges from the social customs of the drinker's community; such a definition may use as a criterion the way a drinker is regarded by those who know him; his arrests, hospitalizations, and clinical diagnoses; or his membership in a self-defining group, such as Alcoholics Anonymous. Legal definitions tend to rest on habitual intemperance that endangers others, injures the public welfare, or threatens the health, welfare, or competence of the person himself.

Many theories of the cause of alcoholism rest on the limited perspectives of specialists in particular disciplines or professions. Thus, alcoholism has been thought to be caused by defects of heredity, nutrition, disorders of endocrine function, latent homosexuality, economic misery or affluence, bad social influences, or sinful gluttony. More discerning definitions and descriptions take into account the complexity of alcoholism, acknowledging that its causes are not yet knowable with certainty. The most comprehensive conceptions recognize that alcoholism may have a genetic or constitutional underlying factor—not a fateful heredity but a predisposition that renders some people more vulnerable to alcoholism than others. Some think the genetic vulnerability is specific not to alcoholism but rather more generally to a neurosis or an affective disorder that may manifest itself as alcoholism; the alcoholism may possibly represent a "choice of symptom" and be for some individuals a useful "sickness." Others think the genetic factor may impose not vulnerability but, on the contrary, immunity to alcoholism, meaning that some people are unable to adapt to drinking on a level sufficient to gain the peculiar rewards that dispose a person to the development of an alcoholismic life pattern.

The comprehensive etiological view suspects that factors in infancy or early childhood, such as lack of parental care and love, overindulgence, or inconsistency in rearing practices, may lay the foundation of a vulnerable personality. On such a foundation, a dependent personality type or one marked by dependence-independence conflict may emerge; in adolescence this may manifest itself in an insecure self-sex image and a need to overcompensate—for example, by defiant exhibitionistic deviance. Such a problem-ridden personality may find exceptionally effective assuagement and reward in alcohol and learn to rely on intoxication as a mechanism for coping with problems. If this learning process is not interrupted and especially if the social surroundings respond encouragingly or permissively or ambivalently to heavy drinking and intoxication, then the vulnerable personality will become conditioned to react to difficulties by resort to intoxication. If the process lasts long enough, the outcome will be addiction to alcohol or a confirmed alcohol dependence. This comprehensive conception takes into account not only the possible genetic, pharmacological, psychological, and social factors but also the sociocultural context. It recognizes that the society defines and labels the phenomenon of alcoholism, that the culture contributes to its development or inhibition, and that behaviour that in one culture matches an adequate rational definition of alcoholism may not constitute alcoholism in another. Thus, periodic intoxication causing sickness for several days and necessitating absence from work may define alcoholism in a modern industrial community, but, in a rural Andean society, periodic drunkenness at appointed communal fiestas, resulting in sickness and suspension of work for several days, is normal behaviour. An essential aspect of the difference is that the drunkenness at fiestas is not individually deviant behaviour.

Causal factors

PREVALENCE OF ALCOHOLISM

Estimates of the prevalence of alcoholism vary greatly, depending on how it is defined as well as on the methods of estimation. In the United States in the late 20th century, according to one sophisticated estimate, there

were approximately 5,400,000 alcoholics—about 4,500,000 men and 900,000 women. In percentage terms, 7.3 percent of men and 1.3 percent of women were alcoholics or 4.2 percent of adults aged 20 and over. There were large variations among regions and states, the rates being higher in urban and industrialized areas. There was no objective evidence that the rates of alcoholism had risen since World War II, although the absolute numbers had increased substantially with the growth of the adult population. A widespread impression that alcoholism was increasing among women apparently reflected the greater visibility of female alcoholics caused by changing public and professional attitudes; formerly, there had been more masking of alcoholism in women than in men.

Alcoholics and pre-alcoholics A constant rate of alcoholism, without any increase in numbers except in proportion to the growth of population, requires an annual incidence of several hundred thousand new cases. The process of becoming an alcoholic usually takes several years. Since in many cases the process is not carried to completion, there must be a population of several million pre-alcoholics (for example, "heavy drinkers" or "heavy-escape" drinkers) from whom the several hundred thousand new cases of alcoholism emerge each year. On the basis of national surveys of U.S. drinking patterns of the last few decades, it is estimated that the size of the "pre-alcoholic" population is about 4,000,000; these, together with the 5,400,000 alcoholics, may be considered the total of problem drinkers. There are indications, however, that among the pre-alcoholics the sex differential is rather smaller than among the alcoholics, probably about four men to one woman. This implies that among women pre-alcoholics a smaller proportion cross the line to become full-fledged alcoholics.

The existence of over 5,000,000 alcoholics in the U.S., plus possibly 4,000,000 other problem drinkers, of whom perhaps between 5 and 10 percent become alcoholics each year, places alcoholism in the front rank of public-health problems. Its gravity is underlined by the higher rates of mortality (2.5 times normal) among alcoholics. Suicide rates are 2.5 times higher; accidental death rates are seven times higher; and there is an enormously higher rate of general morbidity among alcoholics. One study found that among patients in general hospitals, those identifiable as alcoholics range from 13 to 29 percent. Alcoholism-related psychoses account for about 15 percent of the male and roughly 3 to 4 percent of the female admissions to public and private psychiatric hospitals in the U.S. Admissions of alcoholics without psychosis—usually to participate in alcoholism-treatment programs—accounted for another 40 percent of the men and 13 percent of the women admitted to public mental hospitals and for 15 percent of the men and 4 percent of the women admitted to private mental hospitals. These statistics do not include pre-alcoholics and problem drinkers, although, from the viewpoint of preventive public health, they are those most in need of study and help.

Estimates or different countries Variations in the definition of alcoholism make it difficult to compare U.S. rates with those of other countries. The most comparable statistics are those of Canada, where the rate of alcoholism is much lower than in the U.S., about 2.4 percent, and the ratio of incidence among the sexes is about five men to one woman, as in the U.S. A rate of 3.5 percent has been reported from Sweden and 1.1 percent from Finland, each with a ratio of five men to one woman, and 0.8 percent from Northern Ireland, with a ratio of three men to one woman; other rates include 5.4 percent in Chile and 0.41 percent in Italy, with no indications of sex ratios. In England and Wales different estimators have suggested rates varying from as low as 1.1 percent to as high as 8.8 and 11 percent; and in Switzerland the suggested rates have varied from 2.2 to 13 percent. The rate in France has been estimated at as high as 15 percent of the adult population, but more conservative estimates suggest 9.4 percent.

Although the rate in France is probably higher than in any of the other countries mentioned, the degree of validity that may be attached to these estimates is so uncertain that all comparisons must be considered as unreliable. There is a strong subjective element in statistics of alco-

holism. From time to time, professional opinion becomes aroused, a cry of alarm is raised, and the assumption is made that alcoholism is increasing. High estimates are then likely to emerge, based on local and insufficiently refined data. Often, increased admissions to hospitals for alcoholic mental disorders and sometimes increased consumption of alcohol are cited in evidence. But these data invariably fail to take account of changes in availability or use of facilities, changes in admission or diagnostic policies, or changes in the source of beverages—for example, from unrecorded to recorded supplies. In the U.S.S.R. a change in the internal political situation with the death of Stalin resulted in a shift from official denial that any significant problem of alcoholism existed to an outcry that its prevalence was widespread and serious, though no statistics were provided.

TREATMENT OF ALCOHOLISM

The various treatments of alcoholism may be classified as physiological, psychological, and social. Many physiological treatments are given as adjuncts to psychological methods, but sometimes they are applied in "pure" form, without conscious psychotherapeutic intent or even with an effort to avoid it.

Physiological therapies. *Chemical fences.* One of the popular modern drug treatments of alcoholism, initiated in 1948 by Eric Jacobsen of Denmark, uses disulfiram (tetraethylthiuram disulfide). The usual technique is to administer half a gram in tablet form daily for a few days; then, under carefully controlled conditions and with medical supervision, the patient is given a small test drink of an alcoholic beverage. The presence of disulfiram in the drinker's body causes a reaction of hot flushing, nausea, vomiting, a sudden sharp drop of blood pressure, pounding of the heart, and even a feeling of impending death. These symptoms result from an accumulation of the highly toxic first product of alcohol metabolism—acetaldehyde. Normally, as alcohol is converted to acetaldehyde, the latter is rapidly converted, in turn, to other harmless metabolites, but in the presence of disulfiram—itself harmless—the metabolism of acetaldehyde is blocked, with the resulting toxic symptoms. The patient is thus dramatically shown the danger of attempting to drink while under disulfiram medication. A smaller daily dose of disulfiram is then prescribed, and the dread of the consequences of drinking acts as a "chemical fence" to prevent the patient from drinking as long as he continues taking the drug. Most therapists use the period of enforced abstinence to apply psychological and rehabilitative measures that should enable the patient ultimately to refrain from drinking without the chemical crutch. Variations of the technique include group-reaction tests and the substitution of motion pictures or verbal descriptions for the reaction test.

Citrated calcium cyanamide is another drug used with similar effect, preferred by some therapists because the reaction with alcohol is milder, though its protective potency is briefer. In Japan some therapists have reported giving very small doses of the cyanamide compound, thereby allowing the patient to drink very moderately without suffering a severe reaction but provoking the reaction if he attempts to drink immoderately. Other substances that can produce disagreeable reactions with alcohol include animal charcoal, the mushroom *Coprinus atramentarius*, numerous antidiabetic drugs, and the ground pine *Lycopodium selago*, but, except for the latter, which has had some trial in the Soviet Union, they have attracted little clinical interest.

Aversion. The U.S. psychiatrist W.L. Voegtlin developed a method of creating a conditioned reflex of aversion to alcohol by repeatedly giving the patient a precisely timed injection of an emetic drug just before a drink of his favorite beverage, resulting in nausea and vomiting before the alcohol could be absorbed. The consequent association of vomiting with drinking, causing aversion to the taste, smell, and sometimes even sight of alcoholic beverages, does not last indefinitely but may be reinforced periodically. Similar techniques have been tried in several European countries. Other methods of conditioning applied by behaviour therapists and learning psychologists

Drugs that prevent drinking

include associating drinking with mild to painful electrical shocks or with temporary interruption of breathing by injection of a paralyzing drug.

Nutrition, hormones, drugs. A genetotropic theory of disease holds that alcoholism is caused by a genetically determined need for extraordinary amounts of one or more vitamins. Accordingly, alcoholics have been treated with massive doses of multivitamins. Another theory holds that alcoholism is caused by some defect of the endocrine system, the adrenal-hypophyseal axis being most commonly implicated, and, accordingly, alcoholics have been treated by injections of adrenal steroids and adrenocorticotrophic hormones. Other physical and drug therapies that have been tried in alcoholics include intravenous injections of alcohol, apomorphine, injections of autoserum and alcoholized serum, brain surgery, carbon-dioxide inhalation, oxygen by injection, nicotinic acid, nicotinamide-adenine dinucleotide, lysergide (LSD, lysergic acid diethylamide), strychnine, antihistaminic agents, and many tranquilizing and energizing drugs. None of these treatments has been shown in controlled studies to be more effective than others. With some treatments, controlled studies are extremely difficult to carry out. In many cases, moreover, the treatments are accompanied by simultaneous measures having potentially psychotherapeutic and socially rehabilitative effects, especially membership in Alcoholics Anonymous. It is possible that the treatment that works best is the one that is most suitable for the particular patient. But it is also possible that the most effective therapy is the one the therapist believes in, and this factor of subjectivity may account for the inferior results achieved when any of them is tested in controlled experiments. In the use of psychoactive drugs such as LSD, the aim often is not directly to affect the alcoholism but to produce changes in the patient's emotional state that will help him respond to other psychosocial measures.

Treatment
of psy-
chological
factors

Other therapies. *Psychological therapies.* Psychotherapy in alcoholism encompasses the entire range of modalities applied in treating the psychoneuroses and character disorders, including individual and group techniques. The aim varies from eliminating some underlying cause to effecting just enough shift in the patient's emotional state so that he can function at least temporarily without drinking. Psychoanalysis is rarely tried, having shown little success in alcoholism; analytically oriented therapies are more usual, chiefly with supportive aims. The only psychological technique developed specifically for alcoholism consists of gaining the patient's recognition and acceptance of his actual condition, which alcoholics often resist. Such acceptance may then be followed by a therapeutic-rehabilitative regimen. Group therapies are regarded as more effective than individual modalities with alcoholics. These range from instructional lectures and superficial discussions to deep analytic explorations, psychodrama, hypnosis, psychodynamic confrontation, and marathon sessions. Mechanical aids include didactic motion pictures, movies of the patients while intoxicated, and taped records of previous sessions. Some therapists have experimented, as yet without definitive results, with milieus that reward and reinforce socializing behaviour, hoping thereby to extinguish the desocializing drinking behaviour. Many institutional programs rely on "total push," subjecting the patient to a bombardment of methods, including drugs, hypnosis, physiotherapies, group sessions, lectures, Alcoholics Anonymous meetings, and individual psychological and religious counselling, with the hope that each patient will be affected favourably by whatever is most suitable for him. Other institutional programs rely on mere removal from the stressful outside environment, with a period of enforced abstinence. The therapists themselves may be psychoanalysts, psychiatrists, clinical psychologists, pastoral counsellors, social workers, nurses, police or parole officers, or lay counsellors—the latter often former alcoholics with special training.

The places of treatment are as varied as the modalities, ranging from general hospitals to mental hospitals to mental-health outpatient clinics to specialized inpatient sanitariums and specialized alcoholism clinics to jails and penitentiaries to medical and psychiatric private offices,

with patients often moving, randomly or systematically, from one milieu to another.

Awareness of the social and environmental elements in alcoholism has led to the development of treatment for spouses and occasionally for whole families, either separately or jointly, in the recognition that "the patient" is not just the alcoholic but the family unit.

A new trend in the United States, partly stimulated by court decisions prohibiting the jailing of alcoholics for public intoxication, is the establishment of detoxication centres that provide first aid along with guidance toward more fundamental treatment. But even if adequate programs and facilities for treating alcoholism were available, it is unlikely that they would solve the problem, given the large number of new cases each year. Only preventive public-health programs can eliminate alcoholism and thus far no likely methods of prevention have been devised.

Alcoholics Anonymous. The patient-centred self-help fellowship of men and women called Alcoholics Anonymous enables its members to share their common experience and thus to help each other. AA was founded in 1935 by two alcoholics, one of whom had been strongly influenced by the Oxford Movement, and has grown to a worldwide community of hundreds of thousands. The members strive to follow Twelve Steps, a nonsectarian spiritual program the central points of which are reliance on God or a higher power as each individual understands that concept and the value of help to other alcoholics. The fellowship is organized in local groups of indeterminate size, has no dues, and accepts contributions for its expenses only from those attending meetings—where members narrate the stories of their alcoholic careers and their recovery in AA. Affiliation of the society or its groups with churches, politics, organizations, or institutions is barred by the AA Twelve Traditions. AA apparently meets deep-seated needs among its members by enabling them to associate with kindred sufferers who understand them, to accept the disease concept of alcoholism, to admit their powerlessness over alcohol and their need for help, to depend without shame or stigma on others, and to involve themselves in activities within the group and in helping other alcoholics. These seem to provide adequate substitutes for the alcoholic way of life. AA is thought by many to be the single most successful method yet devised for coping with alcoholism. It has spawned some allied but independent organizations: Al-Anon, for spouses and other close relatives and friends of alcoholics, and Alateen, for their adolescent children, the aim of which is to help the members understand alcoholism, understand themselves better, and learn how to help an alcoholic or, at any event, how to live with one. Professionals in the field tend to think of AA as an inexpensive form of group therapy and a useful ally but recognize, as do the more sophisticated members, that it is not suitable for all types of alcoholics. Most experienced therapists agree that any form of treatment is likely to show a higher rate of success if the patient can be persuaded simultaneously to join Alcoholics Anonymous.

The effective-
ness of
Alcoholics
Anony-
mous

AA groups around the world resemble each other and generally use the ideological literature (including translations) published by the central office in New York, although there are some variations in style and conduct. In some countries the AA groups are sponsored by or affiliated with national temperance societies or accept financial support from government health agencies. There are also clubs for former alcoholics, usually sponsored by a particular institution for its former patients. One Scandinavian group seeks to achieve a stable degree of moderate drinking, rather than total abstinence.

Results of treatment. The success of treatment in behavioral or personality disorders is always difficult to appraise, and this is the case in alcoholism. The effects of new treatments tend to be reported enthusiastically, but critical examination of the results tends to reduce or cast doubt on the rate of apparent success. Controlled studies, when carried out, usually undercut the claims. Follow-up studies of persons treated have usually been too brief to determine whether permanent results had been achieved, and in most cases the investigators failed to locate a substantial

proportion of the former patients. Moreover, the measures of "success" are inconsistent. Some investigators regard only total abstinence as a successful outcome; others are satisfied if drinking bouts are curtailed and the patient's life adjustment is improved. Perhaps between 25 and 50 percent of alcoholics who receive some form of treatment either become abstinent or achieve some abatement of the severity of their illness. Alcoholism treatment programs connected with businesses and industries, in which the alcoholic must participate if he wants to keep his job, have reported even higher success rates. Forms of frankly compulsory treatment, even if grudgingly endured by alcoholics, seem to have a high rate of effectiveness. Some investigators have suggested that the older the patient and the longer the duration of his alcoholism, the more frequent is the occurrence of "spontaneous" recovery.

Contemporary alcohol problems and controls

Useful
versus
detrimental
uses of
alcohol

Effects of drugs are commonly discussed in terms with negative inference—as if, with drugs, including alcohol, effect and detriment were necessarily synonymous. The personally functional and socially integrative uses of alcohol tend to be overlooked. Alcohol does indeed serve in prophylactic, nutritional, and medicinal roles. The vast majority of drinkers in most of the world are light, occasional, and moderate drinkers—normal drinkers who experience no harm from their own use of alcoholic beverages. Thus, relatively small minorities fall into the class of heavy or excessive or problem drinkers, including alcoholics. Nevertheless, the problem drinkers invoke sufficient troubles for themselves, their families, their employers, their occupational or social associates, and their communities and society generally so that "alcohol problems" are major causes of disorder and suffering, as well as costly focuses of study and responses.

INDIVIDUAL AND SOCIAL EFFECTS

First, in the realm of health, the most serious and detrimental effect is alcoholism. Although drinking itself is hardly ever regarded as the sufficient cause of alcoholism, this disease could not arise without the use of alcohol. Next come the alcoholic diseases—physical and mental disorders that are caused directly or indirectly by alcoholism or heavy drinking. Moreover, alcoholics and heavy drinkers are especially susceptible to the development of some other diseases, not specifically alcoholic, and are then less able to withstand the vicissitudes of ill health. Finally, alcoholics and problem drinkers undoubtedly contribute to the deterioration of the mental health of other members of their families and often to the breakdown of family life. This is seen in the enormously increased rates of divorce and separation in families in which one of the spouses is an alcoholic (four to 12 times higher than in comparable populations) and in the extraordinarily higher rate of alcoholism in the offspring of alcoholics (up to 10 times higher than in comparable samples). This last is now considered to be a social consequence rather than a result of genetic defect.

The social and economic costs of alcoholism and heavy drinking are essentially incalculable. An estimate of \$2,000,000,000 as the cost of health and welfare services provided to alcoholics and their families in the United States alone suggests the measure of effects worldwide. Furthermore, the millions of problem drinkers who have jobs and businesses are more frequently absent and often less efficient than their occupational associates. In one study in a very large industry, identified alcoholics accumulated two and a half times as many days absent from work and collected nearly three times as much in sickness payments as matched samples of fellow employees. Crude projections of the annual costs of alcoholism to the national economy of the United States range from \$7,000,000,000 to \$10,000,000,000.

Crime
and motor
violations

The role of alcohol in crime has often been gauged by the presence of alcoholics in prisons and jails. It is necessary to discount the self-exculpating blaming of "drink" by convicts as the cause of their crimes. Moreover, the high proportion of alcoholics among those convicted of

serious crimes—estimates range from 22 to 43 percent—may misrepresent the role of alcoholism. It is possible that alcoholics, ineffective in other aspects of life, are also less efficient than nonalcoholic criminals in escaping detection and conviction; this may account for their high frequency in penal institutions. There is no question, however, that a great portion of the work of police departments and costs of local courts and jails is attributable to arrests, prosecutions, and brief incarcerations for public intoxication.

A special offense related to drinking is alcohol-impaired driving of motor vehicles and the resulting high rate of accidents, with fatalities, personal injuries, and property damage. Alcohol, for example, is involved in about one-third of the more than 50,000 annual road traffic fatalities in the United States, in possibly 500,000 injuries to persons, and in more than \$1,000,000,000 worth of property damage. Although people with very low alcohol concentrations in their blood—the equivalent of one or two drinks—do not figure in accidents more often than those with no alcohol, the chances of being involved in a traffic accident rise precipitously with increasing blood alcohol concentrations beyond these minimal levels. Laws making specified blood alcohol concentrations *prima facie* evidence of being drunk, impaired, under the influence of alcohol, or unfit to drive have been passed in most jurisdictions. In some Scandinavian countries the limit is 0.05 percent; in most countries, 0.08 percent; in West Germany, 0.13 percent; in U.S. jurisdictions, from 0.08 to 0.15 percent. Attempts to curb driving while affected by alcohol have taken the form of severe punishments—heavy fines, mandatory jail sentences, and loss of driving licenses for periods ranging from six months to 10 years. Newer ways of coping with this problem are being sought with the consideration that, since drivers and pedestrians involved in accidents after drinking usually have very high blood alcohol concentrations, they are probably alcoholics and should be dealt with under some therapeutic rather than exclusively penal regimen.

ALCOHOL CONTROL

Governmental efforts to control alcoholic beverages go back as far as recorded history. The Code of Hammurabi included regulations of prices, taverns, and sellers. That the laws often failed to produce the desired effects—temperance and good public order and perhaps revenue exceeding the social costs of excess—is inferred from the frequent legislative attempts at total prohibition in numerous lands throughout history, all apparently without lasting success. The most resounding failure was that in the United States from 1920 to 1933. Current prohibitions in parts of India appear to be equally ineffective.

Less totalitarian efforts to control the use of alcohol include licensing systems that limit the number and locations of places of sale; restriction of days and hours of sale; prohibitions of sale to the young, with ages varying from 16 in Yugoslavia to 21 in parts of the United States; regulation of the strength of beverages, the size of containers, advertising, prices, or profits. Some governments—for instance, those of Finland and several states of the U.S.—have sought to eliminate the private-profit motive from the sale of alcoholic beverages by reserving a monopoly in the trade to themselves. All Communist countries have government monopolies. But indications that this has made any difference in the kinds, degree, or severity of problems are lacking; apparently problem drinkers do not need to be persuaded by profit seekers. Some governments—for instance, those of Sweden, Finland, and the U.S. state of Ohio—have attempted to control individual drinking by a system of personal ration books for purchases. In Sweden this system was abandoned after 38 years of trial; evidently, those who needed to drink a lot could find supplies—even when their ration books were withdrawn. The most universal regulation of alcoholic beverages takes the form of taxation (or, in government monopolies, an added profit), which is often quite heavy. Usually, however, though the taxing policy may have the ostensible purpose of reducing consumption or controlling licensees, the real object is revenue. In any event, none of the common forms of government control have proved

Types of
governmental
control

Control by
temper-
ance move-
ments and
religions

themselves able to promote temperance in those whose need to drink heavily is uncontrollable. The persistence of massive restrictions and regulations, with costly enforcing bureaucracies, reflects the tendency of legislatures to give some satisfaction to the substantial minority of convinced opponents of alcohol and the tendency of segments of the drinking population—and even of some people in the liquor trade—to accept the naïve notions of the anti-alcoholists that these regulations do some good.

Though not significantly influenced by governmental efforts, the rate and severity of alcohol problems have indeed been influenced by nongovernmental movements and agencies. The most obvious example is the success of religious movements, such as Buddhism, Islām, and numerous Christian denominations and sects, in confirming their followers as total abstainers. The Methodist and Baptist denominations, the Quakers, the Mormons, the Christian Scientists, the Seventh-day Adventists, and the Jehovah's Witnesses are examples of Christian churches that have made abstinence a condition of loyal membership, though the Methodist Church has modified its stand in recent times. Other Christian denominations, such as the Congregationalists, have advocated abstinence without making it a requirement. Though not formally allied with these churches, the Woman's Christian Temperance Union (WCTU) and other temperance societies, particularly in the United States, once drew much support from them. In several European countries the abstinence movement also drew some support from the Socialist-influenced labour movement and found some organizational expression in the form of fraternal orders, particularly the Order of Good Templars. The importance of the religious orientation is indicated by the relatively larger proportion of abstainers in the United States than in countries where the ideal was more largely politically motivated. The decline in the numbers of abstainers in recent times may reflect the changing character of religious adherence.

THE NEW SCIENTIFIC ORIENTATION

In the past generation the character and influence of citizen movements have changed markedly. Whereas in former times the personnel, teaching aids, and ideologies of the temperance movement had generally dominated the research and education regarding alcohol, the tendency now is toward deriving objective information from academic and scientific sources. Among the major efforts to bring a scientific orientation to bear on the consideration of alcohol problems has been the founding of a systematic documentation and publication of the biological and social-science knowledge of the entire world; this is now a function of the Center of Alcohol Studies at Rutgers University in New Brunswick, New Jersey. The new trend had its repercussions also on international cooperation. The International Bureau Against Alcoholism, founded in 1907, became, in 1964, the International Council on Alcohol and Alcoholism—more recently renamed the Inter-

Internation-
al concern

national Council on Alcohol and Addictions. The change of name represented a change in aims and policies, from total opposition to any drinking to advocacy of an objective consideration of alcohol problems. This change was manifested also in the character of the international congresses convened by anti-alcohol organizations since 1885 and by the International Bureau since 1925. Formerly devoted essentially to descriptions of the horrible effects and denunciations of the evils of alcohol, beginning with the 26th Congress in 1960 the program has been infiltrated by presentations from the scientific-academic world, and the 28th Congress in Washington, D.C., in 1968 was marked by the total absence of representation from the remnants of the old temperance movement; the papers and lectures offered by representatives of religious organizations and societies were on an equal level of scholarship and objectivity with those from the scientific and academic community.

These developments, in turn, have had repercussions in government activities. In the United States and Canada they have led to the establishment of some 55 state and provincial agencies, some independent, most attached to departments of health or mental health, with missions chiefly to provide treatment for alcoholics but often also to participate in education and occasionally to engage in research. A few county and city agencies have also been created. On the federal level in the United States, a National Institute on Alcohol Abuse and Alcoholism has been established, and the Department of Transportation is engaged in a program aimed to reduce the alcohol-and-traffic problem. Other governments have shown recognition of the potential of newer, science-oriented approaches and have supported research and education as well as therapeutic activities, sometimes through special institutions such as the Canadian Addiction Research Foundation, supported by the province of Ontario; the Finnish Foundation for Alcohol Studies; the Norwegian National Institute for Alcohol Research; and the Northern Committee for Alcohol Research, with membership from all the Scandinavian countries. The new ferment discernible in the late 20th century in the field of alcohol problems is thus far stimulated mainly by concern over the human and economic costs of existing problems and the aim to alleviate them. The idea that only the prevention of alcohol problems or that only the reduction of the numbers of persons who become newly involved in alcohol problems can effect permanent gains is universally given lip service but rarely is the object of direct effort. This is owing to two facts: those who have been chiefly involved in bringing about the new ferment have been inspired mainly by the humanitarian and economic motive to bring relief to those who are already suffering from the consequences of alcohol problems, and practical new methods of prevention, going beyond scattershot education, have yet to be invented.

(M.Ke.)

PSYCHOTROPIC DRUGS

Characteristics of drug use and abuse

THE FUNCTIONS OF PSYCHOTROPIC DRUGS

To consider drugs only as medicinal agents or to insist that drugs be confined to prescribed medical practice is to fail to understand man. The remarks of the American sociologist Bernard Barber are poignant in this regard:

Not only can nearly anything be called a "drug," but things so called turn out to have an enormous variety of psychological and social functions—not only religious and therapeutic and "addictive," but political and aesthetic and ideological and aphrodisiac and so on. Indeed, this has been the case since the beginning of human society. It seems that always and everywhere drugs have been involved in just about every psychological and social function there is, just as they are involved in every physiological function.

The enhancement of aesthetic experience is regarded by many as a noble pursuit of human beings. Although there

is no general agreement on either the nature or the substance of aesthetics, certain kinds of experience have been highly valued for their aesthetic quality. To Schopenhauer (*The World as Will and Representation*), contemplation was the one requisite of aesthetic experience; a kind of contemplation that enables one to become so absorbed in the quality of what is being presented to the senses that the "Will" becomes still and all needs of the body silent. Drugs reportedly foster this kind of Nirvana and are so used by many today. For Nietzsche (*Birth of Tragedy*), man is able to lose his futile individuality in the mystic ecstasy of universal life under the Dionysiac spell of music, rhythm, and dance. The American Indians with their peyote and modern jazz musicians with their marijuana have discovered this kind of Dionysian ecstasy without formal knowledge of aesthetics.

Love is a highly valued human emotion. Thus, not surprisingly, there has been a great deal of preoccupation with

Anesthetic
and hallu-
cinogenic
functions

the feeling of love and with those conditions believed to enhance the attainment of love. Little is known concerning the aphrodisiac action of certain foods and drugs, but both have been associated in people's minds with the increased capacity for love. Though the physiological effects may be doubtful, the ultimate effect in terms of one's feeling of love is probably a potent incentive for the repetition of the experience and for those conditions believed to have produced the experience. Hallucinogenic substances such as LSD are said by many to induce a feeling of lovingness. But what the drug user regards as love and what persons around him regard as love in terms of the customary visible signs and proofs often do not coincide. Even so, it is plausible that the dissipation of tensions, the blurring of the sense of competition, the subsidence of hostility and overt acts of aggression—all have their concomitant effect on the balance between the positive and negative forces within the individual, and, if nothing else, the ability of drugs to remove some of the hindrances to loving is valued by the user.

Native societies of the Western Hemisphere have utilized, apparently for thousands of years, plants containing hallucinogenic substances. The sacred mushrooms of Mexico were called "God's flesh" by the Aztecs. During the 19th century, the Mescalero Apaches of the southwestern United States practiced a peyote rite that was adopted by many of the Plains tribes. Psychedelic drugs have the unusual ability to evoke at least one kind of a mystical-religious experience, and positive change in religious feeling is a common finding in studies of the use of these drugs. Whether they are also capable of producing religious lives is an open question. Their supporters argue that the drugs appear to enhance personal security and that from self-trust may spring trust of others and that this may be the psychological soil for trust in God. In the words of Aldous Huxley (*The Doors of Perception*): "When, for whatever reason, men and women fail to transcend themselves by means of worship, good works and spiritual exercise, they are apt to resort to religion's chemical surrogates."

William James (*The Varieties of Religious Experience*) observed at the turn of the century that "Our normal waking consciousness, rational consciousness as we call it, is but one special type of consciousness, whilst all about it, parted from it by the filmiest of screens, there lie potential forms of consciousness entirely different." Some people deliberately seek this other consciousness through the use of drugs; others come upon them by accident while on drugs. Only certain people ever have such a consciousness-expanding (psychedelic) experience in its fullest meaning, and the question of its value to the individual must be entirely subjective. For many people, the search for the psychedelic experience is less a noble aim and more the simple need of a psychic jolt or lift. Human conduct is a paradox of sorts. Although people go to great lengths to produce order and stability in their lives, they also go to great lengths to disrupt their sense of equanimity, sometimes briefly, sometimes for extended periods of time. It has been asserted that there are moments in everyone's life when uncertainty and a lack of structure are a source of threat and discomfort, and moments when things are so structured and certain that unexpectedness can be a welcome relief. Whatever the reason, people everywhere and throughout history have deliberately disrupted their own consciousness, the functioning of their own ego. Alcohol is and has been a favourite tool for this purpose. With the rediscovery of some old drugs and the discovery of some new ones, people now have a wider variety of means for achieving this end.

Many persons face situations with which, for one reason or another, they cannot cope successfully, and in the pressure of which they cannot function effectively. Either the stresses are greater than usual or the individual's adaptive abilities are less than sufficient. In either instance, there are a variety of tranquillizing and energizing drugs that can provide psychological support. This is not chemotherapy in its more ideal sense, but it does enable large numbers of persons to face problems that they might not have otherwise been able to face. Some situations or stresses are beyond the control of the individual, and some

individuals simply find themselves far more human and productive with drugs than without drugs. An enormous amount of drug support goes on by way of such familiar home remedies as the aspirin bottle, the luncheon cocktail, and the customary evening drink without anyone calling it that. There is no clear dividing line between drug support and drug therapy. It is all therapy of sorts, but deliberate drug manipulation is a cut different from drug buffering, and much of the psychological support function is just that—taking the "raw edge" off of stress and stabilizing responses.

The therapeutic use of drugs is so obvious as to require little explanation. Many of the chemical agents that affect living protoplasm are not capable of acting on the brain, but some of those that do are important in medical therapeutics. Examples are alcohol, the general anesthetics, the analgesic (pain-killing) opiates, and the hypnotics, which produce sleep—all classified as central-nervous-system depressants. Certain other drugs, such as strychnine, nicotine, picrotoxin, caffeine, cocaine, and the amphetamines, stimulate the nervous system. Most drugs truly useful in the treatment of mental illness, however, were unknown to science until the middle of the 20th century. With the discovery of reserpine and chlorpromazine, some of the major forms of mental illness, especially the schizophrenias, became amenable to chemotherapeutic treatment. These tranquillizing drugs seem to reduce the incidence of certain kinds of behaviour, particularly hyperactivity and agitation. A second group of drugs has achieved popularity in the management of milder psychiatric conditions, particularly those in which patients manifest anxiety. This group includes drugs that have a mild calming or sedative effect and that are also useful in inducing sleep. Not all drugs in psychiatric use have a tranquillizing action. The management of depression requires a different pharmacological effect, and the drugs of choice have been described as being euphorizing, mood-elevating, or antidepressant, depending on their particularly pharmacological properties. There are also drugs useful in overactive states such as epilepsy and Parkinsonism. The so-called psychedelic drugs also may have therapeutic uses.

Drugs have other functions that are not so intimately related to individual use. Several important early studies in physiology were directed toward understanding the site and mode of action of some of these agents. Such studies have proved indispensable to the understanding of basic physiology, and drugs continue to be a powerful research tool of the physiologist. The ability of drugs to alter mental processes and behaviour affords the scientist the unique opportunity to manipulate mental states or behaviour in a controlled fashion. The use of LSD to investigate psychosis and the use of scopolamine to study the retention of learning are examples. The use of drugs as potential instruments of chemical and biological warfare has received wide public attention and scorn, yet it has been studied and pursued by many nations and powers. The political use of drugs is a frightening possibility. Whether as a "truth serum," a "brainwashing" technique, a way of destroying certain stable elements of culture, or a way of reducing entire societies to a tranquil slavery, this aspect of drug use should be viewed with alarm because all such uses are obviously possible.

THE NATURE OF DRUG ADDICTION AND DEPENDENCE

If opium were the only drug of abuse, and the only kind of abuse were one of habitual, compulsive use, discussion of addiction might be a simple matter. But opium is not the only drug of abuse, and there are probably as many kinds of abuse as there are drugs to abuse, or, indeed, as maybe there are persons who abuse. Various substances are used in so many different ways by so many different people for so many different purposes that no one view or one definition could possibly embrace all the medical, psychiatric, psychological, sociological, cultural, economic, religious, ethical, and legal considerations that have an important bearing on addiction. Prejudice and ignorance have led to the labelling of all use of nonsanctioned drugs as addiction and of all drugs, when misused, as narcotics. The continued practice of treating addiction as a single

Therapeutic functions

Stress-reducing and supportive functions

Confusion
of drug
abuse and
narcotic
addiction

entity is dictated by custom and law, not by the facts of addiction.

The tradition of equating drug abuse with narcotic addiction originally had some basis in fact. Until recent times, questions of addiction centred on the misuse of opiates, the various concoctions prepared from powdered opium. Then various alkaloids of opium, such as morphine and heroin, were isolated and introduced into use. Being the more active principles of opium, their addictions were simply more severe. More recently, new drugs such as methadone and Demerol were synthesized but their effects were still sufficiently similar to those of opium and its derivatives to be included in the older concept of addiction. With the introduction of various barbiturates in the form of sedatives and sleeping pills, the homogeneity of addictions began to break down. Then came various tranquillizers, stimulants, new and old hallucinogens, and the various combinations of each. At this point, the unitary consideration of addiction became untenable. Legal attempts at control often forced the inclusion of some nonaddicting drugs into old, established categories—such as the practice of calling marijuana a narcotic. Problems also arose in attempting to broaden addiction to include habituation and, finally, drug dependence. Unitary conceptions cannot embrace the diverse and heterogeneous drugs currently in use.

Popular misconceptions. The bewilderment that the public manifests whenever a serious attempt is made to differentiate states of addiction or degrees of abuse probably stems from two all-too-common misconceptions concerning drug addiction. The first involves the stereotype that a drug user is a socially unacceptable criminal. The carry-over of this conception from olden times is easy to understand but not very easy to accept today. Ironically, the so-called dope fiend, if indeed one does exist, is likely to be a person who is not using an opiate. The depressant action of opium and its derivatives is simply not consistent with the stereotype. The second misconception involves the naive belief that there is something magically druglike about a drug, which makes a drug a drug. Many substances are capable of acting on a biological system, and whether a particular substance comes to be considered a drug depends, in large measure, upon whether it is capable of eliciting a “druglike” effect that is valued by the user. There is nothing intrinsic to the substances themselves that sets one active substance apart from other active substances; its attribute as a drug is imparted to it by use. Caffeine, nicotine, and alcohol are clearly drugs, and the habitual, excessive use of coffee, tobacco, or an alcoholic drink is clearly drug dependence if not addiction. The same could be extended to cover tea, chocolates, or powdered sugar, if society wished to use and consider them that way. The task of defining addiction, then, is the task of being able to distinguish between opium and powdered sugar while at the same time being able to embrace the fact that both can be subject to abuse. This requires a frame of reference that recognizes that almost any substance can be considered a drug, that almost any drug is capable of abuse, that one kind of abuse may differ appreciably from another kind of abuse, and that the effect valued by the user will differ from one individual to the next for a particular drug, or from one drug to the next drug for a particular individual. This kind of reference would still leave unanswered various questions of availability, public sanction, and other considerations that lead people to value and abuse one kind of effect rather than another at a particular moment in history, but it does at least acknowledge that drug addiction is not a unitary condition.

Char-
acteristics
of the
develop-
ment of
tolerance

Physiological effects of addiction. Certain physiological effects are so closely associated with the heavy use of opium and its derivatives that they have come to be considered characteristic of addictions in general. Some understanding of these physiological effects is necessary in order to appreciate the difficulties that are encountered in trying to include all drugs under a unitary definition that takes as its model opium. *Tolerance* is a physiological phenomenon that requires the individual to use more and more of the drug in repeated efforts to achieve the

same effect. At a cellular level this is characterized by a diminishing response to a foreign substance (drug) as a result of adaptation. Although opiates are the prototype, a wide variety of drugs elicit the phenomenon of tolerance, and drugs vary greatly in their ability to develop tolerance. Opium derivatives rapidly produce a high level of tolerance; alcohol and the barbiturates a very low level of tolerance. Tolerance is characteristic for morphine and heroin and, consequently, is considered a cardinal characteristic of narcotic addiction. In the first stage of tolerance, the duration of the effects shrinks, requiring the individual to take the drug either more often or in greater amounts to achieve the effect desired. This stage is soon followed by a loss of effects, both desired and undesired. Each new level quickly reduces effects until the individual arrives at a very high level of drug with a correspondingly high level of tolerance. Man can become almost completely tolerant to 5,000 milligrams of morphine per day, even though a “normal,” clinically effective dosage for the relief of pain would fall in the 5 to 20 milligram range. An addict can achieve a daily level that is nearly 200 times the dose that would be dangerous for a normal, pain-free adult.

Tolerance for a drug may be completely independent of the drug's ability to produce *physical dependence*. There is no wholly acceptable explanation for physical dependence. It is thought to be associated with central-nervous-system depressants, although the distinction between depressants and stimulants is not as clear as it was once thought to be. Physical dependence manifests itself by the signs and symptoms of abstinence when the drug is withdrawn. All levels of the central nervous system appear to be involved, but a classic feature of physical dependence is the “abstinence” or “withdrawal” syndrome. If the addict is abruptly deprived of a drug upon which the body has physical dependence, there will ensue a set of reactions, the intensity of which will depend on the amount and length of time that the drug has been used. If the addiction is to morphine or heroin, the reaction will begin within a few hours of the last dose and will reach its peak in one to two days. Initially, there is yawning, tears, a running nose, and perspiration. The addict lapses into a restless, fitful sleep and, upon awakening, experiences a contraction of pupils, gooseflesh, hot and cold flashes, severe leg pains, generalized body aches and constant movement. The addict then experiences severe insomnia, nausea, vomiting, and diarrhea. At this time he has a fever, mild high blood pressure, loss of appetite, dehydration, and a considerable loss of body weight. These symptoms continue through the third day and then decline over the period of the next week. There are variations in the withdrawal reaction for other drugs; in the case of the barbiturates, minor tranquillizers, and alcohol, withdrawal may be more dangerous and severe. During withdrawal, drug tolerance is lost rapidly. The withdrawal syndrome may be terminated at any time by an appropriate dose of the addicting drug.

Addiction, habituation, and dependence. The traditional distinction between “addiction” and “habituation” centres on the ability of a drug to produce tolerance and physical dependence. The opiates clearly possess the potential to massively challenge the body's resources, and, if so challenged, the body will make the corresponding biochemical, physiological, and psychological readjustment to the stress. At this point, the cellular response has so altered itself as to require the continued presence of the foreign substance (drug) to maintain normal function. When the substance is abruptly withdrawn or blocked, the cellular response becomes abnormal for a time until a new readjustment is made. The key to this kind of conception is the massive challenge that requires radical adaptation. Some drugs challenge easily, but it is not so much whether a drug can challenge easily as it is whether the drug was actually taken in such a way as to present the challenge. Drugs such as caffeine, nicotine, bromide, the salicylates, cocaine, amphetamine and other stimulants, certain tranquillizers and sedatives are normally not taken in sufficient amounts to present the challenge. They typically but not necessarily induce a strong need or craving emotionally or psychologically without producing the physical dependence that is associated with “hard” addiction. Con-

Physical
depend-
ence

Distinc-
tions
between
addiction
and
habitua-
tion

sequently, their propensity for potential danger is judged to be less, so that continued use would lead one to expect habituation but not addiction. The key word here is *expect*. These drugs, in fact, are used excessively on occasion and, when so used, do produce tolerance and withdrawal signs. Morphine, heroin, other synthetic opiates, and to a lesser extent codeine, alcohol, and the barbiturates, all carry a high propensity for potential danger in that all are easily capable of presenting a bodily challenge. Consequently, they are judged to be addicting under *continued* use. The ultimate effect of a particular drug, in any event, depends as much or more on the setting, the expectation of the user, his personality, and the social forces that play upon him, as it does on the pharmacological properties of the drug itself.

Enormous difficulties have been encountered in trying to apply these definitions of *addiction* and *habituation* because of the wide variations in the pattern of use. (The one common denominator in drug use is variability.) As a result, in 1964 the World Health Organization recommended a new standard that replaces both the term drug addiction and the term drug habituation with the term drug dependence. Drug dependence is defined as a state arising from the repeated administration of a drug on a periodic or continual basis. Its characteristics will vary with the agent involved, and this must be made clear by designating drug dependence as being of a particular type—that is, drug dependence of morphine type, of cannabis type, of barbiturate type, and so forth. As an example, drug dependence of a cannabis (marijuana) type is described as a state involving repeated administration, either periodic or continual. Its characteristics include (1) a desire or need for repetition of the drug for its subjective effects and the feeling of enhancement of one's capabilities that it effects, (2) little or no tendency to increase the dose since there is little or no tolerance development, (3) a psychic dependence on the effects of the drug related to subjective and individual appreciation of those effects, and (4) absence of physical dependence so that there is no definite and characteristic abstinence syndrome when the drug is discontinued.

Considerations of tolerance and physical dependence are not prominent in this new definition, although they are still conspicuously present. Instead, the emphasis tends to be shifted in the direction of the psychological or psychiatric makeup of the individual and the pattern of use of the individual and his subculture. Several considerations are involved here. There is the concept of psychological reliance in terms of both a sense of well-being and a permanent or semipermanent pattern of behaviour. There is also the concept of gratification by chemical means that has been substituted for other means of gratification. In brief, the drug has been substituted for adaptive behaviour. Terms such as hunger, need, craving, emotional dependence, habituation or psychological dependence tend to connote a reliance on a drug as a substitute gratification in the place of adaptive behaviour.

Psychological dependence. Several explanations have been advanced to account for the psychological dependence on drugs, but as there is no one entity called addiction, so there is no one picture of the drug user. The great majority of addicts display "defects" in personality. Several legitimate motives of man can be fulfilled by the use of drugs. There is the relief of anxiety, the seeking of elation, the avoidance of depression, and the relief of pain. For these purposes, the several potent drugs are equivalent, but they do differ in the complications that ensue. Should the user develop physical dependence, euphoric effects become difficult to attain, and the continued use of the drug is apt to be aimed primarily at preventing withdrawal symptoms.

It has been suggested that drug use can represent a primitive search for euphoria, an expression of prohibited infantile cravings, or the release of hostility and of contempt; the measure of self-destruction that follows can constitute punishment and the act of expiation. This type of psychodynamic explanation assumes that the individual is predisposed to this type of psychological adjustment prior to any actual experience with drugs. It has also been

suggested that the type of drug used will be strongly influenced by the individual's characteristic way of relating to the world. The detached type of person might be expected to choose the "hard" narcotics to facilitate indifference and withdrawal from the world. Passive and ambivalent types might be expected to select sedatives to assure a serene dependency. Passive types of persons who value independence might be expected to enlarge their world without social involvement through the use of hallucinogenic drugs, whereas the dependent type of person who is geared to activity might seek stimulants. Various types of persons might experiment with drugs simply in order to play along with the group that uses drugs; such group identification may be joined with youthful rebellion against society as a whole. Obviously, the above descriptions are highly speculative because of the paucity of controlled clinical studies. The quest of the addict may be the quest to feel full, sexually satisfied, without aggressive strivings, and free of pain and anxiety. Utopia would be to feel normal, and this is about the best that the narcotic addict can achieve by way of drugs.

Although many societies associate addiction with criminality, most civilized countries regard addiction as a medical problem to be dealt with in appropriate therapeutic ways. Furthermore, narcotics fulfill several socially useful functions in those countries that do not prohibit or necessarily censure the possession of narcotics. An old League of Nations report said: "The social and hygienic conditions under which a great part of the working classes in the Far East live are of so low a standard that these classes of people strive to find some form of diversion permitting them to forget at least for some moments the hardships of life." In addition to relieving mental or physical pain, opiates have been used medicinally in tropical countries where large segments of the population suffer from dysentery and fever.

HISTORY OF DRUG CONTROL

The first major national efforts to control the distribution of narcotic and other dangerous drugs were the efforts of the Chinese in the 19th century. Commerce in poppy (opium) and coca leaf (cocaine) developed on an organized basis during the 1700s. The Manchus of China attempted to discourage opium importation and use, but the English East India Company, which maintained an official monopoly over British trade in China, was engaged in the profitable export of opium from India to China. This monopoly of the China trade was eventually abolished in 1839–42, and friction increased between the British and the Chinese over the importation of opium. Foreign merchants, including those from France and the United States, were bringing in ever-increasing quantities of opium. Finally, the Manchu government required all foreign merchants to surrender their stocks of opium for destruction. The British objected, and the Opium War (1839–42) between the Chinese and the British followed. The Chinese lost and were forced into a series of treaties with England and other countries that took advantage of the British victory. In 1858 the importation of opium into China was legalized by the Treaty of Tientsin, which fixed a tariff rate for opium importation. Further difficulties followed. An illegal opium trade carried on by smugglers in south China encouraged gangsterism and piracy, and the activity eventually became linked with powerful secret societies in the south of China.

International controls. Throughout the 1800s, the Chinese government considered opium an important moral and economic question, but obviously China needed international help. In 1909, U.S. President Theodore Roosevelt proposed an international investigation of the opium problem; a meeting of 13 nations held in Shanghai in the same year resulted in recommendations that formed the basis of the first opium convention held at The Hague in 1912. Ratification of the Hague Convention occurred during the meetings of 1913 and 1914. Although further regulatory activity was suspended during the course of World War I, ratification of the Versailles peace treaties of 1919–20 also constituted a ratification of the Hague Convention of 1912. The League of Nations was then given respon-

efforts

sibility to supervise agreements with regard to the traffic in opium and other dangerous drugs. A further important development in drug control was the convention of 1925, which placed further restrictions on the production and manufacture of narcotics. Six more international conventions and agreements were concluded between 1912 and 1936.

Under a Protocol on Narcotic Drugs of December 1946 the functions of the League of Nations and of the Office International d'Hygiène Publique were transferred to the United Nations and to the World Health Organization. In 1948 a protocol extended the control system to synthetic and natural drugs outside the scope of the earlier conventions. In 1953 a further protocol was adopted to limit and regulate the cultivation of the poppy plant and the production of, or international and wholesale trade in, and use of opium. Before the protocol became operative in 1963 the international control organs found a need for codifying and strengthening the existing treaties, and a Single Convention on Narcotic Drugs was drawn up in New York in 1961. This Convention drew into one comprehensive control regime all the earlier agreements, limited the use of coca leaves and cannabis to medical and scientific needs, and paved the way for the International Narcotics Control Board. The Convention came into force in 1964, and the new board began duty in 1968.

National controls. The United States is perhaps the nation most preoccupied with drug control, and it is largely the "Americanized" countries that have made narcotics regulation a matter of public policy with the consequent network of laws, criminal detection agencies, and derived social effects. The principal U.S. legislation has been the Harrison Narcotics Act of 1914, the Opium Poppy Control Act of 1942, and the Narcotic Drug Control Act of 1956; the Drug Abuse Control Amendment of 1965 added controls over depressant, stimulant, and hallucinogenic drugs not covered under the other narcotic control acts. Manufacturers and distributors are required to register with the U.S. Food and Drug Administration, retail dealers are required to keep inventories, and physicians are required to limit the period of prescription and the number of refills permitted. Heroin manufacture was prohibited in the United States in 1924, and by 1956 all heroin legally held in the United States was surrendered to the government. The legal use of heroin is practically nonexistent today anywhere in the world—largely because of the action of the League of Nations.

Great Britain controls the manufacture, distribution, and sale of narcotics through the Dangerous Drug Act of 1920. The British system, however, is based on a public policy position different from that of the United States, and narcotic addiction has remained a minor social problem. In 1967, England placed the prescription of narcotics under the control of the National Health Service and its associated clinics. Canada and Japan attempt to control narcotics in much the same manner as the United States with much the same consequence in terms of high rates of addiction. Opium traffic appears to still flourish in Asia, but the East has officially gone through a period of regulation, governmental monopoly over cultivation, and finally prohibition of use.

Extent of contemporary drug abuse. Complete and reliable data on the extent of drug abuse in recent years is simply not available. To specify the size and extent of the drug problem, accurate information as to manufacture, distribution, and sale of drugs would be needed. Complete evaluation would also require knowledge of the incidence of habituation and addiction in the general population, the number of persons admitted to hospitals because of drug intoxication, and the number of arrests for drug sales that do not conform to the law. This kind of determination is not possible under existing laws even for the legitimate sources of drugs. Unfortunately, much of the drug traffic is from uncontrolled, illicit sources, and here there is an almost total absence of reliable information. Black market diversion of drugs may occur at any point from the manufacture of basic chemicals used to synthesize the drugs, through the process of actually preparing the drug, to the distribution of the final drug form, to the retail drugstore,

or even the physician. This is a complex chain involving chemical brokers, exporters, and dealers in addition to those who have more direct involvement with the drug process. Finally, there is the problem of currentness. Time is involved in reporting at each level of information, and the final data may be no more recent than three to five years, and a basic source or reference work may contain figures that have suffered a decade of delay from the actual occurrence of the drug abuse. Drug abuse patterns change over a relatively short time. In the 1960s, the youthful drug abuser tended to use a drug that increased the level of consciousness. In contrast, it had been only a short time earlier that youthful drug abuse involved only the hypnotics and alcohol, which depress consciousness and blunt experience.

The U.S. Federal Bureau of Narcotics maintains a register of so-called active addicts who in the early 1970s numbered approximately 60,000 persons; the actual number of narcotic addicts in the United States was probably closer to 120,000 persons. With the exception of Germany, other European countries have relatively small numbers of narcotic addicts. In the Middle and Far East, the highest rates are found in Egypt, India, and Iran, with lesser rates for Borneo, Burma, China, Japan, and Korea. Opium cultivation has been declining in each of the last several years and is found chiefly in Asia. India, the U.S.S.R., and Turkey accounted for almost the total output of opium as reported to the United Nations. Bolivia and Peru are the chief producers of coca leaf (for cocaine).

The extent of problems involving other drugs can only be guessed from certain superficial indicators. It is probable that about half the production of amphetamines is diverted into illegal channels. Barbiturates are the leading mode of suicide in the U.S., accounting for over several thousand deaths each year.

The varieties of psychotropic drugs

OPIUM, MORPHINE, HEROIN, AND RELATED SYNTHETICS

The opiates are unrivalled in their ability to relieve pain. Opium is the dried milky exudate obtained from the unripe seed pods of the poppy plant (*Papaver somniferum*), which grows naturally throughout most of Asia Minor. Of the 20 or more alkaloids found in opium, only a few are pharmacologically active. The important constituents of opium are morphine (10 percent), papaverine (1 percent), codeine (0.5 percent), and thebaine (0.2 percent). (Papaverine is pharmacologically distinct from the narcotic agents and is essentially devoid of effects on the central nervous system.) In 1803 a young German apothecary's assistant named Sertürner isolated crystalline morphine as the active analgesic principle of opium. Codeine is considerably less potent ($1/6$) and is obtained from morphine. Diacetylmorphine—or heroin—was developed from morphine by the Bayer Company of Germany in 1898 and is five to 10 times as potent as morphine itself. Opiates are not medically ideal. Tolerance is developed quite rapidly and completely in the more important members of the group, morphine and heroin, and they are highly addictive. In addition, they produce respiratory depression and frequently cause nausea and emesis. As a result, there has been a constant search for synthetic substitutes: meperidine (Demerol), first synthesized in Germany in 1939, is a significant addition to the group of analgesics, being one-tenth as potent as morphine; alphaprodine (Nisentil) is one-fifth as potent as morphine but is rapid-acting; methadone, synthesized in Germany during World War II, is comparable to morphine in potency; levorphanol (Levo-Dromoran) is an important synthetic with five times the potency of morphine. These synthetics exhibit a more favourable tolerance factor than the more potent of the opiates, but they fall short of an ideal analgesic in being addictive. Of this entire series, codeine has the least addiction potential and heroin has the greatest (see also DRUGS AND DRUG ACTION: *Narcotic*).

History. The narcotic and sleep-producing qualities of the poppy have been known to humankind throughout recorded history. Sumerian records from the time of Mesopotamia (5000 to 4000 bc) refer to the poppy, and

and related
synthetics

Problems
in
measuring
distribu-
tion
and use

medicinal reference to opium is contained in Assyrian medical tablets. Homer's writings indicate Greek usage of the substance at least by 900 BC; Hippocrates (c. 400 BC) made extensive use of medicinal herbs including opium. The Romans probably learned of opium during their conquest of the eastern Mediterranean; Galen (AD 130–200) was an enthusiastic advocate of the virtues of opium, and his books became the supreme authority on the subject for hundreds of years. The art of medicinals was preserved by the Islamic civilization following the decline of the Roman Empire; opium was introduced by the Arabs to Persia, China, and India. Paracelsus (1493–1541), professor at the University of Basel, introduced laudanum, the modern tincture of opium. Le Mort, a professor of chemistry at the University of Leyden (1702–18), discovered paregoric, useful for the control of diarrhea, by combining camphor with tincture of opium.

19th-century medical uses of opiates

There is no adequate comprehensive history of the addictive aspects of opium use in spite of the fact that it has been known since antiquity. Because there were few alternative therapeutics or painkillers until the 19th century, opium was somewhat of a medical panacea. Thus, although at least one account in 1701, by a London physician named Jones, spoke of an excessive use of opium, there appears to have been no real history of concern until recent times, and opiates were easily available in the West in the 19th century, for instance, in a variety of patent medicines. Physicians prescribed them freely, they were easy to obtain without prescription, and they were used by all social classes. At one time, the extensive use of these medicines for various gynecological difficulties probably accounted for the high addiction rate among women (three times the rate among men). Today, in the United States, only one addict out of six is a woman. The invention of the hypodermic needle in the mid-19th century, and its subsequent use to administer opiates during wartime produced large numbers of addicted soldiers (about 400,000 during the U.S. Civil War alone); it was thought mistakenly that if opiates were administered by vein, no hunger or addiction would develop, since the narcotic did not reach the stomach. Toward the end of the 19th century, various "undesirables" such as gamblers and prostitutes began to be associated with the use of opiates, and narcotics became identified more with the so-called criminal element than with medical therapy. By the turn of the 20th century, narcotic use had become a worldwide problem, and various national and international regulatory bodies sought to control traffic in opium from the Near and Far East.

20th-century patterns of use

In the 20th century, until recently, narcotic use was largely associated with metropolitan slums, principally among poor and culturally deprived. Currently, narcotic use has begun to spread to middle class youth, and, interestingly, there is evidence that the middle class is now beginning to look at narcotic addiction as a mental health problem. When it was confined to the slums, it was considered a police problem.

Physiological effects. The various opiates and related synthetics all produce about the same physiological effects. All are qualitatively similar to morphine in action and differ from each other mainly in degree. The most long-lasting and conspicuous physiological responses are obtained from the central nervous system and the smooth muscle of the gastrointestinal tract. These effects, while restricted, are complex and vary with the dosage and the route of administration (intravenous, subcutaneous, oral). Both depressant and stimulant effects are elicited. The depressant action involves the cerebral cortex, with a consequent narcosis, general depression, and reduction in pain perception; it also involves the hypothalamus and brain stem, inducing sedation, the medulla, with associated effects on respiration, the cough reflex, and the vomiting centre (late effect). The stimulant action involves the spinal cord and its reflexes, the vomiting centre (early effect), the tenth cranial nerve with a consequent slowing of the heart, and the third cranial nerve resulting in pupil constriction. Associated effects of these various actions include nausea, vomiting, constipation, itchiness of the facial region, yawning, sweating, flushing of skin, a

warm sensation in the stomach, fall in body temperature, diminished respiration, and heaviness in the limbs.

The most outstanding effect of the opiates is one of analgesia. All types of pain perception are affected, but the best analgesic response is obtained in relieving dull pain. The analgesic effects increase with increasing doses until a limit is reached beyond which no further improvement is obtained. This point may fall just short of complete relief.

Opiates as analgesics and depressants

Depression of cortical function results in a euphoric response involving a reduction of fear and apprehension, a lessening of inhibitions, an expansion of ego, and an elevation of mood that combine to enhance the general sense of well-being. Occasionally in pain-free individuals, the opposite effect, dysphoria, occurs and there is anxiety, fear, and some depression. In addition to analgesia and associated euphoria, there is drowsiness, mental and physical impairment, a clouding of consciousness, poor concentration and attention, reduced hunger or sex drives, and sometimes apathy.

Apart from their addiction liability, respiratory depression leading to respiratory failure and death is the chief hazard of these drugs. All of the more potent opiates and synthetics produce rapid tolerance, and tolerance to one member of this group always is associated with tolerance to the other members of the group (cross-tolerance). The more potent members of the group have a very great addiction liability with the associated physical dependence and abstinence syndrome.

Types of users. There is no single narcotic addict personality type: addiction is not a unitary phenomenon occurring in a single type. The great variation in addiction rates and classes of addicts in various countries caution against placing too great an emphasis on personality variables as major causative factors. Even within the United States, there is great danger in generalizing from the cases of the patients found at the public health service hospitals in Lexington, Kentucky, and in Fort Worth, Texas. These inmates are a highly select group of adults who have spent previous time in correctional institutions. They are not representative of the adolescent addict or the adult addict who has not had continual difficulty with the law. The United States has recently experienced a new type of slum-dwelling addict who is a member of a closely knit adolescent gang. This subculture is highly tolerant of drug abuse, and the members have ready access to narcotic drugs. They do not actively seek the opportunity to try heroin; neither are they deliberately "hooked" on heroin by adult drug peddlers. They are initiated to narcotic use by friends, gang members, or neighbourhood acquaintances, and the opportunity for such use is almost always casual but ever present. This "kicks" user is apt to abandon narcotics when gang membership is abandoned. The chronic user is more likely to be the immature adolescent at the periphery of gang activities who uses narcotics for their adjustive value in terms of his deep-seated personality problems. He does not abandon drug use for the more conventional pursuits when he enters adulthood. Instead, old ties are severed; interest in previous friendships is withdrawn; athletic and scholastic strivings are abandoned; competitive, sexual, and aggressive behaviour becomes markedly reduced, and he retreats further into his drug-induced state. Identification is now with the addict group: a special culture with a special language. The addict's world revolves around obtaining drugs.

Means of administration and their effects. Most persistent users follow a classic progression from sniffing (similar to the oral route), to "skin popping" (subcutaneous route), to "mainlining" (intravenous route)—each step bringing more intense experience, a higher addiction liability. With mainlining, the initial "thrill" is more immediate. Within seconds, a warm, glowing sensation spreads over the body, most intense in the stomach and intestines, comparable to sexual release. This intense "rush" is then followed by a deep sense of relaxation and contentment. The user is "high" and momentarily free. It is this initial state of intense pleasure that presumably brings the novice to repeat the experience, and it is this mode of administration that hastens him on the way to drug tolerance and physical dependence. Soon he finds that the effects are not quite

Emotional and physical feelings of heroin use

there. Instead, his body is beginning to experience new miseries. At this juncture, he "shoots" to avoid discomfort. The euphoria is gone. He now spends every waking moment in obtaining further supplies to prevent the inevitable withdrawal symptoms should he fail. Habits are expensive. If indigent, the addict must spend all his time "hustling" for drugs—which means that he must steal or raise money by other means such as prostitution, procuring, or small-time narcotics peddling. An addict is judged by his success in supporting his habit. The addict always faces the danger of withdrawal, the danger of arrest, the danger of loss of available supply, the danger of infection, of collapsed veins, or of death from overdosage. Very few individuals are still addicted by the age of 40. They have either died, somehow freed themselves from their addiction, or sought treatment.

Therapy. Drug dependence can be viewed as an ethical problem: Is it right and permissible to need a narcotic agent? How one answers this question dictates the position one will take in regard to addiction therapy. In general, the addict can be given his drug, he can be placed on a substitute drug, or drugs can be barred from him. Narcotic maintenance, which gives the addict his drug, is the system employed in the management of opiate dependence in England. Methadone treatment is a drug substitution therapy that replaces opiate addiction with methadone addiction in order that the addict might become a socially useful citizen. Some drug therapy groups involve an intensive program of family-like resocialization, with total abstinence as the goal. Psychological approaches to total abstinence through reeducation involve psychotherapy, hypnosis, and various conditioning techniques that attempt to attach unpleasant or aversive associations to the thoughts and actions accompanying drug use. Each of these approaches has had successes and has limitations.

Great Britain began to control the use of narcotics in 1950 but, unlike the United States, has embraced the principle of drug maintenance. Supporters of the approach have insisted that, at least until recently, narcotic addiction in Great Britain remained a very minor problem because addiction is considered an illness rather than a crime. (In recent years, however, addiction has apparently become more widespread, for uncertain reasons.) The British physician was earlier allowed to prescribe maintenance doses of a narcotic if, in his professional judgment, the addict was unable to lead a useful life without the drug. But in 1967 the British government took the right to prescribe for maintenance addiction away from the general practitioner and placed it in the hands of drug-treatment clinics. Although some addicts must obtain legal supplies from the clinic, others are allowed to obtain supplies from a neighbourhood pharmacy and medicate themselves. These clinics also provide social and re-educative services such as psychotherapy for the addict. The general experience among these clinics has been that a large proportion of the addicts are becoming productive, socially useful members of the community.

There are two major drawbacks to the maintenance use of narcotic drugs such as employed by the British. Both the physical and the social health of the user remains unsatisfactory. A high incidence of hepatitis, bacterial endocarditis, abscesses, and, on occasion, fatal overdosage accompanies the self-administration of opiates. Socially, the addict on self-administration also tends to remain less productive than his peers—the reason apparently being that the individual on narcotic maintenance is still very preoccupied with certain aspects of narcotic use. Narcotic addiction is a two-faceted problem: the yearning for the "high" and the felt sense of not being physiologically normal. The addict on narcotic maintenance often attempts to obtain or retain both drug effects: frequent intravenous use prevents the feeling of drug hunger and maximizes his attempt to experience euphoria.

Methadone therapy aims to block the abnormal reactions associated with narcotic addiction while permitting the addict to live a normal, useful life as a fully participating member of the community. Methadone provides a "narcotic blockade" in that it is possible to increase methadone medication to a point at which large oral

doses will induce a state of cross-tolerance in which the euphoric effects of other narcotics cannot be felt even in very high doses. Additionally methadone has the ability to allay the feeling of not being right physically, which the addict finds he can correct only by repeated narcotic use. Methadone treatment, then, rests on these two pharmacological actions: the blockade of euphoric effects and the relief of "narcotic hunger." Methadone is not successful in every case (10–15 percent failure), but results, to date, have been dramatic. In various studies conducted on addicts who entered a methadone treatment program, most remained in the program, and virtually none returned to daily use of heroin. The majority either accepted employment or started school, and previous patterns of antisocial behaviour were either eliminated or significantly reduced. Methadone is a drug of addiction in its own right, but it does not have some of the more serious undesirable consequences associated with heroin.

There are various types of drug counseling units that advocate complete abstinence from drug dependency. Such drug therapy, usually involving a group of addicts, tries to promote personal growth and teach self-reliance. Individual counseling and psychotherapy may or may not be provided for the members of the group, but generally it is believed that moral support is derived from the experiences of fellow addicts and former addicts who have or are trying to become chemically independent. Success rates for various drug therapy groups vary widely.

In such countries as the United States, where the addict is treated as a criminal, physicians are prevented from administering opiates for the maintenance of addiction. Acceptable treatment includes enforced institutionalization for about four months, strict regulation against ambulatory care until the person is drug free, and the total prohibition of self-administration of drugs even under a physician's care. Estimates of cures based upon decades of these government-regulated procedures range from 1 to 15 percent.

HALLUCINOGENIC DRUGS

It is difficult to find a suitable generic name for a class of drugs having as many diverse effects as have been reported for "hallucinogens." Abnormal behaviour as profound as the swings in mood, disturbances in thinking, perceptual distortions, delusions, and feelings of strangeness that sometimes occur with these drugs is usually indicative of a major mental disorder; consequently these substances are often called psychotomimetic to indicate that their effects mimic the symptoms of a naturally occurring psychosis. There are indeed points of similarity between the drug states and the natural psychoses, but there are also many dissimilarities—so many as to make the resemblance quite superficial. Such substances as the bromides, heavy metals, belladonna alkaloids, and intoxicants can, however, cause abnormal behaviour to a degree sometimes described as psychotic, and if the list is extended to include the drugs being discussed here, then the objection—that the term psychotomimetic should refer only to the mimicking of a natural psychosis—is no longer valid. Taking this point of view, some investigators prefer the term psychotogenic ("psychosis causing"). One of the most conspicuous features of this kind of drug experience is the occurrence of the distinctive change in perception called hallucination. For this reason the term hallucinogenic is sometimes used. Most people are aware, however, even while under the influence of the drug, that their unusual perceptions have no basis in reality; so this is not a very accurate use of the term. Strictly speaking, very few people truly hallucinate as a result of taking a hallucinogen.

All these terms are borrowed from medicine and are closely identified with pathology. In this sense, all are negative. It has been suggested that these drugs be called psychedelic ("mind manifesting"). This term shifts the emphasis to that aspect of the drug experience that involves an increased awareness of one's surroundings and also of one's own bodily processes—in brief, an expansion of consciousness. The term also shifts emphasis from the medical or therapeutic aspect to the educational or mystical-religious aspect of drug experience. Only certain

therapy

Problems
of terminology and
definition
in hallucinogens

people, however, ever have a psychedelic experience in its fullest meaning, and the question of its value to the individual is entirely subjective. The possibility of dangerous consequences, too, may be masked by such a benign term. None of these terms, then, is entirely satisfactory, and one or two are distinctly misleading. (These terms are used interchangeably henceforth with no particular intent other than to indicate membership in the LSD-type family of drugs.)

Types of hallucinogens. The psychoactive substances that have aroused widespread interest and bitter controversy are the LSD-type drugs that produce marked aberrations of behaviour. The most important of these are (1) d-lysergic acid diethylamide, commonly known as LSD-25, which originally was derived from ergot (*Claviceps purpurea*), a fungus on rye and wheat; (2) mescaline, the active principle of the peyote cactus (*Lophophora williamsii*), which grows in the southwestern United States and Mexico; and (3) psilocybin and psilocin, which come from Mexican mushrooms (notably *Psilocybe mexicana* and *Stropharia cubensis*). Bufotenine, originally isolated from the skin of toads, is the alleged hallucinogenic agent contained in banana peels. It has also been isolated in the plant *Piptadenia peregrina*, the mushroom *Amanita muscaria*, and is thought to be the active principle of the hallucinogenic snuff called cohoba and yopo and used by the Indians of Trinidad and by the Otamaci Indians of the Orinoco Valley. Harmine is an alkaloid found in the seed coats of a plant (*Peganum harmala*) of the Mediterranean region and the Near East and also in a South American vine (*Banisteriopsis caapi*). There are some amides of lysergic acid contained in the seeds of the morning glory (*Rivea corymbosa*), which the Aztecs call *ololiuqui*. Synthetic compounds of interest are DMT (dimethyltryptamine) and STP (dimethoxyphenylethylamine; DOM). Cannabis (discussed separately below) is not usually included in this group of hallucinogenic drugs, but there is no particular justification for its exclusion. It is a resin obtained from the leaves and tops of the hemp plant (*Cannabis sativa*; see also DRUGS AND DRUG ACTION: *Hallucinogen*).

During the late 1970s phencyclidine (PCP), or "angel dust," emerged as a leading street hallucinogen. Developed in 1956 as an anesthetic, PCP was discontinued for human use because of its severe and unpredictable side effects, the psychological effects sometimes persisting for as long as a month. PCP, in liquid or crystal form, can be injected, inhaled, or ingested; most commonly it is sprinkled on marijuana or tobacco and smoked.

History. Native societies of the Western Hemisphere have for 2,000 years utilized various naturally occurring materials such as the "sacred" mushroom of Mexico and the peyote cactus of the southwestern United States. Scientific interest in the hallucinogenic drugs developed slowly. A neurologist wrote about his experience with peyote before the turn of the 20th century, and his account attracted the serious attention of two distinguished psychologists, Havelock Ellis and William James. Mescaline was isolated as the active principle of peyote in 1896, and its structural resemblance to the adrenal hormone epinephrine was recognized by 1919. There followed some interest in model psychoses (that is, drug-induced simulations of abnormal behaviour patterns), but it was not until 1943, when a Swiss chemist accidentally ingested a synthetic preparation of lysergic acid diethylamide and experienced its psychedelic effects, that the search for a natural substance responsible for schizophrenia became widespread. An American mycologist called attention to the powers of the Mexican mushroom in 1953, and the active principle was quickly found to be psilocybin.

Physiological and psychological effects. The psychedelics are capable of producing a wide range of subjective and objective effects; however, there is apparently no reaction that is distinctive for a particular drug. Subjects are unable to distinguish among LSD, mescaline, and psilocybin when they have no prior knowledge of the identity of the drug ingested. These drugs induce a physiological response that is consistent with the type of effect expected of a central-nervous-system stimulant. Usually there is elevation of the systolic blood pressure, dilatation of the pupils, some

facilitation of the spinal reflexes, and excitation of the sympathetic nervous system and the brain.

There is considerable difference in the potency of these drugs. A grown man requires about 500 milligrams of mescaline or 20 milligrams of psilocybin or only 0.1 milligram of LSD for full clinical effects when the substances are ingested orally. The active principle in the seeds of the morning glory is about one-tenth as potent as LSD. There are also differences in the time of onset and the duration of effects. Psilocybin acts within 20 to 30 minutes, and the effects last about five to six hours. LSD acts within 30 to 60 minutes, and the effects usually last for eight to 10 hours, although occasionally some effects persist for several days. Mescaline requires two to three hours for onset, but the effects last for more than 12 hours. All psychedelics presumably are lethal if taken in large enough quantities, but the effective dose is so low as compared to the lethal dose that death has not been a factor in experimental studies. Physiological tolerance for these drugs develops quite rapidly in man—fastest for LSD, somewhat more slowly and less completely for psilocybin and mescaline. The effects for a particular dose level of LSD are lost within three days of repeated administration, but the original sensitivity is quickly regained if several days are allowed to intervene. Cross-tolerance has been demonstrated for LSD, mescaline, psilocybin, and certain of the lysergic acid derivatives. Tolerance to one of the drugs reduces the effectiveness of an equivalent dose of a second drug, thus suggesting a common mode of action for the group.

Most persons regard the experience with one of these drugs as something totally removed from anything they have ever encountered in normal, everyday experience. The subjective effects vary greatly among individuals and, for a particular person, even from one drug session to the next. The variations seem to reflect such factors as the mood and personality of the subject, the setting in which the drug is administered, the user's expectation of a certain kind of experience, the meaning for the individual of the act of taking the drug, and his interpretation of the motives of the person who is administering the drug to him. Nevertheless, certain invariant reactions seem to stand out. The one most easily described by users is the effect of being "flooded" with visual experience, as much when the eyes are closed as when they are open. Light is greatly intensified; colours are vivid and seem to glow; images are numerous and persistent, yielding a wide range of illusions and hallucinations; details are sharp; perception of space is enhanced; and music may evoke visual impressions, or light may give the impression of sounds. A second important aspect, which people have more difficulty in describing, involves a change in the feelings and the awareness of the self. The sense of personal identity is altered. There may be a fusion of subject and object; legs may seem to shrink or become extended, and the body to float; space may become boundless and the passage of time very slow; and the person may feel completely empty inside, or he may believe that he is the universe. This type of reaction has been called depersonalization, detachment, or dissociation. Increased suspiciousness of the intentions and motives of others may also become a factor. At times the mood shifts. Descriptions of rapture, ecstasy, and an enhanced sense of beauty are readily elicited; but there can also be a "hellish" terror, gloom, and the feeling of complete isolation. For some people the experience is so disturbing that psychiatric hospitalization is required. Studies of performance on standardized tests show some reduction in reasoning and memory, but the motivation of the subject probably accounts for much of the performance decrement, since many people are uncooperative in this type of structured setting while under the influence of a drug.

Interest in these drugs was routinely scientific for the first few years following the discovery of LSD, but in the 1950s some professional groups began to explore the use of the psychedelics as adjuncts to psychotherapy and also for certain purposes of creativity. It was at this juncture, when the drugs were employed to "change" people, that they became a centre of controversy. LSD is not an approved drug in most countries; consequently its therapeutic

Subjective experiences under the influence of hallucinogens

LSD, mescaline, and psilocybin

tic applications can only be regarded as experimental. In the 1960s, LSD was proposed as an aid in the treatment of neurosis with special interest in cases recalcitrant to the more conventional psychotherapeutic procedures. LSD also was being given serious trial in the treatment of alcoholism, particularly in Canada, where experimentation is not heavily restricted. LSD has also been employed to reduce the suffering of terminally ill cancer patients. The drug was also under study as an adjunct in the treatment of narcotic addiction, of autistic children, and of the so-called psychopathic personality; and the use of various hallucinogens continue to be advocated in the experimental study of abnormal behaviour because of the degree of control that they offer.

Undesirable or dangerous effects

LSD can be dangerous when used improperly. Swings of mood, time and space distortion, "hallucinations," and impulsive behaviour are complications especially hazardous to the individual when he is alone. Driving while under the influence of one of these drugs is particularly dangerous. Acts of aggression are rare but do occur. The recorded suicide rate was not high in the various investigational (legal use) groups, but the rate of serious untoward psychological effects requiring psychiatric attention climbed steadily. These drugs do induce psychotic reactions that may last several months or longer. Negative reactions, sometimes called bad trips, are most apt to occur in unstable persons or in other persons taking very large amounts of a drug or taking it under strange conditions or in unfamiliar settings. So far as is known, these drugs are nontoxic, and there are no permanent physical effects associated with their use. There is no physical dependence or withdrawal symptom associated with long-term use, but certain individuals may become psychologically dependent on the drug, become deeply preoccupied with its use, and radically change their life-style with continued use.

A new dimension was added to the LSD controversy when laboratory studies began to appear in the scientific literature that linked LSD to chromosomal and genetic damage, thus intimating that future generations of the LSD user might be subject to the fearful issue of malformation and genetic illness. Unfortunately, there remains only the poorest understanding of exactly what has been found, to date, in such studies. The findings are neither clear nor conclusive, and moreover they involve not only LSD but also several classes of drugs in rather common use, such as aspirin, caffeine, tranquilizers, and antibiotics. The LSD chromosome story, then, is the story not just of LSD-induced changes but also of possible chromosomal and genetic damage that might be induced by wide classes of drugs in general use. If the gene pool of the LSD user is in jeopardy, as these studies suggest, then, the gene pool of the whole population is also in jeopardy, as these studies also suggest. The danger of drugs is the excessive reliance on drugs; the culprit is everywhere present.

The several types of research upon which these chromosomal and genetic findings are based are wrought with difficulties. Genetic studies that attempt to produce structural malformation use, of necessity, the experimental animal; and there is thus the basic problem of evaluating the extent to which these findings can be generalized to the human. The conditions of the experiments in general do not sufficiently parallel the conditions of natural LSD use to render the data very meaningful. The chromosomal studies present equal difficulties—trying to infer from the behaviour of a cell in the test tube how a mass of cells that are part of a living organism will act.

Proselytization among LSD users

Types of users. Prior to the mid-1960s, LSD-type drugs were taken by several different types of persons including many who were respected, successful, and well-established socially. Intellectuals, educators, medical and mental health professionals, volunteer research subjects, psychiatric patients, theological students, and participants in special drug-centre communities were some of the first users of these hallucinogenic substances. Beginning in 1966, experimentation in most countries was severely restricted, and subsequent use has been almost entirely of a black market type. LSD use is markedly on the decline, being replaced by cannabis and the amphetamines. Currently, most users tend to be of the middle class—either

young, college-educated persons or those who have drifted to the fringe of society. Drug initiation is typically by way of a personal friend or acquaintance. Employers or teachers also have a powerful influence over subordinates and students in terms of drug acceptance. The user of LSD seems often to have an almost fanatic need to proselytize others to drug use. Those who have taken a hallucinogenic substance generally have had experience with other drugs prior to the LSD experience, and there is also a tendency on the part of those who take these drugs to repeat the drug experience and to experiment with other drugs. The special language, method of proselytizing, and psychological dependence surrounding the use of psychedelics bear striking resemblance to the context of narcotics addiction. The chronic LSD user tends to be introverted and passive. Motives for LSD use are many: psychological insight; expansion of consciousness; the desire to become more loving, more creative, open, religious; a desire for new experience, profound personality change, and simple "kicks."

BARBITURATES, STIMULANTS, AND TRANQUILLIZERS

There are many sanctioned uses for drugs that exert an effect on the central nervous system. Consequently, there are several classes of nonnarcotic drugs that have come into extensive use as sleeping aids, sedatives, hypnotics, energizers, mood elevators, stimulants, and tranquilizers.

Sedatives and hypnotics differ from general anesthetics only in degree. All are capable of producing central-nervous-system depression, loss of consciousness, and death (see also DRUGS AND DRUG ACTION: *Sedative-Hypnotic Drugs*).

The barbiturates, bromides, chloral hydrate, and paraldehyde are well-known drugs—with the barbiturates being of greatest interest because of the increasing number of middle and upper class individuals who have come to rely on them for immediate relaxation, mild euphoria, and an improved sense of well-being. But alcohol has been and continues to be the drug of choice for these same effects (see also DRUGS AND DRUG ACTION: *Sedative-Hypnotic Drugs*).

Of the drugs that excite the nervous system, nicotine, caffeine, the amphetamines, and the potentially addicting cocaine are well known. The use of stimulants to facilitate attention, sustain wakefulness, and mask fatigue has made the amphetamines an increasingly popular drug by students and those who engage in mental work. Originally the drug of truck drivers, amphetamine is now a common cause of arrest among teenagers and young adults who commit drug offenses. Cocaine has always been a potentially dangerous drug, and it has become especially popular among the middle and upper classes. Stimulants do not create energy, and the energy mobilized by these drugs is eventually depleted with serious consequences (see also DRUGS AND DRUG ACTION: *Stimulant*).

The tranquilizers are a heterogeneous group, as are the behaviours that they are employed to alter. In general, tranquilizing drugs reduce hyperactivity, agitation, and anxiety, which tend to cause a loss of behavioral control. Tranquilizing drugs do not characteristically produce general anesthesia, no matter what the dose; this attribute tends to distinguish tranquilizing drugs from the barbiturates (see also DRUGS AND DRUG ACTION: *Tranquillizers*).

All the barbiturates, stimulants, and tranquilizers are widely prescribed by physicians, and all these drugs are available through nonmedical (illegal) sources. Most of these drugs are classified as "habit-forming." The minor tranquilizers are commonly associated with habituation and may induce physical dependence and severe withdrawal symptoms. The amphetamines and cocaine intoxicate at high dosages, and both are capable of inducing serious toxic and psychotic reactions under heavy use. The barbiturates are the leading cause of death by suicide. They are judged to be a danger to health by both the World Health Organization Expert Committee and the United Nations Commission on Narcotic Drugs, which have recommended strict control on their production, distribution, and use. The nonnarcotic drugs in widespread use among middle and upper class citizenry manifest considerable untoward

Dangers of barbiturates, stimulants, and tranquilizers

consequences for the individual and for society when abused—thus placing their problem in a different perspective than that normally associated with the opiates, LSD, and marijuana.

Barbiturates. The barbiturates relieve tension and anxiety at low dose levels without causing drowsiness, although some tendency toward drowsiness may be an initial reaction for the first few days on the drug. These drugs exert a selective action in small amounts on higher cortical (brain) centres, particularly those centres that are involved in the inhibitory or restraining mechanisms of behaviour. As a consequence, there is an increase in uninhibitedness such as talkativeness and unrestricted social interaction following the taking of the drug. There is also an impairment of function at low dose levels. All the barbiturates are capable of inducing sleep when given in sufficient amounts. They do not affect the perception of pain as do the analgesics, but they do alter the individual's response to pain (e.g., decreasing his anxiety) and are useful in this regard. Infrequently, the barbiturates produce undesirable reactions ranging from simple nervousness, anxiety, nausea, and diarrhea to mental confusion, euphoria, and delirium. Some tolerance is developed to these drugs, but no physical dependence occurs in the drug range (100 to 200 milligrams) normally employed clinically. Prolonged use may lead to drug habituation and psychic dependence. When the drug is used chronically in higher amounts (400 milligrams per day), physical dependence may develop. Sudden withdrawal of a barbiturate following chronic use is frequently associated with withdrawal symptoms that are more severe than those produced by the opiates. A barbiturate should never be withdrawn abruptly following long continued use. The barbiturate addict shows many of the symptoms associated with chronic alcoholism, including blackouts, irrationality, slurred speech, poor motor coordination, emotional deterioration, mood swings, and psychosis.

Cocaine. Cocaine is an alkaloid derived from the leaves of the coca plant (*Erythroxylon coca*), a bush that is natural to Bolivia, Chile, and Peru along the western slopes of the Andes Mountains. Cocaine has a pronounced excitant action on the central nervous system and, in small doses, produces a pleasurable state of well-being associated with relief from fatigue, increased mental alertness, physical strength, and a reduction of hunger. In greater amounts, cocaine is an intoxicant that produces excitement, mental confusion, and convulsions. The Incas were acquainted with the ability of cocaine to produce euphoria, hyperexcitability, and hallucinations; the practice of chewing the coca leaf as part of religious ceremonies was an established custom at the time of the Spanish conquest in the 16th century. The natives who now work the mines high in the Andes chew coca leaves for increased strength and endurance. Coca plants are under cultivation in Sri Lanka (formerly Ceylon), India, and Java. The alkaloid, tropacocaine, is chemically related to cocaine and is obtained from the Java coca plant.

Cocaine is habit forming and may also be physically addicting in some individuals, but not to the extent of the opiates. Only certain persons display abstinence symptoms on withdrawal. Significant physiological tolerance does not develop. Chronic use is associated with severe personality disturbances, inability to sleep, loss of appetite, emaciation, an increased tendency to violence, and antisocial acts. When a toxic psychosis develops, it is characteristically accompanied by paranoid delusions. Hallucinations are prominent with continued use of cocaine, particularly the tactile hallucinations that give the impression that bugs are under the skin. The drug is a white crystalline powder in pure form and the practice of "snuffing" cocaine was common in Europe at the turn of the 20th century. It is less potent when taken by mouth. When injected by vein, a favourite method in the United States, the effects are rapid in onset, intense, but of short duration. This is followed by a correspondingly deep depression that prompts the user to repeat the dose to restore the sense of well-being. Cocaine is sometimes mixed with heroin to dampen any extreme excitability produced by the cocaine. The great number of undesired effects that

come on continued use frequently prompts the cocaine user to turn to other drugs.

Amphetamines. These stimulants are of three types having closely related actions on the nervous system: amphetamine proper (Benzedrine), one of its isomers (Dexedrine), and methamphetamine (Methedrine). The amphetamines have been used to alleviate depression, fatigue, the hyperkinetic behaviour disturbances of children, postencephalitic Parkinsonism, enuresis, nausea of pregnancy, and obesity. More recently, the amphetamines have been used in combination with one of the barbiturates, such as amobarbital or phenobarbital, to produce mood elevating effects. It is the effects of the amphetamines on mood that have led to their widespread abuse. A toxic psychosis with hallucinations and paranoid delusions may be produced by a single dose as low as 50 milligrams if no drug tolerance is present. Although the normal lethal dose for adult humans is estimated to be around 900 milligrams, habitual use may increase adult tolerance up to 1,000 milligrams per day.

The ability of amphetamine to produce a psychosis having paranoid features was first reported in 1938, shortly after its introduction as a central stimulant. Sporadic reports of psychosis followed, and in 1958, a monograph on the subject of amphetamine psychosis included these statements:

Psychosis associated with amphetamine usage is much more frequent than would be expected from the reports in the literature.... The clinical picture is primarily a paranoid psychosis with ideas of reference, delusions of persecution, auditory and visual hallucinations in a setting of clear consciousness.... The mental picture may be indistinguishable from acute or chronic paranoid schizophrenia.... Patients with amphetamine psychosis recover within a week unless there is demonstrable cause for continuance of symptoms; e.g., continued excretion of the drug or hysterical prolongation of symptoms.

There have been subsequent attempts to distinguish between amphetamine psychosis and paranoid schizophrenia. Whatever the outcome, amphetamine induces a psychosis that comes closer to mimicking schizophrenia than any of the other drugs of abuse, including LSD. Some behavioral symptoms such as loss of initiative, apathy, and emotional blunting may persist long after the patient stops taking the drug. Methamphetamine was used extensively by the Japanese during World War II, and by 1953 the habitual users of the drug in Japan numbered about 500,000 persons. This large-scale usage created such a serious social problem that the amphetamines were placed under governmental control in Japan in 1954. This Japanese experience has provided the opportunity for systematic studies on chronic methamphetamine intoxication. One group of 492 addicts who had been institutionalized showed a 14 percent rate of chronic psychosis with evidence of permanent organic brain damage. In the language of the street, "Meth is death." The amphetamines produce habituation, drug dependency, physiological tolerance, and toxic effects, but no physical addiction.

Tranquillizers. Serendipity has played a major role in the discovery of tranquillizers (as it has in all facets of medicine). Tranquillizers were unknown to medical science until the middle of the 20th century when the therapeutic value of reserpine and chlorpromazine in psychiatry was discovered by chance. Reserpine was originally derived in the 1930s from *Rauwolfia serpentina*, a woody plant that grows in the tropical areas of the world, but it has since been synthesized. Because this drug has many undesirable side effects such as low blood pressure, ulcers, weakness, nightmares, nasal congestion, and depression, however, it has been largely replaced in psychiatric practice by chlorpromazine (Thorazine) and a number of other phenothiazine derivatives synthesized in the 1950s. These phenothiazines are inexpensive, easily available, produce little immediate pleasurable effects, can usually be taken in large amounts without harm, and are not physically addicting. They are used extensively in the treatment of various hyperactive and agitated states, and as antipsychotic agents. These drugs, however, may produce jaundice, dermatitis, or, infrequently, convulsive seizures, and they

Mood elevation and induced psychosis

Mild
excitation
or intoxication

do not combine well with the drinking of alcohol. Chlorpromazine is effective in reversing "bad trips" such as an LSD-induced panic reaction, but it tends to strengthen rather than reverse the powerful hallucinogenic effects of STP (DOM). There is a second group of drugs, inappropriately termed minor tranquillizers, which have achieved popularity in the management of milder psychiatric conditions, particularly anxiety and tension. The major form is meprobamate (Miltown, Equanil). Although these minor tranquillizers are considered to be entirely safe in terms of side effects, they do produce serious complications, for they are commonly associated with habituation and psychic dependence. Heavy, prolonged use may result in physical dependence and severe withdrawal symptoms including insomnia, tremors, hallucinations, and convulsions.

CANNABIS

Marijuana,
hashish,
ghanja,
and bhang

Cannabis is the general term applied internationally to the Indian hemp plant, *Cannabis sativa*, when the plant is used for its pleasure-giving effects. The plant may grow to a height of 16 feet, but the strains used for drug-producing effects are typically short stemmed and extremely branched. The resinous exudate is the most valued part of the plant because it contains the highest concentration of tetrahydrocannabinol (THC), an active hallucinogenic principle associated with the plant's potency. The term cannabis also encompasses the use of the flowering tops, fruit, seeds, leaves, stems, and bark of the hemp plant even though the potency of these plant parts is considerably less than that of the pure resin itself. Hemp grows freely throughout the temperate zones of the world, but the content of the resin in the plant differs appreciably according to the geographic origin of the plant and the climate of the region in which the plant is grown. A hot, dry, upland climate is considered most favourable in terms of the potency of the plant. Careful cultivation is also considered to be an important factor in resin production. The prevention of pollination and the trimming of top leaves to produce dwarfing enhances the content of resin at plant maturity.

Types of cannabis preparations. Marijuana, hashish, charas, ghanja, bhang, kef, and dagga are names that have been applied to various varieties and preparations of the hemp plant. Hashish, named after the Persian founder of the Assassins of the 11th century (Ḥasan-e Šabbāḥ), is the most potent of the cannabis preparations, being about eight times as strong as the marijuana used in the United States. Very few geographic areas are capable of producing a plant rich enough in resins to produce hashish. Unless sifted and powdered, hashish appears in a hardened, brownish form with the degree of darkness indicating strength. The North African either eats it in a confection or smokes it, the water pipe often being used to cool the smoke. The effects are more difficult to regulate when hashish is either ingested as a confection or drunk. In India, this resinous preparation of cannabis is called charas.

Ghanja is a less active form of cannabis. Whereas hashish and charas are made from the pure resin, ghanja is prepared from the flowering tops, stems, leaves, and twigs, which have less resin and thus less potency. Ghanja is nevertheless one of the more potent forms of cannabis. It is prepared from specially cultivated plants in India, and the flowering tops have a relatively generous resinous exudate. Ghanja is consumed much in the manner of charas.

Bhang is the least potent of the cannabis preparations used in India. It does not contain the flowering tops found in ghanja. As a result, bhang contains only a small amount of resin (5 percent). It is either drunk or smoked. When drunk, the leaves are reduced to a fine powder, brewed, and then filtered for use. Bhang is also drunk in Hindu religious ceremonies.

Marijuana is the variety of cannabis grown in the Western Hemisphere. Considered mild in comparison to other forms of cannabis, it is similar in potency to the bhang used in India. Typically, it is smoked, but occasionally it is brewed as a tea or baked into cakes. Marijuana varies considerably in potency.

History. Cannabis is an ancient plant in terms of use,

having been known in central Asia and China as early as 3000 BC and in India and the Near East shortly thereafter. Its introduction to Europe and the Western Hemisphere was probably by way of Africa. Historically, cannabis has been regarded as having medicinal value, and it was used as a folk medicine prior to the 1900s. Reportedly, it was considered valuable as an analgesic, topical anesthetic, antispasmodic, antidepressant, appetite stimulant, antiasthmatic, and antibiotic. In the 20th century the pattern of pleasure-giving use spread from the lower classes to the middle classes in the West, particularly among intellectuals. From the 1960s it spread throughout various student populations from universities and colleges to secondary schools, finally reaching the elementary schools. This spread to "fad" proportions almost totally obscured the historic use of cannabis as a medicine. Marijuana has been used for victims of glaucoma, and cannabis generally may prove to be of some value in the treatment of depression, loss of appetite, high blood pressure, anxiety, migraine, and various gynecological and menstrual problems.

Physiological and psychological effects. The effects of cannabis are difficult to specify because of the wide variations in the potency of the various preparations of the hemp plant. Hashish or charas would be expected to produce a greater degree of intoxication than marijuana or bhang. It would also make a difference whether the drug is smoked, drunk, eaten, or received as an administration of synthetic tetrahydrocannabinol (THC). In general, hashish produces effects similar to those of mescaline or, in sufficient quantity, to those of LSD—extreme intoxication being more typical when the substance is swallowed. Marijuana, on the other hand, is more apt to produce effects at the opposite or mild end of the continuum from those of LSD. When smoked, physiological manifestations are apparent within minutes. These include dizziness, light-headedness, disturbances in coordination and movement, a heavy sensation in the arms and legs, dryness of mouth and throat, redness and irritation of the eyes, blurred vision, quickened heartbeat, tightness around the chest, and peculiarities in the sense of hearing such as ringing, buzzing, a feeling of pressure in the ears, or altered sounds. Occasionally drug use is accompanied by nausea and an urge to urinate or defecate. There is also a feeling of hunger that may be associated with a craving for sweets. Toxic manifestations are rare and include motor restlessness, tremor, ataxia, congestion of the conjunctivae of the eye, abnormal dilation of the pupil, visual hallucinations, and unpleasant delusions. Marijuana is not a drug of addiction. Use does not lead to physical dependence, and there are no withdrawal symptoms when the drug is discontinued. Psychological dependence does occur among certain types of users. Infrequently, a "cannabis psychosis" may occur, but generally this type of psychiatric reaction is associated only with heavy, long-term use of hashish, such as in India and Morocco. Other effects of chronic hashish use are a debilitation of the will and mental deterioration.

Psychological manifestations are even more variable in response to cannabis. Alterations in mood may include giggling, hilarity, and euphoria. Perceptual distortions may also occur, involving space, time, sense of distance, and sense of the organization of one's own body image. Thought processes may also become disorganized, with fragmentation, disturbances of memory, and frequent shifts of attention acting to disrupt the orderly flow of ideas. One may also experience some loss of reality contact in terms of not feeling involved in what one is doing; this may lead to considerable detachment and depersonalization. On the more positive side, there may be an enhancement in the sense of personal worth and increased sociability. Undesired subjective experiences include fear, anxiety, or panic. These effects vary considerably with practice and with the setting in which the drug is taken.

Many articles have been written on the subject of cannabis, but there is precious little worthwhile data to support any kind of a conclusion with regard to its use. One carefully controlled study on marijuana suggests that it is a very mild substance that requires considerable practice before its full (desired) effects are achieved. Alcohol clearly appears more potent and far more deleterious.

Antiquity

bis use

Inconclu-
sive data
on effects
of cannabis

From the point of view of those who favour the legalization of marijuana, the drug is a mild hallucinogen that bears no similarity to the narcotics. They feel that the evidence clearly indicates that marijuana is not a stepping stone to heroin and that its use is not associated with major crimes. As a means of reducing tension and achieving a sense of well-being, they believe that it is probably more beneficial and considerably safer than alcohol. The current hysteria over the use of marijuana and the harsh penalties that are imposed are perceived by users as a greater threat to society than would be a more rational and realistic approach to drug use.

Social and ethical issues of drug abuse

CONFLICTING VALUES IN DRUG USE

Modern industrialized societies are certainly not neutral with regard to the voluntary nonmedical use of psychotropic drugs. Whether one simply takes the position of psychologist Erich Fromm that people are brought up to desire and value the kinds of behaviour required by their economic and social system or whether one goes further and speaks of the Protestant ethic in the sense that Max Weber used it to delineate the industrialist's quest for salvation through worldly work alone, it is simply judged not "right," "good," or "proper" for people to achieve pleasure or salvation chemically. It is accepted that the only legitimate earthly rewards are those that have been "earned" through striving, hard work, personal sacrifice, and an overriding sense of duty to one's country, the existing social order, and family. This orientation is believed to be fairly coincident with the requirements of industrialization as it has been known up to the middle of the 20th century. But the social and economic requirements of modern society may have undergone a radical change in the last few decades, even though the inertia of the existing social character, its desires and its values, will be felt for some time to come. In one major sense, current drug controversies are a reflection of this cultural lag with all of the consequent conflict of wishes and values that result from the lack of good correspondence between traditional teachings and the view of the world as it is now being perceived by large numbers within society. Modern society is in a state of rapid transition, and this transition is not without its untoward consequences in terms of stability.

Cultural transitions notwithstanding, the dominant social order has strong negative feelings about any nonsanctioned use of drugs that contradicts its existing value system. Can society succeed if individuals are allowed unrestrained self-indulgence? Is it right to dwell in one's inner experience and glorify it at the expense of the necessary ordinary daily pursuits? Is it bad to rely on something so much that one cannot exist without it? Is it legitimate to take drugs if one is not sick? Does one have the right to decide for oneself what one needs? Does society have the right to punish someone if he has done no harm to himself or to others? These are difficult questions that do not admit to ready answers. One can guess what the answers would be to the nonsanctioned use of drugs. The traditional ethic dictates harsh responses to conduct that is "self-indulgent" or "abusive of pleasure." But how does one account for the quantities of the drugs being manufactured and consumed today by the general public? It is one thing to talk of the few hundred thousand or so "hard" narcotic users who are principally addicted to the opiates. One might still feel comfortable in disparaging the widespread illicit use of hallucinogenic substances; these are still the "other guys." But the sedatives, tranquilizers, sleeping remedies, stimulants, alcohol, coffee, tea, and tobacco are complications that trap the advocate in some glaring inconsistencies. It may be asked by partisans whether the cosmetic use of stimulants for weight control is any more legitimate than the use of stimulants to "get with it?"; whether the conflict-ridden businessman or the conflict-ridden housewife is any more entitled to relax chemically (alcohol, tranquilizers, sleeping aids, sedatives) than the conflict-ridden adolescent?; whether physical pain is any less bearable than mental pain or anguish? Billions of pills and capsules of a nonnarcotic type are manufactured yearly.

Sedatives and tranquilizers account for somewhere around 12 to 20 percent of all doctor's prescriptions. In addition there are about 150 different sleeping aids that are available for sale without a prescription. The alcoholic beverage industry produces countless millions of gallons of wine and spirits and countless millions of barrels of beer each year. One might conclude that there is a whole drug culture; that the problem is not confined to the young, the poor, the disadvantaged, or even to the criminal; that existing attitudes are at least inconsistent, possibly hypocritical. One always justifies one's own drug use, but one tends to view the other fellow who uses the same drugs as an abuser who is weak and undesirable. It must be recognized that the social consensus in regard to drug use and abuse is limited, conflict ridden, and often glaringly inconsistent. The problem is not one of insufficient facts but one of multiple objectives that at the present moment appear unreconcilable.

YOUTH AND DRUGS

Young people seem to find great solace in the fact that the "establishment" is a drug user. One cannot deny that many countries today are drug-oriented societies, but the implications of drug use are not necessarily the same for the adult as they are for the adolescent. The adult has already acquired some sense of identity and purpose in life; he has come to grips with the problems of love and sex; he has some degree of economic and social skill; and he has been integrated or at least assimilated into some dominant social order. Whereas the adult may turn to drugs and alcohol for many of the same reasons as the adolescent, drug use does not prevent the adult from remaining productive, discharging his obligations, maintaining his emotional and occupational ties, acknowledging the rights and authority of others, accepting restrictions, and planning for the future. The adolescent, in contrast, is apt to become ethnocentric and egocentric with drug usage. He withdraws within his narrow drug culture and within himself. Drug usage for many adolescents becomes a preposterous "cop-out" at a time when more important developmental experiences are required. To quote one observer:

It all seemed really quite benign in an earlier time of more moderate drug use, except for the three percent who became crazy and the ten percent we described as socially disabled. Since then, however, more and more disturbed kids have been attracted to the drug world, resulting in more unhappy and dangerous behavior. Increasingly younger kids have come into the scene. Individuals who, in psychoanalytic terms, are simply lesser people, with less structure, less ego, less integration, and hence, are less likely to be able to cope with the drugs. Adolescents are at a crisis period in their lives, and when you intrude regularly at this point with powerful chemicals, the potential to solve these problems of growing up by living them through, working them out, is stopped.

But it would appear that the "establishment" is a drug user, and this has important implications in terms of the expectations, roles, values, and rewards of the social order; but the "establishment" does not "cop-out" on drugs, and this is a fact of fundamental importance in terms of youth. Drugs may be physiologically "safe," but the drug experience can be very nonproductive and costly in terms of the individual's chances of becoming a fully participating adult.

(W.G.St./Ed.)

Pharmacological cults

Though the idea is strange to most modern worshippers, drugs have played an important role in the history of religions. The ceremonial use of wine and incense in contemporary ritual is probably a relic of a time when the psychological effects of these substances were designed to bring the worshipper into closer touch with supernatural forces. Modern studies of the hallucinogenic drugs have indicated that such drugs, in certain persons under certain conditions, release or bring about what those persons claim to be profound mystical and transcendental experiences, involving an immediate, subjective experience of ultimate reality, or the divine, resulting from the stirring of deeply buried unconscious and largely nonrational

Escapism
in drug use

of psycho-
tropic
drugs

The claim
that drugs
induce
religious
experience

reactions. Modern students of pharmacological cults who have participated in cultic drug ceremonies and used the drugs themselves have been astonished at the depth of such experiences. R. Gordon Wasson has suggested that the religious impulse itself may have had its origin in the amazement felt by primitives on accidentally finding and ingesting plants with hallucinogenic properties while foraging for food; this view is not held by most scholars of religion.

Whatever the psychological origins of such reactions, they are viewed as religious in nature and have been structured and channelled through cultic forms. Through cultic leaders—such as shamans, witch doctors, and medicine men—as well as through tradition, pharmacological cults have specified not only how the cultic drugs should be assimilated but also how they should be gathered and prepared; generally also there are specifications for participants' behaviour outside the ceremonies, in the practical affairs of living. Western observers of primitive cultures, such as missionaries, colonial administrators, and travelers, have often regarded such practices as demonstrating superstition and folly. Anthropologists and other scientific observers who have attempted to participate sympathetically in tribal rituals, however, not only have reported the useful aspects of such practices in primitive society but also have collected information that is of use to science, medicine, religion, and social theory.

Drugs usually encountered in cultic ceremonies are generally classifiable as narcotic. Few of these are true narcotics, however, in the sense of being numbing or producing sleep. They are called hallucinogens when they produce changes in perception. A hallucinogenic drug may lead to experiences that resemble psychoses, in which case it is called psychotomimetic; under other circumstances it may cause a quasi-mystical, or psychedelic, experience. Most psychedelic drugs tend to stimulate rather than numb the mind, whereas some true narcotics, such as alcohol and opium, in turn stimulate and stupefy the mind at different stages of their physical effect. Most cultic drugs come from plants, though Western cults more recently formed have made use of the active principles of natural drugs in synthetic form and of synthetic analogs of naturally occurring compounds.

TYPES OF DRUGS USED BY CULTS

There are more than 100 plants known to have properties that affect the mind, with more being discovered every year, hence only a few of the major drugs used by cults will be referred to here. Though these drugs vary greatly in composition, their effects on the user tend to be similar. Such factors as the personality, mood, and expectation of the participant, the setting, the nature of those in charge, and the interpretation of the experience may have a more significant determining effect on the experience than the specific properties of the drug.

At one time or another, such common substances as alcohol, tobacco, coffee, and tea have been used in religious cults, but such use is not common today.

Hemp, mushrooms, cacti, and their derivatives. Probably the most widespread plant having psychedelic properties and used in cults is Indian hemp, *Cannabis sativa*, which grows all over the world except in very cold climates. It is used in religious practices in India and Africa (and probably elsewhere) and is also sometimes used illicitly in the United States and Europe.

Certain mushrooms are used by cultists among the Indians in Latin America, especially in the state of Oaxaca in southern Mexico. The chief species is *Psilocybe mexicana*, of which the active principle is psilocybin and its derivative psilocin, in their chemical composition and activity not unlike LSD (D-lysergic acid diethylamide); the latter is synthesized from the alkaloids (principally ergotamine and ergonovine) that are constituents of ergot, a growth present in grasses affected by the disease also called ergot. *Amanita muscaria* (fly agaric) is another mushroom having hallucinogenic properties that has not been thoroughly studied. It may be extremely important, since it may have been the natural source of the ritual soma drink of the ancient Hindus and the comparable *haoma*

used by the Zoroastrians (see below *History of drug use in religion*). Fly agaric, which is extremely toxic, is said to have, in addition to its hallucinogenic properties, the ability to increase strength and endurance; it is said also to be a soporific.

Indians of Mexico discovered other plants with somewhat similar properties. The tops of the peyote cactus, *Lophophora williamsii*, may be dried to form the so-called mescal buttons (to be distinguished from the mescal bean, another mind-expanding but highly poisonous plant found in the same area), which are ingested by widely distributed groups of Indians in Mexico, the United States, and Canada during night-long ceremonies that have been described and studied by a number of anthropologists. The chief active principle of peyote is an alkaloid called mescaline. Like psilocin and psilocybin, mescaline is reputed to produce visions and other evidences of a mystical nature. Despite claims of missionaries and some government agents that peyote—from the Nahuatl word *peyotl* ("divine messenger")—is a degenerative and dangerous drug, there appears to be no evidence of this among the members of the Native American Church, a North American Indian cult that uses peyote in its chief religious ceremony (see below). Peyote, like most other hallucinogenic drugs, is not considered to be addictive and, far from being a destructive influence, is reputed by cultists and some observers to promote morality and ethical behaviour among the Indians who use it ritually.

Other psychedelic substances. Spanish missionaries to Mexico in the 16th century described, primarily in derogatory language, another psychedelic substance, called by the Indians *ololiuqui* and venerated highly. *Ololiuqui* has been identified as the seeds of the morning glory, mainly *Rivea corymbosa* and *Ipomoea violacea*. Since the active principles are the alkaloids D-lysergic and D-isolysergic acids, its properties are very similar to those of LSD, producing visions and mystical experiences.

Columbus described the ceremonial sniffing of a powder encountered during one of his voyages to the West Indies. Of the many kinds of snuff, the chief variety was called *yopo*, *paricá*, or *cohoba*, a powerful hallucinogen derived from parts of a tree, *Piptadenia peregrina*. This narcotic snuff may be confused with others, as yet not clearly differentiated.

Another substance used in South America, especially in the Amazon basin, is a drink called *ayahuasca*, *caapi*, or *yajé*, which is produced from the stem bark of the vines *Banisteriopsis caapi* and *B. inebrians*. Indians who use it claim that its virtues include healing powers and the power to induce clairvoyance, among others. This drink has been certified by investigators to produce remarkable effects, often involving the sensation of flying. The effects are thought to be attributable to the action of harmine, a very stable indole (structurally related to LSD) that is the active principle in the plant.

Other cultic drugs may be mentioned in passing. The kava drink, prepared from the roots of *Piper methysticum*, a species of pepper, and seemingly more of a hypnotic-narcotic than a hallucinogen, is used both socially and ritually in the South Pacific, especially in Polynesia. Iboga, or ibogaine, a powerful stimulant and hallucinogen derived from the root of the African shrub *Tabernanthe iboga* (and, like psilocybin and harmine, a chemical relative of LSD), is used by the Bwiti cult in Central Africa. Coca, source of cocaine, has had both ritual and social use chiefly in Peru. *Datura*, one species of which is the jimsonweed, is used by native peoples in North and South America; the active principle, however, is highly toxic and dangerous. A drink prepared from the shrub *Mimosa hostilis* that is said to produce glorious visions in warriors before battle, is used ritually in the *ajuca* ceremony of the Jurema cult in eastern Brazil.

GOALS OF PRACTITIONERS

The drugs used by cults for their hallucinogenic effects were adopted for explicit and implicit religious functions and purposes. The drugs were and are reported to enhance religious experience. Controlled laboratory investigations of the effects of such drugs, performed outside a culturally

Peyote

Psychedelic
snuffs and
drinks

determined cultic framework, help to make the cults more understandable.

Ecstasy and union with the divine or sacred. The loftiest aim of the cultic use of drugs is the pure delight in what is described as a direct experience of God, ultimate reality, the spirits that preside over one's destiny, or whatever the worshipper may conceive as his object of worship. As a consequence of such worship experience there may ensue a feeling of self-transcendence, sometimes through a melting away of the ego boundaries (with consequent loss of sense of self) and even through the terror of death, resulting in a psychological rebirth that gives a feeling of power and freedom and releases creative energies. Drugs have been used ritually to enhance the puberty ordeal through which, among many peoples, a youth is ushered out of childhood and is certified an adult. The functions of the drugs as teachers, leading participants through experiences of spiritual growth, are attested by many members of contemporary drug cults.

As a means of appropriating such experiences, the rites surrounding the assimilation of the drugs become types of sacraments in which the qualities and the gifts of the gods are appropriated. The visions, self-knowledge, energy, power, and direction reported to be secured from the rite confirm the feeling of the worshipper that he has been in the presence of God or has assimilated some of God's powers. Other specific skills and benefits—either real or the products of fancy—may be extrapolated from this alleged encounter with the gods, such as sexual attractiveness, skill and luck in hunting, protection in war, or even the ability to transcend war and to love one's enemies.

Purification, healing, and divination. Along with the sacramental function of the drug cults is the concept of purification through drug use. This may take the form of certain ritualistic preparations for the ceremony or the observing of certain taboos for days before it, or may be a part of the ceremony itself. Many psychedelic drugs produce nausea, and the consequent vomiting may be looked on as a purging of faults. In more advanced cults the purification may be seen as the pure and ethical living that should both precede and follow the ceremony. Closely related to the latter may be the devotional function, viewed in the most primitive drug cults as acts of propitiation of the gods for expected favours and in the more developed cults as acts directed toward the needs and wishes of the god through the cultic experience. Ritual drug taking may also be viewed as an act of devotion in itself.

In some of the more primitive cults the ordinary participant is relegated to a secondary role, for the priest or shaman may be the one who principally ingests the drug and mediates benefits, real or supposed, to the worshipper or suppliant. Such is the case when healing is the chief function, when the drug is dangerous, or when it is reserved for those persons having the most prestige. Mediation is also likely to occur when divination of the answers to important questions is involved; *e.g.*, whether to set out on a journey or where to find lost property.

Witchcraft and magic. Some pharmacological cults do not rise much above the level of witchcraft, with ceremonies expressing the participants' insecurities, anxieties, and hostilities. This is particularly true of cults operating among a marginal, competitive people, as in the Peruvian cult that uses *ayahuasca* (*Banisteriopsis caapi*). This is a syncretistic cult in which primitive magical beliefs are interwoven with minimal Roman Catholic features. Bad luck is looked on as the result of the curse of an envious neighbour, and the witch doctor is sought to dispel the curse and, if possible, to turn it onto its originator. At other times illness may be interpreted as the result of possession by evil spirits, and the purpose of the ceremony may be exorcism. In all of these cases the visions produced by the drugs, influenced by the assumptions and desires of the participants, will be interpreted according to the hopes and fears, prejudices, and suspicions of those participants.

Psychological goals. The literal meaning of the term psychedelic ("mind-manifesting") suggests the vast amount of material (feelings, images, etc.) released by these drugs from the unconscious. This material, related as it is to the psychological needs and history of the person, is

viewed as both uplifting and creative and, on the other hand, frightening and destructive. Though these drugs are regarded as dangerous by industrially advanced societies and their medical advisers, cults using such drugs have exhibited durability, and in the societies that harbour them there is apparently little or no abuse of the drugs, despite open access to them. Perhaps these cults are so structured that they meet basic psychological needs fairly well, and the resulting cultural expressions are mainly creative and constructive. Hostilities and anxieties expressed in ritual are sublimated and, therefore, less likely to be acted out. Persons who have taken the drugs maintain that they can engender a closeness of feeling among cultic participants that may satisfy the need for comradeship that is one of man's most basic desires, while the excitement of the experience may rescue participants from one of mankind's most pervasive enemies, boredom.

HISTORY OF DRUG USE IN RELIGION

References to the ritual use of drugs are scattered through the history of religions, and there is no doubt that the practice is ancient, its origins lost in prehistory. Presumed ceremonial use of *Cannabis* among the Scythians in the 5th to 2nd century BC is suggested by the censers for burning hemp seeds found in the frozen tombs at Pazyryk in the Altai Mountains. The ancient Greeks used wine in Dionysian rites, and circumstantial evidence points to the use of a hallucinogenic substance in the most solemn moments of the Eleusinian Mysteries of ancient Greece: the drinking of *kykeon*, a thick gruel of unknown composition. Both the secular and the cultic use of the *Amanita muscaria* mushroom in Siberia probably go back more than 6,000 years, and cultic use has spread beyond the cool temperate climates where the mushroom grows. Evidence of the cultic use of opium in the eastern Mediterranean islands, in Greece, and among the Sumerians points to dates as early as 3000 BC, though some of this evidence is disputed.

One of the pharmacological mysteries is the nature of the Zoroastrian *haoma* and the early Hindu *soma*, both sacred drinks made from plants. Their source may have been the *Amanita muscaria* mushroom, the mind-affecting chemicals of which pass into the urine with their properties very little diminished; there are scriptural references to sacred urine drunk as the source of divine insights. Allusions to the twigs and branches of *haoma*, however, suggest other plants, perhaps hemp. The mushroom, which does not grow in hot countries, may have been introduced to India by Aryan invaders from the north; subsequently, other plants may have been substituted until their identity was confused and lost.

There is less evidence for the historical use of drugs in Buddhism or Taoism, though it is mentioned occasionally. In Islam, which prohibits use of alcohol, there has been much more general use of *Cannabis*. The fanatical sect known as the Assassins, founded in the 11th century, used hashish; their name is derived from an Arabic word denoting a consumer of hashish. Sensational and fanciful stories, told by Marco Polo and others, of the use of hashish to heighten the undoubted homicidal proclivities of the sect, may, however, be untrue.

The use of kava was reported by travellers to the Pacific Islands, notably Fiji, in the 18th century, though its use must go back much farther. The same may be said for the cultic use of drugs like iboga, in equatorial Africa, where the discovery of such usage is very recent and where historical records are meagre. Doubtless much remains to be discovered in both of these areas.

More is known of the history and practices of pharmacological cults, as well as of the varieties of botanical sources of the drugs, in the New World than in the Old. The finding of many little images sculptured in the form of mushrooms in Guatemala almost certainly indicates a mushroom cult in the Mayan culture of Central America. Columbus reported the use of snuffs, as referred to above. The Spanish priest-historian Bernardino de Sahagún reported with disapproval the cultic use of mushrooms in Mexico in the 16th century, and there were reports of the widespread use of psychotropic mushrooms during the

Drugs
as sacra-
ments

*Soma and
haoma*

coronation of the Aztec emperor Montezuma in 1502. Suppressed by the Spaniards, the remnants of these once proud cults remain in the backcountry of Mexico, particularly in the state of Oaxaca. In 1955 R. Gordon Wasson and his companions were the first non-Indians invited to eat the sacred mushroom at one of the night ceremonies. Consequent publicity led to an influx of visitors seeking mushrooms and also attracted the attention of Mexican federal police. Despite this attention, the mushroom religion is still alive, though the ceremonies are now carried on less openly.

Spanish reports of about the same era as those dealing with Mexico allude to cultic use of drugs in North America. Sahagún also mentioned in his reports the cultic use of ololiuqui and peyote.

The Native
American
Church

Partly because of the rise of interest in psychedelic drugs, as well as the increased accessibility, the peyote religion has been studied more thoroughly than any other pharmacological cult, mainly by American anthropologists, who have written full and extensive reports of its practices. The peyote cult was harassed by missionaries and government agents alike until, toward the end of the 19th century, Indian cults began to come together in an international body composed of Canadian, American, and Mexican Indians. This federation was finally incorporated in the state of Oklahoma in 1918 as the Native American Church. Despite many laws against the use of peyote, these members of the Native American Church have steadfastly maintained their right to worship in their own way. They have suffered imprisonment and have fought in the courts, which, for the most part, have upheld this right.

The Native American Church has developed into a syncretistic religion, differing from tribe to tribe in minor details and in the degree to which ancient practices have assimilated Christian elements. The ritual surrounding ingestion of peyote is a highly symbolic night-long ceremony in the charge of an experienced Indian. Whites privileged to attend the service invariably speak of its dignity and impressiveness. Peyote itself is highly venerated and spoken of sometimes as a gift of God, sometimes personified as the Peyote Spirit. It is looked on partly as the possessor of magical qualities of protection and healing and the revealer of hidden knowledge, and partly as a guide that motivates and strengthens the worshipper. There is as much controversy among the Indians themselves over peyote as there is over LSD among whites. But the cult seems to be spreading. Contrary to the assertions of Christian missionaries, who find them hard to convert, the peyote Indians, doubtless influenced by the religions of whites around them, are reported to be superior to the nonpeyote Indians in achieving their aims of brotherly love, hard work and self-reliance, family responsibility, and abstinence from alcohol.

Because hallucinogenic drugs, both natural and synthetic, tend to evoke an experience spontaneously recognized by many as religious and therefore of supreme value to the user, small communities of seekers have grown up wherever the drugs are generally used, most recently among whites in large centres of population. Because of what they consider to be harassment by unsympathetic elements in the cities, many such communities have moved to rural or wilderness areas. Emphasis on spontaneity leads to poor organization, and consequently the histories of most of these communities are short. (W.H.C./Ed.)

BIBLIOGRAPHY

Alcohol: The prime sources for scientific, scholarly, and professional information and documentation on all aspects of the human use of beverage alcohol and its effects are the Rutgers University Center of Alcohol Studies, *Quarterly Journal of Studies on Alcohol: Part A, Originals*, Part B, *Documentation* (1940-), and its *Classified Abstract Archive of the Alcohol Literature* (CAAAL), a cumulative indexed collection of world scientific literature, on edge-notched finding cards (1939-). A key to the meanings of both technical and popular terms relating to alcohol is provided by MARK KELLER and MAIRI MCCORMICK, *A Dictionary of Words About Alcohol* (1968). The most complete critical reviews of the acute and chronic pharmacological, physiological, and psychological effects of alcohol intake are in HENRIK WALLGREN and HERBERT BARRY III (eds.), *Actions of Alcohol*, vol. 1, *Biochemical, Physiological and Psy-*

chological Aspects, vol. 2, *Chronic and Clinical Aspects* (1970); H. KALANT, "The Pharmacology of Alcohol Intoxication," *Q. Jl. Stud. Alcohol*, suppl. no. 1, pp. 1-23 (1961); and H. CAPPELL and C.P. HERMAN, "Alcohol and Tension Reduction: A Review," *ibid.*, 33:33-64 (1972). BERTON ROUECHE, *The Neutral Spirit: A Portrait of Alcohol* (1960), is a well-researched, popular account of the history and the beneficent as well as harmful effects of alcoholic beverages. R.G. MCCARTHY (ed.), *Drinking and Intoxication* (1959), is a rich collection of informative writings from the sociological as well as biological fields on every aspect of its title; while D.J. PITTMAN and C.R. SNYDER (eds.), *Society, Culture, and Drinking Patterns* (1962), brings together the best essays on social and cultural factors associated with drinking patterns in many kinds of communities and groups.

Anthropological studies of the drinking practices of early societies, as well as their survival and transmission to and significance for modern man, are described in E.M. LOEB, "Primitive Intoxicants," *Q. Jl. Stud. Alcohol*, 4:387-398 (1943); CHANDLER WASHBURN, *Primitive Drinking: A Study of the Uses and Functions of Alcohol in Prehistoric Societies* (1961); and M.K. BACON *et al.*, "A Cross-Cultural Study of Drinking," *Q. Jl. Stud. Alcohol*, suppl. no. 3 (1965). The prevalence of drinking and abstaining and the distribution and demographic interrelations of alcohol problems and alcoholism in the United States and other countries are dealt with in DON CAHALAN, IRA H. CISEN, and HELEN M. CROSSLEY, *American Drinking Practices: A National Study of Drinking Behavior and Attitudes* (1969); and K. BRUUN *et al.*, "Surveys of Drinking and Abstaining: Urban, Suburban and National Studies," *Q. Jl. Stud. Alcohol*, suppl. no. 6 (1972); while VERA EFRON, MARK KELLER, and CAROL GURIOLI, *Statistics on Consumption of Alcohol and on Alcoholism* (1972), provides comparisons of alcohol consumption in many countries and presents estimates of alcoholism and statistics on alcoholic psychoses and mortality in the United States. CLIFFORD F. GASTINEAU, WILLIAM J. DARBY, and THOMAS B. TURNER (eds.), *Fermented Food Beverages in Nutrition* (1979), discusses the hazardous aspects of alcohol consumption and the often disregarded nutritional aspects, in a collection of papers; JAMES E. ROYCE, *Alcohol Problems and Alcoholism* (1981), is a useful introduction to alcohol use and abuse and alcohol prevention and treatment; PHIL DAVIES, *Alcohol Problems and Alcohol Control in Europe* (1983); ORIANNA J. KALANT, *Alcohol and Drug Problems in Women* (1980); DWIGHT B. HEATH, *Alcohol Use and World Cultures: A Comprehensive Bibliography of Anthropological Sources* (1981), is a thorough listing of more than 1,200 alcohol-use sources on particular topics, regions, and ethnic groups; GRACE M. BARNES, *Alcohol and the Elderly: A Comprehensive Bibliography* (1980), contains more than 1,200 citations dealing with biological and social problems facing elderly persons involved in alcohol abuse; JACK O. WADDELL and MICHAEL W. EVERETT (eds.), *Drinking Behaviour Among Southwestern Indians* (1980); a good companion source is JOHN HAMER (ed.), *Alcohol and Native Peoples of the North* (1980), a collection dealing with the cultural meanings and attachments to alcohol among Arctic and subarctic American Indians.

The NATIONAL INSTITUTE ON ALCOHOL ABUSE AND ALCOHOLISM (U.S.) has published several useful works, including: *Alcohol Consumption and Related Problems* (1982), essays dealing with attitudes toward alcohol among adults and young people, epidemiological problems of alcohol use and abuse, international trends in alcohol consumption and related pathologies, alcohol and family violence, and genetic influences on alcohol-related behaviour; *Biomedical Processes and Consequences of Alcohol Use* (1982), a discussion of the effect of alcohol on membranes, protein synthesis, liver damage, the cardiovascular system, and other topics in several papers; *Prevention, Intervention, and Treatment: Concerns and Models* (1982), a discussion of current research on alcoholism, the problems of drinking and driving, the diagnosis of alcoholism, methods of intervention, treatment, and evaluation; and *Special Population Issues* (1983), problems related to alcohol use among different population groups.

The nature and causes of alcoholism and descriptions of its symptomatology are dealt with in MARK KELLER, *Some Views on the Nature of Addiction* (1969); DAVID LESTER, "Self-Selection of Alcohol by Animals, Human Variation, and the Etiology of Alcoholism," *Q. Jl. Stud. Alcohol*, 27:395-438 (1966); E.M. JELLINEK, *The Disease Concept of Alcoholism* (1960), and "Phases of Alcohol Addiction," *Q. Jl. Stud. Alcohol*, 13:673-684 (1952). Treatments of alcoholism are described in M.J. HILL and H.T. BLANE, "Evaluation of Psychotherapy with Alcoholics: A Critical Review," *Q. Jl. Stud. Alcohol*, 28:76-104 (1967); and MORRIS E. CHAFETZ, HOWARD T. BLANE, and MARJORIE J. HILL (eds.), *Frontiers of Alcoholism* (1970), while the ideology and role of the leading self-help fellowship are detailed in *Alcoholics Anonymous: The Story of How Many Thousands of Men and Women Have Recovered from Alcoholism* (1955); and BARRY LEACH *et al.*, "Dimensions of Alcoholics Anonymous," *Int. J. Addict.*, 4:507-541 (1969). Analyses of classic as well as contemporary

attempts to cope with alcohol problems are outlined in the NEW YORK STATE MORELAND COMMISSION ON THE ALCOHOLIC BEVERAGE CONTROL LAW, *Study Paper No. 1: The Relationship of the Alcoholic Beverage Control Law and the Problems of Alcohol* (1963); and S.D. BACONS, "The Classic Temperance Movement in the U.S.A.: Impact Today on Attitudes, Action and Research," *Br. J. Addict. Alcohol*, 62:5 18 (1967). Broad data and perspectives on alcohol-related health and social problems are presented in THOMAS F.A. PLAUT, *Alcohol Problems: A Report to the Nation, by the Cooperative Commission on the Study of Alcoholism* (1967); and the NATIONAL INSTITUTE ON ALCOHOL ABUSE AND ALCOHOLISM, *Alcohol and Health, 1st Special Report . . . from the Secretary of Health, Education, and Welfare* (1972).

Psychotropic Drugs: BERNARD BARBER, *Drugs and Society* (1967), provides an excellent introduction to the general topic of drugs, especially ch. 1, 5, and 6. MADELINE H. ENGEL, *The Drug Scene* (1974), is a brief sociological treatment; ALFRED R. LINDESMITH, *The Addict and the Law* (1965), offers a broad analysis of the narcotic problem; ROBERT W. FERGUSON, *Drug Abuse Control* (1975), reports on agencies of control and rehabilitation in many countries; DAVID SOLOMON (ed.), *LSD: The Consciousness-Expanding Drug* (1964), provides the reader with some of the history, rationale, subjective accounts, and mystique that launched the drug movement. More specialized works of general interest include BRIAN WELLS, *Psychedelic Drugs: Psychological, Medical and Social Issues* (1973); DONALD R. WESSON and DAVID E. SMITH, *Barbiturates: Their Use, Misuse and Abuse* (1977); and SAMUEL S. EFSTEIN et al. (eds.), *Drugs of Abuse: Their Genetic and Other Chronic Nonpsychiatric Hazards* (1971). RICHARD R. LINGEMAN, *Drugs from A to Z: A Dictionary*, 2nd ed. (1974), offers an impressive array of general information on almost all aspects of drug use. Technical works covering the same broad scope are J.R. DIPALMA

(ed.), *Drill's Pharmacology in Medicine*, 4th ed. (1971); and L.S. GOODMAN and A.Z. GILMAN (eds.), *The Pharmacological Basis of Therapeutics*, 6th ed. (1980). A useful summary of psychological and psychiatric views may be found in JAMES C. COLEMAN, *Abnormal Psychology and Modern Life*, 6th ed. (1980); THEODORE MILLON, *Modern Psychopathology* (1969); and SILVANO ARIETI (ed.), *American Handbook of Psychiatry*, 6 vol. (1974-75). For additional references, see THEODORA ANDREWS, *A Bibliography of Drug Abuse, Including Alcohol and Tobacco* (1977), an annotated guide; and *Drug Abuse and Alcoholism Review* (bimonthly), abstracts of current periodical literature.

Pharmacological cults: D.H. EFRON, B. HOLMSTEDT, and N.S. KLINE (eds.), *Ethnopharmacologic Search for Psychoactive Drugs* (1967), a review by international experts, including material on cults; W. LA BARRE, *The Peyote Cult*, enlarged ed. (1969), and J.S. SLOTKIN, *The Peyote Religion* (1956), detailed and thorough references on the peyote cult; W.T. STACE, *Mysticism and Philosophy* (1960), a very clear account of mysticism that alludes to drugs; V.P. and R.G. WASSON, *Mushrooms, Russia, and History*, 2 vol. (1957), and R.G. WASSON, *Soma: Divine Mushroom of Immortality* (1968), required readings for those who wish to be thoroughly informed on mushroom cults; R.C. ZAEHNER, *Mysticism, Sacred and Profane* (1957), mainly a criticism of the views of Aldous Huxley on drugs, and *Drugs, Mysticism and Make-Believe* (1972; also published as *Zen, Drugs, and Mysticism*, 1973). *Psychedelic Religion?*, ed. by Paul H. Ballard (1972), a collection of papers from a colloquium; FERNANDO BENITEZ, *En la tierra mágica del peyote* (1968); *In the Magic Land of Peyote*, 1975, and *Los hongos alucinantes* (1964), both by an authority on the use of hallucinogens among the Indians of Mexico; and Peter T. Furst (ed.), *Flesh of the Gods: The Ritual Use of Hallucinogens* (1972), based on a lecture series in 1970.

(M.Ke./W.G.St./W.H.C./Ed.)

Alexander the Great

Alexander the Great (Alexander III), king of Macedonia, overthrew the Persian Empire, carried Macedonian arms to India, and laid the foundations for the Hellenistic world of territorial kingdoms. Already in his lifetime the subject of fabulous stories, he later became the hero of a full-scale legend bearing only the sketchiest resemblance to his historical career.

LIFE

He was born in 356 BC at Pella in Macedonia, the son of Philip II and Olympias (daughter of King Neoptolemus of Epirus). From age 13 to 16 he was taught by Aristotle, who inspired him with an interest in philosophy, medicine, and scientific investigation; but he was later to advance beyond his teacher's narrow precept that non-Greeks should be treated as slaves. Left in charge of Macedonia in 340 during Philip's attack on Byzantium, Alexander defeated the Maedi, a Thracian people; two years later he commanded the left wing at the Battle of Chaeronea, in which Philip defeated the allied Greek states, and displayed personal courage in breaking the Sacred Band of Thebes. A year later Philip divorced Olympias; and, after a quarrel at a feast held to celebrate his father's new marriage, Alexander and his mother fled to Epirus, and Alexander later went to Illyria. Shortly afterward, father and son were reconciled and Alexander returned; but his position as heir was jeopardized.

Alexander the Great, portrait head on a coin of Lysimachus (355–281 BC). In the British Museum.

Alexander
succeeds
Philip

In 336, however, on Philip's assassination, Alexander, acclaimed by the army, succeeded without opposition. He at once executed the princes of Lyncestis, alleged to be behind Philip's murder, along with all possible rivals and the whole of the faction opposed to him. He then marched south, recovered a wavering Thessaly, and at an assembly of the Greek League at Corinth was appointed generalissimo for the forthcoming invasion of Asia, already planned and initiated by Philip. Returning to Macedonia by way of Delphi (where the Pythian priestess acclaimed him "invincible"), he advanced into Thrace in spring 335 and, after forcing the Shipka Pass and crushing the Triballi, crossed the Danube to disperse the Getae; turning west, he then defeated and shattered a coalition of Illyrians who had invaded Macedonia. Meanwhile, a rumour of his death had precipitated a revolt of Theban democrats; other Greek states favoured Thebes, and the Athenians, urged on by Demosthenes, voted help. In 14 days Alexander marched 240 miles from Pelion (near modern Korçë, Albania) in Illyria to Thebes. When the Thebans refused to surrender, he made an entry and razed their city to the ground, sparing only temples and Pindar's house; 6,000 were killed and all survivors sold into slavery. The other Greek states

were cowed by this severity, and Alexander could afford to treat Athens leniently. Macedonian garrisons were left in Corinth, Chalcis, and the Cadmea (the citadel of Thebes).

Beginnings of the Persian expedition. From his accession Alexander had set his mind on the Persian expedition. He had grown up to the idea. Moreover, he needed the wealth of Persia if he was to maintain the army built by Philip and pay off the 500 talents he owed. The exploits of the Ten Thousand, Greek soldiers of fortune, and of Agesilaus of Sparta, in successfully campaigning in Persian territory had revealed the vulnerability of the Persian Empire. With a good cavalry force Alexander could expect to defeat any Persian army. In spring 334 he crossed the Dardanelles, leaving Antipater, who had already faithfully served his father, as his deputy in Europe with over 13,000 men; he himself commanded about 30,000 foot and over 5,000 cavalry, of whom nearly 14,000 were Macedonians and about 7,000 allies sent by the Greek League. This army was to prove remarkable for its balanced combination of arms. Much work fell on the lightarmed Cretan and Macedonian archers, Thracians, and the Agrianian javelin men. But in pitched battle the striking force was the cavalry, and the core of the army, should the issue still remain undecided after the cavalry charge, was the infantry phalanx, 9,000 strong, armed with 13-foot spears and shields, and the 3,000 men of the royal battalions, the hypaspists. Alexander's second in command was Parmenio, who had secured a foothold in Asia Minor during Philip's lifetime; many of his family and supporters were entrenched in positions of responsibility. The army was accompanied by surveyors, engineers, architects, scientists, court officials, and historians; from the outset Alexander seems to have envisaged an unlimited operation.

After visiting Ilium (Troy), a romantic gesture inspired by Homer, he confronted his first Persian army, led by three satraps, at the Granicus (modern Kocabaş) River, near the Sea of Marmara (May/June 334). The Persian plan to tempt Alexander across the river and kill him in the melee almost succeeded; but the Persian line broke, and Alexander's victory was complete. Darius' Greek mercenaries were largely massacred, but 2,000 survivors were sent back to Macedonia in chains. This victory exposed western Asia Minor to the Macedonians, and most cities hastened to open their gates. The tyrants were expelled and (in contrast to Macedonian policy in Greece) democracies were installed. Alexander thus underlined his Panhellenic policy, already symbolized in the sending of 300 panoplies (sets of armour) taken at the Granicus as an offering dedicated to Athena at Athens by "Alexander son of Philip and the Greeks (except the Spartans) from the barbarians who inhabit Asia." (This formula, cited by the Greek historian Arrian in his history of Alexander's campaigns, is noteworthy for its omission of any reference to Macedonia.) But the cities remained *de facto* under Alexander, and his appointment of Calas as satrap of Hellespontine Phrygia reflected his claim to succeed the Great King of Persia. When Miletus, encouraged by the proximity of the Persian fleet, resisted, Alexander took it by assault; but, refusing a naval battle, he disbanded his own costly navy and announced that he would "defeat the Persian fleet on land," by occupying the coastal cities. In Caria, Halicarnassus resisted and was stormed; but Ada, the widow and sister of the satrap Idrieus, adopted Alexander as her son and, after expelling her brother Pixodarus, Alexander restored her to her satrapy. Some parts of Caria held out, however, until 332.

Asia Minor and the Battle of Issus. In winter 334–333 Alexander conquered western Asia Minor, subduing the hill tribes of Lycia and Pisidia; and in spring 333 he advanced along the coastal road to Perga, passing the cliffs of Mt. Climax, thanks to a fortunate change of wind.

Exploits
of the Ten
Thousand

ie
rdian
ot

The fall in the level of the sea was interpreted as a mark of divine favour by Alexander's flatterers, including the historian Callisthenes. At Gordium in Phrygia, tradition records his cutting of the Gordian knot, which could only be loosed by the man who was to rule Asia; but this story may be apocryphal or at least distorted. At this point Alexander benefitted from the sudden death of Memnon, the competent Greek commander of the Persian fleet. From Gordium he pushed on to Ancyra (modern Ankara) and thence south through Cappadocia and the Cilician Gates (modern Külek Boğazi); a fever held him up for a time in Cilicia. Meanwhile, Darius with his Grand Army had advanced northward on the eastern side of Mt. Amanus. Intelligence on both sides was faulty, and Alexander was already encamped by Myriandrus (near modern Iskenderun, Turkey) when he learned that Darius was astride his line of communications at Issus, north of Alexander's position (autumn 333). Turning, Alexander found Darius drawn up along the Pinarus River. In the battle that followed, Alexander won a decisive victory. The struggle turned into a Persian rout and Darius fled, leaving his family in Alexander's hands; the women were treated with chivalrous care.

Conquest of the Mediterranean coast and Egypt. From Issus Alexander marched south into Syria and Phoenicia, his object being to isolate the Persian fleet from its bases and so to destroy it as an effective fighting force. The Phoenician cities Marathus and Aradus came over quietly, and Parmenio was sent ahead to secure Damascus and its rich booty, including Darius' war chest. In reply to a letter from Darius offering peace, Alexander replied arrogantly, recapitulating the historic wrongs of Greece and demanding unconditional surrender to himself as lord of Asia. After taking Byblos (modern Jubayl) and Sidon (Arabic Şaydā), he met with a check at Tyre, where he was refused entry into the island city. He thereupon prepared to use all methods of siegecraft to take it, but the Tyrians resisted, holding out for seven months. In the meantime (winter 333–332) the Persians had counterattacked by land in Asia Minor—where they were defeated by Antigonus, the satrap of Greater Phrygia—and by sea, recapturing a number of cities and islands.

ie siege
Tyre

While the siege of Tyre was in progress, Darius sent a new offer: he would pay a huge ransom of 10,000 talents for his family and cede all his lands west of the Euphrates. "I would accept," Parmenio is reported to have said, "were I Alexander"; "I too," was the famous retort, "were I Parmenio." The storming of Tyre in July 332 was Alexander's greatest military achievement; it was attended with great carnage and the sale of the women and children into slavery. Leaving Parmenio in Syria, Alexander advanced south without opposition until he reached Gaza on its high mound; there bitter resistance halted him for two months, and he sustained a serious shoulder wound during a sortie. There is no basis for the tradition that he turned aside to visit Jerusalem.

In November 332 he reached Egypt. The people welcomed him as their deliverer, and the Persian satrap Mazaces wisely surrendered. At Memphis Alexander sacrificed to Apis, the Greek term for Hapi, the sacred Egyptian bull, and was crowned with the traditional double crown of the pharaohs; the native priests were placated and their religion encouraged. He spent the winter organizing Egypt, where he employed Egyptian governors, keeping the army under a separate Macedonian command. He founded the city of Alexandria near the western arm of the Nile on a fine site between the sea and Lake Mareotis, protected by the island of Pharos, and had it laid out by the Rhodian architect Deinocrates. He is also said to have sent an expedition to discover the causes of the flooding of the Nile. From Alexandria he marched along the coast to Paraetonium and from there inland to visit the celebrated oracle of the god Amon (at Siwah); the difficult journey was later embroidered with flattering legends. On his reaching the oracle in its oasis, the priest gave him the traditional salutation of a pharaoh, as son of Amon; Alexander consulted the god on the success of his expedition but revealed the reply to no one. Later the incident was to contribute to the story that he was the son of Zeus and, thus, to his "de-

ification." In spring 331 he returned to Tyre, appointed a Macedonian satrap for Syria, and prepared to advance into Mesopotamia. His conquest of Egypt had completed his control of the whole eastern Mediterranean coast.

In July 331 Alexander was at Thapsacus on the Euphrates. Instead of taking the direct route down the river to Babylon, he made across northern Mesopotamia toward the Tigris, and Darius, learning of this move from an advance force sent under Mazaeus to the Euphrates crossing, marched up the Tigris to oppose him. The decisive battle of the war was fought on the plain of Gaugamela between Nineveh and Arbela. Alexander pursued the defeated Persian forces for 35 miles to Arbela, but Darius escaped with his Bactrian cavalry and Greek mercenaries into Media.

Battle of
Gauga-
mela

Alexander now occupied Babylon, city and province; Mazaeus, who surrendered it, was confirmed as satrap in conjunction with a Macedonian troop commander, and quite exceptionally was granted the right to coin. As in Egypt, the local priesthood was encouraged. Susa, the capital, also surrendered, releasing huge treasures amounting to 50,000 gold talents; here Alexander established Darius' family in comfort. Crushing the mountain tribe of the Ouxians, he now pressed on over the Zagros range into Persia proper and, successfully turning the Pass of the Persian Gates, held by the satrap Ariobarzanes, he entered Persepolis and Pasargadae. At Persepolis he ceremonially burned down the palace of Xerxes, as a symbol that the Panhellenic war of revenge was at an end; for such seems the probable significance of an act that tradition later explained as a drunken frolic inspired by Thais, an Athenian courtesan. In spring 330 Alexander marched north into Media and occupied its capital Ecbatana. The Thessalians and Greek allies were sent home; henceforward he was waging a purely personal war.

As Mazaeus' appointment indicated, Alexander's views on the empire were changing. He had come to envisage a joint ruling people consisting of Macedonians and Persians, and this served to augment the misunderstanding that now arose between him and his people. Before continuing his pursuit of Darius, who had retreated into Bactria, he assembled all the Persian treasure and entrusted it to Harpalus, who was to hold it at Ecbatana as chief treasurer. Parmenio was also left behind in Media to control communications; the presence of this older man had perhaps become irksome.

In midsummer 330 Alexander set out for the eastern provinces at a high speed via Rhagae (modern Rayy, near Tehrān) and the Caspian Gates, where he learned that Bessus, the satrap of Bactria, had deposed Darius. After a skirmish near modern Shāhrūd, the usurper had Darius stabbed and left him to die. Alexander sent his body for burial with due honours in the royal tombs at Persepolis.

Death of
Darius

Campaign eastward, to Central Asia. Darius' death left no obstacle to Alexander's claim to be Great King, and a Rhodian inscription of this year (330) calls him "lord of Asia"—i.e., of the Persian Empire; soon afterward his Asian coins carry the title of king. Crossing the Elburz Mountains to the Caspian, he seized Zadracarta in Hyrcania and received the submission of a group of satraps and Persian notables, some of whom he confirmed in their offices; in a diversion westward, perhaps to modern Āmol, he reduced the Mardi, a mountain people who inhabited the Elburz Mountains. He also accepted the surrender of Darius' Greek mercenaries. His advance eastward was now rapid. In Aria he reduced Satibarzanes, who had offered submission only to revolt, and he founded Alexandria of the Arians (modern Herāt). At Phrada in Drangiana (either near modern Nad-e 'Ali in Seistan or farther north at Farah), he at last took steps to destroy Parmenio and his family. Philotas, Parmenio's son, commander of the elite Companion cavalry, was implicated in an alleged plot against Alexander's life, condemned by the army, and executed; and a secret message was sent to Cleander, Parmenio's second in command, who obediently assassinated him. This ruthless action excited widespread horror but strengthened Alexander's position relative to his critics and those whom he regarded as his father's men. All Parmenio's adherents were now eliminated and men close to Alexander promoted. The Companion cavalry was re-

organized in two sections, each containing four squadrons (now known as hipparchies); one group was commanded by Alexander's oldest friend, Hephaestion, the other by Cleitus, an older man. From Phrada, Alexander pressed on during the winter of 330–329 up the valley of the Helmand River, through Arachosia, and over the mountains past the site of modern Kābul into the country of the Paropamisadae, where he founded Alexandria by the Caucasus.

Revolt in Bactria and Sogdiana Bessus was now in Bactria raising a national revolt in the eastern satrapies with the usurped title of Great King. Crossing the Hindu Kush northward over the Khawak Pass (11,650 feet), Alexander brought his army, despite food shortages, to Drapsaca (sometimes identified with modern Banu [Andarab], probably farther north at Qunduz); outflanked, Bessus fled beyond the Oxus (modern Amu Darya), and Alexander, marching west to Bactra-Zariaspa (modern Balkh [Wazirabad] in Afghanistan), appointed loyal satraps in Bactria and Aria. Crossing the Oxus, he sent his general Ptolemy in pursuit of Bessus, who had meanwhile been overthrown by the Sogdian Spitamenes. Bessus was captured, flogged, and sent to Bactra, where he was later mutilated after the Persian manner (losing his nose and ears); in due course he was publicly executed at Ecbatana.

From Maracanda (modern Samarkand) Alexander advanced by way of Cyropolis to the Jaxartes (modern Syrdarya), the boundary of the Persian Empire. There he broke the opposition of the Scythian nomads by his use of catapults and, after defeating them in a battle on the north bank of the river, pursued them into the interior. On the site of modern Leninabad (Khojent) on the Jaxartes, he founded a city, Alexandria Eschate, "the farthest." Meanwhile, Spitamenes had raised all Sogdiana in revolt behind him, bringing in the Massagetai, a people of the Śaka confederacy. It took Alexander until the autumn of 328 to crush the most determined opponent he encountered in his campaigns. Later in the same year he attacked Oxyartes and the remaining barons who held out in the hills of Paraetacene (modern Tadzhikistan); volunteers seized the crag on which Oxyartes had his stronghold, and among the captives was his daughter, Roxana. In reconciliation Alexander married her, and the rest of his opponents were either won over or crushed.

Progress toward absolutism An incident that occurred at Maracanda widened the breach between Alexander and many of his Macedonians. He murdered Cleitus, one of his most trusted commanders, in a drunken quarrel; but his excessive display of remorse led the army to pass a decree convicting Cleitus posthumously of treason. The event marked a step in Alexander's progress toward Eastern absolutism, and this growing attitude found its outward expression in his use of Persian royal dress. Shortly afterward, at Bactra, he attempted to impose the Persian court ceremonial, involving prostration (*proskynesis*), on the Greeks and Macedonians too; but to them this custom, habitual for Persians entering the king's presence, implied an act of worship and was intolerable before a man. Even Callisthenes, historian and nephew of Aristotle, whose ostentatious flattery had perhaps encouraged Alexander to see himself in the role of a god, refused to abase himself. Macedonian laughter caused the experiment to founder, and Alexander abandoned it. Shortly afterward, however, Callisthenes was held to be privy to a conspiracy among the royal pages and was executed (or died in prison; accounts vary); resentment of this action alienated sympathy from Alexander within the Peripatetic school of philosophers, with which Callisthenes had close connections.

Invasion of India. In early summer 327 Alexander left Bactria with a reinforced army under a reorganized command. If Plutarch's figure of 120,000 men has any reality, however, it must include all kinds of auxiliary services, together with muleteers, camel drivers, medical corps, peddlers, entertainers, women, and children; the fighting strength perhaps stood at about 35,000. Recrossing the Hindu Kush, probably by Bamian and the Ghorband Valley, Alexander divided his forces. Half the army with the baggage under Hephaestion and Perdicas, both cavalry commanders, was sent through the Khyber Pass, while he

himself led the rest, together with his siege train, through the hills to the north. His advance through Swāt and Gandhāra was marked by the storming of the almost impregnable pinnacle of Aornos, the modern Pir-Sar, a few miles west of the Indus and north of the Buner River, an impressive feat of siegecraft. In spring 326, crossing the Indus near Attock, Alexander entered Taxila, whose ruler, Taxiles, furnished elephants and troops in return for aid against his rival Porus, who ruled the lands between the Hydaspes (modern Jhelum) and the Acesines (modern Chenāb). In June Alexander fought his last great battle on the left bank of the Hydaspes. He founded two cities there, Alexandria Nicaea (to celebrate his victory) and Bucephala (named after his horse Bucephalus, which died there); and Porus became his ally.

Battle of the Hydaspes

How much Alexander knew of India beyond the Hyphasis (probably the modern Beas) is uncertain; there is no conclusive proof that he had heard of the Ganges. But he was anxious to press on farther, and he had advanced to the Hyphasis when his army mutinied, refusing to go farther in the tropical rain; they were weary in body and spirit, and Coenus, one of Alexander's four chief marshals, acted as their spokesman. On finding the army adamant, Alexander agreed to turn back.

On the Hyphasis he erected 12 altars to the 12 Olympian gods, and on the Hydaspes he built a fleet of 800 to 1,000 ships. Leaving Porus, he then proceeded down the river and into the Indus, with half his forces on shipboard and half marching in three columns down the two banks. The fleet was commanded by Nearchus, and Alexander's own captain was Onesicritus; both later wrote accounts of the campaign. The march was attended with much fighting and heavy, pitiless slaughter; at the storming of one town of the Malli near the Hydraotes (Ravi) River, Alexander received a severe wound which left him weakened.

On reaching Patala, located at the head of the Indus delta, he built a harbour and docks and explored both arms of the Indus, which probably then ran into the Rann of Kutch. He planned to lead part of his forces back by land, while the rest in perhaps 100 to 150 ships under the command of Nearchus, a Cretan with naval experience, made a voyage of exploration along the Persian Gulf. Local opposition led Nearchus to set sail in September (325), and he was held up for three weeks until he could pick up the northeast monsoon in late October. In September Alexander too set out along the coast through Gedrosia (modern Baluchistan), but he was soon compelled by mountainous country to turn inland, thus failing in his project to establish food depots for the fleet. Craterus, a high-ranking officer, already had been sent off with the baggage and siege train, the elephants, and the sick and wounded, together with three battalions of the phalanx, by way of the Mulla Pass, Quetta, and Kandahar into the Helmand Valley; from there he was to march through Drangiana to rejoin the main army on the Amanis (modern Minab) River in Carmania. Alexander's march through Gedrosia proved disastrous; waterless desert and shortage of food and fuel caused great suffering, and many, especially women and children, perished in a sudden monsoon flood while encamped in a wadi. At length, at the Amanis, he was rejoined by Nearchus and the fleet, which also had suffered losses.

Return from India

Consolidation of the empire. Alexander now proceeded farther with the policy of replacing senior officials and executing defaulting governors on which he had already embarked before leaving India. Between 326 and 324 over a third of his satraps were superseded and six were put to death, including the Persian satraps of Persis, Susiana, Carmania, and Paraetacene; three generals in Media, including Cleander, the brother of Coenus (who had died a little earlier), were accused of extortion and summoned to Carmania, where they were arrested, tried, and executed. How far the rigour that from now onward Alexander displayed against his governors represents exemplary punishment for gross maladministration during his absence and how far the elimination of men he had come to distrust (as in the case of Philotas and Parmenio) is debatable; but the ancient sources generally favourable to him comment adversely on his severity.

Attempt at
creating a
master race

In spring 324 he was back in Susa, capital of Elam and administrative centre of the Persian Empire; the story of his journey through Carmania in a drunken revel, dressed as Dionysus, is embroidered, if not wholly apocryphal. He found that his treasurer, Harpalus, evidently fearing punishment for peculation, had absconded with 6,000 mercenaries and 5,000 talents to Greece; arrested in Athens, he escaped and later was murdered in Crete. At Susa Alexander held a feast to celebrate the seizure of the Persian Empire, at which, in furtherance of his policy of fusing Macedonians and Persians into one master race, he and 80 of his officers took Persian wives; he and Hephaestion married Darius' daughters Barsine (also called Stateira) and Drypetis, respectively, and 10,000 of his soldiers with native wives were given generous dowries.

This policy of racial fusion brought increasing friction to Alexander's relations with his Macedonians, who had no sympathy for his changed concept of the empire. His determination to incorporate Persians on equal terms in the army and the administration of the provinces was bitterly resented. This discontent was now fanned by the arrival of 30,000 native youths who had received a Macedonian military training and by the introduction of Orientals from Bactria, Sogdiana, Arachosia, and other parts of the empire into the Companion cavalry; whether Orientals had previously served with the Companions is uncertain, but if so they must have formed separate squadrons. In addition, Persian nobles had been accepted into the royal cavalry bodyguard. Peucestas, the new governor of Persis, gave this policy full support to flatter Alexander; but most Macedonians saw it as a threat to their own privileged position.

The issue came to a head at Opis (324), when Alexander's decision to send home Macedonian veterans under Craterus was interpreted as a move toward transferring the seat of power to Asia. There was an open mutiny involving all but the royal bodyguard; but when Alexander dismissed his whole army and enrolled Persians instead, the opposition broke down. An emotional scene of reconciliation was followed by a vast banquet with 9,000 guests to celebrate the ending of the misunderstanding and the partnership in government of Macedonians and Persians—but not, as has been argued, the incorporation of all the subject peoples as partners in the commonwealth. Ten thousand veterans were now sent back to Macedonia with gifts, and the crisis was surmounted.

In summer 324 Alexander attempted to solve another problem, that of the wandering mercenaries, of whom there were thousands in Asia and Greece, many of them political exiles from their own cities. A decree brought by Nicanor to Europe and proclaimed at Olympia (September 324) required the Greek cities of the Greek League to receive back all exiles and their families (except the Thebans), a measure that implied some modification of the oligarchic regimes maintained in the Greek cities by Alexander's governor Antipater. Alexander now planned to recall Antipater and supersede him by Craterus; but he was to die before this could be done.

Last year
and death

In autumn 324 Hephaestion died in Ecbatana, and Alexander indulged in extravagant mourning for his closest friend; he was given a royal funeral in Babylon with a pyre costing 10,000 talents. His post of chiliarch (grand vizier) was left unfilled. It was probably in connection with a general order now sent out to the Greeks to honour Hephaestion as a hero that Alexander linked the demand that he himself should be accorded divine honours. For a long time his mind had dwelt on ideas of godhead. Greek thought drew no very decided line of demarcation between god and man, for legend offered more than one example of men who, by their achievements, acquired divine status. Alexander had on several occasions encouraged favourable comparison of his own accomplishments with those of Dionysus or Heracles. He now seems to have become convinced of the reality of his own divinity and to have required its acceptance by others. There is no reason to assume that his demand had any political background (divine status gave its possessor no particular rights in a Greek city); it was rather a symptom of growing megalomania and emotional instability. The cities perforce

complied, but often ironically: the Spartan decree read, "Since Alexander wishes to be a god, let him be a god."

In the winter of 324 Alexander carried out a savage punitive expedition against the Cossaeans in the hills of Luristan. The following spring at Babylon he received complimentary embassies from the Libyans and from the Bruttians, Etruscans, and Lucanians of Italy; but the story that embassies also came from more distant peoples, such as Carthaginians, Celts, Iberians, and even Romans, is a later invention. Representatives of the cities of Greece also came, garlanded as befitted Alexander's divine status. Following up Nearchus' voyage, he now founded an Alexandria at the mouth of the Tigris and made plans to develop sea communications with India, for which an expedition along the Arabian coast was to be a preliminary. He also dispatched Heracleides, an officer, to explore the Hyrcanian (*i.e.*, Caspian) Sea. Suddenly, in Babylon, while busy with plans to improve the irrigation of the Euphrates and to settle the coast of the Persian Gulf, Alexander was taken ill after a prolonged banquet and drinking bout; 10 days later, on June 13, 323, he died in his 33rd year; he had reigned for 12 years and eight months. His body, diverted to Egypt by Ptolemy, the later king, was eventually placed in a golden coffin in Alexandria. Both in Egypt and elsewhere in the Greek cities he received divine honours.

No heir had been appointed to the throne, and his generals adopted Philip II's half-witted illegitimate son, Philip Arrhidaeus, and Alexander's posthumous son by Roxana, Alexander IV, as kings, sharing out the satrapies among themselves, after much bargaining. The empire could hardly survive Alexander's death as a unit. Both kings were murdered, Arrhidaeus in 317 and Alexander in 310/309. The provinces became independent kingdoms, and the generals, following Antigonus' lead in 306, took the title of king.

EVALUATION

Of Alexander's plans little reliable information survives. The far-reaching schemes for the conquest of the western Mediterranean and the setting up of a universal monarchy, recorded by Diodorus, a 1st-century Greek historian, are probably based on a later forgery; if not, they were at once jettisoned by his successors and the army. Had he lived, he would no doubt have completed the conquest of Asia Minor, where Paphlagonia, Cappadocia, and Armenia still maintained an effective independence. But in his later years Alexander's aims seem to have been directed toward exploration, in particular of Arabia and the Caspian.

In the organization of his empire, Alexander had been content in many spheres to improvise and adapt what he found. His financial policy is an exception; though the details cannot be wholly recovered, it is clear that he set up a central organization with collectors perhaps independent of the local satraps. That this proved a failure was partly due to weaknesses in the character of Harpalus, his chief treasurer. But the establishment of a new coinage with a silver standard based on that of Athens in place of the old bimetallic system current both in Macedonia and in Persia helped trade everywhere and, combined with the release of vast amounts of bullion from the Persian treasuries, gave a much-needed fillip to the economy of the whole Mediterranean area.

Alexander's foundation of new cities—Plutarch speaks of over 70—initiated a new chapter in Greek expansion. No doubt many of the colonists, by no means volunteers, deserted these cities, and marriages with native women led to some dilution of Greek ways; but the Greek (rather than Macedonian) influence remained strong in most of them, and since the process was carried further by Alexander's Seleucid successors, the spread of Hellenic thought and customs over much of Asia as far as Bactria and India was one of the more striking effects of Alexander's conquests.

His plans for racial fusion, on the other hand, were a failure. The Iranian satraps were perhaps not efficient, for out of 18, ten were removed or executed—with what justice it is no longer possible to say. But, more important, the Macedonians, leaders and men alike, rejected the idea, and in the later Seleucid Empire the Greek and Macedonian element was to be clearly dominant.

Achieve-
ment

How far Alexander would have succeeded in the difficult task of coordinating his vast dominions, had he lived, is hard to determine. The only link between the many units that went to make up an empire more disparate than that of the Habsburgs, and far larger, was his own person; and his death came before he could tackle this problem.

What had so far held it all together was his own dynamic personality. He combined an iron will and ability to drive himself and his men to the utmost with a supple and flexible mind; he knew when to draw back and change his policy, though he did this reluctantly. He was imaginative and not without romantic impulses; figures like Achilles, Heracles, and Dionysus were often in his mind, and the salutation at the oracle of Amon clearly influenced his thoughts and ambitions ever afterward. He was swift in anger, and under the strain of his long campaigns this side of his character grew more pronounced. Ruthless and self-willed, he had increasing recourse to terror, showing no hesitation in eliminating men whom he had ceased to trust, either with or without the pretense of a fair trial. Years after his death, Cassander, son of Antipater, a regent of the Macedonian Empire under Alexander, could not pass his statue at Delphi without shuddering. Yet he maintained the loyalty of his men, who followed him to the Hyphasis without complaining and continued to believe in him throughout all hardships. Only when his whim would have taken them still farther into unknown India did he fail to get his way.

General-
ship

As a general Alexander is among the greatest the world has known. He showed unusual versatility both in the combination of different arms and in adapting his tactics to the challenge of enemies who commanded novel forms of warfare—the Śaka nomads, the Indian hill tribes, or Porus with his elephants. His strategy was skillful and imaginative, and he knew how to exploit the chances that arise in every battle and may be decisive for victory or defeat; he also drew the last advantage from victory by relentless pursuit. His use of cavalry was so effective that he rarely had to fall back upon his infantry to deliver the crushing blow.

Alexander's short reign marks a decisive moment in the history of Europe and Asia. His expedition and his own personal interest in scientific investigation brought many advances in the knowledge of geography and natural history. His career led to the moving of the great centres of civilization eastward and initiated the new age of the Greek territorial monarchies; it spread Hellenism in a vast colonizing wave throughout the Near East and created,

if not politically, at least economically and culturally, a single world stretching from Gibraltar to the Punjab, open to trade and social intercourse and with a considerable overlay of common civilization and the Greek *koinē* as a lingua franca. It is not untrue to say that the Roman Empire, the spread of Christianity as a world religion, and the long centuries of Byzantium were all in some degree the fruits of Alexander's achievement.

Alexandria

Alexandria (Arabic al-Iskandariyah), once the greatest city of the ancient world, was the capital of Egypt from its founding by Alexander the Great in 332 BC to AD 642, when it was subdued by the Arabs. It is the second largest city, an urban governorate (*muḥāfaẓah*), and the chief seaport of Egypt. It lies on the Mediterranean Sea at the western edge of the Nile Delta, about 114 air miles (183 kilometres) northwest of Cairo.

Alexandria has always occupied a special place in the popular imagination by virtue of its association with Alexander and with Mark Antony and Cleopatra, immortalized by Shakespeare. Alexandria also played a key role in passing on Hellenic culture to Rome and in the theological disputes over the nature of Christ's divinity that divided the early church. The legendary reputation of ancient Alexandria grew through a thousand years of serious decline following the Arab conquests, during which time virtually all traces of the Greco-Roman city disappeared. By the time Napoleon invaded Egypt in 1798, Alexandria had been reduced to a fishing village. The modern city and port that flourished on the back of the cotton boom in the 19th century has, therefore, little in common with the Alexandria of the past.

The free port status granted Alexandria by the Ottoman Turks accentuated the cultural ambivalence inherent in the city's location—extended along a spit of land with its back to Egypt and its face to the Mediterranean. This idea of a free city, open to all manner of men and ideas, was something the new Alexandria had in common with the old. It was a theme the Greek Constantine Cavafy, drawing heavily on its legendary past, developed in his poems of the city. This idea of Alexandria was taken further by the English writer Lawrence Durrell in his four-part novel, *The Alexandria Quartet*.

Since the 1952 coup in Egypt most of Alexandria's foreign community has departed. Nevertheless, the city remains a thriving commercial community, an important industrial centre, and Egypt's principal holiday resort.

Physical and human geography

THE LANDSCAPE

The city site. The modern city extends 25 miles east to west along a limestone ridge, one to two miles wide, that separates the salt lake of Maryūt, or Mareotis, now partly drained and cultivated, from the Egyptian mainland. An

hourglass-shaped promontory formed by the silting up of a mole (the Heptastadium), which was built soon after Alexandria's founding, links the island of Pharos with the city centre on the mainland. Its two steeply curving bays now form the basins for the Eastern Harbour and the Western Harbour.

Climate. The prevailing north wind, blowing across the Mediterranean, gives Alexandria a markedly different climate from that of the desert hinterland. The summers are relatively temperate, although humidity can build up in July and in August, the hottest month, when the average temperature reaches 87° F (31° C). Winters are cool and invariably marked by a series of violent storms, which can bring torrential rain and even hail. The mean daily temperature in January, which is the coldest month, is 64° F (18° C).

The city plan. Designed by Alexander's personal architect, Dinocrates, the city incorporated the best in Hellenic planning and architecture. Within a century of its founding, its splendours rivaled anything known in the ancient world. Pride of ancient Alexandria and one of the Seven Wonders of the World was the great lighthouse, the Pharos of Alexandria, which stood on the eastern tip of the island of Pharos. Reputed to be more than 440 feet (135 metres) high, it was still standing in the 12th century. In 1477, however, the sultan Qā'it Bāy used stones from the dilapidated structure to build a fort (named for him), which stands near the original site of the Pharos.

The Canopic Way (now al-Hurriyah Avenue) was the principal thoroughfare of the Greek city, running east and west through its centre. Most of the Ptolemaic and, later, Roman monuments stood nearby. The Canopic Way was intersected at its western end by the Street of the Soma (now an-Nabī Dānyāl Street), along which is the legendary site of Alexander's tomb, thought to lie under the mosque an-Nabī Dānyāl. Close to this intersection was the Museion (museum), the city's academy of arts and sciences, which included the great Library of Alexandria. At the seaward end of the Street of the Soma were the two obelisks known as Cleopatra's Needles, which were given in the 19th century to the cities of London and New York.

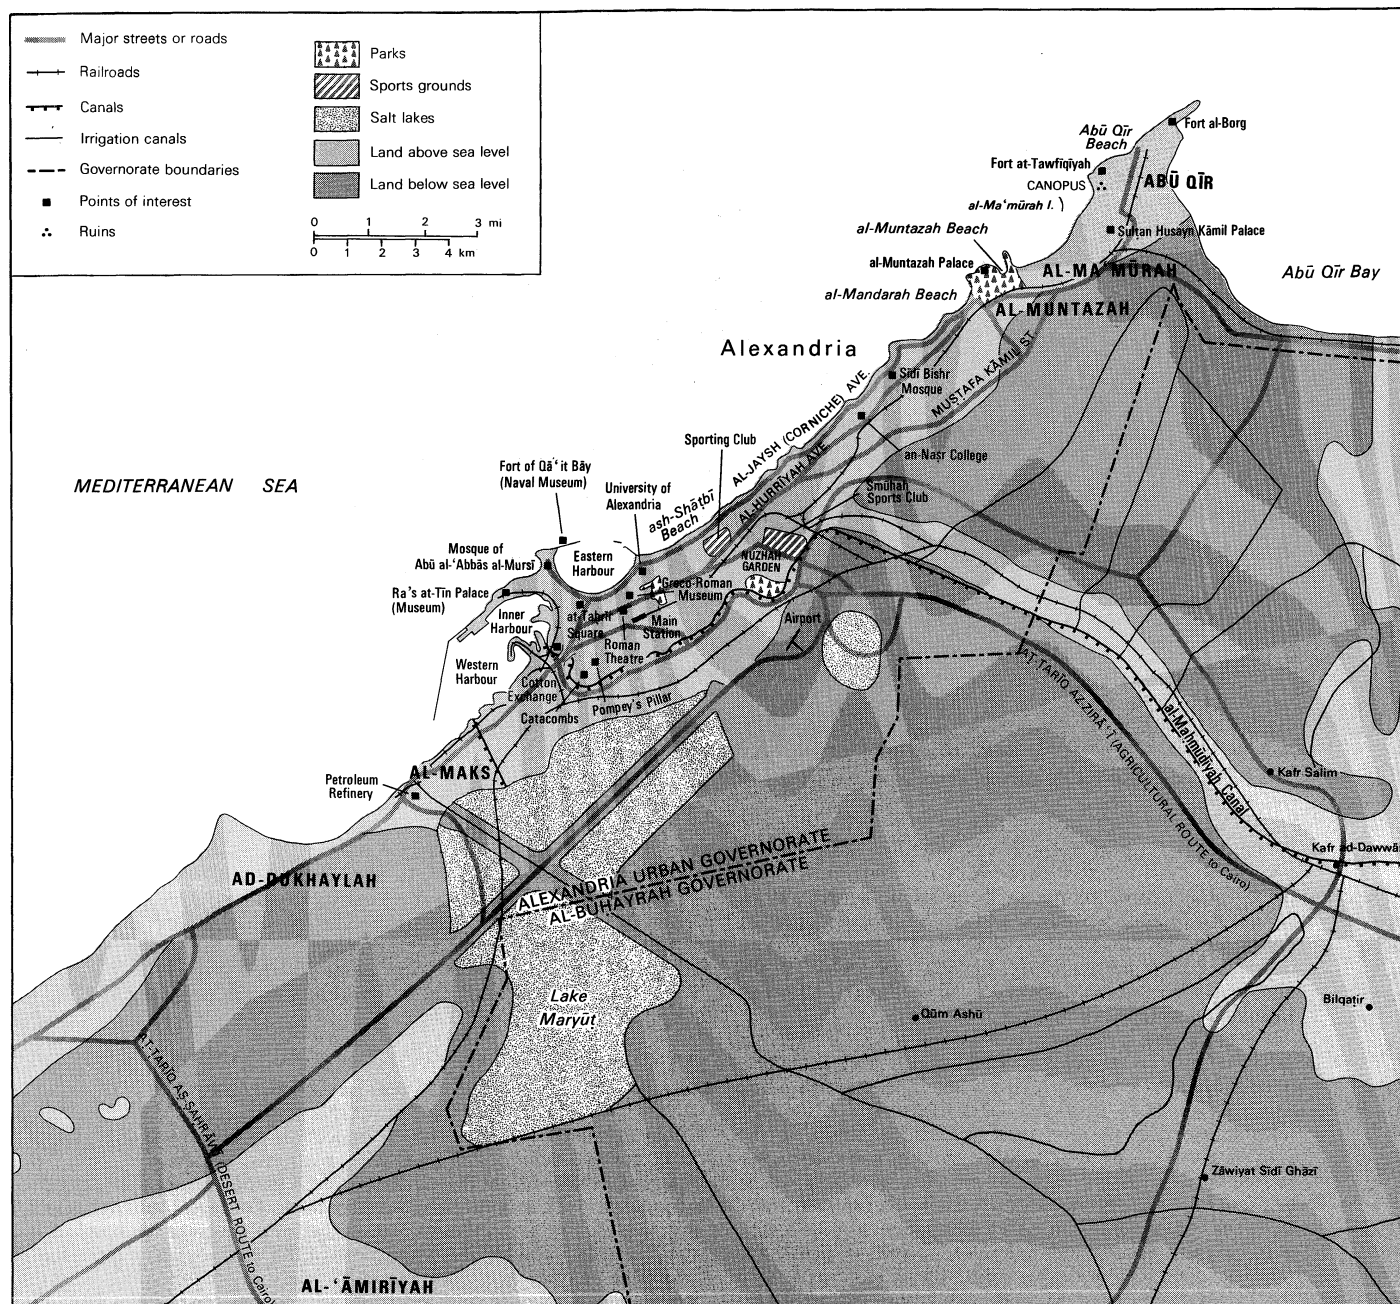

Between al-Hurriyah Avenue and the railway station is the Roman Theatre, which was uncovered in 1959 at the Kawm al-Dikkah archaeological site. At the southwestern extremity of the ancient city are the Kawm ash-Shuqāfah burial grounds, with their remarkable Hadrianic catacombs dating from the 2nd century AD. Nearby, on the site of the ancient fort of Rakotis, is one of the few classical monuments still standing: the 88-foot-high marble column known as Pompey's Pillar (actually dedicated to Diocletian soon after 297). Parts of the Arab wall, encompassing a much smaller area than the Greco-Roman city, survive on al-Hurriyah Avenue, but the city contracted still further in Ottoman times to the stem of the promontory, now the Turkish Quarter. It is the oldest surviving section of the city, housing its finest mosques and worst slums.

The modern city only exceeded the size of the old Greek one at the turn of the 19th century, after which it expanded dramatically. Miḍān at-Taḥrīr ("Liberation Square") used to be the commercial centre, close to the Cotton Exchange and the Bourse. The commercial centre has moved eastward to Sa'd Zaghlūl Square, where the Cecil Hotel and the regional headquarters of the World Health Organization are situated, and inland toward the railway station. Blocked to the west by the port and the industrial area, urban development moved eastward along the Corniche, a seaside promenade officially called al-Jaysh Street, and then inland. Today the Corniche is a ribbon of beach huts, bathing clubs, and cafés faced across the road by a continuous wall of hotels and holiday/apartment blocks.

THE PEOPLE

From the late 19th century to the 1980s the population grew tenfold—the result of high birthrates and migration from the countryside. At the 1976 census the population stood at more than 2,000,000, with half the people under 20 years of age. Projections show that the city will have more than twice that number of people by the year 2000. The once sizable foreign community, which in 1947 still formed one-tenth of the population, has shrunk to insignificant numbers, largely in reaction to the nationalization program and the Israeli-Egyptian conflict. Most Alexandrians belong to one of two main religious groups, the Egyptian Muslims and the Christian Egyptian Copts.

THE ECONOMY

Industry and commerce. Alexandria's chief economic activities, banking, shipping, warehousing, and textile manufacturing, reflect the importance of the port and the cotton trade. The city has become an important industrial centre, accounting for about one-third of Egypt's industrial output. Most industrial development has taken place in the western approaches to the city around the more

modern Western Harbour and along its southern flank. Industry is now the city's chief employment sector.

The area around the port known as Mīnā' al-Baṣāl contains the warehouses and the Cotton Exchange. West across the al-Mahmūdīyah Canal is al-Qabbārī neighbourhood, site of the asphalt works and rice and paper mills. Farther to the west is al-Maks with its salt and tanning industries. There, also, are Alexandria's principal oil refinery, a cement works, and, farther on, the limestone quarries. Other industrial development is taking place still farther west in ad-Dukhaylah, to the south in al-Āmirīyah, and south of Lake Maryūt. Lighter industry is concentrated on the banks of the al-Mahmūdīyah Canal.

Agriculture is an important economic activity in the hinterland, and land reclamation has been attempted with some success.

The port. The major portion of Egypt's foreign trade passes through Alexandria's two main harbours, of which the Western Harbour is by far the more important. All of the country's cotton and a large part of its oil are exported through the port, as are traditional items such as fruits, vegetables, perfumes, and some finished goods. By

ditions

far the largest import is grain. The port handles considerably more than its rated capacity, but improvements are being implemented to relieve congestion, which can be severe. A container terminal was added, and a container port across the bay at ad-Dukhaylah is expected to double Alexandria's port capacity. Egypt's dependence on the port of Alexandria will gradually diminish as the port at Damietta develops.

Transportation. Alexandria is linked to other Egyptian urban centres by railway, roads, and air services. It also is connected by canal with the Nile. The main rail link to Cairo has been upgraded, and Alexandria is also the terminus for the rail line that runs to as-Sallūm on the Libyan border. The desert route to Cairo has been improved, thus relieving pressure on the agricultural route through the delta region. Another main road links the city to Libya. Twice-daily air services operate to Cairo, but plans to introduce scheduled international services have not developed. Given the severe limitations on expanding the existing airport at Nuzhah, built on land reclaimed from Lake Maryūt, al-ʿAmiriyah was selected as the site of the new airport.

ADMINISTRATION AND SOCIAL CONDITIONS

Government. In 1895 Alexandria became the first fully constituted municipality in Egypt. Based upon an earlier organization formed by the foreign merchants, it had a high degree of autonomy in financing the city government. After the 1952 revolution the municipality lost its money-raising powers and underwent other changes. In 1960, in accordance with the national government's decentralization policy, the city and its hinterland were incorporated into a *muḥāfaẓah* (governorate). An appointed governor and mostly elected council administer the *muḥāfaẓah* and are responsible to the Ministry of Local Affairs.

Services. In city services Alexandria is on a par with other urban *muḥāfaẓāt* of Egypt, providing electricity and pure drinking water to all but a small percentage of homes. Less than half of the city is provided with sewerage, however, and pollution of the beaches is becoming a major health hazard. A new sewerage system is under development, part of an overall plan of city improvements.

Education. In Alexandria, the great learning centre of the ancient world, the state supervises education, as is the

rule throughout Egypt. The state system is divided into primary, preparatory, secondary, and technical schools and is the path taken by the vast majority of Egyptians. A few private schools survive from before the 1952 revolution. The University of Alexandria, founded as a state university in 1942 and accommodating about 100,000 students, lies just east of the city centre. Its library is among the largest in Egypt.

CULTURAL LIFE

Alexandria's most important museum, the Greco-Roman Museum, situated behind the Municipality Building on al-Ḥurriyah Avenue, is noted for its collection of antiquity, most of which comes from finds within the city. Renewed interest in the classical period has revived archaeological exploration, which is focusing on Kawm ad-Dikkah, the underwater site of the Pharos lighthouse, and the search for Alexander's tomb. The Museum of Fine Art, located across the railway line from the city's stadium, presents exhibitions of modern and local art. In addition, two of the royal palaces, Ra's at-Tin Palace on Pharos island and al-Muntazah Palace at the eastern end of al-Jaysh Avenue are open to the public. Alexandria is well endowed with outdoor recreational establishments. The most popular is the Shallālāt Gardens surrounding the remnants of the Arab walls. The Sporting Club and the Smūhah Sports Club provide a variety of sporting facilities. There are also fine botanical gardens and popular weekend beach resorts.

History

FOUNDATION AND MEDIEVAL GROWTH

The Greek period. Alexander the Great founded the city in 332 BC after the start of his Persian campaign; it was to be the capital of his new Egyptian dominion and a naval base that would control the Mediterranean. The choice of the site that included the ancient settlement of Rakotis (which dates back to 1500 BC) was determined by the abundance of water from Lake Maryūt, then a spur of the Canopic Nile, and the good anchorage provided offshore by the island of Pharos.

After Alexander left Egypt his viceroy, Cleomenes, continued the creation of Alexandria. With the breakup of the empire on Alexander's death in 323, control of the

Greatest
ancient
city

city passed to his viceroy, Ptolemy I, who founded the dynasty that took his name. The early Ptolemies successfully blended the religions of ancient Greece and Egypt in the cult of Sarapis and presided over Alexandria's golden age. Alexandria profited from the demise of Phoenician power and from Europe's growing trade with the East via the Nile and the canal that then linked it with the Red Sea. Indeed Alexandria became within a century of its founding the greatest city in the world and a centre of Greek scholarship and science. Such scholars as Euclid, Archimedes, Plotinus the philosopher, and Ptolemy and Eratosthenes the geographers studied at the Mouseion, the great research institute founded by the Ptolemies.

The Roman period. The decline of the Ptolemies in the 1st and 2nd centuries BC was matched by the rise of Rome. Alexandria played a major part in the intrigues that led to the establishment of imperial Rome. In Alexandria, Cleopatra, the last of the Ptolemies, courted Julius Caesar and claimed to have borne him a son. Her attempts at restoring the dynasty's fortunes, however, were thwarted by Caesar's assassination and her unsuccessful support of Mark Antony against Caesar's great-nephew Octavian. In 30 BC, Octavian (later Augustus) formally brought Alexandria and Egypt under Roman rule.

In AD 45 St. Mark reputedly made his first convert to Christianity in Alexandria. Thenceforth the city's growing Christian and Jewish communities united against Roman paganism. Periodic persecutions by various early emperors failed to subdue these communities, and, when the empire formally adopted Christianity under Constantine I, the stage was set for schisms within the church.

The first conflict that split the early church was between two Alexandrian prelates, Athanasius and Arius, over the nature of Christ's divinity. It was settled in 325 by the adoption of the Creed of Nicaea, which affirmed Christ's spiritual divinity and branded Arianism, the belief that Christ was lower than God, as heresy. Arianism, however, had many imperial champions, and this sharpened the conflict between the Alexandrian church and the state. In 391 Christians destroyed the Sarapeum, sanctum of the Ptolemaic cult and what had been saved by Cleopatra of the great Mouseion library. In 415 a Christian faction killed the Neoplatonist philosopher Hypatia, and Greek culture in Alexandria quickly declined.

Acceptance of
Mono-
physitism

With the ascendancy of the patriarchate of Constantinople, the local church adopted Monophysitism (belief in the single nature and therefore physical divinity of Christ) as a way of asserting its independence. Although Monophysitism was rejected by the Council of Chalcedon (451), the Alexandrian church resisted Constantinople's attempts to bring it into line. An underground church developed to oppose the established one and became a focus of Egyptian loyalties. Disaffection with Byzantine rule created the conditions in which Alexandria fell first to the Persians, in 616, and then, in 642, to the Arabs.

The Islāmic period. The Arabs occupied Alexandria without resistance. Thenceforth, apart from an interlude in 645 when the city was briefly taken by the Byzantine fleet, Alexandria's fortunes were tied to the new faith and culture emanating from the Arabian deserts. It was soon eclipsed politically by the new Arab capital at al-Fuṣṭāṭ (later to be absorbed into the modern capital, Cairo), which became the strategic prize for those wanting to control Egypt. Nevertheless, Alexandria continued to flourish as a trading centre, principally for textiles and luxury goods.

Key trade
lost

Having survived the early Crusades relatively unscathed, the city came into its own again with the development of the East-West spice trade, which Egypt monopolized. Unfortunately this trade was lost after the discovery of the sea route to India in 1498 and the Turkish conquest of Egypt in 1517. Under Turkish rule the canal linking Alexandria to the Rosetta branch of the Nile was allowed to silt up, strangling the city's commercial lifeline. Alexandria once again contracted into a small fishing village.

EVOLUTION OF THE MODERN CITY

Alexandria's rebirth began when Muḥammad 'Alī Pasha was appointed Ottoman viceroy of Egypt in 1805. Hoping to modernize Egypt, he reopened Alexandria's access

to the Nile by building the 45-mile-long al-Maḥmūdīyah Canal (completed between 1818 and 1820), new docks, and an arsenal (1828–33), where he located industry. Foreign traders were encouraged by the Capitulations, which gave them certain legal rights and privileges (for instance, to be tried in their own courts), and they began to settle in and develop the city. Cotton was introduced into Egypt in the 1820s, and by the 1840s Europe's growing appetite for the commodity was making Alexandria rich. The city became an increasingly important banking and commercial centre. The opening of the Cairo railway in 1856, the cotton boom created by the American Civil War in the early 1860s, and the opening of the Suez Canal in 1869, which reestablished Egypt as the principal staging post to India, led to another cycle of rapid growth.

The British bombardment of the city in 1882 to put down a local nationalist revolt led directly to the British occupation that lasted until 1922. The city nevertheless continued to prosper and expand, retaining its position as the second (summer) capital of Egypt. Under British patronage the foreign community continued to flourish. Alexandria played its part in the nationalist struggle between and after the world wars. In 1952 it witnessed King Farouk's departure from Egyptian soil after the revolution. In 1956 the failure of the tripartite British, French, and Israeli invasion discouraged continued residence of the foreign community. The sequestrations that followed Suez and the subsequent nationalizations in the early 1960s drove many more foreigners out.

During the 1960s Alexandria was thoroughly Egyptianized and brought firmly under Cairo's control. It benefited, however, from Pres. Gamal Abdel Nasser's industrialization program, particularly in food processing and textiles, which had been much expanded between the wars. The city was adversely affected by the devastating defeat in the Six-Day War of June 1967, the dislocation created by the closure of the Suez Canal, and the evacuation of the Canal Zone. The port was swamped by trade diverted from Port Said and had not fully recovered when in 1974 the introduction of an open-door policy led to a flood of imports.

Liberalization, coupled with tentative moves at decentralization under Pres. Anwar el-Sadat, revived calls by the merchant community for greater financial autonomy. These in turn have created a new sense of civic identity and pride. The discovery in 1976 of offshore and onshore natural gas has spurred industrial development, principally at ad-Dukhaylah, a major iron and steel centre. Refinery facilities are being upgraded, and Egypt's embryonic petrochemical industry has been established at al-ʿAmīriyah. Alexandria's access to the outside world is also being promoted to encourage light industry. A free zone has been established in al-ʿAmīriyah. The city has launched a master plan designed to bring massive civic improvements in the late 20th century.

BIBLIOGRAPHY. ANTHONY DE COSSON, *Mareotis* (1935), is an authoritative, well-written history and description of the Mar-yūt district; and PERCIVAL G. ELGOOD, *The Ptolemies of Egypt* (1938), is a scholarly but lively history of the Ptolemies, from Ptolemy I (died 283 BC) to Cleopatra (died 30 BC). MARY ROWLATT, *A Family in Egypt* (1956), based on family letters, includes descriptions of 19th- and 20th-century European life in Alexandria. The same author's *Founders of Modern Egypt* (1962), is a detailed account of Egyptian events of the 1870s and 1880s that culminated in Alexandria. JACQUES BERQUE, *Egypt: Imperialism and Revolution* (1972; originally published in French, 1967), is a monumental history of Egypt under British rule; it contains vivid firsthand accounts of late 19th- and early 20th-century Alexandria. LAWRENCE DURRELL, *The Alexandria Quartet: Justine, Balthazar, Mountolive, Clea*, 4 vol. (1957–60; reissued 1970 in 1 vol.), is a group of four novels, set in Alexandria between the world wars; it is widely attributed with having revived modern interest in Alexandria. E.M. FORSTER, *Alexandria: A History and a Guide*, new ed. (1982), is a revision of the classic guide to the city, as it was in the 1920s, with notes describing how the same places look half a century later; it includes a detailed account of the Greco-Roman Museum. C.P. CAVAFY, *Collected Poems*, trans. by EDMUND KEELEY and PHILIP SHERRARD, ed. by GEORGE SAVIDIS (1975), is the first English publication of the poems of the city's most illustrious modern poet writing in Greek.

(Ma.R./J.A.Ma.)

Algae

Algae (singular alga) are a group of predominantly aquatic, photosynthetic organisms that defy precise definition. They range in size from the tiny flagellate *Micromonas* that is 1 micrometre (0.00004 inch) in diameter to giant kelp that reach 60 metres (200 feet) in length. Algae provide much of the Earth's oxygen, they are the food base for almost all aquatic life, they are an original source of petroleum products, and they provide foods and industrial products for humans. The algae have many types of life cycles, from simple to complex. Their photosynthetic pigments are more varied than those of plants, and their cells have features not found among plants and animals. Some algae are ancient, while other groups have evolved more recently. The taxonomy of algae is changing rapidly because so much new information is being discovered. The study of algae is termed phycology, and one who studies algae is known as a phycologist.

The algae as treated in this article do not include the prokaryotic (nucleus-lacking) blue-green algae (cyanobacteria) and prochlorophyte algae. Beginning in the 1970s, some scientists suggested that the study of the prokaryotic algae should be incorporated into the study of bacteria because of shared cellular features. Other scientists consider the oxygen-producing photosynthetic capability of blue-green and prochlorophyte algae to be as significant as cell structure, and they continue to classify them as algae.

In this article the algae are defined as eukaryotic (nucleus-bearing) organisms that photosynthesize but lack the specialized reproductive structures of plants. Plants always have multicellular reproductive structures where the fertile, gamete-producing cells are surrounded by sterile cells; this never occurs in algae. Algae lack true roots, stems, and leaves, but they share this feature with the plant division Bryophyta (e.g., mosses and liverworts).

Beginning in the 1830s, algae were classified into major groups based on colour. The red, brown, and green seaweeds are well known to those who have walked along a rocky seashore. The colours are a reflection of

the chloroplast pigment molecules—i.e., the chlorophylls, carotenoids, and phycobiliproteins. Many more than three groups are now recognized, and each class of algae shares a common set of pigment types that is distinct from those of all other groups.

The algae are not closely related in an evolutionary sense. Specific groups of algae share enough features with protozoa and fungi that it is difficult to distinguish them from certain protozoa or fungi without using the presence of chloroplasts and photosynthesis as delimiting features. Thus, some algae have a closer evolutionary relationship with the protozoa or fungi than they do with other algae, and the converse is also true—some protozoa or fungi are more closely related to algae than to other protozoa or fungi. In fact, if the algae are united into one evolutionary group with a common ancestor, then that evolutionary group will include animals, fungi, plants, and protozoa as well.

Knowledge and use of algae are perhaps as old as mankind (*Homo sapiens*), and possibly earlier species such as *H. erectus* also knew of, and used, algae. Seaweeds are still eaten by coastal societies, and algae are considered acceptable foods in many restaurants. Anyone who has slipped on a “slimy” rock (covered with diatoms) while crossing a stream has had firsthand experience with algae. Others know algae as green sheens on pools and ponds. The algae are the base of the food chain for all marine organisms since most plants do not live in the oceans. Because the oceans occupy about 71 percent of the Earth's surface area, the role of algae in supporting aquatic life is essential.

This article discusses the algae in general terms. For a discussion of the related protists, see the articles PROTOZOA and PROTISTS. For a more complete discussion of photosynthesis, see the articles PHOTOSYNTHESIS and PLANTS.

For coverage of related topics in the *Macropædia* and *Micropædia*, see the *Propædia*, section 313, and the *Index*.

GENERAL FEATURES

Size range and diversity of structure. Algae span seven orders of magnitude in size. Many algae consist of only one cell, others have two or more cells, and the largest have millions of cells. In large, macroscopic algae, groups of cells are specialized for specific functions, such as anchorage, transport, photosynthesis, and reproduction. Specialization involving thousands of cells is sometimes interpreted as a measure of complexity and evolutionary advancement. An alga that can accomplish the same functions using only one cell, however, should not be interpreted as a “simple” alga.

The algae are artificially divided into several types based on the morphology of their vegetative, or growing, state (Figures 1–3). Filamentous forms have cells arranged in chains and an overall appearance like strings or filaments. Some filaments (like *Spirogyra*, Figure 1) are unbranched, while others, like *Stigeoclonium*, are branched and appear bushlike. In many red algae—for example, *Palmaria*—numerous adjacent filaments lie together and create the

gross morphological form of the alga. Parenchymatous (tissuelike) forms, such as the giant kelp *Macrocystis*, can become very large. Other algae grow to large sizes without forming distinct cells (i.e., the protoplasm flows together as a large living mass); the green seaweed *Codium*, commonly known as dead-man's-fingers, is an example. Some algae have flagella and swim through the water. These flagellates (Figure 1) range from single cells, as in *Ochromonas*, to colonial organisms with thousands of cells. Coccoid and capsoid algae (Figure 1) are unicellular or multicellular. Coccoid organisms, such as *Scenedesmus*, have an exact number of cells, and that number is produced by a series of rapid cell divisions when the organism is first formed; once the exact cell number is obtained, the organism grows in size but not in cell number. Capsoid organisms, such as *Chrysocapsa*, have variable numbers of cells; the cell number increases gradually, and the cells are embedded in a copious gel.

Distribution and abundance. Algae are ubiquitous, although they are most common in aquatic habitats. Algae

Figure 1. Representative algae.

Categorization by habitat

are often categorized ecologically by their habitat. Planktonic algae are suspended in the water, while neustonic algae grow on the water surface. Cryophilic algae grow in snow and ice, while thermophilic algae live in hot springs. Epidaphic algae live on soil, and endodaphic algae live in soil. Algae can live attached to other organisms: epizoic algae grow on animals such as turtles, polar bears, and tree sloths; epiphytic algae grow on fungi, plants, or other algae. Algae can be classified even more specifically. For example, corticolous algae grow on the bark of trees. Epilithic algae live on rocks, endolithic algae live in rocks, and chasmolithic algae grow in rock fissures. Some algae live inside other organisms, and in a general sense these are called endosymbionts. Specifically, endozoic endosymbionts live in protozoa or animals, while endophytic endosymbionts live in fungi, plants, or other algae. Algae also live in the atmosphere, moving with air currents and receiving moisture and nutrients from clouds.

Algal abundance and diversity varies from one environment to the next, just as plant abundance and diversity varies from tropical rain forests to deserts. Terrestrial vegetation (plants and algae) is influenced most by precipitation and temperature, while aquatic vegetation (pri-

marily algae) is influenced most by light and nutrients. When nutrients are abundant, as occurs in some polluted waters, algal cell numbers can become great enough to produce obvious patches of algae. These patches are called "blooms" or "red tides." The number of organisms necessary for a bloom varies with the size of the organism and the concentration of cells. Blooms are usually linked to favourable growing conditions, including an abundance of nutrients, but blooms do not occur every time favourable conditions exist, and therefore it is difficult to explain or predict their occurrence.

Importance. Algae use photosynthesis to form organic food molecules from carbon dioxide and water. Like plants, algae are located at the base of the food web, and nonphotosynthetic organisms depend upon this photosynthetic food base for their existence. Nearly three-fourths of Earth is covered by water, and plants are virtually absent from the major water sources, the oceans. Marine life—including whales, seals, fish, turtles, shrimps, lobsters, clams, octopuses, starfish, and worms—ultimately depends upon algae for its existence.

In addition to making organic molecules, algae produce oxygen as a by-product of photosynthesis. Algae produce an estimated 30 to 50 percent of the net global oxygen. This oxygen is available to humans and other terrestrial animals for respiration, and it is consumed when coal, wood, or oil is burned. Although terrestrial ecosystems also produce large amounts of oxygen, the organisms living in these ecosystems consume it relatively rapidly on a geologic time scale, so that the net oxygen production by rain forests over time is low.

Crude oil and natural gas are the remnants of the photosynthetic products of ancient algae, which were subsequently modified by bacteria. The North Sea oil deposits were formed from coccolithophore algae (class Prymnesiophyceae), and the Colorado oil shales were produced by an alga similar to *Botryococcus*. Today, *Botryococcus* (a green alga) produces blooms in Lake Baikal, in the Soviet Union, and produces large amounts of oil. The oil is so abundant on the surface of the lake that it is collected with a special skimming apparatus. Several companies have grown oil-producing algae in high-salinity ponds and have extracted the oil as an alternative to fossil fuels.

Algae, as processed and unprocessed food, have a commercial value of several billion dollars annually. Approximately 500 species are eaten by humans, and some 160 are commercially important. In addition to the use of algal extracts in prepared foods (see below), algae are eaten directly in many parts of the world. Algae are a significant food item in the diets of East Asian and Pacific Island societies, and unprocessed algae are eaten by South Americans, North Americans, and northern Europeans. Hawaiians have the most diverse diet of algae. In the 1800s at least 75 species were eaten by Hawaiians, and in the 1980s more than 50 species of algae were still being consumed.

The red alga *Porphyra* is the most important commercial food alga. In Japan alone approximately 100,000 hectares (247,000 acres) of shallow bays and seas are farmed. *Porphyra* has two major stages in its life cycle, the *Conchocelis* stage and the *Porphyra* stage. The *Conchocelis* stage is a small, shell-boring stage that is artificially propagated on oyster shells. The mature *Conchocelis* produces conchospores that germinate and grow into the large *Porphyra* stage. Either the oyster shells are tied to ropes or nets, or the conchospores are seeded directly onto the ropes or nets. The large, mature *Porphyra* blades are removed from the nets and washed, chopped, and pressed into sheets to dry.

Palmaria palmata, another red alga, is eaten in the north Atlantic region. Known as dulse in Canada and the United States, as dillisk in Ireland, and as *söl* in Iceland, it is harvested by hand from intertidal rocks during low tide. *Laminaria* species (brown algae) are also harvested from wild beds along rocky shores, particularly in Japan. *Laminaria* is eaten with meat or fish and in soups. The green algae *Monostroma* and *Ulva* look like lettuce leaves (their common name is sea lettuce), and they are eaten as salads or in soups, relishes, and meat or fish dishes.

The microscopic, freshwater green alga *Chlorella* is cul-

Ecological importance

Commercial value

tivated and eaten in Taiwan, Japan, Malaysia, and the Philippines. It has a high protein content (53–65 percent) and has been considered as a possible food source during extended space travel.

The cell walls of many seaweeds contain phycocolloids that have received increasing use in prepared foods. The term phycocolloid means “algal colloid” and is based upon the colloidal substances that are extracted from cell walls. The usefulness of these compounds is based on the colloidal property of alternating between sol (fluid) and gel (solid) states. The three major phycocolloids are alginates, agars, and carrageenans. Alginates are extracted primarily from brown seaweeds, and agar and carrageenan are extracted from red seaweeds. These phycocolloids are cell-wall polysaccharides that are formed by the polymerization of chemically modified galactose sugar molecules (agars and carrageenans) or of organic acids, such as manuronic acid and glucuronic acid (alginates). Phycocolloids are safely consumed by humans and other animals and are therefore used in a wide variety of prepared foods, such as “ready-mix” cakes, “instant” puddings and pie fillings, and artificial dairy toppings.

Alginates

Alginates, or alginic acids, are commercially extracted from brown seaweeds, especially the kelp *Macrocystis*, *Laminaria*, and *Ascophyllum*. Alginates are used in ice creams to limit ice crystal formation, thereby producing a smooth texture, and are also used as emulsifiers and thickeners in syrups and as fillers in candy bars and salad dressings.

Agars are extracted primarily from species of the red alga *Gelidium*, but they are also obtained from other red algae, especially *Gracilaria*, *Pterocladia*, *Acanthopeltis*, and *Ahnfeltia*. Agars are used in instant pie fillings, canned meats or fish, and bakery icings. Agar is also used as a clarifying agent in beer and wine.

Carrageenans, from the Irish word “carraigin” (meaning Irish moss), are extracted from various red algae: *Eucheuma* in the Philippines, *Chondrus crispus* in the United States and the Canadian Maritime Provinces, and *Iridaea* in Chile. Carrageenans are widely used in food products, and it is estimated that the average human consumption of carrageenans in the United States is 250 milligrams (0.01 ounce) a day. Carrageenans are used as thickening and stabilizing agents in dairy products, imitation creams, puddings, syrups, and canned pet foods.

Industrial uses

The diatoms have played an important role in industrial development during the 20th century. The frustules, or cell walls, of diatoms (class Bacillariophyceae) are made of opaline silica and contain many fine pores. Occasionally, large quantities of frustules are deposited in ocean sediments, and the fossilized remains are called diatomite. When geologic uplifting brings these deposits above sea level, the diatomite is easily mined. Diatomite contains

approximately 50 million diatom frustules per cubic inch. The deposit at Lompoc, Calif., U.S., for example, covers 13 square kilometres (5 square miles) and is up to 425 metres (1,400 feet) deep.

Diatomite is relatively inert. It has a high absorptive capacity, large surface area, low bulk density, and relatively low abrasion. It consists of approximately 90 percent silica, and the remainder consists of compounds such as aluminum and iron oxides. The fine pores in the frustules make it an excellent filtering material for beverages (fruit juices, soft drinks, beer, wine), chemicals (sodium hydroxide, sulfuric acid, gold salts), industrial oils (those used as lubricants or in rolling mills or for cutting), cooking oils (vegetable and animal), sugars (cane, beet, corn), water supplies (municipal, swimming pool, waste, boiler), varnishes, lacquers, jet fuels, and antibiotics, to name a few. The low abrasive properties make it suitable for use in toothpaste, “nonabrasive” cleansers, polishes (silver, automobile), and buffing compounds.

Diatomite is widely used as a filler and extender in paint, paper, and rubber and plastic products; the gloss and sheen of “flat” paints can be controlled using diatomite. During the manufacture of plastic bags, diatomite is added to the newly formed sheets to act as an antiblocking agent so that the plastic (polyethylene) can be rolled while it is still hot. Because diatomite can absorb approximately 2.5 times its weight in water, it also makes an excellent anticaking carrier for powders used to dust roses or for cleansers used to clean rugs. Diatomite is also used in making welding rods, battery boxes, concrete, explosives, and animal foods.

Chalk is another fossilized deposit of protistan remains. It consists in part of calcium carbonate scales, or coccoliths, from the coccolithophore members of the class Prymnesiophyceae. Chalk deposits, such as the White Cliffs of Dover in England, contain large amounts of coccoliths as well as the shells of foraminiferan protozoa. Coccoliths can be observed in fragments of ordinary blackboard chalk examined under a light microscope.

By the end of the 18th century, kelp (class Phaeophyceae) was harvested and burned as a means of producing soda commercially. When mineral deposits containing soda were discovered, the use of kelp declined. Kelp was again harvested in abundance during the 19th century when salts and iodine were extracted for commercial use. Once again, however, newly discovered mineral deposits, this time of salt and iodides, led to a demise of the kelp industry. During the 20th century the kelp industry again flourished. During World War I the United States used kelp as a source of potash and acetone.

Kelp

Seaweeds have been used as agricultural fertilizers for centuries in many parts of the world. Coastal farmers cut seaweeds that were spread over the soil. Kelp is now used

to extract macronutrients and micronutrients for specialized plant fertilizers and animal feed supplements. Dried kelp is almost 50 percent mineral matter; *Ascophyllum nodosum*, for example, contains 55 trace elements. Commercial extracts used as plant fertilizers contain a mixture of macronutrients, micronutrients, and trace elements that provide robust plant growth. The metal and other trace elements are chelated (bound) to organic sugars so that the concentration of free metals, which can be toxic to plants and animals, is very low. The equilibrium between chelated and free forms provides a gradual release of nutrients from the extract (fertilizer) as plants use the free forms.

Phycocolloids have industrial uses in addition to their important roles in food products. Because they are relatively inert and have good gelling properties, they are used as creams and gels for carrying minute amounts of active additives, as in medical drugs or insecticides. Agar is used extensively as a bacteriologic culturing substrate in medical and research facilities and is also used as a substrate for eukaryotic cell and tissue culture, including the culture of algae themselves. Carrageenans are used in the manufacture of shampoos, cosmetics, and medicines.

The green unicellular flagellate *Dunaliella* is cultivated in saline ponds. The culture conditions are manipulated so that carotene or glycerol are produced in large amounts. These compounds are extracted and sold commercially.

Toxic algae

Algae can be harmful to humans. Some algae produce toxins that become concentrated in shellfish and finfish. Although they have little effect on shellfish and finfish, the toxins accumulate in the seafood flesh, making it unsafe or poisonous for human consumption. The dinoflagellates (class Dinophyceae) are the most notorious producers of toxins. Paralytic shellfish poisoning is caused by saxitoxin or any of at least 12 related compounds. Saxitoxin is probably the most toxic compound known and is 100,000 times more toxic than cocaine. Saxitoxin and saxitoxin-like compounds are nerve toxins that interfere with neuromuscular junctions. *Alexandrium tamarense* and *Gymnodinium catenatum* are the two species most often associated with paralytic shellfish poisoning. Diarrhetic shellfish poisoning is caused by okadaic acids that are produced by several algae, especially species of *Dinophysis*. Neurotoxic shellfish poisoning is caused by toxins produced in *Gymnodinium breve*, a red tide organism. This alga is notorious for fish kills and shellfish poisoning along the coast of Florida, U.S. When the red tide blooms are blown to shore, wind-sprayed toxic cells can cause health problems for animals that breathe the air.

Ciguatera is a disease of humans caused by consumption of tropical fish infected with the algae *Gambierdiscus* or

Ostreopsis. Unlike many other dinoflagellate toxins, ciguatera toxin and maitotoxin are concentrated in fish rather than shellfish. Levels as low as one part per billion in fish are sufficient to cause human intoxications.

Not all shellfish poisons are produced by dinoflagellates. Amnesiac shellfish poisoning is caused by domoic acid, which is produced by diatoms (Bacillariophyceae) such as *Nitzschia pungens* f. *multiseries*, and *Nitzschia pseudodelicatissima*. Symptoms of this poisoning in humans progress from abdominal cramps to vomiting to memory loss to disorientation and finally to death.

Several algae produce toxins that are lethal to fish. *Prymnesium parvum* (class Prymnesiophyceae) has caused massive die-offs in ponds where fish are cultured, and *Chrysochromulina polylepis* (class Prymnesiophyceae) has caused major fish kills along the coasts of the Scandinavian countries. Other algae, such as *Heterosigma* (class Raphidophyceae) and *Dictyocha* (class Dictyochophyceae), are suspected fish killers as well.

Algae can cause human diseases by directly attacking human tissues, although the frequency is rare. Protothecosis is caused by a chloroplast-lacking green alga, *Prototheca*. The alga infects skin lesions, grows subcutaneously, and can eventually spread to the lymph glands. *Prototheca* is also believed to cause ulcerative dermatitis in the Australian platypus. Similar infections, in humans and cattle, are caused by chloroplast-bearing species of *Chlorella* of the class Chlorophyceae.

Some seaweeds contain high concentrations of arsenic and when eaten cause arsenic poisoning. For example, the brown alga *Hizikia* has sufficient arsenic that it was used as a rat poison in Asian countries.

Diatoms have been used in forensic medicine. Where death by drowning is suspected, lung tissue is examined. The presence of silica diatom cell walls can verify death by drowning; in mysterious cases, the diatom species can be used to pinpoint the exact location of death because the species are characteristic for a given lake, bog, or bay. Diatomite used in the manufacture of car polishes, paints, and matches, for example, is used in solving crimes as well.

FORM AND FUNCTION

The algal cell. Eukaryotic algal cells contain three types of double-membrane-bound organelles: the nucleus, the chloroplast, and the mitochondrion. The nucleus contains most of the genetic material of the cell, and the DNA (deoxyribonucleic acid) molecules exist as linear strands. The DNA is condensed into obvious chromosomes only at the time of nuclear division (mitosis) in most algae; however, the nuclear DNA of the classes Dinophyceae and Euglenophyceae is always condensed. The two mem-

branes surrounding the nucleus are referred to as the nuclear envelope, which typically has specialized nuclear pores that regulate the movement of molecules into and out of the nucleus.

The chloroplast is the site of photosynthesis, the complex set of biochemical reactions that convert light energy, carbon dioxide, and water into sugars. The chloroplast contains flattened, membranous sacs, called thylakoids, that contain the photosynthetic light-harvesting pigments, the chlorophylls, carotenoids, or phycobiliproteins (see below *Photosynthesis*).

The mitochondrion is the site where food molecules are broken down and carbon dioxide, water, and chemical bond energy are released, a process called cellular respiration (see below *Cellular respiration*). Photosynthesis and respiration are approximately opposite processes, the former building sugar molecules and the latter breaking them down. The inner membrane of the mitochondrion is infolded to a great extent, and this provides the surface area necessary for respiration. The infoldings, called cristae, have three morphologies: (1) flattened or sheetlike, (2) fingerlike or tubular, and (3) paddlelike. Plants and animals, by comparison, have only flattened cristae.

Chloroplasts and mitochondria also have their own DNA. This DNA is not like nuclear DNA, however, because it is circular rather than linear, and therefore it resembles the DNA of prokaryotes. The similarity of chloroplastic and mitochondrial DNA to prokaryotic DNA has led many scientists to accept the hypothesis that these organelles resulted from a long and successful symbiosis of prokaryote cells inside eukaryote host cells. These symbioses have been used in defining the endosymbiosis hypothesis, which states that eukaryotic cells are formed in part by incorporating prokaryotes as specialized organelles.

Cell organelles

Algae have several single-membrane-bound organelles, including the endoplasmic reticulum, Golgi apparatus, lysosome, peroxisome, vacuole, contractile vacuole, and ejectile organelles. The endoplasmic reticulum is a complex membranous system that forms intracellular compartments, acts as a transport system within the cell, and serves as a site for synthesizing fats, oils, and proteins. The Golgi apparatus is a series of membranous sacs that are stacked like pancakes. The Golgi apparatus performs four distinct functions: it sorts many molecules synthesized elsewhere in the cell; it produces carbohydrates like cellulose or sugars, and sometimes it attaches the sugars to other molecules; it packages molecules in small vesicles; and it marks the vesicles so that they are routed to the proper destination. The lysosome is a specialized vacuole that contains digestive enzymes used to break down old organelles, cells or cellular components during certain developmental stages, and particulate matter that is ingested by species that engulf food. Peroxisomes specialize in metabolically breaking down certain organic molecules and in destroying dangerous peroxide compounds, such as hydrogen peroxide, that are produced during some biochemical reactions. Vacuoles are membranous sacs that store many different substances depending upon the organism and its metabolic state. The contractile vacuole is not involved in long-term storage; rather, it is a highly specialized organelle that regulates the water content of cells. When too much water enters the cells, the contractile vacuole "squirts" it out. Some algae have special ejectile organelles that apparently act as protective structures. The Dinophyceae has trichocysts—harpoonlike structures that lie beneath the cell surface and explode from the disturbed or irritated cell. Ejectosomes, of analogous structure, are found in the class Cryptophyceae. Several classes of algae in the division Chromophyta have mucous organelles. *Gonyostomum semen*, a freshwater member of the class Raphidophyceae, has numerous mucocysts, and when it is collected in a plankton net the mucocysts discharge, giving the net and sample a mucous consistency.

The nonmembrane-bound organelles include the ribosomes, pyrenoids, microtubules, and microfilaments. The ribosome serves as the "workbench" during protein synthesis. It provides the site where genetic information, as messenger RNA, is translated into proteins. The ribosome carefully interprets the genetic code of the DNA so that

the protein is made exactly to the genetic specifications. The pyrenoid, a dense structure that occurs within or beside chloroplasts of algae, has a concentration of ribulose biphosphate carboxylase, the enzyme necessary in photosynthesis for carbon fixation and thus sugar formation (see below *Photosynthesis*). Starch, the storage form of sugar, is often found around pyrenoids. The microtubules are tubelike structures formed from tubulin proteins. Some microtubules are almost always present in the cell, but others appear suddenly when needed and then disassemble after use. Microtubules provide a rigid structure, or cytoskeleton, in the cell that helps determine the shape of the cell, and in species without cell walls the cytoskeleton maintains the cell shape. Microtubules also provide a "rail" system along which vesicles are transported. The spindle apparatus, which separates the chromosomes when the nucleus divides, consists of microtubules. Finally, microtubules also form the basic structure, or axoneme, of the flagellum, and they are a major component of the flagellar root system that anchors the flagellum in the cell. Microfilaments are formed by the polymerization of proteins such as actin. Actin microfilaments contract and relax, and they function as tiny muscles inside the cell.

Microtubules

Flagella. A flagellum, when present, is structurally complex and contains more than 250 types of proteins. Each flagellum consists of an axoneme, or cylinder, with nine outer pairs of microtubules surrounding two central microtubules. The whole cylinder is surrounded by a membrane. Each of the nine pairs of microtubules has an *a* tubule and a *b* tubule. The *a* tubule has numerous molecules of the protein dynein attached along its length. Dynein is involved in converting the chemical energy of adenosine triphosphate (ATP) into the mechanical energy that permits flagellar movement. The scales and hairs apparently aid in swimming. The swellings and para-axonemal structures (crystalline rods and noncrystalline rods and sheets) are often involved in photoreception, providing the swimming cell with a means for detecting light, toward or from which it may swim. The flagellum bends as the dynein arms on one side of the axoneme move up the microtubules during the power stroke. These dynein molecules are then inactivated, and those on the opposite side slide up, causing the flagellum to bend in the opposite direction during the recovery stroke. The result is the whiplike movement characteristic of eukaryotic flagella.

The flagellum membrane is also complex. It contains special chemoreceptors that aid the algal cell in recognizing cues ranging from environmental changes to mating partners. Often, scales, hairs, swellings, and para-axonemal structures cover the flagellum surface. The scales and hairs apparently aid in swimming. The swellings and para-axonemal structures (crystalline rods and noncrystalline rods and sheets) are often involved in photoreception, providing the swimming cell with a means for detecting light, toward or from which it may swim. The flagellum membrane flows into the plasma (cell) membrane, where the nine pairs of axonemal microtubules enter the main body of the cell. Each pair is joined by an additional microtubule, forming nine triplets. The cylinder of nine triplets, called the basal body, anchors the flagellum. Musclelike fibres and special microtubules (called microtubular roots) extend from the basal body and provide a greater anchorage base. Most flagellate cells have two flagella, and therefore two basal bodies. Typically, each basal body gives rise to two sets of microtubular roots. The orientation of the flagella and the arrangement of the microtubular roots and musclelike fibres are used to classify algae.

Mitosis. Mitosis, or the division of the nucleus, is relatively similar among plants and animals, but the algae have a wide diversity of mitotic features. The nuclear envelope breaks apart in some algal groups but remains intact in others. The spindle microtubules remain outside the nucleus in some algae, they enter the nucleus through holes in the nuclear envelope in other algae, and they form inside the nucleus and nuclear envelope in still other algae. The diversity and complexity of algal mitosis has been studied in detail, and it provides a better understanding of how mitosis operates in plants and animals.

Cellular respiration. Cellular respiration is the process

by which food molecules are “burned” to obtain chemical energy for the cell. Algae, like all organisms, sustain life by using the energy from the chemical bonds of food molecules. Most algae are aerobic (*i.e.*, they live in the presence of oxygen), although certain Euglenophyceae live anaerobically in environments without oxygen. The biochemical pathways for respiration in algae are similar to those of other eukaryotes; the initial breakdown of food molecules (sugars, fatty acids, and proteins) occurs in the cytoplasm, but the final high-energy-releasing steps occur inside the mitochondria.

Photosynthesis. Photosynthesis is the process by which light energy is converted to chemical energy as carbon dioxide and water are converted into organic molecules. The process occurs in almost all algae, and in fact much of the knowledge of photosynthesis was first discovered by studying the green alga *Chlorella*.

Photosynthesis is divided into the light reactions and the dark reactions (or Calvin-Benson cycle). During the dark reactions, carbon dioxide is bound to ribulose biphosphate, a 5-carbon sugar with two attached phosphate groups, by the enzyme ribulose biphosphate carboxylase. This is the initial step of a complex process leading to the formation of sugars. During the light reactions, light energy is converted into chemical energy that is used in the dark reactions.

The light reactions of many algae differ from those of plants because these algae use different pigments to harvest light. Chlorophylls absorb primarily blue and red light, whereas carotenoids absorb primarily blue and green light, and phycobiliproteins absorb primarily blue or red light. Since the amount of light absorbed depends upon the pigment composition and concentration found in the alga, some algae absorb more light at a given wavelength, and therefore, potentially, those algae can convert more light energy of that wavelength to chemical energy via photosynthesis. All algae use chlorophyll *a* to collect photosynthetically active light. Green algae and euglenophytes also use chlorophyll *b*. In addition to chlorophyll *a*, the remaining algae also use various combinations of other chlorophylls, chlorophyllides, carotenoids, and phycobiliproteins to collect additional light from wavelengths of the spectrum not absorbed by chlorophyll *a* or *b*. The chromophyte algae, dinoflagellates, cryptomonads (class Cryptophyceae), and the class Micromonadophyceae, for example, also use chlorophyllides. (Chlorophyllides, often incorrectly called chlorophylls, differ from true chlorophylls in lacking a long, fat-soluble phytol tail.) Some green algae use carotenoids for harvesting photosynthetically active light, but the Dinophyceae and chromophyte algae almost always use carotenoids. Phycobiliproteins, which appear either blue (phycocyanins) or red (phycoerythrins), are found in red algae and cryptomonads.

The effects of water on light. Red wavelengths are absorbed in the first few metres of water. Blue wavelengths are readily absorbed if the water contains average or abundant amounts of organic material. Thus, green wavelengths are often the most common light in deep water.

Chlorophylls absorb red and blue wavelengths much more strongly than they absorb green wavelengths, which is why chlorophyll-bearing plants appear green. The carotenoids and phycobiliproteins, on the other hand, strongly absorb green wavelengths. Algae with large amounts of carotenoid appear yellow to brown, those with large amounts of phycocyanin appear blue, and those with large amounts of phycoerythrin appear red.

At one time it was believed that algae with specialized green-absorbing accessory pigments outcompeted green algae and plants in deeper water. Some green algae, however, grow as well as other algae in deep water, and the deepest attached algae include green algae. The explanation of this paradox is that the cell structure of the deep-water green algae is designed to capture virtually all light, green or otherwise. Thus, while green-absorbing pigments are advantageous in deeper waters, evolutionary changes in cell structure can compensate for the absence of these pigments.

Not all algae have chloroplasts and photosynthesize. The “colourless” algae obtain their energy from organic

molecules, which they absorb from the environment or digest from engulfed particles. They are classified as algae, rather than fungi or protozoa, because in all other features they resemble algae.

As in plants, the major carbohydrate storage product of the green algae is usually starch in the form of amylose starch or amylopectin. (These starches are polysaccharides in which the monomer, or fundamental unit, is the sugar glucose.) In green algae, starch consists of more than 1,000 sugar molecules and is stored as a solid grain inside the chloroplast. The individual sugar molecules are bound together, primarily or entirely, with an alpha linkage between the number 1 and 4 carbons. The cell walls of many, but not all, algae contain cellulose. (Cellulose is formed from the same glucose molecules but with a beta linkage between the number 1 and 4 carbons. Although all animals can digest starch, no animals can by themselves digest cellulose. The beta linkage in cellulose causes alternating sugar molecules to be upside down, and this “flip-flop” configuration requires a special enzyme to link or unlink the sugar molecules. The enzyme is absent in animals, although cows, beavers, and other cellulose-eaters harbour intestinal bacteria that have the cellulose-digesting enzyme.)

The Cryptophyceae also store amylose and amylopectin starch. It is stored outside the chloroplast but within the surrounding membranes of the chloroplast endoplasmic reticulum. The Dinophyceae make starch that stains blue-black with iodine (the standard test for amylose starch), but the chemical nature has not been studied in detail. Dinophycean starch is stored outside the chloroplast, often as a cap over a bulging pyrenoid. The major carbohydrate storage product of red algae is a type of starch (Floridean starch) that is more highly branched than amylopectin. Floridean starch is stored as grains outside the chloroplast.

The major carbohydrate storage product of the chromophyte algae and Euglenophyceae is formed from glucose molecules interconnected with beta linkages between the number 1 and 3 carbons. These polysaccharide compounds are distinctly different from starch (and cellulose), and they are always stored outside the chloroplast. The number of glucose units in each storage product varies among the algal classes. Each type is given a special name—*i.e.*, chrysolaminarin in diatoms, laminarin in brown algae, leucosin in chrysophytes, and paramylon in euglenophytes. The exact chemical constituency of the major polysaccharide storage products is unknown for the classes Bicosoecophyceae, Dictyochophyceae, Eustigmato-phyceae, Raphidophyceae, Synurophyceae, and Xanthophyceae. In the chromophyte algae, the molecule is usually small (16–40 units of sugar) and is stored in a vacuole; the paramylon of euglenophytes is larger (approximately 150 units of sugar) and is stored as a grain.

The algae also produce many sugars and sugar alcohols, such as rhamnose, trehalose, and xylose. While they are not polysaccharides in that the monomer is not glucose, various algae store energy using these small carbohydrate molecules.

Reproduction and life histories. Algae are formed by either sexual reproduction involving male and female gametes or asexual reproduction; many algae can reproduce in both ways (Figure 4).

Asexual reproduction is the production of progeny without the union of cells or nuclear material. Algae, especially small algae, can reproduce asexually by ordinary cell division or by fragmentation, while others, especially large algae, reproduce via spores. Some red algae produce monospores (walled, nonflagellate, spherical cells) that are carried by water currents and upon germination produce a new organism. The same type of spore is called an aplanospore in the green algae. In contrast, zoospores lack true cell walls and bear one or more flagella. Zoospores are motile and can swim to a favourable environment, whereas monospores and aplanospores rely on water currents for transport.

Sexual reproduction occurs by the union of cells, nuclei, and chromosomes and genes through the process of meiosis. It can complement or replace asexual reproduction, depending upon the organism. Sexual reproduction is usu-

Storage products

Asexual reproduction

Chlorophyll and other pigments

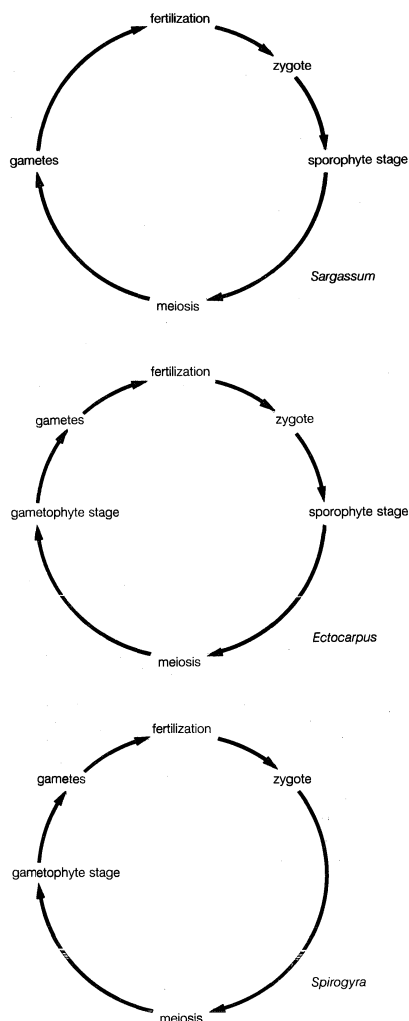

Figure 4: Three types of life cycles found in algae.

ally regulated by environmental events. For example, when temperature, salinity, inorganic nutrients (phosphorus, nitrogen, magnesium), or day length become unfavourable, sexual reproduction is induced. A sexually reproducing organism has two phases in its life cycle. One stage has a single set of chromosomes (or half that of the parent) and is called haploid, whereas the second stage has two sets of chromosomes (or the same as that of the parent) and is called diploid. When one haploid gamete (sex cell) fuses with another haploid gamete during fertilization, the resulting combination has two sets of chromosomes and is called a zygote. Either immediately or at some later time, a diploid cell undergoes a special reductive cell division process called meiosis. During meiosis the chromosome number is halved, and the resulting daughter cells are haploid. At some time, immediately or later, haploid cells act as gametes. In algae, as in plants, a haploid vegetative stage is called the gametophyte stage because it is the gamete-producing stage. Similarly, a diploid vegetative stage is called a sporophyte stage because it is the spore-producing stage (via meiosis).

The life cycles of sexually reproducing algae vary; in some, the dominant stage is the sporophyte, in others it is the gametophyte (Figure 4). For example, *Sargassum* (class Phaeophyceae) has a diploid (sporophyte) body, and the haploid phase is represented by gametes. *Ectocarpus* (class Phaeophyceae) has alternating diploid and haploid vegetative stages, while *Spirogyra* (class Charophyceae) has a haploid vegetative stage, and the zygote is the only diploid cell.

In freshwater organisms especially, the fertilized egg, or zygote, often passes into a dormant state called a zygospore. The zygospore has a large store of food reserves

and a thick, resistant cell wall. Following the appropriate environmental stimulus (often changes in light, temperature, or nutrients), the zygospore germinates and starts another period of growth.

Most algae live for days, weeks, or months. Often, small algae are found in abundance during a short period of the year; for the remainder of the year, some remain dormant in resistant cysts and others remain in the vegetative state but at very low population numbers. Some large, attached species are true perennials. They may lose the main body at the end of the growing season, but the attachment site, or holdfast, then produces new growth at the beginning of the next growing season.

The red algae, as exemplified by *Polysiphonia* (Figure 5), have some of the most complex life cycles known for living organisms. Following meiosis, a haploid tetraspore, one of four spores produced following meiosis, is produced. The tetraspore germinates to produce either a male or female gametophyte. When mature, the male gametophyte produces special spermatangial branches that bear structures, called spermatangia, which contain spermatia, the male gametes. The female gametophyte produces special carpogonial branches that bear carpogonia, the female gametes. Fertilization occurs when the male spermatium, carried by water currents, "bumps into" the extended portion of the female carpogonium and the two gametes fuse. The fertilized carpogonium (the zygote) and the female gametophyte tissue around the carpogonium develop into a basketlike or pustulelike structure, the carposporophyte. The carposporophyte produces and releases diploid carpospores that develop into tetrasporophytes. Certain cells of the tetrasporophyte undergo meiosis to produce tetraspores, and the cycle continues. In the life cycle of *Polysiphonia*, and many other red algae, there are separate male and female gametophytes, a carposporophyte growth on the female gametophyte, and a separate tetrasporophyte.

The life cycle of diatoms is unique as well. Diatom walls, or frustules, are composed of two overlapping parts (the valves). During cell division, two new valves form in the middle of the cell and partition the protoplasm into two parts. Consequently, the new valves are slightly smaller than the originals. Over many successive generations, most of the cells in the growing population become smaller.

Diatom life cycle

Figure 5: The life cycle of the red alga *Polysiphonia* (see text).

When the diatoms reach a critically small size, sexual reproduction is stimulated. The small diploid cells undergo meiosis, and the resulting gametes form and fuse into a zygote, which grows quite large and forms a special cell, the auxospore. The auxospore divides, forming two large, vegetative cells. In this manner, the larger size is renewed.

EVOLUTION AND PALEONTOLOGY

The evolutionary relationships of algae (Figure 4) are not well understood. Modern ultrastructural and molecular studies have added so much new and important information that the evolution of algae is being reassessed. The poor fossil record for some groups of algae also hinders evolutionary studies. Finally, the realization that some algae are more closely related to protozoa or fungi than they are to other algae came late, producing confusion in evolutionary thought and delays in understanding the evolution of the algae.

Alternative
relation-
ships

The Euglenophyceae are believed to be on an ancient lineage that includes some zooflagellate protozoa, which is supported by ultrastructural and molecular data. Most scientists consider the colourless euglenophytes to be an older group and believe that the chloroplasts were added more recently.

Some scientists consider the red algae to be very primitive eukaryotes that evolved from the prokaryotic blue-green algae. Evidence in support of this view are the nearly identical photosynthetic pigments and the very similar starches. Many scientists, however, attribute the similarity to an endosymbiotic origin of the red algal chloroplast from a blue-green algal symbiont. Other scientists suggest that the red algae evolved from the Cryptophyceae with the loss of flagella. It is difficult to imagine, however, the evolutionary selection of a nonflagellate stage for an aquatic organism. Still other scientists suggest that the red algae evolved from the fungi by obtaining a chloroplast. Evidence in support of this view are similarities in mitosis and in cell wall plugs, special structures inserted in a cell wall hole that interconnects two cells. Some evidence suggests that the plug regulates movement between the two cells. Ribosomal gene sequence data from studies in molecular biology suggest that the red algae arose suddenly along with the animal, fungal, and plant (as green algae) lineages. Whatever the origin of the red algae, they bear little resemblance to any other living group.

The green algal classes are evolutionarily related, but their origin is unclear. Most consider the classes Micromonadophyceae to be the most ancient group, and fossil data support this view. The class Ulvophyceae is also ancient, whereas the classes Charophyceae and Chlorophyceae are more recent.

The class Dinophyceae is also of uncertain origin. During the 1960s and '70s the unusual structure and chemical composition of the nuclear DNA was interpreted as a very primitive feature. Some scientists considered the Dinophyceae to be mesokaryotes (an intermediate between the prokaryotes and the eukaryotes). That view is no longer accepted by most scientists, and the peculiar structure is considered simply an evolutionary divergence. Some scientists consider the Dinophyceae to be distantly related to the chromophyte algae. Ribosomal gene sequence data suggest that their closest living relatives are the ciliates, a large, complex group of protozoa.

As in the case of the other algae, the origin of the chromophyte algae is unknown. Ultrastructural and molecular data suggest that they are on a protistan lineage which diverged a long time ago. That lineage, however, apparently remained one of protozoa and later aquatic fungi until about 300 to 400 million years ago. At that time a chloroplast was added (originally as a symbiont), and since then the many chromophyte groups have been evolving. Fossil, ultrastructural, and ribosomal gene sequence data support this hypothesis.

The Cryptophyceae are truly an enigma. They have no fossil record, and other data are conflicting. Although some workers align them near the red algae, because both groups possess phycobiliproteins in their chloroplasts, most scientists suggest that independent symbiotic origins for their chloroplasts could explain the similarity. Crypto-

phytes have flagellar hairs and other flagellar features that resemble those of the chromophyte algae; however, the mitochondrial structure and other ultrastructural features are distinct and argue against such a relationship. Much like the platypus, the cryptophytes appear as though they were constructed by an administrative committee.

The fossil record for the algae is not nearly as complete as it is for plants and animals (Figure 6). Red algal fossils are the oldest known algal fossils. Microscopic spherical algae (*Eosphaera* and *Huroniospora*) resembling the living genus *Porphyridium* are known from the Gunflint Iron Formation of North America (1.9 billion years ago). Fossils that resemble modern tetraspores are known from the Amelia Dolomites of Australia (1.5 billion years ago). The best fossils are the coralline red algae that are represented in fossil beds since the Precambrian era.

Some of the green algal classes are also very old. Organic cysts resembling modern Micromonadophyceae cysts date from about 1.2 billion years ago. *Tasmanites* formed the Permian "white coal," or tasmanite, deposits of Tasmania and accumulated to a depth of several feet in deposits that extend for miles. Similar deposits in Alaska produce up to 150 gallons of oil per ton of sediment. The Ulvophyceae fossils date from about 1 billion years ago and are abundant in Paleozoic rocks. Some deposit calcium carbonate along their cell walls, and these algae produced some limestone formations. The Charophyceae, as represented by the large stoneworts (order Charales), date from about 400 million years ago. The oospore, the fertilized female egg, has spirals on its surface, a result of pressing

Fossil
record

Figure 6: The fossil record for algae. The origin of major photosynthetic systems is shown at the bottom.

against the spiraling protective cells that surround the oospore. Oospores before about 225 million years ago had right-handed spirals, while those formed since that time have had left-handed spirals. The reason for the switch remains a mystery.

Fossil Dinophyceae date from the Silurian period (430 million years ago). Some workers consider at least a portion of the acritarchs, a group of cystlike fossils of unknown affinity, to be Dinophyceae, but most scientists do not agree with that view. The acritarchs occurred as early as 700 million years ago.

The chromophytes

The Chromophyta have the shortest fossil history of the major algal groups. Some believe that the group is ancient, but there are no fossils. Others point out that there is a lack of data to support this view and suggest that the group evolved recently, as indicated by fossil and molecular data. The oldest chromophyte fossils, a putative brown alga, are approximately 400 million years old. Coccolithophores, coccolith-bearing members of the Prymnesiophyceae, date from the late Triassic epoch (230 to 208 million years ago), with one reported from approximately 280 million years ago. Coccolithophores were extremely abundant during the Mesozoic era, contributing to deep deposits such as the White Cliffs of Dover. Most species became extinct at the end of the Cretaceous period (66.4 million years ago), along with the dinosaurs, and there are more extinct species of coccolithophores than there are living species. The Chrysophyceae, Bacillariophyceae, and Dictyochophyceae date from about 100 million years ago, and following the mass extinctions 66.4 million years ago, these algae flourished. Their siliceous remains form deposits of diatomite almost 0.5 kilometre (0.3 mile) in depth. The enormous deposits and the siliceous nature of the fossils strongly suggest that these organisms evolved very recently. In fact, mammals and birds evolved before these algae. The Xanthophyceae may be even more recent, with fossils dating from about 20 million years ago.

The remaining groups of algae, especially the Euglenophyceae and the Cryptophyceae, lack a good fossil record. These groups are without hard parts, which may explain the lack of fossils.

CLASSIFICATION

Diagnostic features. The classification of algae into taxonomic groups is based upon the same rules as for the classification of plants. The organization of groups above the order level has changed substantially since 1960. Research using electron microscopes has demonstrated new and important features of the flagellar apparatus, cell division process, and organelle structure and function. Similarities and differences among algal, fungal, and protozoan groups have led scientists to propose taxonomic changes, and these changes are continuing. Molecular studies, especially comparative gene sequencing studies, have supported some of the changes that followed electron microscopic studies, but they have suggested additional change as well. Since 1960 the number of classes has nearly doubled and algal classification has changed constantly. Furthermore, the apparent evolutionary scattering of algal groups among protozoan and fungal groups implies that a natural classification of algae by themselves is impossible.

Kingdoms are the most encompassing of the taxonomic groups, and scientists are actively debating which organisms belong in which kingdoms. Some scientists have suggested as many as 30 or more kingdoms, while others argue that all eukaryotes should be combined into one large kingdom. Using cladistic analysis (a method for determining evolutionary relationships), the green algae should be grouped with the plants, and the chromophyte algae should be grouped with the aquatic fungi and certain protozoa. The Euglenophyceae are most closely related to the trypanosome flagellates, the protozoa that cause sleeping sickness. It is unclear where the red algae or cryptomonads belong. In summary, the algae are not all closely related, and they do not form a single evolutionary lineage devoid of other organisms.

Division-level classification, like kingdom-level classification, is tenuous for algae. For example, some phycologists place the classes Bacillariophyceae, Phaeophyceae, and

Xanthophyceae in the division Chromophyta, while others place each class in separate divisions: Bacillariophyta, Phaeophyta, Xanthophyta. Yet, almost all phycologists agree on the definition of the classes Bacillariophyceae, Phaeophyceae, and Xanthophyceae. In another example, the number of classes of green algae (Chlorophyta), and the algae placed in those classes, has varied greatly since 1960. The five classes given below are accepted by a large number of phycologists, but at least an equal number of phycologists would suggest one of many alternative classification schemes. The classes are distinguished by the structure (scales, angle of insertion, microtubular roots, striated roots) of flagellate cells, the nuclear division process (mitosis), the cytoplasmic division process (cytokinesis), and the cell covering. Many scientists combine the Micromonadophyceae with the Pleurastrorphyceae and name the group the Prasinophyceae.

Because classes are better defined and more accepted than divisions, taxonomic discussions of algae are usually conducted at the class level. The divisions provided below are commonly used, but they are by no means accepted by all phycologists.

"Phylum" and "division" represent the same level of organization; the former is the zoological term, the latter is the botanical term. The classification of protists continues to be debated, and a standard outline of the kingdom has not been established. The differences between the classification presented below and that in the article PROTISTS reflect the taxonomic variations that arise from individual interpretations.

Annotated classification.

DIVISION CHLOROPHYTA (green algae)

Chlorophylls *a* and *b*; starch stored inside chloroplast; mitochondria with flattened cristae; flagella, when present, lack tubular hairs (mastigonemes); unmineralized scales on cells or flagella of flagellates and zoospores; conservatively, between 9,000 and 12,000 species.

Class Chlorophyceae

Primarily freshwater; includes *Chlamydomonas*, *Chlorella*, and *Oedogonium*.

Class Charophyceae

Includes the macroscopic pondweed *Chara*, filamentous *Spirogyra*, and desmids.

Class Micromonadophyceae

Primarily marine; includes the smallest eukaryotic alga, *Micromonas*.

Class Pleurastrorphyceae

Freshwater and marine; includes marine flagellate *Tetraselmis*.

Class Ulvophyceae

Primarily marine; includes sea lettuce *Ulva*.

DIVISION CHROMOPHYTA

Most with chlorophyll *a*; one or two with chlorophyllide *c*; carotenoids present; storage product β -1,3-linked polysaccharide outside chloroplast; mitochondria with tubular cristae; biflagellate cells and zoospores usually with tubular hairs on one flagellum; mucous organelles common.

Class Bacillariophyceae (diatoms)

Silica cell walls, or frustules; centric diatoms commonly planktonic and valves radially symmetrical; pennate diatoms found attached to substrate and valves bilaterally symmetrical; primarily in freshwater, marine, and soil environments; at least 12,000 to 15,000 living species; tens of thousands more species described from fossil diatomite deposits; *Cyclotella* and *Thalassiosira* (centrics) and *Navicula* and *Nitzschia* (pennates).

Class Bicosoecophyceae

May be included in the Chrysophyceae or in the protozoan group Zoomastigophora; colourless flagellates found in vase-shaped loricas (wall-like coverings); cell attached to lorica using flagellum as a stalk; lorica attaches to plants, algae, animals, or water surface; in freshwater and marine; fewer than 50 species described; *Bicosoea*.

Class Chrysophyceae (golden algae)

Many unicellular or colonial flagellates; also capsoid, coccoid, amoeboid, filamentous, parenchymatous, or plasmodial; many produce silica cysts (statospores); predominantly freshwater; approximately 1,200 species; *Chrysamoeba*, *Chrysocapsa*, and *Ochromonas*.

Class Dictyochophyceae

Predominantly marine flagellates, including silicoflagellates, which are common in diatomite deposits; fewer than 25 described species.

Order Pedinellales

When pigmented, has 6 chloroplasts in a radial arrangement; flagella bases attach almost directly to nucleus.

Order Dictyochaetales (silicoflagellates)

Typically forms siliceous skeleton that appears as spiny basket in which cell sits; flagella bases attach almost directly to nucleus; silicoflagellate skeletons common in diatomite deposits; *Dictyocha*, *Pedinella*, and *Pseudopedinella*.

Class Eustigmatophyceae

Newly described, with probably more to be discovered; mostly small, pale green, and spherical; fewer than 15 species; *Eustigmatos* and *Nannochloropsis*.

Class Phaeophyceae (brown algae or brown seaweeds)

Microscopic forms to large kelp more than 60 metres long; more than 1,500 species, almost entirely marine; *Ectocarpus*, *Macrocystis*, and *Sargassum*.

Class Prymnesiophyceae (Haptophyceae)

Many with haptoneura, a hairlike appendage between two flagella; no tubular hairs; many with organic scales; some deposit calcium carbonate on scales to form coccoliths; coccolithophorids may play a role in global warming because they can remove large amounts of carbon from the ocean water; predominantly marine and planktonic species; approximately 300 species; more fossil coccolithophores known; *Chrysochromulina*, *Emiliania*, and *Prymnesium*.

Class Raphidophyceae (Chloromonadophyceae)

Flagellates; mucocysts (mucilage-releasing bodies) commonly found in freshwater forms; sharply divided between freshwater and marine environments; fewer than 50 species; *Heterosigma*, *Vacuolaria*, and *Olisthodiscus*.

Class Synurophyceae

Previously placed in Chrysophyceae; silica-scaled; unicellular or colonial flagellates sometimes alternating with capsoid benthic stage; cells covered with elaborately structured silica scales; approximately 250 species, with approximately 10 new described each year since 1970; *Mallomonas*, *Synura*, and *Tessellaria*.

Class Xanthophyceae (yellow-green algae)

Primarily coccoid, capsoid, or filamentous; mostly freshwater environments; about 600 species; *Bumilleriopsis*, *Tribonema*, and *Vaucheria*.

DIVISION CRYPTOPHYTA

Unicellular flagellates.

Class Cryptophyceae

Chlorophyll *a*, chlorophyllide *c*₂, and phycobiliproteins; starch stored outside of chloroplast; mitochondria with flattened cristae; tubular hairs on 1 or both flagella; special ejectosomes lie in a furrow or gullet near the flagella; cell covered with periplast, often elaborately decorated sheet or scale covering; nucleomorph may represent reduced nucleus of symbiotic organism; approximately 200 described species; *Chilomonas*, *Cryptomonas*, *Falconomonas*, and *Rhinomonas*.

DIVISION PYRRHOPHYTA (DINOFLAGELLATA)

Predominantly unicellular flagellates; approximately half of the species are heterotrophic rather than photosynthetic; photosynthetic forms with chlorophyll *a*, 1 or more chlorophyllide *c* types, and peridinin or fucoxanthin; mitochondria with tubular cristae and flagella without tubular hairs; ejectile trichocysts below surface in many members; many with cellulosic plates that form an armour around cell; some bioluminescent, some containing symbionts; nucleus contains permanently condensed chromosomes; several produce toxins that either kill fish or accumulate in shellfish and cause sickness or death in humans when ingested; more than 1,200 species described, most in the class Dinophyceae; *Alexandrium*, *Dinophysis*, *Peridinium*, and *Polykrikos*.

DIVISION EUGLENOPHYTA

Primarily unicellular flagellates; both photosynthetic and heterotrophic.

Class Euglenophyceae

Chlorophylls *a* and *b*; paramylon stored outside chloroplasts; mitochondria with paddle-shaped cristae; flagella lack tubular hairs, but some with hairlike scales; unusual pellicle covering of sliding sheets allows organisms to change shape easily; approximately 1,000 described species; *Colacium*, *Euglena*, and *Eutreptiella*.

DIVISION RHODOPHYTA (red algae or red seaweeds)

Predominantly filamentous; mostly photosynthetic but almost one-third parasitic; photosynthetic species with chlorophyll *a*; chlorophyll *d* present in some species; phycobiliproteins (phycocyanin and phycoerythrin) organized into discrete structures (phycobilisomes); starch occurs outside chloroplast; mitochondria with flattened cristae; flagella completely absent; coralline red algae contribute to coral reefs and coral sands; predominantly marine; approximately 4,100 described species; *Bangia*, *Palmaria*, *Polysiphonia*, and *Porphyra*.

JOHN (eds.), *Systematics of the Green Algae* (1984). (R.A.An.)

Algebra

Algebra may be described as a generalization and extension of arithmetic. Elementary arithmetic is concerned primarily with the effect of certain operations, such as addition or multiplication, on specified numbers, hence, for instance, the multiplication tables; elementary algebra is concerned with properties of arbitrary numbers. For instance, the fact that 2 added to 3 gives the same result as 3 added to 2 is one of arithmetic; the formula $a + b = b + a$ for all numbers a, b is one of algebra.

The particular operations of arithmetic that came to be extended and generalized to provide the materials of algebra emerged only slowly. The earliest writings on the subject dealt with many topics that are not now regarded as part of algebra. (For a treatment of the evolution of algebra as a well-defined branch of mathematics, see *MATHEMATICS, THE HISTORY OF*.) The earliest extant work with any claim to be regarded as a treatise on algebra is by the Greek philosopher Diophantus of Alexandria (c. AD 250). This work is devoted mainly to problems in the solution of equations. For this purpose a suitable notation had to be invented, and Diophantus gave rules for generating powers of a number and for the multiplication and division of simple quantities. Of great significance is his statement of the laws governing the use of the minus sign, which did not, however, imply any idea of negative quantities.

During the 6th century the ideas of Diophantus were improved on by Hindu mathematicians, and many deficiencies in the Greek symbolism were remedied. The development of symbolic algebra by the use of general symbols to denote numbers is due to a 16th-century French mathematician, François Viète, a usage that led to the idea of algebra as generalized arithmetic. Sir Isaac Newton gave it the name Universal Arithmetic in 1707.

The main step in the modern development of algebra was the evolution of a correct understanding of negative quantities, contributed in 1629 by a French mathematician, Albert Girard, whose work was later overshadowed by that of his contemporary, René Descartes. While it is convenient to view Descartes' work as the starting point of modern algebra, for the sake of clarity notations and terminology will be used that were developed later.

Algebra is concerned with certain operations on numbers, and it is necessary to be precise about what a number is. The numbers dealt with are either the natural numbers, 0, 1, 2, 3, 4, . . . (some authors exclude 0); rational numbers, which have the form p/q , in which p and q are integers (natural numbers and their negatives), with $q \neq 0$; real numbers, which correspond to all the points on a line; or complex numbers, which are constructed from the real numbers together with a number i , the square of which is -1 . The essential property that these numbers have is that they can be added and multiplied by well-established rules. Arithmetic becomes algebra when general rules are stated regarding these operations, as, for example, the commutative law of addition (see below). First the basic algebraic properties of such numbers are considered.

Linear algebra is the branch of algebra that deals primarily with linear problems, that is to say, problems that depend for the most part on the solution of linear equations.

An equation in two or more variables, or "unknowns," is linear if it contains no terms of the second degree or greater; that is, if it contains no products or powers of the variables. The term linear derives from the fact that the graph of a linear equation in x and y is a straight line in the Cartesian xy -plane. Thus a linear equation represents a linear relationship between the variables x and y in a geometric sense. Similarly, a linear equation in three variables x, y, z represents a plane in three-dimensional space, and two such equations considered simultaneously represent the line of intersection of the two planes, provided they are not parallel. When the number of variables is greater than three, there is no longer a simple geometric interpretation because physical space is limited to three dimensions. Nevertheless, it is customary to continue the geometric analogy and to think of the solutions of a linear equation in four variables as constituting a "hyperplane" in a four-dimensional space, and similarly for any finite higher dimension.

The theoretical investigation and solution of general systems of linear equations are facilitated by the introduction of entities called vectors and matrices. Vectors were originally introduced in order to interpret mathematically a physical quantity such as a velocity or force that has both a magnitude and an associated direction. A matrix is a rectangular array of numbers in a definite order, such as the array of coefficients of the unknowns in a system of linear equations. Rules of computation with vectors, which stem from their original physical interpretation, lead to closed systems of vectors called vector spaces, and matrices can be identified with special functions on these vector spaces called linear transformations. The theory of linear transformations of finite-dimensional vector spaces, which embraces the theory of matrices and that of systems of linear equations, constitutes the subject matter of linear algebra. Vectors are more fully treated in the article *ANALYSIS: Vector and tensor analysis*; matrices are covered in the article *MATRIX THEORY*.

Out of the developments of elementary algebra evolved the abstract algebra used today and the idea of an algebraic structure. Elementary algebra was originally concerned with a set of elements, the numbers used in arithmetic. Together with these elements there were two operations, addition and multiplication (subtraction and division being the inverse of these). It became recognized that there was also a collection of basic rules that constitute an axiomatic structure. The axiomatic structure describes even today the assumptions made in elementary algebra and arithmetic. Certain entities, however, do not follow these rules. Abstract algebra is concerned with the formulation and properties of quite general axiomatic abstract systems of this type. These systems are sets of elements with general operations and with a number of axioms. Just as new self-consistent geometries can be based on axioms other than those of Euclid, new algebras can be based on axioms that differ from those of elementary algebra. These new algebras may describe mathematical objects other than numbers. (Ed.)

This article is divided into the following sections:

Elementary and multivariate algebra 253

Basic theory 253

Elementary operations

Complex numbers and root extraction

Geometric representation of numbers

Quaternions and hypercomplex numbers

Polynomials and rational functions 255

Polynomials

Rational functions

Elementary properties of polynomials and rational functions

Elementary and multivariate algebra

BASIC THEORY

Laws of
addition
and multi-
plication

Elementary operations. Addition has the following properties: The order of addition does not affect the result (see Box, equation 1)—that is, addition is commutative. If three numbers are being added, parentheses can be placed around either the first two or the last two, while the terms in the parentheses are added first, and their sum is added to the remaining term. The two results are, however, always equal (see 2). This second property is expressed by saying that addition is associative, and as a result either sum may be expressed as $a + b + c$. There is a number 0 (zero) such that the sum of any number a and zero is a (see 3). Corresponding to each number a there is a number

$(-a)$ such that the sum of a and $(-a)$ is zero (see 4). From the second and fourth of these laws it follows that for any two numbers a, b , there is a unique number x such that $a + x = b$, namely, $x = b + (-a)$, more commonly written $x = b - a$. A set of numbers with the law of addition satisfying the above properties is called an additive group.

The result of multiplication of two numbers a, b is usually denoted by ab , but sometimes to avoid confusion $a \times b$ is written.

Multiplication of numbers has the following properties: The order of multiplication does not affect the result (commutativity; see 5) nor does the way the numbers are placed in parentheses (associativity; see 6). The product of a number and the sum of two numbers equals the sum of two appropriate products. This last is known as

- (1) $a + b = b + a$
- (2) $(a + b) + c = a + (b + c) = a + b + c$
- (3) $a + 0 = a$
- (4) $a + (-a) = 0$
- (5) $ab = ba$
- (6) $a \times (bc) = (ab) \times c = abc$
- (7) $a \times (b + c) = ab + ac$
- (8) $1 \times a = a = a \times 1$
- (9) $0a = 0$, and if $ab = 0$, either a or b is zero.

the distributive law (see 7). There exists a unique element 1 (unity) such that the product of any number a and 1 is a (see 8).

Any set of elements in mathematics that has two laws of composition, addition and multiplication, such that (1) with addition as the law of combination it forms an additive group, and (2) with multiplication is commutative and associative, and distributive over addition, is called a ring. It is because so much of modern algebra is concerned with groups and rings that it is important to realize that ordinary numbers have these properties. Because the numbers have unity the ring is a ring with unity. One other property of numbers that should be noted is that the product of 0 and a is 0 for all a , and if $ab = 0$, either a or b is 0 (see 9). With this last property the ring with unity becomes what is called an integral domain.

All accepted systems of numbers, integers, rational numbers, and real and complex numbers have the above properties (see ARITHMETIC; ANALYSIS: *Real analysis*). If the system has the property that when a is different from zero there is a number x such that $ax = 1$ (see 10), then

- (10) $ax = 1, \quad a \neq 0$
- (11) $\begin{cases} (a + ib) + (c + id) = (a + c) + i(b + d) \\ (a + ib) \times (c + id) = (ac - bd) + i(bc + ad) \end{cases}$
- (12) $\alpha = r(\cos \theta + i \sin \theta), \quad \beta = \rho(\cos \phi + i \sin \phi)$
- (13) $\alpha\beta = r\rho[\cos(\theta + \phi) + i \sin(\theta + \phi)]$

the nonzero numbers of the system form a group in which multiplication is the group operation, and the integral domain is a field. The systems consisting of the rational, real, or complex numbers form a field, but the system of integers does not.

Complex numbers and root extraction. The operations so far considered—namely, addition, subtraction, multiplication, and division—are known as the elementary operations of algebra. In another section the extension of these operations to more complex systems, such as polynomials (see below), will be considered. One other operation on real or complex numbers must be considered here. A theorem states that: If a is any positive real number and n is any positive integer, there exists a unique positive real number x such that $x^n = a$, in which x^n is the product of n factors each equal to x .

It is important to note that if a is an integer (rational number, negative real number) there is, in general, no integer (rational number, real number) such that $x^n = a$. Thus this operation called extracting the n th root is not a satisfactory algebraic operation as it stands. To obtain a satisfactory operation, it is necessary to use complex numbers.

A complex number, symbolized here by the Greek letter alpha, a , is any formal combination $a = a + ib$ of two real numbers a, b , with addition and multiplication defined by certain appropriate rules (see 11). With addition and multiplication so defined, the complex numbers form a field. It should be noted that $i \times i = -1$.

Now, $a = a + ib$ may be considered. Because $a^2 + b^2$ is a positive real number, there exists a unique positive real number r such that $r^2 = a^2 + b^2$, r being called the amplitude of a . If a, b are not both zero, there is an angle, symbolized by the Greek letter theta, θ , uniquely defined to within a multiple of 2π (Greek letter pi, the ratio of the circumference to the diameter of a circle), such that $a/r = \cos \theta$, $b/r = \sin \theta$, and hence a can be written in terms of r and θ (see 12). Let the Greek letter β stand for any other complex number (see 12). Following the rule for multiplying complex numbers, and again using elementary trigonometry, the product of two complex numbers is given in terms of the product of the amplitudes and the sum of the two angles (see 13).

It is possible to consider the problem of finding a complex number z such that $z^n = a$. From the formula for the product, the amplitude s must satisfy $s^n = r$, and the angle ψ must satisfy $n\psi = \theta$ to within a multiple of 2π ; that is, $n\psi - \theta = 2t\pi$ for some integer t . Because r is a positive real number, there must be a unique positive real number s satisfying $s^n = r$; ψ must have the form $\psi = (\theta/n) + (2t\pi/n)$, and there are n possible values of ψ (to within a multiple of 2π) satisfying this condition, corresponding to $t = 0, 1, 2, \dots, n-1$, for example. Hence there are n possible numbers z such that $z^n = a$.

If z_1 is any one of these n numbers, the others can all be written $z_1\omega$, in which ω (omega) is an n th root of unity; that is, $\omega^n = 1$. Thus the problem of finding the n th roots of unity is basic in the theory of complex numbers.

It is clear that for any complex number a there are n solutions of $z^n = a$, and this shows one of the advantages of complex numbers over the other kinds of numbers considered. In order to extract roots of integers, or rational numbers or real numbers, one notes that each of these number systems is a subsystem of the succeeding one, and that they are all subsystems of the complex numbers. To find z such that $z^n = a$, when a is, say, a rational number, is to consider a as a complex number that just happens to belong to the subsystem of real numbers, and then to consider the problem for complex numbers. This process is usually referred to as extending the field of rational numbers to the complex field.

Geometric representation of numbers. Numbers may be represented geometrically, and the operations of algebra can be carried out by geometrical methods. The following representation of real numbers (which include the integers and rational numbers) was introduced by Descartes in the 17th century. On a straight line OX point O is fixed, called the origin, and corresponding to each real number a the point A_a is taken, the distance of which from O is equal to a (if a is positive, $-a$ if it is negative), measuring distances to the right when a is positive, to the left when it is negative. One of the postulates of geometry is that there is a one-to-one correspondence between the real numbers and the points of the line established in this way. For convenience another line OY is considered, through O perpendicular to OX , and on it the point B_1 is marked corresponding to the real number b , as before. The operations of addition, subtraction, multiplication, and division can then be obtained by simple geometrical constructions. The accompanying diagram (Figure 1) illustrates the geometric constructions necessary for multiplication, division, and the extraction of square roots.

1. To add a and b the points A_a, A_b are marked. A segment A_aA_d , equal in length and direction to OA_b , is laid off on OX . Then $d = a + b$. By constructing the segment OA_d equal in length to OA_b but in the opposite direction, $-b$ is found. In this way $a - b$ is constructed and geometrical representations of addition and subtraction are obtained.

2. To multiply a and b , A_a is marked on OX and OB_b is marked on OY . B_1 is marked on OY distant one unit from O . A_aB_1 is joined and, through B_b , B_bA_c is drawn parallel to B_1A_a . Then, by the geometry of similar triangles it may

expressions

$a_i x^{n-i}$, for $i = 0, 1, \dots, n$ (see 15), in which the coefficients a_i are in the coefficient field, and each expression only involves a finite number of terms $a_i x^{n-i}$. Here, and in what follows, $f(x)$ is an abbreviation for the expression that follows. If $a_0 \neq 0$, $f(x)$ is said to be a polynomial in x of degree n and $a_i x^{n-i}$ is the term of degree $n-i$ in $f(x)$. If $g(x)$ is another polynomial of degree m (see 16), $f(x) + g(x)$ is obtained by adding the terms of like degree, and $f(x) \times g(x)$ is the polynomial of degree $n+m$ obtained by multiplication. With these laws of addition and multiplication, the polynomials in x form a ring. The ring has unity: the polynomial of degree zero written 1. Further, if neither $f(x)$ nor $g(x)$ is zero, their product $f(x) \times g(x)$ is not zero, because its leading term is $a_0 b_0 x^{n+m}$, and $a_0 b_0$ is not zero unless one of a_0, b_0 is zero. Hence the ring of polynomials in x is an integral domain. It is easily seen, however, that it is not a field; for example, there is no polynomial $p(x)$ such that $p(x)(x+1) = 1$.

It is now a straightforward matter to define polynomials in more than one variable. To the polynomials in x a new variable y is adjoined. Products are defined by $ax^p y^q \times bx^r y^s = abx^{p+r} y^{q+s}$, $ax^p y^q + bx^p y^q$ is identified with $(a+b)x^p y^q$, and x^0 and y^0 are identified with unity in the coefficient field. In this way the integral domain of polynomials in two variables is built up; a general element is written as a sum of these products (see 17). In a similar way the integral domain of polynomials in r variables may be constructed.

Elementary algebra is rich in identities concerning polynomials. Perhaps the most important is the binomial theorem, which expresses the sum of two terms raised to a power as a sum of products (see 18).

The ring
of poly-
nomials

Rational functions. The ring of polynomials in r variables is an integral domain, but not a field. It is possible, however, to embed the ring of polynomials in r variables in a field, the field of rational functions of r variables, just as the integers are embedded in the field of rational numbers. The case of one variable illustrates the general procedure. A rational function is one of the form $f(x)/g(x)$, in which $f(x)$ and $g(x)$ are polynomials; the following discussion makes this idea precise and rigorous. All pairs of polynomials $[f(x), g(x)]$ in which $g(x) \neq 0$, are considered and two pairs $[f(x), g(x)]$, $[F(x), G(x)]$ are defined to be equivalent if $f(x)G(x) - g(x)F(x) = 0$. This relation has all the necessary and sufficient properties of a true equivalence:

1. $[f(x), g(x)]$ is equivalent to itself (reflexive);
2. if $[f(x), g(x)]$ is equivalent to $[F(x), G(x)]$, then $[F(x), G(x)]$ is equivalent to $[f(x), g(x)]$ (symmetric); and
3. if $[f(x), g(x)]$ is equivalent to $[F(x), G(x)]$, and $[F(x), G(x)]$ is equivalent to $[P(x), Q(x)]$, then $[f(x), g(x)]$ is equivalent to $[P(x), Q(x)]$ (transitive).

As an illustration, this last property is proved. If $f(x)G(x) - g(x)F(x) = 0$, and $F(x)Q(x) - G(x)P(x) = 0$, then $Q(x)f(x)G(x) - Q(x)g(x)F(x) = g(x)G(x)P(x)$ and hence $G(x)[f(x)Q(x) - g(x)P(x)] = 0$. Because the ring of polynomials is an integral domain, and $G(x) \neq 0$, by hypothesis, $f(x)Q(x) - g(x)P(x) = 0$, which is the condition that $[f(x), g(x)]$ is equivalent to $[P(x), Q(x)]$.

Addition and multiplication of pairs are defined by the appropriate formulas (see 19), which arise from the fact that the pair $[f(x), g(x)]$ is to represent the rational function $f(x)/g(x)$. By methods similar to that used to prove the transitivity of the equivalence relation, it can be shown that if $[f(x), g(x)]$ or $[p(x), q(x)]$ is replaced by an equivalent pair, their sum, or product, is replaced by an equivalent pair. Now consider a new set Σ of elements, one representing each class of equivalent pairs. Addition and multiplication can be defined in Σ and it can be verified that with those operations Σ is an integral domain. The unity of Σ is the class of pairs containing $[1, 1]$; and if $[f(x), g(x)]$ represents a class a that is not zero, $f(x)$ is not zero, and there is a class β represented by $[g(x), f(x)]$. Then $a\beta$ is equal to the unity of Σ , and Σ is a field.

The set Σ contains a subring consisting of elements represented by pairs $[f(x), 1]$. If this class of pairs is identified with $f(x)$, it is seen that addition and multiplication in this subring are consistent with addition and multiplication in the ring of polynomials. Therefore Σ is regarded as

$$(19) \quad \begin{cases} [f(x), g(x)] + [p(x), q(x)] \\ \quad = [f(x)q(x) + p(x)g(x), g(x)q(x)] \\ [f(x), g(x)] \times [p(x), q(x)] = [f(x)p(x), g(x)q(x)] \end{cases}$$

$$(20) \quad \begin{cases} f(x) \equiv a_0 x^n + a_1 x^{n-1} + \dots + a_n, & a_0 \neq 0 \\ g(x) \equiv b_0 x^m + b_1 x^{m-1} + \dots + b_m, & b_0 \neq 0 \end{cases}$$

$$(21) \quad f_2(x) = f_1(x) - kx^{n_1-m}g(x)$$

$$(22) \quad f(x) = a(x)g(x) + b(x)$$

$$(23) \quad \begin{cases} f(x) = a_1(x)g(x) + b_1(x) \\ [a(x) - a_1(x)]g(x) = b_1(x) - b(x) \end{cases}$$

$$(24) \quad g(x) = a_1(x)b(x) + b_1(x)$$

$$(25) \quad \begin{cases} f(x) = a(x)g(x) + b(x) \\ g(x) = a_1(x)b(x) + b_1(x) \\ b(x) = a_2(x)b_1(x) + b_2(x) \\ \vdots \\ b_{r-2}(x) = a_{r-1}(x)b_{r-1}(x) + b_r(x) \\ b_{r-1}(x) = a_{r+1}(x)b_r(x) \end{cases}$$

$$(26) \quad \begin{cases} f(x) = [a(x)a_1(x) + 1]b(x) + a(x)b_1(x), \\ f(x) = c_j(x)b_j(x) + d_j(x)b_{j+1}(x), \text{ in which } c_j(x) \text{ and } d_j(x) \text{ are polynomials.} \end{cases}$$

an extension of the ring of polynomials. In this extension a class of pairs is represented by $f(x)/g(x)$ in which $[f(x), g(x)]$ is any pair representing the class of equivalent pairs. Thus the ring of polynomials in x has been extended to the field of rational functions of x . By a similar process the ring of polynomials in r variables can be extended to the field of rational functions of r variables.

Elementary properties of polynomials and rational functions. The remainder of this section deals with elementary properties of polynomials and rational functions. The division algorithm (procedure) for polynomials in one variable is discussed first. If $f(x)$ and $g(x)$ are two polynomials of degree n and m , respectively (see 20), and if $m \leq n$, then $f(x) - (a_0/b_0)x^{n-m}g(x)$ is a polynomial $f_1(x)$ of degree n_1 ($n_1 < n$). If $n_1 \geq m$, in the same way, a number k in the coefficient field may be found such that a similar expression can be formed in terms of $f_1(x)$ and $g(x)$ (see 21). If $n_2 \geq m$, the process is repeated, and eventually $f(x)$ can be written as the sum of $a(x)g(x)$ and $b(x)$ (see 22), in which $a(x), b(x)$ are polynomials [with coefficients in the coefficient field of $f(x)$ and $g(x)$] and the degree of $b(x)$ is less than m . This representation is unique, for if another such expression is formed and subtracted from the first (see 23), the right-hand side will be of degree less than m . Because $g(x)$ is of degree m , the left-hand side is of degree m at least unless $a(x) = a_1(x)$.

The equality therefore shows that $a(x) = a_1(x)$, $b(x) = b_1(x)$, and that the representation of $f(x)$ is unique. For use below (see *Solution of equations*) note that if $g(x) = x - a$, $b(x)$ is a polynomial of degree zero equal to $f(a) = a_0 a^n + a_1 a^{n-1} + \dots + a_n$ (the remainder theorem).

Returning to the case in which $g(x)$ is a polynomial of degree m , suppose that $b(x) \neq 0$. The same process is applied to the polynomials $g(x), b(x)$, leading to a similar formula expressing $g(x)$ as the sum of $a_1(x)b(x)$ and $b_1(x)$ (see 24), in which $a_1(x), b_1(x)$ are polynomials the coefficients of which are in the coefficient field of $f(x), g(x)$; and the degree of $b_1(x)$ is less than that of $b(x)$. If $b_1(x)$ is not zero, the process is repeated, until a stage is reached

Division
of poly-
nomials

in which the remainder is zero. A set of equations of this form is obtained (see 25) ending when $b_{r+1}(x) = 0$.

From the first equation $b(x) = f(x) - a(x)g(x)$; substituting in the second, an expression $b_1(x) = p(x)f(x) + q(x)g(x)$ is obtained, and by successive substitution $b_i(x) = p_i(x)f(x) + q_i(x)g(x)$, in which $p_i(x)$, $q_i(x)$ are polynomials.

Next, starting from $f(x) = a(x)g(x) + b(x)$, one obtains by substitution two expressions for $f(x)$ involving the above quantities and the polynomials $c_i(x)$ and $d_i(x)$ (see 26).

Because $b_{r+1}(x)$ is zero, $f(x) = c_r(x)b_r(x)$. Starting from the second equation of (25), the same procedure gives $g(x) = e_r(x)b_r(x)$, in which $e_r(x)$ is a polynomial.

If $r(x)$ is a polynomial that is a factor of $f(x)$ and $g(x)$, so that $f(x) = l(x)r(x)$, $g(x) = m(x)r(x)$, then $b_r(x) = [p_r(x)l(x) + q_r(x)m(x)]r(x)$; that is, $r(x)$ is a factor of $b_r(x)$. Conversely, if $r(x)$ is a factor of $b_r(x)$, so that $b_r(x) = r(x)s(x)$, then $f(x) = c_r(x)r(x)s(x)$, $g(x) = e_r(x)r(x)s(x)$, so that $r(x)$ is a factor of $f(x)$ and $g(x)$. For this reason $b_r(x)$ is called the highest common factor of $f(x)$ and $g(x)$.

A polynomial $f(x)$ with coefficients in a field K is called reducible if it can be written in the form $f(x) = g(x)h(x)$, in which $g(x)$ and $h(x)$ are polynomials of degree greater than zero; otherwise it is irreducible. If $f(x)$ is reducible it can be written $g(x)h(x)$; if $g(x)$ or $h(x)$ is reducible it can be written as $h(x) = l(x)m(x)$. Thus, after a finite number of steps, one obtains $f(x) = p_1(x)p_2(x) \cdots p_r(x)$, in which each $p_i(x)$ is irreducible.

This representation of $f(x)$ as a product of irreducible factors is unique, for suppose that $f(x) = q_1(x)q_2(x) \cdots q_s(x)$ is another such representation; $p_1(x)$ is a factor of $q_1(x)q_2(x) \cdots q_s(x)$, and so must be a factor of $q_i(x)$ for some i . This is proved by supposing $p_1(x)$ and $q_i(x)$ are not factors of one another; then their highest common factor is in the coefficient field, and from the above there exist polynomials $a(x)$, $b(x)$ such that $a(x)p_1(x) + b(x)q_i(x) = 1$; $b(x)q_i(x)p_2(x) \cdots p_r(x) = [1 - a(x)p_1(x)]q_2(x) \cdots q_s(x)$.

Hence $p_1(x)[b(x)p_2(x) \cdots p_r(x) + a(x)q_2(x) \cdots q_s(x)] = q_2(x) \cdots q_s(x)$. Thus $p_1(x)$ is a factor of $q_2(x) \cdots q_s(x)$. The same argument can be repeated to show that if $p_1(x)$ is not a factor of $q_2(x)$, it must be a factor of $q_3(x) \cdots q_s(x)$, and so on, so that $p_1(x)$ must be a factor of $q_i(x)$ for some i . Since $p_1(x)$ and $q_i(x)$ are both irreducible, they can differ only by multiplication by an element of the coefficient field. In this way a pairing is obtained between factors $p_i(x)$ and $q_j(x)$, and the unique factorization theorem is proved.

It is easy to extend the theorem to polynomials in several variables: it is sufficient to demonstrate how it may be done for polynomials in two variables x and y . If $f(x, y)$ be a polynomial in x, y , it may be regarded as a polynomial in y , with coefficients in the field of rational functions of x . Because the unique factorization theorem for one variable is proved by purely rational processes—that is, using only operations of addition and subtraction, and multiplication and division in the coefficients—it follows that $f(x, y) = r_1(x, y)r_2(x, y) \cdots r_k(x, y)$, in which $r_i(x, y)$ is an irreducible polynomial in y with coefficients that are rational functions of x , the k polynomials being uniquely determined save for order and factors that are rational functions of x . Let $b(x)$ be a common denominator of the coefficients of y in $r_i(x, y)$, so that each coefficient may be written $a_i(x)/b(x)$, in which $a_i(x)$ is a polynomial, and let $a_i(x)$ be the highest common factor of the coefficients of y in $b_i(x)r_i(x, y)$. Then $r_i(x, y) = [a_i(x)/b(x)]g_i(x, y)$, in which $g_i(x, y)$ is a polynomial in x and y , uniquely determined save for a factor in the field of coefficients. Hence $b_1(x)b_2(x) \cdots b_k(x)f(x, y) = a_1(x) \cdots a_k(x)g_1(x, y) \cdots g_k(x, y)$. Applying the unique factorization for polynomials in one variable to the coefficients of y , $b_i(x) \cdots b_k(x)$ is seen to be a factor of $a_1(x) \cdots a_k(x)$, and so $f(x, y) = c_1(x) \cdots c_s(x)g_1(x, y) \cdots g_k(x, y)$, in which the $c_i(x)$ and $g_j(x, y)$ are irreducible and uniquely determined to within a factor in the coefficient field.

Symmetric polynomials. Polynomials in r variables, x_1, \dots, x_r , which are of importance in many parts of

mathematics, for instance in the theory of equations, are the symmetric polynomials. A polynomial $f(x_1, \dots, x_r)$ is a symmetric polynomial in its arguments x_1, \dots, x_r , if the coefficients are rational numbers and if its value is unchanged whenever the subscripts in the arguments are replaced by any permutation of $(1, \dots, r)$. For example, $(2, 1, 3)$ is a permutation of $(1, 2, 3)$. Important examples include the elementary symmetric polynomials (see 27), and sums of terms, each of the form x_i^k , for $i = 1, 2, \dots, r$ (see 28).

In general (except for a plus or minus sign) the elementary symmetric polynomial γ_k in r variables x_1, \dots, x_r is the coefficient of t^k in $(t - x_1)(t - x_2) \cdots (t - x_r)$ ($k = 1, 2, \dots$). The principal result concerning symmetric polynomials is that any such polynomial $F(x_1, \dots, x_r)$ can be obtained by applying the operations of addition and multiplication to the elementary symmetric polynomials $\gamma_1, \gamma_2, \dots, \gamma_r$, so that F is a polynomial in $\gamma_1, \dots, \gamma_r$. This may be proved by the process of induction on r . There is, indeed, nothing to prove if $r = 1$. To begin the induction, it may be assumed that the theorem is true

Operations on symmetrical polynomials

$$(27) \quad \begin{cases} \text{The elementary symmetric polynomials:} \\ \gamma_1 = x_1 + x_2 + \cdots + x_r, \\ \gamma_2 = x_1x_2 + x_1x_3 + \cdots + x_2x_3 + \cdots + x_{r-1}x_r, \\ \gamma_r = x_1x_2 \cdots x_r. \end{cases}$$

$$(28) \quad \begin{cases} \text{The sums of powers: } \rho_k = x_1^k + x_2^k + \cdots + x_r^k, \\ k = 1, 2, \dots \end{cases}$$

$$(29) \quad \begin{cases} \gamma_1 = \gamma'_1 + x_r, & \gamma_2 = \gamma'_2 + x_r\gamma'_1, \dots \\ \gamma_r = x_r\gamma'_{r-1} \end{cases}$$

$$(30) \quad \gamma'_1 = \gamma_1 - x_r, \quad \gamma'_2 = \gamma_2 - x_2\gamma_1 + x_r^2, \dots$$

$$(31) \quad F(x_1, \dots, x_r) = \alpha_0 x_r^m + \alpha_1 x_r^{m-1} + \cdots + \alpha_m$$

$$(32) \quad f(z) = (z - x_1)(z - x_2) \cdots (z - x_r) \\ = z^r - \gamma_1 z^{r-1} + \gamma_2 z^{r-2} - \cdots \pm \gamma_r$$

$$(33) \quad F(x_1, \dots, x_r) = \beta_0 x_r^{r-1} + \beta_1 x_r^{r-2} + \cdots + \beta_{r-1}$$

$$(34) \quad F(x_1, \dots, x_r) = \beta_0 x_i^{r-1} + \beta_1 x_i^{r-2} + \cdots + \beta_{r-1} \\ i = 1, \dots, r$$

$$(35) \quad H(z) = \beta_0 z^{r-1} + \beta_1 z^{r-2} + \cdots + \beta_{r-1} - F(x_1, \dots, x_r)$$

$$(36) \quad F(x_1, \dots, x_r) = \beta_{r-1}$$

$$(37) \quad F_i(x_1, x_2, \dots, x_n) = 0, \quad i = 1, \dots, r$$

$$(38) \quad F_i(\alpha_1, \alpha_2, \dots, \alpha_n) = 0, \quad i = 1, \dots, r$$

if applied to symmetric polynomials in x_1, \dots, x_{r-1} . If $\gamma'_1, \gamma'_2, \dots, \gamma'_{r-1}$ denote the elementary symmetric polynomials in x_1, \dots, x_{r-1} , then $\gamma_1, \dots, \gamma_r$ can be expressed in terms of $\gamma'_1, \dots, \gamma'_{r-1}$ and x_r (see 29). These equations can be solved for $\gamma'_1, \dots, \gamma'_{r-1}$ (see 30).

Writing $F(x_1, \dots, x_r)$ as a polynomial in x_r (see 31), with the coefficients α_i being polynomials in x_1, \dots, x_{r-1} , one finds that because $F(x_1, \dots, x_r)$ is unaltered by any permutation of x_1, \dots, x_r , in particular by any permutation leaving x_r fixed, α_i is a symmetric polynomial in x_1, \dots, x_{r-1} , and can therefore be represented as a polynomial in $\gamma'_1, \dots, \gamma'_{r-1}$. Replacing γ'_1 by $\gamma_1 - x_r$, γ'_2 by $\gamma_2 - x_r\gamma_1 + x_r^2$, etc., it is possible to write $F(x_1, \dots, x_r)$ as a polynomial $G(\gamma_1, \dots, \gamma_{r-1}, x_r)$ in $\gamma_1, \dots, \gamma_{r-1}, x_r$. Now if $f(z)$ is a product of terms of the form $(z - x_i)$, for $i = 1, 2, \dots, r$ (see 32), then $f(x_r) = 0$. Using this, powers of x_r in $G(\gamma_1, \dots, \gamma_{r-1}, x_r)$

The unique factorization theorem

of degree greater than $r-1$ can be replaced by expressions involving $\gamma_1, \dots, \gamma_r$ and lower powers of x_r . Finally an equation is reached for $F(x_1, \dots, x_r)$ as a sum of terms $\beta_{r-1}x_r^{r-1}$ (see 33), in which $\beta_0, \dots, \beta_{r-1}$ are polynomials in $\gamma_1, \dots, \gamma_r$ —and hence symmetric polynomials in (x_1, \dots, x_r) . Because $F(x_1, \dots, x_r)$ is symmetric, r similar equations result (see 34).

Now consider the polynomial $H(z)$, formed by subtracting $F(x_1, \dots, x_r)$ from a similar polynomial in the variable z (see 35), with coefficients in the field of rational functions of x_1, \dots, x_r . $H(z)$ has r zeros, namely $z = a_1, \dots, a_r$. But (see below *Solution of equations*) a polynomial of degree $r-1$ or less that has r zeros is identically zero. Hence putting $z = 0$, $F(x_1, \dots, x_r)$ equals β_{r-1} (see 36), in which β_{r-1} is a polynomial in the elementary symmetric polynomials $\gamma_1, \dots, \gamma_r$. So if any polynomial in $r-1$ variables may be expressed as a polynomial in the $r-1$ elementary symmetric polynomials, it follows that any polynomial in r variables may be so expressed. Because the theorem is true for one variable, it is true for any number of variables.

The symmetric polynomials play an important role in the theory of equations (see below). A simple calculation enables expressions to be given for the sums s_r of the r th powers of (x_1, \dots, x_r) in terms of $\gamma_1, \dots, \gamma_r$; from these relations it can be shown that $\gamma_1, \dots, \gamma_r$ are equal to polynomials in s_1, \dots, s_r ; hence any symmetric polynomial can be expressed as a polynomial in s_1, \dots, s_r .

SOLUTION OF EQUATIONS

One of the principal problems of elementary algebra is the solution of a set of equations in which r polynomials $F_i(x_1, x_2, \dots, x_r)$, $i = 1, 2, \dots, r$, with coefficients in a field (rational numbers, real numbers, or complex numbers), are set equal to zero (see 37). By a solution of these equations is meant a set of numbers (a_1, a_2, \dots, a_r) in the coefficient field, or in some extension of the coefficient field, that, when substituted for x_1, x_2, \dots, x_r , causes the polynomials all to equal zero (see 38).

The problem falls into three parts. (1) Does there exist a solution of the equations, and how can a given set of equations be tested for solvability? This question can be refined by asking whether there exist solutions in the field of the coefficients, or in some prescribed extension of this field. A particular case of this arises when the coefficients are natural numbers, and it is desired to find solutions (a_1, a_2, \dots, a_r) in which a_i is rational. Such problems really belong to the theory of numbers, though methods of algebraic geometry (see below) play an important role in these investigations. (2) The criteria for determining whether a set of equations has a solution do not, as a rule, give any clue to finding a solution when one is known to exist. One asks whether there exists some algebraic process, involving the elementary operations of addition, subtraction, multiplication, and division, together with the extraction of roots, which, when applied to the coefficients of the equation, will lead to a solution. More precisely, it is of considerable interest to ask whether the solution can be obtained by elementary operations only (the solutions are then said to be rational) or if they can be found by elementary operations together with the extraction of square roots so that the solutions can be constructed geometrically by ruler and compass only (see above). (3) Whether or not it is possible to find the solution of a set of equations explicitly, it may be possible to develop a theory of the aggregate of solutions of a set of equations. This leads to algebraic geometry. In elementary geometry of the plane coordinates (x, y) are introduced consisting of pairs of real numbers x and y , and a one-to-one correspondence is established between all pairs (x, y) and all points of the plane. This notion can be extended in several ways: First the plane may be replaced by the real affine space of n dimensions, in which there is a one-to-one correspondence between the points of the space and all possible sets (a_1, a_2, \dots, a_n) of real numbers. Again, this notion may be extended to obtain complex affine space, in which the coordinates are sets of n complex numbers. Then each real (complex) solution of the equation defines a unique point in real (complex) affine space of n dimensions. The aggregate

$$(39) \quad y_0^{\pi_i} F_i\left(\frac{y_1}{y_0}, \frac{y_2}{y_0}, \dots, \frac{y_r}{y_0}\right) \equiv G_i(y_0, y_1, \dots, y_r)$$

$$(40) \quad G_i(ty_0, ty_1, \dots, ty_r) = t^{\pi_i} G_i(y_0, y_1, \dots, y_r)$$

$$(41) \quad G_i(y_0, y_1, \dots, y_r) = 0, \quad i = 1, \dots, r$$

$$(42) \quad f(x) \equiv a_0 x^n + a_1 x^{n-1} + \dots + a_n = 0$$

$$(43) \quad f(x) = f_1(x)(x - \alpha) + f(\alpha)$$

$$(44) \quad f_1(x) = (x - \beta)f_2(x), \quad f(x) = (x - \alpha)(x - \beta)f_2(x)$$

$$(45) \quad f(x) = a_0(x - \alpha_1)(x - \alpha_2) \dots (x - \alpha_n)$$

$$(46) \quad \alpha_0(\beta - \alpha_1)(\beta - \alpha_2) \dots (\beta - \alpha_n) = 0$$

$$(47) \quad \begin{cases} a_0 x^n + a_1 x^{n-1} + \dots + a_n \\ = a_0(x - \alpha_1)(x - \alpha_2) \dots (x - \alpha_n) \\ = a_0 x^n - a_0(\alpha_1 + \alpha_2 + \dots + \alpha_n)x^{n-1} + \dots \\ = a_0 x^n - a_0 \delta_1 x^{n-1} + a_0 \delta_2 x^{n-2} - \dots \end{cases}$$

$$(48) \quad x^2 + a_1 x + a_2 = (x + \frac{1}{2}a_1)^2 + a_2 - \frac{1}{4}a_1^2 \\ = (x + \frac{1}{2}a_1 + \alpha)(x + \frac{1}{2}a_1 - \alpha)$$

gate of the solutions defines a locus in the affine space, and the geometrical properties of this locus provide important information about the solution of the equations.

It is familiar that, in the elementary geometry of the plane, simple theorems such as "two (distinct) lines have one point in common" have to be qualified by adding "or else are parallel." This difficulty is overcome by adding to the affine plane a "line at infinity" to make the plane into a projective plane, the points being given by sets of numbers (a, β, γ) not all zero, two sets of numbers which are proportional determining the same point so that (a, β, γ) and $(\lambda a, \lambda \beta, \lambda \gamma)$ represent the same point. The points of the affine plane are identified with the points of the projective plane for which a is not zero. The affine coordinates of the point are $(\beta/a, \gamma/a)$. The same process can be used to extend the real (complex) affine space of n dimensions to a projective space of n dimensions. Now let (a_1, a_2, \dots, a_n) be any solution of the equations being considered (see 38). This is represented in projective space of n dimensions by the point $(\beta_0, \beta_1, \dots, \beta_n)$, in which $\beta_0 a_i = \beta_i$, $i = 1, \dots, n$. In $F_i(x_1, x_2, \dots, x_n)$ replace x_i by β_i/β_0 and multiply by the lowest power of β_0 that yields a polynomial G_i (see 39). This polynomial is homogeneous (see 40). Now consider the set of homogeneous equations (see 41) in which the G_i are set equal to zero. If $(\beta_0, \beta_1, \dots, \beta_n)$ is a solution, so is $(\lambda \beta_0, \lambda \beta_1, \dots, \lambda \beta_n)$ for any λ . If not all β_i are zero, the solution $(\lambda \beta_0, \lambda \beta_1, \dots, \lambda \beta_n)$ defines a unique point in the projective space of n dimensions. If $\beta_0 \neq 0$, then $(\beta_1/\beta_0, \beta_2/\beta_0, \dots, \beta_n/\beta_0)$ is a solution of the original equations (see 37). Thus the homogeneous equations (see 41) define a locus in projective space of n dimensions; and the points of this locus not in $y_0 = 0$ can be identified with the points of the affine space from which the projective space was constructed, which corresponds to the solutions of the original equations (see 37).

Just as the use of projective space allows certain difficulties arising in the geometry of affine space to be eliminated, so the restriction to homogeneous equations simplifies some difficulties in algebra, which arise when the solutions of nonhomogeneous equations are considered.

Existence of solutions. As a preliminary to the algebraic study of the equation in r variables, it is necessary to consider the solution of an n -degree polynomial equation in one variable (see 42), in some detail. The fundamental theorem of algebra states that if $n > 0$ and the coefficients are rational, or real, or complex numbers, there exists at least one complex number a such that $f(a) = 0$. The

The fundamental theorem of algebra

Nature of the problem

Solution as a unique point in affine space

number a is called a root of $f(x)$, or a solution of $f(x) = 0$. No elementary algebraic proof of this theorem exists, and the result is not proved here. There is an extension of the theorem which states that if the coefficients of $f(x)$ are in any field K , there exists an extension of K in which $f(x)$ has a root. In what follows, however, the coefficients of $f(x)$ are in the complex field: $f(x)$ then has a root in this field.

The remainder theorem proved above (see *Elementary properties of polynomials and rational functions*) can be applied (see 43) to express $f(x)$ as the sum of $f(a)$ and the product $f_1(x)(x - a)$, in which $f_1(x)$ is a polynomial of degree $n - 1$. If a is a root of $f(x)$, this implies that $(x - a)$ is a factor of $f(x)$. If $(n - 1) > 0$, $f_1(x)$ also has a root β , and the process can be continued to express $f(x)$ as a product (see 44 and 45) of terms of the form $(x - a_i)$, for $i = 1, 2, \dots, n$, in which a_1, a_2, \dots, a_n are complex numbers. Because $f(a_i) = 0$, each a_i is a root of $f(x)$. If β is any root of $f(x)$, then this expression equals zero (see 46), and because the complex numbers form a field, one term $(\beta - a_i)$ must be zero. Hence a_1, a_2, \dots, a_n are the only roots of $f(x)$. So now the polynomial can be written in terms of δ_i (see 47), the result of replacing x_1, x_2, \dots, x_n by a_1, a_2, \dots, a_n in the elementary symmetric polynomial γ_i (see 27). A function δ_i is usually called an (elementary) symmetric function of the roots of $f(x)$, and a considerable body of algebra deals with properties of the symmetric functions of the roots of an equation. For example, note that $a_0\delta_i = -a_i$ if i is odd, and that $a_0\delta_i = a_i$ if i is even. Thus the symmetric functions of the roots lie in the coefficient field of $f(x)$, though the individual roots may not.

Extraction of the roots of a polynomial. Although the fundamental theorem of algebra enables one to show that a polynomial $f(x)$ of degree n has n roots, it gives no clue to finding the roots. In algebra, it is desired to give rules for applying a series of elementary operations, together with the extraction of r th roots (the standard operations of algebra) on the coefficients of $f(x)$ to find the roots. In considering this problem, note that the roots of $f(x)$ are the same as the roots of $bf(x)$ in which b is any nonzero number of the coefficient field; b can be chosen so that $ba_0 = 1$; this means that without loss of generality a_0 may be set equal to one in $f(x)$; by doing this the notation is greatly simplified.

(I) $n = 1$. The equation is $x + a_1 = 0$, which has the unique solution $-a_1$ in the coefficient field.

(II) $n = 2$. Any quadratic expression can be put in the form $x^2 + a_1x + a_2$ and then can be factored, giving the solutions $-1/2a_1 + a$, $-1/2a_1 - a$ (see 48), in which a , $-a$ are the square roots of $1/4a_1^2 - a_2$. The root a can be constructed by use of ruler and compass, and the roots $-1/2a_1 + a$, $-1/2a_1 - a$ are obtained by the standard operations of algebra.

(III) $n = 3$. The variable in $f(x)$ is changed by writing $y = x + 1/3a_1$ giving a cubic equation with no quadratic term (see 49), in which the constants p and q are obtained from a_1, a_2, a_3 by elementary operations. If a root β of $g(y)$ can be found, $\beta - 1/3a_1$ is a root of $f(x)$. If $p = 0$, the roots of $g(y)$ are determined by extracting a cube root, and the solution of $f(x) = 0$ is complete.

Consider now $p \neq 0$ and make another change of variable determined by $y = z - p/3z$. Then express $g(y)$ in terms of z (see 50), and it is clear that if γ is any root of $h(z)$, $\gamma - p/3\gamma$ is a root of $g(y)$, and so a root of $f(x)$ is obtained. Defining two new quantities ξ and η and using the properties of homogeneous equations (see 40), one can factor $h(z)$ into a product (see 51), with terms of the product constructed by standard processes. By a standard process (but not by ruler and compass) a number a can be constructed such that $a^3 = \xi$. If $1, \omega_1, \omega_2$ are the cube roots of unity, the other roots of $z^3 - \xi$, one of the factors of $h(z)$, are $a\omega_1, a\omega_2$. It can be shown (see 52) that β is a cube root of η . The other cube roots are obtained, similarly, using $a\omega_1, a\omega_2$; they are in fact $\beta\omega_2, \beta\omega_1$, respectively.

If $\gamma_1 = a - p/3a$, γ_1 is a root of $g(y)$. Replacing a in this by $a\omega_1, a\omega_2$ or $\beta, \beta\omega_2, \beta\omega_1$ the other roots of $g(y)$ are obtained. On account of the relation $\beta = -p/3a$, however, the pairs $(a, \beta), (a\omega_1, \beta\omega_2), (a\omega_2, \beta\omega_1)$ give the same roots

$$(49) \quad f(x) = g(y) \equiv y^3 + py + q$$

$$(50) \quad g(y) = \frac{z^6 + qz^3 - p^3/27}{z^3} = \frac{h(z)}{z^3}$$

$$(51) \quad \begin{cases} h(z) = (z^3 - \xi)(z^3 - \eta) \\ \xi = -\frac{1}{2}q + p, & \eta = -\frac{1}{2}q - p \end{cases}$$

$$(52) \quad \begin{cases} \beta = \frac{-p}{3\alpha} \\ \beta^3 = \frac{-p^3}{27\xi} = \frac{-p^3}{27} \frac{1}{-\frac{1}{2}q + p} = \frac{-p^3 - \frac{1}{2}q - p}{27} = -\frac{1}{2}q - p \end{cases}$$

$$(53) \quad x^4 + a_1x^3 + a_2x^2 + a_3x + a_4 = 0$$

$$(54) \quad y^2 + a_1xy + a_2y + a_3x + a_4 = 0$$

$$(55) \quad y - x^2 = 0$$

$$(56) \quad F(x, y, \lambda) \equiv \lambda(x^2 - y) + y^2 + a_1xy + a_2y + a_3x + a_4$$

$$(57) \quad \lambda(\lambda - a_2)^2 + a_1a_3(\lambda - a_2) - 4a_4\lambda + a_3^2 + a_2^2a_4 = 0$$

$$(58) \quad F(x, y, \lambda_i) = (a_ix + b_iy + c_i)(\alpha_ix + \beta_iy + \gamma_i) \\ i = 1, 2, 3$$

$$(59) \quad a_1x + b_1y + c_1 = 0, \quad a_2x + b_2y + c_2 = 0$$

$$(60) \quad a_1x + b_1y + c_1 = 0, \quad \alpha_2x + \beta_2y + \gamma_2 = 0$$

$$(61) \quad f(x) \equiv a_0x^n + a_1x^{n-1} + \dots + a_n = 0$$

$$(62) \quad g(x) \equiv b_0x^m + b_1x^{m-1} + \dots + b_m = 0$$

$$(63) \quad H(f, g) = p(x)f(x) + q(x)g(x)$$

$$(64) \quad f(x) = r(x)H(f, g), \quad g(x) = s(x)H(f, g)$$

$$(65) \quad a_0^m b_0^n (\alpha_1 - \beta_1)(\alpha_1 - \beta_2) \cdots (\alpha_n - \beta_m) \\ = a_0^m g(\alpha_1)g(\alpha_2) \cdots g(\alpha_n) \\ = \pm b_0^n f(\beta_1)f(\beta_2) \cdots f(\beta_m)$$

of $g(y)$. Thus three roots of $g(y)$ are obtained by the standard processes of algebra, and hence three roots of $f(x)$.

(IV) $n = 4$. It can also be proved that the fourth degree equation (see 53) can be solved by the standard processes of algebra. It is instructive to see how one is led to the solution by simple considerations of geometry in the complex affine plane. In this plane define two conics by equations in x and y (see 54 and 55). A conic in the real plane is formed by the intersection of the plane with a cone. A circle, ellipse, hyperbola, parabola, or pair of intersecting straight lines is a conic. The concept is generalized to the complex plane. If a is any root of the fourth-degree equation (see 53), (a, a^2) is a point common to the conics. Conversely, if (a, β) is any point common to the two conics, $\beta = a^2$ from the second conic, a is a root of the fourth-degree equation (see 53). So it is necessary to find the four points common to the two conics. Define a function $F(x, y, \lambda)$, in which λ is any complex number, from these two conics (see 56). $F(x, y, \lambda) = 0$ is the equation of a conic in the plane. It is clear that if λ, μ are different complex numbers, the points common to $F(x, y, \lambda) = 0$ and $F(x, y, \mu) = 0$ are the points common to the conics (see 54 and 55). Now it is a theorem of geometry that $F(x, y, \lambda) = 0$ becomes a pair of lines if λ is a root of a certain cubic polynomial (see 57). By (III), this polynomial in λ has three roots $\lambda_1, \lambda_2, \lambda_3$, which can be found by the standard processes. Then, by solving quadratic equations, as in (II),

Finding the roots

$F(x, y, \lambda)$ can be written as a product of two terms, each linear in x and y (see 58). To find the four points common to the conics it is necessary to find the points common to $F(x, y, \lambda_1) = 0$ and $F(x, y, \lambda_2) = 0$. To find these, four pairs of linear equations (see 59 and 60) must be solved.

Because the four points so obtained satisfy the original equation and the second conic (see 37 and 55), the solution of the fourth-degree equation (see 53) is deduced, and can therefore be obtained by the standard processes of algebra.

In the 18th century, much effort was put into attempts to find methods of finding the solution of an equation of degree higher than four by the standard processes of algebra. Early in the 19th century the Norwegian mathematician Niels Henrik Abel proved that the general equation of degree five could not be solved in this way. Before his untimely death in 1832, the French mathematician Évariste Galois extended Abel's result to equations of degree greater than five and developed a general theory of equations that threw much light on the problem (see below *Fields*).

Common roots of two polynomials. Now let $f(x)$ and $g(x)$ be polynomials of degree n and m , respectively, and let $f(x) = 0$ and $g(x) = 0$ (see 61 and 62). One may ask if these equations have any common solution, and if so how it is found. It was shown above how to construct the highest common factor of $f(x)$, $g(x)$. This is a polynomial $H(f, g)$, such that there exist polynomials $p(x)$, $q(x)$, $r(x)$, $s(x)$, in terms of which $f(x)$ and $g(x)$ can be written (see 63 and 64). From these equations it follows that any common root of $f(x)$ and $g(x)$ is a root of $H(f, g)$, and any root of $H(f, g)$ is a common root of $f(x)$, $g(x)$. Thus $f(x)$ and $g(x)$ have a common root if and only if the highest common factor is of degree greater than zero. The process described can easily be extended to find the common roots, if any, of any finite set of polynomials $f_i(x)$ ($i = 1, \dots, r$). The highest common factor $H(f_1, f_2)$ of $f_1(x)$, $f_2(x)$ is constructed; the highest common factor $H(f_1, f_2, f_3)$ of this and $f_3(x)$, and so on. The common roots of $f_i(x)$ are simply the roots of $H(f_1, f_2, \dots, f_r)$.

If $f(x)$ and $g(x)$ have a common root, then let $\alpha_1, \dots, \alpha_n$ be the roots of $f(x)$, β_1, \dots, β_m the roots of $g(x)$. Consider a product with terms of the form $(\alpha_i - \beta_j)$, for $i = 1, 2, \dots, n$, and $j = 1, 2, \dots, m$ (see 65). The first expression is a symmetric function of the roots of $f(x)$, and hence can be expressed in terms of the elementary symmetric functions of these roots, that is, in terms of a_0, a_1, \dots, a_n . The expression is therefore a polynomial $R(f, g)$ in the coefficients $a_0, \dots, a_n, b_0, \dots, b_m$. If, for any given polynomials $f(x)$ and $g(x)$ in which a_0 and b_0 are not zero, $R(f, g) = 0$, it follows that the equations have a common solution, and conversely if the equations have a common solution $R(f, g) = 0$.

In later developments, the condition of $a_0 \neq 0$, $b_0 \neq 0$ turns out to be an undesirable restriction. This restriction may be removed to some extent. Suppose that $a_0 \neq 0$, $b_0 = 0$. Because $R(f, g)$ can be written as a product of a_0^m and the n terms $g(\alpha_i)$ (see 66), in which $\alpha_1, \dots, \alpha_n$ are roots of $f(x)$, $R(f, g) = 0$ implies $g(\alpha_i) = 0$ for some root α_i of $f(x)$. Hence this α_i is a common root of $f(x)$, $g(x)$. If $a_0 = 0 = b_0$, however, this argument breaks down. It can be verified that if a_0 and b_0 both vanish, $R(f, g) = 0$, whatever values are given to $a_1, \dots, a_n, b_1, \dots, b_m$, and nothing is learned about the roots of $f(x)$, $g(x)$.

To overcome this difficulty a new variable y is introduced in $f(x)$, $g(x)$ by replacing a_i by $A_i y^i$, b_j by $B_j y^j$; then three homogeneous polynomials $F(x, y)$, $G(x, y)$ and $R(f, g)$ are obtained (see 67). The polynomial $T(F, G)$ in $A_0, \dots, A_n, B_0, \dots, B_m$ is obtained by replacing $a_0, \dots, a_n, b_0, \dots, b_m$ by $A_0, \dots, A_n, B_0, \dots, B_m$ in $R(f, g)$.

If $F(x, y)$ and $G(x, y)$ both equal to zero (see 68) have a common solution (α, β) in which $\beta \neq 0$, α/β is a common root of $f(x)$, $g(x)$, and hence $T(F, G) = 0$. If the homogeneous equations have a common solution $(\alpha, 0)$ in which $\alpha = 0$, then A_0, B_0 are zero, and $T(F, G) = 0$. Conversely, if $T(F, G) = 0$ and A_0, B_0 are not both zero, $F(x, 1)$ and $G(y, 1)$ have a common root α , and $(\alpha, 1)$ is a common solution (see 68). If A_0, B_0 are zero the equations have the common solution $(1, 0)$. Hence $T(F, G) = 0$ is a necessary

$$(66) \quad R(f, g) = a_0^m g(\alpha_1) \cdots g(\alpha_n)$$

$$(67) \quad \begin{cases} F(x, y) = A_0 x^n + A_1 x^{n-1} y + \cdots + A_n y^n \\ G(x, y) = B_0 x^m + B_1 x^{m-1} y + \cdots + B_m y^m \\ R(f, g) = y^{mn} T(F, G) \end{cases}$$

$$(68) \quad F(x, y) = 0, \quad G(x, y) = 0$$

$$(69) \quad f(x, y) = a_0 x^n + a_1 x^{n-1} y + \cdots + a_n y^n = 0$$

$$(70) \quad g(x, y) = b_0 x^m + b_1 x^{m-1} y + \cdots + b_m y^m = 0$$

$$(71) \quad \begin{cases} F(x, y, z) = A_0(y, z)x^N + A_1(y, z)x^{N-1} + \cdots + A_N(y, z) = 0 \\ G(x, y, z) = B_0(y, z)x^M + B_1(y, z)x^{M-1} + \cdots + B_M(y, z) = 0 \end{cases}$$

$$(72) \quad \begin{cases} F(x, y, z) = A_0(u, v)x^N + A_1(u, v)tx^{N-1} + \cdots + A_N(u, v)t^N \\ G(x, y, z) = B_0(u, v)x^M + B_1(u, v)tx^{M-1} + \cdots + B_M(u, v)t^M \end{cases}$$

$$(73) \quad l_i = a_i x + b_i y + c_i z, \quad i = 1, \dots, r$$

$$(74) \quad b_i c_j - b_j c_i = c_i a_j - c_j a_i = a_i b_j - a_j b_i = 0 \\ i, j = 1, \dots, r$$

$$(75) \quad l_i = \rho_i l_1$$

$$(76) \quad a_1 x + b_1 y + c_1 z = 0$$

$$(77) \quad b_i l_j - b_j l_i = (b_i a_j - b_j a_i)x + (b_i c_j - b_j c_i)z = 0$$

$$(78) \quad (b_i c_j - b_j c_i)a_k + (c_i a_j - c_j a_i)b_k + (a_i b_j - a_j b_i)c_k = 0$$

$$(79) \quad \begin{pmatrix} a_1 & a_2 & \cdots & a_r \\ b_1 & b_2 & \cdots & b_r \\ c_1 & c_2 & \cdots & c_r \end{pmatrix}$$

$$(80) \quad M_i = a_i x + b_i y + c_i z = 0, \quad i = 1, \dots, r$$

$$(81) \quad b_i M_j - b_j M_i = 0x + b_i c_j - b_j c_i = 0$$

and sufficient condition for the homogeneous equations (68) to have a common solution.

The problem of solving equations in two variables (x, y) is now considered. If a simple equation $f(x, y) = 0$ is taken, y is given an arbitrary value η in the complex field, and the equation $f(x, \eta) = 0$ in one variable remains. If ξ is a root of $f(x, \eta)$, (ξ, η) is a solution for $f(x, y) = 0$.

Two simultaneous equations. Now consider two simultaneous nonhomogeneous polynomial equations (see 69 and 70) in which the coefficients a_i, b_j are now polynomials in y . $R(f, g)$ is then a polynomial in y ; and it is clear that if (ξ, η) is a common solution of the two equations, then η satisfies $R(f, g) = 0$. If, on the other hand, η is a root of $R(f, g)$ and the polynomials a_0, b_0 do not both have η as a root, there exists a common root of $f(x, \eta)$, $g(x, \eta)$ and so a common solution of the two equations (see 69 and 70). If η is a common zero of a_0, b_0 , however, the difficulty described above arises. To get over this difficulty, a new variable z is again introduced to make $f(x, y)$, $g(x, y)$ homogeneous, and $F(x, y, z)$ is defined as a sum of $N+1$ terms of the form $A_i(y, z)x^{N-i}$, for $i = 0, 1, \dots, N$, and $G(x, y, z)$ as a similar sum of terms of the form $B_j(y, z)x^{M-j}$, for $j = 0, 1, \dots, M$ (see 71), where $A_i(y, z)$ is homogeneous of degree i and $B_j(y, z)$ homogeneous of

factor

degree j . Then ut is written for y , vt for z (see 72). Regarding these as equations in (x, t) , $T(F, G)$ is constructed as before. It is homogeneous in (u, v) . If A_0 and B_0 are both zero, the equation $F(x, y, z) = 0$, $G(x, y, z) = 0$ have a common solution $(1, 0, 0)$. If they are not both zero, $F(x, y, z) = 0$ and $G(x, y, z) = 0$ have a common solution (λ, μ, ν) if and only if (μ, ν) is a solution of $T(F, G) = 0$.

This again illustrates the advantages of studying homogeneous equations and the associated loci in projective space.

Linear systems. To conclude, there follows a brief consideration of the solution of a system of linear homogeneous equations in three variables x, y, z , with coefficients a_i, b_i, c_i , respectively, for $i = 1, 2, \dots, r$ (see 73). If each a_i, b_i, c_i is zero ($i = 1, \dots, r$), the problem is trivial. Next, suppose, for instance, that a_i, b_i, c_i are not all zero, and that a certain relation of the coefficients (see 74) holds. Then there is a nonzero number such that l_i equals the product of p_i and l_i (see 75), and the problem reduces to finding the solution of a single such equation (see 76).

Next, suppose that $b_i c_j - b_j c_i, c_i a_j - c_j a_i, a_i b_j - a_j b_i$ are not all zero for a particular pair i, j , say $b_i c_j - b_j c_i \neq 0$. Then y can be eliminated yielding a simpler problem (see 77). This equation has a unique solution $[p(b_i c_j - b_j c_i), \rho(a_i b_j - a_j b_i)]$ in which $\rho \neq 0$, and substituting in the expressions for $l_i, l_j, l_i = 0 = l_j$ have the unique solution $(b_i c_j - b_j c_i, c_i a_j - c_j a_i, a_i b_j - a_j b_i)$. If equations being considered have any solution, it must be unique and this must be it. This solution, then, substituted into the original system, gives the condition for the existence of a solution (see 78). It must hold for all i, j, k . In the language of linear algebra the equations (73) have an infinity of solutions, a unique solution, or no solution according as the rank of the matrix of coefficients (see 79) is one, two, or three.

It should be noted that if the nonhomogeneous equations (see 80) had been considered, there would have been more possibilities. For instance, suppose that $a_i b_j - a_j b_i = 0, b_i c_j - b_j c_i \neq 0$, for given values of i, j . Then a system of equations (see 81) is reached that has no solution, and hence the nonhomogeneous equations have no solution. In this case, the geometrical explanation is that the lines $M_i = 0, M_j = 0$ are parallel, but not identical. To obtain an intersection, it is necessary to pass from the affine plane to the projective plane.

Linear and multilinear algebra

LINEAR ALGEBRA

Historical and conceptual introduction. Although the term linear algebra is comparatively recent, the mathematical ideas that it embraces are found in the works of many mathematicians over the past two or three hundred years. The main development of the subject, however, has taken place since 1850. Linear algebra originated in the study of systems of linear equations in several unknowns and in the attempt to find general methods for their solution. This attempt led quite early to the notion of a determinant, in 1693 by the German mathematician Gottfried Wilhelm Leibniz. In 1750 the Swiss physicist Gabriel Cramer gave the rule bearing his name, for expressing the solution of n linear equations in n unknowns in terms of determinants. The French mathematician Joseph-Louis Lagrange noted in 1773 the connection between a third-order determinant and the volume of a tetrahedron. Lagrange and Germany's greatest mathematician, Carl Friedrich Gauss, both observed that if the quadratic form $F = ax^2 + 2bxy + cy^2$ is subjected to a linear transformation (see Box, equations 82), expressed in two linear equations, to obtain the new form $f = a'u^2 + 2b'uv + c'v^2$ in the variables u and v , then the effect (see 83) of the transformation is to multiply the discriminant of the form (a function expressed in terms of the coefficients) by a factor depending on the transformation and not the forming.

The concept of a vector space grew out of the work of Hamilton on the algebra of vectors. An example of a vector space is the set, \mathcal{U}_3 , of all ordered triples $[x, y, z]$ in which x, y, z are real numbers. These triples are called vectors with components x, y, z and are added according

$$(82) \quad \begin{cases} x = \alpha u + \beta v \\ y = \gamma u + \delta v \end{cases}$$

$$(83) \quad a'c' - b'^2 = (\alpha\delta - \beta\gamma)^2(ac - b^2)$$

$$(84) \quad [x_1, y_1, z_1] + [x_2, y_2, z_2] = [x_1 + x_2, y_1 + y_2, z_1 + z_2]$$

$$(85) \quad cX = [cx, cy, cz]$$

to the rule (see 84) that respective components of two vectors are added to yield a sum vector. Moreover, if $X = [x, y, z]$ is a vector and c is a real number, then the product cX , called a scalar multiple of X , is defined (see 85) to be the vector obtained by multiplying each component of X by c . In this context a real number is called a scalar, as opposed to a triple $[x, y, z]$ that is a vector. The vector $[0, 0, 0]$ is called the null vector or zero vector and is denoted by $\mathbf{0}$.

The vectors of \mathcal{U}_3 have a geometric interpretation. The vector $X = [x, y, z]$ is represented, relative to a Cartesian coordinate system with origin at O , by the directed line segment \mathbf{OP} with initial point O and terminal point at the point P the coordinates of which are (x, y, z) . It is further stipulated that two directed line segments that have the same length and the same direction represent the same vector. Thus, vectors are invariant under translation and hence the vector represented by \mathbf{AB} with initial point $A(x_1, y_1, z_1)$ and terminal point $B(x_2, y_2, z_2)$ is (see Figure 3) the same (see 86) as the vector with initial point at the origin and with terminus at the point with coordinates $(x_2 - x_1, y_2 - y_1, z_2 - z_1)$. If X_1 and X_2 are vectors with geometric representations \mathbf{OP} and \mathbf{OQ} , respectively, then $X_1 + X_2$ has the geometric representation \mathbf{OR} in which R is the point determined by $\mathbf{PR} = \mathbf{OQ}$. If O, P , and Q are not collinear, then \mathbf{OR} is the diagonal of the parallelogram of which \mathbf{OP} and \mathbf{OQ} are adjacent edges (Figure 4). If c is any scalar, the geometric representation of cX is a directed segment the length of which is $|c|$ times the length of the segment representing X , and the direction of which is

Geometric interpretation of vectors

Figure 3: Geometric interpretation of the fact that vectors are invariant under translation. Specifically, the vector represented by the line segment \mathbf{AB} is the same as the vector represented by \mathbf{OP} . The coordinates of each point are shown in parentheses (see text).

the same or opposite to that of X according as $c > 0$ or $c < 0$. If $c = 0$ then $0X = \mathbf{0}$.

The set \mathcal{U}_2 of all ordered pairs $[x, y]$ of real numbers, with similar definitions of addition and multiplication by scalars, is another example of a vector space. The vectors of \mathcal{U}_2 can be represented geometrically by directed line segments in a Cartesian plane.

A function of mapping τ from \mathcal{U}_3 to \mathcal{U}_3 can be defined by a system of three linear equations (for example, see 87) that give the components u, v, w of the vector $\tau[x, y, z]$ onto which $[x, y, z]$ is mapped by τ (see 88). The vector $[u, v, w]$ is called the image of $[x, y, z]$ under τ and images of particular vectors such as $[1, 2, 3]$ and $[1, 0, 0]$ can be computed from the given equations (see 89). Because the equations defining the mapping are linear, τ has the properties (see 90) that the image of the sum of two vectors is the sum of their images, and the image of a scalar multiple of a vector is the same scalar multiple of its image. A mapping with these properties is called a linear transform-

Equations in three variables

Concept of a determinant

Figure 4: Geometric interpretation of the sum of two vectors. The vectors with representations \overrightarrow{OP} and \overrightarrow{OQ} add to yield the vector with representation \overrightarrow{OR} , which is the diagonal of a parallelogram (see text).

mation, in this case from \mathcal{U}_3 to \mathcal{U}_3 . Using Cayley's definition of matrix products, equations (87) defining the mapping τ can be written (see 91) $\mathbf{Y} = \mathbf{AX}$ in which \mathbf{A} is the matrix (92) of coefficients of the equations, and \mathbf{X} and \mathbf{Y} are the vectors $[x, y, z]$ and $[u, v, w]$ written, for technical reasons, as columns. Thus the matrix \mathbf{A} represents the linear transformation τ and operates on the vector \mathbf{X} to give the vector \mathbf{Y} . The linearity properties (90) of τ thus become two rules of matrix algebra (see 93). In the same way, a system (see 94) of two equations in three variables determines a linear transformation σ from \mathcal{U}_3 into \mathcal{U}_2 defined (see 95) by specifying the image in \mathcal{U}_2 of each vector in \mathcal{U}_3 under the mapping σ . The equations defining σ can also be written in matrix form (see 96). In general, both matrices and

$$(86) \quad \overrightarrow{AB} = [x_2 - x_1, y_2 - y_1, z_2 - z_1] = \overrightarrow{OP}$$

$$(87) \quad \begin{cases} 2x - 3y + z = u \\ x + y - 2z = v \\ 3x + y + 5z = w \end{cases}$$

$$(88) \quad \tau[x, y, z] = [u, v, w]$$

$$(89) \quad \begin{cases} \tau[1, 2, 3] = [-1, -3, 20], & \tau[1, 0, 0] = [2, 1, 3] \\ \tau[1, 1, 1] = [0, 0, 9] \end{cases}$$

$$(90) \quad \begin{cases} \tau(\mathbf{X} + \mathbf{Y}) = \tau\mathbf{X} + \tau\mathbf{Y} \\ \tau(c\mathbf{X}) = c(\tau\mathbf{X}) \end{cases}$$

$$(91) \quad \begin{bmatrix} u \\ v \\ w \end{bmatrix} = \begin{bmatrix} 2 & -3 & 1 \\ 1 & 1 & -2 \\ 3 & 1 & 5 \end{bmatrix} \begin{bmatrix} x \\ y \\ z \end{bmatrix}$$

$$(92) \quad \mathbf{A} = \begin{bmatrix} 2 & -3 & 1 \\ 1 & 1 & -2 \\ 3 & 1 & 5 \end{bmatrix}$$

$$(93) \quad \mathbf{A}(\mathbf{X}_1 + \mathbf{X}_2) = \mathbf{AX}_1 + \mathbf{AX}_2, \quad \mathbf{A}(c\mathbf{X}) = c(\mathbf{AX})$$

$$(94) \quad \begin{cases} 5x - y + 2z = u \\ x + 3y - 4z = v \end{cases}$$

$$(95) \quad \sigma[x, y, z] = [u, v]$$

$$(96) \quad \begin{bmatrix} u \\ v \end{bmatrix} = \begin{bmatrix} 5 & -1 & 2 \\ 1 & 3 & -4 \end{bmatrix} \begin{bmatrix} x \\ y \\ z \end{bmatrix}$$

systems of linear equations may be considered as representations of linear transformations.

A subset \mathcal{U} of \mathcal{U}_3 is called a subspace of \mathcal{U}_3 if it is closed under addition of vectors and multiplication by scalars; that is, if, whenever \mathbf{X} and \mathbf{Y} belong to \mathcal{U} , then also $\mathbf{X} + \mathbf{Y}$ and $c\mathbf{X}$ also belong to \mathcal{U} , for all scalars c . The set of all scalar multiples of a fixed vector \mathbf{X} in \mathcal{U} , is a subspace of \mathcal{U}_3 that consists, if $\mathbf{X} \neq \mathbf{0}$, of all vectors with geometric representations \overrightarrow{OP} lying in a fixed line through the origin. Similarly, if \mathbf{X}, \mathbf{Y} are two vectors the geometric representations of which do not lie in one line (or are not parallel), then the set of all vectors of the form $c_1\mathbf{X} + c_2\mathbf{Y}$ is a subspace consisting of all vectors with geometric representations in the plane through the origin determined by the two vectors \mathbf{X} and \mathbf{Y} . Apart from the space \mathcal{U}_3 itself (dimension 3), and the zero subspace consisting of the zero vector only (dimension 0), the subspaces of \mathcal{U}_3 are essentially the straight lines (dimension 1) and the planes (dimension 2) that pass through the origin. Linear transformations always map subspaces onto subspaces, but they may or may not preserve the dimensionality of all subspaces.

Vector spaces. In general, a nonempty set \mathcal{U} , the elements of which will be called vectors, is called a vector space, or a linear space, over a field \mathfrak{F} if addition of vectors and multiplication of vectors by elements of \mathfrak{F} are defined and satisfy 10 postulates (see 97).

Subspaces

- (97) { (1) The sum $V_1 + V_2$ of any two vectors V_1, V_2 is a uniquely defined vector in \mathcal{U} . (2) Addition of vectors is commutative: $V_1 + V_2 = V_2 + V_1$. (3) Addition of vectors is associative: $(V_1 + V_2) + V_3 = V_1 + (V_2 + V_3)$. (4) There is a zero vector $\mathbf{0}$ such that $V + \mathbf{0} = V$ for all V in \mathcal{U} . (5) Every vector V has a unique negative $-V$ such that $V + (-V) = \mathbf{0}$. (6) For any element c of \mathfrak{F} and any vector V in \mathcal{U} the product cV is a uniquely defined vector in \mathcal{U} . (7) $c(V_1 + V_2) = cV_1 + cV_2$. (8) $(c_1 + c_2)V = c_1V + c_2V$. (9) $c_1(c_2V) = (c_1c_2)V$. (10) $1V = V$.

$$(98) \quad \frac{d^ny}{dx^n} + a_1 \frac{d^{n-1}y}{dx^{n-1}} + \cdots + a_n y = 0$$

$$(99) \quad \sum c_i V_i$$

Basic concepts. The elements of \mathfrak{F} are called scalars and \mathfrak{F} is called the field of scalars. The field of scalars may be any field (see below *Fields*), but in most applications is either the field \mathfrak{R} of real numbers or the field \mathfrak{C} of complex numbers. The postulates just referred to imply that $\mathbf{0V} = \mathbf{0}$, and $(-1)V = -V$. An essential property of a vector space is that if V_1, V_2, \dots, V_r are vectors in \mathcal{U} and c_1, c_2, \dots, c_r are scalars, then the sum $c_1V_1 + c_2V_2 + \cdots + c_rV_r$, called a linear combination of V_1, V_2, \dots, V_r , is a vector in \mathcal{U} .

Examples of a vector space are the spaces \mathcal{U}_2 and \mathcal{U}_3 discussed in the introduction or, more generally, the vector space $\mathcal{U}^n(\mathfrak{F})$ of all n -tuples $[x_1, x_2, \dots, x_n]$ in which x_1, x_2, \dots, x_n belong to \mathfrak{F} , and addition and multiplication by scalars are defined as in \mathcal{U}_3 . Other examples are the set \mathfrak{B} of all polynomials with coefficients in \mathfrak{F} , the set \mathfrak{B}_n of all polynomials of degree $\leq n$ with coefficients in \mathfrak{F} . Similarly, the set of all continuous real-valued functions defined on the interval of real numbers between two fixed numbers a and b is a vector space over the field \mathfrak{R} of real numbers. The set of all solutions of a linear differential equation (see 98) with real coefficients is also a vector space over \mathfrak{R} .

Subspaces. A subset \mathcal{S} of a vector space \mathcal{U} over \mathfrak{F} is called a subspace of \mathcal{U} if \mathcal{S} itself is a vector space over \mathfrak{F} under addition and scalar multiplication that it inherits from \mathcal{U} ; that is, if, whenever V_1, V_2 belong to \mathcal{S} , $V_1 + V_2$ is in \mathcal{S} and cV_1 is in \mathcal{S} , for every scalar c . The space \mathcal{U} , itself, and the zero space consisting of the zero vector only are included among the subspaces of \mathcal{U} . If \mathcal{S} is any subset

of \mathcal{U} , the set \mathcal{S} of all linear combinations of vectors in \mathcal{H} is a subspace of \mathcal{U} , called the subspace spanned by the set \mathcal{H} . It is the smallest subspace of \mathcal{U} containing all vectors in \mathcal{H} . The set \mathcal{H} may be finite or infinite, but a linear combination (see 99) must have only a finite number of nonzero terms. If the subspace spanned by the set \mathcal{H} is \mathcal{U} itself, then \mathcal{H} is called a spanning set or generating system of \mathcal{U} . If \mathcal{U} is spanned by a finite set of vectors, \mathcal{U} is said to be finitely generated or finite-dimensional. Linear algebra is concerned primarily with finite-dimensional vector spaces. Although many of the theorems of linear algebra can be generalized to infinite-dimensional spaces, in order to do so it is usually necessary to introduce a topology on the space, and the results that are obtained are generally analytic in nature rather than purely algebraic (see ANALYSIS: *Functional analysis*).

Sums and
inter-
sections of
subspaces

If $\{\mathcal{E}_\alpha\}$ is any set of subspaces of \mathcal{U} , then their intersection, consisting of all vectors of \mathcal{U} that belong to each of the subspaces \mathcal{E}_α , is a subspace of \mathcal{U} . For example, the space spanned by the set \mathcal{H} is the intersection of all subspaces \mathcal{E}_α that contain all vectors in \mathcal{H} . The sum of the subspaces \mathcal{E}_α is the space spanned by the set of all vectors \mathbf{V} such that \mathbf{V} belongs to at least one of the subspaces \mathcal{E}_α . The sum of a finite number of subspaces $\mathcal{E}_1, \mathcal{E}_2, \dots, \mathcal{E}_r$ is the set of all vectors $\sum_{i=1}^r \mathbf{S}_i$ in which \mathbf{S}_i belongs to \mathcal{E}_i .

Linear dependence. The vectors $\mathbf{V}_1, \mathbf{V}_2, \dots, \mathbf{V}_r$ in a vector space \mathcal{U} over \mathcal{F} are linearly dependent, or constitute a linearly dependent set, if there exist scalars c_1, c_2, \dots, c_r in \mathcal{F} , not all zero, such that $c_1\mathbf{V}_1 + c_2\mathbf{V}_2 + \dots + c_r\mathbf{V}_r = \mathbf{0}$. If no such scalars exist, the vectors are linearly independent. For example, the vectors $\mathbf{X} = [2, 5, -1]$, $\mathbf{Y} = [1, 1, 4]$, $\mathbf{Z} = [1, 3, -2]$ in $\mathcal{U}_3(\mathcal{R})$ are linearly dependent, because $2\mathbf{X} - 1\mathbf{Y} - 3\mathbf{Z} = \mathbf{0}$; but the vectors $\mathbf{V} = [2, 5]$, $\mathbf{W} = [4, 1]$ in $\mathcal{U}_2(\mathcal{R})$ are linearly independent because $c_1\mathbf{V} + c_2\mathbf{W} = \mathbf{0}$ implies $2c_1 + 4c_2 = 0$, $5c_1 + c_2 = 0$, and the only solution of these two equations is $c_1 = c_2 = 0$. An infinite set of vectors is linearly dependent if it contains a finite subset that is linearly dependent. Linear dependence of two vectors means that one of them is a scalar multiple of the other. Linear dependence of three vectors in $\mathcal{U}_3(\mathcal{R})$ means that the three vectors have geometric representations that lie in one plane passing through the origin. In general, a set of vectors in \mathcal{U} is linearly dependent if, and only if, one of the vectors is in the subspace of \mathcal{U} spanned by the other vectors of the set.

A basis of the vector space \mathcal{U} comprises a linearly independent set of vectors that spans \mathcal{U} . Every vector space has a basis. If \mathcal{U} has a basis containing a finite number of vectors, then every basis of \mathcal{U} contains the same number of vectors. The number of vectors in a basis of \mathcal{U} is called the dimension of \mathcal{U} . A finitely generated vector space has finite dimension, because every set of vectors that spans \mathcal{U} has a maximal linearly independent subset that forms a basis of \mathcal{U} .

The space $\mathcal{U}_n(\mathcal{F})$ is n -dimensional, because it is spanned by the n linearly independent vectors $\mathbf{E}_1 = [1, 0, \dots, 0]$, $\mathbf{E}_2 = [0, 1, 0, \dots, 0]$, $\mathbf{E}_n = [0, 0, \dots, 1]$, which therefore form a basis of $\mathcal{U}_n(\mathcal{F})$. If \mathcal{U} has dimension n , then any set of n linearly independent vectors is a basis of \mathcal{U} , and any set of r linearly independent vectors, r less than n , is a subset of a basis.

Basis of
a vector
space

If $\mathbf{F}_1, \mathbf{F}_2, \dots, \mathbf{F}_n$, or, more briefly, (\mathbf{F}) , is a basis of \mathcal{U} , then every vector \mathbf{V} in \mathcal{U} has a unique representation, namely, $\mathbf{V} = x_1\mathbf{F}_1 + x_2\mathbf{F}_2 + \dots + x_n\mathbf{F}_n$ as a linear combination of the basis vectors. The vector $\mathbf{X} = [x_1, x_2, \dots, x_n]$ in $\mathcal{U}_n(\mathcal{F})$ is called the coordinate vector of \mathbf{V} relative to the \mathbf{F} -basis, and x_1, x_2, \dots, x_n are called the coordinates of \mathbf{V} relative to this basis. If the coordinate vector \mathbf{X} is denoted by $\alpha(\mathbf{V})$, the mapping α maps the space \mathcal{U} onto the space $\mathcal{U}_n(\mathcal{F})$. This is one-to-one and satisfies the rules that the image of the sum of vectors is the sum of the images and the image of a scalar multiple of a vector is the same scalar multiple of its image. Such a mapping is called an isomorphism and the two spaces \mathcal{U} and $\mathcal{U}_n(\mathcal{F})$ are isomorphic. Every n -dimensional vector space over \mathcal{F} is isomorphic to $\mathcal{U}_n(\mathcal{F})$, and every basis of \mathcal{U} provides such an isomorphism.

Linear transformations. If \mathcal{U} and \mathcal{W} are vector spaces over the same field \mathcal{F} , a mapping σ that associates a unique vector $\sigma\mathbf{V}$ in \mathcal{W} with each vector \mathbf{V} of \mathcal{U} is a linear transformation if the image of the sum of any two vectors is the sum of their images and the image of a scalar multiple of any vector is the same scalar multiple of its image (see 100). A linear oper-

Linear
operators

$$(100) \quad \sigma(\mathbf{V}_1 + \mathbf{V}_2) = \sigma\mathbf{V}_1 + \sigma\mathbf{V}_2 \quad \text{and} \quad \sigma(c\mathbf{V}) = c(\sigma\mathbf{V})$$

$$(101) \quad (\tau f)(x) = \int_0^x f(t) dt$$

$$(102) \quad \tau(\mathbf{0}) = \mathbf{0} \quad \text{and} \quad \tau(c_1\mathbf{V}_1 + c_2\mathbf{V}_2 + \dots + c_n\mathbf{V}_n) = c_1(\tau\mathbf{V}_1) + c_2(\tau\mathbf{V}_2) + \dots + c_n(\tau\mathbf{V}_n)$$

$$(103) \quad \tau(c_1\mathbf{E}_1 + c_2\mathbf{E}_2 + \dots + c_n\mathbf{E}_n) = c_1\mathbf{F}_1 + c_2\mathbf{F}_2 + \dots + c_n\mathbf{F}_n$$

ator in \mathcal{U} is a linear transformation of \mathcal{U} into itself. If A is any $m \times n$ matrix over \mathcal{F} , then the mapping σ from $\mathcal{U}_n(\mathcal{F})$ to $\mathcal{U}_m(\mathcal{F})$, defined by $\sigma\mathbf{X} = A\mathbf{X}$, is a linear transformation. If \mathcal{B} is the vector space, over the field \mathcal{R} of real numbers, of all polynomials in x with real coefficients, and if $\delta[p(x)]$ is the derivative of $p(x)$, then δ is a linear operator in \mathcal{B} . Similarly, the integral (see 101) defines a linear operator τ in the space of continuous functions f from \mathcal{R} into \mathcal{R} . If τ is any linear transformation that maps a vector space \mathcal{U} into a vector space \mathcal{W} , then τ maps the zero vector of \mathcal{U} on the zero vector of \mathcal{W} . Moreover, τ preserves linear combinations (see 102) and maps subspaces of \mathcal{U} onto subspaces of \mathcal{W} . If \mathcal{U} is finite-dimensional with basis (\mathbf{E}) , and if $\mathbf{F}_1, \mathbf{F}_2, \dots, \mathbf{F}_n$ are arbitrary vectors of \mathcal{W} , there exists a unique linear transformation τ from \mathcal{U} into \mathcal{W} such that $\tau\mathbf{E}_i = \mathbf{F}_i$, and hence (see 103) τ is completely determined by its effect on a basis of \mathcal{U} .

The set $\mathcal{L}(\mathcal{U}, \mathcal{W})$ of all linear transformations from \mathcal{U} to \mathcal{W} can be given the structure of a vector space. If σ, τ are such linear transformations, then sums and scalar multiples are defined by forming sums and scalar multiples of images (see 104). The zero element of $\mathcal{L}(\mathcal{U}, \mathcal{W})$ is the zero mapping $\mathbf{0}$, defined by $\mathbf{0}\mathbf{V} = \mathbf{0}$ for all \mathbf{V} , and $(-\sigma)\mathbf{V}$ is defined to be $-(\sigma\mathbf{V})$. If \mathcal{U} and \mathcal{W} are finite-dimensional, and σ is a linear transformation that maps \mathcal{U} into \mathcal{W} , then σ is uniquely determined by equations (105) or by the matrix $A_\sigma^{(\mathbf{E}, \mathbf{F})}$ (see 106), called the matrix of σ relative to the \mathbf{E} - and \mathbf{F} -bases. If a vector \mathbf{V} in \mathcal{U} has a coordinate vector \mathbf{X} relative to the \mathbf{E} -basis, and if $\sigma\mathbf{V}$ has a coordinate vector \mathbf{Y} relative to the \mathbf{F} -basis, then $\mathbf{Y} = A_\sigma^{(\mathbf{E}, \mathbf{F})}\mathbf{X}$. Because there is an isomorphism of the vector space $\mathcal{L}(\mathcal{U}, \mathcal{W})$ onto the vector space of all $m \times n$ matrices over \mathcal{F} (see 107), the dimension of $\mathcal{L}(\mathcal{U}, \mathcal{W})$ is mn .

If \mathcal{U}, \mathcal{W} , and \mathcal{Z} are vector spaces over \mathcal{F} , and if σ and τ are linear transformations that map \mathcal{U} into \mathcal{W} and \mathcal{W} into \mathcal{Z} , respectively, then the composite mapping, or product, $\tau\sigma$ that maps \mathcal{U} into \mathcal{Z} is defined by $(\tau\sigma)\mathbf{V} = \tau(\sigma\mathbf{V})$ and is a linear transformation. Hence, by taking $\mathcal{Z} = \mathcal{W} = \mathcal{U}$, a multiplication is defined (see 108) in the vector space $\mathcal{L}(\mathcal{U}, \mathcal{U})$ that is associative and distributive with respect to addition, and $\mathcal{L}(\mathcal{U}, \mathcal{U})$ becomes a linear associative algebra over \mathcal{F} . In the case of a linear operator σ that maps \mathcal{U} into \mathcal{U} , the corresponding matrix $A_\sigma^{(\mathbf{E}, \mathbf{E})}$ is denoted by $A_\sigma^{(\mathbf{E})}$ and is called the matrix of σ relative to the \mathbf{E} -basis of \mathcal{U} . The vector space isomorphism α , which is defined by $\alpha(\sigma) = A_\sigma^{(\mathbf{E})}$, is also an algebra isomorphism of the algebra of linear operators in \mathcal{U} onto the algebra of $n \times n$ matrices over \mathcal{F} .

If τ is a linear transformation of \mathcal{U} into \mathcal{W} , the image of τ , written $\text{im } \tau$, is the subspace of \mathcal{W} consisting of all vectors $\tau\mathbf{V}$ where \mathbf{V} belongs to \mathcal{U} . The rank of τ is the dimension of $\text{im } \tau$. The subspace \mathcal{N} of \mathcal{U} , consisting of all vectors \mathbf{V} such that $\tau\mathbf{V} = \mathbf{0}$, is called the nullspace or kernel of τ . The dimension of \mathcal{N} , written $\dim \mathcal{N}$, is called the nullity

$$(106) \quad A_{\sigma}^{(E,F)} = \begin{bmatrix} a_{11} & a_{12} & \cdots & a_{1n} \\ a_{21} & a_{22} & \cdots & a_{2n} \\ \cdots & \cdots & \cdots & \cdots \\ a_{m1} & a_{m2} & \cdots & a_{mn} \end{bmatrix}$$

$$(107) \quad \begin{cases} \text{Because } A_{\sigma+\tau}^{(E,F)} = A_{\sigma}^{(E,F)} + A_{\tau}^{(E,F)} \text{ and } A_{c\sigma}^{(E,F)} = cA_{\sigma}^{(E,F)} \\ \text{the mapping } \alpha: \mathfrak{L}(\mathfrak{U}, \mathfrak{W}) \rightarrow [\mathfrak{Y}]_{m,n} \text{ defined by} \\ \alpha(\sigma) = A_{\sigma}^{(E,F)} \text{ is an isomorphism.} \end{cases}$$

(108) { Also, if (E) , (F) and (G) are bases for the three spaces, then $A_{\sigma\tau}^{(E,G)} = A_{\sigma}^{(E,F)} A_{\tau}^{(F,G)}$. If σ and τ are both linear operators in \mathfrak{U} then $\tau\sigma$ and $\sigma\tau$ are also linear operators in \mathfrak{U} .

(109) $\left\{ \begin{array}{l} \text{The isomorphism } \alpha: \mathfrak{L}(\mathfrak{U}, \mathfrak{B}) \rightarrow [\mathfrak{K}]_{m,n} \text{ maps im } \tau \\ \text{onto the column space of } A^{(E,F)}_{\tau} \text{ and hence rank } \tau = \\ \text{rank } A^{(E,F)}_{\tau}. \text{ Also } \alpha \text{ maps the nullspace of } \tau \text{ onto the} \\ \text{nullspace of } A^{(E,F)}_{\tau}. \end{array} \right.$

$$(110) \quad A_{\tau}^{(F)} = P^{-1} A_{\tau}^{(E)} P$$

of τ . If \mathfrak{U} is finite-dimensional, then for every τ in $\mathfrak{L}(\mathfrak{U}, \mathfrak{W})$, a simple relationship holds between rank, nullity, and dimension, namely: $\text{rank } \tau + \text{nullity } \tau = \dim \mathfrak{U}$. This relationship states, in effect, (see 109) that the solution space of the system of equations $A\mathbf{X} = \mathbf{0}$ has dimension $n - r$, in which n is the number of unknowns and $r = \text{rank } A$. A linear transformation is one-to-one (that is, $\tau\mathbf{V}_1 = \tau\mathbf{V}_2$ implies $\mathbf{V}_1 = \mathbf{V}_2$) if, and only if, its nullspace is $\mathbf{0}$. If \mathfrak{U} is finite-dimensional and τ belongs to $\mathfrak{L}(\mathfrak{U}, \mathfrak{U})$ then $\text{im } \tau = \mathfrak{U}$ only if the nullspace of τ is $\mathbf{0}$. In this case, τ is called a nonsingular or invertible operator, and there exists an inverse mapping τ^{-1} , also a linear operator, such that $\tau^{-1}\tau = \tau\tau^{-1} = I$, in which I is the identity mapping on \mathfrak{U} . An operator τ is nonsingular, if and only if the matrix $A_{\tau^{(E)}}$ is nonsingular; then the matrix of the inverse of τ is the inverse of the matrix of τ relative to the E-basis.

If (E) and (F) are two different bases of \mathcal{U} , and if \mathbf{X} and \mathbf{Y} are the coordinate vectors of vector \mathbf{V} relative to the E- and F-bases, respectively, then $\mathbf{X} = P\mathbf{Y}$ in which P is a nonsingular $n \times n$ matrix, depending only on the two bases, and is called the transition matrix from the E- to the F-basis. If τ is a linear operator in \mathcal{U} , then the matrices of τ relative to the two bases are related by equation (110) in which P is the transition matrix from the E- to the F-basis. $A_\tau^{(F)}$ and $A_\tau^{(E)}$ have the same determinant. Thus $\det A_\tau^{(E)}$ is independent of the basis (E) and is called the determinant of the linear operator τ and written $\det \tau$. If τ is a linear operator in $\mathcal{U}_2(\mathcal{R})$, then the area of the parallelogram with adjacent edges $\tau \mathbf{V}_1$ and $\tau \mathbf{V}_2$ is equal to $\det \tau$ times the area of the parallelogram with edges \mathbf{V}_1 and \mathbf{V}_2 . Similarly in $\mathcal{U}_3(\mathcal{R})$, the parallelepiped with edges $\mathbf{V}_1, \mathbf{V}_2, \mathbf{V}_3$ is mapped by τ onto the parallelepiped with edges $\tau \mathbf{V}_1, \tau \mathbf{V}_2, \tau \mathbf{V}_3$ whose volume is $\det \tau$ times that of the original parallelepiped. If $\det \tau = 0$, τ is singular and $\text{im } \tau$ is a proper subspace of \mathcal{U} .

Linear functionals. If \mathfrak{U} is a vector space over \mathfrak{F} , then a linear functional on \mathfrak{U} is a mapping τ from \mathfrak{U} into \mathfrak{F} such that the linearity properties (see 111) are satisfied. If \mathfrak{F} itself is considered as a vector space over \mathfrak{F} , with field addition as vector addition, and field multiplication as scalar multiplication, then a linear functional

on \mathfrak{U} is simply a linear transformation from \mathfrak{U} into \mathfrak{F} . If \mathfrak{U} has dimension n and a basis (E), examples (see 112) of linear functionals are easily constructed. In particular, the mapping of each vector \mathbf{V} onto its i th coordinate, relative to the E-basis, is a linear functional. Other examples are the mapping σ that carries \mathfrak{B} into \mathfrak{F} defined by $\sigma f(x) = f(a)$ for a fixed scalar a , in which \mathfrak{B} is the space of all polynomials in x with coefficients in \mathfrak{F} , and the mapping φ defined on the space of all continuous real-valued functions on the closed interval of real numbers between a and b in which φ is the integral (see 113) of f over that interval. The set of all linear functionals on \mathfrak{U} can be given the algebraic structure of a vector space by identifying it with $\mathfrak{V}(\mathfrak{U}, \mathfrak{F})$ in which \mathfrak{F} is viewed as a one-dimensional vector space over \mathfrak{F} . The vector space $\mathfrak{V}(\mathfrak{U}, \mathfrak{F})$ of linear functionals on \mathfrak{U} is called the dual space of \mathfrak{U} and is denoted by \mathfrak{U}^* . Since $\dim \mathfrak{F} = 1$, if $\dim \mathfrak{U} = n$, then \mathfrak{U}^* also has dimension n . If (E) is a basis of \mathfrak{U} , since $\mathbf{F}_1 = 1$ is a basis of \mathfrak{F} , there is a unique linear functional τ in \mathfrak{U}^* such that, for each i , $\tau \mathbf{E}_i = a_i$ in which the $\{a_i\}$ are n arbitrary scalars. The matrix (see 114) of τ relative to the E- and F-bases is the vector with components a_i . Thus every linear functional on a finite-dimensional space is defined by a fixed linear homogeneous function of the coordinates relative to the E-basis. Corresponding to an E-basis of \mathfrak{U} , there is a dual τ -basis of \mathfrak{U}^* , defined by $\tau_i \mathbf{E}_i = 1$ and $\tau_i \mathbf{E}_j = 0$ if $j \neq i$. Thus, τ_i is the functional that maps each vector \mathbf{V} of \mathfrak{U} on its i th coordinate relative to the E-basis. The matrix of τ_i , relative to the E-basis, is the vector with 1 in the i th place and 0 elsewhere, and every vector \mathbf{V} of \mathfrak{U} expressed in the E-basis has the i th coordinate $\tau_i(\mathbf{V})$ (see 115). The dual space $(\mathfrak{U}^*)^*$ of \mathfrak{U}^* is denoted by \mathfrak{U}^{**} and is called the double dual of \mathfrak{U} . There is a natural isomorphism α from \mathfrak{U} onto \mathfrak{U}^{**} defined by $\alpha \mathbf{V} = \sigma_{\mathbf{V}}$ in which $\sigma_{\mathbf{V}}$ is the linear functional on \mathfrak{U}^* , defined by $\sigma_{\mathbf{V}} \tau = \tau \mathbf{V}$ for all τ in \mathfrak{U}^* . The isomorphism α maps the E-basis of \mathfrak{U} onto its double dual basis of \mathfrak{U}^{**} (see 116).

If σ is a linear transformation of \mathfrak{U} into \mathfrak{W} , and τ is a linear functional on \mathfrak{W} , then the composite $\tau\sigma$ is a linear functional on \mathfrak{U} . Thus, σ induces a linear transformation of σ^T of \mathfrak{W}^* into \mathfrak{U}^* , defined by $\sigma^T\tau = \tau\sigma$, and called the

$$(111) \quad \tau(V_1 + V_2) = \tau V_1 + \tau V_2 \quad \text{and} \quad \tau(cV) = c(\tau V)$$

$$(112) \quad \tau(x_1 E_1 + x_2 E_2 + \cdots + x_n E_n) = a_1 x_1 + a_2 x_2 + \cdots + a_n x_n \text{ in which } a_1, a_2, \cdots a_n \text{ are any fixed scalars}$$

$$(113) \quad \phi f = \int_a^b f(x) dx$$

$$(114) \quad A_{\tau}^{(E,F)} = [a_1, a_0, \dots, a_r]$$

$$(115) \quad V = \tau_1(V)E_1 + \tau_2(V)E_2 + \cdots + \tau_n(V)E_n$$

$$(116) \quad \begin{cases} \text{If } \tau_1, \dots, \tau_n \text{ is the basis of } \mathbb{L}^* \text{ dual to the basis} \\ E_1, \dots, E_n \text{ of } \mathbb{L} \text{ then the basis of } \mathbb{L}^{**} \text{ dual to} \\ \tau_1, \dots, \tau_n \text{ is } \alpha E_1, \dots, \alpha E_n \end{cases}$$

$$(117) \quad (X, Y) = x_1 y_1 + x_2 y_2 + x_3 y_3$$

$$(118) \quad \|X\| = \sqrt{(X, X)} \quad \cos \theta = \frac{(X, Y)}{\|X\| \|Y\|}$$

$$(119) \quad \begin{cases} \text{If } X = [x_1, \dots, x_n] \text{ and } Y = [y_1, \dots, y_n], \\ (X, Y) = x_1y_1 + x_2y_2 + \dots + x_ny_n \end{cases}$$

$$(120) \quad \begin{cases} \phi(V_1 + V_2, W) = \phi(V_1, W) + \phi(V_2, W) \\ \phi(V, W_1 + W_2) = \phi(V, W_1) + \phi(V, W_2) \\ \phi(cV, W) = \phi(V, cW) = c\phi(V, W) \end{cases}$$

transpose of σ . If (E) and (F) are bases of \mathcal{U} and \mathcal{W} , and (α) and (β) are the dual bases of ${}^*\mathcal{U}$ and \mathcal{W}^* , then the matrix of σ^T , relative to the bases (β) and (α) , is the transpose of the matrix $A_\sigma^{(E, F)}$.

Inner products. If X and Y are any two vectors in $\mathcal{U}_n(\mathfrak{R})$, then their classical inner product or dot product (see 117) is a scalar-valued function of the pair of vectors X, Y . Its importance lies in the fact that the length of the vector X , denoted by $\|X\|$, and the angle θ between the directions of X and Y , can be defined in terms of inner products (see 118). Similarly, if X and Y are two vectors of $\mathcal{U}_n(\mathfrak{C})$, their dot product or standard inner product is defined as a sum (see 119) of products of respective components. Because $(X, X) > 0$ if $X \neq 0$, and because the Cauchy-Schwarz inequality ensures that $|(X, Y)| \leq \sqrt{(X, X)}\sqrt{(Y, Y)}$, the length of a vector and the angle between vectors can be defined by the same formulas as those used in \mathcal{U}_3 . In general, an inner product is used to introduce metric concepts in an abstract vector space over either the real or the complex field.

Inner
products
and metric
concepts

An important property of the dot product in $\mathcal{U}_n(\mathfrak{R})$ is that the mappings defined by $\sigma_X(Y) = (X, Y)$ for a fixed X , and $\sigma_Y(X) = (X, Y)$ for a fixed Y , are both linear functionals on $\mathcal{U}_n(\mathfrak{R})$. The dot product is therefore an example of a bilinear functional. In general, if $\mathcal{U} \times \mathcal{U}$ denotes the set of all ordered pairs (V, W) in which V, W are vectors in a vector space \mathcal{U} over \mathfrak{F} , a bilinear functional on \mathcal{U} is a mapping ϕ from $\mathcal{U} \times \mathcal{U}$ into \mathfrak{F} having linearity properties (see 120) with respect to both members of the pair. A bilinear functional ϕ is symmetric if $\phi(V, W) = \phi(W, V)$, and is positive if $\phi(V, V)$ is a real number for every vector V and $\phi(V, V) > 0$ whenever $V \neq 0$.

If \mathcal{U} is any vector space over \mathfrak{R} , an inner product in \mathcal{U} is a positive symmetric bilinear functional on \mathcal{U} . The dot product in $\mathcal{U}_n(\mathfrak{R})$ is clearly an inner product under this definition. More generally, if (E) is any basis of \mathcal{U} , an inner product in \mathcal{U} is obtained by defining (V, W) to be the dot product of the coordinate vectors of V and W , relative to the E -basis. A vector space over \mathfrak{R} in which a fixed inner product is designated is called a real inner product space. A finite-dimensional real inner product space is called a Euclidean vector space. Inner products that lead to a suitable metric can also be defined in a vector space over the complex field \mathfrak{C} , but the linearity and symmetry conditions have to be modified. If \mathcal{U} is a vector space over \mathfrak{C} , an inner product on \mathcal{U} is a function that associates with each ordered pair of vectors V, W in \mathcal{U} a scalar (V, W) such that (see 121) (V, W) is linear in the first member of

the pair, (V, W) is equal to the complex conjugate of (W, V) , and (V, V) is real and is positive if $V \neq 0$.

These postulates can be used to define an inner product on either a real or complex vector space. In the complex case σ_v , defined by $\sigma_v W = (V, W)$, is a linear functional on \mathcal{U} into \mathfrak{C} and, in fact, every linear functional of \mathcal{U} has this form for some vector W . The behaviour of σ_v , defined by $\sigma_v W = (V, W)$, is, however, not linear because the functional value of σ_v at cW is c times the value at W . An example of an inner product (X, Y) in the complex case is the standard inner product of $\mathcal{U}_n(\mathfrak{C})$ defined by the sum (see 122) of products of the type $x_i \bar{y}_i$. In general, if \mathfrak{F} is either \mathfrak{R} or \mathfrak{C} , and α is the isomorphism that maps each vector V on its coordinate vector αV in $\mathcal{U}_n(\mathfrak{F})$, then $(V, W) = (\alpha V, \alpha W)$, in which $(,)$ denotes the standard inner product in $\mathcal{U}_n(\mathfrak{F})$, defines an inner product (V, W) in \mathcal{U} .

If \mathfrak{F} denotes either the real field \mathfrak{R} or the complex field \mathfrak{C} , and \mathcal{U} is a vector space over \mathfrak{F} with basis (E) , then an inner product (V, W) in \mathcal{U} is completely determined by the n^2 scalars (E_i, E_j) . If these scalars are denoted by a_{ij} , then the matrix $A = [a_{ij}]$ has the property $A^* = A$, in which A^* is the transpose of the complex conjugate matrix $\bar{A} = [\bar{a}_{ij}]$. The matrix A^* is called the conjugate of A , and a matrix A for which $A^* = A$ is called a self-conjugate or Hermitian matrix, named for the French mathematician Charles Hermite. If A has real elements, then $A^* = A^T$, and hence a real Hermitian matrix is symmetric in the sense that $A^T = A$. An expression formed from a sum of terms of the type $a_{ij} x_i \bar{y}_j$ in which $a_{ij} = \bar{a}_{ji}$ naturally occurs when taking the inner product of two vectors V and W with coordinate vectors X and Y (see 123). Such an expression (see 124) is called a Hermitian bilinear form. It can be written in matrix notation as XAY^* , in which X and Y are the coordinate vectors of V and W , and $Y^* = \bar{Y}^T$.

Hermitian
matrices

A Hermitian bilinear form has the property that XAX^* is real for all X . If in addition $XAX^* > 0$ for all nonzero X , then the Hermitian form and the Hermitian matrix A are said to be positive. Every inner product in \mathcal{U} has the form $(V, W) = XAY^*$ in which X, Y are the coordinate vectors of V, W relative to some basis, and A is a positive Hermitian matrix. Conversely, every positive Hermitian bilinear form in the coordinates of V and W defines an inner product on \mathcal{U} .

If \mathcal{U} is an inner product space over \mathfrak{R} or \mathfrak{C} , then for any two vectors V, W the Cauchy-Schwarz inequality holds (see 125). The length of V is defined by $\|V\| = \sqrt{(V, V)}$ and has the three properties (see 126) that are normally associated with length. If $\|V\| = 1$, then V is called a unit vector. Two vectors V, W are said to be orthogonal if $(V, W) = 0$. The zero vector is orthogonal to every vector in \mathcal{U} and is the only vector with this property. Every n -dimensional inner product space has an orthonormal basis; that is, a basis consisting of n mutually orthogonal unit vectors. If (E) is an orthonormal basis of \mathcal{U} , a second basis (F) is orthonormal if, and only if, the transition matrix P from the E - to the F -basis has the property $PP^* = I$. Such a matrix P is called a unitary matrix. The columns (and the rows) of a unitary matrix constitute an orthonormal basis of $\mathcal{U}_n(\mathfrak{C})$ relative to the standard inner product. If a unitary matrix P has real elements, then $PP^T = I$ and P is called an orthogonal matrix and its columns (and rows) form an orthonormal basis of $\mathcal{U}_n(\mathfrak{R})$. If \mathcal{U} is an inner product space with orthonormal basis E_1, E_2, \dots, E_n and α is the isomorphism that maps each vector V on its coordinate vector αV relative to the E -basis, then the inner product (V, W) in \mathcal{U} is equal to the standard inner product $(\alpha V, \alpha W)$ of the coordinate vectors in $\mathcal{U}_n(\mathfrak{F})$. Hence the standard inner product in $\mathcal{U}_n(\mathfrak{F})$ is invariant under transformation from one orthonormal basis to another.

Linear operators in an inner product space. If \mathcal{U} is a finite-dimensional inner product space over \mathfrak{F} , in which \mathfrak{F} is either \mathfrak{R} or \mathfrak{C} , then for any linear operator τ on \mathcal{U} there exists a unique linear operator τ^* on \mathcal{U} , called the adjoint of τ , such that $(\tau V, W) = (V, \tau^* W)$ for all vectors V, W in \mathcal{U} . If A_τ is the matrix of τ relative to an orthonormal basis, then the matrix A_{τ^*} of τ^* , relative to the same basis, is the adjoint matrix A_τ^* of A_τ . If

The
adjoint of
a linear
operator

$$(72) \quad \begin{cases} (1) (V_1 + V_2, W) = (V_1, W) + (V_2, W), (2) (W, V) \\ = \bar{(V, W)}, \text{ in which } \bar{z} \text{ denotes the complex conjugate} \\ \text{of } z, (3) (cV, W) = c(V, W), \text{ and } (4) (V, V) \text{ is real} \\ \text{and } (V, V) > 0 \text{ if } V \neq 0. \end{cases}$$

$$(73) \quad (X, Y) = x_1 \bar{y}_1 + x_2 \bar{y}_2 + \dots + x_n \bar{y}_n$$

$$(74) \quad \begin{cases} \text{If } V = x_1 E_1 + \dots + x_n E_n, W = y_1 E_1 + \dots + y_n E_n \\ \text{the postulates require that} \\ (V, W) = \sum_{i=1}^n \sum_{j=1}^n x_i \bar{y}_j (E_i, E_j) = \sum_{i=1}^n \sum_{j=1}^n a_{ij} x_i \bar{y}_j, \\ \text{in which } A = [a_{ij}] \text{ is Hermitian.} \end{cases}$$

$$(75) \quad \sum_{i=1}^n \sum_{j=1}^n a_{ij} x_i \bar{y}_j \quad \text{in which } a_{ij} = \bar{a}_{ji}$$

$$(76) \quad |(V, W)| \leq (V, V)^{1/2} (W, W)^{1/2}$$

$$(77) \quad \begin{aligned} (a) \|V\| > 0 \quad \text{if } V \neq 0, \quad (b) |cV| &= |c| \|V\| \\ (c) \|V + W\| &\leq \|V\| + \|W\| \end{aligned}$$

$$(78) \quad c_1 y_1 \bar{y}_1 + c_2 y_2 \bar{y}_2 + \dots + c_n y_n \bar{y}_n$$

σ, τ are linear operators on \mathfrak{U} , and if c is any scalar, then $(\sigma + \tau)^* = \sigma^* + \tau^*$, $(c\sigma)^* = c\sigma^*$, $(\sigma\tau)^* = \tau^*\sigma^*$, and $(\sigma^*)^* = \sigma$. An operator τ is self-adjoint, or Hermitian, if $\tau^* = \tau$. If τ is Hermitian, then $(\tau V, V) = (V, \tau V) = (\tau V, V)$, and hence $(\tau V, V)$ is real for all V . A Hermitian operator τ is positive if $(\tau V, V) > 0$ when $V \neq 0$. If τ is a linear operator in an inner product space with inner product $(V, W)_1$, then the function $(V, W)_2 = (\tau V, W)_1$ is an inner product in \mathfrak{U} if, and only if, τ is positive Hermitian. An operator is positive Hermitian if, and only if, its matrix, relative to an orthonormal basis, is positive Hermitian. A Hermitian operator on an n -dimensional inner product space \mathfrak{U} has n real eigenvalues and n mutually orthogonal eigenvectors. Thus, if τ is Hermitian, it is diagonalizable, and \mathfrak{U} is the direct sum of mutually orthogonal one-dimensional subspaces invariant under τ . Applied to the operator τ in $\mathfrak{U}_n(\mathbb{C})$, defined by $\tau X = HX$ in which H is a Hermitian matrix, this implies that H has n mutually orthogonal unit eigenvectors in $\mathfrak{U}_n(\mathbb{C})$ and, hence, that there exists a unitary matrix U such that $U^{-1}HU = U^*HU$ is a real diagonal matrix whose diagonal elements are the eigenvalues of H . Similarly, in the real case, if A is a real symmetric matrix, there exists a real orthogonal matrix P such that $P^{-1}AP$ is diagonal, and A has n mutually orthogonal eigenvectors in $\mathfrak{U}_n(\mathbb{R})$. Using this diagonalization procedure, any Hermitian form XHX^* can be reduced by a unitary transformation $X^T = UY^T$ to a canonical form (see 127) in which the coefficients c_i are the eigenvalues of H . It follows that H is positive if, and only if, all its eigenvalues are positive, and the same is true of a positive Hermitian operator.

A unitary operator is a linear operator τ on \mathfrak{U} that preserves lengths, that is, such that for every vector V in \mathfrak{U} , $\|\tau V\| = \|V\|$. A necessary and sufficient condition that τ preserves lengths is that for any two vectors V, W in \mathfrak{U} , $(\tau V, \tau W) = (V, W)$. Hence, unitary operators preserve orthogonality as well as lengths. Since $(\tau V, \tau W) = (V, \tau^* \tau W)$ it follows that τ is unitary if, and only if, $\tau^* \tau = I$. Thus a unitary operator τ is invertible, with inverse $\tau^{-1} = \tau^*$, and τ^{-1} is also unitary. If σ and τ are unitary, the same is true also of $\sigma\tau$. Thus, the unitary operators on \mathfrak{U} form a group called the unitary group. An operator τ is unitary if, and only if, its matrix A_τ relative to an orthonormal basis, is unitary. The unitary matrices over \mathbb{C} also form a group under matrix multiplication, and the mapping of τ on A_τ is an isomorphism of the group of unitary operators onto the group of unitary matrices. A unitary operator on a real vector space is called an orthogonal operator. Its matrix relative to an orthonormal basis is orthogonal, and the mapping of τ on A_τ is an isomorphism of the (real) orthogonal group of orthogonal operators onto the group of real orthogonal matrices. Every nonsingular linear operator τ on \mathfrak{U} has a unique polar factorization, $\tau = \rho\sigma$, into the product of a positive Hermitian operator ρ and a unitary operator σ . If τ is singular, it can still be factored in this way, but the Hermitian factor ρ is merely nonnegative (that is, has nonnegative eigenvalues) and the unitary factor σ is not uniquely determined.

An operator τ on \mathfrak{U} is normal if $\tau\tau^* = \tau^*\tau$. Hermitian, unitary, and real orthogonal operators are all normal. In general, an operator is normal if and only if it has n mutually orthogonal eigenvectors with $n = \dim \mathfrak{U}$. Thus, a normal operator is diagonalizable; its matrix, relative to the orthonormal basis of \mathfrak{U} , consisting of n mutually orthogonal unit eigenvectors of τ , is a diagonal matrix with the eigenvalues of τ as diagonal elements. An $n \times n$ matrix A over \mathbb{C} is normal if $AA^* = A^*A$, and an operator is normal if and only if its matrix relative to an orthonormal basis is normal. Just as in the Hermitian case, if A is normal, then there exists a unitary matrix U such that $U^{-1}AU$ is a diagonal matrix. Conversely, every matrix that is unitarily similar to a diagonal matrix, is normal.

If \mathfrak{U} is finite-dimensional, and if \mathfrak{S} is any subspace of \mathfrak{U} , then the set \mathfrak{S}^\perp of all vectors of \mathfrak{U} such that $(T, S) = 0$ for all S in \mathfrak{S} is a subspace of \mathfrak{U} called the orthogonal complement of \mathfrak{S} . For any subspace \mathfrak{S} of \mathfrak{U} , $(\mathfrak{S}^\perp)^\perp = \mathfrak{S}$, and $V = \mathfrak{S} \oplus \mathfrak{S}^\perp$. Thus every vector V has a unique representation $V = S + T$, in which S is in \mathfrak{S} , and T is in \mathfrak{S}^\perp . The

mapping π from \mathfrak{U} onto \mathfrak{S} defined by $\pi V = S$ is a linear operator called the orthogonal projection of \mathfrak{U} on \mathfrak{S} . Since $\pi V = 0$ if and only if V is in \mathfrak{S}^\perp , the nullspace of π is \mathfrak{S}^\perp .

If τ is a normal operator on an n -dimensional inner product space \mathfrak{U} , c_1, \dots, c_r are the distinct eigenvalues of τ , and π_i is the orthogonal projection of \mathfrak{U} onto the nullspace of $\tau - c_i I$, then a basic result (see 128) expresses τ as a linear combination of the orthogonal projection π . The result is called the spectral theorem for normal operators.

$$(128) \quad \begin{cases} \tau = c_1 \pi_1 + c_2 \pi_2 + \dots + c_r \pi_r, & \pi_i \pi_j = 0 \text{ if } i \neq j \\ \text{and } \pi_1 + \pi_2 + \dots + \pi_r = I \end{cases}$$

$$(129) \quad \begin{cases} \tau(V_1, \dots, V_i + V'_i, \dots, V_r) \\ = \tau(V_1, \dots, V_i, \dots, V_r) + \tau(V_1, \dots, V'_i, \dots, V_r) \\ \tau(V_1, \dots, cV_i, \dots, V_r) = c\tau(V_1, \dots, V_i, \dots, V_r). \end{cases}$$

$$(130) \quad \begin{cases} (x_1 V_1 + x_2 V'_1, V_2) - x_1 (V_1, V_2) - x_2 (V'_1, V_2) \\ \text{or } (V_1, y_1 V_2 + y_2 V'_2) - y_1 (V_1, V_2) - y_2 (V_1, V'_2). \end{cases}$$

$$(131) \quad \begin{cases} V_1 \otimes (V_2 + V'_2) = V_1 \otimes V_2 + V_1 \otimes V'_2 \\ (V_1 + V'_1) \otimes V_2 = V_1 \otimes V_2 + V'_1 \otimes V_2 \\ (cV_1) \otimes V_2 = V_1 \otimes (cV_2) = c(V_1 \otimes V_2) \end{cases}$$

$$(132) \quad \begin{array}{c} \mathfrak{U}_1 \times \mathfrak{U}_2 \xrightarrow{\tau} \mathfrak{M} \\ \searrow \sigma \quad \swarrow \phi \\ \mathfrak{S} \end{array}$$

MULTILINEAR ALGEBRA

The tensor product of vector spaces. If $\mathfrak{U}_1, \mathfrak{U}_2, \dots, \mathfrak{U}_r$ are vector spaces over a field \mathfrak{F} then, the set of all r -tuples (V_1, V_2, \dots, V_r) in which V_i belongs to \mathfrak{U}_i , is called the Cartesian product of $\mathfrak{U}_1, \dots, \mathfrak{U}_r$ and is denoted by $\mathfrak{U}_1 \times \mathfrak{U}_2 \times \dots \times \mathfrak{U}_r$. The Cartesian product of r copies of a vector space \mathfrak{U} is called the r th Cartesian power of \mathfrak{U} and is denoted by $\times^r \mathfrak{U}$. If \mathfrak{W} is also a vector space over \mathfrak{F} , a mapping τ from $\mathfrak{U}_1 \times \mathfrak{U}_2 \times \dots \times \mathfrak{U}_r$ into \mathfrak{W} is multilinear if for each value of i from 1 to r linearity holds (see 129) for the i th variable. A multilinear mapping from $\times^r \mathfrak{U}$ to \mathfrak{W} is called an r -linear mapping. If \mathfrak{W} is the scalar field \mathfrak{F} considered as a vector space, then an r -linear mapping τ from $\times^r \mathfrak{U}$ into \mathfrak{F} is called an r -linear functional on \mathfrak{U} .

If $\mathfrak{U}_1, \mathfrak{U}_2$ are vector spaces over \mathfrak{F} , and if \mathfrak{M} is the free vector space over \mathfrak{F} on the basis set $\mathfrak{U}_1 \times \mathfrak{U}_2$, then one may let \mathfrak{N} be the subspace of \mathfrak{M} spanned by the set of all elements having one of the two forms (130). The factor space $\mathfrak{M}/\mathfrak{N}$ consists of elements $Z + \mathfrak{N}$, Z in \mathfrak{M} , and is a vector space over \mathfrak{F} when addition and scalar multiplication are defined by $(Z_1 + \mathfrak{N}) + (Z_2 + \mathfrak{N}) = (Z_1 + Z_2) + \mathfrak{N}$ and $c(Z + \mathfrak{N}) = cZ + \mathfrak{N}$, respectively. The mapping π from \mathfrak{M} onto $\mathfrak{M}/\mathfrak{N}$ defined by $\pi Z = Z + \mathfrak{N}$ is a homomorphism called the canonical projection of \mathfrak{M} onto $\mathfrak{M}/\mathfrak{N}$. The space $\mathfrak{M}/\mathfrak{N}$ is called the tensor product of \mathfrak{U}_1 and \mathfrak{U}_2 and is denoted by $\mathfrak{U}_1 \otimes \mathfrak{U}_2$. If π is the canonical projection, $\pi(V_1, V_2)$ is written $V_1 \otimes V_2$ (read V_1 tensor V_2). The elements $V_1 \otimes V_2$, with V_1 in \mathfrak{U}_1 , and V_2 in \mathfrak{U}_2 , span $\mathfrak{U}_1 \otimes \mathfrak{U}_2$, and the operation \otimes satisfies three basic relations (see 131). Thus the mapping τ , defined by $\tau(V_1, V_2) = V_1 \otimes V_2$, is bilinear.

The tensor product $\mathfrak{U}_1 \otimes \mathfrak{U}_2$, together with the bilinear mapping τ from $\mathfrak{U}_1 \times \mathfrak{U}_2$ into $\mathfrak{U}_1 \otimes \mathfrak{U}_2$, has the following "universal property." If σ is any bilinear mapping of $\mathfrak{U}_1 \times \mathfrak{U}_2$ into an arbitrary vector space \mathfrak{S} over \mathfrak{F} , then there exists a unique linear transformation ϕ from $\mathfrak{U}_1 \otimes \mathfrak{U}_2$ into \mathfrak{S} , such that $\phi\tau = \sigma$. Most modern writers use this universal property to define the tensor product. From this point of view, and if $\mathfrak{U}, \mathfrak{U}_1$ and \mathfrak{U}_2 are vector

Orthogonal
operators

The tensor
product

spaces over \mathfrak{F} , and if τ is a bilinear mapping from $\mathfrak{U}_1 \times \mathfrak{U}_2$ into \mathfrak{A} , then the pair (\mathfrak{A}, τ) is a tensor product of the vector spaces $\mathfrak{U}_1, \mathfrak{U}_2$, if for every bilinear mapping σ from $\mathfrak{U}_1 \times \mathfrak{U}_2$ into \mathfrak{A} , there exists a unique linear transformation φ from \mathfrak{A} into an arbitrary vector space \mathfrak{Z} over \mathfrak{F} , such that $\varphi\tau = \sigma$ (see 132).

The existence of a tensor product, so defined, is proved by showing that $(\mathfrak{M}/\mathfrak{N}, \pi)$ has the required universal property. Moreover, the tensor product (\mathfrak{A}, τ) is unique in the sense that if (\mathfrak{A}', τ') is a second tensor product, then there exists an isomorphism α from \mathfrak{A} onto \mathfrak{A}' such that $\alpha\tau = \tau'$. Again, $\tau(V_1, V_2)$ is written $V_1 \otimes V_2$ and (\mathfrak{A}, τ) is written $\mathfrak{U}_1 \otimes \mathfrak{U}_2$. The tensor product $\mathfrak{U}_1 \otimes \mathfrak{U}_2$ is spanned by the elements $V_1 \otimes V_2$, with V_1 in \mathfrak{U}_1 , and V_2 in \mathfrak{U}_2 ; and $V_1 \otimes V_2 = 0$ if and only if $V_1 = 0$ or $V_2 = 0$. If $\mathfrak{U}_1 = \mathfrak{E}_1 \oplus \mathfrak{E}_2 \oplus \cdots \oplus \mathfrak{E}_n$ and $\mathfrak{U}_2 = \mathfrak{U}_1 \oplus \mathfrak{U}_2 \oplus \cdots \oplus \mathfrak{U}_m$, then $\mathfrak{U}_1 \otimes \mathfrak{U}_2$ is the direct sum of the nm spaces $\mathfrak{E}_i \otimes \mathfrak{U}_j$. If (E) and (F) are bases of \mathfrak{U}_1 and \mathfrak{U}_2 , then the elements $(E_i \otimes F_j)$ form a basis of $\mathfrak{U}_1 \otimes \mathfrak{U}_2$. Thus $\dim(\mathfrak{U}_1 \otimes \mathfrak{U}_2) = (\dim \mathfrak{U}_1)(\dim \mathfrak{U}_2)$ if \mathfrak{U}_1 and \mathfrak{U}_2 are finite-dimensional. If τ and σ are linear transformations from the vector spaces \mathfrak{U}_1 and \mathfrak{W}_1 to vector spaces $\mathfrak{U}_2, \mathfrak{W}_2$, respectively, then the linear transformation ρ , defined by $\rho(V_1 \otimes W_1) = \tau V_1 \otimes \sigma W_1$, is called the tensor product of τ and σ and is denoted by $\tau \otimes \sigma$. If τ' and σ' are also linear transformations defined on the vector spaces \mathfrak{U}_2 and \mathfrak{W}_2 , the rule for composition is $(\tau' \otimes \sigma')(\tau \otimes \sigma) = \tau' \tau \otimes \sigma' \sigma$, and $1 \otimes 1$ is the identity on $\mathfrak{U}_1 \otimes \mathfrak{W}_1$. The image of the tensor product of two linear transformations is the tensor product of the images. The kernel (nullspace) of a tensor product of linear transformation is given by $\ker(\tau \otimes \sigma) = \ker \tau \otimes \mathfrak{W}_1 + \mathfrak{U}_1 \otimes \ker \sigma$. For a fixed space \mathfrak{W} a linear transformation σ from \mathfrak{U}_1 into \mathfrak{U}_2 induces a linear transformation σ^* from $\mathfrak{U}_1 \otimes \mathfrak{W}$ into $\mathfrak{U}_2 \otimes \mathfrak{W}$ defined by $\sigma^* = \sigma \otimes 1$; for fixed \mathfrak{W} the mappings $f(\mathfrak{U}) = \mathfrak{U} \otimes \mathfrak{W}$, $f(\sigma) = \sigma^*$ define a covariant functor from the category of vector spaces over \mathfrak{F} to itself. Similarly for a fixed space \mathfrak{U} , the mappings $\mathfrak{W} \rightarrow \mathfrak{U} \otimes \mathfrak{W}$ and $\tau \rightarrow 1 \otimes \tau$ define a covariant functor.

The tensor product of r vector spaces $\mathfrak{U}_1, \mathfrak{U}_2, \dots, \mathfrak{U}_r$ over \mathfrak{F} is defined similarly. If τ is a multilinear mapping

of the set $\mathfrak{U}_1 \times \mathfrak{U}_2 \times \cdots \times \mathfrak{U}_r$ into a vector space \mathfrak{A} , then the pair (\mathfrak{A}, τ) is a tensor product of $\mathfrak{U}_1, \dots, \mathfrak{U}_r$ if, for every multilinear mapping σ from $\mathfrak{U}_1 \times \mathfrak{U}_2 \times \cdots \times \mathfrak{U}_r$ into an arbitrary vector space \mathfrak{Z} over \mathfrak{F} , there exists a unique linear transformation φ of \mathfrak{A} into \mathfrak{Z} such that $\varphi\tau = \sigma$. As before $\tau(V_1, V_2, \dots, V_r)$ is written as $V_1 \otimes V_2 \otimes \cdots \otimes V_r$ and (\mathfrak{A}, τ) is denoted by $\mathfrak{U}_1 \otimes \mathfrak{U}_2 \otimes \cdots \otimes \mathfrak{U}_r$. Existence and uniqueness of \mathfrak{A} follow as in the case $r=2$. There is an isomorphism β of $\mathfrak{U}_1 \otimes \mathfrak{U}_2 \otimes \mathfrak{U}_3$ onto $(\mathfrak{U}_1 \otimes \mathfrak{U}_2) \otimes \mathfrak{U}_3$, such that $\beta(V_1 \otimes V_2 \otimes V_3) = (V_1 \otimes V_2) \otimes V_3$ and similarly for $\mathfrak{U}_1 \otimes (\mathfrak{U}_2 \otimes \mathfrak{U}_3)$. This associativity principle extends to the tensor product of any finite number of vector spaces over \mathfrak{F} (see 133).

The tensor algebra of a vector space. If \mathfrak{U} is a vector space over \mathfrak{F} , then the tensor product $\mathfrak{U} \otimes \mathfrak{U} \otimes \cdots \otimes \mathfrak{U}$ of r copies of \mathfrak{U} is called the r th tensorial power of \mathfrak{U} and is denoted by $\otimes^r \mathfrak{U}$ or by \mathfrak{A}_r . Its elements are called tensors of order r . If E_1, \dots, E_n is a basis of \mathfrak{U} , then $(E_{i_1} \otimes E_{i_2} \otimes \cdots \otimes E_{i_r})$ is a basis for $\otimes^r \mathfrak{U}$ and every tensor T of order r can be written in summation form (see 134). The n^r scalars $x_{i_1 \dots i_r}$ that appear in this form are called the components of T relative to the E -basis of \mathfrak{U} .

As a notational convenience, \mathfrak{A}_1 is identified with \mathfrak{U} and \mathfrak{A}_0 with the scalar field \mathfrak{F} . The direct sum $\mathfrak{A}(\mathfrak{U}) = \bigoplus_{r=0}^{\infty} \mathfrak{A}_r$

is a vector space over \mathfrak{F} and each tensorial power \mathfrak{A}_r can be considered a subspace of $\mathfrak{A}(\mathfrak{U})$. Multiplication can be defined formally for the generating elements of $\mathfrak{A}(\mathfrak{U})$ (see 135) and can be extended linearly to arbitrary elements. With this definition of multiplication $\mathfrak{A}(\mathfrak{U})$ becomes an associative algebra over \mathfrak{F} , with unity element 1 , and is called the tensor algebra of the vector space \mathfrak{U} .

The tensor algebra has the following universal mapping property: If τ is the canonical injection of \mathfrak{U} into $\mathfrak{A}(\mathfrak{U})$, and if σ is a linear transformation of \mathfrak{U} into an arbitrary associative algebra \mathfrak{A} over \mathfrak{F} with unity, then there exists a unique algebra homomorphism φ of $\mathfrak{A}(\mathfrak{U})$ into \mathfrak{A} such that $\varphi\tau = \sigma$. This property can be used as the definition of $\mathfrak{A}(\mathfrak{U})$, in which case existence is implied by the construction already given, and uniqueness follows in the same sense as the uniqueness of the tensor product. The universal property of $\mathfrak{A}(\mathfrak{U})$ also implies that every linear transformation σ of \mathfrak{U} into a second vector space \mathfrak{W} over \mathfrak{F} induces a unique algebra homomorphism $T(\sigma)$ of $\mathfrak{A}(\mathfrak{U})$ into $\mathfrak{A}(\mathfrak{W})$ such that $T(\sigma)1 = 1$. Moreover, $T(I) = I$ and if ρ from \mathfrak{W} into \mathfrak{Z} is a second linear transformation $T(\rho\sigma) = T(\rho)T(\sigma)$. Thus the mappings $\mathfrak{U} \rightarrow \mathfrak{A}(\mathfrak{U})$ and $\sigma \rightarrow T(\sigma)$ define a covariant functor, from the category of vector spaces over \mathfrak{F} to the category of associative algebras with unit over \mathfrak{F} .

If \mathfrak{U}^* is the dual space of \mathfrak{U} , the tensor product $\mathfrak{U} \otimes \cdots \otimes \mathfrak{U}^* \otimes \cdots \otimes \mathfrak{U}^*$ of r copies of \mathfrak{U} and s copies of \mathfrak{U}^* is denoted by $\otimes_s^r \mathfrak{U}$. If $s=0$, $\otimes_0^r \mathfrak{U}$ is identified with $\otimes^r \mathfrak{U}$ and its elements are called contravariant tensors of order r . If $r=0$, then $\otimes_0^s \mathfrak{U} = \otimes^s \mathfrak{U}^*$ and its elements are called covariant tensors of order s . Elements of $\otimes_s^r \mathfrak{U}$ are called mixed tensors of contravariant order r and covariant order s . Finally, $\otimes_0^0 \mathfrak{U}$ is identified with $\mathfrak{U} \otimes_1^0 \mathfrak{U}$ with \mathfrak{U}^* and $\otimes_0^0 \mathfrak{U}$ with the scalar field \mathfrak{F} . If E_1, E_2, \dots, E_n is a basis of \mathfrak{U} and E^1, E^2, \dots, E^n is the dual basis of \mathfrak{U}^* , then $n^{(r+s)}$ elements (136) form a basis for $\otimes_s^r \mathfrak{U}$. Every tensor T of $\otimes_s^r \mathfrak{U}$ can be written

in terms of these (see 137). The $n^{(r+s)}$ scalars $x_{j_1 \dots j_r}^{i_1 \dots i_s}$

are called the components of T relative to the E -basis of \mathfrak{U} . By a process analogous to the construction of the tensor algebra $\mathfrak{A}(\mathfrak{U})$, the mixed tensors of all orders can be embedded in a mixed tensor algebra $\mathfrak{A}(\mathfrak{U}, \mathfrak{U}^*)$.

If \mathfrak{U} is an inner product space with inner product (\cdot, \cdot) , then an inner product on $\otimes \mathfrak{U}$ can be defined (see 138), and $\otimes \mathfrak{U}$ is then an inner product space. If (E) is an orthonormal basis for \mathfrak{U} , then $(E_{i_1} \otimes E_{i_2} \otimes \cdots \otimes E_{i_m})$ is an orthonormal basis for $\otimes^m \mathfrak{U}$. Now, if $T = \sum T_r$, $U = \sum U_r$, T_r, U_r in $\otimes^r \mathfrak{U}$ are any two elements of the tensor algebra $\mathfrak{A}(\mathfrak{U})$, then an inner product (T, U) in $\mathfrak{A}(\mathfrak{U})$ (as a vector space) can also be defined (see 139).

tensors

$$(133) \quad \begin{cases} \beta: (\mathfrak{U}_1 \otimes \cdots \otimes \mathfrak{U}_r) \otimes (\mathfrak{U}_{r+1} \otimes \cdots \otimes \mathfrak{U}_{r+s}) \\ \rightarrow \mathfrak{U}_1 \otimes \cdots \otimes \mathfrak{U}_{r+s} \\ \beta[(\mathfrak{U}_1 \otimes \cdots \otimes \mathfrak{U}_r) \otimes (\mathfrak{U}_{r+1} \otimes \cdots \otimes \mathfrak{U}_{r+s})] \\ = \mathfrak{U}_1 \otimes \cdots \otimes \mathfrak{U}_{r+s} \end{cases}$$

$$(134) \quad T = \sum_{(i)} x_{i_1 \dots i_r} E_{i_1} \otimes \cdots \otimes E_{i_r}$$

$$(135) \quad \begin{cases} 1(V_1 \otimes V_2 \otimes \cdots \otimes V_n) = (V_1 \otimes V_2 \otimes \cdots \otimes V_n)1 \\ = V_1 \otimes V_2 \otimes \cdots \otimes V_n \\ (V_1 \otimes V_2 \otimes \cdots \otimes V_n)(V'_1 \otimes V'_2 \otimes \cdots \otimes V'_m) \\ = V_1 \otimes V_2 \otimes \cdots \otimes V_n \otimes V'_1 \otimes \cdots \otimes V'_m \end{cases}$$

$$(136) \quad \begin{cases} E_{i_1 i_2 \dots i_n}^{j_1 j_2 \dots j_n} = E_{i_1} \otimes E_{i_2} \otimes \cdots \otimes E_{i_n} \otimes \\ \otimes E^{j_1} \otimes E^{j_2} \otimes \cdots \otimes E^{j_n} \end{cases}$$

$$(137) \quad \begin{cases} T = \sum x_{j_1 j_2 \dots j_r}^{i_1 i_2 \dots i_s} E_{i_1 i_2 \dots i_r}^{j_1 j_2 \dots j_s} \\ \text{the summation extending over each } i \text{ and each } j \end{cases}$$

$$(138) \quad (V_1 \otimes V_2 \otimes \cdots \otimes V_r, W_1 \otimes W_2 \otimes \cdots \otimes W_r) \\ = (V_1, W_1)(W_2, W_2) \cdots (V_r, W_r)$$

$$(139) \quad (T, U) = \sum (T_r, U_r)$$

$$(140) \quad G^* = \sum (X_i, X_j) X^i \otimes X^j \\ \text{and } G = \sum (X^i, X^j) X_i \otimes X_j$$

The tensor $G = \sum_{i=1}^n E_i \otimes E_i$ is independent of the choice

of the orthonormal basis (E) and is called the contravariant metric tensor of the Euclidean space \mathcal{U} ; the covariant metric tensor G^* is defined similarly in terms of the dual basis (E^*) of \mathcal{U}^* . In general if X_1, \dots, X_n and X^1, \dots, X^n are arbitrary dual bases of \mathcal{U} and \mathcal{U}^* , respectively, then G^* and G can be expressed in terms of these bases (see 140).

The exterior algebra of a vector space. For the following discussion, three definitions are needed. (1) \mathcal{U} is a vector space over \mathcal{F} ; (2) $\mathcal{A}_r(\mathcal{U}) = \otimes^r \mathcal{U}$ is the r th tensorial power of \mathcal{U} ; (3) $\mathcal{A}_r(\mathcal{U})$, $r \geq 2$, is the subspace of $\mathcal{A}_r(\mathcal{U})$ spanned by the elements $V_1 \times V_2 \times \dots \times V_r$ in which $V_i = V_j$ for at least one pair of indices i, j with $i \neq j$. With these definitions, the factor space $\mathcal{A}_r(\mathcal{U})/\mathcal{N}_r(\mathcal{U})$ is called the r th exterior power of \mathcal{U} and is denoted by $\mathcal{U} \wedge \mathcal{U} \wedge \dots \wedge \mathcal{U}$ or $\wedge^r \mathcal{U}$, and the element $V_1 \otimes \dots \otimes V_r + \mathcal{N}_r(\mathcal{U})$ is denoted by $V_1 \wedge V_2 \wedge \dots \wedge V_r$.

The r th exterior power of vector space

The r th exterior power can also be defined, like the r th tensorial power, by a universal mapping property. If \mathcal{B} is a second vector space over \mathcal{F} , then a multilinear mapping τ from $\mathcal{U} \times \mathcal{U} \times \dots \times \mathcal{U}$ into \mathcal{B} is said to be skew symmetric if, for every permutation σ of the subscripts, $\tau(V_1, V_2, \dots, V_r) = \varepsilon(\sigma)\tau(V_{\sigma(1)}, V_{\sigma(2)}, \dots, V_{\sigma(r)})$, in which $\varepsilon(\sigma) = 1$ if σ is an even permutation, and $\varepsilon(\sigma) = -1$ if σ is an odd permutation. A necessary and sufficient condition that τ be skew symmetric is that $\tau(V_1, V_2, \dots, V_r) = 0$ whenever $V_i = V_j$ for at least one pair of indices i, j with $i \neq j$. A vector space \mathcal{B} , over \mathcal{F} , together with a skew symmetric mapping τ from \mathcal{U} into \mathcal{B} , is called an r th exterior power of \mathcal{U} if for every skew symmetric multilinear mapping ρ , from \mathcal{U} into an arbitrary vector space \mathcal{Z} over \mathcal{F} , there exists a unique linear transformation ϕ from \mathcal{B} into \mathcal{Z} , such that $\phi\tau = \rho$; that is, the relevant diagram (see 141) is commutative. If $\tau(V_1, V_2, \dots, V_r)$ is written as $V_1 \wedge V_2 \wedge \dots \wedge V_r$, the definition implies that \mathcal{B} is spanned by the elements of the form $V_1 \wedge V_2 \wedge \dots \wedge V_r$, and is unique in the sense that, if (\mathcal{B}, τ) and (\mathcal{B}', τ') are two r th exterior powers, then there is an isomorphism α of \mathcal{B} to \mathcal{B}' , such that $\alpha\tau = \tau'$. The existence of \mathcal{B} is proved by showing that $\mathcal{B} = \mathcal{A}_r(\mathcal{U})/\mathcal{N}_r(\mathcal{U})$ has the universal property illustrated in the diagram.

The exterior algebra $\mathcal{B}(\mathcal{U})$ of the vector space is constructed from the r th exterior powers by a process analogous to that by which the tensor algebra is constructed

from the r th tensorial powers. Defining $\mathcal{B}_1(\mathcal{U})$ to be \mathcal{U} , $\mathcal{B}_0(\mathcal{U})$ to be \mathcal{F} , the direct sum (see 142) of the $\mathcal{B}_r(\mathcal{U})$ can be formed. Each of the spaces $\mathcal{B}_r(\mathcal{U})$ is considered as a subspace of $\mathcal{B}(\mathcal{U})$. A unique associative multiplication can be defined in $\mathcal{B}(\mathcal{U})$ such equations (143) hold. Thus $\mathcal{B}(\mathcal{U})$ becomes a linear associative algebra with unity element. It is called the exterior algebra of \mathcal{U} . The product of any two elements X, Y of $\mathcal{B}(\mathcal{U})$ can be written $X \wedge Y$ without conflict with the previous use of the symbol \wedge .

If $\mathcal{N}(\mathcal{U})$ is the direct sum $\bigoplus_{r=2}^{\infty} \mathcal{N}_r(\mathcal{U})$, then $\mathcal{N}(\mathcal{U})$ is an

ideal in the tensor algebra $\otimes \mathcal{U}$ and $\mathcal{B}(\mathcal{U})$ is isomorphic, as an algebra, to $\otimes \mathcal{U}/\mathcal{N}(\mathcal{U})$. Any elements X in $\wedge^r \mathcal{U}$ and Y in $\wedge^s \mathcal{U}$ satisfy the commutation rule $X \wedge Y = (-1)^{rs} Y \wedge X$. In particular, for any vector V in \mathcal{U} , $V \wedge V = 0$ or, more precisely, if τ is the canonical projection of \mathcal{U} into $\mathcal{B}(\mathcal{U})$, then $\tau V = 0$. This property can be used to formulate a universal mapping definition of the exterior algebra: \mathcal{U} is taken to be a vector space over \mathcal{F} . An associative algebra \mathcal{B} over \mathcal{F} , with unity element, together with a linear transformation τ , from \mathcal{U} into \mathcal{B} , will be called an exterior algebra over \mathcal{U} if (1) for all V in \mathcal{U} , $(\tau V)^2 = 0$; and (2) for every associative algebra \mathcal{A} over \mathcal{F} , with unity, and for every linear transformation σ from \mathcal{U} into \mathcal{A} such that $(\sigma V)^2 = 0$ for all V in \mathcal{U} , there exists a unique algebra homomorphism ϕ from \mathcal{B} into \mathcal{A} such that $\phi\tau = \sigma$. It then follows that $\mathcal{B}(\mathcal{U})$, as previously defined, has this universal property and that if (\mathcal{B}, τ) and (\mathcal{B}', τ') are two exterior algebras over \mathcal{U} , then there is an isomorphism α from \mathcal{B} to \mathcal{B}' such that $\alpha\tau = \tau'$.

The universal property for $\mathcal{B}(\mathcal{U})$ implies, as in the case of the tensor algebra, that a linear transformation σ from \mathcal{U} into \mathcal{B} induces a unique algebra homomorphism $\mathcal{B}(\sigma)$ from $\mathcal{B}(\mathcal{U})$ into $\mathcal{B}(\mathcal{B})$ such that the relevant diagram (see 144) is commutative, $\mathcal{B}(I) = I$, and $\mathcal{B}(\sigma\rho) = \mathcal{B}(\sigma)\mathcal{B}(\rho)$ and hence the mapping of \mathcal{U} on $\mathcal{B}(\mathcal{U})$ and σ on $\mathcal{B}(\sigma)$ is a functor on the category of vector spaces over \mathcal{F} to the category of associative algebras over \mathcal{F} .

If \mathcal{U} is finite-dimensional with basis (E), then a basis for the r th exterior power $\wedge^r \mathcal{U}$ is the set of exterior products $\{E_{i_1} \wedge \dots \wedge E_{i_r}\}$ in which $i_1 < i_2 < \dots < i_r$. Thus every vector U in $\wedge^r \mathcal{U}$ can be expressed in the form (145) in which scalars $x_{i_1} \dots x_{i_r}$ are called the components of U with respect to the E -basis of \mathcal{U} . If $\dim \mathcal{U} = n$, then $\dim \wedge^r \mathcal{U} = \binom{n}{r}$ if $r \leq n$. If $r > n$, then $\wedge^r \mathcal{U} = 0$, because in that case $\otimes^r \mathcal{U}$ is a subset of $\mathcal{N}_r(\mathcal{U})$. Thus, if $\mathcal{B} = \wedge \mathcal{U}$ is the exterior algebra of an n -dimensional space \mathcal{U} , $\dim \mathcal{B}$ is determined by (146). Finally, if \mathcal{U} is an inner product space with inner product $(,)$ then an inner product can be defined in \mathcal{B} (see 147). If (E) is an orthonormal basis of \mathcal{U} , then $\{E_{i_1} \wedge \dots \wedge E_{i_r}\}$, with $i_1 < i_2 < \dots < i_r$, is an orthonormal basis of \mathcal{B} . (Ed.)

The universal mapping definition of the exterior algebra

$$(141) \quad \begin{array}{ccc} \times^r \mathcal{U} & \xrightarrow{\tau} & \mathcal{B}_r \\ \downarrow \rho & \searrow \phi & \\ \mathcal{Z} & & \end{array}$$

$$(142) \quad \mathcal{B}(\mathcal{U}) = \bigoplus_{r=0}^{\infty} \mathcal{B}_r(\mathcal{U})$$

$$(143) \quad \begin{cases} 1 \cdot V_1 \wedge V_2 \wedge \dots \wedge V_r = V_1 \wedge V_2 \wedge \dots \wedge V_r \cdot 1 \\ = V_1 \wedge V_2 \wedge \dots \wedge V_r \\ V_1 \wedge V_2 \wedge \dots \wedge V_r \cdot V_{r+1} \wedge V_{r+2} \wedge \dots \wedge V_{r+s} \\ = V_1 \wedge V_2 \wedge \dots \wedge V_{r+s} \end{cases}$$

$$(144) \quad \begin{array}{ccc} \mathcal{U} & \xrightarrow{\tau} & \mathcal{B}(\mathcal{U}) \\ \sigma \downarrow & & \downarrow \mathcal{B}(\sigma) \\ \mathcal{A}' & \xrightarrow{\tau'} & \mathcal{B}(\mathcal{A}') \end{array}$$

$$(145) \quad U = \sum x_{i_1} \dots x_{i_r} E_{i_1} \wedge \dots \wedge E_{i_r}, \quad i_1 < i_2 < \dots < i_r$$

$$(146) \quad \dim \mathcal{B} = \sum_{r=0}^n \binom{n}{r} = 2^n$$

$$(147) \quad (V_1 \wedge V_2 \wedge \dots \wedge V_r, W_1 \wedge W_2 \wedge \dots \wedge W_r) = \det[(V_i, W_j)]$$

Lattice theory

Lattice theory is the branch of mathematics that deals in precise mathematical language with the relation of different parts of the same whole to each other. The fundamental concept is that one part x may include (or contain) another part y , a relation written symbolically as $x \geq y$. A lattice, defined in more detail below, is a set of elements related by an inclusion relation such that, for any x and y in the set, there is a largest element, denoted $x \wedge y$, that is contained in both x and y and a smallest element, denoted $x \vee y$, that contains both x and y .

In general, in lattice theory the concepts of order and structure are analyzed from a mathematical standpoint, much as group theory (described later) analyzes the concept of symmetry. Thus, lattice theory considers families of subsets X, Y, \dots of a given set U under the operation of intersection of sets, denoted $X \cap Y$, in much the same spirit that group theory considers families of symmetry transformations (symbolized by Greek letters alpha, beta, \dots) α, β, \dots of a given configuration when combined by performing them in succession (i.e., taking their composite $\alpha \circ \beta$). As a generalization of set theory, it forms a fundamental part of higher algebra, geometry, and mathematical logic.

DEFINITIONS AND EXAMPLES

The
reflexive
law

Partial orderings. In detail, given a selected family S of different parts of the same whole, these parts can be represented symbolically by letters x, y, \dots , $x \geq y$ signifying that x contains y . The resulting inclusion relation is characterized by the reflexive law, which states that $x \geq x$ for all x ; the transitive law, which states that if $x \geq y$ and $y \geq z$, then $x \geq z$; and the antisymmetric law, which states that if $x \geq y$ and $y \geq x$, then $x = y$. In general, any relation having the above properties is called a partial ordering; and a partially ordered set, usually called a poset for short, is just a set S together with a partial ordering of its elements.

The inclusion relation is basic for the study of the subsets of a set (class, or aggregate). The relation of implication in logic has the same formal properties. In logic, $p \supset q$ signifies that the proposition (or statement) p implies the proposition q ; that "if p , then q ." The reflexive law $p \supset p$ of logic states that any proposition p implies itself; the transitive law, that if p implies q and q implies r , then p implies r ; the antisymmetric law, that if p implies q and q implies p , then p and q are logically equivalent. Thus the propositions of any deductive system (e.g., lattice theory or group theory) form a poset when partially ordered by the implication relation.

Mathematics is concerned with many other familiar partial orderings, such as the relation $x \leq y$ of inequality between real numbers, and the relation $a \mid b$ of divisibility (a is said to divide b when $b = na$ for some integer n) between positive integers. That is, if \mathcal{R} denotes the set of all real numbers and inequality has its usual meaning, then $[\mathcal{R}, \leq]$ is a partially ordered set or poset. Likewise, if P denotes the set of all positive integers and $a \mid b$ means that $b = na$ for some positive integer n , then $[P, \mid]$ is a poset.

Universal bounds. In a poset P , the identical inequalities relating an element x with an element 0 , for all x , and relating an element x with an element I , for all x (see Box, inequalities 148), can be satisfied by at most one element

$$(1) \quad 0 \leq x \quad \text{for all } x, \quad x \leq I \quad \text{for all } x$$

0 and by at most one I , respectively. When they exist, 0 is called the null element and I the universal element of the poset, which is said to have universal bounds. In the poset of the subsets X, Y, \dots of a set U , for example, the empty set, represented by the symbol \emptyset , is the null element and U the universal element, because $\emptyset \subset X \subset U$ for any subset X of U . In the poset $[P, \mid]$, 1 is the null element because 1 is a divisor of every positive integer n (in symbols, $1 \mid n$ for all n in P). The poset $[P, \mid]$ has no universal element.

Formal definition. A formal definition of a lattice can now be given. It is in general any abstract system L of elements x, y, z, \dots having a reflexive, transitive, and antisymmetric relation that satisfies the following lattice condition. For any two elements x and y of L there is a least element including both x and y , denoted by $x \vee y$, and a greatest element included in both x and y , denoted by $x \wedge y$. More precisely, it is required that $x \leq x \vee y$, that $y \leq x \vee y$, and that $x \leq z$ and $y \leq z$ together imply $x \vee y \leq z$. Similarly, it is required that $x \wedge y \leq x$, that $x \wedge y \leq y$, and that $w \leq x$ and $w \leq y$ together imply $w \leq x \wedge y$. Such elements $x \vee y$ and $x \wedge y$ are called the least upper bound (l.u.b.) and greatest lower bound (g.l.b.) of x and y , respectively; when they exist, they are unique.

The preceding examples of posets satisfy this lattice condition. In the case of the subsets X, Y, \dots of an aggregate U , $X \vee Y$ is the set-union (or sum $X \cup Y$) of X and Y , and $X \wedge Y$ the set of elements common to X and Y (their intersection $X \cap Y$). In logic, $p \wedge q$ is the statement " p and q "; $p \vee q$ means " p or q " (or both p and q); with real numbers, $x \vee y$ is simply the greater and $x \wedge y$ the lesser of x and y . In the example of the positive integers, $m \vee n$ is the least common multiple of m and n and $m \wedge n$ is the greatest common divisor of m and n .

Examples of lattices. Lattices of various kinds arise in all sorts of mathematical situations. Some of these have very few elements and can be conveniently described by diagrams: any graph with sloping lines defines a poset, the elements of which are the nodes of the graph (the points at which two or more lines meet), and in which $a \geq b$ means that one can go from a to b along a sequence of line segments that slope downward. Figures 5A–5D describe

Posets

Figure 5: Diagrams of lattices and one non-lattice (see text).

lattices, of which Figure 5A represents the lattice of all subsets of a set of two elements and Figure 5B that of all subsets of a set of three elements. Figure 5C represents the lattice of all subgroups of the group G of all six symmetries of an equilateral triangle. The bottom element represents the (trivial) subgroup consisting of the group identity; the first three elements (nodes) above it the subgroups generated by the reflections in the three altitudes; the fourth the subgroup of rotations of the triangle into itself; and the top element G itself.

Figure 5D represents a poset that is not a lattice: the two elements immediately above the bottom element (the universal lower bound 0) do not have a least upper bound. All four posets of Figures 5A–5D have universal bounds: their bottom and top elements.

Figure 6 represents the partition lattice π_4 of all partitions

Figure 6: The partition lattice π_4 (see text).

of a set of four elements, in which by a partition of a set is meant a division of its elements into nonoverlapping subsets. In Figure 6, the square nodes represent the three partitions of the set $\{a, b, c, d\}$ into two subsets, each containing two elements, namely: $(ab)(cd)$, $(ac)(bd)$, and $(ad)(bc)$. The circles on the same level represent the four partitions $(123)(4)$, $(124)(3)$, $(134)(2)$, $(234)(1)$ into two subsets, one containing three elements and the other containing one element; and so on.

Algebraic definitions. Lattices can also be defined in terms of the algebraic properties of the two operations \wedge and \vee just defined, without reference to the concept of order. In a general poset P , the l.u.b. $x \vee y$ of two elements x and y (when it exists) is called the join of x and y , and the g.l.b. $x \wedge y$ (when it exists) is called their meet. The relatively colourless words "join" and "meet" are intended to suggest "union" and "intersection" but to refer only to the underlying order abstractly. In any lattice, the join and meet operations are commutative and associative, so that $x \vee y = y \vee x$, $x \wedge y = y \wedge x$, $x \vee (y \vee z) = (x \vee y) \vee z$, and also $x \wedge (y \wedge z) = (x \wedge y) \wedge z$ for all x, y, z . They are idempotent, which means that $x \vee x = x \wedge x = x$ for all x ; and they satisfy the law of contraction: $x \wedge (x \vee y) = x \vee (x \wedge y) = x$ for all x, y .

It is easy to verify the preceding laws in the examples described above; the essential fact is that they can also be deduced formally from the reflexive, transitive, and anti-

The law of
contraction

symmetric laws, considered as postulates used to define the abstract concept of a poset.

Conversely, a lattice can be defined as an algebraic system, or algebra, having two commutative, associative, idempotent, and contractive operations. This system can be designated symbolically as $[S, \wedge, \vee]$, in which S stands for the set consisting of all the elements of the lattice, and \wedge, \vee for its two operations. The inclusion relation may be defined in terms of either lattice operation, because $x \leq y$ is equivalent either to $x \wedge y = x$ or to $x \vee y = y$. In particular, 0 is characterized in any lattice by either of the laws $0 \wedge x = 0$ or $0 \vee x = x$, valid for all x ; while I is characterized by $x \wedge I = x$ or by $x \vee I = I$.

Thus, the lattice of Figure 5A is defined by means of the tables for combining elements with the operations \wedge and \vee (see 149). From either of these tables, it can be deduced

(149)	\wedge	0	a	b	I	\vee	0	a	b	I
	0	0	0	0	0	0	0	a	b	I
	a	0	a	0	a	a	a	a	I	I
	b	0	0	b	b	b	b	I	b	I
	I	0	a	b	I	I	I	I	I	I

that $0 < a, b < I$, and that these are the only proper inclusion relations.

More generally, $L = [S, \wedge, \vee]$ is assumed to be any algebraic system having two operations \vee, \wedge that are idempotent, commutative, associative, and satisfy the contraction laws. $x \leq y$ is defined in L to mean that $x \vee y = y$ (or equivalently, that $x \wedge y = x$). Then the relational system $[S, \leq]$ defined thereby is a lattice in the sense of the definition above, in which $x \wedge y$ is the meet (g.l.b.) and $x \vee y$ the join (l.u.b.) of x and y . Hence the idempotent, commutative, associative, and contraction laws can also be used as postulates with which to define the concept of a lattice.

Other examples. There are many kinds of lattices. Thus, a wide class of lattices arises from the study of groups. The subgroups of any group G form a lattice, in which G itself and the identity element 1 act as universal bounds. Figure 7E shows the lattice of all subgroups of the octic group of symmetries of a square. A few other small

Figure 7: Lattices with special properties (see text).

lattices are depicted in Figures 7A–7D. Thus Figure 7A depicts a chain; i.e., a poset in which for all x, y , either $x \leq y$ or $y \leq x$. Figure 7C depicts the smallest lattice in which not all chains from 0 to I have the same length.

Duality. The concepts of a poset and of a lattice have important duality properties. If $y \leq x$ is defined to mean that $x \geq y$ (by conversion), it is evident that the relation \leq is reflexive, transitive, and antisymmetric if and only if \geq is. Furthermore, if \geq is replaced by \leq , \vee and \wedge are simply interchanged in the statement of the lattice condition without affecting the set of postulates as a whole. In other words, the concepts of a poset and of a lattice are self-dual under the duality between greater and less (container and the contained).

In the particular lattice $[P, |]$, for instance, the dualization effected by the preceding construction changes greatest common divisors (g.c.d.) into least common multiples (l.c.m.), and vice versa. More generally, it turns the diagram of any finite lattice upside-down.

Isotonicity. Lattices have many general properties. Thus, any lattice with a finite number of elements x_1, \dots, x_n has the universal bounds $x_1 \wedge \dots \wedge x_n = 0$ and $x_1 \vee \dots \vee x_n = I$. More im-

portant is the following isotonicity principle, valid in any lattice. This principle is: If for any elements u, u^*, v , and v^* , in a lattice L , $u \geq u^*$ and $v \geq v^*$, then $u \vee v \leq u^* \vee v^*$ and $u \wedge v \geq u^* \wedge v^*$; the lattice operations preserve order.

Power set lattices. The power set lattice $[P(U), \subseteq]$, defined by the inclusion relation on the power set $P(U)$ of all subsets of a set U , has important special properties not shared by lattices in general. One of these is distributivity (see 150) that holds for any three subsets X, Y, Z of U . In

$$(150) \quad \begin{aligned} X \cap (Y \cup Z) &= (X \cap Y) \cup (X \cap Z) \\ X \cup (Y \cap Z) &= (X \cup Y) \cap (X \cup Z) \end{aligned}$$

$$(151) \quad \begin{cases} x \wedge (y \vee z) = (x \wedge y) \vee (x \wedge z) \\ x \vee (y \wedge z) = (x \vee y) \wedge (x \vee z) \end{cases}$$

$$(152) \quad x \wedge x' = 0, \quad x \vee x' = I$$

$$(153) \quad (x \wedge y)' = x' \vee y', \quad (x \vee y)' = x' \wedge y'$$

$$(154) \quad \begin{aligned} (x \wedge y) \vee (y \wedge z) \vee (z \wedge x) \\ = (x \vee y) \wedge (y \vee z) \wedge (z \vee x) \end{aligned}$$

$$(155) \quad x \wedge y = x, \quad x \vee y = y$$

other words, defining a distributive lattice as a lattice in which this property holds, as expressed with the operations \wedge and \vee (see 151), for all x, y, z , $[P(U), \subseteq]$ is always a distributive lattice.

Second, every power set lattice $[P(U), \subseteq]$ has the universal bounds property: the empty set \emptyset and U itself are universal bounds (in the sense of (1)).

Finally, in the lattice $[P(U), \subseteq]$ each set X has a complement X' , consisting of all elements of U that are not in X . Clearly, two specific properties hold with respect to the complement of a set and the operations \wedge and \vee ; these are to be expressed in more general form (see 152) in what follows. A poset P may now be defined to be complemented when: (A) it has universal bounds 0 and I satisfying (1), and (B) any x in P has a complement x' in P such that two properties hold (see 152). Summarizing the above, then, it can be said that any power set lattice $[P(U), \subseteq]$ is a complemented distributive lattice.

BOOLEAN ALGEBRA

Boolean polynomials. Complemented distributive lattices arise in many other contexts besides set theory. They were first studied systematically by the English logician George Boole around 1850, because of their applications to logic, and are called Boolean algebras.

One of the most important concepts of Boolean algebra is that of a Boolean polynomial, by which is meant any symbolic expression built up by repeated application of the two binary lattice operations \wedge, \vee , and the unary operation $'$, and the special symbols 0 and I . The algebraic manipulations of Boolean polynomials are governed by the laws given below: the idempotent, commutative, associative, contractive, and distributive laws, plus the universal bounds and complementation laws (see 151 and 152). From these many others can be deduced, among which de Morgan's laws (see 153), the law $(x')' = x$, and the curious identity involving three elements combined in pairs with the operations \wedge and \vee (see 154) are especially noteworthy. Also, the inclusion relation $x \leq y$ is equivalent to either $x \wedge y' = 0$ or $x' \vee y = I$ as well as to a pair of inequalities that do not involve 0 and I (see 155).

Extensive research into the foundations of Boolean algebra has shown that the list of laws given in the preceding paragraph is highly redundant, and that various small subsets taken from this list imply the others. For example, if $[L, \vee, ']$ is an algebraic system that is assumed to have one binary operation \vee and one unary operation $'$, then the following was proved by the U.S. mathematician Edward V. Huntington in 1933.

Laws governing manipulation of Boolean polynomials

Huntington's theorem. In an algebraic system $[L, \vee, \wedge]$ define $a \wedge b = (a' \vee b')'$. Suppose $a \vee b = b \vee a$, $a \vee (b \vee c) = (a \vee b) \vee c$, and $(a \wedge b) \vee (a \wedge b') = a$ for all elements a, b, c in L , then $[L, \vee, \wedge]$ is a Boolean algebra.

Venn's diagram. The study of the laws of Boolean algebra, including Huntington's theorem, was motivated by the desire to reduce all of logic and set theory to a purely symbolic calculus. This study is helped by using so-called Venn diagrams, of which two are shown in Figure 8. In

Figure 8: Venn diagrams (see text).

them, U has been taken to be a rectangle. Figure 8A depicts two discs S and T ; they are to be imagined as typical subsets of U . Clearly the intersections $S \cap T$, $S \cap T'$, $S' \cap T$ and $S' \cap T'$ divide U into four nonoverlapping parts. If boundaries are neglected, the unions of these parts give precisely $2^4 = 16$ different Boolean combinations of the original sets S, T .

Likewise, John Venn, the British logician for whom the diagram was named, considered three discs R, S , and T as typical subsets of U . The intersections of these discs and their complements divide U into $8 = 2^3$ nonoverlapping regions, the unions of which give $2^8 = 256 = 2^{2^3} = 16^2$ different Boolean combinations of the original sets S, T .

Free Boolean algebra. These examples suggest the conjecture that, in general, there are exactly 2^{2^n} different Boolean polynomials in n symbols x_1, \dots, x_n , such that any given polynomial can be reduced to one, and only one, of these by repeated applications of the basic laws listed above. The truth of this conjecture is part of the following basic theorem, essentially due (in another terminology) to Boole himself.

Boole's theorem. A Boolean polynomial (x_1, \dots, x_n) can be reduced to one and only one join $\bigvee_s p_k$ of meets $p_k = z_1 \wedge \dots \wedge z_m$, in which each z_i is x_i or x'_i (there being 2^n possibilities), depending on k , and S is any subset of the $2^n p_k$.

The preceding form, $\bigvee_s p_k$, is called the disjunctive normal form of the polynomial and provides a systematic way of testing for the equivalence of two Boolean polynomials. Thus it solves the so-called word problem for Boolean algebra in an elementary way.

Isomorphism; direct product. Two general algebraic concepts, which are applicable to groups and rings (for example) as well as to posets, lattices, and Boolean algebras, are those of isomorphism and direct product. They will now be defined in the general context of posets.

An isomorphism between two posets P and Q is, by definition, a pairing of the elements of P with the elements of Q (a so-called bijection $\beta: P \leftrightarrow Q$, the symbol \leftrightarrow denoting bijection) such that $x \leq y$ in P if and only if $\beta(x) \leq \beta(y)$ in Q . If P is a lattice, then the preceding condition implies that Q is also a lattice and that $\beta(x \wedge y) = \beta(x) \wedge \beta(y)$ and $\beta(x \vee y) = \beta(x) \vee \beta(y)$. If P is a Boolean algebra, then so is Q , and in addition $\beta(x') = [\beta(x)]'$: isomorphisms of posets carry complements into complements.

Again, the direct product $P \times Q$ of two posets P and Q is the set of all ordered pairs (x, y) of elements, x from P and y from Q , the inclusion relation $(x, y) \leq (x_1, y_1)$ in $P \times Q$ being defined to mean that $x \leq x_1$ in P and $y \leq y_1$ in Q . If P and Q are both lattices or both Boolean algebras, then the same is true of $P \times Q$; moreover, the combination of pairs is achieved by the operation \wedge (see 156) in $P \times Q$, and dually by the operation \vee .

It is easy to show that the direct product of two posets is always a poset and that the formation of direct products is a commutative and associative operation on posets, relative to isomorphism: that $P \times Q \cong Q \times P$ and $P \times (Q \times R) \cong (P \times Q) \times R$. For instance, the bijection that pairs $(x, (y, z))$ with $((x, y), z)$ for any x in P , y in Q , and z in R is an isomorphism of $P \times (Q \times R)$ with $(P \times Q) \times R$.

It can therefore be written $P \times P = P^2$,

$$(156) \quad (x, y) \wedge (x_1, y_1) = (x \wedge x_1, y \wedge y_1)$$

$$(157) \quad \begin{array}{c|cc} \vee & 0 & 1 \\ \hline 0 & 0 & 1 \\ 1 & 1 & 1 \end{array} \quad \begin{array}{c|cc} \wedge & 0 & 1 \\ \hline 0 & 0 & 0 \\ 1 & 0 & 1 \end{array} \quad \begin{array}{c|cc} a & a' \\ \hline 0 & 1 \\ 1 & 0 \end{array}$$

$$(158) \quad \xi(a_i) = \begin{cases} 1 & \text{if } x \geq a_i \\ 0 & \text{otherwise} \end{cases}$$

$(P \times P) \times P = P^3, \dots$, with the understanding that $P^m \times P^n = P^{m+n}$ for any positive integers m, n ; i.e., that the usual laws for powers hold.

Binary strings. The simplest nontrivial Boolean algebra has two elements, 0 and 1, on which its three operations act as is prescribed by certain tables (see 157). Boolean algebra has been called the algebra of 0 and 1, because every Boolean algebra can be built up by combining copies of this simple Boolean algebra, which will be designated by the symbol 2.

Thus, if the set U has n elements, then the power set lattice (Boolean algebra) $P(U)$ is isomorphic with $2^n = 2 \times \dots \times 2$ (n factors). To establish the isomorphism $P(U) = 2^n$, the elements of U must be arranged in some order, as a sequence p_1, p_2, \dots, p_n . Each subset A of U is then associated with an n -tuple $a = (a_1, \dots, a_n) = \beta(A)$ of 0's and 1's, by setting $a_i = 1$ when p_i is in A and $a_i = 0$ when it is not. Dropping commas and parentheses, this associates with each A a binary string $a_1 a_2 \dots a_n$.

Logic networks. Boolean algebra is used for designing so-called logic networks for digital computers. Such a network typically has a finite number n of input leads, each of which goes into one of two states when pulsed, which can be designated as 0 and 1. The state of the set of all n leads can therefore be described by a binary string of length n . The problem is to design a circuit that, when it is interposed between these input leads and a specified set of output leads, will put each of the latter in a specified state, 0 or 1, determined by the states of the input leads.

The problem is thus to implement electronically a given Boolean function $f: 2^n \rightarrow 2$ from the set of all binary strings of length n to the set $2 = \{0, 1\}$; but these functions constitute precisely the free Boolean algebra with n generators, namely, the functions $\delta_i: (x_1, \dots, x_n) \rightarrow x_i$ that associate with each string its i th member. Boole showed that every function $f: 2^n \rightarrow 2$ can be represented as a Boolean polynomial in the δ_i (in disjunctive normal form).

The problem of optimal logic network design is to find the Boolean polynomial that does this most economically. Roughly, this corresponds to finding the shortest Boolean polynomial that has a given disjunctive normal form. This problem still lacks a general solution.

DISTRIBUTIVE LATTICES

Switching circuits. The three basic Boolean operations $\wedge, \vee, '$ (corresponding to "and," "or," and "not" in logic) can be realized electronically by three kinds of simple circuits, called AND-gates, OR-gates, and inverters, respectively. The first general purpose digital computers used, instead of electronic circuits, ordinary relay networks the connections of which could be open or closed. The Boolean operations of "and" and "or" are realized by putting relay networks in series and parallel, respectively. This raises the problem of constructing Boolean functions $f: 2^n \rightarrow 2$ from \wedge and \vee alone without using "not."

Algebraically, this amounts to determining the most general distributive lattice—i.e., the lattice satisfying the distributive laws (see 151)—with n generators. This is also the set of all lattice polynomials in n symbols $\delta_1, \dots, \delta_n$, two polynomials being considered equal when equality follows from the idempotent, commutative, associative, contractive, and distributive laws. This free distributive lattice had been considered by the German mathematician Richard Dedekind in 1900, and in 1912 the Norwe-

Basic
elements

gian mathematician Thoralf Albert Skolem showed that it contained precisely those Boolean functions $f: 2^n \rightarrow 2$ that were order-preserving in the following sense. The domain 2^n of the function f may be considered as itself a Boolean algebra, by defining $x \leq y$ for two binary strings $x = (x_1, \dots, x_n)$ and $y = (y_1, \dots, y_n)$ to mean that $x_i \leq y_i$ for all $i = 1, 2, \dots, n$. Then f preserves order (is isotone) when $x \leq y$ implies $f(x) \leq f(y)$.

eneral-
ation of
olem's
eorem

Finite distributive lattices. The most general finite distributive lattice may be constructed by a simple generalization of Skolem's theorem. Namely, L is assumed to be any finite distributive lattice, and A is assumed to be the set of all properly join-irreducible elements of L ; that is, the set of all elements $a > 0$ in L with the property that $x \wedge y = a$ implies $x = a$ or $y = a$. The elements of a may be imagined as listed in some order, a_1, \dots, a_n . Then each x in L can be associated with the subset $S(x)$ of A , consisting of exactly those elements a_i in A such that $x \geq a_i$. This is clearly order-preserving: $x \geq y$ implies $S(x) \supset S(y)$. Alternatively, each x in L can be associated with the function $\xi: A \rightarrow 2$ defined by assigning the value 1 to $\xi(a_i)$ when $a_i \leq x$, and 0 otherwise (see 158); this function is isotone.

The fundamental theorem on finite distributive lattices asserts that the converse is also true: that every isotone function $f: A \rightarrow 2$ is associated in this way with some x in L .

Some examples. Figures 9A–9D exhibit the diagrams

Figure 9: Some distributive lattices (see text).

of four distributive lattices, illustrating the preceding statements. The posets of join-irreducible elements, corresponding to the black circles, have the diagrams respectively.

In particular, Figure 9C exhibits similarly the free distributive lattice with two generators: the poset of all isotone functions $f: 2^n \rightarrow 2$; it should be noted that it has four properly join-irreducible elements, which form a poset having the diagram of 2^2 , as stated in Skolem's theorem.

It should also be noted that this distributive lattice has length three, which means that one can ascend from the universal lower bound 0 to the universal upper bound 1 in four steps. This illustrates the fact that, in general, a distributive lattice of finite length n contains exactly n properly join-irreducible elements, a result that can also be verified (with $n = 3$) in the other examples of Figure 9.

MODULAR AND GEOMETRIC LATTICES

Modular lattices. Although distributive lattices (including especially Boolean algebras) are very important, they are not typical. Most lattices are not distributive and cannot be characterized so simply. The rest of this section will describe properties of nondistributive lattices.

The simplest nondistributive lattice is the five-element lattice of Figure 7B. Its elements satisfy the modular law (see 159). This is clearly implied by the distributive law $x \wedge (y \vee z) = (x \wedge y) \vee (x \wedge z)$, because $x \wedge z = z$ when $x \geq z$. It is also self-dual, in the sense of being equivalent to its dual (see above; see 160).

Modular lattices arise in many parts of algebra. Thus the subgroups of any Abelian group form a modular lattice.

$$(159) \quad \text{If } x \geq z, \text{ then } x \wedge (y \vee z) = (x \wedge y) \vee z.$$

$$(160) \quad \text{If } z \leq x, \text{ then } z \vee (y \wedge x) = (z \vee y) \wedge x.$$

More generally, the normal subgroups of any group form a modular lattice, in which, moreover, the quotient-group $M \vee N / N$ is isomorphic to $M / M \wedge N$. In 1937 the Norwegian-born U.S. mathematician Oystein Ore showed that most of the structural properties of groups can be derived from these properties alone.

Covering properties. In any poset P , the relation " a covers b " is defined to mean that $a > b$, but $a > x > b$ for no x . Graphically, " a covers b " means that a is just above b in the diagram of P .

In 1900, Dedekind proved that a lattice of finite length was modular if and only if its covering relation has the following two dual properties:

1. If b and c both cover a , then $b \vee c$ covers both b and c .
2. If a covers both b and c , then b and c both cover $b \wedge c$ (It is understood here that $b \neq c$.)

Projective geometries. If F is any field (see below *Fields*) or division ring, and if $V = V_{n+1}(F)$ is the vector space (see above *Linear and multilinear algebra*) of all vectors $x = (x_0, x_1, \dots, x_n)$ of length $n+1$ with coordinates x_i in F , then the subspaces of V form a modular lattice under the relation of inclusion, which is called the n -dimensional projective geometry over F , and denoted $PG(F; n)$. (See GEOMETRY.)

In any projective geometry $PG(F; n)$, the universal lower bound 0 is the trivial subspace consisting of the null vector $0 = (0, 0, \dots, 0)$ alone. Geometrically, it is interpreted as the empty set, and the projective points are the elements that cover it. The (projective) lines are the elements that cover points, and every projective line contains at least three points.

Figure 10 exhibits the diagram of the lattice $PG(Z_2; 2)$,

Figure 10: Poset diagram of the Fano plane.

the so-called Fano plane; it has seven points and seven lines, with exactly three points on each line. Its points are the strings of three binary digits, not all 0: 001, 010, 011, 100, 101, 110, 111; its lines are the sets of points $x_1x_2x_3$ that satisfy an equation of the form $a_1x_1 + a_2x_2 + a_3x_3 \equiv 0 \pmod{2}$, in which $a_1a_2a_3$ is one of the strings just listed.

Geometric lattices. In any poset with universal lower bound 0, a point (or atom) is an element p that covers 0. That is, it is necessary that $p > 0$ (meaning that $p \geq 0$ but that $p \neq 0$), while $p > x > 0$ for no x . This definition is essentially the same as Euclid's: "a point is that which has no parts." A lattice of finite length is called a geometric lattice when: (1) each of its elements is a join of points, and (2) it satisfies the covering condition (:) under covering properties above. The partition lattice π_n of Figure 6 and the Fano plane of Figure 10 are (finite) geometric lattices. More generally, any projective geometry is a (modular) geometric lattice, and the lattice of all partitions of any finite set is a geometric, which is not modular if the set contains more than three elements.

Again, if Ω is any map, then the submaps formed from Ω by obliterating boundaries forms a geometric lattice $G(\Omega)$. The number of ways in which Ω can be coloured

The Fano
plane

The five-
element
attice

in λ colours so that no two adjacent regions have the same colour is called the chromatic polynomial of Ω [and of $G(\Omega)$]. This can also be constructed from the Möbius function of $G(\Omega)$, a function that can be defined on any poset and that has many applications to number theory and combinatorial questions.

OTHER LATTICE-ORDERED STRUCTURES

Relation algebras. Ordering relations play an important role in many algebraic structures having operations that, unlike the meet and join operations, cannot be defined purely in terms of order. One such class of structures is defined by binary relations.

Structures defined by binary relations

By a binary relation on a set S is meant a rule ρ that tells for any two elements x and y of S whether x and y are in the given relation or not. If they satisfy the relation, $x\rho y$ is written; if they do not satisfy the relation, $x\rho' y$ is written. The set of all binary relations on S forms a Boolean algebra under the operations $\rho \wedge \sigma$, $\rho \vee \sigma$, and ρ' corresponding to the words "and," "or," and "not." [Thus, $x(\rho \wedge \sigma)y$ means that $x\rho y$ and $x\sigma y$.] In this Boolean algebra, the order relation $\rho \geq \sigma$ defined by the statement that $\rho \wedge \sigma = \sigma$ (ρ and σ is the same as σ) is clearly tantamount to saying that σ "implies" ρ (the statement that $x\rho y$ "adds nothing" to the statement that $x\sigma y$). In logic, this is written $\sigma \supset \rho$.

The algebra of binary relations on a set S involves also the operation of composition. The composite $\rho\sigma = \rho \circ \sigma$ of ρ and σ is defined by the statement:

$x(\rho\sigma)y$ means that, for some z in S , $x\rho z$ and $z\sigma y$.

For functions of a real variable—i.e., when $S = R$, the real field—the definition of composite is equivalent to the usual definition of $\tau = \rho\sigma$, by $\tau(x) = \sigma(\rho(x))$. As another illustration: if the relation ρ (on the set of all people) is defined by " $x\rho y$ if and only if x is a sibling (brother or sister) of y ," and σ by " $x\sigma y$ if and only if y is a son of x ," then $x(\rho\sigma)y$ means that y is a nephew of x .

The operation of composition is associative: $\rho(\sigma\tau) = (\rho\sigma)\tau$ for any three binary operations on the same set S . The equality relation e ($x e y$ means $x = y$) is an identity for composition: $e\rho = \rho e = \rho$ for all ρ . These facts are summarized in the statement that the algebra $[S^2, \circ]$ defined by the set S^2 of all binary relations on S is a monoid under composition.

Like \wedge and \vee , the operation of composition is order-preserving (isotone): if $\rho \geq \rho_1$ and $\sigma \geq \sigma_1$, then $\rho\sigma \geq \rho_1\sigma_1$. Moreover, $\rho(\sigma \vee \tau) = \rho\sigma \vee \rho\tau$ and $(\rho \vee \sigma)\tau = \rho\tau \vee \sigma\tau$, two laws that imply isotonicity. [It is, however, not in general true that $\rho(\sigma \wedge \tau) = \rho\sigma \wedge \rho\tau$ or that $(\rho \wedge \sigma)\tau = \rho\tau \wedge \sigma\tau$.] Lattices that are also monoids and in which the isotonicity relations hold are called lattice-ordered monoids; it has just been shown that the binary relations on any set S form a lattice-ordered monoid.

Vector lattices. Many other kinds of lattice-ordered monoids arise in mathematics, such as the lattice of all ideals of any ring (under the operations of set inclusion

and ideal multiplication). One example is provided by the set of all continuous functions f of a real variable x , order being defined (see 161) and the monoid operation being defined as ordinary addition (see 162). Here a previous equation assumes a simpler form (see 163) because addition is commutative.

Another example is provided by the set of all real vectors (see 164), the order relation meaning that $x_j \geq y_j$ for all $j = 1, 2, 3$. In this the positive cone of all $x \geq O = (0, 0, 0)$ consists of the first octant: it is a trihedron with the positive quadrants of the coordinate planes as faces. For any fixed vector c , the set of all $x \geq c$ is obtained by translating the positive cone parallel to the vector c through a distance equal to its length (see 164).

These and other vector lattices are, by definition, (real) vector spaces that are also lattices, in which vector addition and order are related (see 163) and in which if $\lambda > 0$ is any positive scalar and $x > O$ any positive vector, $\lambda x > O$.

The preceding examples should give some idea of the enormous variety of lattices and lattice-ordered algebraic structures; they arise in every branch of mathematics.

(G.Bi.)

Groups

Groups, in mathematics, are systems of elements with a composition satisfying certain laws (these are given below). The elements may be operations; for example, the rotations of a sphere. The symmetries of a geometrical figure are best described as a group. The ornamental wall designs of the ancient Egyptians exhibit all possible combinations of symmetries. Euclid studied the properties of the regular polygons and the five regular solids. Not until the late 18th and 19th centuries, however, were groups recognized as mathematical systems. The French mathematician Joseph-Louis Lagrange was one of the first to consider them. Another French mathematician, Augustin-Louis Cauchy, began a study of permutation groups. In studying the solution of polynomial equations, a Norwegian mathematician, Niels Henrik Abel, showed that in general the equation of fifth degree cannot be solved by radicals. Then the French mathematician Évariste Galois, using groups systematically, showed that the solution of an equation by radicals is possible only if a group associated with the equation has certain specific properties; these groups are now called solvable groups.

The group concept is now recognized as one of the most fundamental in all of mathematics and in many of its applications. The German mathematician Felix Klein considered geometry to be those properties of a space left unchanged by a certain specific group of transformations. In topology geometric entities are considered equivalent if one can be transformed into another by an element of a continuous group.

Early work on groups

DEFINITION

A group, denoted G , is a nonempty set of elements with a composition defined for any ordered pair x, y of its elements. If the composition is written as the product xy , then the following laws hold:

- G1. The Associative Law: $(xy)z = x(yz)$ for all x, y, z , of G .
- G2. Existence of an identity. There is an identity element 1 , such that $1x = x1 = x$ for every x of G .
- G3. Existence of an inverse. For every x of G there is an element x^{-1} such that $x^{-1}x = xx^{-1} = 1$, in which 1 is the identity element.

These laws are redundant. Instead of G2 and G3 it is enough to assume the existence of an identity 1 such that $1x = x$ for any x , and that for any x there is a left inverse u such that $ux = 1$. Then let v be the left inverse of u so that $vu = 1$. The desired consequences follow (see 165).

If a group G satisfies the further law:

- G4. The Commutative Law. If $yx = xy$ for all x, y of G , then G is called an Abelian group.

The composition of a group may be written as addition, though this is not usually done except for Abelian groups. In this case the laws take the form:

- G1. Associative Law (see 166).

$$(161) \quad f \geq g \text{ means that } f(x) \geq g(x) \text{ for all } x.$$

$$(162) \quad h = f + g \text{ means that } h(x) = f(x) + g(x) \text{ for all } x.$$

$$(163) \quad f + (g \vee h) = (f + g) \vee (f + h)$$

$$(164) \quad \begin{cases} x = (x_1, x_2, x_3), & x \geq y = (y_1, y_2, y_3) \\ \sqrt{c_1^2 + c_2^2 + c_3^2} = \text{length of } c \end{cases}$$

$$(165) \quad \begin{cases} xu = 1(xu) = (vu(xu)) \\ = ((vu)x)u = (v(ux))u = (v \cdot 1)u = v(1u) = vu = 1 \\ x = 1x = (xu)x = x(ux) = x1 \end{cases}$$

$$(166) \quad \begin{cases} (x + y) + z = x + (y + z) & \text{for all } x, y, z \\ x + y = y + x & \text{for all } x, y \end{cases}$$

G2. Existence of zero. There is a zero element 0 such that its composition with x yields x for every x of G .

G3. Existence of negative. For every x of G there is an element $-x$ such that its composition with x yields 0.

G4. Commutative Law (see 166).

mappings

Many of the important applications of groups come from the fact that groups arise naturally from one-to-one mappings (sometimes called bijections). A mapping a of a set S into a set T may be considered a rule (or function) that associates with each element x of S a unique element y of T called the image of x . This mapping may be written $y = (x)a$. Of particular importance is the case in which the set T is the same as the set S . The product $a\beta$ of two mappings a and β of a set S into itself is defined by the rule $(x)a\beta = z$ if $(x)a = y$ and $(y)\beta = z$. This definition of product automatically satisfies the associative law. For if $(x)a = y$, $(y)\beta = z$, $(z)\gamma = w$, then $(x)(a\beta)\gamma = (z)\gamma = w$ and $(x)a(\beta\gamma) = (y)\beta\gamma = w$ so that the two mappings $(a\beta)\gamma$ and $a(\beta\gamma)$ are identical and so $(a\beta)\gamma = a(\beta\gamma)$.

A mapping a is said to be a mapping of S onto T (rather than into T) providing that for every y of T there is at least one x of S such that $y = (x)a$. Such a mapping is also called a surjection. If the mapping a also has the property that there is exactly one x of S such that $y = (x)a$ for y in T , then a is called a one-to-one mapping or a one-to-one correspondence, or a bijection.

The one-to-one mappings of a set S onto itself form a group. The identity mapping 1 is naturally defined by the rule $(x)1 = x$ for every x of S . And if a is a one-to-one

mapping of S onto itself, then an inverse mapping a^{-1} is defined by saying that if $(x)a = y$ then $(y)a^{-1} = x$. For because a is a one-to-one mapping, then given y in S there is exactly one x in S with $(x)a = y$ so that y determines x uniquely. Also $(x)aa^{-1} = x$ for every x and $(y)a^{-1}a = y$ for every y , from which it follows that $aa^{-1} = 1$, $a^{-1}a = 1$.

A nonempty set H of elements with a composition rule xy satisfying the associative law $(xy)z = x(yz)$ is called a semigroup. As has been shown above, the mappings of a set S into itself form a semigroup. In case S consists of the points of a plane, one mapping is to map all the points onto the points of a single line; for example, by mapping a point onto the foot of the perpendicular to the line through the point. Such a mapping does not have an inverse because a point not on the line is not the image of any point. Semigroups are considerably more general than groups and, by the same token, have fewer properties common to all of them.

A group G is said to be finite or infinite if the number of distinct elements in it is respectively finite or infinite. Many properties can be proved for finite groups but are false for infinite groups. The number of distinct elements in a group G is called the order of G .

When two groups can be considered as essentially the same group under certain conditions, these conditions require a precise definition as well as a name. The groups are said to be isomorphic. The formal definition is that: Two groups G_1 and G_2 are said to be isomorphic if there is a one-to-one correspondence a between the elements of G_1 and the elements of G_2 , such that if $(x_1)a = x_2$ and $(y_1)a = y_2$, then $(x_1y_1)a = x_2y_2$, in which x_1, y_1 are arbitrary elements of G_1 , and x_2, y_2 are their images in G_2 . From this definition it is easy to see that the identities of the two groups correspond and that if elements correspond, then also their inverses correspond. In particular, any two groups of order 2 are isomorphic because such a group consists of the identity and one further element the square of which must be the identity. A less obvious example of isomorphism is that between the multiplicative group of positive real numbers and the additive group of all real numbers, the logarithmic function $\log x$ has the property $\log(xy) = \log x + \log y$, and this gives the isomorphism of these two groups.

EXAMPLES OF GROUPS

A permutation of a set S is a one-to-one mapping of the elements of S onto themselves. If S consists of the integers $1, 2, \dots, n$, a permutation a may be written in two rows with a_i below the integer i (see 167) in which this is interpreted to mean that $(i)a = a_i$ for $i = 1, 2, \dots, n$. As has been observed, the permutations of a set form a group. If S is the set $1, 2, 3$, there are $3!$ (=6) permutations (see 168). Here, for example, the product $a_2a_4 = a_5$ because for $i = 1, 2, 3$ $((i)a_2)a_4 = (i)a_5$ (see 168).

Symmetries of a cube. A rotation taking a cube into itself is fully described by the permutation that this yields on the 8 vertices. Here a rotation of 90° about an axis through the midpoints of the top and bottom faces is given by a specific permutation (see 169). A rotation about the axis through the vertex 1 and the opposite vertex 7 is given by a specific permutation that holds the integer 7 fixed (see 170). Combinations of a and β give a total of

24 rotations (including, of course, the identity rotation). Apart from these rotations that can be achieved by motions in three-dimensional space, there is also a mirror image reflection about a plane through the midpoints of the edges 14, 23, 67, 58 expressed as a permutation of integers that inverts the order of the first four of eight integers and the last four, similarly (see 171). Combining this reflection with the 24 rotations gives the full group of 48 symmetries of the cube.

Symmetries of the regular octahedron. The midpoints of the faces of the cube may be taken as the vertices of the

regular octahedron. For this reason, it is intuitively clear that the symmetry group of the octahedron is isomorphic to that of the cube. The corresponding symmetries as they affect the vertices of the octahedron are described by three permutations (see 172).

Collineations of the Euclidean plane. If the points of the plane are given by coordinates (x, y) in which x, y are real numbers, the transformations that transform pairs into pairs of linear combinations (see 173) with coefficients a, b, c, d, e , in which $ad - bc$ is not equal to zero, form a group consisting of the one-to-one mappings of the points onto themselves with the property of taking straight lines into straight lines, and this is called the collineation group. The subsystem of collineations β fixing the origin $(0, 0)$ is also a group (see 174). A subsystem of this consists of rotations γ about the origin. The rotation γ corresponding to an angle θ is also expressible as a transformation on pairs, in which coefficients in the linear combinations after transformation depend on θ (see 175).

ELEMENTARY GROUP STRUCTURE

In a group G the common value of $(xy)z = x(yz)$ can be written xyz . The same principle applies to four factors (see 176), and the common value of these products may be written $xyzw$. It is not difficult to prove that any bracketing of $x_1x_2 \cdots x_n$ without changing the order of the factors gives the same product. This fact is known as the generalized associative law. A consequence of it is that the inverse of a product is the corresponding product of inverses taken in reverse order (see 177). Similarly, if both the associative and commutative laws hold, a product $x_1x_2 \cdots x_n$ has the same value as the product of any rearrangement of these factors.

A subset H of the elements of a group G that is itself a group under the composition for G is called a subgroup. In many important cases the elements of a group that have certain properties form a subgroup. For example, the one-to-one mappings of the points of the Euclidean plane onto themselves form a group G . Those mappings that take straight lines into straight lines, the group of collineations, form a subgroup G_1 of G . The group G_1 in turn has a subgroup G_2 , called the orthogonal group, which consists of the one-to-one mappings that leave distances unchanged.

If a_1, a_2, \dots, a_n are elements of a group G , then all expressions $x_1x_2 \cdots x_n$ in which every value of x is one of the a_i or an inverse a_i^{-1} form a subgroup H that is said to be generated by a_1, a_2, \dots, a_n and this is written $H = \langle a_1, a_2, \dots, a_n \rangle$. If H is generated by a single element, $H = \langle a_1 \rangle$, H is called a cyclic group. The product of n factors $a_1a_1 \cdots a_1$ can be written a_1^n and similarly $a_1^{-1}, \dots, a_1^{-1} = a_1^{-n}$. Then the elements of H are of the form a_1^m with m any integer, positive or negative, and the product rule is $a_1^r a_1^s = a_1^{r+s}$. It may happen that all the powers of a_1 are different, in which case H is essentially the additive group of the exponents that are the integers. If two different powers a_1^r and a_1^s represent the same element, then $a_1^{r-s} = 1$. In this case H is finite and there is a positive integer n such that $1, a_1, \dots, a_1^{n-1}$ are different and $a_1^n = 1$. In this case n is the order of H , and $a_1^r = a_1^s$ if and only if $r - s$ is some integral multiple of n .

SUBGROUPS

It is not difficult to show that a group G with no subgroup except itself and the identity subgroup must be a finite cyclic group the order of which is a prime number. This describes these groups completely. For a more general group the nature of its subgroups and their interrelations are important in describing the group and its structure.

If H is assumed to be a subgroup of a group G and x some fixed element of G , the set of elements of the form hx with h belonging to H is called a left coset of H and is written Hx . Similarly, the set of elements xh is called a right coset and is written xH . It is easily seen that a left coset Hx contains the same number of elements as the subgroup H because the element hx of Hx can be matched with the element h of H . Similarly a right coset xH has the same number of elements as H . If h_1 and h_2 are any elements of H , and if $x_1 = h_1x$ and $x_2 = xh_2$, then it is easily shown that Hx and Hx_1 are the same set of elements, and also xH and x_2H are the same set of elements. From this it readily follows that any two left (right) cosets of H are identical or disjoint. If $H1 = H$, the subgroup itself and Hx_2, \dots, Hx_n are all the distinct left cosets of H in G , this fact is represented symbolically by $G = H + Hx_2 + \dots + Hx_n$. The plus sign has no arithmetical significance here and the expression means that G is the union of the disjoint cosets. For this reason some writers use a different notation. The number of distinct cosets of H in G is called the index of H in G and is written $[G:H]$. The inverses of the elements hx are the elements $x^{-1}h^{-1}$ so that the inverses of the elements in a left coset Hx are precisely the elements of the right coset $x^{-1}H$, because as h runs over all elements of H so also does h^{-1} . Thus even if H is infinite there is a one-to-one correspondence between right and left cosets, and the index $[G:H]$ is the same for right cosets as it is for left cosets. If G is a finite group and the subgroup H is taken to be the identity, then each coset consists of a single element so that the index $[G:1]$ is the order of G ; that is, the number of elements in G . A simple but very important consequence of the fact that distinct cosets of a subgroup are disjoint and have the same number of elements is the theorem of Lagrange. It states that the order of a finite group is the product of the order of a subgroup and the index of the subgroup.

The theorem of Lagrange is not true for semigroups, illustrating the sharp differences in the theories of groups and semigroups. For a given semigroup S of order n , it is possible to take one additional element u and define $u^2 = u$, $xu = ux = u$ for every x of S , to obtain a semigroup of order $n + 1$ containing S .

From the theorem of Lagrange, the order of a subgroup H of a finite group G divides the order of G . In particular, if the order of G is a prime number p , then G has no subgroups except itself and the identity. As observed above, G must be a cyclic group. The converse of the theorem of Lagrange is false. If G is a finite group of order n and if m is a divisor of n , there may not be a subgroup of G of order m . As a simple example of this, there is a group of order 12 that does not have a subgroup of order 6.

A partial converse to the theorem of Lagrange was proved by the Norwegian mathematician Ludwig Sylow in 1872. In order to describe this theorem fully it is necessary to introduce the concept of conjugate subgroups. If H is a subgroup of the group G and if x is a fixed element of G , then the elements $x^{-1}hx$ in which h ranges over the elements of H form a subgroup that is designated as $x^{-1}Hx$. It is called the conjugate of H by x . There are three main parts to the Sylow theorem. The first part asserts that if p^r is the highest power of the prime p dividing the order of a finite group G , then there is a subgroup P of order p^r , called a Sylow p -subgroup, and that if P_1 is another Sylow p -subgroup, then for some x of G , $P_1 = x^{-1}Px$. Second, the number of distinct groups of order p^r in G is of the form $1 + kp$ for some integers k and p is a divisor of the order of G . A third part of Sylow's theorem says that if p^r is the highest power of the prime p dividing the order of G , then there are subgroups of order p, p^2, \dots, p^{r-1} , and each subgroup of order p^i is contained in at least one subgroup of order p^{i+1} for $i = 1, 2, \dots, r-1$. These Sylow theorems give a great deal of valuable information on the existence of subgroups of prime power order and their interrelations. For example, if G is of order 12, then it has 1 or 4 subgroups of order 3 and has 1 or 3 subgroups of order 4. Also G has subgroups of order 2, each of which is contained in at least one subgroup of order 4. These facts are not independent. It is not possible for a

The theorem of Lagrange

The generalized associative law

group G of order 12 to have 3 subgroups of order 4 and also 4 subgroups of order 3.

The mapping $(h)a = x^{-1}hx$ from the subgroup H onto the subgroup $x^{-1}Hx$ is an isomorphism because products are preserved (see 178) and also inverses are preserved

$$(178) \quad (x^{-1}h_1x)(x^{-1}h_2x) = x^{-1}h_1h_2x$$

$$(179) \quad (x^{-1}h_1x)^{-1} = x^{-1}h_1^{-1}x$$

(see 179). In other words, one of the consequences of the Sylow theorems is that any two Sylow p -subgroups are isomorphic.

Of particular importance are those subgroups H of a group G that are conjugate only to themselves; that is, $H = x^{-1}Hx$ for every x of G . This is so important that it is given a special name. A subgroup H of a group G is called a normal subgroup if for every x of G , $H = x^{-1}Hx$. Other names have been used for this property. Normal subgroups have also been called invariant subgroups or self-conjugate subgroups. If the right coset xH contains exactly the same elements as the left coset Hx , then from the equality of the sets $xH = Hx$ it follows that $H = x^{-1}(xH) = x^{-1}Hx$. Conversely, if $H = x^{-1}Hx$, then also $xH = Hx$. Thus H is a normal subgroup of a group G if and only if every right coset xH is also a left coset Hx .

HOMOMORPHISMS; FACTOR GROUPS

It is often possible to map a group G onto a smaller group H , mapping several elements of G onto the same element of H , and to do this so that the product rules are preserved. Such a mapping is called a homomorphism. For example, the real numbers with zero excluded form a group M under multiplication, and mapping every positive number onto $+1$ and every negative number onto -1 gives a homomorphism of M onto the multiplicative group H of the two numbers $+1$ and -1 .

A formal definition is: A mapping β of the elements of a group G onto the elements of a group H is called a homomorphism if $(xy)\beta = (x)\beta(y)\beta$ for any x, y of G . It should be noted that in this definition, if it should happen that the mapping β is one-to-one, then β is an isomorphism. Thus an isomorphism may be regarded as a special case of a homomorphism.

$$(180) \quad \begin{cases} (t_1)\beta = 1, & (t_2)\beta = 1 \\ (t_1t_2)\beta = (t_1)\beta(t_2)\beta = 1 \cdot 1 = 1 \\ ((t_1^{-1})\beta = ((t_1)\beta)^{-1} = (1)^{-1} = 1 \end{cases}$$

$$(181) \quad (x^{-1}tx)\beta = ((x)\beta)^{-1} \cdot 1 \cdot (x)\beta = 1$$

$$(182) \quad (tx)\beta = (t)\beta(x)\beta = 1 \cdot (x)\beta = (x)\beta$$

$$(183) \quad G = G_0 \supset G_1 \supset G_2 \cdots G_{r-1} \supset G_r = \{1\}$$

$$(184) \quad w = b_1v + \cdots + b_mv \quad \text{with } b_1, \dots, b_m$$

$$(185) \quad \begin{cases} (w_1 + w_2)\alpha = (w_1)\alpha + (w_2)\alpha \\ (w_1w_2)\alpha = (w_1)\alpha(w_2)\alpha \end{cases}$$

$$(186) \quad (x_1, x_2)(y_1, y_2) = (x_1y_1, x_2y_2)$$

$$(187) \quad (x_1, 1)(1, x_2) = (x_1, x_2) \in G_1 \times G_2$$

$$(188) \quad \begin{aligned} (x_1, x_2, \dots, x_n)(y_1, y_2, \dots, y_n) \\ = (x_1y_1, x_2y_2, \dots, x_ny_n) \end{aligned}$$

$$(189) \quad \begin{aligned} (x_1, x_2, \dots, x_i, \dots)(y_1, y_2, \dots, y_i, \dots) \\ = (x_1y_1, x_2y_2, \dots, x_iy_i, \dots) \end{aligned}$$

It can be demonstrated that in a homomorphism β the image of the identity of G is the identity of H and that the image of the inverse of an element is the inverse of the image.
